EXECUTIVE SUMMARY

KGHM Ajax Mining Inc. proposes to develop the Ajax Project (the Project), an open pit copper-gold mine, near the City of Kamloops, British Columbia. The Project is located within the Thompson River watershed, Thompson – Okanagan Plateau Ecoregion of the Southern Interior Ecoprovince of British Columbia, which is within the Interior Plateaus and Highlands Ground Water Region of British Columbia (Province of British Columbia 2013 and Zubel 2001). The immediate project area is within the smaller Peterson Creek watershed and is on the eastern side of the previous Afton Mine property. Previously mined areas on site include the partially backfilled Ajax East open pit and the two Ajax West open pits, and two reclaimed mine rock piles. The proposed open pit will further develop and encompass the previously mined Ajax East and Ajax West open pits east of Jacko Lake. The remainder of the Project footprint is comprised of forested land and ranching property. Residential and industrial neighbourhoods are located in proximity to the creeks.

Water quality and quantity in the local area is influenced significantly by the arid climate conditions. Jacko Lake and Edith Lake are managed water features. The outflow management strategies are not formally documented and as a result it is difficult to correlate flows with observed chemistry, though seasonality is evident. The primary objective for the management of outflows from Jacko Lake is to sustain the requirements of the numerous water licences on Peterson Creek and the Edith Lake outlet is managed to maintain lake levels in that lake.

In the spring, freshet runoff is the major contributor to surface water flows, however, outside of this spring freshet, flows are observed to be low in the local creeks (Peterson Creek, Keynes Creek, Humphrey Creek, Anderson Creek, Cherry Creek, and Alkali Creek) and groundwater is the primary source of flow. Even under high flow conditions, surface connections between Keynes Creek and Humphrey Creek with Peterson Creek were not observed, and flow connection is assumed through the subsurface. The baseline water quality study was strategically planned to provide insight into surface water and groundwater quality in the Project area and to provide appropriate coverage both up-gradient and down-gradient of the historical and proposed mine features, and local land uses.

The primary objectives of the water quality study were to characterize the complex environment and understand the interactions between surface water and groundwater in the project area, to provide valuable insight into current and potential future stresses on surface and ground water resources and management strategies to address these issues, and to provide a basis for predicting future water quality. The water quality analytical results have been compared against an exhaustive list of relevant guidelines as specified in the Application Information Requirements for the Project. The relevant guidelines were based on all potential water users in the project area and include aquatic life, drinking water, agricultural water uses (irrigation and livestock), wildlife, and recreation. Aquatic life guidelines tend to be the most stringent and the report discussion is generally focussed on these guidelines, though the others are discussed to provide context.

Surface Water Quality

The surface water quality sampling program includes 38 established sites, 33 of which are part of the ongoing monthly sampling program. The study area is characterized as dry, with variable flow in the creeks; at times, some creeks run dry and cannot be sampled. During spring freshet, flows change at a faster rate than other times of year and weekly samples have been collected to document the changes in water quality associated with the changing flows.

All surface waters in the project area are neutral to basic pH, hard to very hard, and alkaline with high buffering capacity. Concentrations of most parameters were noted to increase with distance downstream in the creeks in every watershed sampled in the baseline surface water quality program. This increase was most evident outside of spring freshet. Surface water quality within the project area is highly variable depending on whether the system is a lake, slough, creek, or historical mine site features. Total dissolved solids (TDS) is a key parameter that differentiates these surface water features within the baseline study program. The creeks, Makaoo Lake, and Jacko Lake qualify as freshwater sources, the historical mine site features and Polygon Pond are within the slightly to moderately saline range, and Inks Lake and Wallender Lake are saline, though Wallender Lake is verging upon hyper-saline. Wallender Lake, Inks Lake and the historical mine site features are local groundwater discharge zones, with no outlet channels, within a net evaporative climate. The parameter concentrations in these man-made features and lakes tend to be higher than the surrounding groundwater and surface water and in Wallender Lake and Inks Lake, parameter concentrations appear to have stabilized under natural equilibrium conditions, whereas concentrations in the historical mine features are typically trending upwards.

Sulphate or bicarbonate are the dominant anions in all surface waters and the major cation is generally magnesium, with significant sodium and calcium. Sulphate concentrations are lower in Anderson Creek, Cherry Creek, Alkali Creek and Jacko Lake than in lower Peterson Creek. Sulphate loading in Peterson Creek is generally understood to be associated with groundwater inflows as concentrations reach maximum values under low flow conditions in late summer and late winter, when runoff due to precipitation is non-existent and surface flows are supported almost exclusively by local groundwater discharge. Sulphate levels in Inks Lake, Wallender Lake, Polygon Pond and the historical mine site features were elevated and exceed the 1000 mg/L livestock water use guidelines. Due to high hardness in the surface water environmental in the project area site specific toxicity testing was required for sulphate and science based environmental benchmarks (SBEBs) were developed for the site. Two SBEB thresholds were developed specific to the presence or absence of early life stages for trout (early life stages present: Sulphate 429 mg/L – hardness up to 800 mg/L $CaCO_3$; and early life stages absent: Sulphate 730 mg/L – hardness up to 1,377 mg/L $CaCO_3$). Sulphate surface water concentrations rarely exceeded the SBEBs but occasional samples from the Peterson Creek, in the lower reaches of the baseline study area were above these thresholds.

Chloride concentrations were elevated seasonally in samples collected from surface water sites in Peterson Creek and Anderson Creek that were downstream of highways (Highways 5, 5A and Lac La Juene) and samples occasionally exceeded aquatic life guidelines for long-term exposure. Road salt application is the likely source, as groundwater sample concentrations from monitoring wells in the immediate project area are all low in chloride. Samples from residential water well sources in the vicinity of the Davidson Creek Aquifer (parallel to Highway 5A) are also elevated in chloride. Seasonal increases typically occur between August and October, and sites upstream of the highways are not affected. Fluoride concentrations were elevated in samples from project area groundwater wells and surface water samples. Fluoride surface water concentrations did not tent to exceed the BC aquatic life guideline (hardness dependent), and concentrations did not show consistent increasing trends with distance downstream, but tended to be elevated in the samples from Humphrey Creek, and Keynes Creek and samples from the mid-reaches of Peterson Creek, which are downstream of Humphrey Creek and Keynes Creek.

Total phosphorus concentrations in the creeks varied significantly on a seasonal basis, resulting in a wide range of trophic classification from eutrophic to hyper-eutrophic. Nutrient loading within the project area is dominantly phosphorus related and nitrogen based inorganics (nitrite, nitrate, and ammonia) concentrations were somewhat variable in the creeks and aquatic life guideline exceedances were infrequent.

In the Peterson Creek watershed (including Keynes Creek and Humphrey Creek), Anderson Creek, Cherry Creek and Alkali Creek aluminum, copper, and iron frequently exceeded the aquatic life guideline limits and molybdenum and manganese concentrations frequently exceeded the guidelines for irrigation and/or livestock water uses. With the exception of manganese and molybdenum, the total concentrations of these parameters were generally elevated in response to freshet flows. Manganese and molybdenum concentrations were elevated in local groundwater and in seepage downstream of historical waste rock, and surface water concentrations were higher during non-freshet periods when surface water flows are predominantly sustained by groundwater. Molybdenum sample concentrations seasonally exceeded the wildlife and livestock water quality guideline in Peterson Creek downstream of the historical mine site area. Selenium aquatic life guideline exceedances were also noted within the project area creeks, generally in association with late winter low flow periods, and although concentrations tended to decrease through spring freshet, guidelines were still exceeded during this period. Selenium concentrations were highest in samples from Keynes Creek and lower Humphrey Creek and were also high in the lower reaches Peterson Creek. In Jacko Lake only aluminum, selenium, and zinc were reported above fresh water aquatic life guideline limits, though exceedances were infrequent. Metal parameters were generally below aquatic life guidelines in Makaoo Lake.

The historical mine site features water quality samples revealed elevated concentrations of arsenic, cadmium, copper, molybdenum, selenium, and uranium, and aquatic life guideline exceedances were frequent for these parameters. In Inks Lake and Wallender Lake arsenic and boron regularly exceeded guidelines and aluminum, copper, and selenium exceeded guidelines, though elevated MDLs due to sample matrix interference often resulted in MDLs that exceeded the guidelines for these and other parameters.

Groundwater

A total of 73 monitoring wells have been installed in the project area, 51 of which have been sampled and are the basis for the groundwater quality characterization provided in this report. Forty-six (46) of these monitoring wells continue to be sampled in the ongoing groundwater monitoring program. The first wells were installed in 2007 and the most recent drilling event occurred in 2014. At some well locations, paired wells (deep and shallow) have been installed to characterize any differences in water quality at different depths. Each well is generally sampled quarterly, with sampling events targeted to capture water quality associated with the lowest and highest water levels.

Regional groundwater quality in the Thompson River watershed, in the Thompson Plateau (Interior Plateau and Highlands groundwater region of British Columbia) is described as having high concentrations of total dissolved solids (TDS) (>500 mg/L) and in some areas the sulphate concentrations are above the 500 mg/L Health Canada Drinking Water Standards (Zubel 2001). Water quality in the area is characterized as very hard and highly mineralized, and of the carbonate to sulphate water type; however, these interpretations are based upon limited data (Zubel 2001). The groundwater quality analysis for the local study area support observations in this reference.

Groundwater quality in the local study area is characterized as alkaline, hard to very hard, and generally classified as fresh water to slightly saline, with TDS that was typically higher than that described by Zubel (2001). The dominant anion was sulphate and the dominant cation was sodium, typically in association with sulphate, though intermediate geochemical facies were identified. Magnesium was also a dominant cation but generally with significant proportions of sodium and calcium and rarely as a major contributing cation. Calcium was proportionally dominant in samples from a few monitoring wells installed immediately east of Jacko Lake, but typically only slightly greater than magnesium and/or sodium. Hydrochemical signatures were not distinct for the specific bedrock or overburden lithological units but were more easily distinguished by location in the project area. Major ion and dissolved solids concentrations were typically lower in the groundwater samples from wells in the upland areas (groundwater recharge areas) of the project and were more concentrated in samples collected from wells at lower points along the Peterson Creek valley (i.e. groundwater discharge areas), and generally increased from west to east along the Peterson Creek valley and into the Peterson Creek aquifer.

Sulphate concentrations were elevated in all of the groundwater samples collected from within the baseline study area, and with few exceptions, concentrations frequently exceeded livestock water use guideline (1000 mg/L). The highest sulphate concentrations were noted for those wells that are in the vicinity of local groundwater discharge areas, such as the Ajax West open pits, sloughs, Inks Lake, and Peterson Creek. Fluoride was elevated throughout the project area though locally enriched in the vicinity of the proposed Ajax Pit, where concentrations were often greater than the livestock and irrigation water use guideline limits.

Trace metal and metalloid concentrations in groundwater were not always well correlated with the major ions and the distribution appears to be more strongly influenced by local geological enrichment in specific minerals (deposit area and historic waste rock storage areas) and by proximity to local scale groundwater discharge areas which are typically at lower elevations in the project area. Arsenic, boron, iron, manganese, molybdenum, and selenium were metals and metalloids that were elevated in the groundwater quality baseline study area, though the spatial extent varied somewhat by parameter. Concentrations of some metals were higher in groundwater samples collected from monitoring wells in the vicinity of the open pit (deposit area) and the historical mine features (arsenic, boron, iron, manganese, molybdenum, and selenium), whereas others are elevated in the vicinity of the proposed East Mine Rock Storage Facility (EMRSF) (North Peterson Creek watershed) (iron and manganese), Humphrey Creek area (manganese), Keynes Creek area (arsenic and manganese), and the Upper Peterson Creek area (arsenic, boron, and manganese).

Aquatic life guideline exceedances for groundwater quality were most common through the majority of the baseline groundwater quality study area for fluoride, sulphate, and arsenic, less common for boron, copper, iron, manganese, molybdenum, and selenium, and rare for aluminum, antimony, cadmium, chromium, cobalt, mercury, uranium, and zinc.

The groundwater in the project area is generally not suitable as a raw drinking water source and drinking water quality guideline exceedances are common for pH, TDS, sulphate, fluoride, manganese and sodium, and are less common for nitrate, ammonia, arsenic, selenium, and uranium.

Livestock water use guideline exceedances are common throughout the Project area for specific conductance, TDS, and molybdenum, and less common for sulphate, fluoride, and arsenic. Irrigation

water use guideline exceedances are common for specific conductance, TDS, manganese and molybdenum, and less common for chloride, selenium, and uranium.

1 – INTRODUCTION

1.1 PROJECT DESCRIPTION AND BACKGROUND

KGHM Ajax Mining Inc. (KAM) proposes to develop the Ajax Project (the Project), an open pit copper-gold mine with a planned processing rate of 65,000 t/d, near the City of Kamloops, British Columbia. The Project location and facility footprints are shown on Figure 1.1, in relation to the city of Kamloops and the major watershed boundaries.

The proposed Project is partially located on a historical mine site and mining activities in the immediate project area began in 1989. Mining operations ceased under Teck Cominco in the Afton, Ajax East and Ajax West open pits in 1997. Previously mined areas on site include the partially backfilled Ajax East open pit and the two Ajax West open pits, and two reclaimed waste rock piles. Historical-mined rock has been stored to the east of the open pit, adjacent to Peterson Creek. After mining operations terminated, reclamation was carried out. The proposed open pit will further develop and encompass the previously mined Ajax East and Ajax West open pits east of Jacko Lake.

1.2 REPORT SCOPE

Knight Piésold Ltd. (KP) was requested by KAM to complete a baseline water quality study to support the application for an Environmental Assessment (EA) certificate for the Project. This report provides a detailed assessment of the baseline water quality data collected from 2007 through September 2014 for surface water quality and groundwater quality within the project area. The Project is located within the Peterson Creek watershed (Figure 1.1), which is the focus of the baseline water quality characterization; however, the Cherry Creek and Anderson Creek watersheds have been included in the baseline characterization due to their proximity to the Project.

2 – PHYSICAL SETTING

2.1 OVERVIEW

The Project is located within the Thompson River watershed, Thompson – Okanagan Plateau Ecoregion of the Southern Interior Ecoprovince of British Columbia, which is within the Interior Plateaus and Highlands Ground Water Region of British Columbia (Province of British Columbia 2013 and Zubel 2001). The immediate project area is within the smaller Peterson Creek and Cherry Creek watersheds.

The landforms of the project area are reflective of the glacial history of the region. Extensive glacial action has created topography of low rolling hills with local deep accumulations of glacial till on the southeast flanks of larger rock outcroppings and drumlins (Province of British Columbia 2013 and Zubel 2001). The area consists of rolling grasslands surrounded by local relief that ranges from 800 metres above sea level (masl) to 1,100 masl and forested areas at higher elevations. Sugarloaf Hill is the prominent landform in the area and has an elevation of 1,130 masl.

Most of the forested portion of the project area is structural stages 4 and 5 as a result of a frequent fire regime. A recent fire south of Ned Roberts Lake (south of Hughes Lake tailings pond) has removed most of the older forest in that area. Very little old forest is currently present in the vicinity of the Project.

2.2 GEOLOGICAL OVERVIEW

The geological summary provided below is based upon the geology description from the BGC Engineering Inc. (BGC), *Baseline Groundwater Hydrology Assessment* report (BGC 2015a). For a more detailed description please reference that report.

The bedrock in the project area consists of the Upper Triassic Nicola Group (volcanics, volcaniclastics, and picrite), Late Triassic to Early Jurassic Iron Mask Batholith (dioritic intrusive rock), and the Eocene Kamloops Group (volcanic and sedimentary rock groups); listed in order from oldest to youngest. The Ajax deposit is included within the Iron Mask pluton of the Iron Mask Batholith. The Iron Mask pluton is the larger of the two plutons of which the Iron Mask Batholith is comprised; the Cherry Creek pluton forms the smaller northwest section of this batholith. A discussion of the major faults and structures is not provided here, but can be referenced from the above mentioned document.

Quaternary deposits in the local project area are comprised of Kamloops Drift resulting from the Fraser Glaciation and post-glacial deposits in lacustrine, fluvial, eolian, and colluvial depositional environments. The glaciofluvial deposits in the project area placed during the Fraser glaciation have been mapped in the Peterson Creek and Davidson Creek Aquifers and in the vicinity of the proposed Tailings Storage Facility (TSF) and South Mine Rock Storage Facility (SMRSF) and *"…consist broadly of gravel, sandy gravel and sand*" (BGC 2015a). Drumlinoid moraines, consisting of till with lenses of sand, gravel and silt and these deposits are "…*the most common surficial material within the study area and is mapped around all project facilities*" (BGC 2015a). The post-glacial deposits are more limited than the glacial deposits in project area. Lacustrine deposits, consisting of bedded fine sands, silts and clays are limited to ponds in the project area. "*Fluvial deposits consisting of loosely packed, non-cohesive sand and silt. These are fans that formed floodplains and terraces. These deposits have been mapped in the Peterson Creek area, south of the planned open pit and*

[East Mine Rock Storage Facility] *EMRSF* (BGC 2015a)". "*Colluvial/mass movement deposits consist of loose, unconsolidated sediments of various sizes that have been deposited at the base of hillslopes. These materials have been mapped near the eastern limit of the open pit, to the north of the WMRSF* [West Mine Rock Storage Facility] *and near and within the footprints of the TSF, SMRSF and EMRSF"* (BGC 2015a).

2.3 CLIMATE AND HYDROMETEOROLOGY

Situated within the rain shadow of the Coast Mountains, this region has a semi-arid steppe climate characterized by generally cool dry winters and hot dry summers. The hydrograph generally peaks in April or May, during spring freshet and decreases quickly in June, when evaporation is high and rainfall is low. Creek flows remain low throughout the summer. Despite higher rainfall in the fall season, creek flows remain very low relative to those observed during freshet. Winters are very dry and cold and some creeks cease to flow. Results from the 2014 KPL Hydrometeorology Report (KPL 2014) indicate a long-term average annual temperature of 6.4 °C, with average monthly temperatures ranging from 18.7 °C in July to -4.9 °C in January. Relative humidity varies throughout the year, but it is typically highest in mid-winter and lowest in mid-summer, with monthly average values of approximately 88.5% and 48.6% respectively. The long-term mean annual precipitation was estimated to be 336 mm, 30% of which falls as snow. Convective storm cell events are frequent in the summer months and as a result precipitation is generally highest in June and July. The mean annual lake evaporation was estimated to be 585 mm.

2.4 WATERSHED

The proposed Project components are all situated within the Peterson Creek watershed, which drains to the South Thompson River. Because of their close proximity to the Project, the Anderson Creek and Cherry Creek watersheds are included in the baseline study. The Peterson Creek and Cherry Creek watersheds have been studied extensively and detailed reports are summarized below; however, the physical hydrology of the sites located in the Thompson River and Anderson Creek watersheds (located north and south of the Peterson Creek watershed, respectively), has not been characterized as extensively as those of the Peterson Creek and Cherry Creek watersheds. The topography of the project area is consistent between watersheds and the physical hydrological and climatic properties of the Anderson Creek watershed are expected to be similar to those observed in Peterson Creek. The Thompson River watershed is much larger than the watersheds that make up the majority of the project area and is expected to be very different; however, the section of this watershed that is included in the baseline water quality study is limited to a very small area close to the borders of the Cherry Creek and Peterson Creek watersheds. The physical properties of the similar terrain observed in the Cherry Creek and Peterson Creek watersheds is assumed to apply to the two water bodies studied for water quality within the Thompson River watershed: Polygon Pond and Makaoo Creek.

Within the Peterson Creek, Cherry Creek, and Anderson Creek watersheds, the mean annual hydrographs at each site show the same general trends. A sample hydrograph from the JACINF hydrology station, located near the site and considered representative of the Ajax site, is shown on Figure 2.1. Creek flows are generally low to dry from late summer (September) through the winter months (up to and including February) with increased flow from early spring (March) through summer (August). Spring freshet generally happens in late May and June and is characterized by higher

runoff contributing to creek flow. Precipitation is often higher in October and November, causing a period where creek flow is predominantly recharged by surface runoff, while groundwater recharge is the main source of surface water discharge in the winter months (December through February).

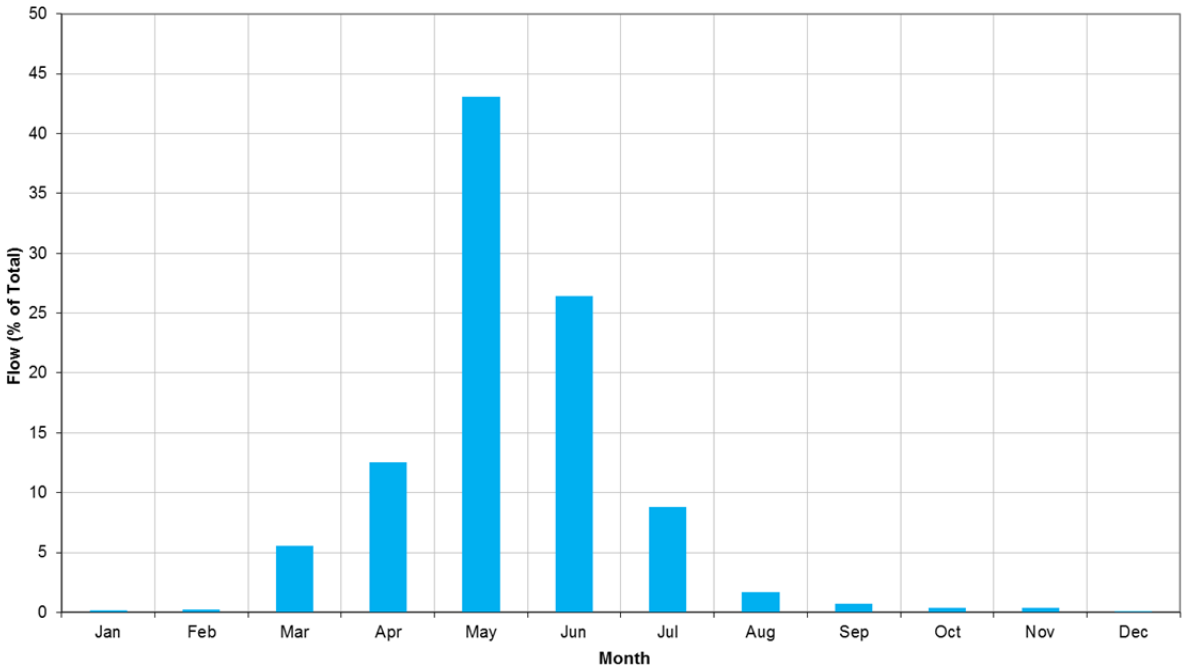

Figure 2.1 Representative Hydrograph of the Ajax Site

NOTES:
1. HYDROGRAPH IS FOR THE JACINF HYDROLOGY STATION, WHICH IS CONSIDERED REPRESENTATIVE OF THE AJAX SITE.

2.4.1 Peterson Creek Watershed

Peterson Creek has a mainstem length of approximately 40 km and a watershed area of approximately 130 km^2 (BGC 2015b). The creek is a tributary to the South Thompson River, and the lower reaches run through Peterson Creek Park and an urbanized portion of the City of Kamloops, BC. The majority of the creek within the City of Kamloops is now buried in culverts and channelled in concrete waterways from Columbia Street to the South Thompson River; an example of these modifications is provided on Photo 13 in the Photograph Section. The creek also runs through ranch land and the historical Afton Mine site. The creek has been used as a source of drinking water, irrigation, and as a drainage channel since the late 1800s. To help mitigate water losses due to seepage and evapotranspiration a 1,000 m portion of the Peterson Creek channel immediately downstream of Jacko Lake was lined with impervious till in 1990 (Price 1991).

The major tributaries of Peterson Creek include Keynes Creek and Humphrey Creek. Peterson Creek has its headwaters southwest of the City of Kamloops in a marshy area to the east of Eureka Lake. From the headwaters, the creek flows northeast and forms the sole inlet to Jacko Lake (KPL 2012). Peterson Creek continues at the controlled outlet of Jacko Lake. Keynes Creek flows north into Peterson Creek less than 1 km downstream of the outflow of Jacko Lake and Humphrey

Creek flows north into Peterson Creek approximately 2.5 km downstream of the confluence with Keynes Creek.

Small, mostly alkaline lakes are relatively common in the Peterson Creek watershed. Jacko Lake, located adjacent to the proposed pit, is the largest water body in the project area. Edith Lake is the second largest lake included in the baseline water quality study and is located at the headwaters of Humphrey Creek. Goose Lake is a shallow lake located in one of the three branches of the headwaters of Keynes Creek.

Jacko Lake has been altered due to human activities dating back to the late 1940s when the outlet channel (Peterson Creek) was modified for irrigation purposes. In order to accommodate irrigation requirements the lake was raised in the 1970s leading to the expansion into the northeast and southeast arms and an expansion of the two westerly arms. In 1990 the lake was again altered with the addition of 1 m to the outlet structure at Peterson Creek and the dredging of silt to effectively double the live storage capacity of the lake. Currently the surface area of the lake is approximately 48 ha. Water licences for extraction from Jacko Lake and Peterson Creek date back to the late 1800s and on wetter years the current requirements can be met through effective management, however, these requirements are not met on drier years (Price 1991).

The two open pit lakes within the Peterson Creek watershed are the Ajax West-East Pit and the smaller Ajax West-West Pit. The two pits were created during previous open pit mining operations and the lakes formed when mining ceased. The lake in Ajax West-East Pit is approximately 30 m at its deepest point and has an estimated surface area of 1.7 ha. The lake in Ajax West-West Pit, was 9 m at its deepest point measured in 2008, and has been dry for periods in the baseline water quality program. The lake surface elevations remain well below the natural ground surface in the area and as such there are no surface discharges. The Ajax East Pit was previously mined but was backfilled with waste rock during reclamation efforts. This open pit was immediately east of the Ajax West Pits open pits and the high walls along the west, north and eastern boundaries are still visible.

2.4.2 Cherry Creek Watershed

The Cherry Creek mainstem length is approximately 24 km and encompasses an area of approximately 190 km^2 (Rescan 2007). Cherry Creek flows into a broad reach of the Thompson River known as Kamloops Lake, approximately 22 km east of the City of Kamloops. The major tributaries of Cherry Creek include Alkali Creek, Beaton Creek, Ned Roberts Creek, and Pendleton Creek (KPL, 2012). The Cherry Creek watershed is a relatively large perennial creek system flowing northwest from Greenstone Mountain to Kamloops Lake. Prior to mining activity in the area, Alkali Creek flowed into what was Hughes Lake (now the site of the historical Afton TSF) before entering Cherry Creek further downstream.

Chuwhels Lake forms the headwaters of Cherry Creek, and has approximately 11.7 ha of surface area. Chuwhels Lake is immediately upstream of the historical and proposed mine facility influence, from a seepage perspective, with water flowing from the lake downstream into the creek through a control structure at its outlet (KPL 2012). Intermittent dry conditions have been observed in downstream reaches of Cherry Creek, which may be attributed to the operating practices for Chuwhels Lake.

Inks Lake is located within the vicinity of the proposed TSF, immediately northeast of the mine site. Inks Lake is located at an elevation of 850 masl and is made up of three distinct lobes, the northwest

lobe (3.1 ha), the northeast lobe (2.0 ha), and the main south lobe (8.1 ha). The total surface area of the lake is approximately 13.2 ha. Throughout the study period no flowing inlet or outlet channels have been observed, and Inks Lake is isolated from nearby fish bearing water bodies.

Wallendar Lake is similar to Inks Lake in that it is sustained by spring melt, groundwater inflows and precipitation and there are no outlet channels. Water levels are highly dependent on precipitation, and the pond remains dry for the better part of the year. The lake is smaller than Inks Lake (approximately 3.2 ha) and is immediately east of Lac La Jeune Highway, approximately 1 km north of Inks Lake.

2.5 HYDROGEOLOGICAL SETTING AND CONCEPTUAL MODEL

The hydrogeological setting and conceptual model provided below is based upon the Ajax Project *Baseline Groundwater Hydrology Assessment* report (BGC 2015a). For a more detailed description of the Project groundwater resources and the hydrogeological setting please reference that report.

A total of 13 aquifers have been mapped within the region, eight of which are sand and gravel aquifers and five are bedrock aquifers. Five of the 13 aquifers are located within the immediate project area. Three of the aquifers in the immediate project area, the Sugarloaf Hill (No. 0276), Knutsfords (No. 0275), and Brigade Lake (No. 0278) are bedrock aquifers, and the Davidson Creek (No. 0277) and Peterson Creek (No. 0278) are sand and gravel aquifers. These aquifers have been classified based on the vulnerability to potential contamination and the level of use (development). The methodology for classification is provided in the Ministry of Environment online resource entitled An Aquifer Classification System for Ground Water Management in British Columbia (Kreye et.al. 2013). In accordance with this classification system the Davidson Creek and Knutsford aquifers are classified as moderately developed and the Sugarloaf Hill, Peterson Creek, and Brigade Lake aquifers are classified as lightly developed.

"*Surficial materials in the RSA are comprised of glacial and post-glacial deposits consisting primarily of discontinuous glacial till, with occasional sand and gravel hummocks. Lacustrine silts and clays are common in valley bottoms. Surficial materials have been grouped into glaciofluvial/fluvial, glacial till, glaciolacustrine/lacustrine, waste rock and colluvium hydrostratigraphic units based on geologic provenance, available drill hole, test pit and mapping data. The fluvial/glaciofluvial hydrostratigraphic unit consists of glacial sand and gravel complexes and post-glacial fluvial deposits. The connectivity of hydraulically conductive gravels within these deposits could be limited due to their complex depositional history. Variable states of aquifer confinement throughout the fluvial/glaciofluvial unit are conceptualized due to layering and heterogeneity. This hydrostratigraphic unit includes the mapped Peterson and Davidson Creek Aquifers near the Mine Site. Bedrock has been divided into Nicola Group, Picrite, Iron Mask Hybrid, Sugarloaf Diorite and Kamloops Group hydrostratigraphic units consistent with mapped and modelled geology. The mapped Sugarloaf Hill bedrock aquifer is included with the Iron Mask Hybrid unit and the mapped Knutsford bedrock aquifer is included in the Kamloops Group unit. The sub-horizontal deposition of Kamloops Group could impart a layered characteristic giving it a macroscale anisotropy.*

Available hydraulic conductivity (K) data indicate that, within overburden, fluvial/glaciofluvial deposits are generally the most conductive, and glacial till deposits are the least conductive. The distribution of K data in bedrock suggest that the bedrock hydrostratigraphic units may be ordered from most to least conductive as follows: Kamloops Group, Iron Mask Hybrid, Picrite, Sugarloaf Diorite, Nicola

Group. There is a general trend of decreasing K with depth within the LSA, where below approximately 200 m bgs, bedrock K is typically less than 1 x 10^{-8} m/s. This suggests a potential for a separation of shallow and deep groundwater flow systems, with groundwater flow most active within overburden and shallow bedrock, particularly within aquifer complexes comprising the fluvial/glaciofluvial hydrostratigraphic unit. Estimates of specific storage for the various units vary by material type and include values calculated from the results of pumping tests and slug tests near the Mine Site. Specific storage estimates reported in this assessment were augmented by calibrated results from a companion numerical groundwater flow model being completed for the Project EA.

Alteration zones and geologic faults of potential hydrogeologic significance include swelling clays/bentonite and the Hugh Allen and Versatile faults in Aberdeen, and serpentinized picrite and the Edith Lake Fault Zone (ELFZ) near the Mine Site. The swelling clays in Aberdeen are susceptible to instability when groundwater pressures are raised due to development-related recharge [Golder, 2008a]. The Hugh Allen and Versatile faults have been interpreted to act as barriers to groundwater flow, contributing to local artesian conditions [Golder, 2008a]. The serpentenized picrite has been noted to be weaker and more altered than adjacent rocks and is considered to be a unique hydrostratigraphic unit in this assessment. Preliminary results of drilling investigations suggest a potentially enhanced K within the ELFZ compared to the surrounding country rock."

Groundwater flow on a local and regional scale has been interpreted to be controlled by topography, with recharge in the upland areas and discharge in the low-lying areas. On a regional scale, the conceptual groundwater model extends from Chuwhels Mountain (approximately 20 km southwest of the project area, elevation 1900 masl (metres above sea level)) to Kamloops Lake/Thompson River area (approximately 7 km north, elevation 340 masl). Groundwater flows, on a regional scale, are from south to north and are understood to be dominantly along deeper (i.e., > 200 m) slow moving bedrock flow pathways, that become more shallow in the vicinity of Kamloops Lake. The abstraction of water in the Aberdeen area to maintain slope stability is considered a regional scale sink for groundwater flows. *"Project-scale groundwater flow is predicted to be dominated by local-scale systems within overburden and the top 200 m of bedrock. Principal discharge zones near the Mine Site include reaches of Peterson Creek and Jacko Lake, the existing Ajax West Pit lakes as well as other local ephemeral streams, sloughs and ponds. Local artesian conditions are observed in the lower lying region that extends from the north arm of Jacko Lake and in topographic depressions around the WMRSF, TSF and SMRSF footprints.*

The available groundwater elevation data support a separation of shallow overburden and deep bedrock groundwater flow in the project area. The shallow system is driven more strongly by topography and is interpreted to recharge the deeper regional system. The deeper regional system has a slower component of flow moving down-gradient (north) towards Kamloops Lake/Thompson River. Near the Mine Site, groundwater converges locally towards the existing Ajax West Pits. Groundwater also converges towards the towards topographic saddle that occurs near the confluence of Peterson Creek with Jacko Lake, and then flows either northwestward from Jacko Lake beyond the Project area, or eastward following the Peterson Creek drainage. The available potentiometric data suggest that groundwater follows this trend northwestward or eastward away from the project site to merge with flow systems beyond the LSA.

Seasonal fluctuations in groundwater levels range from less than 0.1 m to approximately 3 m, annually. Groundwater elevations monitored within the Project area typically decline through the

winter and spring (i.e., September to March), and are highest during the summer and fall quarter (i.e. June to September). The seasonal variation in groundwater levels is consistent with precipitation and temperature trends. Some monitoring locations near the Mine Site also show rapid water level recoveries (i.e., within a month) following precipitation events. These locations are interpreted to receive localized sources of recharge due to an enhanced hydraulic connection to surface water. Groundwater at locations where water levels appear to reach seasonal maxima in September or October likely receive recharge from more regional sources (i.e., inter-aquifer flow) in addition to infiltration of surface water.

A number of faults have been mapped in the vicinity of the Mine Site. At the pit-scale, faults have not been defined as distinct hydrogeologic structures because the available hydraulic conductivity test data did not indicate that these zones are significantly more or less conductive than the surrounding rock mass at the time this report was prepared. However, recent investigations around the ELFZ suggest that this feature may exhibit an enhanced local hydraulic conductivity compared to the surrounding country rock to the south of Jacko Lake" (BGC 2015a).

3 – METHODOLOGY

3.1 OBJECTIVES

The primary objectives of the baseline surface water and groundwater quality programs are to:

- Collect and analyze baseline water quality data to characterize the existing conditions.
- Evaluate the water quality data to develop a conceptual understanding of the hydrological and hydrogeological environment.
- Provide the basis for assessing potential water quality effects, mitigation measures, monitoring and contingency planning as the mine planning proceeds.

The methods described in this section are employed for the surface water and groundwater quality programs to meet the objectives of the study and the data quality objectives, outlined in the quality assurance/quality control report (QA/QC) in Appendix A. Groundwater and surface water samples have been collected since 2007, either by KP or under the technical guidance of Knight Piésold Consulting (KP) or under the technical guidance of KP personnel. Field staff who have collected samples were provided with work instructions and training which are summarized in the following subsections.

3.2 SURFACE WATER SAMPLING METHODOLOGY

The water quality program and sampling protocols were implemented following the general requirements of the following documents:

- Guidelines for Designing and Implementing a Water Quality Monitoring Program in British Columbia. BC Ministry of Environment, Lands and Parks, Wildlife Branch. Resource Inventory Committee. 1998.
- British Columbia Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-emission, Water, Wastewater, Soil, Sediment and Biological Samples. 2003 Edition. BC Ministry of Water, Land and Air Protection.
- Protocols Manual for Water Quality Sampling in Canada. Canadian Council of Minister of the Environment. 2011.
- Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators. Prepared by the Ministry of Environment. October 9, 2012 (MoE 2012).

In situ parameters were routinely collected for each sample using a regularly calibrated multi-parameter probe. The multi-parameter probe was exposed to surface water conditions downstream of the sampling area so as not to disturb the sediment and was left in place until the parameters have stabilized. These parameters are pH, temperature, turbidity, dissolved oxygen, conductivity, and specific conductance (SpC).

Grab samples were collected from the active flow channel of the creeks, either obtained by wading into the creek or by reaching out from the bank. Water samples were collected by inserting the bottle neck down into the water; once submerged, the bottle was tipped with the mouth facing upstream. The bottle remained submerged until full. This method minimizes the amount of surface debris that can contaminate the sample. In cases where water levels were not sufficient to submerge the bottles, a disposable 60 mL syringe was used to extract water samples from below the surface. Dissolved metals and dissolved organic carbon samples were filtered using a 60 mL syringe with

0.45 µm syringe filters. All samples were preserved and filtered in the field, unless otherwise specified, according to the instructions sent from the laboratory.

3.3 GROUNDWATER SAMPLING METHODOLGOY

The sampling procedures were adapted from the following documents:

- British Columbia Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-emission, Water, Wastewater, Soil, Sediment and Biological Samples. 2003 Edition. BC Ministry of Water, Land and Air Protection.
- Low-Flow (Minimum Drawdown) Ground-Water Sampling Procedures. 1996. United States Environmental Protection Agency. EPA/540/S-95/504 (Puls, W. and Barcelona, M. 1996).
- Water and Air Baseline Monitoring Guidance Document for Mine Proponents and Operators. Prepared by the Ministry of Environment. October 9, 2012 (MoE 2012).

The groundwater sampling methodology for the Project has evolved since its inception in 2007. New practices to improve sample integrity have been established through the baseline program. Initially, the monitoring wells were purged and sampled using Waterra inertial pumps (tubing with foot valves) and/or bailers (for slow recovery wells), and all wells were purged of three well volumes, or so to dry, prior to collecting a sample. High turbidity values were a common result of these methods, so the methodology was changed and electronic submersible pumps were used. The three well volume approach to purging was phased out to current methods which are specific to low-flow (minimum draw-down) purging and sampling. Current methods have resulted in lower turbidity samples which are more representative of the groundwater conditions. The following methods description is specific to the current groundwater sampling practices at site, which have been the dedicated methods of sample collection since 2011.

3.3.1 Low-Flow Sampling

To collect representative groundwater samples, stagnant water present in the well was purged prior to sampling. The purging and sampling methods employed were dictated by the conditions of each individual well. Two approaches were applied to the purging and sampling, as the wells fall into two categories: wells that recover very quickly (i.e. a minimum drawdown can be maintained while purging), and wells with slow to very slow recovery rates where minimum drawdown cannot be maintained (despite pumping rates below 0.2 L/min). Both methods, described in detail in the following sub-sections, are considered low-flow methods and require the use of a submersible pump.

The submersible pump was placed approximately 1 m above the top of the screen and was set at a low pumping rate during purging and sampling to minimize turbulence in the well and surrounding formation. Target pumping rates ranged from 0.2 litres per minute (L/min) to 0.5 L/min, though higher rates were sometimes employed in cases where the turbidity was low and the water levels in the well were maintained. The following pump systems were used for purging and sampling the Ajax Project wells:

- QED SamplePro submersible pump, and
- Grundfos RediFlo2 submersible pump.

During the purging process *in situ* parameters were monitored using a regularly calibrated multi-parameter probe with a flow-through cell. The flow-through cell provides a closed environment for the collection of *in situ* data, minimizing interaction with ambient atmospheric conditions. Final *in situ*

parameters for each sampling event were recorded immediately prior to collecting the sample. The *in situ* parameters recorded are as follows: pH, temperature, dissolved oxygen, conductivity, SpC, turbidity and oxidation-reduction potential. Depth to water is recorded throughout each sampling event using a water level meter. Well stick-up and total well depth were also recorded for each sampling event.

Once the purging conditions were met and the final in situ parameters were recorded, the water line was disconnected from the flow-through cell and water samples were collected. Samples for dissolved parameters were filtered in the field by attaching a 0.45 µm in-line filter to the water line. Any required preservatives were added immediately after sample collection. Groundwater is generally in a reducing environment and efforts were made to preserve the samples in their original form. Using in-line filters reduces sample contact with ambient surface conditions and immediate preservation of the samples assists in this process also.

3.3.1.1 Low-Flow Minimum Drawdown Purging and Sampling Approach

The low-flow minimum drawdown procedure was used to purge and sample the Project wells when hydraulic conductivity of the formation was high enough to allow stable drawdown conditions during pumping. The primary objective of this sampling method is to match the pumping rate with that of the groundwater flow rate in the formation. This was achieved by adjusting the pumping rate such that the water level in the well would stabilize during pumping at an elevation relatively close to the pre-pumping water level. When a stable water level was attained, the water entering the pump was assumed to be coming from the formation around the screened interval below the pump intake and not from the stagnant overlying water column.

Well purging was complete and samples were collected when all of the following objectives were met during the purging process:

- Minimum purge volume was removed (volume in drawdown plus the volume below the pump intake)
- Stable *in situ* parameters (pH, SpC, temperature, turbidity, oxidation reduction potential, and dissolved oxygen), and
- The water level was confirmed to be stable or rising.

Final *in situ* parameters were recorded for the sampling event immediately prior to collecting the sample.

The key advantages of the low-flow groundwater quality sampling method are:

- Minimise the groundwater velocity (and thus turbulence) as the water enters the well during pumping
- More representative samples due to reduced turbidity, and
- Reducing purge volume.

3.3.1.2 Low Hydraulic Conductivity Well Purging and Sampling Approach

The low hydraulic conductivity sampling approach was used when the water levels in the wells were slow to recover (low hydraulic conductivity) and the groundwater flow rate was less than the lowest pumping rate (i.e. less than 0.01 L/min). This approach was used when the water level continued to drop during the purging process, despite pumping at the lowest rate. The stagnant water above the

pump was purged and the well was allowed to recover overnight, or longer, with the pump in place. As the well recovered, the stagnant water below the pump was assumed to be displaced and fresh groundwater surrounded the pump. Additional water was often purged from the well, provided there was sufficient recovery. The objective was to purge a minimum of 1 full well volume prior to sample collection. This process often took place over several days, with several visits to the well to record water levels and to purge water.

The key disadvantages of this approach are:

- Potentially less representative samples due to mixing of stagnant water with formation water
- Increased hydraulic gradient imposed on the surrounding aquifer and potential for turbulence as the water enters the well
- Greater purge volume, and
- Longer sampling time.

In situ parameters were routinely monitored and recorded through the purging process and final values were recorded immediately prior to sampling.

3.4 LABORATORY ANALYSIS

Water samples were submitted to ALS Environmental in Burnaby for the following analyses:

- Physical Tests – Hardness, pH, SpC, total dissolved solids (TDS), total suspended solids (TSS), and turbidity
- Dissolved Anions – Alkalinity (bicarbonate, carbonate, and hydroxide), bromide, chloride, fluoride, and sulphate
- Nutrients – Ammonium nitrogen, nitrate, nitrite, dissolved orthophosphate, and total and dissolved phosphate
- Total and Dissolved Metals - analyzed at low levels to meet the B.C. Water Quality Guidelines (BCWQG) and the Canadian Environmental Quality Guidelines (CEQG) criteria values
- Cyanide - Free, total, and weak acid dissociable (WAD), and
- Organics – Total organic carbon (TOC).

Sample dilution was often required for the analysis of samples of high TDS (i.e. greater than 500 mg/L), which resulted in raised method detection limits (MDL). The requirement for sample dilution is based on matrix interference and the magnitude of dilution varied depending on specific concentrations of the constituents of the TDS. Alternative analytical procedures were used to achieve lower MDLs when necessary.

3.5 GUIDELINES

Baseline water quality analytical and *in situ* data were examined and compared to relevant guidelines with respect to the most sensitive receptors in the downstream environment. The guidelines relevant to the water quality data for the Project are as follows:

- British Columbia Ministry of Environment Approved and Working Water Quality Guidelines (BCWQG) (BC MOE 2015a and BC MOE 2015b):
  - Drinking Water Supply (BCWQG-DW)
  - Fresh Water Aquatic Life (BCWQG-Aq)
    - Maximum (BCWQG-Max)
    - 30 Day Average (BCWQG-30 D)

  - Livestock Water Supply (BCWQG-Livestock)
  - Irrigation (BCWQG-Irrigation)
  - Recreation (BCWQG-Rec)
- Canadian Council of Ministers of the Environment (CCME), Canadian Environmental Quality Guidelines (CCME 2014):
  - Water Quality Guidelines for the Protection of Aquatic Life (Freshwater) (CEQG-PAL)
  - Water Quality Guidelines for the Protection of Agriculture (Livestock) (CEQG-Livestock)
  - Water Quality Guidelines for the Protection of Agriculture (Irrigation) (CEQG-Irrigation)
  - Water Quality Guidelines for the Protection of Wildlife (CEQG-Wildlife)
- Health Canada (Health Canada 2012):
  - Guidelines for Canadian Drinking Water Quality (HC-DW)
  - Guidelines for Canadian Recreational Water Quality (HC-Rec)

Guidelines for some parameters are hardness or pH dependent. In these cases, the guideline was assessed based on the measured hardness or pH in each sample. For sample summary statistics and figures, the guideline value was based on the average hardness or pH of all samples in the dataset or data subset used in the statistical analysis.

Aquatic life guidelines developed for British Columbia generally refer to the total fraction of the parameter being evaluated. The water quality guidelines for the protection of aquatic life have been applied to both total and dissolved concentrations for all parameters, unless the guideline specifically addresses the dissolved fraction. For example, in British Columbia, the aquatic life guidelines for aluminum are for the dissolved fraction only, and the iron guidelines have different values for total and dissolved, recognizing the difference in biological availability of these parameters based on the form present in the water column. Iron and aluminum are the only metals that have aquatic life guidelines that differentiate between the total and dissolved concentrations, the remaining aquatic life guidelines are stated to apply to the total fraction. Since the dissolved fraction should never exceed the total fraction, applying the guidelines to both total and dissolved fractions is deemed appropriate and understanding the relative relationship between the total and dissolved fractions is very important for water quality characterization. The CEQG-PAL limits are not specific to total or dissolved fractions and have been applied to both.

The BCWQG – 30 D for aquatic life is based on the average of five samples collected over a 30-day period. Project surface water samples were collected on a monthly basis for all seasons except during freshet, when samples were collected weekly; bi-monthly samples were also collected outside of the freshet period in 2014 in order to provide a more advanced characterization of seasonal water quality and to provide a robust dataset for the sites that were added to the sampling program in 2014. During freshet, if the average of any five samples collected within a 30-day period was higher than the BCWQG – 30 D, it was considered to represent the potential for chronic toxic effects to aquatic life. The observed sample concentrations in exceedance of this guideline outside of the freshet period are not necessarily true exceedances of the guideline; rather, they provide an indication of the possibility of chronic toxic effects to aquatic life as a result of prolonged exposure to concentrations at or above a chronic guideline. Groundwater samples were collected on a quarterly basis and the BCWQG-30 D are not directly applicable; however, these guidelines have been used as benchmarks for the groundwater quality assessment as regular exceedances of these thresholds may indicate chronic toxicity in local receiving water environments.

The BCWQG-30 D for sulphate specifies that site specific toxicity testing is required when hardness exceeds 250 mg/L $CaCO_3$, as was frequently the case in the baseline surface water environment in the project area. The toxicity testing, documented in *Testing in support of development of a science based environmental benchmark for sulphate for the Ajax Mine* (Nautilus 2015), resulted in a recommended science based environmental benchmark (SBEB) for a maximum sulphate concentration of 429 mg/L, which is the same as the current BCWQG-30 D, but with the maximum hardness adjusted up to 800 mg/L $CaCO_3$ which is protective of early life stages for trout (present from May through June). An alternative SBEB of 730 mg/L for a hardness of up to 1,377 mg/L $CaCO_3$ was recommended for surface waters where early life stages for trout are never present, or for periods of the year when these life stages are not expected to be present in a given reach of Peterson Creek (July through April). All of the baseline water quality samples have been screened against the BCWQG-30 D and highlighting in the tables and lines on figures are specific to this guideline. The discussion in the text is expanded to account for the SBEB and specific details with respect to presence or absence of fish and the early life stages.

Drinking water quality guidelines are not typically applicable to source waters such as those sampled for the purposes of this baseline surface water and groundwater quality characterization, but are intended to protect human health and as such are applicable to treated waters or that which comes from a tap for human use. For the purposes of characterizing the existing conditions, these guidelines have been used for comparison to untreated source waters. In some cases, the HC-DW and BCWQG-DW limits are aesthetic objectives and are not based on health effects; the aesthetic objectives are used as a basis of comparison, but are qualified in the text as such. It is recognized that surface water sources are rarely of sufficient quality for direct use as a source of drinking water without some form of conventional treatment, whereas groundwater may not require treatment. The guidelines have been applied to both total and dissolved sample concentrations for all parameters that have been reported accordingly.

The varied terrain of the project area and its proximity to densely populated areas contribute to the multidisciplinary water use and the relevance of many different guidelines. While twelve relevant guidelines have been identified and listed above, the guidelines vary and some are more stringent than others. The most stringent guidelines are generally for aquatic life which have been used to screen the data and identify parameters that exceed guidelines. While all types of guideline exceedances are discussed within the scope of this report, most exceedances of guidelines are within the subset of aquatic life guideline exceedances. The least stringent guidelines are the recreational category, which are discussed in the text, but are not highlighted in the data tables. Surface water and groundwater data tables are presented in comparison with the following groupings of guidelines in Appendix C and Appendix D, respectively:

- Aquatic life guidelines
- Drinking water guidelines
- Agricultural guidelines
- Wildlife guidelines, and
- Recreational guidelines.

Some guidelines are relevant to both surface water and groundwater; however, recreational guidelines are applicable only to surface water bodies, since groundwater is never used directly for recreation. Aquatic life guidelines are specifically targeted to surface water bodies; however, they have been applied to groundwater as well, since they are generally the most stringent guidelines and

are good indicators of potential concerns to aquatic life in areas where groundwater contributes significantly to surface water flows. Groundwater discharge to surface water varies during the water year and has a greater influence on surface water during low-flow months (i.e. winter) when groundwater comprises nearly all flow in surface water. Understanding the groundwater chemistry in relation to aquatic life guidelines is important in determining the effects of changes in groundwater on aquatic habitat. Wildlife guidelines have been applied to groundwater for similar reasons. Agricultural (livestock and irrigation) water quality guidelines can be directly applied to groundwater as these water uses can be specifically sourced from groundwater.

3.6 QUALITY ASSURANCE/QUALITY CONTROL

A QA/QC program was implemented from the on-set of the environmental baseline program. The program assists with obtaining representative data in a manner which is scientifically defensible, repeatable, and well documented. Quality assurance is facilitated at the project management level through organization and planning and the enforcement of both external and internal quality control. The following lists are a summary of the QA/QC procedures and practices being followed, which are described in detail in Appendix A:

- Internal Quality Control:
  - Staffing the project with experienced/trained individuals
  - Providing representative, meaningful data are collected through planning and efficient research
  - Use of standard protocols for sample collection, preservation, and documentation
  - Regular calibration and maintenance of all field equipment, and
  - Collection of duplicate, blank and filter blank samples for submission for analysis (approximately 10% of overall samples).
- External Quality Control:
  - Employment of fully accredited analytical laboratories for the analysis of all samples, and
  - Determination of analytical precision and accuracy through the interpretation of the analysis reports for the blind duplicate, blank, and filter blank samples.

The quality of the dataset included in this report was assessed based on adherence to the pre-set data quality objectives (DQOs). DQOs provide a means of assessing the QA/QC data and determining whether the data in question were precise, accurate, representative, and complete. The results from QA/QC samples (blanks and duplicates) were reviewed to determine if sample contamination has occurred, and these data were further used to determine if contamination occurred during collection, handling, storage, or shipping. Upon receipt from the laboratory the data were uploaded into KP's in-house data management system, FULCRUM, along with copies of field notes, photos, Microsoft Excel data, and Certificates of Analysis. The data were then routinely reviewed by the procedures outlined in Appendix A, including the following:

- Sample holding times
- Duplicate samples
- Blank samples
- Total and dissolved metals comparison
- Data validation
- Method detection limits (MDL)
- Analytical precision

- Analytical accuracy
- Ion balance (groundwater quality only)
- Turbidity (groundwater quality only), and
- Outliers.

The data were assessed compared to the DQOs on a timely basis upon receipt of analytical data from the laboratory. Flagged data were investigated, but may or may not be included in the baseline data set, depending on the level of the deviation from the acceptable limits and on the suspected reason for that deviation. In cases where the investigation indicated a potential lack of integrity of the data, the data were not used in the analysis. In some cases, however, flagged data were the result of an error in the collection or analysis of a QA/QC sample that did not affect the representative samples of the field site (ex. contaminated blank samples due to low grade deionized water from the lab). In these cases, flagged data were included in the baseline data set. Details of the data quality assessment procedures and results are provided in Appendix A.

4 – SURFACE WATER QUALITY ASSESSMENT

4.1 OVERVIEW

The surface water quality and *in situ* data collection program began in 2007, and with the exception of one year (2009), has continued to the present day. Surface water sampling sites were strategically selected based on proximity to Project facilities and historical mine site features. A total of 38 surface water sampling sites have been established to date, of which five are no longer actively sampled as they are not related to the current project plan. A summary of the samples collected to date is shown in in Table 4.1 and the site locations are shown on Figure 4.1. A broad overview of the project setting within catchment boundaries is shown on Figure 1.1.

The baseline characterization of surface water quality is focused on summarizing the physical characteristics of the waters found in the project area and defining seasonal and spatial trends. This analysis is intended to be used as a basis for determining and quantifying potential changes in water quality as a result of the Project. In compliance with government regulations, and to provide context for the observations in water quality, data have been compared to relevant guidelines. The parameters discussed in this report have been selected based on the relevance of guideline exceedances, using the aquatic life guidelines as the most relevant and most stringent basis of comparison. In general, parameter concentrations are described qualitatively as low, high, very high, and elevated. These qualitative descriptions are based on observations of water quality typical of natural waters and refer to spatial and seasonal variations in concentrations. Where concentrations exceed guidelines, the exceedances are stated explicitly.

Summaries of parameters for which aquatic life guidelines were exceeded are shown as percentages of the total number of samples at each site that exceeded one or more aquatic life guidelines in Table 4.2 for sites in the Peterson Creek watershed and in Table 4.3 for sites in the Cherry Creek, Anderson Creek, and Thompson River watersheds. The parameters that exceeded drinking water and agricultural guidelines are shown in the same watershed groupings in Table 4.4 and Table 4.5 (drinking water guideline exceedances) and in Table 4.6 and Table 4.7 (agricultural guideline exceedances). Parameters that regularly exceeded guideline categories other than aquatic life (i.e. drinking water, agriculture, wildlife, and recreational water quality guidelines; Section 3.5) are also discussed in this report; however, most of these parameters also exceed aquatic life guidelines.

Physical parameters are an important part of water quality characterization; however guidelines are often not directly applicable. For total dissolved solids, hardness, and alkalinity, ranges of parameter concentrations are used to define water types. The ranges used for descriptions in this report are listed below.

Hardness is defined as soft to very hard, based on the following ranges of $CaCO_3$ concentrations:

- Soft: 0 mg/L to 60 mg/L
- Moderately hard: 61 mg/L to 120 mg/L
- Hard: 121 mg/L to 180 mg/L, and
- Very hard: ≥181 mg/L.

TDS is used to classify water salinity in the following categories (NGWA 2010):

- Freshwater: less than 1,000 mg/L
- Slightly saline water: 1,000 mg/L to 3,000 mg/L

- Moderately saline water: 3,000 mg/L to 10,000 mg/L, and
- Highly saline water: 10,000 mg/L to 35,000 mg/L (ocean water contains 35,000 mg/L salt).

Alkalinity is a measure of the sensitivity of a waterbody to changes in pH and is usually reported as a concentration of $CaCO_3$ (BC MoE 2015b):

- Highly sensitive to acidic inputs/low buffering capacity: <10 mg/L $CaCO_3$
- Moderate sensitivity to acidic input/buffering capacity: 10 mg/L $CaCO_3$ to 20 mg/L $CaCO_3$, and
- Low sensitivity to acidic input/good buffering capacity: >20 mg/L $CaCO_3$.

Guideline limits are not applicable to some nutrient parameters, including phosphorous, which is used instead to define the trophic status of surface water bodies. The trophic status is generally categorized by the dissolved phosphorus concentrations, as well as chlorophyll A and Secchi depth. Phosphorus is often the limiting nutrient in a water body, though this is not likely the case for the project area. The trophic status is determined as a baseline for which to assess changes from current conditions, as specified in *Phosphorus: Canadian Guidance Framework for the Management of Freshwater Systems* (CCME 2004). The ranges of total phosphorus (TP) used to define each trophic category are as follows:

- Ultra-oligotrophic <0.004 mg/L
- Oligotrophic 0.004 mg/L to 0.010 mg/L
- Mesotrophic 0.010 mg/L to 0.020 mg/L
- Meso-eutrophic 0.020 mg/L to 0.035 mg/L
- Eutrophic 0.035 mg/L to 0.100 mg/L, and
- Hyper-eutrophic >0.100 mg/L.

Major ion concentrations were used in piper diagrams to characterize surface water types that could be compared with the water types observed in groundwater. A piper diagram is a trilinear plot of the major dissolved ions in water, which provides a visual interpretation of water types. Groundwater recharge has greatest influence on creek water quality during winter, when surface water runoff is at a minimum; this is the best season to compare groundwater samples to surface water. The median winter low-flow concentrations of the major ions at surface water sites were plotted on piper diagrams, grouped by catchment area, on Figure 4.2 through Figure 4.5 to demonstrate these ion signatures. Groundwater is often characterized as the sodium-potassium-sulphate type, while surface water is higher in calcium and bicarbonate. Inks Lake, Keynes Creek, Goose Lake, and the historical mine feature sites are all water bodies that are recharged by surfacing groundwater and are generally higher in sulphate, sodium, and potassium, with lower contributions from calcium and bicarbonate. Within Peterson Creek, sulphate concentrations relative to bicarbonate concentrations vary spatially, increasing from upstream to downstream. This indicates that the lower-gradient sites are affected by groundwater recharge more than the sites closer to the headwaters, where ion signatures are more consistent with surface water runoff. A similar trend is observed in Humphrey Creek, where relative sulphate is higher at the site furthest downstream from the source (Humph-02) than the upstream sites and the headwaters at Edith Lake, where bicarbonate is the dominant anion.

M:\1\01\00246\31\A\Report\3 - Baseline Water Quality - GW SW\Rev1\Tables\[Tables - Rev0.xlsx]5.6

NOTES:

1. GUIDELINES ARE PRESENTED IN mg/L UNLESS OTHERWISE STATED; SAMPLE COUNTS ARE INTEGER VALUES; ALL OTHER UNITS ARE %.
2. BRITISH COLUMBIA WATER QUALITY GUIDELINES (APPROVED AND WORKING) - 30 DAY AVERAGE LIMITS (BCWQG-30 D) - FRESHWATER AQUATIC LIFE.
3. BRITISH COLUMBIA WATER QUALITY GUIDELINES (APPROVED AND WORKING) - MAXIMUM LIMITS (BCWQG-MAX) - FRESHWATER AQUATIC LIFE.
4. CANADIAN ENVIRONMENTAL QUALITY GUIDELINES - WATER QUALITY GUIDELINE FOR THE PROTECTION OF AQUATIC LIFE (CEQG-PAL) - FRESHWATER.
5. VALUES REPRESENT PERCENTAGES OF SAMPLES COLLECTED AT EACH SITE THAT EXCEED ONE OR MORE AQUATIC LIFE GUIDELINE.
6. HARDNESS (H) DEPENDENT GUIDELINE LIMIT (DISSOLVED).
7. pH DEPENDENT GUIDELINE LIMIT (*IN SITU* VALUE PREFFERED).
8. TEMPERATURE DEPENDENT GUIDELINE LIMIT.
9. GUIDELINE IS SPECIFIC TO TOTAL CONCENTRATION ONLY.
10. GUIDELINE IS SPECIFIC TO DISSOLVED CONCENTRATION ONLY.
11. GUIDELINE IS APPLIED ONLY FOR WATERS OF DISSOLVED HARDNESS >250 mg/L AND IS DEPENDENT ON TOXICITY TESTING.
12. THE PERCENTAGE IS BASED ON THE NUMBER OF SAMPLES THAT EXCEED THE LOWEST APPLICABLE GUIDELINE.

M:\1\01\00246\31\A\Report\3 - Baseline Water Quality - GW SW\Rev1\Tables\[Tables - Rev0.xlsx]5.6

NOTES:

1. GUIDELINES ARE PRESENTED IN mg/L UNLESS OTHERWISE STATED; SAMPLE COUNTS ARE INTEGER VALUES; ALL OTHER UNITS ARE %.
2. BRITISH COLUMBIA WATER QUALITY GUIDELINES (APPROVED AND WORKING) - 30 DAY AVERAGE LIMITS (BCWQG-30 D) - FRESHWATER AQUATIC LIFE.
3. BRITISH COLUMBIA WATER QUALITY GUIDELINES (APPROVED AND WORKING) - MAXIMUM LIMITS (BCWQG-MAX) - FRESHWATER AQUATIC LIFE.
4. CANADIAN ENVIRONMENTAL QUALITY GUIDELINES - WATER QUALITY GUIDELINE FOR THE PROTECTION OF AQUATIC LIFE (CEQG-PAL) - FRESHWATER.
5. VALUES REPRESENT PERCENTAGES OF SAMPLES COLLECTED AT EACH SITE THAT EXCEED ONE OR MORE AQUATIC LIFE GUIDELINE.
6. HARDNESS (H) DEPENDENT GUIDELINE LIMIT (DISSOLVED).
7. pH DEPENDENT GUIDELINE LIMIT (*IN SITU* VALUE PREFFERED).
8. TEMPERATURE DEPENDENT GUIDELINE LIMIT.
9. GUIDELINE IS SPECIFIC TO TOTAL CONCENTRATION ONLY.
10. GUIDELINE IS SPECIFIC TO DISSOLVED CONCENTRATION ONLY.
11. GUIDELINE IS APPLIED ONLY FOR WATERS OF DISSOLVED HARDNESS >250 mg/L AND IS DEPENDENT ON TOXICITY TESTING.
12. THE PERCENTAGE IS BASED ON THE NUMBER OF SAMPLES THAT EXCEED THE LOWEST APPLICABLE GUIDELINE.

M:\1\01\00246\31\A\Report\3 - Baseline Water Quality - GW SW\Rev1\Tables\[Tables - Rev0.xlsx]5.6

NOTES:

1. GUIDELINES ARE PRESENTED IN mg/L UNLESS OTHERWISE STATED; SAMPLE COUNTS ARE INTEGER VALUES; ALL OTHER UNITS ARE %.
2. VALUES REPRESENT PERCENTAGES OF SAMPLES COLLECTED AT EACH SITE THAT EXCEED ONE OR MORE AQUATIC LIFE GUIDELINE.
3. BCWQG-Irrigation: BC WATER QUALITY GUIDELINES FOR IRRIGATION.
4. BCWQG-Livestock: BC WATER QUALITY GUIDELINES FOR LIVESTOCK.
5. CCME-Irrigation: CCME GUIDELINES FOR IRRIGATION.
6. CCME-L CCME GUIDELINES FOR IRRIGATION.
7. THE PERCENTAGE IS BASED ON THE NUMBER OF SAMPLES THAT EXCEED THE LOWEST APPLICABLE GUIDELINE.

REV	DATE	DESCRIPTION	PREP'D	RVW'D
1	10JUL'15	ISSUED WITH REPORT VA101-246/31-3	CJ	JEM

The *in situ* and analytical sample data are provided in tabular form in Appendix C, with a separate table for each site and grouping of guidelines. The guideline exceedance discussions below are related specifically to the freshwater aquatic life guidelines. The guideline exceedance tables specific to aquatic life are presented in Appendix C1. The drinking water and agricultural water use guideline comparisons are tabulated in Appendix C2 and Appendix C3, respectively. Summaries of the relatively few guideline exceedances for wildlife and recreational water uses are listed in Appendix C4 and Appendix C5, respectively. Exceedances related to guidelines other than aquatic life have been noted in the text, but have not been discussed at length. Surface water summary statistics are included in Appendix C6. Depth profiles of *in situ* parameters in Jacko Lake have been recorded since 2007 and Edith Lake has been profiled in 2014 and are provided for dissolved oxygen, temperature, and pH in Appendix C7; the most recent (2014) lake profiles have been included as examples embedded in the relevant sections of the report.

Throughout the following discussion graphs have been used to help demonstrate the spatial and seasonal variability in some of the more abundant parameters or those that exceeded one or more guidelines. Boxplot graphs were most frequently used to help demonstrate the spatial variability in the watersheds. Boxplots, or box and whisker plots, have been used to graphically portray the 75th, 50th, and 25th (quartiles) percentile summary data for a given parameter, and the whiskers are representative of the maximum and minimum concentrations; outliers were included. Guidelines provided on these plots are specific to aquatic life as these guidelines tend to be the most conservative. Exceedances of other guidelines are addressed in the text.

Seasonality and spatial variability of the data are similar for most parameters discussed in this report and this discussion for each parameter may seem repetitive with respect to these observations. The intention is that these details are not lost for the reader that will only focus on a couple of parameters and not read the report from beginning to end.

4.2 SAMPLING FREQUENCY

The majority of the water quality monitoring sites has been sampled on a monthly basis for the last four years; however, the sampling frequency prior to that was quarterly. Spring freshet sampling programs were also conducted in 2011, 2012, and 2014; these programs included the collection of weekly samples for five consecutive weeks, with focus on adequately characterizing water quality during a period of rapid change in hydrological conditions. All sites were attempted to be sampled on a monthly basis; however, the frequency of sample collection was largely influenced by the seasonal presence or absence of flowing water at some of the locations. Sites that were added to the monitoring program in 2014 were sampled twice monthly for the first year in order to establish a more robust dataset in a shorter period of time.

The dataset includes numerous years of sampling programs, which capture the seasonality of surface water quality. The amount of data and quality of data is considered adequate for characterizing the spatial and seasonal variability of the parameters of interest. The data are managed within the FULCRUM data management system, allowing Project connectivity and efficiency through integration of its numerous functionalities.

4.3 SURFACE WATER QUALITY SAMPLE SITE LOCATIONS

The surface water quality site locations and rationale are described in the subsections below, grouped by watershed. A summary of the sampling history is provided for each site in Table 4.1. Historical and current surface water quality site locations are shown on Figure 4.1. The main focus of the baseline surface water quality characterization is on the Peterson Creek watershed, where the project facilities and most of the water quality monitoring sites are located; however, water quality monitoring sites have been established in the following four watersheds:

- Peterson Creek
- Cherry Creek
- Thompson River, and
- Anderson Creek.

4.3.1 Peterson Creek Watershed

The proposed Project features are located within the Peterson Creek watershed; as such, most of the surface water quality monitoring sites are located within this watershed. The Peterson Creek watershed has been subdivided into six distinct areas or features to assist in the characterization of the water quality, which are described in the following subsections: (1) Peterson Creek, (2) Jacko Lake, (3) Keynes Creek, (4) Edith Lake, (5) Humphrey Creek, and (6) historical mine site features.

4.3.1.1 Peterson Creek Water Quality Sites

The section of Peterson Creek that was actively sampled for this baseline water quality program extends from approximately 1.5 km upstream of Jacko Lake to the Long Lake Road Quarry in Knutsford. Water extraction and anthropogenic activity in and around Peterson Creek is extensive and six water quality monitoring sites have been established in this creek, which are as follows, listed from upstream to downstream:

- JC03 – Established in 2008 on agricultural land approximately 1.5 km upstream of Jacko Lake, below the confluence of Jacko Creek and Peterson Creek. This site is no longer active and served as an upstream reference site as it is located upstream of all the historical mine workings planned Project facilities. Winter samples have not been collected from this site as it is either frozen or dry at this time of the year. This site was sampled monthly until July 2013, when access was no longer granted by the land owner, and was replaced by a new site (PC10) in February, 2014.
- PC10 – Established in 2014 to replace the inactive site at JC03 and serve as an upstream reference site. This site is located on Peterson Creek, approximately 1 km upstream of Jacko Lake.
- PC08 – Established in 2007 at the outlet of Jacko Lake, located immediately downstream of the Jacko Lake Spillway.
- PC03 – Established in 2007 on Peterson Creek downstream of all historical mine features (the open pits and historical waste rock pile to the south of Peterson Creek).
- PC02.5 – Established in 2011 along Goose Lake Road on Peterson Creek between PC02.
- PC02.3 – Established in 2014 on Peterson Creek, downstream of all surface drainages that may be influenced by runoff from project facilities.

- PC02 – Established in 2008 to supplement surface water sites PC03 and PC08 along Peterson Creek. The site is located downstream of a trailer park, a rock quarry/gravel pit operation, agricultural lands, and adjacent to the Princeton-Kamloops Highway.
- PC02WH – One sample was collected from this site, located in the well house of the property at PC02. This site was sampled to supplement water quality data collected at PC02.
- PC-EF-04 – Established in 2010 along Peterson Creek within Peterson Creek Park, upstream of Bridal Veil Falls (over 2 km upstream of the North Thompson River). This site was established as an aquatic ecology site and samples collected at this site coincide with ecological data collection dates. This is not a regular water quality site.

4.3.1.2 Jacko Lake Water Quality Sites

Jacko Lake is located east of the Open Pit facility and northeast of the other Project features. Upper Peterson Creek contributes to the inflow to Jacko Lake and the lower portion of the Peterson Creek is the main outflow, which is controlled by a wier. One sampling location has been established on Jacko Lake, with three samples collected from distinct depths:

- JACL – Established in 2007 at approximately the deepest part of Jacko Lake. Samples have been collected from shallow (JACL-S), middle (JACL-M) and deep (JACL-D) depths, upon evaluation of the vertical temperature and dissolved oxygen profiles at the time of sampling.

4.3.1.3 Keynes Creek Water Quality Sites

Keynes Creek is located within the Peterson Creek watershed and flows north towards Peterson Creek, downstream of PC08. A surface drainage connection between Keynes Creek and Peterson Creek has not been located and flow from Keynes Creek into Peterson Creek is through the subsurface. The TSF facility footprint covers most of the Keynes Creek watershed. Two water quality monitoring sites have been established in the Keynes Creek watershed:

- GOOSE LAKE – Established in 2014, in the east branch of the upper headwaters of Keynes Creek. This is the only sampling location on Goose Lake and is collected as a grab sample from the shore.
- KC03 – Established in 2014 immediately upstream of Peterson Creek.

4.3.1.4 Edith Lake Water Quality Sites

Edith Lake is located at the headwaters of Humphrey Creek, which flows north into Peterson Creek, downstream of most of the project features, except the east mine rock storage facility. Edith Lake levels are often supplemented by diversion of water from Anderson Creek, which results in a surface connection between the Peterson Creek and Anderson Creek watersheds. One sampling site has been established on Edith Lake, with three samples collected from distinct depths:

- EDITH-01 – Established in 2014 at approximately the deepest part of Edith Lake. Samples have been collected from shallow (EDITH-01S), middle (EDITH-01M), and deep (EDITH-01D) depths, upon evaluation of the vertical temperature and dissolved oxygen profiles at the time of sampling.

4.3.1.5 Humphrey Creek Water Quality Sites

Humphrey Creek flows north towards Peterson Creek, between PC03 and PC02.5, a surface connection is not evident and flow in Humphrey Creek goes subsurface in the lower portion of the

catchment. The following three water quality monitoring sites have been established on Humphrey Creek, listed from upstream to downstream:

- HUMPH-10: Established in 2014 at the outflow of Edith Lake.
- HUMPH-08: Established in 2014, immediately downstream of the confluence with a tributary located within the Project footprint.
- HUMPH-02: Established in 2014, immediately upstream of a small tributary flowing from the west, outside of the Project footprint.

4.3.1.6 Historical Mine Site Features Water Quality Sites

Historical mining activities in the Peterson Creek watershed are evident with the three existing open pits. The two western open pits have lakes formed in them with no surface discharge, and the eastern open pit was backfilled with waste rock during reclamation of the former mine. In addition to the open pits there are two mine rock piles, one to the south of Peterson Creek and one to the north of the open pits. In order to characterize the water quality in the project area, water quality sites were established within, or down-gradient of these features, at the following sites:

- WR-Seep – Established in 2011 at the historical mine rock seepage collection pond to the south of Peterson Creek between the toe of the mine rock pile and creek.
- North Seepage Pond (NSP) – Established in 2010, this site is at the south end of the pond. Other than the open pits, this site is a seepage collection point for the historical mine rock pile located to the north of the exiting open pits.
- Ajax West-West Pit (AJWW) – Established in 2007 in the western most historical open pit, this site is sampled at two discrete depths. A shallow depth sample (S) and deeper sample (D) are collected at this site, from approximately 1 m below surface and above the bottom, respectively (Photo 19).
- Ajax West-East Pit (AJWE) – Established in 2007 in the eastern historical open pit (that contain water), this site is sampled at three discrete depths. A shallow depth sample (S), medium depth sample (M), and deeper sample (D) are collected at this site, from approximately 1 m below surface, half way between the surface and the bottom, and 1 m above the bottom, respectively (Photo 20).
- S.Catchment – This site was established in 2013 on the south catchment pond, south of Peterson Creek. This site is located within the Project footprint and is in close proximity to the historical waste rock area.

4.3.2 Cherry Creek Watershed Water Quality Sites

The project facilities under the current mine plan are not located within the Cherry Creek watershed; however, previous mine layout plans have included facilities within this area. As such, water quality sites have been established along Cherry Creek and other water bodies within the Cherry Creek watershed. Some of the established sites continue to be monitored as reference sites, because of the close proximity of the project facilities to the Cherry Creek watershed boundary.

Cherry Creek runs adjacent to the western extent of the historical Afton Mine TSF. There are numerous water licences currently in effect in Cherry Creek, including domestic and commercial usage in the lower extent of the baseline study area. Alkali Creek lies within agricultural property and is commonly used for irrigation and livestock watering purposes. The lower reaches of Alkali Creek are diverted around the historical Afton Mine TSF, where it drains through a swampy area into

Cherry Creek. The three creek based water quality sites in this watershed are as follows (listed from upstream to downstream):

- CC08 – Established in 2007 upstream of the Project footprint on Greenstone Mountain. This site is a suitable reference site for this watershed as it is situated upstream of historical mining areas and it is also not heavily influenced by agricultural activity.
- AC02 – Established in 2007 in Alkali Creek, approximately 300 m upstream of the historical Afton Mine tailings storage facility and 4 km downstream (west) of the TSF.
- CC02 – Established in 2007 along Cherry Creek approximately 2 km west and down-gradient of the historical Afton Mine tailings storage facility.

In addition to Cherry Creek and Alkali Creek there are two other water bodies that have been part of this baseline investigation: Inks Lake and Wallander Lake. Both of these lakes are situated in low topographic points with no surface expression of connectivity to other surface water bodies. These lakes were within the catchment area of the project facilities under a previous mine plan, but are not relevant to the current design. As such, they are no longer sampled; however, data collected from these sites may be used to support the baseline characterization. The sample sites are listed below:

- INKS – Established in 2010, surface grab samples were collected regularly until 2013, from the south end of Inks Lake (along Lac Le Jeune road, east of the TSF and southwest of the North Mine Rock Storage Facility (NMRSF).
- WALL – Established in April 2011 and is located between Lac Le Jeune road and the NMRSF; several samples have been collected since its establishment.

4.3.3 Thompson River Watershed Water Quality Sites

Two sites are located on water bodies which drain directly to the Thompson River, downstream of the confluence of the North Thompson River and the South Thompson River:

- PP01: Established in 2007 and sampled until the end of 2008, on Polygon Pond.
- MAKAOO-05: Established in 2013, on Makaoo Creek immediately downstream of Makaoo Lake. Makaoo Creek drains south into the Thompson River. This creek is normally dry and is not sampled regularly.
- MAKAOO-01: Established in 2013, within Makaoo Lake.

4.3.4 Anderson Creek Watershed Water Quality Sites

Anderson Creek flows from east to west, south of the Project footprint and the Peterson Creek watershed. Two water quality sites have been established (from upstream to downstream):

- ANDR15: Established in 2014 upstream of Hull Lake, and
- ANDR10: Established in 2014 downstream of Hull Lake.

4.4 PETERSON CREEK WATERSHED SURFACE WATER QUALITY

The majority of surface water monitoring sites and all of the project features are located within the Peterson Creek watershed, which is the main focus of the baseline surface water quality characterization study. The 28 monitoring sites in the Peterson Creek watershed have been subdivided into the following categories to assist in the interpretation of the water quality results:

- Peterson Creek
- Jacko Lake

- Historical Mine Site Features, and
- Tributaries to Peterson Creek (including Keynes Creek, Goose Lake, Humphrey Creek, and Edith Lake).

The Peterson Creek watershed monitoring sites are focused around Peterson Creek itself and the historical mine features; however, sites have also been established to characterize the main tributaries to Peterson Creek. The most extensively sampled section of Peterson Creek extends from just upstream of Jacko Lake to downstream to the Long Lake Road Quarry in Knutsford. Peterson Creek is the only outlet channel for Jacko Lake, and the Historical Mine Site Features are downstream of the Jacko Lake to the north and south of the upper reaches of Peterson Creek. The main tributaries that have been included in the baseline water quality study flow north into Peterson Creek, upstream (Keynes Creek) and downstream (Humphrey Creek) of the majority of the project features. Edith Lake has been included in the baseline study as its outflow is the headwaters to Humphrey Creek.

4.4.1 Peterson Creek Water Quality Assessment

Flow in Peterson Creek, downstream of Jacko Lake, is managed through the control structure at the lake outlet, and there are numerous water licenses for extraction along this channel. As such, it has not been possible to strongly correlate flows and concentrations observed through the channel; however, seasonality is still evident in the analytical data set. Sample collection at various sites along Peterson Creek has been hampered on occasion due to insufficient flow (winter and summer months). Surface water flows in Peterson Creek have been observed both upstream and downstream of sites that are dry during a specific sampling event, which indicates that groundwater inflows have a strong influence on the baseflow to this creek. Additionally, numerous beaver dams have been noted along this creek over the course of the baseline program.

Spatial trends for some parameters are evident and boxplots showing the spatial variability of parameter concentrations have been used to demonstrate this trend. For this purpose, the results of the nine water quality sites along Peterson Creek have been combined into six groups, with each of the six defining a localized section of the creek. The grouping of site data was done in cases where sites were located close to one another and when minimal data was available from one site, with a larger sample number from a site nearby. The groupings are as follows:

- JC03 and PC10: upper Peterson Creek; JCO3 has been replaced by the newly established PC10.
- PC08: downstream of the outlet of Jacko Lake.
- PC03.
- PC02.5 and PC02.3: PC02.3 is a new site, established in 2014, with a lower sample count at when this report was compiled (9 samples).
- PC02 and PC02WH: PC02 is an established long-term monitoring site, while PC02WH represents a single sampling event.
- PCEF-04: only four samples have been collected from this site, which is not a long-term monitoring site. The site has been included to show spatial variability because of its location further downstream, towards the City of Kamloops.

4.4.1.1 Physical Parameters, Major Ions and Nutrients

Peterson Creek waters are generally characterized as neutral to moderately basic pH, very hard with high buffering capacity. The pH has been observed to be somewhat more variable immediately downstream of Jacko Lake (PC08) than the other Peterson Creek water quality sites, but was generally within the range of pH observed within Jacko Lake (shallow and deep). Measured pH values never exceeded the acceptable range for aquatic life (6.5-9); however, the upper bound for drinking water (pH 8.5) was exceeded on occasion. Total dissolved solids (TDS) were elevated in the creek and specific conductance (SpC) was typically higher than the normal range for interior streams, which is up to 500 µS/cm (RISC 1998). The measured SpC was typically between 400 µS/cm and 2,200 µS/cm. The majority of the TDS values exceeded the 500 mg/L drinking water and irrigation water guidelines and the main constituents of the elevated TDS were calcium, magnesium, sodium, sulphate, and bicarbonate.

Hardness, alkalinity, SpC, and TDS values have demonstrated similar trends in seasonal and spatial variability. Seasonal minimum values were typically reached during spring freshet and early summer and increased to sustained higher values from late summer through to late winter. Examples of this seasonal trend are shown in seasonal boxplots on Figure 4.6, for hardness and TDS. The seasonal distribution in this figure is used in comparison to the example hydrograph shown on Figure 2.1 to identify seasonal trends. Spatial boxplots of hardness and TDS concentrations are shown on Figure 4.7 as examples to demonstrate the spatial trends in concentrations of physical parameters, which increased from upstream to downstream. The spatial and seasonal trends of dissolved physical parameters are indicative of a flow system that is predominantly sustained by groundwater, as these parameters are all elevated in the subsurface water quality samples. Parameters associated with suspended solids, such as turbidity and TSS were inversely proportional to these parameters; values increased during freshet and were lower through the remainder of the years. The seasonal maximum pH values were typically measured in the late summer, when surface water runoff is lower and creek flows are predominantly sustained by groundwater discharge. This trend is shown on Figure 4.6 and supports the hypothesis that groundwater is the main contributor to surface water flow in Peterson Creek.

Water temperature in Peterson Creek was highly variable and is very strongly influenced by ambient air temperature. Temperatures over 20^{o}C have been measured regularly during summer sampling events, with temperatures as low as 0.05^{o}C observed in winter months, in open water amongst iced over sections. Water temperature in Peterson Creek, above Jacko Lake (JC03 and PC10), was generally colder than locations downstream of the lake where temperatures were generally similar to the shallow lake water. Water temperatures were noted to increase with distance downstream, particularly during the summer months. With the exception of spring freshet, the flow in the creek is generally very low and slow moving, and the creek is generally poorly shaded for long stretches, resulting in significant exposure to ambient conditions.

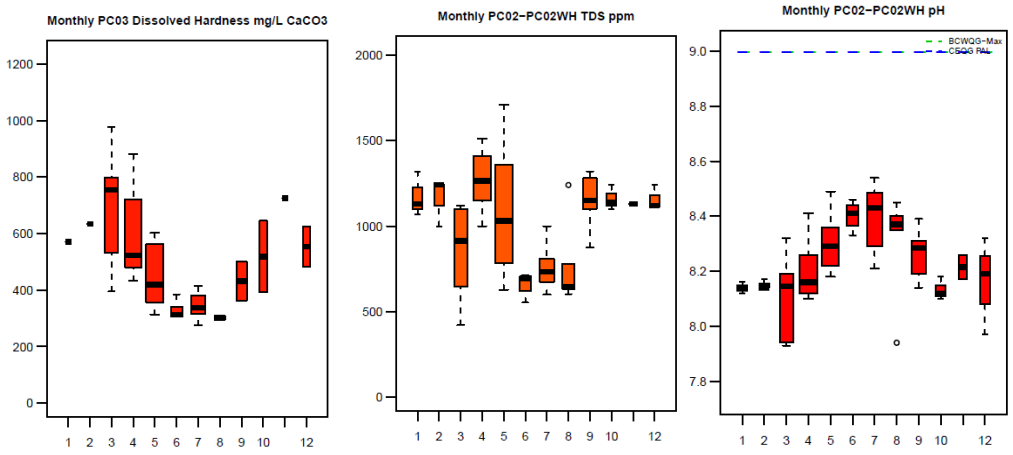

Figure 4.6 Seasonal Boxplot of Physical Parameters (Hardness, TDS, and pH) in Peterson Creek

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED (pH IS SHOWN IN pH UNITS).
2. X-AXIS UNITS ARE MONTHS.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE GRAPHS SHOWN IN THIS FIGURE ARE SHOWN AS EXAMPLES TO REPRESENT SEASONAL TRENDS THAT WERE GENERALLY OBSERVED AT EACH SITE WITHIN THE PETERSON CREEK WATERSHED.
6. THERE ARE NO AQUATIC LIFE GUIDELINES FOR HARDNESS; HOWEVER, HARDNESS GREATER THAN 250 mg/L TRIGGERS A REQUIREMENT FOR SULPHATE TOXICITY TESTING UNDER THE GUIDANCE OF THE BCWQG-30 D.
7. THERE ARE NO AQUATIC LIFE GUIDELINES FOR TDS; HOWEVER, 500 mg/L IS APPLIED FOR DRINKING WATER AND IRRIGATION WATER (HC-DW, BCWQG-IRRIGATION, CEQG-IRRIGATION).
8. THE CEQG-PAL AND THE BCWQG-MAX FOR pH SPECIFY AN ACCEPTABLE pH RANGE OF 6.5 TO 9; THE ACCEPTABLE DRINKING WATER RANGE IS FROM 6.5 TO 8.5 AND IS NOT SHOWN ON THIS FIGURE.

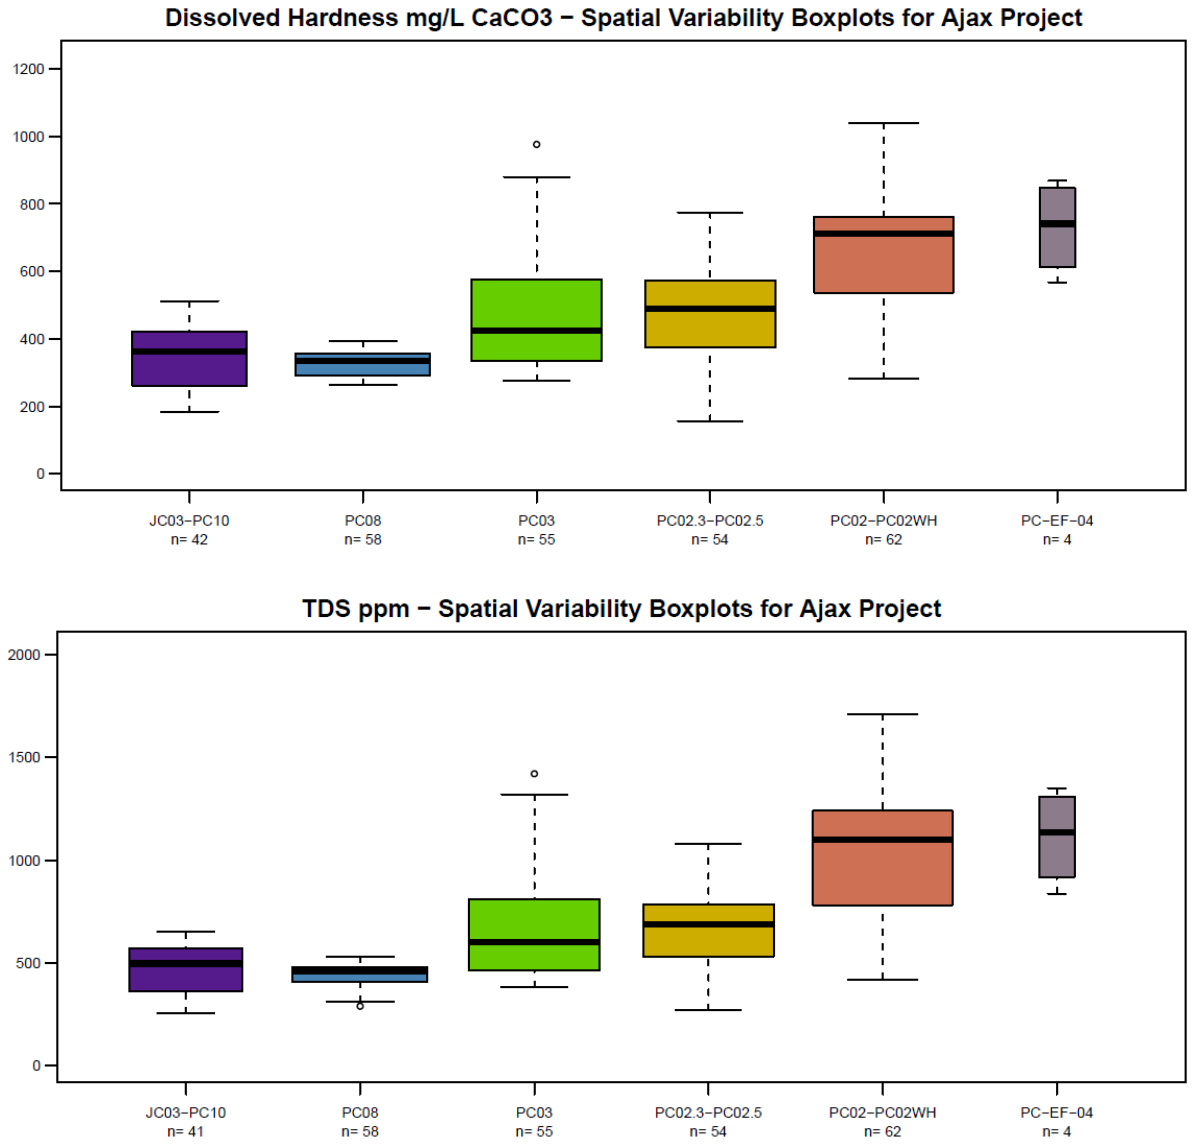

Figure 4.7 Spatial Boxplot of Physical Parameters (Hardness and TDS) in Peterson Creek

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. SITE ORDER ALONG THE X-AXIS IS FROM UPSTREAM TO DOWNSTREAM. n=NUMBER OF SAMPLES.
3. SITES ALONG PETERSON CREEK HAVE BEEN COMBINED INTO SIX GROUPINGS, EACH REPRESENTING ONE SECTION OF THE CREEK (FROM UPSTREAM TO DOWNSTREAM): 1) JC03 AND PC10; 2) PC08; 3) PC03; 4) PC02.5 AND PC02.3; 5) PC02WH AND PC02; AND 6) PCEF-04.
4. BOXPLOTS SHOW THE DISTRIBUTION OF DATA AT EACH SITE (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
5. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
6. THERE ARE NO AQUATIC LIFE GUIDELINES FOR HARDNESS; HOWEVER, HARDNESS GREATER THAN 250 mg/L TRIGGERS A REQUIREMENT FOR SULPHATE TOXICITY TESTING UNDER THE GUIDANCE OF THE BCWQG-30 D.
7. THERE ARE NO AQUATIC LIFE GUIDELINES FOR TDS; HOWEVER, 500 mg/L IS APPLIED FOR DRINKING WATER AND IRRIGATION WATER (HC-DW, BCWQG-IRRIGATION, CEQG-IRRIGATION).

Major Ions

The seasonal trends for the major ion concentrations were similar to most other parameters monitored in the baseline water quality characterization; concentrations decreased during freshet to seasonal minimums and generally increased during periods of lower surface discharge (examples of the seasonality of major ion concentrations are shown on Figure 4.8); however, the major ions within Peterson Creek varied between sites and the spatial trends were not always clear. The major anion was either sulphate or bicarbonate at each site, with minor contributions of the others, and the major cation was either magnesium or calcium, although significant contributions of calcium, magnesium, and sodium were present at each site. These observations are shown visually on the Piper diagram on Figure 4.2. A piper diagram is a trilinear plot of the major dissolved ions in water, which provides a visual interpretation of the similarities and differences in the water types. Figure 4.2 shows two groupings of sites within Peterson Creek in terms of dominant cations; however, the characterization of each site does not appear to be related to any spatial trends.

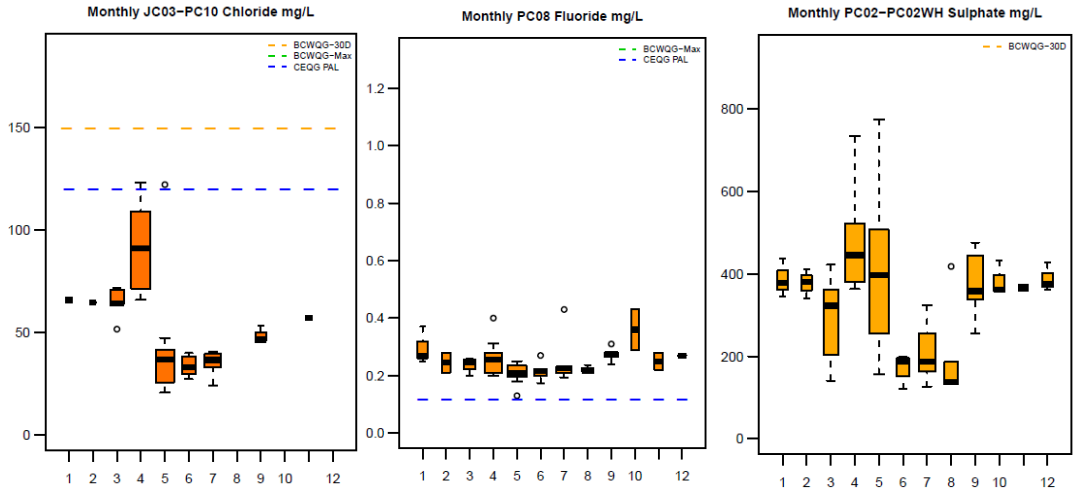

Figure 4.8 Seasonal Boxplot of Major Ion Parameters (Chloride, Fluoride, Sulphate) in Peterson Creek

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE CEQG-PAL FOR CHLORIDE OF 120 mg/L IS SPECIFIC TO LONG-TERM EXPOSURE; THE CEQG-PAL FOR SHORT-TERM EXPOSURE IS 640 mg/L AND IS NOT WITHIN THE SCALE OF THE GRAPH.

Sulphate concentrations increased with distance downstream in Peterson Creek and the greatest increase happened between sample locations PC02.5 and PC02 (Figure 4.9). Relatively similar sulphate concentration ranges were noted for PC03, PC02.5/PC02.3 and Lower Humphrey Creek (HUMPH02), indicating uniform loading through that region of the Peterson Creek watershed. There are no major surface tributaries that inflow to Peterson Creek between PC02.5 and PC02, however, PC02 is located in a reach of Peterson Creek that is likely affected by local groundwater discharge

from the Davison Creek Aquifer and the other sites are upstream of this aquifer. Sulphate rarely exceeded the drinking water guidelines (BCWQG-DW and HC-DW; both 500 mg/L) and exceeded the aquatic life guideline in very few of the seasonal maximum sample concentrations. The BCWQG-30 D for sulphate specifies that site specific toxicity testing is required when hardness exceeds 250 mg/L $CaCO_3$, as was frequently the case in the baseline surface water environment in the project area. The toxicity testing, documented in *Testing in support of development of a science based environmental benchmark for sulphate for the Ajax Mine* (Nautilus 2015), resulted in a recommended science based environmental benchmark (SBEB) for a maximum sulphate concentration of 429 mg/L, which is the same as the current BCWQG-30 D, but with the maximum hardness adjusted up to 800 mg/L $CaCO_3$ which is protective of early life stages for trout (present from May through June). An alternative SBEB of 730 mg/L for a hardness of up to 1,377 mg/L $CaCO_3$ was recommended for surface waters where early life stages for trout are never present, or for periods of the year when these life stages are not expected to be present in a given reach of Peterson Creek (July through April). Samples from PC02 were often reported at hardness values that exceeded 800 mg/L $CaCO_3$, but were never reported above the 1,377 mg/L $CaCO_3$ threshold. Higher hardness concentrations (>800 mg/L $CaCO_3$) were generally reported through the winter months when early life stages for trout would not be expected in this reach of Peterson Creek, but in 2011 and 2012, higher hardness and sulphate persisted into May (2011 and 2012) and June (2011 only) and in May 2011 one sample was reported with a sulphate concentration of 775 mg/L and a hardness of 1,040 mg/L. A sample collected in April 2014 from PC02 also exceeded the upper benchmark (sulphate concentration of 734 mg/L and a hardness of 911 mg/L $CaCO_3$). Samples collected upstream of this location were rarely observed to exceed this benchmark.

Sulphate concentrations were observed at elevated concentrations in groundwater samples collected from monitoring wells in the Peterson Creek catchment area, including the groundwater monitoring site up-gradient of Jacko Lake (MW11-08D), indicating that sulphate is naturally elevated within the region (Project wide groundwater average sulphate concentration is in excess of 500 mg/L). Seepage from the historical waste rock in the area is likely contributing to sulphate concentrations in Peterson Creek; however, the elevated concentrations observed in the surface water are also sustained by regional geochemistry as is evidenced by the elevated sulphate concentrations in the groundwater samples collected from all areas of the baseline study area.

Fluoride concentrations were elevated above the 0.12 mg/L CEQG-PAL in most samples collected from Peterson Creek, with the highest concentrations generally occurring in late summer and fall (Figure 4.8). Fluoride was not a parameter that was noted to consistently increase with distance downstream in Peterson Creek and concentrations in mid reaches (PC02.5) were often higher than upstream of downstream concentrations, likely due to subsurface inflows from groundwater, and Humphrey Creek and Keynes Creek watersheds, which were typically higher than Peterson Creek concentrations. Values generally did not exceed the BCWQG-Max which is hardness dependent because samples containing high fluoride concentrations were generally higher in hardness as well. The MDL values were also frequently elevated above the CEQG-PAL and the majority of the noted exceedances occurred for samples for which the desired 0.02 mg/L detection limit could not be achieved. Fluoride concentrations in groundwater samples from the area of the historical open pit were elevated and guideline exceedances were frequent. In some groundwater samples, the BCWQG limit was exceeded, despite elevated hardness. The high fluoride concentrations in

groundwater samples and the seasonality evident in surface water samples indicate that groundwater discharge is likely the primary source for fluoride in this area.

Chloride concentrations were elevated in baseline surface water samples collected from throughout the study area, and spatial and seasonal trends were evident. Spatially, chloride concentrations were highest in samples collected from Peterson Creek sites PC02, PC-EF-04, and JC03 and Anderson Creek site ANDR-15, all sites that are located in close proximity to highways where road salting would be common practice during the winter months. Seasonally, chloride concentrations were highest in the winter months and at monitoring sites PC02 and JC03 concentrations typically doubled between August and September or September and October, depending on the year; this increase was less emphasized at other sites in Peterson Creek. Chloride concentrations were low in all groundwater samples collected from drilled monitoring wells in the project area (less than 20 mg/L), but were elevated in samples collected from residential water supply wells RES-1 and RES-4, which are located in the vicinity of the Davidson Creek aquifer and near the surface water site PC02. These higher concentrations indicate that chloride is elevated in the groundwater system in that reach of Peterson Creek. Exceedances of the CEQG-PAL short-term (120 mg/L) were common at the above mentioned sites from September through March and only the occasional sample exceeded the BCWQG-30 D (150 mg/L) and no samples exceeded the BCWQG-Max (600 mg/L) or the CEQG-PAL long-term (640 mg/L). Irrigation guidelines (CEQG and BCWQG; 100 mg/L) were also regularly exceeded for chloride at these sites.

3. SITES ALONG PETERSON CREEK HAVE BEEN COMBINED INTO SIX GROUPINGS, EACH REPRESENTING ONE SECTION OF THE CREEK (FROM UPSTREAM TO DOWNSTREAM): 1) JC03 AND PC10; 2) PC08; 3) PC03; 4) PC02.5 AND PC02.3; 5) PC02WH AND PC02; AND 6) PCEF-04.
4. BOXPLOTS SHOW THE DISTRIBUTION OF DATA AT EACH SITE (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
5. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
6. THE BCWQG-30 D FOR SULPHATE IS DEPENDENT ON ONGOING TOXICITY TESTS; PRELIMINARY RESULTS HAVE INDICATED A RECOMMENDED LIMIT OF 730 mg/L.

Nutrients

Phosphorus concentrations in Peterson Creek were highly variable and generally lower during the winter months. The total phosphorus (TP) concentrations in Peterson Creek extend over several trophic status ranges at any given site. TP concentrations within this creek are clearly influenced by the surrounding agricultural/livestock rearing land uses, and even at the baseline level there are extreme fluctuations across multiple trophic status ranges which can induce stress on a creek system and the aquatic flora and fauna.

The TP concentrations upstream of Jacko Lake (JC03 and PC10) were higher than those immediately downstream of the lake. The trophic status of those sites upstream of Jacko Lake ranged from eutrophic to hyper-eutrophic, with the seasonal median values generally falling within the hyper-eutrophic range. The TP concentrations within Jacko Lake at depth were generally higher and more variable than the shallow sample concentrations and the concentrations immediately downstream (PC08) were generally similar to the shallow water Jacko Lake sample values. Seasonal turnover in the lake was apparent in the fall and supported by the observation of similar TP concentrations in the shallow and deep samples (the deep sample concentrations decreased and the shallow sample concentrations increased to match). The difference in concentrations is significant

during the summer when stratification is observed; in winter, when stratification is known to occur in some lakes, very little difference in TP concentrations between shallow and deep samples from Jacko Lake is observed. The average TP concentration in the shallow water in the lake was within the lower eutrophic range (0.04 mg/L) and the deeper water was well within the hyper-eutrophic range (0.17 mg/L).

TP concentrations increased with distance downstream between PC08 (below outlet of Jacko Lake) to PC02.5 (along Goose Lake Road), and then were noted to decrease slightly below that point. The upper trophic status achieved was in the hyper-eutrophic range and all sites had several samples that were within this range. The average TP concentrations for mid-Peterson Creek (PC02.5 and PC02.3) were greater than 0.1 mg/L and thus within this hyper-eutrophic range. The average TP for the section of Peterson Creek that extends from the lake outlet to just beyond the extent of the open pit was within the upper range of the eutrophic status.

The nitrogen based inorganic nutrient (nitrite, nitrate, and ammonia) concentrations were somewhat variable in Peterson Creek; however, guideline exceedances were infrequent. The nitrogen parameter concentrations were seasonally variable, with concentrations generally lowest during the higher flows of spring freshet, increasing through the summer and early fall, and decreasing through the late fall and winter (a seasonal boxplot of nitrate is shown as an example on Figure 4.10). The area is frequented by cattle and as such cow dung was often noted in and near the creek, which is likely the primary driving factor for the presence of the nitrogen parameters. Additionally, cows were noted to cross the creek at many locations, further disturbing the substrate and mixing the waters.

Organic Carbon and Nitrogen

Total organic carbon (TOC) and dissolved organic carbon (DOC) concentrations varied seasonally and were generally found at the lowest concentrations in samples collected through the winter months and highest soon after freshet, in the summer months. TOC and DOC concentrations were generally highest in mid-Peterson Creek, at the sites between PC03 and PC02.3 and were generally lowest at the PC02 site, further downstream. Upstream of Jacko Lake, the organic carbon concentrations are very similar to that of Jacko Lake deep and shallow samples, which are also similar to each other. The organic carbon is predominantly present in the dissolved form and seasonal median concentrations within the creek generally ranged from 6 mg/L to 20 mg/L. Guidelines for organic carbon are available for drinking water (BCWQG limit of 4 mg/L) and most samples from all sites in Peterson Creek exceeded this limit. Organic carbon in drinking water can result in the formation of trihalomethanes when chlorinated, which are toxic for human consumption. Aquatic life and wildlife guidelines have not been established for background levels; however, an understanding of the background concentrations is required in order to assess for changes. A change of no greater the ±20% from background is recommended for the protection of aquatic life and wildlife.

Organic nitrogen concentrations were low and exhibited some seasonality, with generally lower concentrations observed in samples collected through the winter and higher concentrations noted during spring freshet, with some variability, through the summer months.

5. THE GRAPHS SHOWN IN THIS FIGURE ARE SHOWN AS EXAMPLES TO REPRESENT SEASONAL TRENDS THAT WERE GENERALLY OBSERVED AT EACH SITE WITHIN THE PETERSON CREEK WATERSHED.
6. THE BCWQG-MAX FOR NITRATE IS 32.8 mg/L AND THE CEQG-PAL IS 3 mg/L; GUIDELINE EXCEEDANCES WERE NOT OBSERVED; THIS GRAPH IS INCLUDED TO SHOW THE SEASONAL TREND IN NUTRIENT CONCENTRATIONS.

4.4.1.2 Metals and Metalloids

In Peterson Creek aluminum, chromium, copper, iron, and selenium were the only metals parameters that exceeded aquatic life guidelines on a regular basis. Iron and manganese were the only metals parameters that exceeded drinking water guidelines. Manganese and molybdenum were the only metals that exceeded agricultural (irrigation) guidelines regularly in Peterson Creek; molybdenum also exceeded the livestock and wildlife guideline often in samples collected from the Peterson Creek baseline surface water site PC03.

Total and dissolved concentrations of most metals parameters tended to decrease during spring freshet, though a few metals parameters were noted to increase under these flow conditions; concentrations of these same parameters also tended to increase again in late summer / early fall, though rarely achieved the same freshet peak concentrations. Particulate contributions to total concentrations tended to be greater at the sites upstream of Jacko Lake (JC03 and PC10), immediately downstream of Jacko Lake (PC08), and much further downstream at PC02, which is located downstream of a trailer park, a rock quarry/gravel pit operation, extensive ranch lands with active cattle crossings along the creek, and adjacent to the Princeton-Kamloops Highway. The correlation between TSS and total metals concentrations for iron, aluminum, copper, and chromium tends to be poor with respect to r-squared valued due to the prevalence of non-detect values for TSS

when flow conditions are lower, but the relationship is more clearly demonstrated with time-series graphs, as provided on Figure 4.11, for baseline samples from a water quality site upstream of Jacko Lake (JC03). Anthropogenic activity in the area make is difficult to differentiate changes in water chemistry that may have natural origins, from those that do not. Elevated particulate metals downstream of Jacko Lake may be attributed to suspension of particulate as a result of turbulent flow through the outlet control structure.

Metals parameters that sporadically exceeded guidelines for aquatic life include cadmium, mercury, and molybdenum. Selenium sporadically exceeded the BCWQG-DW of 0.01 mg/L, but was below the HC-DW guideline of 0.05 mg/L in nearly all samples. Arsenic concentrations approached the aquatic life guideline in sites further downstream in Peterson Creek (CEQG-PAL and BCWQG-Max; both 0.005 mg/L), reaching concentrations up to 0.004 mg/L. Arsenic concentrations typically increased with distance downstream, with notable increases downstream of the confluence with Keynes Creek and Humphrey Creek; arsenic was elevated in samples from these creeks compared to Peterson Creek, and the aquatic life guideline was almost always exceeded for samples from Keynes Creek. These guideline exceedances are highlighted in the data tables in Appendix C, but are not discussed in the text.

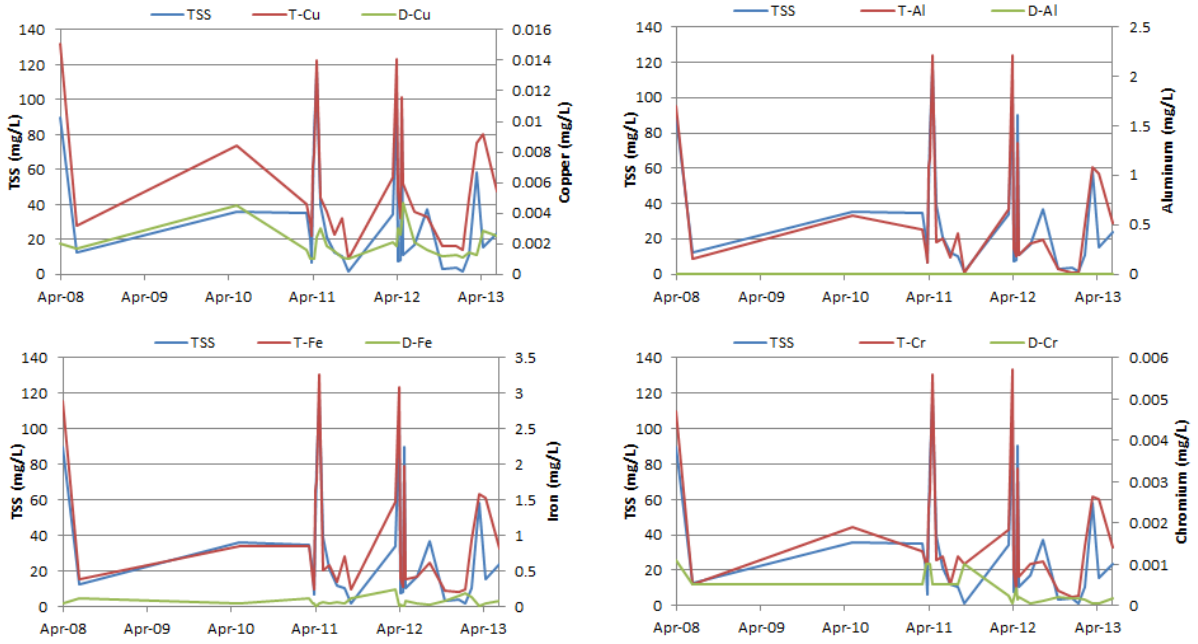

Figure 4.11 TSS Compared with Total and Dissolved Metals Concentrations in Peterson Creek, Upstream of Jacko Lake (JC03)

NOTES:

1. TIME-SERIES DATA PLOTS FOR TSS WITH COPPER, IRON, ALUMINUM, AND CHROMIUM AT BASELINE SURFACE WATER SITE JC03.
2. SIMILAR TRENDS NOTED AT OTHER SURFACE WATER SITES IN THE PROJECT AREA; SHORT-TERM ELEVATION IN TOTAL CONCENTRATIONS OF SELECT PARAMETERS IN RESPONSE TO HIGHER ENERGY FLOWS DURING SPRING FRESHET.

Aluminum

Total aluminum concentrations were much more variable than dissolved concentrations and peak values occurred during spring freshet (an example of a seasonal boxplot within Peterson Creek is

shown on Figure 4.12). The spatial variation in total aluminum is shown on the lower graph on Figure 4.12. Median total aluminum concentrations were highest at JC03, upstream of Jacko Lake, and were generally sustained at higher median concentrations through April, May, and June. Few samples from JC03 were below the CEQG-PAL limit (0.1 mg/L for samples with pH>6.5) and most samples were over three times the CEQG-PAL (median concentration 0.36 mg/L). Many sample concentrations were over ten times the CEQG-PAL and the maximum value of 2.22 mg/L is 22 times greater than the limit. Concentrations of aluminum at PC10, which is downstream of JC03 and upstream of Jacko Lake, were lower than at JC03 and reached a seasonal maximum in June, immediately after freshet. The seasonal distribution of concentrations immediately downstream of Jacko Lake, at PC08, is similar but lower than at JC03 and also lower than at PC10. At this site 48% of the samples exceeded the guideline, with median value slightly below the guideline limit (0.09 mg/L). Total aluminum concentrations were lowest at the PC03 monitoring site in Peterson Creek, increased slightly downstream at PC02.5 and PC02.3, and then decreased again at PC02 and PCEF-04.

The BCWQG for aquatic life apply to only the dissolved aluminum concentrations. Dissolved aluminum concentrations are generally very low, and all values were less than the BCWQG-30 D- (0.05 mg/L for samples with pH>6.5), and well below the acute limit (0.1 mg/L; pH>6.5). Dissolved aluminum concentrations distribution throughout the Peterson Creek sample sites is similar to that of the total concentrations.

Chromium

Total chromium has two tiers of guidelines (BCWQG-Max and CEQG-PAL): 0.001 mg/L for Cr(VI) and 0.0089 mg/L for the less toxic Cr(III). Only one sample collected from Peterson Creek exceeded 0.0089 mg/L; all other guideline exceedances were for the more toxic Cr(VI) species. Since a species analysis has not been conducted, it is not confirmed whether the chromium present in Peterson Creek is in the Cr(III) or Cr(VI) form, though the Cr(VI) form is most likely in well oxygenated surface waters and Cr(III) in reducing conditions such as deeper groundwater sources.

Seasonal and spatial variability of total chromium concentrations in Peterson Creek are shown on Figure 4.13. Like other metals, the highest concentrations of total chromium at each site were observed during freshet, although sporadic exceedances of aquatic life guidelines were observed during the periods of lower flow at some sites. Concentrations generally decrease from upstream (JC03) to downstream (PC02.3); however, at PC02, concentrations increase over those observed at the sites upstream and an additional increase in chromium concentrations was observed in the samples collected at PCEF-04. Similar but slightly lower seasonal and spatial trends were observed for dissolved chromium, indicating that some of the total chromium concentration is due to particulate chromium. This is especially relevant to JC03, where the difference between total and dissolved chromium concentrations is greater than at the downstream sites.

7. THE BCWQG-MAX AND CEQG-PAL THRESHOLDS FOR AQUATIC LIFE ARE 0.0089 mg/L FOR Cr(VI) (SHOWN ON THE FIGURE); THE SAME GUIDELINES ARE 0.001 mg/L FOR THE CR(III) SPECIES; IT IS NOT KNOWN WHICH SPECIES IS PREVALENT.

Copper

Total and dissolved copper varied seasonally and spatially and exceeded the CEQG-PAL seasonally at most sites. The seasonal and spatial variations in total copper concentrations are shown in boxplots on Figure 4.14; the same trends were observed for dissolved copper, but with lower concentrations. Aquatic life guideline exceedances during freshet were common for total copper, but were observed only sporadically for dissolved copper. The highest concentrations of total copper also exceeded the BCWQG-30 D limit; however, these exceedances are not true exceedances of the chronic guidelines because the freshet samples were not observed to consistently exceed the BCWQG-30 D over the required five-week period. No samples in Peterson Creek exceeded the BCWQG-Max limit.

Total copper concentrations were highest in the samples collected at the Peterson Creek, upstream of Jacko Lake (JC03 and PC10) and were lower in the samples collected within the lake. Samples collected from Peterson Creek downstream of the outlet of Jacko Lake (PC08) had slightly higher concentrations of copper than in the lake and concentrations generally increased with distance downstream.

Iron

Iron is dominantly present in the particulate form in the water quality samples from most sites in Peterson Creek and concentrations varied seasonally and spatially (Figure 4.15). The seasonality of iron concentrations in Peterson Creek is generally similar to that of other metals, with higher concentrations occurring during freshet; however, this trend is inconsistent at the first two monitoring sites downstream of the outflow of Jacko Lake (PC08 and PC03). The highest dissolved iron concentrations in Peterson Creek were measured at PC08, with the highest total and dissolved iron concentrations typically observed from September through May. More water is typically released through the Jacko Lake spillway from June through August, likely diluting the iron concentrations in the samples collected from the sites nearest the lake. In general, total iron concentrations were highest upstream and immediately downstream of Jacko Lake (JC03 and PC08); however, the lake sample concentrations were low in total iron and were mostly below the MDL (<0.03 mg/L). Downstream of the outlet of Jacko Lake, total iron varied between sites with no clear trend from upstream to downstream. The relatively high and spatially and seasonally inconsistent particulate iron concentrations could result from groundwater discharge being oxidized in surface water or from frequent creek bed disturbance from livestock, which could cause intermittent oxidizing conditions.

Aquatic life and drinking water guideline exceedances were prevalent throughout Peterson Creek for total iron. Exceedances of dissolved iron guidelines were rarely observed. Total iron concentrations frequently exceeded the HC-DW aesthetic objective (0.3 mg/L), the CEQG-PAL (0.3 mg/L), and the BCWQG-Max (1 mg/L) at all sites along Peterson Creek.

7. THE BCWQG-MAX FOR IRON IS 1 mg/L (SPECIFIC TO TOTAL IRON) AND THE CEQG-PAL IS 0.3 mg/L.
8. THE HC-DW AESTHETIC OBJECTIVE FOR IRON IS 0.3 mg/L.

Selenium

Selenium was predominantly detected in the dissolved form in Peterson Creek and the distribution of concentrations within the creek is somewhat different than the other parameters discussed. In earlier analyses, the MDLs were elevated, and as such clear resolution of the selenium concentrations has been hampered. The MDLs for more recent sampling events (October 2011 to date) have decreased due to the request for alternative low levels metals analysis. Low levels of selenium have been detected in almost all of the samples since this time. Selenium concentrations trended upwards through the winter months, typically reaching peak concentrations in April, when groundwater inflows are the predominant waters contributing to surface flows. Similar trends were observed for selenium at Peterson Creek tributary sites in Keynes Creek (KC03) and lower Humphrey Creek (HUMPH02), though peak concentrations were much higher at these sites. Selenium concentrations at monitoring site PC02 (located in agricultural property immediately adjacent to the Princeton-Kamloops Highway and north of a quarry in Knutsford, BC) were typically the highest compared to other Peterson Creek sites and often exceeded the 0.001 mg/L CEQG-PAL and occasionally also exceeded the less stringent 0.002 mg/L BCWQG-30 D. The total and dissolved selenium seasonal and spatial variability boxplots are provided for the Peterson Creek water quality sites on Figure 4.16.

4.4.2 Jacko Lake Water Quality Assessment

4.4.2.1 Physical Parameters, Major Ions and Nutrients

Physical Parameters

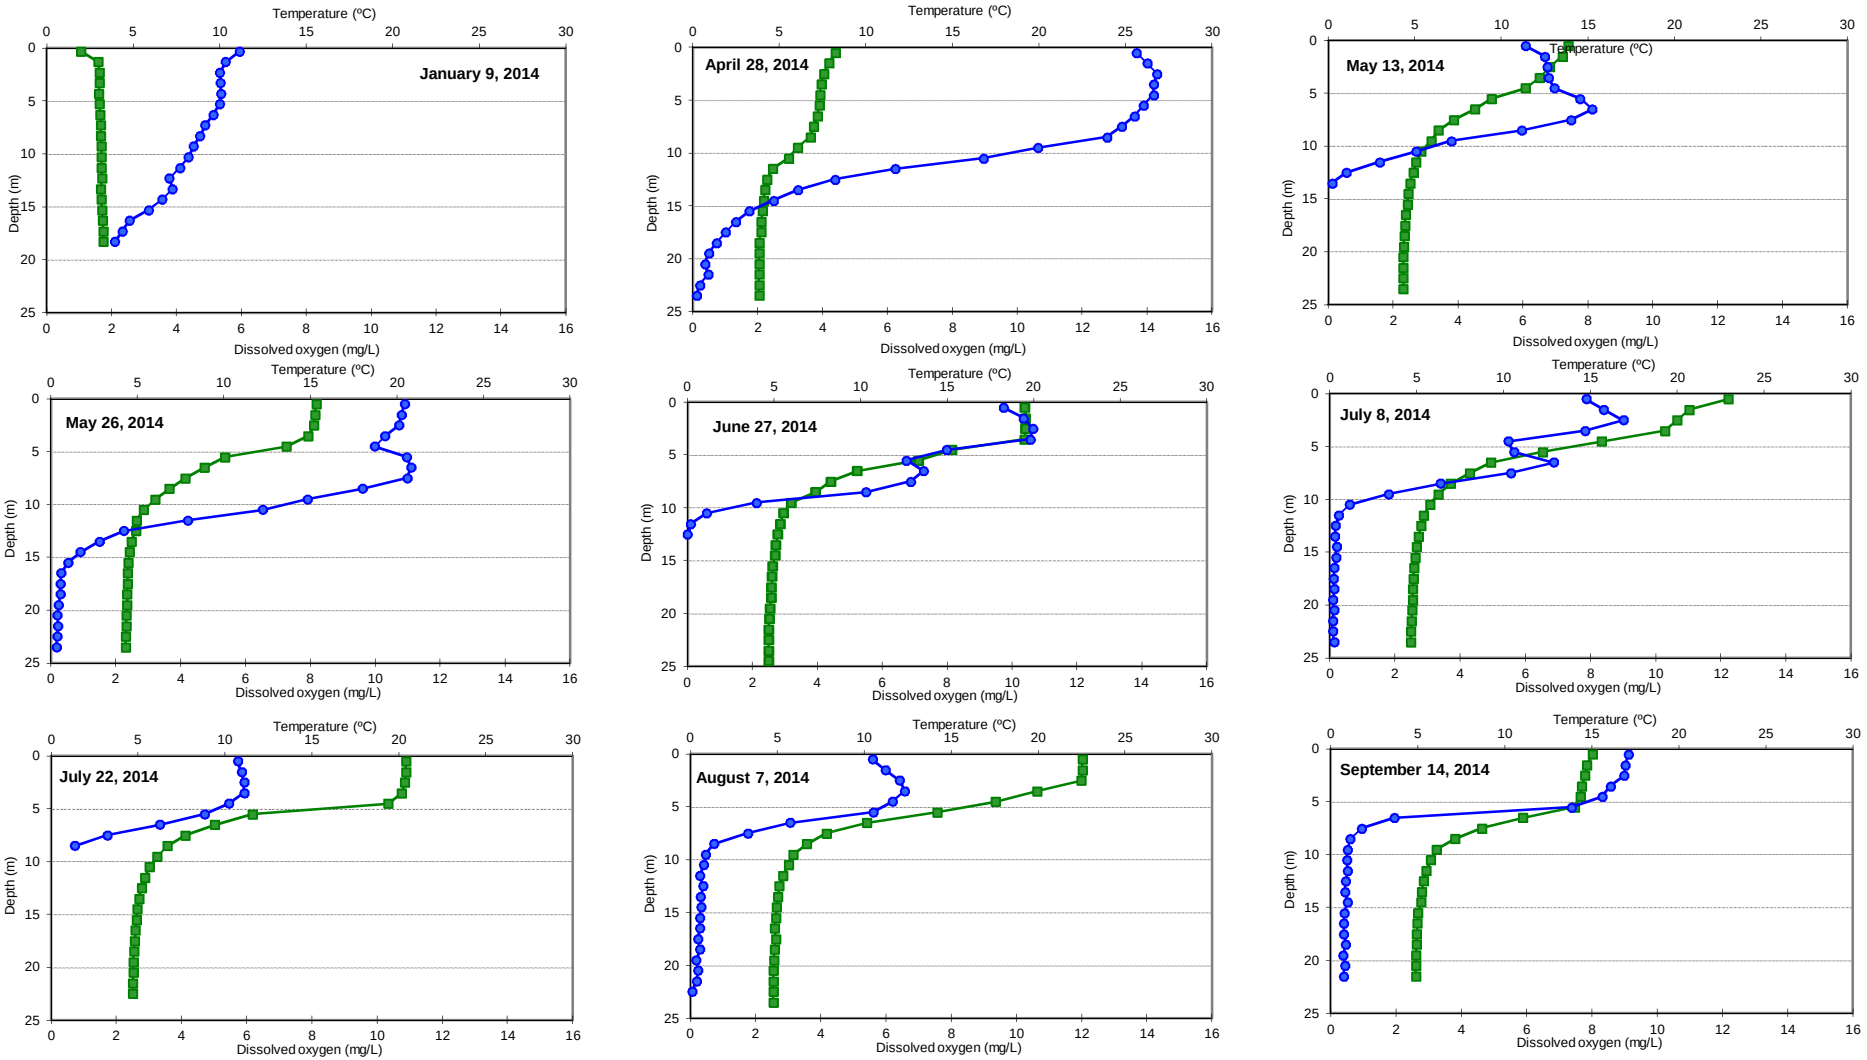
Depth profiles of *in situ* parameters have been recorded since 2007 and are provided for dissolved oxygen, temperature, and pH in Appendix C; the most recent (2014) lake profiles have been included as examples embedded in this section of the report: Figure 4.17 (dissolved oxygen and temperature) and Figure 4.18 (pH).

Jacko Lake waters are generally characterized as neutral to basic pH, very hard, with high buffering capacity. Shallow water samples had higher pH compared to deeper samples and exhibited greater seasonal variability; pH tended to exceed the drinking water acceptable upper limit of 8.5 during the summer, though remained below the aquatic life upper limit of pH 9.0. TDS concentrations were higher in the deep samples than the shallow samples (median concentrations of 453 mg/L and 413 mg/L, respectively) and remained consistent through the sampling program with little seasonal variability. The TDS values observed classify this water body as freshwater. Specific conductance (SpC) for the lake also increased with depth was higher than typical for the BC interior, with median values of 740 µS/cm and 663 µS/cm in the deep and shallow samples, respectively (RISC 1998). Higher than typical conductivity (and TDS) is likely due to the net evaporative climate conditions in the Project area which can result in greater concentrations of dissolved species in local waters. TSS and turbidity values for the lake and creek area are low. Secchi depth measurements were collected on the majority of the ice free sample collection dates and the and were generally between 3 m and 5 m, which is typical for lakes with the trophic status descriptions of eutrophic to meso-eutrophic.

Water temperature for Jacko Lake was seasonally affected throughout the year. *In situ* measurements taken along the surface of Jacko Lake showed temperatures just above freezing in the winter, with median summer temperatures of 20^{o}C. *In situ* measurements taken at depth showed a more consistent temperature profile, with a median temperature of 3.2 ^{o}C in the winter and close to 5 ^{o}C during the other three seasons.

The dissolved oxygen and temperature profiles for Jacko Lake (Figure 4.17) are indicative of mesotrophic (moderately biologically productive) conditions where the dissolved oxygen concentrations remain high in the epilimnion (the upper wind-mixed layer), throughout the summer. This is likely due to photosynthesis and diffusion from the atmosphere. Dissolved oxygen and temperature tend to decline rapidly with depth across the thermocline, and fall more gradually in the hypolimnion where no wind-mixing and little photosynthetic influences occur. Anoxic conditions were commonly observed near bottom-sediments in summer sampling events, likely due to decomposition of organic matter and the oxygen consumption of lake bed dwelling organisms.

During spring and fall turnover, temperate lakes tend to have uniform, well-mixed conditions throughout the water column. Spring turnover tends to happen as soon as the ice melts from the lake, which is typically in April or early May, though this has been noted to occur earlier and is highly dependent on the climatic conditions of a given year. Fall turnover conditions have been reported for sampling events in September, predominantly, but have occurred as late as November.



NOTES:

1. DEPTH UNITS ARE METRES BELOW SURFACE.
2. TEMPERATURE IS SHOWN ON THE PRIMARY X-AXIS.
3. DISSOLVED OXYGEN IS SHOWN ON THE SECONDARY X-AXIS.

Major Ions

The ion characterization of Jacko Lake is shown on the Piper diagram on Figure 4.2. The dominant anion in the Jacko Lake water samples is bicarbonate, with significant contributions of chloride in the deeper samples. There are no dominant cations (none contribute greater than 50%), though magnesium is weekly dominant in the shallow water samples, with significant calcium, while magnesium is the dominant cation at mid- and deep depth ranges, with equally significant calcium and sodium contributions.

Fluoride concentrations were observed in similar concentrations to what those in samples collected in Peterson Creek and the Open Pit area, and frequently exceeded the 0.12 mg/L CEQG-PAL, indicating that fluoride is persistent throughout the baseline study area. CEQG-PAL exceedances for fluoride were observed in 92% of the samples collected in Jacko Lake; however, all sample concentrations remained below the hardness dependent BCWQG-Max (1.57 mg/L for hardness 180 mg/L $CaCO_3$ or greater).

Sulphate and chloride concentrations were observed in lesser concentrations that what were found in the greater Peterson Creek watershed area samples and both of these parameters were noted to increase in concentration with depth. Chloride concentrations remained below all applicable guidelines. The SBEB developed for sulphate was necessary for the assessment of Jacko Lake water quality due to the hard water conditions in the lake, despite the lower sulphate concentrations (ranged from 37 mg/L to 84.5 mg/L); hardness rarely dropped below 250 mg/L CaCO3, which is the threshold in the BCWQG-30 D for sulphate that triggers the requirement for site specific toxicity testing. The recommended SBEB for the lake, which supports early life stages for trout, is a maximum sulphate concentration of 429 mg/L, which is the same as the current BCWQG-30 D, but with the maximum hardness adjusted up to 800 mg/L $CaCO_3$ (Nautilus 2015). There were no reported sulphate concentrations that exceeded the SBEB and sulphate concentrations have been trending down since sampling began in 2007, with concentrations typically above 80 mg/L in 2007 and the maximum concentration reported at 55.1 mg/L in 2014.

Nutrients

Phosphorous concentrations in Jacko Lake varied with depths and season. Surface concentrations of total phosphorous (TP) decreased during freshet and remained stable through the summer, while at the depths of Jacko Lake, this trend was reversed: TP typically remained stable during freshet and increased in the summer, with highest concentrations observed in the fall season. The median TP concentrations observed along the surface of the lake were in the eutrophic range in winter and spring and in the upper range of meso-eutrophic in the summer and fall, while concentrations at depth were generally in the upper eutrophic and hyper-eutrophic ranges. The TP concentrations within Jacko Lake at depth were significantly more variable than the shallow sample concentration and the concentrations immediately downstream (PC08) were generally similar to the shallow water sample values. Using the average TP concentrations the shallow water in the lake was within the eutrophic range and the deeper water was within the hyper-eutrophic range.

The nitrogen based inorganic nutrient (nitrite, nitrate, and ammonia) concentrations were generally low in Jacko Lake and few guideline exceedances were noted. Ammonia was the only parameter to exceed the temperature- and pH dependent aquatic life guidelines and these exceedances were

observed only in the samples collected at depth (15% of JACL-D samples exceeded the guidelines for ammonia).

Organic Carbon and Nitrogen

Organic carbon in Jacko Lake was mainly observed in the dissolved form and was remained consistent seasonally and with depth, ranging between 12 mg/L and 18 mg/L and exceeded the 4.0 mg/L BCWQG-Drinking Water. This guideline is applicable only to treated water sources because the presence of organic carbon can result in the formation of toxic trihalomethanes when chlorinated. Organic nitrogen concentrations were low and exhibited a slight increase with depth.

4.4.2.2 Metals and Metalloids

Total and dissolved metal concentrations within Jacko Lake have remained low over the course of the baseline water quality sampling program when compared to other sites in the local watershed. The majority of total and dissolved metal concentrations were observed below detection limits and those that were reported above the MDL were typically below the aquatic life guidelines. Isolated exceedances (i.e. fewer than 10% of samples) were observed for selenium, copper, and zinc, and manganese concentrations regularly exceed the drinking water aesthetic objectives in the samples collected at depth. Jacko Lake, unlike the Historical Mine Site Features and Inks Lake and Wallander Lake, has inlet creeks and an outlet channel, and as a result loading to the lake is moderated. Parameters in the evaporative lakes and anthropogenic features continually rise, as they are low points that receive groundwater inflows and contact water (Historical Mine Site Features), and they are effectively evaporative features with no means of load removal, except through precipitations due to natural solubility constraints.

Manganese was the only metal parameter that was continuously elevated. Concentrations were greater at depth and were generally lower in the spring immediately following spring turnover, increasing in samples collected between July and September. Exceedances of the HC-DW aesthetic objective were observed when thermal stratification was also observed. When a thermocline develops sediments and the immediately overlying water column become depleted of oxygen (anoxic) which can result in an increase in dissolved manganese as a result of reduction reactions with manganese oxide sediment deposits (Hem 1985).

4.4.3 Historical Mine Site Features Water Quality Assessment

This section of the baseline water quality report is focused on characterizing water quality in areas of the water quality study area that have been affected by previous mining activities. These features include the North Seepage Collection Pond (NSP), the historical mine rock seepage area (WR-Seep), the south catchment (S. Catchment), and the two open pit areas (west and east). All sites are recharged by groundwater and surface water inflows and outflows have not been observed. The water level in the open pit lakes are well below the natural ground surface and below observed water levels in the surrounding ground water wells and as such seepage losses to the surrounding environment from the lakes are not likely, though seepage losses are suspected from the seepage collection ponds.

4.4.3.1 Physical Parameters, Major Ions, Nutrients, and Organics

The water at all the historical mine features sites is generally characterized as neutral to basic pH, very hard with high to very high alkalinity (buffering capacity). Samples collected from S. Catchment and NSP had high pH, which frequently exceeded the upper acceptable limits of the HC-DW guideline; no samples exceeded the upper acceptable limit of the aquatic life guidelines (pH 9). The waters at each location are very high in dissolved solids and are generally considered to be brackish.

The TDS of the water at all the historical mine site feature sites is high relative to freshwater, and is generally considered brackish. TDS is a measure of the combined content of ionic constituents in water and includes calcium, phosphate, nitrate, sodium, potassium, and chloride. Typically the Ajax West-West Pit (AJWW) water is more saline than the Ajax West-East Pit (AJWE), though both are classified as moderately saline (TDS between 3,000 mg/L and 10,000 mg/L). The AJWW pit is periodically dry and cannot be sampled regularly. TDS, a measure of the combined content of substances (including calcium, phosphate, nitrate, sodium, potassium, and chloride) contained in water, was used to classify the salinity of each water body. The mine rock seepage pond (WR-Seep) to the south of Peterson Creek was classified as freshwater only during spring melt, after which it becomes slightly to moderately saline. The samples collected from NSP were moderately saline (TDS >5,000 mg/L) and the samples collected from S. Catchment were slightly to moderately saline (TDS 2,000 mg/L to 3,500 mg/L). In comparison with other water bodies in the area, Inks Lake, in the Cherry Creek watershed, is more saline than the NSP, demonstrating the high TDS of the general area of the Project. Additionally, samples from Wallander Lake demonstrated extreme TDS concentrations for an inland water feature, similar to and greater than those found in ocean water (>35,000 mg/L). These mine features and other water bodies (Wallander Lake and Inks Lake) are in effect evaporative basins in local groundwater discharge zones within a net evaporative climate and as a result the concentration of the majority of parameters will continue to rise over time. The parameters in the man-made features and the natural lakes tend to have significantly higher concentrations than the surrounding groundwater and surface water. In situations like this, parameter concentrations are generally controlled by solubility limits, and clear resolution of parameter concentrations can be hampered due to sample matrix interference and the dilution requirements for analysis.

Major Ions

The water types in the Historical Mine Site Features vary slightly between sites but are generally classified as magnesium-sulphate, though magnesium is weekly dominant in the waters from the open pit lakes and the WR-Seep and strongly dominant in the S.Catchment and NSP samples. The piper diagram is provided on Figure 4.3.

Most samples collected from the historical mine site features had sulphate concentrations that were typically greater than 1,000 mg/L and exceeded guidelines. The distribution of sulphate concentrations at each site is shown in the boxplots on Figure 4.19. The SBEB of 730 mg/L for a hardness of up to 1,377 mg/L $CaCO_3$ was recommended for surface waters where early life stages for trout are not expected to occur (Nautilus 2015). The majority of the water samples from the historical mine features exceeded the SBEB; though it should be noted that the factor of safety incorporated into the SBE was two-fold and no adverse effects were observed for concentrations of sulphate up to 1,460 mg/L (Nautilus 2015). All of the samples exceeded the drinking water guidelines (BCWQG-DW and HC-DW; both 500 mg/L) and most exceeded the 1,000 mg/L BCWQG-Livestock

and CEQG-Livestock. A few samples from WR-Seep were below the livestock guideline, typically those collected immediately following spring freshet.

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG-30 D FOR SULPHATE IS DEPENDENT ON ONGOING TOXICITY TESTS; PRELIMINARY SCIENCE-BASED ENVIRONMENTAL BENCHMARK TESTING RESULTS HAVE INDICATED A RECOMMENDED LIMIT OF 730 mg/L FOR THE PROTECTION OF AQUATIC LIFE. THIS IS NOT SHOWN ON THE PLOTS.

Fluoride sample concentrations remained below the BCWQG-Max (1.57 mg/L for hardness of 108 mg/L $CaCO_3$ or greater) and exceeded the more stringent CEQG-PAL (0.12 mg/L) in almost every sample collected from the historical mine site features. The distribution of fluoride concentrations in comparison with aquatic life guidelines is shown on Figure 4.20. Fluoride occasionally exceeded the 1 mg/L BCWQG/CEQG thresholds for livestock and irrigation but remained below the BCWQG and HC thresholds for drinking water (both 1.5 mg/L).

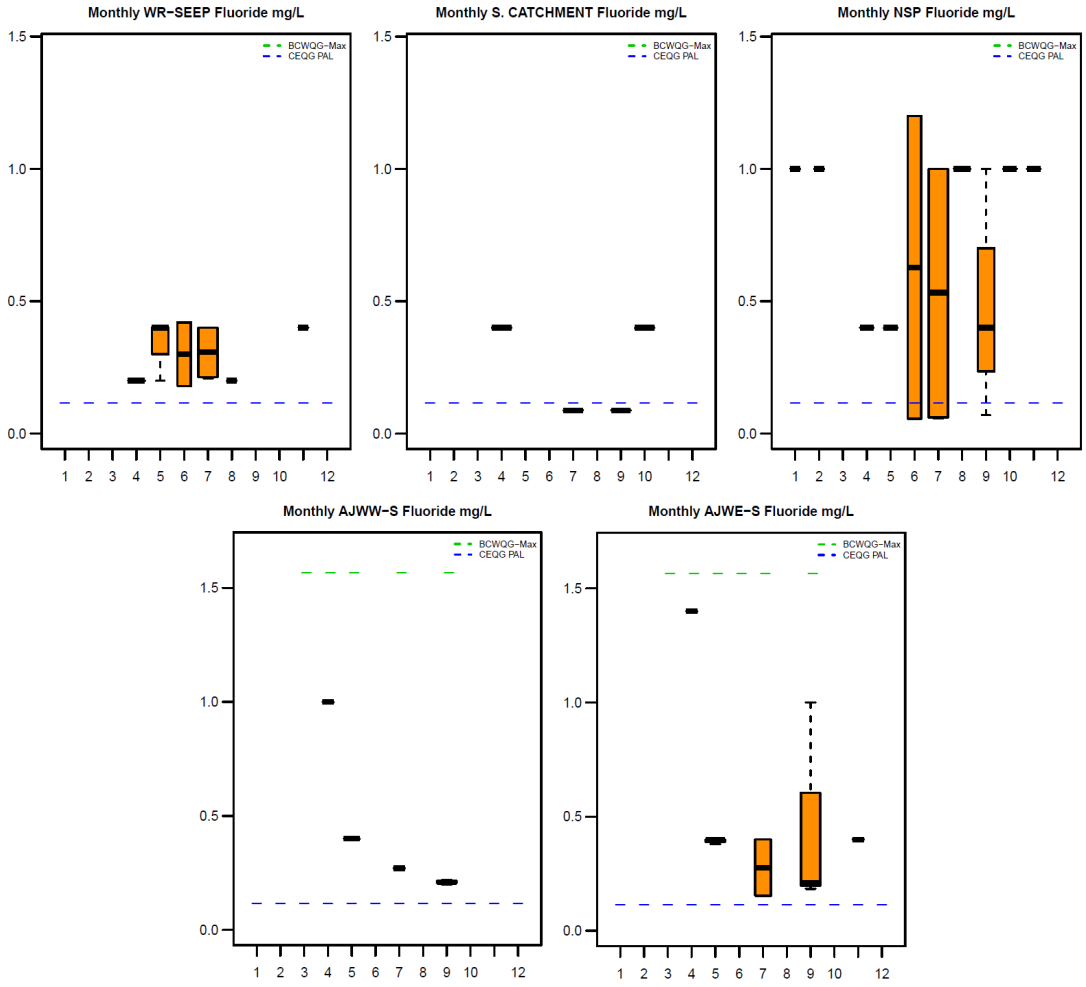

Figure 4.20 Boxplot of Fluoride at the Historical Mine Site Features

4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE CEQG-PAL FOR FLUORIDE IS 0.12 mg/L; THE BCWQG-MAX FOR FLUORIDE IS HARDNESS-DEPENDENT AND IS NOT WITHIN THE SCALE OF THIS GRAPH.

Nutrients

Nitrate and nitrite concentrations are elevated in the water samples collected from the Ajax West open pits and in the historical mine rock seepage collection pond south of Peterson Creek. In the AJWW open pit, the nitrate concentrations were continually over 60 mg/L, exceeding the 32.8 mg/L BCWQG-Max and well above the 3 mg/L CEQG-PAL and BCWQG-30 D for this parameter. Sample nitrate concentrations in the AJWE open pit were lower, with all samples below the less stringent BCWQG-Max, but still exceeded the CEQG-PAL and BCWQG-30 D. The CEQG-PAL and BCWQG-30 D referenced in this report are specific to long-term exposure and are directly relevant for the comparison with the average concentration of the 5-in-30 sampling programs. The short-term exposure limit under the CEQG-PAL is 124 mg/L; however, given the continuous nature of the exceedances in the open pit it is reasonable to apply the long-term exposure limits. All samples collected from both pits exceeded the drinking water guidelines (BCWQG-DW and HC-DW; both 1 mg/L). The range of nitrate concentrations at each site is shown on the boxplots on Figure 4.21; the sample concentrations were similar in the shallow and deep samples in both of the historical open pits so only the shallow sample results are provided graphically. Only one sample from the WR-Seep site exceeded the CEQG-PAL and BCWQG-30 D (not the BCWQG-Max).

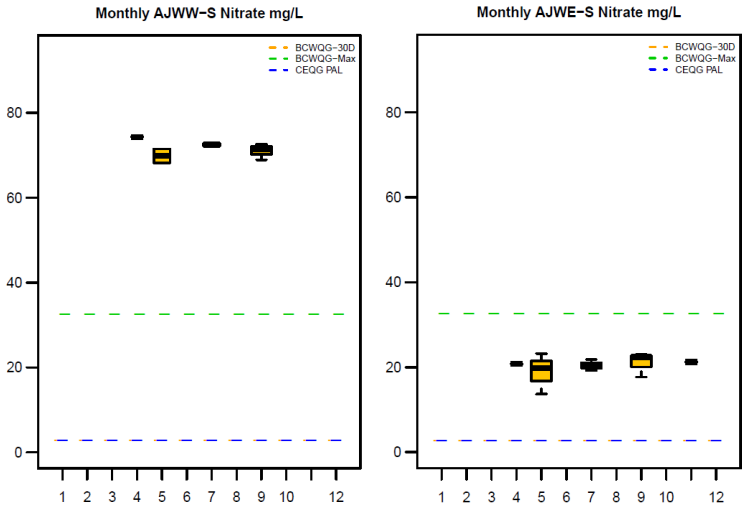

Figure 4.21 Boxplot of Nitrate at the Historical Open Pits

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG-MAX FOR NITRATE IS 32.8 mg/L AND THE CEQG-PAL IS 3 mg/L; GUIDELINE EXCEEDANCES WERE NOT OBSERVED; THIS GRAPH IS INCLUDED TO SHOW THE SEASONAL TREND IN NUTRIENT CONCENTRATIONS.

Nitrite concentrations in the Ajax West open pits and the WR-Seep often exceeded the 0.06 mg/L N CEQG-PAL and on several occasions exceeded the BCWQG-Max (chloride-dependent); however, none exceeded the BCWQG-30 D (3 mg/L). Chloride concentrations in the waters of the Historical

Mine Site Features were high (33 mg/L on average), resulting in much higher BCWQG-Max values (maximum guideline value of 0.6 mg/L for chloride greater than 10 mg/L).

Although nitrate and nitrite concentrations were not an issue in the NSP or the S Catchment, ammonia concentrations were elevated. All but one of the samples from the NSP exceeded the CEQG-PAL and several samples also exceeded the BCWQG-Max. The majority of the S Catchment samples exceed the CEQG-PAL, but none exceed the BCQWG-Max. The ammonia guidelines are both pH and *in situ* temperature specific, becoming more restrictive under high pH and temperature conditions. The high pH of these water features results in greater potential toxic effects from this parameter, which is further exacerbated with the high water temperatures achieved in the shallow water features during the summer months.

Phosphorus levels were elevated in samples collected from NSP, S. Catchment, and WR-Seep (all eutrophic to hyper-eutrophic) and were consistently low in samples collected from the open pit. The open pit TP concentrations were very low and indicative of oligotrophic to ultra-oligotrophic tropic status.

4.4.3.2 Metals and Metalloids

Metals were elevated in the water quality samples from the Historical Mine Site Features in the Peterson Creek watershed, which is expected based on the ion concentrations and the evaporative nature of the water bodies. As previously stated, clear resolution of parameter concentrations was hindered due to sample matrix interference and the dilution requirements for analysis of the majority of these samples, for which the greatest effects were noted for the detection of cadmium. Other parameters had similar issues, but to a lesser degree and these included copper, chromium, and selenium. Metals were predominantly present in the dissolved form and all exceedances discussed below should be assumed to apply to both the total and dissolved concentrations, unless otherwise specified. There is little seasonality to the metals analytical data and concentrations were generally high. The discussion in this section is brief and provides a summary of the exceedances as they pertain specifically to the aquatic life guidelines. The discussion of these guideline exceedances is kept brief because these waters are not fish-bearing and are not used for drinking water or for agricultural purposes. For simplicity and ease of viewing, figures showing boxplots of the range of metal parameter concentrations at each site have been summarized at the end of each section (i.e. graphs showing the range of all metal parameter concentrations for sites in each subsection are compiled into one figure at the end of the subsection). The exceedances of the other relevant guidelines will be addressed in brief.

Ajax West-West and Ajax West-East Open Pits (AJWW and AJWE)

The following metals exceeded guidelines on a continuous basis (boxplots showing ranges of concentrations of metal parameters for which aquatic life guideline exceedances were observed often are shown on Figure 4.22):

- Arsenic – Concentrations were consistently well over aquatic life guidelines (CEQG-PAL and BCWQG-Max; both 0.005 mg/L) and were higher in samples collected from AJWE than from AJWW. Drinking water and livestock water use guidelines were also exceeded in the open pit samples.
- Cadmium – Concentrations exceeded aquatic life guideline limits regularly at each site. It should be noted that many samples for this parameter were in fact below the MDL, but the MDL was

significantly higher than the guideline and other detected values. The high non-detect values were assumed to exceed guidelines, but were not used in the calculation of the average concentration to determine the exceedance factor presented above and were not highlighted as exceedances in the summary tables in Appendix C.

- Copper – Concentrations were higher in samples collected from AJWW than AJWE, but exceeded all three aquatic life guidelines (BCWQG-30 D, BCWQG-Max, and CEQG-PAL; in both pits). At AJWE, only the samples collected at depth exceeded the BCWQG-Max, while samples collected in the middle of the water column and from the surface were below this threshold.
- Molybdenum – Concentrations were higher in samples collected from AJWW than AJWE, but exceeded all three aquatic life guidelines (BCWQG-30 D, BCWQG-Max, and CEQG-PAL) at all sites. The open pit molybdenum concentrations also exceeded the drinking water, livestock, irrigation, and wildlife water use guidelines.
- Selenium – Concentrations were over ten times greater than the 0.002 mg/L BCWQG-30 D limit over 20 times greater than the more stringent 0.001 mg/L CEQG-PAL limit at all sites in the historical open pit, but were higher in samples collected from AJWW than from AJWE. The open pit selenium concentrations also exceeded the drinking water and agricultural (irrigation and livestock) water use guideline limits.
- Antimony – Concentrations consistently exceeded the 0.009 mg/L BCWQG in samples collected from both AJWE and AJWW. Concentrations were generally higher in the sample collected at depth and fewer guideline exceedances were observed in the shallow samples.
- Uranium – Concentrations of this parameter exceeded the BCWQG of 0.0085 mg/L in almost all samples and often exceeded the 0.01 mg/L BCWQG and CEQG for irrigation water uses. Concentrations of uranium in natural waters ranged from 0.001 mg/L to 0.010 mg/L and concentrations in excess of 1 mg/L are indicative of uranium-ore deposits nearby (Hem 1985). The concentrations present in the historical open pits are at the upper limits of the natural water range, but are not indicative of a uranium-ore deposit, though there are several known uranium deposits in the Kamloops-North Thompson Region.

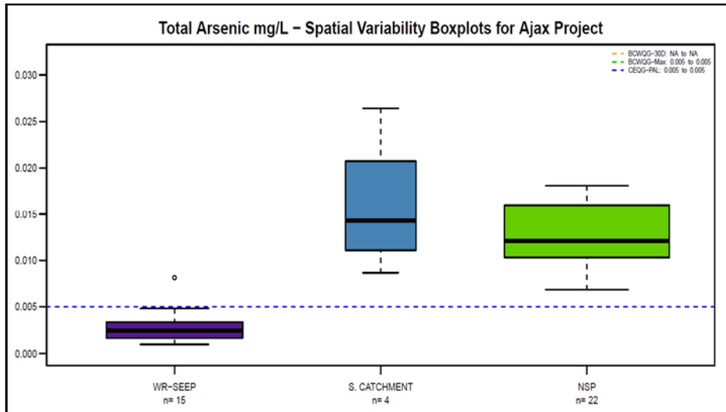
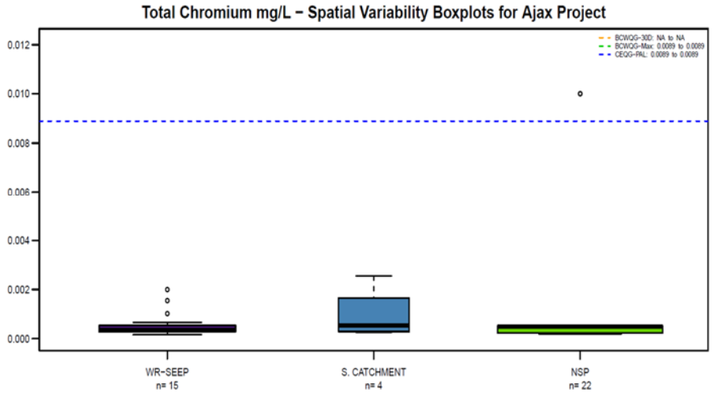
Historical Seepage Collection Ponds

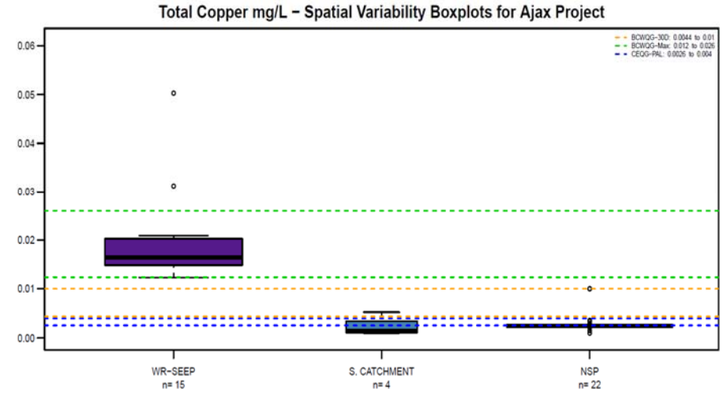
The discussion in this subsection focuses on metal parameters observed in the historical seepage collection areas, including the following sites: NSP, WR-Seep, and S. Catchment. The analysis of chemistry of the historical seepage collection ponds is complicated due to the brackish nature of the water. For simplicity, all figures have been compiled at the end of the text, on Figure 4.23, showing all boxplots of metal parameters of interest for all three sites in comparison to aquatic life guidelines (the figures do not include metals for which only sporadic guideline exceedances were observed).

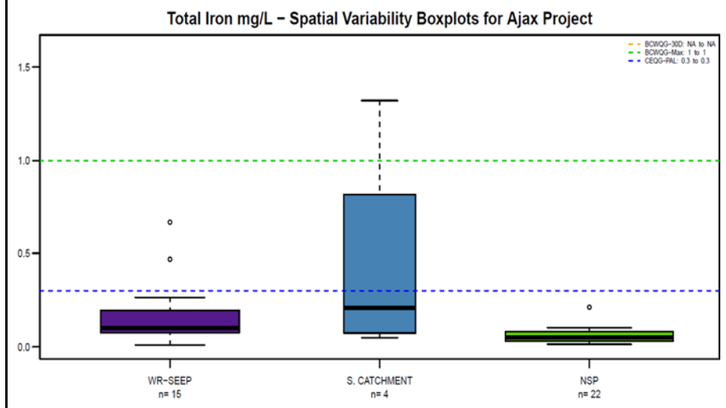
The following metals exceeded guidelines on a continuous basis:

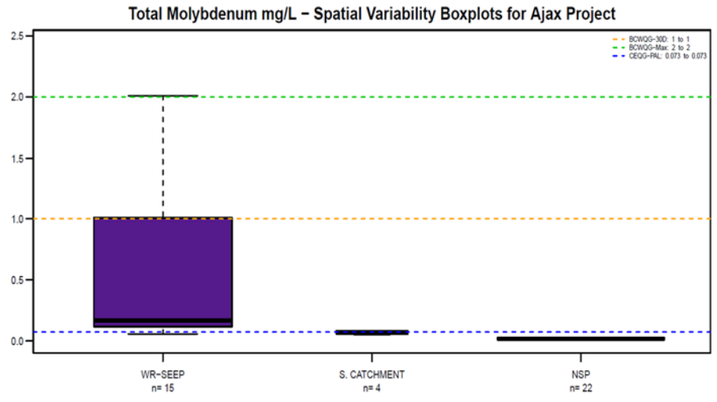
- Arsenic – Concentrations were on average two times greater than the 0.005 mg/L aquatic life guideline limits (BCWQG-Max and CEQG-PAL) in samples collected from S.Catchment and NSP; however, almost all samples collected from WR-Seep were below the guideline.
- Chromium – Exceedances of the CEQG-PAL for Cr(VI) were observed sporadically in samples collected from WR-Seep and more often in samples collected from S.Catchment.
- Copper – Concentrations exceeded the CEQG-PAL in all samples collected from WR-Seep and in several samples collected from S.Catchment and NSP. The samples collected from WR-Seep also exceeded the BCWQG-30 D, but did not exceed the BCWQG-Max. The BCWQG-30 D is relevant in this case, since concentrations were consistently over the guideline.
- Iron – Iron concentrations were below the guideline thresholds at NSP and WR-Seep, but exceeded the CEQG-PAL of 0.3 mg/L in two of the four samples collected from S.Catchment. One sample also exceeded the less stringent BCWQG-Max of 1 mg/L.
- Molybdenum – Only one sample, collected from WR-Seep, was noted to exceed the 2 mg/L BCWQG-Max limit, while several samples exceeded the 1 mg/L BCWQG-30 D, and all exceeded the 0.073 mg/L CEQG-PAL. The WR-Seep molybdenum concentrations also exceeded the drinking water and livestock and irrigation water use guideline limits. The samples collected from S.Catchment and NSP were lower and only two samples, collected from S.Catchment, exceeded the CEQG-PAL.
- Selenium – Concentrations were on average 10 times greater than the 0.002 mg/L BCWQG-30 D and 20 times greater than the 0.001 mg/L CEQG-PAL. The WR-Seep selenium concentrations were often 10 times greater than the 0.002 mg/L BCWQG-30 D and 20 times greater than the 0.001 mg/L CEQG-PAL and also exceeded the drinking water and irrigation water use guidelines. Sample concentrations observed at S.Catchment and NSP exceed the 0.01 mg/L BCWQG-Irrigation and 0.02 mg/L CEQG-Irrigation.

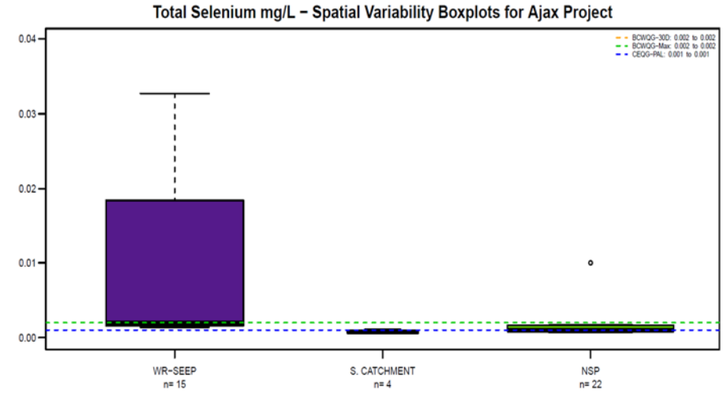


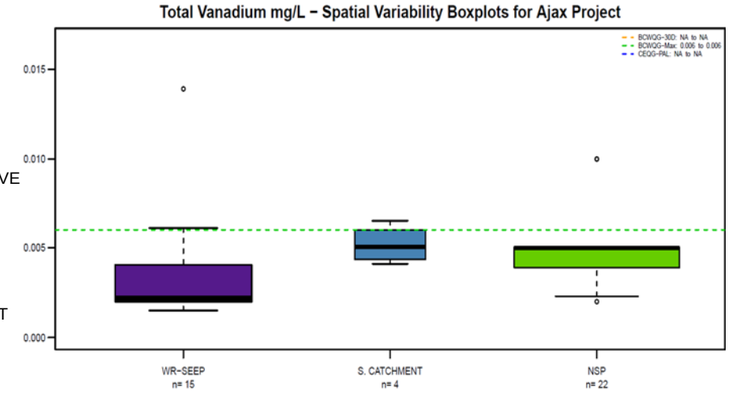












NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE BASELINE MONITORING SITES. n=NUMBER OF SAMPLES COLLECTED.
3. BOX PLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH SITE (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES)
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG-MAX AND THE CEQG-PAL FOR ARSENIC ARE 0.005 mg/L.
6. THE HC-DW GUIDELINE FOR ARSENIC IS 0.01 mg/L AND THE BCWQG-DW IS 0.025 mg/L.
7. AGRICULTURAL GUIDELINES (BCWQG AND CEQG-PAL) FOR ARSENIC ARE 0.1 mg/L FOR IRRIGATION USE AND 0.025 mg/L FOR LIVESTOCK DRINKING WATER.
8. THE CHROMIUM BCWQG-MAX AND CEQG-PAL THRESHOLDS FOR AQUATIC LIFE ARE 0.0089 mg/L FOR Cr(III) (SHOWN ON THE FIGURE); THE SAME GUIDELINES ARE 0.001 mg/L FOR THE CR(VI) SPECIES; THE SPECIES HAS NOT BEEN ANALYZED BUT IT IS TYPICALLY Cr(VI) IN WELL OXYGENATED WATERS AND Cr(III) IS REDUCING ENVIRONMENTS.
9. THE CEQG-PAL, BCWQG-MAX, AND BCWQG-30DAY THRESHOLDS FOR COPPER ARE HARDNESS-DEPENDENT AND WERE CALCULATED BASED ON THE MEDIAN MONTHLY HARDNESS OBSERVED AT EACH SITE.
10. THE BCWQG-MAX FOR IRON IS 1 mg/L (SPECIFIC TO TOTAL IRON) AND THE CEQG-PAL IS 0.3 mg/L.
11. THE HC-DW AESTHETIC OBJECTIVE FOR IRON IS 0.3 mg/L.
12. AQUATIC LIFE GUIDELINES FOR MOLYBDENUM INCLUDE THE BCWQG-30DAY OF 1 mg/L, THE BCWQG-MAX OF 2 mg/L, AND THE CEQG-PAL OF 0.073 mg/L.
13. THE BCWQG-DW FOR MOLYBDENUM IS 0.25 mg/L..
14. THE AGRICULTURAL AND WILDLIFE GUIDELINES FOR MOLYBDENUM ARE 0.05 mg/L FOR LIVESTOCK DRINKING WATER (BCWQG AND CEQG) AND 0.02 mg/L AND 0.01 mg/L FOR IRRIGATION (BCWQG AND CEQG, RESPECTIVELY.
15. THE BCWQG-MAX FOR SELENIUM IS 0.002 mg/L AND THE CEQG-PAL IS 0.001 mg/L.
16. THE DRINKING WATER GUIDELINES FOR SELENIUM ARE 0.01 mg/L (BCWQG AND HC).
17. THE BCWQG-MAX FOR VANADIUM IS 0.006 mg/L.

4.4.4 Tributaries to Peterson Creek – Water Quality Assessment

Two major tributaries contribute to Peterson Creek, downstream of Jacko Lake and have been included in the baseline water quality data collection program: Keynes Creek and Humphrey Creek. Both tributaries flow from south to north, away from the divide between the Peterson Creek and Anderson Creek catchment areas. Goose Lake is included in the Keynes Creek catchment area and is also within the Project footprint. The confluence of Keynes Creek with Peterson Creek is immediately downstream of PC08 (close to the outlet of Jacko Lake). The headwaters of Keynes Creek and most of the creek itself are within the Project footprint. Humphrey Creek is located downstream of the Project footprint and some of the proposed facilities are within its drainage area. The headwaters of this creek extend from Edith Lake, which was also included in the baseline water quality study. The confluence of Humphrey Creek with Peterson Creek is slightly upstream of PC02.5 and a surface connection is not evident; Humphrey Creek goes subsurface downstream of the HUMPH02 monitoring location.

4.4.4.1 Keynes Creek Watershed – Water Quality Assessment

Water quality samples have been collected from one site along Keynes Creek (KC03), upstream of the confluence with Peterson Creek. Samples have also been collected from Goose Lake (GOOSE LAKE). Goose Lake is formed at a low elevation point in this catchment and there are no surface flow channels that connect this lake to Peterson Creek, though it is considered to be in the headwaters of Keynes Creek. Six samples were collected from KC03 in March through June 2014; sampling was terminated when the site dried up early in the summer.

Physical Parameters

Water in the Keynes Creek watershed is characterized as basic, very hard, with high SpC and buffering capacity. Samples collected from Goose Lake were higher in all physical parameters (hardness, pH, SpC, alkalinity, and TDS) than samples collected from KC03. Physical parameters generally increased during the summer months, reaching maximum concentrations in the fall season. The seasonal and spatial trends in physical parameters are demonstrated for hardness and TDS on Figure 4.24. Guideline exceedances were observed in Goose Lake for pH (CEQG-PAL, BCWQG-Max, HC-DW, and BCWQG-DW); however, pH at KC03 was below guidelines in all samples. The distribution of pH of the samples collected from both sites is shown on Figure 4.25.

4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE CEQG-PAL AND THE BCWQG-MAX FOR pH SPECIFY AN ACCEPTABLE pH RANGE OF 6.5 TO 9; THE ACCEPTABLE DRINKING WATER RANGE IS FROM 6.5 TO 8.5 AND IS NOT SHOWN ON THISFIGURE.

Dissolved Anions

The average water types and TDS of the samples collected Keynes Creek and Goose Lake are shown on Figure 4.4, which demonstrates the high variability in water types between the two sites in this watershed (KC03 and GOOSE LAKE). Goose Lake has very high TDS (greater than 3,000 mg/L) is classified as moderately saline, while KC03 had lower TDS (below 1,000 mg/L) and was classified as slightly saline. Samples collected from Goose Lake are of the bicarbonate-magnesium type with significant calcium and sodium, while samples collected from KC03 were of the sodium-sulphate type with significant magnesium. The outflow of Goose Lake contributes to one of the three main branches of the headwaters of Keynes Creek, but the difference in water types demonstrates that this outflow is unlikely to be the main source of water to the creek. The water type of Goose Lake is similar to that of the surrounding shallow groundwater samples (BGC14-016 and BGC14-017S), which is consistent with the expected water type of a lake located in the upper headwaters area. The water type of KC03 is more consistent with the groundwater types observed close to the site (BGC14-002S/D and in the west branch of the Keynes Creek headwaters (BGC14-011S/D).

Guideline exceedances were observed often for chloride and sulphate and the distribution of concentrations of these parameters in the Keynes Creek watershed is shown seasonally on Figure 4.26. Neither Goose Lake or Keynes Creek are surface water bodies that support early life stages of trout and therefore the SBEB of 730 mg/L for a hardness of up to 1,377 mg/L $CaCO_3$ applies (Nautilus 2015). The sulphate concentrations in Goose Lake samples were greater than 1,400 mg/L and exceeded the SBEB in all samples and consistently exceeded the 500 mg/L drinking water

guidelines (BCWQG-DW and HC-DW). Keynes Creek (KC03) sulphate sample concentrations were consistently below the SBEB and the drinking water guidelines. Chloride concentrations in Goose Lake samples increased through spring and summer and exceeded the BCWQG-30 D (150 mg/L) and the CEQG-PAL for long-term exposure (120 mg/L) by the late summer months; however, no exceedances of the short-term exposure guidelines were observed (BCWQG-Max and CEQG-PAL; 600 mg/L and 640 mg/L, respectively). Continued monitoring at this location will provide further insight into whether or not the chloride levels are above the chronic level continuously through the fall and winter months. Chloride concentrations in the Keynes Creek samples were below all applicable guidelines.

Fluoride sample concentrations remained below the hardness dependent BCWQG-Max (1.57 mg/L for hardness 180 mg/L $CaCO_3$ or greater) but exceeded the CEQG-PAL of 0.12 mg/L in all samples collected from KC03, though none of the Goose Lake samples exceeded the CEQG-PAL. For some samples, the MDL was elevated above the CEQG-PAL for this parameter due to matrix interference; however, the samples of detectable concentrations indicate that the fluoride concentrations are generally elevated above the guideline.

Nutrients and Organic Carbon

Phosphorous concentrations in samples collected from both KC03 and Goose Lake were in the eutrophic to hyper-eutrophic range (i.e. greater than 0.1 mg/L). TP in Goose Lake increased dramatically during the late summer and reached a peak of 0.4 mg/L in the August. At KC03, TP concentrations were similar, but showed less seasonality.

Nitrogen levels in the Keynes Creek watershed were low; however, ammonia exceeded the pH- and temperature-dependent CEQG-PAL in samples collected from Goose Lake.

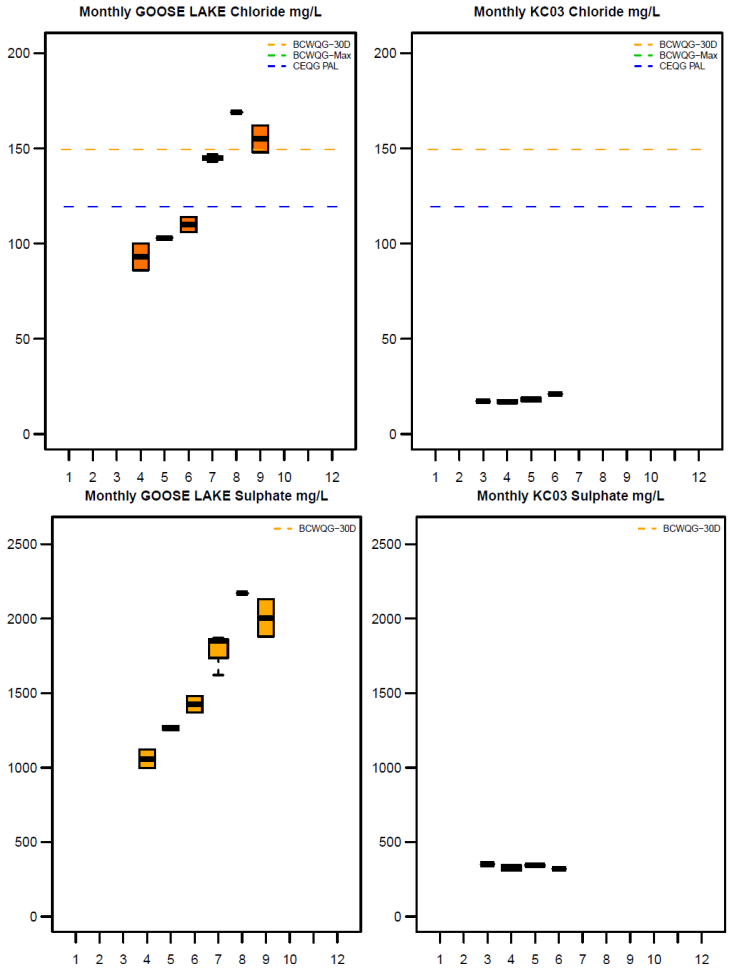

Figure 4.26 Seasonal Boxplot of Chloride and Sulphate Concentrations in the Keynes Creek Watershed

NOTES:

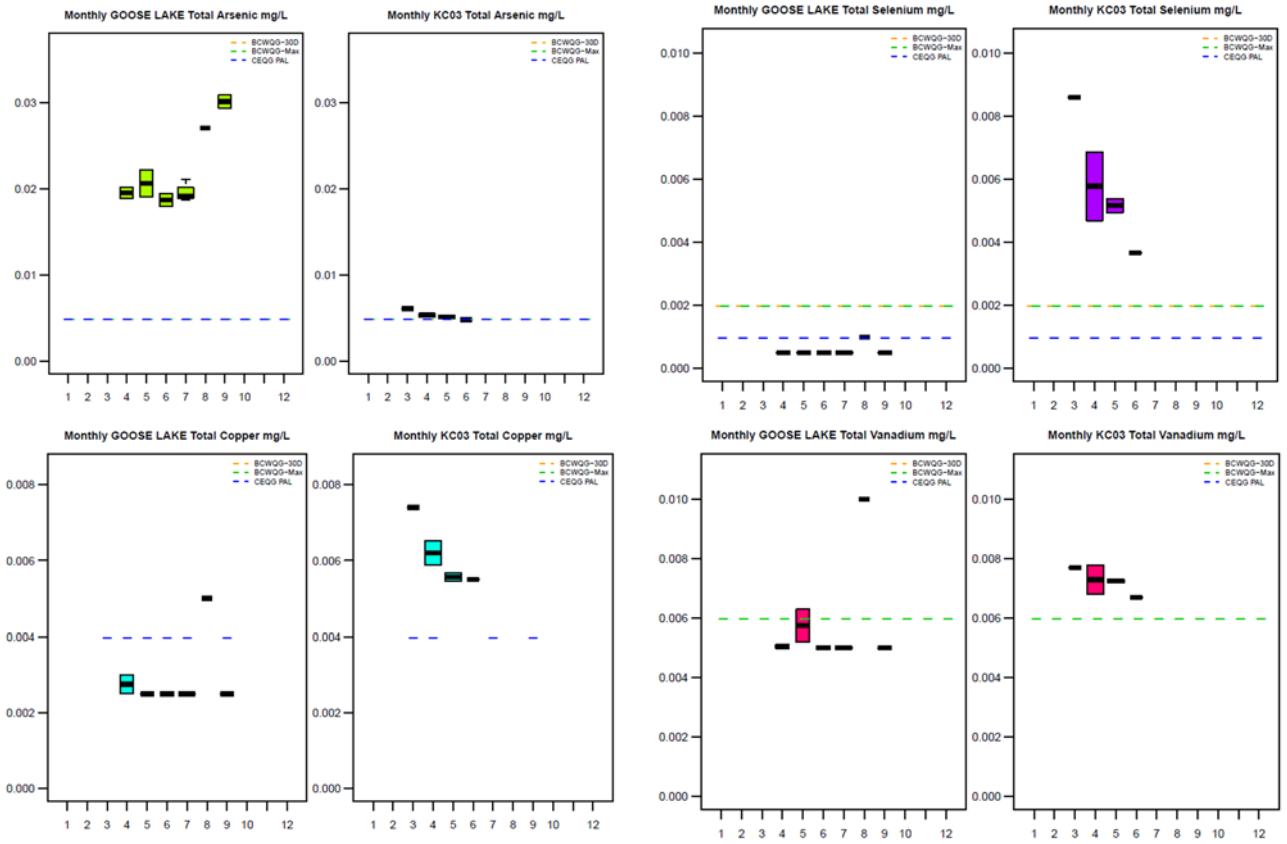
1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. CHLORIDE GRAPHS ARE SHOWN IN THE TOP ROW; SULPHATE GRAPHS ARE SHOWN ON THE BOTTOM ROW.
6. THE BCWQG-30DAY CHRONIC EXPOSURE GUIDELINE FOR CHLORIDE IS 150 mg/L; THE BCWQG-MAX IS 600 mg/L AND IS NOT WITHIN THE SCALE OF THIS GRAPH.
7. THE CEQG-PAL FOR CHLORIDE OF 120 mg/L IS SPECIFIC TO LONG-TERM EXPOSURE; THE CEQG-PAL FOR SHORT-TERM EXPOSURE IS 640 mg/L AND IS NOT WITHIN THE SCALE OF THE GRAPH.
8. THE BCWQG-30D FOR SULPHATE IS DEPENDENT ON ONGOING TOXICITY TESTS; PRELIMINARY RESULTS HAVE INDICATED A RECOMMENDED SBEB LIMIT OF 730 mg/L.

Metals

Metals in this watershed were generally present predominantly in the dissolved form. Arsenic was the only metal parameter to exceed guidelines in samples collected from Goose Lake; however, arsenic, copper, and selenium regularly exceeded aquatic life guidelines at KC03. Seasonal boxplots for metal parameters that regularly exceeded guidelines are shown on Figure 4.27. Single sample aquatic life guideline exceedances were observed in Goose Lake for aluminum, copper, and iron. Agricultural and wildlife guideline exceedances were observed for molybdenum in all samples collected from KC03 and for arsenic in a few of the samples collected from Goose Lake. Drinking water guidelines for metal parameters were not exceeded at KC03; however, all samples collected from Goose Lake exceeded arsenic and selenium drinking water guidelines.

Arsenic exceeded the aquatic life guidelines (CEQG-PAL and BCWQG-Max; both 0.005 mg/L) in all samples collected from Goose Lake and in most samples collected from KC03. The concentrations of arsenic at both sites are shown seasonally in comparison to aquatic life guidelines on Figure 4.27. All arsenic concentrations in the Goose Lake samples exceeded the HC-DW guideline of 0.01 mg/L and several samples also exceeded the BCWQG-DW of 0.025 mg/L and the livestock guidelines (BCWQG-Livestock and CEQG-Livestock; both 0.025 mg/L). The seasonal and spatial distribution of copper in the Keynes Creek watershed is shown on Figure 4.27. Copper exceeded the hardness-dependent CEQG-PAL for copper in every sample collected, but did not exceed the limits of the BCWQG for aquatic life.

Selenium was elevated in all samples collected from KC03 and exceeded the BCWQG-Max of 0.002 mg/L and the CEQG-PAL of 0.001 mg/L in all samples. The distribution of selenium concentrations in the Keynes Creek watershed is shown on Figure 4.27. Samples collected from Goose Lake did not exceed this guideline.



NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.

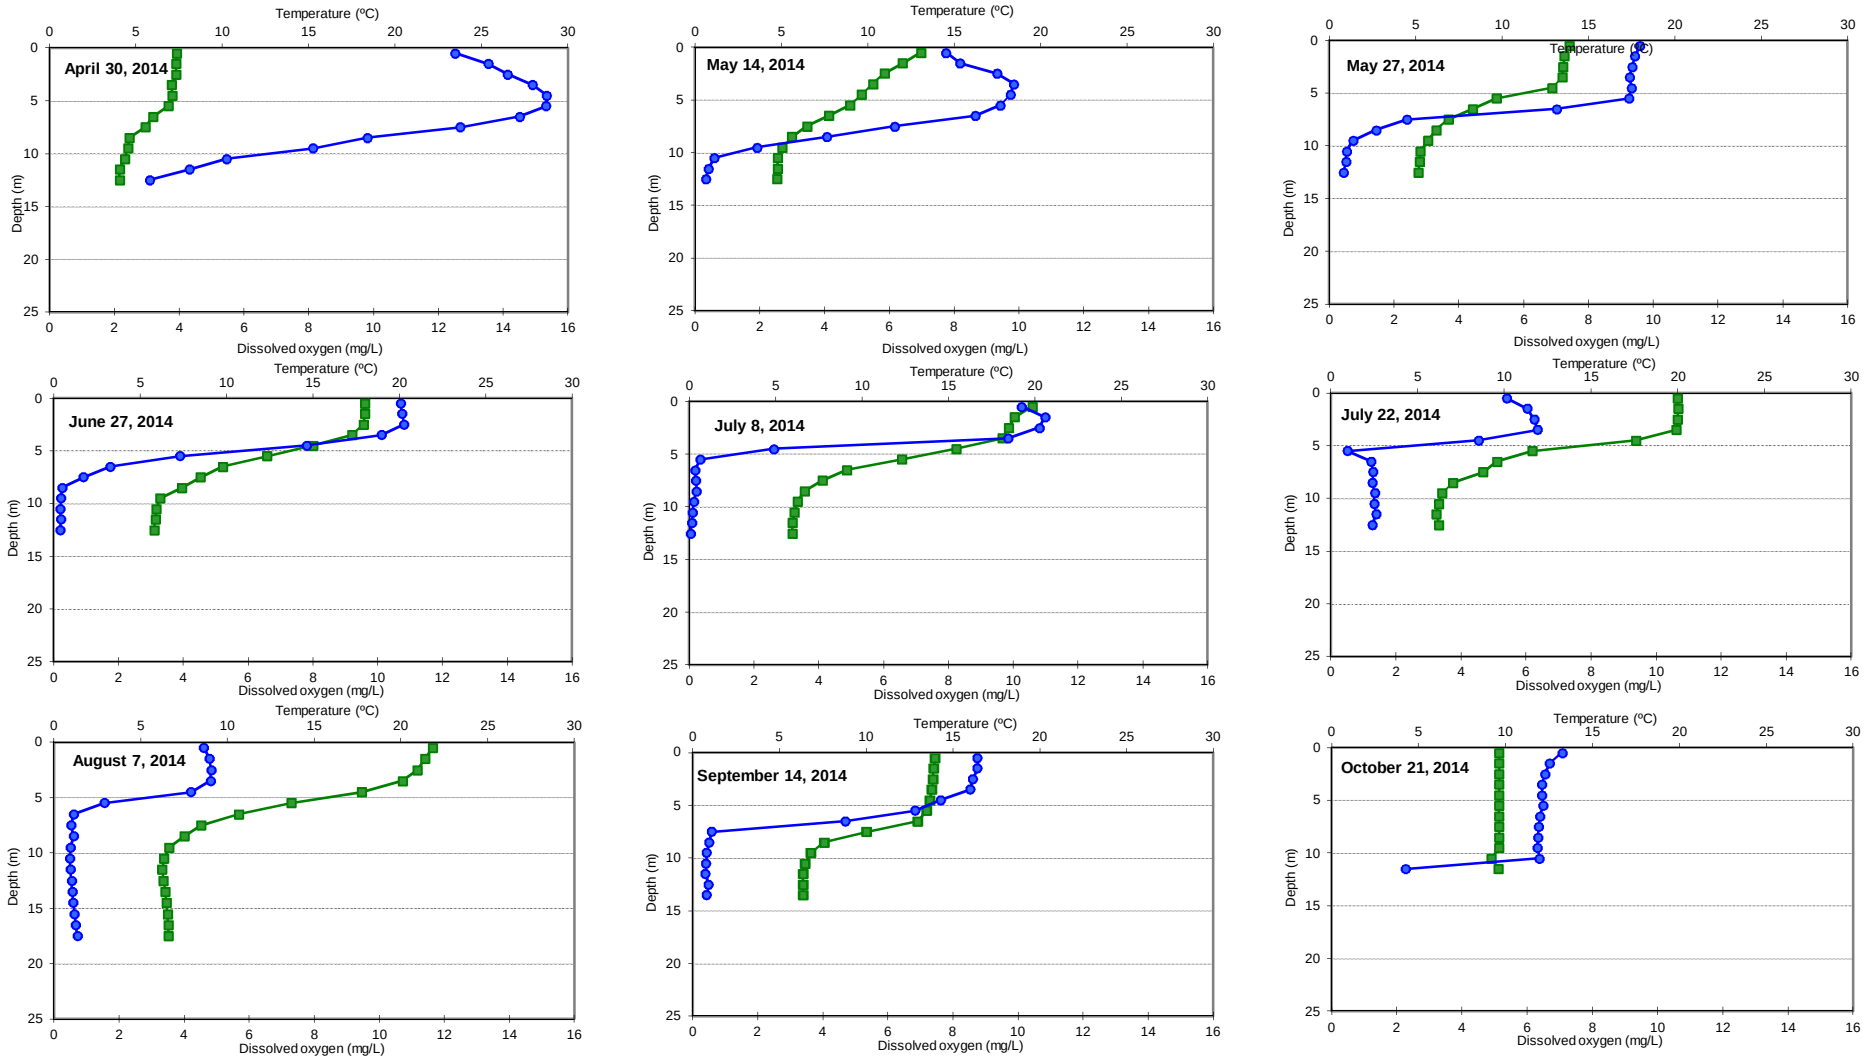
4.4.4.2 Humphrey Creek Watershed – Water Quality Assessment

Samples have been collected from the Humphrey Creek watershed in 2014 twice per month from May through September. The creek flows north from Edith Lake towards Peterson Creek but a surface connection between Humphrey Creek and Peterson Creek was not visible during the baseline program to date. This upper watershed baseline surface water site (HUMPH-10) is typically highly disturbed by livestock activity and samples are often collected from low volume, slow flowing depressions in the area. The outlet of the lake is often closed and flowing waters are understood to represent seepage from the lake through the marshy area upstream of the outlet and the sample location. Humphrey Creek goes to ground downstream of the lowest sample location and flows are understood to enter Peterson Creek through shallow groundwater flow. Edith Lake was been sampled monthly throughout the open water season in 2014 with depth profiles recorded with every sampling event. Creek samples have been collected at three sites along Humphrey Creek: HUMPH-10 (outflow of Edith Lake), HUMPH-08 (mid-creek), and HUMPH-02 (upstream of the confluence with Peterson Creek, between PC03 and PC02.5).

Physical Parameters, Dissolved Anions, and Nutrients

Water in Humphrey Creek and Edith Lake is typically slightly basic and very hard with high buffering capacity. Exceedances of the CEQG-PAL upper limit of the aquatic life guidelines for pH (pH 9) were not observed; however, exceedances of the upper drinking water acceptable limit (BCWQG-DW and HC-DW; both pH 8.5) were observed in all samples collected from the shallow site of Edith Lake, frequently in lower Humphrey Creek, and rarely at the other sites. The spatial distribution of pH values in the Humphrey Creek watershed is shown on Figure 4.30, with reference to the drinking water and aquatic life upper guidelines. The highest pH values recorded in this watershed were associated with the shallow samples of Edith Lake. Samples collected at depth and at the outflow of Edith Lake (HUMPH-10) were lower. Very little seasonal variability was observed in dissolved hardness, specific conductance and TDS in the lake samples; however, TSS in the creek samples typically increased during spring and summer, when surface water runoff was higher. TDS was elevated throughout the lake water column and exceeded the HC-DW guideline of 500 mg/L in almost every sample. Along Humphrey Creek, TDS increased with distance downstream. While TDS was elevated, it was still within the range of fresh water classification.

During spring and fall turnover, temperate lakes tend to have uniform, well-mixed conditions throughout the water column. The depth profiles for Edith Lake in 2014 are shown on (dissolved oxygen and temperature) and Figure 4.29 (pH). The Edith Lake water quality study commenced in April 2014 and is ongoing. The data collected prior to the cut-off date for data included in this report extends to the end of September; however, depth profiles were recorded only from April to August. The spring lake turnover event appears to occur in April, when temperatures are relatively constant with depth (Figure 4.28); the fall turnover event occurred after August 2014, but the precise date cannot be deciphered with the data available.



NOTES:

1. DEPTH UNITS ARE METRES BELOW SURFACE.
2. TEMPERATURE IS SHOWN ON THE PRIMARY X-AXIS.
3. DISSOLVED OXYGEN IS SHOWN ON THE SECONDARY X-AXIS.

Major Ions

The water type transitioned from magnesium-bicarbonate in Edith Lake and upper Humphrey Creek to magnesium-sulphate-bicarbonate with distance downstream in Humphrey Creek and TDS was noted to increase as well (Figure 4.4). The cation signature is based on a weak dominance of magnesium, with low but equal contributions of sodium and calcium at all monitoring locations.

Ion concentrations in Humphrey Creek decreased during freshet and increased during the late summer and fall, which is consistent throughout the baseline study area and generally supports the understanding that surface flows are dominantly supported by baseflow (groundwater) contributions for all months outside of the spring freshet period. Seasonality in ion concentrations in Edith Lake

was more subtle, but a muted version of the same trend was observed in the shallow samples. Fluoride was elevated in the lake and throughout Humphrey Creek, exceeding the CEQG-PAL of 0.12 mg/L, but not the less stringent BCWQG-Max (hardness-dependent).

The SBEB developed for sulphate was necessary for the assessment of Edith Lake water quality due to the hard water conditions in the lake, despite the lower sulphate concentrations (ranged from 25.6 mg/L to 42.7 mg/L); hardness was never below 250 mg/L CaCO3, which is the threshold in the BCWQG-30 D for sulphate that triggers the requirement for site specific toxicity testing. The recommended SBEB for the lake, which supports early life stages for trout, is a maximum sulphate concentration of 429 mg/L, which is the same as the current BCWQG-30 D, but with the maximum hardness adjusted up to 800 mg/L $CaCO_3$ (Nautilus 2015). No Edith Lake samples exceeded the SBEB for sulphate. Fish are not found in Humphrey Creek and the alternative SBEB of 730 mg/L for hardness up to 1,377 mg/L CaCO3 is applicable, but it should be noted that with the exception of one sample from lower Humphrey Creek (HUMPH-02), all samples are below the SBEB lower benchmark and none exceed the alternative benchmark.

Nutrients

Phosphorous was generally found in the dissolved form in Edith Lake and Humphrey Creek, although some of the TP in Humphrey Creek was found in the particulate form. Orthophosphate made up for a significant proportion of the dissolved phosphorous at each site except the shallow site on Edith Lake, where orthophosphate concentrations were very low. TP was relatively constant seasonally in the shallow Edith Lake samples and samples collected from Humphrey Creek, but varied seasonally in the depth samples collected from Edith Lake. In the samples collected from the mid- and deep depths of Edith Lake, TP was in the eutrophic range during freshet and increased drastically during the summer and fall, peaking in the hyper-eutrophic range (approximately 0.2 mg/L TP). In contrast, the shallow samples collected from Edith Lake were classified as meso-eutrophic to eutrophic throughout the season. In the upper reaches of Humphrey Creek, TP concentrations were higher than those found in the shallow samples of Edith Lake and varied seasonally, generally above the hyper-eutrophic classification threshold. Further downstream, at HUMPH-08, TP increased to a seasonal median approaching 0.25 mg/L, then decreased again at HUMPH-02, to concentrations similar to those observed at HUMPH-10.

Nitrogen levels in Humphrey Creek were generally low; however, Samples collected from the two upper sites (HUMPH-10 and HUMPH-08) sporadically exceeded the CEQG-PAL for ammonia (pH- and temperature-dependent). Nitrogen levels were also generally low in Edith Lake; however, samples collected at depth increased in ammonia concentrations throughout the summer and fall, when most samples exceeded the CEQG-PAL.

Organic Carbon and Nitrogen

Organic carbon was elevated throughout Edith Lake and Humphrey Creek and exceeded the BCWQG-DW limit of 4 mg/L in every sample. This guideline is applicable only to treated water sources because the presence of organic carbon can result in the formation of toxic trihalomethanes when chlorinated. Most of the organic carbon was in the dissolved form (DOC). Concentrations remained relatively stable seasonally at all sites.

Metals

Metal concentrations were generally low in Edith Lake, but were elevated in Humphrey Creek. Aluminum, chromium, iron, and mercury were found predominantly in the particulate form with higher concentrations observed in samples collected during freshet and with lower concentrations observed during the drier seasons. Other metals (arsenic, copper, and selenium) were predominantly in the dissolved form and were lower during freshet, increasing in the drier seasons, when surface water flow is predominantly by groundwater discharge. Metal concentrations varied spatially along Humphrey Creek, with the highest concentrations observed in the middle section (HUMPH-08) for some parameters and in the lower section (HUMPH-02) for other parameters.

Metal parameters that regularly exceeded aquatic life guidelines in the Humphrey Creek watershed include aluminum, chromium, copper, iron, mercury, and selenium, though only copper exceeded the aquatic life guidelines in Edith Lake. Sporadic aquatic life guideline exceedances were observed for arsenic, which was generally observed to be higher in samples from the HUMPH-08 compared to samples upstream (HUMPH-10) and downstream (HUMPH-02). Manganese regularly exceeded the irrigation guidelines (BCWQG-Irrigation and CEQG-Irrigation; both 0.2 mg/L) and the HC-DW aesthetic objective of 0.05 mg/L in creek and lake samples. Iron exceeded the HC-DW aesthetic objective of 0.3 mg/L. All other guideline exceedances refer only to the aquatic life guidelines, which are described in the sections below. The spatial distributions of metal parameters that exceeded aquatic life guidelines in Humphrey Creek are included following the discussion below. Monthly boxplots are shown for select metal parameters that showed seasonal trends.

Aluminum

Total aluminum concentrations exceeded the pH-dependant CEQG-PAL of 0.1 mg/L in every sample collected from HUMPH-08 and in most samples collected from the upstream and downstream sites (HUMPH-10 and HUMPH-02, respectively). Dissolved aluminum concentrations remained below the aquatic life guidelines in all samples. The distribution of aluminum concentrations in Humphrey Creek is shown on Figure 4.31.

Chromium

Chromium concentrations exceeded the aquatic life guideline for the Cr (VI) species of 0.001 mg/L in all samples collected from HUMPH-08 and in some samples collected from HUMPH-10 and HUMPH-02; however, the Cr(III) guideline of 0.0089 mg/L was not exceeded. Since species analyses have not been conducted, it is not confirmed whether the chromium present in Peterson Creek is in the Cr (III) or Cr (VI) form, though the Cr (VI) form is most likely in well oxygenated surface waters and Cr (III) in reducing conditions such as deeper groundwater sources. The species analysis often results in elevated detection limits, especially in the presence of other ions and high TDS; speciation analysis was not conducted because it was unlikely to provide results with appropriate detection limits. The distribution of chromium concentrations is shown on Figure 4.32 with reference to the Cr (III) guideline.

Copper

Copper is the only metal parameter that exceeded aquatic life guidelines in Edith Lake. Copper exceeded the hardness-dependent CEQG-PAL in some samples collected from the deeper water monitoring location in Edith Lake and in most samples collected from the Humphrey Creek sites. No samples exceeded the less stringent BCWQG-Max threshold for copper (hardness-dependent) and

samples collected from the shallower regions of Edith Lake did not exceed any guidelines. Dissolved copper concentrations increased with distance downstream in Humphrey Creek, whereas the total copper concentrations were highest at HUMPH-08 (mid-channel). The range of concentrations of total copper in Edith Lake and total and dissolved copper Humphrey Creek are shown on Figure 4.33.

Iron

Iron concentrations exceeded the CEQG-PAL of 0.3 mg/L regularly in samples collected from HUMPH-10 and HUMPH-02 and in all samples collected from HUMPH-08. The less stringent BCWQG-Max of 1 mg/L was exceeded regularly at HUMPH-08 only. Total iron concentrations were highest in the samples collected from mid-channel but dissolved concentrations were highest in the uppermost site (HUMPH-10), though dissolved concentrations were consistently below guidelines. The spatial distribution of copper in Humphrey Creek is shown on Figure 4.34.

Mercury

Mercury sample concentrations were elevated at HUMPH-10, in the upper reaches of the Humphrey Creek, just downstream of the lake outlet, but were typically below detection at all other sample locations in this watershed. This baseline surface water site is typically highly disturbed by livestock activity and samples are often collected from low volume slow flowing depressions in the area. The outlet of the lake is often closed and flowing waters are understood to represent seepage from the lake through the marshy area upstream of the outlet and the sample location. Mercury, at this site, is dominantly detected in the particulate form, though low dissolved concentrations were also reported for some of the samples. Seasonal trends are not yet fully apparent for total mercury, but several of the samples had total mercury concentrations that exceeded the CEQG-PAL (0.000026 mg/L) and the BCWQG-30 D (0.00002 mg/L) at this location. These exceedances of the BCWQG-30 D are not considered true exceedances as the average of the 5-weekly samples collected between March 12, 2014 and April 9, 2014 was 0.00002 mg/L, which is equivalent to the guideline. The total mercury concentrations measured in the three samples collected July through September 2014 were all above the BCWQG-30 D; although the sampling frequency does not satisfy the chronic guideline requirements, the understanding is that these mercury concentrations represent conditions that persist above the chronic threshold. Spatial and seasonal trends in total mercury concentrations in Humphrey Creek are shown on Figure 4.35.

Selenium

Selenium concentrations increased with distance downstream in Humphrey Creek and seasonality was evident, with highest concentrations reported for samples collected in March at lower Humphrey Creek (HUMPH-02), concentrations progressively decreased through July and then increased slightly in August and September. Selenium was predominantly present in the dissolved form and this observation would support the understanding that the loading in the lower watershed was as a result of local groundwater inflows. However, samples from monitoring wells in the Humphrey Creek catchment (BCG14-016, BGC14 013, BGC14-015S/D, BGC14-014D, and BGC14-009) were all reported with relatively low levels of selenium, so if it is groundwater that is contributing the selenium it is either through shallow infiltration or there is local enrichment that has not been intercepted with the monitoring well network in the area. Selenium sample concentrations were continuously above the 0.002 mg/L BCWQG-30D at HUMPH-02 from March 2014 through May 2014 and the average of

the five weekly freshet samples was 0.0046 mg/L. Samples collected from late June through September 2014 were all below the BCWQG-30 D at this site. Selenium concentrations did not exceed the BCWQG-30 D at HUMPH-08, but they did exceed the CEQG-PAL in a few samples. The CEQG-PAL is equivalent to the “alert level” identified in the BCWQG for aquatic life. Boxplots have been provided on Figure 4.36 to demonstrate the spatial and seasonal variability for selenium in Humphrey Creek.

4.5 CHERRY CREEK WATERSHED SURFACE WATER QUALITY

The Cherry Creek watershed borders the western extent of the Peterson Creek watershed, which encompasses the Project footprint. Four water bodies were investigated within the Cherry Creek watershed during the baseline data collection program: Cherry Creek, Alkali Creek, Inks Lake, and Wallender Lake. Cherry Creek runs adjacent to the western extent of the historical Afton Mine tailings storage facility. There are numerous water licences currently in effect in Cherry Creek, including domestic and commercial usage in the lower extent of the baseline study area. Alkali Creek is a main tributary to Cherry Creek. It lies within agricultural property and is commonly used for irrigation and livestock watering purposes. Alkali Creek is subject to intermittent flows and was often dry during the course of the baseline data collection program to date. The lower reaches of Alkali Creek are diverted around the historical Afton Mine tailings storage facility, where it drains through a swampy area into Cherry Creek. The drainage area of Cherry Creek, upstream of the confluence with Alkali Creek was estimated to be 104.1 km^2 (Rescan 2007).

Inks Lake is situated immediately northwest of the intersection of Lac La Jeune Road and Inks Lake Road. The lake is comprised of two basins: the South Basin, approximately 6.7 ha in size, is joined by an approximately 40 m long channel to a smaller basin to the north (1.3 ha). During drier seasons there is no surface flow connecting the two basins. The deepest spot in the South Basin is 5 m. Immediately northwest of Inks Lake North Basin is a small (0.3 ha), unnamed kidney-shaped pond. No surface channel is visible between this pond and Inks Lake. Although Inks Lake is within the Cherry Creek watershed, there is no surface connection between Inks Lake and Cherry Creek, or between Inks Lake and Alkali Creek (Knight Piésold Ltd 2012b). Wallender Lake is similar to Inks Lake, in that it is a very shallow water body that has no defined surface outflow channel.

Water quality sampling in the Cherry Creek watershed was initiated prior to the commencement of the current baseline water quality study, with samples collected in support of the Afton Mine water discharge permit (PE-3904), which includes sampling in Cherry Creek (two sites – CC08 and CC02), Alkali Creek, the historical TSF supernatant pond, the North West Seepage Recovery Pond (NWSRP), and the Seepage Pipe (Spring of 2012). The permit requirements for analysis were limited compared to the full suite of parameters analyzed for in the current baseline program, and earlier data are limited by higher analytical detection limits. The TSF and NWSRP water quality data are not included in this report. The historical data are not within our database, but have been submitted in support of the reclamation reports (Afton Operating Corporation 1999, 2001, 2004, and Knight Piésold Ltd 2012a).

For ease of presentation, the water quality assessment for this watershed has been divided into two main sections based on water feature characteristics and flow patterns. Alkali Creek and Cherry Creek have been presented in one sub-section and Inks Lake and Wallender Lake in another.

The guideline exceedance discussion below is related specifically to the freshwater aquatic life guidelines. The guideline exceedance tables specific to aquatic life, drinking water, agricultural use, wildlife drinking water, and recreational water use are tabulated in Appendix C. Exceedances related to these guidelines have been noted in the text, but have not been discussed at length. Summary statistics for each water quality site are also shown in Appendix C. The aquatic life and drinking water guideline exceedances have been reduced to percentage of total samples per site and are provided in Table 4.3, Table 4.4, and Table 4.5.

4.5.1 Cherry Creek and Alkali Creek Water Quality Assessment

Physical Parameters, Dissolved Anions, and Nutrients

Water in Cherry Creek and Alkali Creek is typically neutral to slightly basic and moderately hard to very hard. Dissolved hardness, specific conductance and TDS were seasonally variable, and decreased with the dilution effects of spring freshet and increased through the summer and winter as flows become increasingly influenced by the dominance of groundwater inflows. Average TDS was higher in Alkali Creek than in Cherry Creek and within Cherry Creek, TDS was higher at the downstream site (CC02) than the site upstream of the confluence with Alkali Creek (CC08). The TDS concentrations in Alkali Creek and lower Cherry Creek (CC02 – Greenstone Mountain Road and Highway #1) often exceeded the 500 mg/L drinking water and irrigation water use guideline limits. The TDS concentrations at the upper Cherry Creek (CC08) sample location generally remained well below these guidelines (average concentration of 172 mg/L), indicative of a change in contributing water quality below this point, which includes the water from Alkali Creek and groundwater inputs and run-off from the lower watershed (potential influence of historical mine workings and agricultural practices). TSS and turbidity values followed a similar pattern to other sampling sites within the area and were observed to increase during spring freshet flows.

Major Ions

All major ions showed the same seasonal and spatial trends in the Cherry Creek watershed. Ion concentrations were generally higher in Alkali Creek than in Cherry Creek and increased from upstream to downstream along Cherry Creek. Fluoride was the only major ion noted to exceed water quality guidelines in the Cherry Creek and Alkali Creek. Most of the Alkali Creek samples exceeded the 0.12 mg/L CEQG-PAL as did the majority of samples collected from CC02 during the low flow months; most samples collected from CC02 during freshet were below aquatic life guidelines for fluoride. None of the samples exceeded the BCWQG-Max hardness dependent guideline or the drinking water guidelines for this parameter.

Nutrients

Phosphorus concentrations in Cherry Creek and Alkali Creek were highly variable and generally lower during the winter months in Cherry Creek, with both creeks showing rapid increases in TP concentrations in response to spring freshet flows. Alkali Creek TP data collected support the classification of that creek within the hyper-eutrophic range. The TP concentrations in Cherry Creek extend over several trophic status ranges at each site. TP concentrations within this creek are clearly influenced by the surrounding agricultural/livestock rearing land uses, and even at the baseline level there are extreme fluctuations across multiple trophic status ranges which can induce stress on a creek system and the aquatic flora and fauna. Cherry Creek during non-freshet flows is generally classified within the meso-eutrophic to eutropic range. The downstream section of Cherry Creek was clearly influenced by greater phosphorus loading sources, including Alkali Creek. This was especially apparent during freshet, when surface runoff was higher (maximum concentration 0.87 mg/L); phosphorous concentrations at the upstream site (CC08) reached their maximum during the same sampling events where the highest concentrations were found at CC02; however, the peak concentrations were lower (maximum concentration 0.24 mg/L).

Nitrogen levels in Cherry and Alkali Creeks were observed in low concentrations. In the upper area of Cherry Creek (CC08), ammonia and total nitrogen increased during freshet, with nitrate

decreasing during the same period. In Alkali Creek (AC02) and lower Cherry Creek (CC02), ammonia, total nitrogen and nitrate decreased during freshet and increased during the fall and winter seasons.

Organic Carbon and Nitrogen

TOC and DOC concentrations varied through the sampling program and the highest concentrations were typically observed during freshet. Concentrations of TOC and DOC were higher in Alkali Creek than in Cherry Creek and exceeded the BCWQG-DW of 4 mg/L at all sites (maximum concentration 19.3 mg/L at AC02). This guideline is applicable only to treated water sources because the presence of organic carbon can result in the formation of toxic trihalomethanes when chlorinated.

Organic nitrogen concentrations in Cherry Creek and Alkali Creek do not exceed the any of the provincial or federal guidelines.

4.5.1.1 Metals

In Cherry Creek and Alkali Creek aluminum, chromium, and copper regularly exceeded aquatic life guidelines and iron and manganese regularly exceeded drinking water guidelines. Sporadic exceedances (i.e. fewer than 10% of samples) of aquatic life guidelines for arsenic, cobalt, mercury, selenium and zinc and of drinking water guidelines for arsenic and sodium were observed. Seasonal variance was evident for total metal parameters and most tended to increase through spring freshet.

Aluminum

Concentrations of aluminum in Cherry Creek increased significantly in response to freshet flows and then stabilized at much lower concentrations through the remaining part of the year while in Alkali Creek, the highest aluminum concentrations were observed during the fall season. Concentrations of aluminum were typically higher at CC02 than samples collected at CC08; dissolved aluminum concentrations were lower and did not increase as dramatically with distance downstream. Aluminum in Alkali Creek appears to be somewhat more stable, though this could be an artefact of the reduced sampling frequency achieved at this location. Dissolved aluminum rarely exceeded any guidelines; however, total aluminum concentrations exceeded the CEQG-PAL (pH-dependent) in most samples collected from Alkali Creek and frequently in samples collected from Cherry Creek (16% of samples from CC08 and 22% of samples from CC02). The seasonal/spatial distribution of total aluminum concentrations in Cherry Creek and Alkali Creek is shown on Figure 4.37 (sites are shown from upstream to downstream). Both figures, showing the spatial and seasonal trends in total aluminum are shown in comparison with aquatic life guidelines.

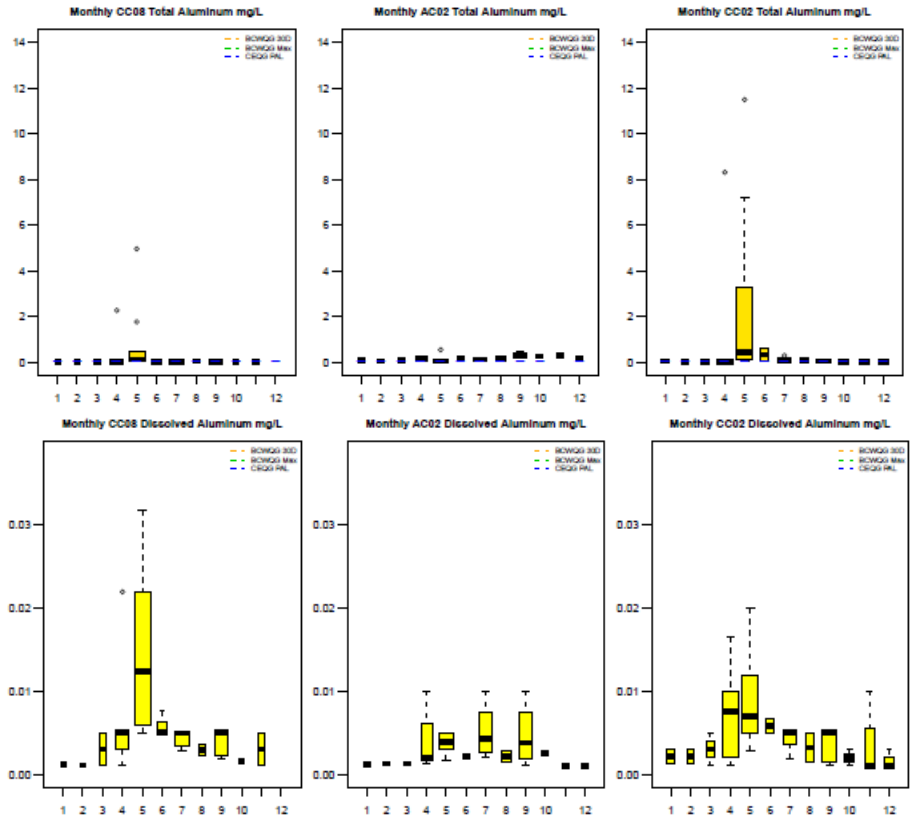

Figure 4.37 Seasonal Boxplot of Total and Dissolved Aluminum in Cherry Creek and Alkali Creek

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS AND SITES ARE LISTED FROM UPSTREAM TO DOWNSTREAM.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG -MAX, BCWQG-30DAY AND CEQG-PAL FOR FRESHWATER AQUATIC LIFE FOR ALUMINUM ARE DEPENDENT ON WHETHER pH IS ABOVE OR BELOW 6.5; ALL pH VALUES ARE GREATER THAN 6.5.
6. THE BCWQG-MAX AND BCWQG-30DAY ARE SPECIFIC TO DISSOLVED (D) ALUMINUM AND THE CEQG-PAL IS SPECIFIC TO TOTAL ALUMINUM.

Chromium

Dissolved chromium did not exceed aquatic life or drinking water guidelines; however, the highest total chromium concentrations observed during freshet in both Alkali Cherry Creek exceeded the CEQG-PAL of 0.001 mg/L for Cr(VI). The CEQG-PAL for the less toxic Cr(III) is 0.0089 mg/L and was not exceeded in any samples from either creek in the Cherry Creek watershed. Since species analyses have not been conducted, it is not confirmed whether the chromium present in Cherry Creek is in the Cr(III) or Cr(VI) form, though the Cr(VI) form is most likely in well oxygenated surface waters and Cr(III) in reducing conditions such as deeper groundwater sources; therefore, samples

have been compared to both tiers of guidelines. The concentrations of total chromium were lower in samples collected from Alkali Creek than Cherry Creek and the highest concentrations were only slightly above the CEQG-PAL. Total chromium concentrations in Cherry Creek increased with distance downstream and exceeded the CEQG-PAL only sporadically during the highest flow season. The seasonal and spatial distribution boxplots for total chromium are shown on Figure 4.38, in comparison with aquatic life guidelines.

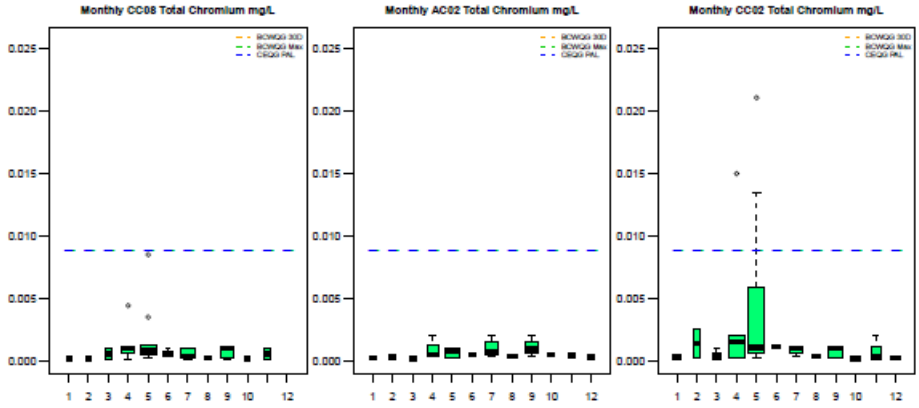

Figure 4.38 Seasonal/Spatial Boxplot of Total Chromium in Cherry Creek and Alkali Creek

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS AND SITES ARE LISTED FROM UPSTREAM TO DOWNSTREAM. n-NUMBER OF SAMPLES.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG-MAX AND CEQG-PAL THRESHOLDS FOR AQUATIC LIFE ARE 0.0089 mg/L FOR Cr(VI) (SHOWN ON THE FIGURE); THE SAME GUIDELINES ARE 0.001 mg/L FOR THE CR(III) SPECIES; IT IS NOT KNOWN WHICH SPECIES IS PREVALENT.

Copper

The seasonal and spatial distribution boxplots for total copper are shown on Figure 4.39, in comparison with aquatic life guidelines. Copper concentrations in Cherry Creek followed the same seasonal trend as other metals, showing a sharp increase through spring freshet, with relatively low concentrations through the remainder of the year, though the total concentrations were higher than dissolved. Total copper concentrations in Cherry Creek increased distance downstream, yet there were more exceedances in the upper catchment samples due to lower hardness.

Copper concentrations in samples collected at each of the sites within the two creeks exceeded the hardness dependent CEQG-PAL guideline. Most guideline exceedances were limited to the most stringent CEQG-PAL; however, samples collected from the two sites on Cherry Creek frequently also exceeded the BCWQG-Max and occasionally exceeded the BCWQG-30 D, these exceedances were not sustained for the required 30 day period. Outside of the freshet period, the range of dissolved copper concentrations in Alkali Creek is similar to that of lower Cherry Creek and dissolved copper concentrations are generally higher in upper Cherry Creek than at the downstream site.

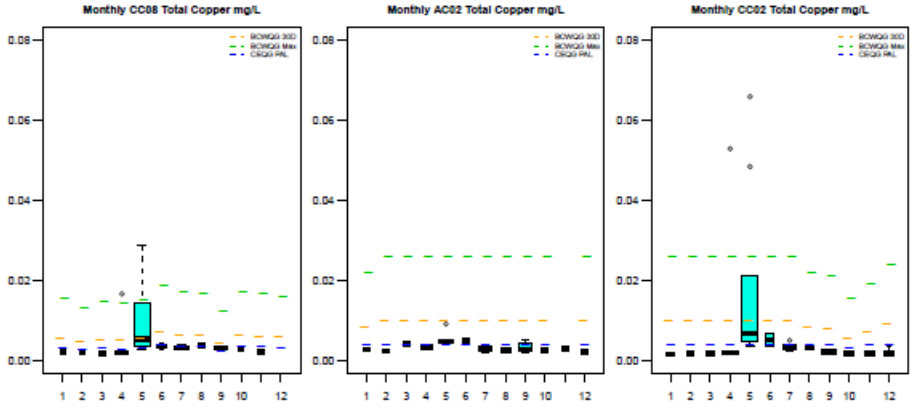

Figure 4.39 Seasonal/Spatial Boxplot of Total Copper in Cherry Creek and Alkali Creek

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS AND SITES ARE LISTED FROM UPSTREAM TO DOWNSTREAM. n-NUMBER OF SAMPLES.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE CEQG-PAL, BCWQG-MAX, AND BCWQG-30DAY THRESHOLDS ARE HARDNESS-DEPENDENT AND WERE CALCULATED BASED ON THE MEDIAN MONTHLY HARDNESS OBSERVED AT EACH SITE.

Iron

Iron concentrations in Cherry Creek followed the seasonal trend observed for other metals, with peak concentrations achieved in samples collected during freshet. Total iron concentrations increased with distance downstream in Cherry Creek; however Alkali Creek concentrations were generally lower than Cherry Creek. Dissolved iron concentrations remain relatively unchanged between the two sampling points in Cherry Creek. The seasonal and spatial trends in total iron concentrations are shown on Figure 4.40.

Dissolved iron did not exceed aquatic life, drinking water, or agricultural guidelines; however, total iron exceeded the CEQG-PAL in both Cherry Creek and Alkali Creek and also exceeded the BCWQG-Max and the CEQG-Irrigation in Cherry Creek only. The 0.3 mg/L HC-DW guideline was also exceeded at all sites, though it should be noted that this is an aesthetic guideline (not health-based).

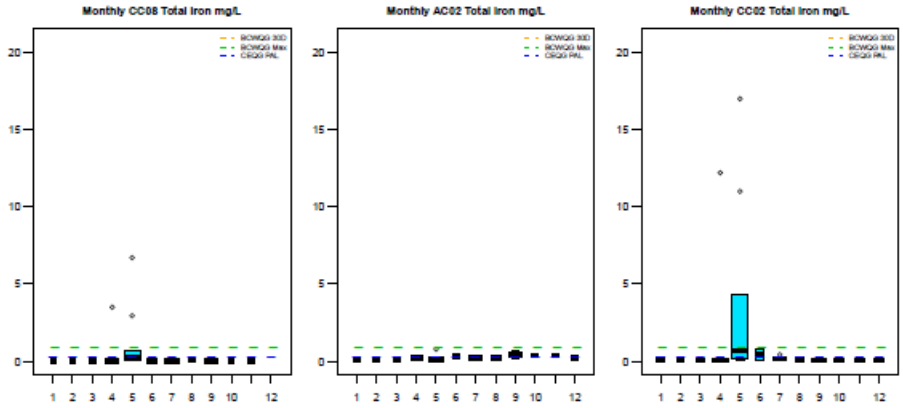

Figure 4.40 Seasonal Boxplot of Total Iron in Cherry Creek and Alkali Creek

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS AND SITES ARE LISTED FROM UPSTREAM TO DOWNSTREAM.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG-MAX FOR IRON IS 1 mg/L (SPECIFIC TO TOTAL IRON) AND THE CEQG-PAL IS 0.3 mg/L.
6. THE HC-DW AESTHETIC OBJECTIVE FOR IRON IS 0.3 mg/L.

Manganese

Drinking water and irrigation guideline exceedances were observed in Cherry Creek and Alkali Creek. Manganese drinking water guidelines are for aesthetic purposes only (HC-DW 0.05 mg/L). The highest concentrations of manganese in Cherry Creek were generally associated with freshet samples, whereas Alkali Creek manganese concentrations decreased during freshet and increased in late summer and early fall. A similar distribution of concentrations was observed for dissolved manganese in Alkali Creek, indicating that this is a parameter that is dominantly present in the dissolved form in that creek. In Cherry Creek, however, the seasonal distribution of dissolved manganese was similar to that of both total and dissolved manganese in Alkali Creek and opposite to that of total manganese in Cherry Creek, indicating the presence of both particulate and dissolved manganese in this creek. Irrigation water use guidelines (BCWQG-Irrigation and CEQG-Irrigation; both 0.2 mg/L) were exceeded in almost half of the samples collected from Alkali Creek and more sporadically in samples collected from Cherry Creek.

Molybdenum

Molybdenum has been found at higher concentrations in Cherry Creek than in Alkali Creek and concentrations were generally higher in upper Cherry Creek during the winter months and higher at the lower sample location (CC02) through the summer and fall sapling events. Molybdenum concentrations are, on average, approximately five times higher in Cherry Creek than in Alkali Creek. Molybdenum concentrations were well below the aquatic life guidelines, but exceeded the CEQG-Irrigation (0.01 mg/L) on a regular basis in Cherry Creek. None of the samples exceeded the 0.02 mg/L BCWQG-Irrigation water use limit or the CEQG-Livestock, BCWQG-Livestock, or

BCWQG-Wildlife limits (all 0.05 mg/L). A similar pattern of exceedances were noted for dissolved molybdenum as this parameter was dominantly found in the dissolved form.

4.5.2 Inks Lake and Wallender Lake Water Quality Assessment

While Inks Lake and Wallender Lake are located in the Cherry Creek drainage, there is no observed connection between these lakes and Cherry Creek. It should be noted that the lower parameter concentrations encountered in the March 2011 sampling event for Inks Lake were influenced by sampling conditions. The lake was starting to thaw, so a sample was collected from shore using an extended pole sampler; however it was difficult to get a clean sample because of the ice slurry, so the values are more likely representative of the ice and snow rather than lake water.

4.5.2.1 Physical Parameters, Dissolved Anions, and Nutrients

Inks Lake and Wallender Lake have elevated TDS and are more saline than the Historical Mine Site Features in the Peterson Creek watershed (NSP (North Seepage Pond), Ajax West-West open pit lakes, and the WR-Seep located south of Peterson Creek). Similar observations related to ponds in the vicinity of the New Afton mine were made during the baseline investigation to support the Mines Act Application for that project (Rescan 2007). TDS is a measure of the ionic constituents in water and is used to define the salinity classification. A single sample from Wallander Lake had a TDS concentration of 47,900 mg/L, which is higher than that of ocean water (>35,000 mg/L). These mine features and natural water bodies (Wallander Lake and Inks Lake) are basins in local groundwater discharge zones within a net evaporative climate and as a result the concentration of the majority of parameters will continue to rise over time. The parameters in the man-made features and the natural lakes tend to have higher concentrations than the surrounding groundwater and surface water. In situations like this, parameters concentrations are generally controlled by solubility limits, and clear resolution of parameter concentrations can be hampered due to sample matrix interference and the dilution requirements for analysis. Limited samples of Wallender Lake have been collected as there was rarely water present to be sampled; the discussion below is based only four samples from this location.

Boxplots of the distribution of sample pH, dissolved hardness, and TDS are shown on Figure 4.41, Figure 4.42, and Figure 4.43, respectively. The waters in Inks Lake and Wallender Lake are slightly basic, extremely hard, with very high buffering capacity. The pH values generally exceeded the upper range (pH 8.5) for drinking water and on occasion exceeded the pH 9.0 upper range for aquatic life. TDS and turbidity exceeded the HC-DW limits of 500 mg/L and 0.1 NTU, respectively in all samples.

Dissolved oxygen (DO) at the surface of Inks Lake ranged from 0.66 mg/L on August 31, 2011 to 13.1 mg/L on March 6, 2012. DO was also profiled at lake depth on June 5, 2010 and decreased significantly with depth (from 8.80 mg/L at the surface to 0.23 mg/L at 3.5 m below surface). This was also consistent for a profile completed on June 1, 2011 (DO decreased with depth from 8.51 mg/L at the surface to 0.33 mg/L at 3.5 m below the surface) (Knight Piésold Ltd 2012b).

4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THERE ARE NO AQUATIC LIFE GUIDELINES FOR TDS; HOWEVER, 500 mg/L IS APPLIED FOR DRINKING WATER AND IRRIGATION WATER (HC-DW, BCWQG-IRRIGATION, CEQG-IRRIGATION).

Major Ions

Both lakes are classified as the sulphate-magnesium type with significant sodium; Inks Lake also has significant contributions of other cations (calcium) and anions (chloride and bicarbonate). The water types observed are consistent with the major water types observed in the groundwater samples in close proximity to the lakes: MW11-02, MW11-07D/S, and MW11-01S.

Sulphate concentrations are elevated in both lakes; however, higher and more variable concentrations were observed in samples collected from Wallander Lake (Figure 4.44). The recommended aquatic life toxicity limit of 730 mg/L is a preliminary estimate that may be refined based on ongoing toxicity tests; however, sample sulphate concentrations are well over this estimated limit and are unlikely to be below the toxicity threshold. Although these waters would never be used for drinking water purposes, it should be noted that all samples exceeded the 500 mg/L guideline limit.

Clear resolution on fluoride was not achieved due to elevated detection limits (greater than guideline); however, detectable concentrations at both sites indicated exceedances of the CEQG-PAL of 0.12 mg/L. Few samples exceeded the HC-DW limit of 1.5 mg/L (Figure 4.45).

The chloride concentrations measured in Wallander Lake and Inks Lake were extremely high (average 1991 mg/L and 440 mg/l, respectively) and exceeded the BCWQG-30 D (150 mg/L), the CEQG-PAL for chronic exposure (120 mg/L), the BCWQG-DW (250 mg/L), and the irrigation guidelines (BCWQG-Irrigation and CEQG-Irrigation; both 100 mg/L) in all samples. Some samples collected from Inks Lake and all samples collected from Wallander Lake also exceeded BCWQG-

Max (600 mg/L), the CEQG-PAL for short-term exposure (640 mg/L), and the BCWQG-Livestock (600 mg/L). Concentration distributions are shown for both lakes on Figure 4.46.

BOXPLOTS SHOW THE DISTRIBUTION OF DATA AT EACH SITE (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG-30DAY CHRONIC EXPOSURE GUIDELINE FOR CHLORIDE IS 150 mg/L; THE BCWQG-MAX IS 600 mg/L AND IS NOT SHOWN ON THIS GRAPH.
6. THE CEQG-PAL FOR CHLORIDE OF 120 mg/L IS SPECIFIC TO LONG-TERM EXPOSURE; THE CEQG-PAL FOR SHORT-TERM EXPOSURE IS 640 mg/L AND IS NOT SHOWN ON THIS GRAPH.

Nutrients

The nitrogen based inorganic nutrient (nitrite, nitrate, and ammonia) concentrations were variable in both Inks Lake and Wallander Lake and aquatic life guideline exceedances for ammonia were frequent (CEQG-PAL; pH- and temperature dependent). Exceedances of the CEQG-PAL for nitrite (3 mg/L) also occurred in samples collected from Wallander Lake.

Total phosphorus (TP) concentrations were in the hyper-eutrophic range for both lakes, but were much higher in Wallander Lake than in Inks Lake. TP varied seasonally and was highest in summer and fall.

Organic Carbon and Nitrogen

Organic carbon was generally present in the dissolved form in both lakes and was higher and more variable in samples collected from Wallander Lake than Inks Lake. Samples collected from both lakes exceeded the BCWQG-DW of 4 mg/L by at least an order of magnitude. TOC and DOC at Inks Lake varied around 50 mg/L and varied seasonally from 25 mg/L to 270 mg/L at Wallander Lake. The drinking water guideline is applicable only to treated water sources because the presence of organic carbon can result in the formation of toxic trihalomethanes when chlorinated.

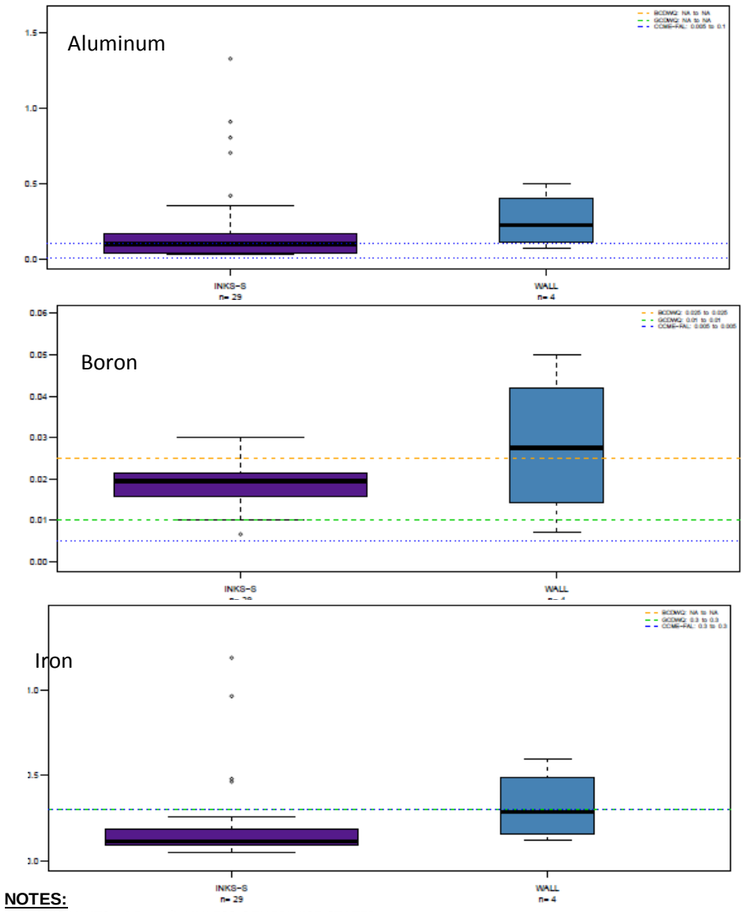
4.5.2.2 Metals

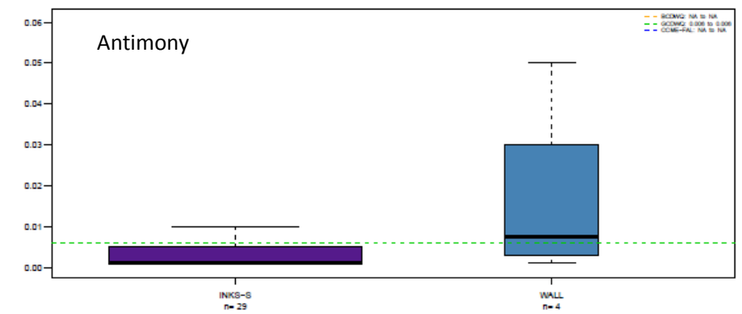
Samples collected from Inks Lake and Wallander Lake required extensive dilution for analysis because of the extremely high TDS (average 10,306 mg/L and 61,150 mg/L, respectively); as a result, several parameters tested had elevated MDLs that were greater than or equal to the

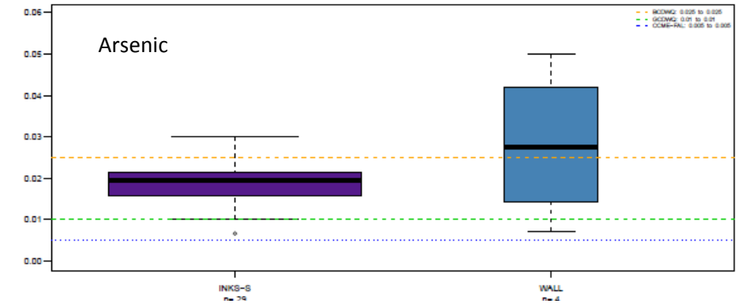
guidelines. In cases where the MDL concentration was higher than the guideline limit concentration it is not possible to determine if the sample actually exceeded guidelines. MDLs for the following parameters exceeded guideline limits during one or more sampling events: aluminum, beryllium, cadmium, chromium, cobalt, copper, lead, manganese, selenium, and thallium. Of these parameters, intermittent analytical resolution was achieved for aluminum, copper, and selenium and guidelines were generally exceeded for each true measured concentration. This was considered in the interpretation of results; however, in most cases, sample concentrations in exceedance of guidelines were greater than five times the MDL and were considered valid.

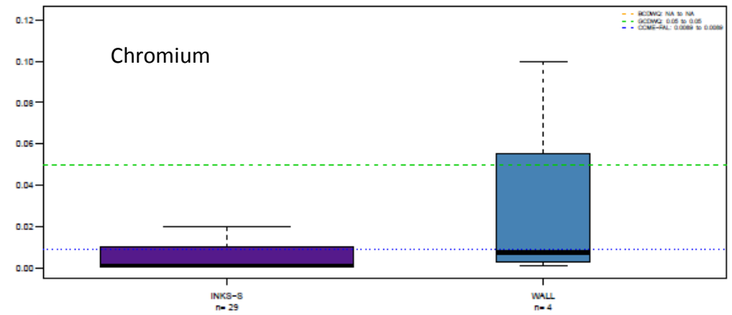
Many aquatic life guidelines were exceeded for metal parameters in Wallander Lake and Inks Lake, which is expected based on the ion concentrations and general conditions of these lakes. Concentration distributions for some metals with their guidelines are shown on boxplots on Figure 4.47 as examples; however, these guideline exceedances are not discussed in detail, since these waters are not fish-bearing and are not used for drinking water or for agricultural purposes. Rather, it should be noted that these waters may pose a risk to human, fish, and wildlife health, based on concentrations of the following metal parameters:

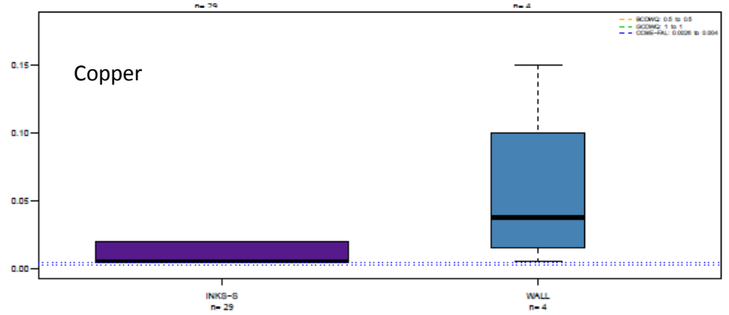
- Aluminum
- Antimony
- Arsenic
- Boron
- Chromium
- Copper
- Iron
- Manganese
- Molybdenum
- Selenium, and
- Silver.

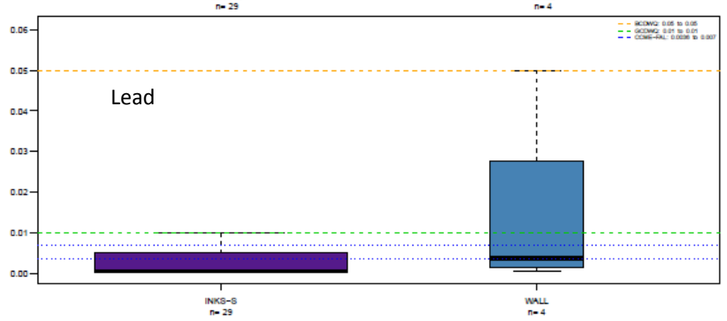


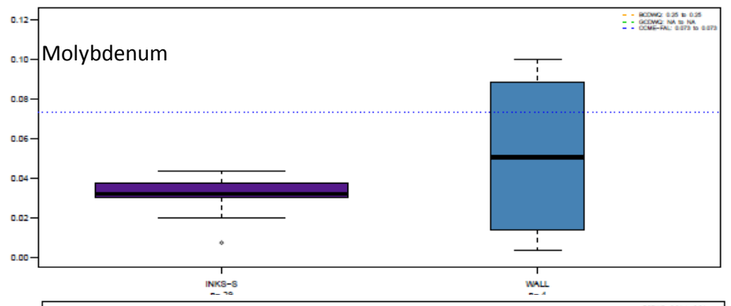


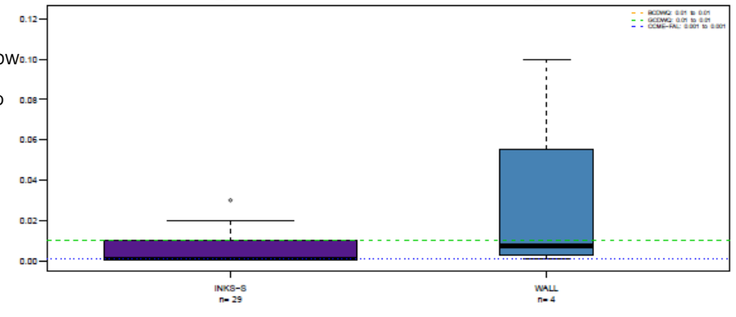












NOTES:

2. X-AXIS UNITS ARE BASELINE MONITORING SITES. n=NUMBER OF SAMPLES COLLECTED.
3. BOX PLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH SITE (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES)
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG -MAX, BCWQG-30DAY AND CEQG-PAL FOR FRESHWATER AQUATIC LIFE FOR ALUMINUM ARE DEPENDENT ON WHETHER pH IS ABOVE OR BELOW 6.5; ALL pH VALUES ARE GREATER THAN 6.5.
6. THE BCWQG-MAX AND BCWQG-30DAY ARE SPECIFIC TO DISSOLVED (D) ALUMINUM AND THE CEQG-PAL IS SPECIFIC TO TOTAL ALUMINUM.
7. THE BCWQG-MAX FOR ANTIMONY IS 0.02 mg/L.
8. THE BCWQG-MAX AND THE CEQG-PAL FOR ARSENIC ARE 0.005 mg/L.
9. THE HC-DW GUIDELINE FOR ARSENIC IS 0.01 mg/L AND THE BCWQG-DW IS 0.025 mg/L.
10. AGRICULTURAL GUIDELINES (BCWQG AND CEQG-PAL) FOR ARSENIC ARE 0.1 mg/L FOR IRRIGATION USE AND 0.025 mg/L FOR LIVESTOCK DRINKING WATER.
11. THE BCWQG-MAX FOR BORON IS 1.2 mg/L.
12. THE CHROMIUM BCWQG-MAX AND CEQG-PAL THRESHOLDS FOR AQUATIC LIFE ARE 0.0089 mg/L FOR Cr(III) (SHOWN ON THE FIGURE); THE SAME GUIDELINES ARE 0.001 mg/L FOR THE CR(VI) SPECIES; THE SPECIES HAS NOT BEEN ANALYZED BUT IT IS 13. TYPICALLY Cr(VI) IN WELL OXYGENATED WATERS AND Cr(III) IS REDUCING ENVIRONMENTS.
13. THE CEQG-PAL, BCWQG-MAX, AND BCWQG-30DAY THRESHOLDS FOR COPPER ARE HARDNESS-DEPENDENT AND WERE CALCULATED BASED ON THE MEDIAN MONTHLY HARDNESS OBSERVED AT EACH SITE.
14. THE BCWQG-MAX FOR IRON IS 1 mg/L (SPECIFIC TO TOTAL IRON) AND THE CEQG-PAL IS 0.3 mg/L.
15. THE HC-DW AESTHETIC OBJECTIVE FOR IRON IS 0.3 mg/L.

THE AQUATIC LIFE GUIDELINES FOR LEAD (BCWQG-30DAY, BCWQG-MAX, AND CEQG-PAL) ARE HARDNESS-DEPENDENT AND WERE CALCULATED BASED ON THE MEDIAN HARDNESS AT EACH SITE.

16. AQUATIC LIFE GUIDELINES FOR MOLYBDENUM INCLUDE THE BCWQG-30DAY OF 1 mg/L, THE BCWQG-MAX OF 2 mg/L, AND THE CEQG-PAL OF 0.073 mg/L.
17. THE BCWQG-DW FOR MOLYBDENUM IS 0.25 mg/L..
18. THE AGRICULTURAL AND WILDLIFE GUIDELINES FOR MOLYBDENUM ARE 0.05 mg/L FOR LIVESTOCK DRINKING WATER (BCWQG AND CEQG) AND 0.02 mg/L AND 0.01 mg/L FOR IRRIGATION (BCWQG AND CEQG, RESPECTIVELY.
19. THE BCWQG-MAX FOR SELENIUM IS 0.002 mg/L AND THE CEQG-PAL IS 0.001 mg/L.
20. THE DRINKING WATER GUIDELINES FOR SELENIUM ARE 0.01 mg/L (BCWQG AND HC).

4.6 ANDERSON CREEK WATERSHED SURFACE WATER QUALITY

Anderson Creek is a recent watershed addition to the surface water quality baseline data collection program. Samples have been collected extensively in 2014 (17 sampling events) and have been used, along with assumptions based on the known characteristics of the surrounding watersheds, to characterize water quality in Anderson Creek. The sampling frequency was increased to twice monthly to improve upon the baseline characterization efforts for this watershed. Two sampling locations have been established: ANDR15 (upstream) and ANDR-10 (downstream).

Physical Parameters, Dissolved Anions, and Nutrients

Water in Anderson Creek is typically slightly basic, very hard, with high buffering capacity. TDS was elevated at both sites and frequently exceeded the HC-DW guideline (500 mg/L) and the irrigation guidelines (BCWQG and CEQG; both 500 mg/L), but was always below the 1,000 mg/L threshold for freshwater classification. Water at both sites is classified as the calcium-magnesium-bicarbonate type (shown on the Piper diagram on Figure 4.5), which is consistent with the water types observed in samples collected from the adjacent watershed (Humphrey Creek and lower Peterson Creek; Figure 4.2).

Ion concentrations generally decreased during freshet and increased throughout the summer months. Chloride concentrations were elevated at ANDR-15 at the end of winter and exceeded the BCWQG-30 D (150 mg/L) and the CEQG-PAL for long-term exposure (120 mg/L); however these concentrations decreased during freshet to below the guideline threshold (Figure 4.48). One likely contributing factor for the elevated chloride may be proximity of this site to the Coquihalla Hwy and Lac Le Jeune Road, which are salted during the winter months. Fluoride was elevated at both sites and exceeded the CEQG-PAL of 0.12 mg/L in all samples (Figure 4.49), but did not exceed the less stringent BCWQG-Max (hardness-dependent). Fluoride concentrations are very similar at both sampling locations, indicating that fluoride loading is uniform in this watershed.

Nutrients

Nitrogen-containing nutrient parameters were generally found in low concentrations; however, total phosphorous (TP) was elevated at both sites. TP concentrations were generally lower upstream and higher at the downstream site (ANDR-10). Seasonally, TP decreased during freshet, increased during the summer months, and decreased again in the fall. Waters at the upper site (ANDR-15) are characterized as meso-eutrophic in the winter and spring and eutrophic in the summer and fall. ANDR-10 is generally classified as eutrophic in the winter, spring, and fall and hyper-eutrophic in summer.

Organic Carbon and Nitrogen

TOC and DOC concentrations varied through the sampling program and the highest concentrations were typically observed during summer. Dissolved carbon made up the majority of the total carbon, which exceeded the BCWQG-DW in all samples. The BCWQG-DW limit of 4 mg/L is applicable only to treated water sources because the presence of organic carbon can result in the formation of toxic trihalomethanes when chlorinated.

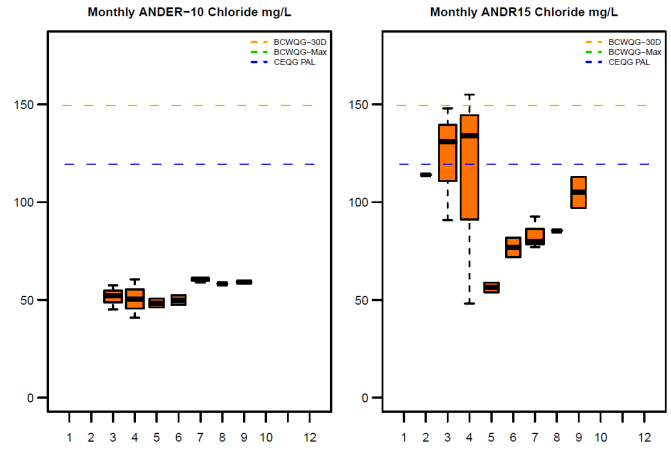

Figure 4.48 Monthly Boxplot of Chloride Concentrations in Anderson Creek

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG-30DAY CHRONIC EXPOSURE GUIDELINE FOR CHLORIDE IS 150 mg/L; THE BCWQG-MAX IS 600 mg/L AND IS NOT WITHIN THE SCALE OF THIS GRAPH.
6. THE CEQG-PAL FOR CHLORIDE OF 120 mg/L IS SPECIFIC TO LONG-TERM EXPOSURE; THE CEQG-PAL FOR SHORT-TERM EXPOSURE IS 640 mg/L AND IS NOT WITHIN THE SCALE OF THE GRAPH.

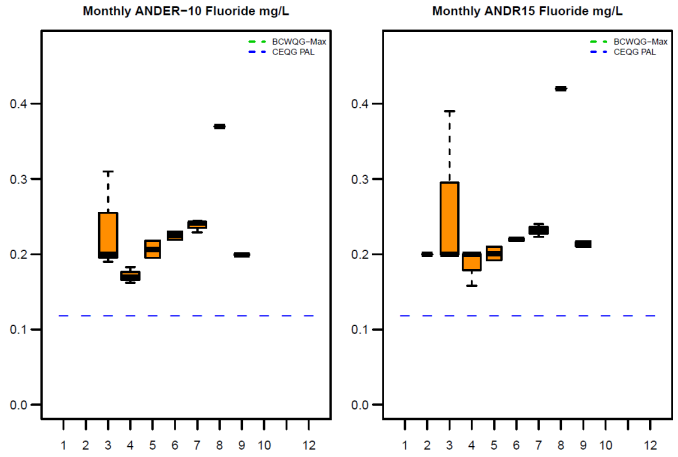

Figure 4.49 Monthly Boxplot of Fluoride Concentrations in Anderson Creek

NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS.
3. BOXPLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES).
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE CEQG-PAL FOR FLUORIDE IS 0.12 mg/L; THE BCWQG-MAX FOR FLUORIDE IS HARDNESS-DEPENDENT AND IS NOT WITHIN THE SCALE OF THIS GRAPH.

Organic Carbon and Nitrogen

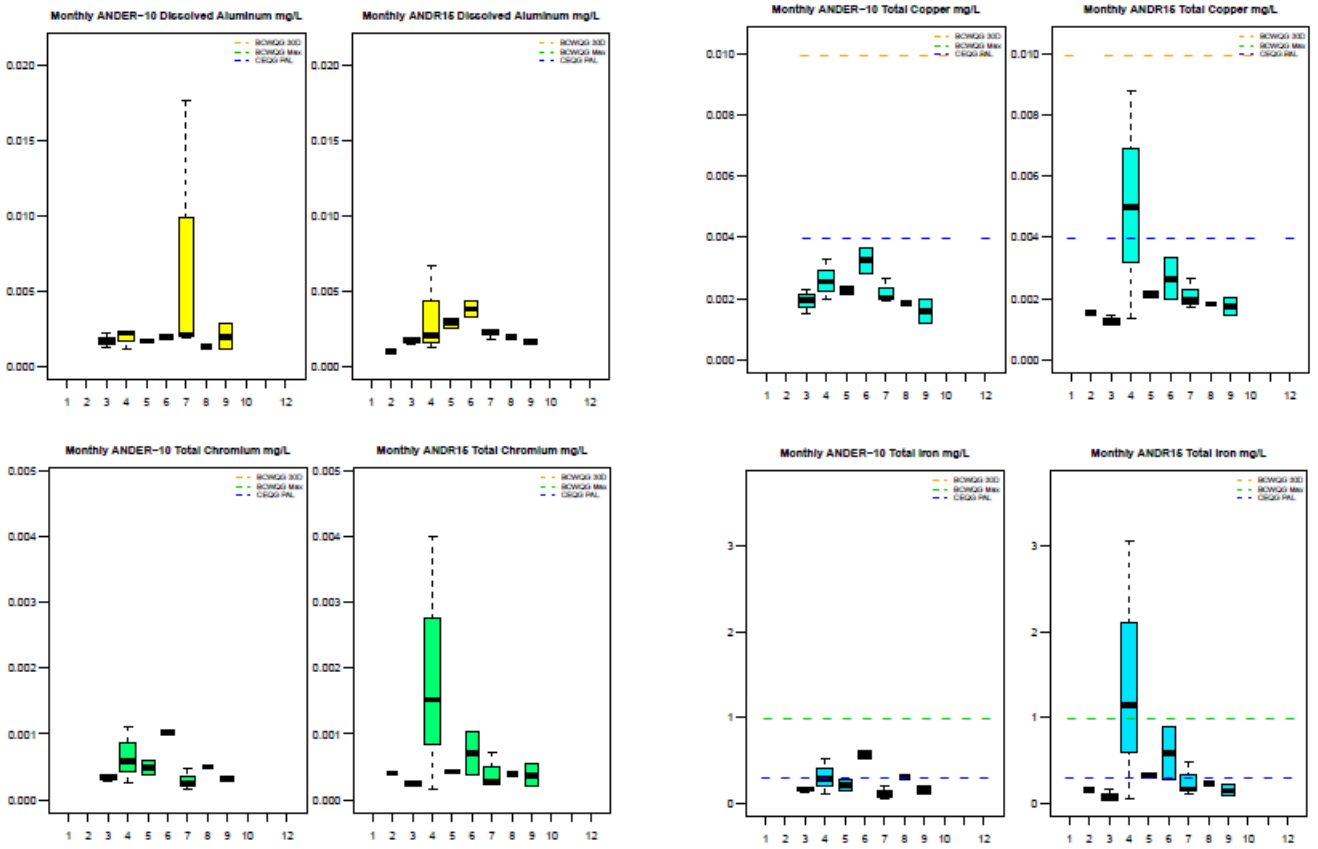
TOC and DOC concentrations varied through the sampling program and the highest concentrations were typically observed during summer. Dissolved carbon made up the majority of the total carbon, which exceeded the BCWQG-DW in all samples. The BCWQG-DW limit of 4 mg/L is applicable only to treated water sources because the presence of organic carbon can result in the formation of toxic trihalomethanes when chlorinated.

Metals

Metal parameters occurred mainly in the dissolved form in Anderson Creek and were generally detected in low concentrations that were below guidelines. These metal parameters varied seasonally with the same trend as the major ions, which are driven by local groundwater discharge: concentrations decreased during freshet and increased during the months of lower flow. Aluminum, chromium, copper, and iron were the exception and were typically measured at higher concentrations in samples collected during high flow conditions, but with low dissolved concentrations. These parameters increased during freshet with higher runoff and decreased during the seasons of lower flow. The following metals exceeded aquatic life guidelines in Anderson Creek (seasonal variability boxplots are shown on Figure 4.50):

- Aluminum
- Chromium
- Copper, and
- Iron.

Single sample exceedances of the HC-DW aesthetic objectives were reported iron and manganese were observed at both sites.



NOTES:

1. Y-AXIS UNITS ARE mg/L UNLESS OTHERWISE STATED.
2. X-AXIS UNITS ARE MONTHS.
3. BOX PLOTS SHOW THE DISTRIBUTION OF DATA FOR EACH MONTH (BOXES REPRESENT DATA BETWEEN THE 25TH PERCENTILE AND THE 75TH PERCENTILE, WITH THE MEDIAN VALUE SHOWN AS A BLACK LINE WITHIN THE BOX; ERROR BARS SHOW THE HIGHEST AND LOWEST VALUES WITHIN 1.5 TIMES THE INTERQUARTILE RANGE; OUTLIERS ARE SHOWN AS CIRCLES)
4. VALUES BELOW THE DETECTION LIMIT ARE EQUATED TO HALF THE DETECTION LIMIT FOR STATISTICAL AND GRAPHING PURPOSES. BASED ON THIS METHOD, SOME VALUES SHOWN TO BE ABOVE GUIDELINES MAY NOT ACTUALLY EXCEED GUIDELINES.
5. THE BCWQG -MAX, BCWQG-30DAY AND CEQG-PAL FOR FRESHWATER AQUATIC LIFE FOR ALUMINUM ARE DEPENDENT ON WHETHER pH IS ABOVE OR BELOW 6.5; ALL pH VALUES ARE GREATER THAN 6.5.
THE BCWQG-MAX AND BCWQG-30DAY ARE SPECIFIC TO DISSOLVED (D) ALUMINUM AND THE CEQG-PAL IS SPECIFIC TO TOTAL ALUMINUM.
6. THE CHROMIUM BCWQG-MAX AND CEQG-PAL THRESHOLDS FOR AQUATIC LIFE ARE 0.0089 mg/L FOR Cr(VI) (SHOWN ON THE FIGURE); THE SAME GUIDELINES ARE 0.001 mg/L FOR THE CR(III) SPECIES; IT IS NOT KNOWN WHICH SPECIES IS PREVALENT IN THE LSA.
7. THE CEQG-PAL, BCWQG-MAX, AND BCWQG-30DAY THRESHOLDS FOR COPPER ARE HARDNESS-DEPENDENT AND WERE CALCULATED BASED ON THE MEDIAN MONTHLY HARDNESS OBSERVED AT EACH SITE.
8. THE BCWQG-MAX FOR IRON IS 1 mg/L (SPECIFIC TO TOTAL IRON) AND THE CEQG-PAL IS 0.3 mg/L.
THE HC-DW AESTHETIC OBJECTIVE FOR IRON IS 0.3 mg/L.

4.7 THOMPSON RIVER WATERSHED SURFACE WATER QUALITY

The Thompson River watershed encompasses a large area, most of which is not within the baseline study area. The objective of the baseline water quality study is not to characterize the whole watershed; rather, two water quality sites have been established to characterize the water quality in two water bodies in close proximity to the Project: Makaoo Lake (MAKAOO-01) and Polygon Pond (PP01). Seven sampling events have been conducted to characterize these water bodies and the results have been used to interpret a broad understanding of the water quality within the greater project area.

The physical parameters of the two water bodies (Polygon Pond and Makaoo Lake) differ, but are both defined by high pH, very high hardness, especially in Polygon Pond. Makaoo Lake is classified as freshwater, while Polygon Pond is slightly to moderately saline, with a wide range of TDS concentrations greater than 2,000 mg/L. The high TDS of Polygon Pond may be attributed to net evaporative conditions. A surface water outlet of this pond has not been discovered and it is suspected that the pond is a groundwater sink where parameter concentrations increase due to evaporative loss of water without a loss in load. Instead, parameters concentrations are likely controlled by solubility limits. The high TDS results in matrix interference in the analysis of samples and the samples often require dilution. This results in elevated MDLs, which are often higher than the guidelines. In these cases, the elevated MDLs are not considered guideline exceedances and are discussed only in cases where measured concentrations were detected over five times the MDL.

Both Polygon Pond and Makaoo Lake are classified as the calcium-magnesium-bicarbonate type, which is consistent with water types found in the project area water features. Fluoride, chloride, and sulphate were exceptionally high in Polygon Pond and exceeded aquatic life guidelines in most samples. The sulphate toxicity limit recommendation (BCWQG-30 D) is in review, based on ongoing site toxicity testing; however, preliminary data acquired in the development of an SBEB has indicated a recommended limit of 730 mg/L for aquatic life. The concentrations observed in Polygon Pond are much higher than the preliminary limit.

Nutrient parameters were elevated in both Makaoo Lake and Polygon Pond. Total phosphorous concentrations classified these water bodies as hyper-eutrophic (with phosphorous concentrations greater than 1 mg/L) and eutrophic, respectively. Ammonia exceeded the CEQG-PAL in all samples collected from MAKAOO-01 and nitrite CEQG-PAL exceedances were observed at PP01.

High concentrations of TDS in Polygon Pond resulted in elevated MDLs, due to matrix interference. For some metal parameters, the elevated MDLs exceeded guidelines. The confirmed metals parameters that exceed guidelines are aluminum and boron. Metal concentrations in Makaoo Lake were generally low and did not exceed guidelines.

5 – GROUNDWATER QUALITY ASSESSMENT

5.1 OVERVIEW

The groundwater characterization program was initiated in 2007, and with the exception of one year (2009), has continued to the present day. Groundwater monitoring well locations were strategically selected based on proximity to proposed project facilities and historical mine site features, and the monitoring well network has expanded over time as the project design changed. A total of 73 monitoring wells have been installed in the project area, 51 of which have been sampled and are the basis for the groundwater quality characterization provided in this report. Forty-six (46) of these monitoring wells continue to be sampled in the ongoing groundwater monitoring program. The focus of this report is on groundwater quality, the groundwater hydrology and detailed hydrogeological conceptual model are presented under separate cover in the BGC Engineering Inc. (BGC) *Baseline Groundwater Hydrology Assessment* report (BGC 2015a).

The primary objectives of the water quality study were to characterize the complex environment and understand the interactions between surface water and groundwater in the project area, to provide valuable insight into current and potential future stresses on surface and ground water resources and management strategies to address these issues, and to provide a basis for predicting future water quality (baseline comparison and inputs to predictive models). To facilitate this discussion, specific areas within the baseline study area are often referenced, some of which are specific to the locations of proposed project facilities and others that are not. These areas and the monitoring wells included in each are described below (project/facility area is provided for reference in brackets):

- Cherry Creek watershed (Project Site West and Jacko Lake North areas) – located west of the project area and includes monitoring wells MW11-01S, MW11-02, MW11-07D/S, and MW11-09S/D. These monitoring wells are all outside of the project facility areas and groundwater quality in this area is not expected to be affected by the future mine development.
- North Peterson Creek watershed (Jacko Lake North and EMRSF areas) – area north of Peterson Creek, excluding the historical mine area. Includes monitoring wells BGC14-006D, MW11-04D/S, MW11-05D/S, and MW11-06D/S. Monitoring wells MW11-04D/S and MW11-06D/S are north of any proposed mine facilities and groundwater quality is not expected to be affected by seepage from the future mine development. Monitoring wells MW11-05D/S and BCG14-006D in the immediate vicinity of the proposed EMRSF and groundwater quality in that area is expected to be affected by seepage from that facility and potentially due to drawdown influence from open pit dewatering.
- Upper Peterson Creek watershed (Jacko Lake South and TSF areas) – west and southwest of Jacko Lake. Includes monitoring wells BGC14-001D, BGC14-010, BGC14-012D/S, and MW11-08D. Monitoring well MW11-08 is located west of Jacko Lake and is not expected to be affected by seepage from the proposed TSF and serves as a reference site for the Jacko Lake catchment area. Monitoring wells BGC14-001D, BGC14-012D/S and BGC14-010 (listed from north to south) are located northwest of the proposed TSF and WMRSF and are located in areas where seepage may affect groundwater quality and water management ponds are proposed.
- Keynes Creek watershed (TSF area) – BGC14-002D/S, BGC14-011D/S, BGC14-016, and BGC14-017D/S. Monitoring wells BGC14-011D/S, BGC14-016, and BGC14-017D/S are located at topographic highs to the southwest, southeast and east of the proposed TSF and were situated to provide insight into groundwater quality and groundwater gradients in this vicinity of

the TSF. Monitoring well BGC14-002D/S is located adjacent to the Keynes Creek channel, down-gradient of the proposed TSF, where seepage from the TSF may affect groundwater quality and in the location of potential proposed water management pond.

- Open pit area – in the vicinity of the existing open pits and proposed open pit. Includes monitoring wells AJGW01-D, AJGW02-D/S, AJGW03-D, AJGW04-D, AJGW05-S, AJGW06-D, AJGW07-D/S, BGC11-003D/I/S, KAX-14-107S, KAX-14-108S, KAX-14-114S, KAS-14-128D, MW12-01, MW12-02, MW12-04, and PW01. Monitoring wells AJGW07D/S, KAX-14-107S, KAX-14-108S, KAX-14-114S, KAX-14-128D, and PW01 are located along the western extent of the proposed expanded open pit and installed to characterize the hydrogeological conditions between Jacko Lake and the current and proposed open pit. Monitoring wells AJGW01-D, AJGW02-D/S, AJGW03-D, AJGW04-D, AJGW05-S, and AJGW06-D were installed within the proposed open pit area to characterize groundwater quality in that area. Monitoring wells MW12-01 and MW12-02 were installed within the backfilled waste rock in the historical Ajax East Pit and MW14-04 was installed in natural ground down-gradient of the historical waste rock south of Peterson Creek in order to characterize the geochemistry associated with infiltration and flushing of waste rock for the project area and assist in geochemical source term development for future water quality predictions.
- Humphrey Creek watershed (SMRSF and TSF areas) – south of Peterson Creek. Includes monitoring wells BGC14-009, BGC14-013, BGC14-014D, and BGC14-015D/S, and residential water supply wells RES-3 and RES-6. The monitoring wells in this watershed are all down-gradient of the proposed plant site and SMRSF and were located to characterize groundwater quality and flow in this watershed, to assist in the placement of water management ponds. Residential water supplies RES-3 and RES-6 are located further east; RES-6 is not likely to be affected directly or indirectly by mine facility seepage.
- Peterson Creek aquifer area (EMRSF area) – Includes monitoring wells BGC14-005 and MW11-10D, and water supply wells RES-2 and RES-5. The Peterson Creek aquifer extended along the subsurface of Peterson Creek to the east of the project area and seepage from the TSF, SMRSF and EMRSF are likely to interact with this aquifer, as well as seepage losses from the proposed Downstream Peterson Creek Pond (DPCP).
- Davidson Creek aquifer area (not in vicinity of the project facilities) – There are no monitoring wells in this area and the characterization is based on limited samples from RES-1 and RES-4.

Emphasis in the discussion of groundwater quality is placed on dissolved concentrations in groundwater samples as this is the predominant form for transport of parameters through a groundwater formation; exceptions have been made where dissolved metal concentrations are not available, such as in the residential wells (RES-1 through RES-6). Total metals concentrations that exceed dissolved concentrations are generally found in samples as a result of entrainment of sediment during pumping. Sediments will accumulate at the bottom of most wells, despite rigorous well development, and these sediments generally contain many metals found in the local geology. Metals will also accumulate in the bottom sediments as a result of oxidation reactions that occur at the water-air interface in the well and in the stagnant well water column. Mobilization of these sediments through the well purging process tends to result in total metals concentrations exceeding dissolved concentrations. The following discussion is based on dissolved metals concentrations, unless otherwise stated.

Relevant water quality guidelines were determined based on the potential uses/receptors in the project area and are summarized in Section 3.5. These receptors/users include aquatic life, humans (domestic and drinking water), agricultural (livestock and irrigation), and wildlife drinking water. While aquatic life and wildlife are not in direct contact with groundwater sources, groundwater contributes significantly to surface water flows, particularly in the late summer, fall and winter, when runoff due to precipitation is very low in the project area. Aquatic life guidelines are specifically targeted to surface water bodies; however, they have been applied to groundwater as well, since they are generally the most stringent guidelines. Understanding groundwater chemistry in relation to aquatic life and wildlife guidelines provides an important benchmark for baseline conditions and for determining the effects of changes in groundwater on these potential receptors. Drinking water guidelines are used as a reference for groundwater quality, but for most parameters these guidelines are specific to treated water sources and are therefore not of direct relevance to raw water sources that are collected from the monitoring wells in the project area. Agricultural guidelines are directly applicable to groundwater quality in the project area due to potential extraction for irrigation and livestock watering purposes.

Groundwater quality sample results are available in Appendix D. The number of guideline exceedances at each site is summarized as a percentage of the total number of samples in exceedance of one or more of the relevant aquatic life, drinking water, and agricultural guidelines in Appendix D1 in Table D1.1 (aquatic life guideline exceedances by baseline area), Table D1.2 (aquatic life guideline exceedances by lithological unit in each baseline area), Table D1.3 (drinking water guideline exceedances), and Table D1.4 (agricultural guideline exceedances). The groundwater quality sample results are also provided in guideline comparison tables in Appendix D2, D3, D4, and D5 for aquatic life, drinking water, agriculture, and wildlife, respectively. Summary statistics for the samples from each well are in Appendix D6.

Maps showing the relative median groundwater concentrations were used to demonstrate how concentrations vary spatially and with depth between monitoring wells. The circle size represents the median concentration (or value for pH) and is directly proportional to the concentration relative to the lowest median value for all of the monitoring well data. A table of median values at each well location are embedded on each figure for reference. Where two or more monitoring wells have been installed at one location (i.e. deep, intermediate, and shallow), coloured outlines were used to differentiate results.

5.2 MONITORING WELL INSTALLATION HISTORY AND RATIONALE

The primary objectives of the hydrogeological program are to characterize the current conditions in the immediate and greater project area in order to assess the potential environmental effects of the proposed mine, and to provide input to mitigation and management features of the mine design to assist in preservation of groundwater resources in the project area. Monitoring wells were typically installed in the vicinity of proposed project facilities to provide valuable information on groundwater gradients (vertical gradients assessed through installation of wells at multiple depths at the same location), flow, and chemistry up-gradient and down-gradient and within facility footprints, in order to assess the potential seepage into and out of each facility and plan for ideal locations for seepage interception mitigation measures (i.e., water management ponds). The Project has evolved since the monitoring program was initiated in 2007 and the monitoring well installation history is provided below as a high-level overview of the evolution of the hydrogeological program as it specifically pertains to groundwater quality characterization:

- AJGW Series Monitoring Wells – installed by KP in 2007 at seven locations in the vicinity of the historical Ajax Pit area, with paired wells (shallow (S) and deep (D)) installed at four of the locations. Four of these monitoring wells are included in the ongoing groundwater quality sampling program. Monitoring well installation logs for the AJGW series monitoring wells are provided in Appendix F1.
- MW11 Series Monitoring Wells – installed by KP in 2011 at 10 locations. Nineteen (19) monitoring wells were installed, with paired wells (shallow (S) and deep (D)) installed at nine locations. The project layout has be updated since this monitoring well installation program was conducted, but many of the wells are well placed to characterize the hydrogeological conditions in the vicinity of project facilities for the current proposed project layout. Thirteen (13) of these monitoring wells are included in the ongoing groundwater quality sampling program. Monitoring well installation logs for the MW11 series monitoring wells are provided in Appendix F2.
- MW12/L12 Series Monitoring Wells – installed by Lorax Environmental Services Ltd. (Lorax) in 2012 at three locations, with the primary objective of characterizing groundwater geochemistry in the vicinity of the historic mine waste rock (two monitoring wells installed in the waste rock backfill in the Ajax East Historic Pit and two monitoring wells installed in the vicinity of the reclaimed waste rock south of Peterson Creek). Three of these monitoring wells are included in the ongoing groundwater quality sampling program. Monitoring well installation logs for the MW12/L12 series monitoring wells are provided in Appendix F3.
- BGC14 Series Monitoring Wells – installed by BGC in 2014 for the purposes of groundwater characterization in areas that were not previously within the vicinity of project facilities in the current proposed project layout. The focus of the investigation was predominantly south of Jacko Lake and Peterson Creek, in the Keynes Creek and Humphrey Creek catchment areas, which are the locations of the proposed TSF, West Mine Rock Storage Facility (WMRSF), Ore Stockpiles, South Mine Rock Storage Facility (SMRSF), and the Plant Site. Additional monitoring wells were also installed in the vicinity of the East Mine Rock Storage Facility (EMRSF). BGC installed 29 monitoring wells at 17 locations, with paired wells (shallow (S) and deep (D)) installed at 10 locations, a shallow (S), intermediate (I), and deep (D) monitoring well and one location, and single wells installed at six locations. Twenty-one (21) of these monitoring wells are included in the ongoing groundwater quality sampling program. Monitoring well installation logs for the BGC14 series monitoring wells are provided in Appendix F4.
- KAX-14 Series Monitoring Wells – installed by Klohn Crippen Berger Ltd (KCBL) in 2014 for the primary purpose of characterizing the hydrogeological conditions between Jacko Lake and the current and proposed open pit. KCBL installed nine monitoring wells at 5 locations along the east side of Jacko Lake. Four of these monitoring wells are included in the ongoing groundwater quality sampling program. Monitoring well installation logs for the KAX-14 series monitoring wells are provided in Appendix F5.

Pressure transducers have been installed in the majority of the wells to record continuous water level and groundwater temperature data. In some cases, the monitoring wells installed were not suitable for monitoring groundwater quality (e.g. low recharge conditions or QA/QC DQOs were not met); in these cases monitoring wells were used for water levels and temperature data only and were not sampled. Generally, the wells are screened in overburden and/or in the upper fractured bedrock (shallow wells) or the bedrock-overburden interface (deeper wells). The locations of the monitoring wells that were used to sample groundwater quality are shown on Figure 5.1. The monitoring well

locations and site selection rationale are provided in Table 5.1, grouped by proximity to proposed project facilities and general project area.

5.3 GROUNDWATER QUALITY MONITORING FREQUENCY

Groundwater quality samples have been collected for the project area since 2007, and with the exception of one year (2009), have continued to the present day. The sampling frequency has typically been quarterly, targeting seasonally representative months. The sampling frequency was increase to monthly for new wells that were installed in the spring of 2014, in order to enhance the groundwater quality database for the new areas that were included in the baseline characterization at this time. A detailed sample history for the monitoring well data used in the baseline groundwater quality characterization for the Project is provided in Table 5.2.

M:\1\01\00246\31\A\Report\3 - Baseline Water Quality - GW SW\Rev1\Tables\[Tables - Rev0.xlsx]5.6

NOTES:

1. GPS COORDINATES ARE IN UTM WGS84 ZONE 10 U. GROUND SURFACE ELEVATIONS ESTIMATED FROM LIDAR. COORDINATES FOR DOMESTIC WATER SOURCES MAY NOT BE ACCURATE FOR THE WELL, BUT ARE SPECIFIC TO THE PROPERTY AREA.
2. COMPLETION ZONE IS TOP AND BOTTOM OF WELL SCREENS.
3. RATIONALE BASED ON PROXIMITY TO PROPOSED FACILITY: UP-GRADIENT MONITORING LOCATIONS TO ASSESS INTERACTIONS WITH PROJECT FACILITIES; DOWN-GRADIENT MONITORING LOCATIONS TO ASSESS POTENTIAL SEEPAGE PATHWAYS; WITHIN FACILITIES TO ASSESS BASIN CHARACTERISTICS.
4. EDITH LAKE FAULT ZONE - ELFZ, TAILINGS STORAGE FACILITY - TSF, WEST MINE ROCK STORAGE FACILITY - WMRSF, SOUTH MINE ROCK STORAGE FACILITY - SMRSF, EAST MINE ROCK STORAGE FACILITY - EMRSF

5.4 REGIONAL GROUNDWATER QUALITY

Regional groundwater quality in the Thompson River watershed, in the Thompson Plateau (Interior Plateau and Highlands groundwater region of British Columbia) is described as having high levels of total dissolved solids (TDS) (>500 mg/L) and in some areas the sulphate concentrations are above the 500 mg/L Health Canada Drinking Water Standards (Zubel 2001). Water quality in the area is characterized as very hard and highly mineralized and of the carbonate to sulphate water type; however, these interpretations are based upon limited data (Zubel 2001).

Groundwater quality in the greater project area was reported by Golder Associates (2008) in a *Hydrogeological Investigation (1998 – 2000), Aberdeen Area, Kamloops, BC* report. The groundwater quality characterization covered a broad area, extending from Chuwels Mountain to the Aberdeen subdivision and included samples from monitoring wells, springs, seeps, and lakes. Groundwater was reported to generally increase in TDS and sodium with depth. Major anions ranged from sulphate to bicarbonate (alkalinity-dominated) and major cations were typically either sodium or magnesium. Chloride concentrations were reported to increase with decreasing elevation and were related to high evaporation of meteoric (rain) water. Nitrate concentrations were elevated (>0.1 mg/L) in the samples from springs and seeps in the Aberdeen area, though concentrations were not reported to increase with depth of sample location.

A *Water Quality Check Program* that was carried out by the Ministry of Environment through the late 1970s and 1990s and arsenic (BC MOE 2007a) and nitrate (BC MOE 2007b) were two parameters that were identified as elevated with respect to drinking water quality guidelines in groundwater samples from the Kamloops area.

5.5 LOCAL GROUNDWATER QUALITY

5.5.1 Overview

The groundwater quality samples from the monitoring well network for the project area have been used to characterize groundwater quality in the immediate project area (in the vicinity of proposed project facilities). Groundwater monitoring wells were installed north and west of the proposed project area based on proximity to facilities relevant to outdated project layouts. The shallow monitoring wells were typically completed in overburden (colluvium, fluviual/glaciofluvial, glacial till, lacustrine, and anthropogenic materials (waste rock)) and the deeper wells were completed in bedrock lithological units (Iron Mask Hybrid and Nicola Volcanics). Pumping well PW01 (western extent to the proposed Open Pit) was the only well that was completed in the Picrite and Sugarloaf Diorite bedrock units, but this well has a much longer completion zone (166.4 m) compared to the typical monitoring wells (3 m to 18 m) which were installed at targeted zones. Monitoring wells that were completed in the Iron Mask Hybrid bedrock unit are located in the eastern extent of the proposed Open Pit, and north and east of the Open Pit; all but one of the monitoring wells competed in this bedrock unit are located north of Peterson Creek. Monitoring wells completed in the Nicola Volcanics are located within the Open Pit area, west and south of Jacko Lake, and south of Peterson Creek.

The hydrochemical signature (facies) of water is influenced by the interactions with the lithological units that it flows through and is further influenced by the length of time it interacts with various units along a flow pathway. Groundwater quality data for the project area was assessed with respect to

the lithology of the monitoring well completion zone and was further interpreted with respect to proximity to local groundwater recharge (upland areas) and discharge zones (historical open pits, Jacko Lake, Peterson Creek, and local sloughs) and proximity to the deposit area and historic waste rock. Hydrochemical signatures were not distinct for the specific bedrock or overburden lithological units but were more easily distinguished by location in the project area. The major water types identified in the project area were sodium-sulphate, magnesium-sulphate, or sulphate type with only weakly dominant cations. Sodium was typically the dominant cation in samples from deeper monitoring wells located in the Open Pit area, and wells to the west and north of Jacko Lake; whereas magnesium was the dominant cation in samples from shallower monitoring wells located in the Open Pit area and most wells to the east and southeast of the Open Pit. Calcium was weakly dominant in samples from a few wells which were all located between Jacko Lake and the Ajax West open pits. Bicarbonate was only dominant in samples collected from monitoring wells in the upland areas of the Humphrey Creek and Keynes Creek watersheds and a few monitoring wells south of Jacko Lake, likely indicative of closer proximity to local groundwater recharge areas compared to other monitoring sites in the project area.

Groundwater quality in the project area is generally characterized as alkaline, hard to very hard, and high in dissolved solids. Groundwater TDS concentrations were typically lower in samples collected from monitoring wells at higher elevations or in the upper reaches of local catchments (local groundwater recharge areas) and higher in samples from wells at lower elevations in the project area (local groundwater discharge areas such as sloughs and creeks). Highest TDS concentrations were observed for samples from monitoring wells in the existing open pit area and the backfilled Ajax East Pit, and in samples collected from monitoring wells along Peterson Creek, in the vicinity of the Peterson Creek aquifer.

Arsenic, boron, iron, manganese, molybdenum, and selenium were metals and metalloids that were elevated in the groundwater quality baseline study area, though the spatial extent varied somewhat by parameter. Arsenic, boron, manganese, and selenium concentrations tend to be higher in samples collected from monitoring wells in the open pit area. Arsenic, molybdenum, and selenium are specifically elevated in samples collected from the monitoring wells installed in the waste rock backfill in the historical Ajax East Pit. Manganese and iron concentrations were elevated in samples from monitoring wells installed in the vicinity of the proposed EMRSF and in the lower reaches of the Humphrey Creek watershed. Aluminum, chromium, cobalt, copper, mercury, uranium, and zinc were generally low in concentration compared to the above mentioned parameters and major ions, and were generally reported at concentrations below water quality guidelines, though isolated water quality guideline exceedances were reported for each of these parameters in one or two wells in a given area of the Project, if at all.

Groundwater hydraulic gradients were assessed by BGC (2015) wherever monitoring wells and piezometers were installed at multiple depths at the same location. Groundwater quality samples from shallow, intermediate, and deep wells at these sites were compared to understand what, if any, correlation the direction of these hydraulic gradients have with concentrations of specific parameters. More samples were collected from monitoring well sets where upward hydraulic gradients or artesian conditions were observed (AJGW07-D/S, MW11-06D/S, MW11-07D/S, MW11-09D/S, BGC14-001D/S, BGC14-002D/S, BGC14-003D/I/S, BGC14-006D/S, BGC14-011D/S, BGC14-012D/S, BGC14-015D/S, and BGC14-017D/S) compared to well sets were downward hydraulic gradients were observed (MW11-05D/S and AJGW02-D/S; the dataset for AJGW02-D is

limited compared to the dataset for the shallow well at this location). General observations on parameters concentrations where upward hydraulic gradients were observed are summarized here and trends have not been summarized for downward hydraulic gradients based on the limited dataset for groundwater quality data specific to those areas. Groundwater pH was generally higher in shallower wells and hardness and alkalinity concentrations were observed to decrease with depth. Fluoride, arsenic, boron, iron, and manganese concentrations tended to increase with depth. Exceptions were noted for manganese and fluoride at the BGC14-003D/I/S monitoring location and iron at the BGC14-002D/S monitoring location; concentrations for these parameters at these monitoring sites decreased with depth. TDS and sulphate concentrations were typically similar in the samples from deep and shallow wells at the same monitoring locations. No trends were noted for selenium or molybdenum.

Trace metal and metalloid concentrations in groundwater were not well correlated with the major lithological units and the distribution appears to be more strongly influenced by local geological enrichment in specific minerals (deposit area) and by proximity to local scale groundwater discharge areas which are typically at lower elevation in the Project area (historical open pit, Peterson Creek, Peterson Creek aquifer). Correlation between parameters that are at elevated concentrations in the open pit area to specific overburden lithological units is also not obvious, with the exception of samples from wells installed in the waste rock backfill in the historical Ajax East Pit. The majority of the overburden wells are completed in either glacial till or fluvial/glaciofluvial lithological units and reported concentrations were variable within these units. The aquatic life water quality guidelines tend to be the most conservative and therefore provide the lowest common thresholds for parameters in the project area. A correlation between potential parameter enrichment and lithological unit was conducted by assessing the number of guideline exceedances in each lithologic unit. The groundwater quality sample results are summarized by area (Table 5.5) and by lithological unit (Table 5.6) with respect to aquatic life guideline exceedances and further broken down by lithological unit (Table D1.1) and project area (Table D1.2) in Appendix D. Although not directly relevant to groundwater, the aquatic life guidelines have been identified as required for comparison with baseline groundwater quality in accordance with the Application Information Requirements for the Project.

5.5.2 Physical Parameters

The groundwater in the vicinity of the project area is typically slightly basic, hard to very hard (although several monitoring sites were classified as soft to moderately hard), and alkaline with very high buffering capacity. The spatial variability in pH, dissolved hardness and alkalinity are shown on Figure 5.2, Figure 5.3, and Figure 5.4. At locations where monitoring wells were installed at multiple depths, samples from the deeper wells were generally observed to have higher pH than the shallower wells and hardness and alkalinity concentrations were observed to decrease with depth. The shallow wells were typically completed in overburden and the deeper wells tended to be completed in either the Iron Mask Hybrid or Nicola Volcanics bedrock unit. The decrease in hardness and alkalinity with depth was less pronounced in the samples from monitoring wells in the Iron Mask Hybrid bedrock unit compared to those in the Nicola Volcanic (open pit area and western portion of the project area). Typically, the highest hardness and alkalinity were observed in samples collected from monitoring wells installed at lower elevations through the Peterson Creek valley, and concentrations of these parameters generally increased from west to east.

TDS is used to define the salinity of groundwater: freshwater is defined as having TDS concentrations less than 1,000 mg/L, slightly saline water is defined as having TDS concentrations between 1,000 mg/L and 3,000 mg/L, and water of TDS concentrations between 3,000 mg/L and 10,000 mg/L is defined as moderately saline. For reference, the TDS of ocean water is approximately 35,000 mg/L (NGWA 2010). According to this classification system, the majority of the wells (52%) produced freshwater, though typically with TDS near the upper end of this classification, and the remaining monitoring wells are installed within aquifer units that produced slightly saline (35%) to moderately saline (12%) water. Groundwater TDS concentrations were typically lower in samples collected from wells at higher elevations or in the upper reaches of local catchments (local groundwater recharge areas) and higher in samples from wells at lower elevations in the project area (local groundwater discharge areas such as sloughs and creeks). TDS concentrations tended to remain similar with depth (no noteworthy increase or decrease) where multiple monitoring wells were installed at one site. Highest TDS concentrations were observed for samples from wells in the existing open pit area and the backfilled Ajax East pit, and in samples collected from monitoring wells along Peterson Creek in the vicinity of the Peterson Creek aquifer. Median TDS concentrations are presented spatially on Figure 5.5 and with the piper diagram on Figure 5.6. TDS of all groundwater samples are provided for each monitoring well on piper diagrams in Appendix E.

Physical parameter guidelines for pH, colour, TDS, and turbidity were exceeded for many of the groundwater samples and are summarized as follows:

- The highest observed pH results were greater than the upper limit of the aquatic life guidelines (BCWQG-Max and CEQG-PAL; both pH 9) and were reported most often for samples collected from monitoring wells in the open pit area and on occasion at sites elsewhere in the baseline study area. Exceedances of the more stringent drinking water guidelines for pH (BCWQG-DW and HC-DW; both pH 8.5) were more common throughout the baseline study area.
- Colour exceeded the drinking water aesthetic objectives (BCWQG-DW and HC-DW; both 15 TCU) occasionally at in the samples collected from several groundwater monitoring wells throughout the project area.
- TDS exceeded the drinking water and irrigation guidelines (HC-DW, CEQG-Irrigation, and BCWQG-Irrigation; all 500 mg/L) at almost all samples from every groundwater monitoring well. TDS exceedances of the less stringent livestock guidelines (BCWQG-Livestock of 1,000 mg/L

and CEQG-Livestock of 3,000 mg/L) were observed more sporadically; however in the open pit area, groundwater sample TDS concentrations greater than 1,000 mg/L was commonly observed.

- Turbidity often exceeded the provincial agricultural guidelines (BCWQG-Irrigation of 10 NTU and BCWQG-Livestock of 5 NTU), particularly in the samples collected from earlier in the baseline monitoring program prior to initiation of the low-flow sampling protocols. The higher turbidity samples were typically from wells in the open pit area and along Peterson Creek.

SPATIAL REPRESENTATION OF TOTAL DISSOLVED SOLIDS CONCENTRATIONS IN GROUNDWATER

Knight Piésold CONSULTING

P/A NO.	REF NO.
VA101-246/31	3

FIGURE 5.5 REV 0

SAVED: M:\1\01\00246\31\A\GIS\Figs\Report3_BaselineWaterQuality\GWSW\Fig5-5_SpatialRepresentation_TotalDissolvedSolids.mxd; Jul 07, 2015 9:54 AM; adinca

5.5.3 Geochemical Facies and Major Ions

The hydrochemical signature (facies) of water is influenced by the interactions with the lithological units that it flows through and is further influenced by the length of time it interacts with various units along a flow pathway. Trilinear (Piper) diagrams were used to assess the groundwater types based on ionic contributions of major cations (calcium, magnesium, sodium, and potassium) and anions (chloride, bicarbonate, and sulphate) exhibited within the project area monitoring well samples. The median concentrations of the major ions at each groundwater quality monitoring site are plotted on a Piper diagram (Figure 5.7) to demonstrate these ion signatures visually and are summarized in Table 5.5. The water types are also provided in a spatial context on Figure 5.6. Piper diagrams of individual samples collected at each site are provided in Appendix E.

Sulphate was the dominant anion in the project area, with 82% of the monitoring wells sampled characterized with this dominant anion. The remaining 18% of the wells were characterized as dominantly bicarbonate or an intermediate bicarbonate-sulphate type. Chloride was proportionally very low in all of the groundwater samples. The dominant cation was sodium, typically in association with sulphate, though intermediate geochemical facies were identified with water types ranging from Na-SO4 to Na-Mg-Ca-SO_4-HCO_3 to Na-HCO_3. Magnesium was also a dominant cation but generally with significant proportions of sodium and calcium and rarely as a major contributing cation (typically never greater than 60% of the total cation contribution). Calcium was proportionally dominant in samples from a few monitoring wells, but typically only slightly greater than magnesium and/or sodium. Potassium was proportionally very low in all of the monitoring well samples.

Sodium-sulphate is the dominant water type for samples collected from monitoring wells to the north and west of Jacko Lake and for samples collected from some of the monitoring wells due east of Jacko Lake and adjacent to the existing open pits, with varying intermediate contributions of magnesium and/or calcium. The sulphate water type is dominant in most of the samples from monitoring wells in the vicinity of the exiting open pits, in the Goose Lake (Keynes Creek watershed) area, and along Peterson Creek, and magnesium was the dominant cation if sodium wasn't.

Calcium-magnesium-sulphate or calcium-sodium-sulphate water types were dominant in samples from three of the deeper wells immediately west of Jacko Lake (PW01, AJGW07-D and KAX-14-128D). Calcium is not a dominant cation in the groundwater anywhere else in the project area, with the exception of the sample from RES-2, which is further east adjacent to Peterson Creek. Calcium was also relatively dominant in the winter low flow surface water samples collected from monitoring sites in Peterson Creek, upstream of Jacko Lake (PC10 and JC03) (Figure 4.2).

The water type was more intermediate with respect to contributions from sulphate and bicarbonate and relatively lower in TDS for samples from monitoring wells in the in the upper reaches of the Keynes Creek and Humphrey Creek catchments. The higher bicarbonate contributions and lower TDS concentrations are typically indicative of close proximity to groundwater recharge areas. TDS typically increased in the groundwater samples from monitoring wells at lower elevations and at greater depths in both the Keynes Creek and Humphrey Creek catchments and the dominant anion transitioned to sulphate. Similar trends of increasing TDS and sulphate concentrations with distance downstream in Humphrey Creek was noted for the surface water samples (Figure 4.4) Magnesium and/or sodium were the dominant cations in samples from monitoring wells in these catchments.

The water types were cross-referenced with the surficial and bedrock lithological units that the monitoring wells were screened in (completion zones) in order to assess whether a specific water type was associated with specific lithological units (Table 5.4 and Table 5.5). The water types for groundwater samples collected from monitoring wells completed in overburden materials (colluvium, fluviual/glaciofluvial, glacial till, and lacustrine) were somewhat varied but sulphate was typically the dominant anion and magnesium or sodium were the dominant cations. Samples from monitoring wells completed in the Iron Mask Hybrid bedrock unit were dominantly sulphate type and sodium was the dominant cation in the samples from wells in the vicinity of Jacko Lake and the Open Pit/historical mine features, while magnesium was the dominant cation in wells located further east in the vicinity of the proposed EMRSF (North Peterson Creek watershed). Sodium was also the dominant anion in the samples collected from the majority of the monitoring wells (68%) completed in the Nicola Volcanics bedrock unit, bicarbonate was dominant in samples from a few monitoring wells (16%) completed in this unit, and the remaining samples were intermediate bicarbonate-sulphate type. Similar to all other monitoring locations, the major cations were sodium or magnesium, though samples from two of the monitoring wells completed in the Nicola Volcanics were weakly dominant in calcium (monitoring wells AJGW07-D and KAX-14-128D).

Sulphate concentrations were elevated in groundwater samples collected from throughout the baseline study area and the highest sulphate concentrations were noted for those wells that are in the vicinity of local groundwater discharge areas, such as the Ajax West open pits, sloughs, Inks Lake, and Peterson Creek. Sulphate concentrations were typically highly variable between monitoring wells in the open pit area and were more consistent between monitoring wells in the EMRSF area and the Peterson Creek aquifer. Similar to TDS, sulphate concentrations tended to be lower in samples from monitoring wells installed at higher elevations in the project area watersheds and typically concentrations increased in samples from wells installed at lower elevations or near local groundwater discharge areas (Ajax West Open Pit, Inks Lake, Peterson Creek, etc.). The spatial variability in concentration distribution of sulphate is shown on Figure 5.8. Sulphate guideline exceedances were common for the groundwater samples collected from throughout the project area. The high surface water hardness triggered a requirement to complete site specific toxicity testing for sulphate in the surface water environment (Nautilus 2015). Given that this is groundwater, the focus is on the value presented for systems where early life stages are absent which is 730 mg/L for a hardness of up to 1,377 mg/L $CaCO_3$. This SBEB was exceeded regularly in groundwater samples collected from the baseline study area, particularly in the open pit area, Peterson Creek aquifer, and the north Peterson Creek watershed. Drinking water guidelines for sulphate (BCWQG-DW and HC-DW of 500 mg/L) were exceeded in most groundwater samples collected from the baseline study area, though the higher sulphate concentrations were limited to samples from two wells (of seven) in the Humphrey Creek watershed and there were no drinking water quality guideline exceedances noted for monitoring wells in the Keynes Creek watershed. The livestock water quality guidelines for sulphate are double the drinking water guidelines (BCWQG-Livestock and CEQG-Livestock; both 1,000 mg/L) and the majority of the samples collected from monitoring wells in the Peterson Creek aquifer area and from several monitoring wells in the North Peterson Creek watershed (proposed ERMSF), Cherry Creek watershed, and historical open pit areas exceeded this guideline.

Fluoride is one of the major ions measured in groundwater quality samples from the project area. Fluoride concentrations tended to be highest in samples collected from the open pit area in monitoring wells completed in overburden units and from wells located around Jacko Lake

(completed in both the Iron Mask Hybrid and Nicola Volcanics bedrock units). Fluoride groundwater concentrations exceeded the CEQG-PAL (0.12 mg/L) throughout the baseline study area. Fluoride concentrations were reported at levels that exceeded the BCWQG-Max and the drinking water guidelines (BCWQG-DW and HC-DW; both 1.5 mg/L) in a few samples from wells in the open pit area. The spatial variability in fluoride groundwater concentrations is shown on Figure 5.9.

5.5.4 Nutrients, and Organic Carbon

Nitrogen based inorganic nutrients (ammonia, nitrate, and nitrite) were typically found in higher concentrations in 2007 and 2008, in association with the higher turbidity samples, with concentrations generally stabilizing since sampling methods were amended to collect more representative samples. A number of exceedances were observed for nitrate and nitrite associated with these earlier samples. More recently, nutrients were reported at concentrations that exceeded guidelines in samples from one monitoring well in the Cherry Creek watershed (MW11-01S; nitrate, nitrite and ammonia aquatic life guideline exceedances) and two monitoring wells in the open pit area (MW12-01 and MW12-02; nitrate and nitrite aquatic life guideline exceedances; nitrate drinking water guideline exceedances). Only sporadic guideline exceedances were observed elsewhere. Nitrate was identified as a parameter that was elevated in groundwater wells in the Kamloops area through the *Water Quality Check Program* that was carried out by the Ministry of Environment through the late 1970s and 1990s (BC MOE 2007b).

Organic carbon concentrations were generally low in groundwater samples from throughout the project area. However, exceedances of the drinking water guideline of 4 mg/L (BCWQG-DW) extensively in the groundwater samples collected from wells in the Cherry Creek, north Peterson Creek, and upper Peterson Creek watersheds and more sporadically in the other areas. The drinking water guideline is applicable only to treated water sources because the presence of organic carbon can result in the formation of toxic trihalomethanes when chlorinated and these exceedances are not indicative of baseline concentrations that are toxic.

5.5.5 Cyanide

Measureable concentrations of total cyanide were seldom observed; cyanide concentration that were detected have been excluded from the baseline characterization due to QA/QC issues particular to false positives due to earlier analytical methods. Cyanide species have remained below the method detection limits since the analytical methods were improved in 2012.

SPATIAL REPRESENTATION OF FLUORIDE CONCENTRATIONS IN GROUNDWATER

Knight Piésold CONSULTING

P/A NO. VA101-246/31 | REF NO. 3

FIGURE 5.9 | REV 0

SAVED: M:\1\01\00246\31\A\GIS\Figs\Report3_BaselineWaterQuality\GWSW\Fig5-9_SpatialRepresentation_Fluoride.mxd, Jul 07, 2015 9:55 AM, adinca

5.5.6 Metals and Metalloids

Trace metal and metalloid concentrations in groundwater were not always well correlated with the major ions and their distribution appears to be more strongly influenced by local geological enrichment in specific minerals and by proximity to the open pit area (deposit area). The majority of the wells in the open pit area are completed in overburden and those that are installed in bedrock tend to be in the Nicola Volcanics. Some metals concentrations were higher in groundwater samples collected from monitoring wells in the vicinity of the open pit (deposit area) and the historical mine features (arsenic, boron, iron, manganese, molybdenum, and selenium), whereas others are elevated in groundwater samples from monitoring wells in the vicinity of the proposed EMRSF (North Peterson Creek watershed) (iron and manganese), Humphrey Creek area (manganese), Keynes Creek area (arsenic and manganese), and the Upper Peterson Creek area (arsenic, boron, and manganese). The following metals regularly exceeded guidelines in groundwater samples collected from the project area:

- Arsenic
- Boron
- Iron
- Manganese
- Molybdenum, and
- Selenium.

Infrequent or rare guideline exceedances were noted for the parameters listed below. Antimony and uranium concentrations were only elevated in samples collected from monitoring wells installed in waste rock backfill in the Ajax East Pit and one sample collected from these monitoring wells was elevated in mercury. Mercury was also elevated in one other sample from the open pit area. Nickel was only elevated in one sample from the open pit area. Aluminum, cadmium, chromium, cobalt, and copper were not specifically elevated in one area of the groundwater study area, but were measured at concentrations that occasionally exceeded guidelines in a few of the monitoring wells in the project area. The specific guidelines that were exceeded are listed below and are highlighted in the tables provided in Appendix D:

- Aquatic life guidelines: Antimony, cadmium, chromium, cobalt, copper, mercury, uranium, and zinc.
- Drinking water guidelines: Antimony and uranium.
- Agricultural guidelines: Chromium, uranium, and nickel.

Arsenic

Arsenic was identified as a parameter that was elevated in groundwater wells in the Kamloops area through the *Water Quality Check Program* that was carried out by the Ministry of Environment through the late 1970s and 1990s (BC MOE 2007a) and this is supported by the groundwater quality data collected for the project area. Arsenic concentrations were generally higher in samples collected from groundwater monitoring wells in the open pit and north Peterson Creek watershed areas than in other areas of the project, though the highest arsenic groundwater concentrations were reported for samples from a monitoring well located south of Jacko Lake (BGC14-012D). Where more than one monitoring well was installed at a single location, the higher arsenic concentrations were typically associated with the samples collected from the deeper installations or there was very little change in concentration with depth. The monitoring wells in the open pit area are predominantly completed

within overburden units or the Nicola Volcanics bedrock unit and the well to the south of Jacko Lake is also completed in the Nicola Volcanics, whereas the monitoring wells in the north Peterson Creek watershed area are predominantly installed in the Iron Mask Hybrid bedrock unit, or in deep overburden (MW11-10D). It should be noted that higher arsenic concentrations in the open pit are not pervasive, but were limited to samples from a few of monitoring wells, specifically those that were installed in and near the waste rock backfill in the Ajax East pit and those that were installed between Jacko Lake and the existing Ajax West Pits. The spatial variability in arsenic groundwater sample concentrations is demonstrated on Figure 5.10.

Aquatic life guideline exceedances (BCWQG-Max and CEQG-PAL; both 0.005 mg/L) were most common in groundwater samples collected from monitoring wells in the historical open pit area and north Peterson Creek watershed area, but were frequently observed in samples collected from MW11-10D (Peterson Creek Aquifer), BGC14-012D (upper Peterson Creek watershed/TSF area), and MW11-09D (Cherry Creek watershed). Exceedances of the aquatic life guidelines were also noted for the occasional sample from monitoring wells in the Humphrey Creek watershed (BGC14-009) and the Davidson Creek aquifer (domestic water supply wells RES-4 and RES-1). Drinking water guideline exceedances were less prevalent in the project area groundwater samples and arsenic concentrations in excess of the HC-DW (0.01 mg/L) were common for samples from some monitoring wells in the historical open pit and north Peterson Creek watershed areas, but were seldom observed in groundwater samples from other areas of the project baseline study area. Exceedances of the less stringent BCWQG-DW (0.025 mg/L) and livestock guidelines (0.025 mg/L) were reported for one sample (of eight) from MW12-02 (installed in the historic mine waste rock backfill in open pit), two of the samples (19 in total) from AJGW06-D (located south of the backfilled open pit, and all of the samples (five in total) from BGC14-012D (south of Jacko Lake). No samples exceeded the least stringent guidelines for irrigation (BCWQG-Irrigation and CEQG-Irrigation; both 0.1 mg/L).

Boron

Boron groundwater concentrations were only elevated in samples from monitoring wells in the vicinity of Jacko Lake, though not in all of the wells in that area. The highest boron concentrations were reported for samples from the deep (D) well at monitoring location BGC14-003; at this location concentrations were noted to increase with depth with median concentrations of 1.00 mg/L, 1.73 mg/L, and 8.90 mg/L for the shallow (S), intermediate (I) and deep (D) wells, respectively. The median boron concentration for samples from BGC14-003D is approximately three times higher than the median concentrations for all other wells in the baseline study area. The wells with the highest boron sample concentrations were completed within the Nicola Volcanics bedrock unit, with the exception of monitoring well MW11-04S which was completed in the Iron Mask Hybrid unit. Spatial variability in boron groundwater concentrations in the project area are depicted on Figure 5.11.

The most stringent relevant guidelines for boron are for irrigation water supply (BCWQG-Irrigation and CEQG-Irrigation; both 0.5 mg/L) and the second most stringent guidelines are for drinking water and livestock water supply (BCWQG-Livestock, CEQG-Livestock, BCWQG-DW, and HC-DW; 5 mg/L). The drinking water and livestock water supply guidelines were only exceeded for samples from the deep monitoring well installed at BGC14-003D, south of Peterson Creek in the vicinity of the proposed open pit area. The irrigation water use guidelines were exceeded regularly in samples collected from ten monitoring wells, with the highest concentrations reported for samples from four

monitoring locations in the vicinity of Jacko Lake (KAX-14-128D, BGC14-003I/D, MW11-08D, and MW11-04S).

Iron

Iron groundwater concentrations were highest in samples collected from monitoring wells installed the vicinity of the proposed EMRSF (MW11-05D/S, BGC14-006D, and BGC14-005; north Peterson Creek watershed area) and all of these wells were completed in the Iron Mask Hybrid bedrock unit. Higher iron concentrations were also reported for samples from monitoring wells installed between Jacko Lake and the historical open pit (BCC14-002S, KAX-14-107S, KAX-14-108S, KAX-14-114S, and AJGW07-D, listed from south to north), and with the exception of AJGW07-D which was completed within the Nicola Volcanics bedrock unit, these wells were all completed in overburden units (glacial till, fluvial/glacialacustrine, or lacustrine units). Higher iron concentrations were also reported for samples from monitoring wells BGC14-014D (Humphrey Creek watershed) and BGC14-010 (upper Peterson Creek watershed); both completed in the Nicola Volcanics, but otherwise physically separate with comparably lower iron concentrations in samples from nearby monitoring wells.

Iron concentrations in some or all of the samples from the above mentioned wells exceeded the aquatic life guidelines (BCWQG-Max of 0.35 mg/L; CEQG-PAL of 0.3 mg/L) and the drinking water aesthetic guideline (0.3 mg/L). Highest concentrations were reported for samples collected from monitoring wells MW11-05S/D and BGC14-006D, where median iron concentrations ranged from 1.5 mg/L to 3.6 mg/L. The spatial variability in median iron groundwater sample concentrations is shown on Figure 5.12.

Manganese

Groundwater manganese concentrations were generally elevated in the samples from monitoring wells in the vicinity of the open pit where the majority of the monitoring wells are completed in overburden. The highest manganese concentrations were for samples from monitoring wells MW11-05D/S, located in the vicinity of the proposed EMRSF, and monitoring well BGC14-014D, located in the Humphrey Creek watershed. Manganese concentrations are represented spatially on Figure 5.13. Unlike many of the other metals, higher manganese concentrations were more frequently observed in samples collected from the shallower monitoring installation depths where more than one well has been installed at a single location.

Exceedances of the hardness-dependent aquatic life guidelines for manganese (BCWQG-Max and BCWQG-30 D) were sporadic; however, manganese almost always exceeded the CEQG-Irrigation of 0.2 mg/L and the HC-DW aesthetic objective of 0.05 mg/L throughout the baseline study area. With the exception of the monitoring wells completed in the overburden units in the historical open pit area, there does not appear to be differentiation in manganese concentrations in samples collected from monitoring wells completed in the Iron Mask Hybrid or the Nicola Volcanics bedrock units.

SPATIAL REPRESENTATION OF IRON CONCENTRATIONS IN GROUNDWATER

Knight Piésold CONSULTING

P/A NO. VA101-246/31 | REF NO. 3

FIGURE 5.12 | REV 0

SAVED: M:\1\101\00246\031\A\GIS\Figs\Report3_BaselineWaterQualityGWSW\Fig5-12_SpatialRepresentation_Iron.mxd: Jul 07, 2015 9:47 AM: adinca

Molybdenum

Molybdenum concentrations were notably higher in the samples from monitoring wells MW12-01 and MW12-02 compared to all other monitoring wells in the project area. These monitoring wells were installed in the historical Ajax East Pit that was backfilled with waste rock when mining ceased under the previous operation. The median molybdenum concentrations were 3.42 mg/L and 3.33 mg/L for MW12-01 and MW12-02, respectively, compared to the site wide median concentration of 0.031 mg/L. Molybdenum concentrations were similarly elevated in the samples collected from the standing water in the Ajax West Pit lakes, and these higher concentrations are likely due to loading from precipitation flushing of oxidation products from the exposed pit walls and waste rock in combination with high rates of evaporation in the project area. Groundwater samples collected from wells in the vicinity of the historical waste rock pile to the south of Peterson Creek reported much lower concentrations of molybdenum (0.147 mg/L median concentration MW12-04), but were still higher compared to the site wide median concentration. Molybdenum concentrations were elevated in the historical seepage collection pond located down-gradient of the waste rock pile (WR Seep). Relative median concentrations for all groundwater quality monitoring sites are shown on Figure 5.14.

Molybdenum concentrations exceeded the CEQG-PAL of 0.073 mg/L and the livestock guidelines (CEQG-Livestock and BCWQG-Livestock; both 0.05 mg/L) regularly at some sites in the open pit area and north Peterson Creek watershed area and the more stringent CEQG-Irrigation of 0.01 mg/L in most samples collected from almost every site. Exceedances of the less stringent aquatic life guidelines (BCWQG-Max and BCWQG-30 D) were only reported for samples from MW12-01 and MW12-02 and exceedances of the BCWQG-DW of 0.25 mg/L were limited to several sites in the open pit area (MW12-01, MW12-02, AJGW01-D, AJGW02-D, and PW01).

Selenium

Selenium concentrations were highest in groundwater samples from monitoring wells located in the open pit area, the majority of which are completed within the overburden or waste rock backfill. Median selenium concentrations for samples from seven of the wells in the open pit area exceeded the BCWQG-30 D (0.002 mg/L) and median concentrations in four of these monitoring wells (MW12-01, MW12-02, AJGW07-S/D, and AGJW01-D) also exceeded the provincial drinking water quality guideline (BCWQG-DW; 0.01 mg/L), but did not exceed the HC drinking water guideline of 0.05 mg/L. The BCWQG-DW was also exceeded for the sample collected from the domestic water supply well RES-1, located further east in the Knutsford area and installed near or within the Davidson Creek aquifer. Selenium concentrations in the nearby domestic water supply well RES-4 exceeded the BCWQG-30 D (aquatic life) but did not exceed the drinking water guidelines. Samples from groundwater monitoring well MW11-01S were also frequently reported at concentrations that exceeded the BCWQG-30 D; monitoring well MW11-01S is located northwest in the Cherry Creek watershed area. There does not appear to be a correlation between selenium concentrations and specific bedrock or overburden units in the project area, with the exception of those monitoring wells completed in the overburden and waste rock backfill units in the open pit area. Even in the open pit area, selenium concentrations are not elevated in all of the monitoring wells. The spatial variability in selenium groundwater concentrations is demonstrated on Figure 5.15.

6 – CONCLUSIONS AND ONGOING STUDIES

6.1 GENERAL

Baseline water quality has been monitored within the Peterson Creek and Cherry Creek watersheds as part of the baseline program to support permitting of the proposed Ajax Project (the Project). The majority of the Project area is located near historical and present mining activities, as is evident with the presence of the recently permitted New Afton mine in the vicinity of old Afton Mine site. There are three historical open pits in the immediate project area (Peterson Creek watershed), two with lakes formed at base and one that has been backfilled with mine rock during reclamation. There are also two reclaimed mine rock piles, with seepage collection ponds, in close proximity to these open pits. Direct impacts to Peterson Creek water quality from these open pits and the northern mine rock pile are not evident; however, seepage and runoff from the mine rock pile to the south of Peterson Creek and seepage losses from the base of the seepage collection pond, down-gradient of this reclaimed facility are assumed to influence water quality in Peterson Creek. The remainder of the project area is comprised of forested land and extensive agricultural property as is evidenced by grazing cattle throughout the baseline study area. Furthermore, residential and industrial neighbourhoods are located in close proximity to the creeks.

Water quality and quantity in the project area is influenced significantly by the arid climate conditions. The lakes in the Project area are managed water features, and the outflow management strategies are not formally documented; as a result it is difficult to correlate flows with observed chemistry, though seasonality is evident. The primary objective for the management of outflows from Jacko Lake is to sustain the requirements of the numerous water licences on Peterson Creek.

Outside of the spring freshet, surface water flows are minimal in the Project area creeks (Peterson Creek, Keynes Creek, Humphrey Creek, Anderson Creek, Cherry Creek, and Alkali Creek) and groundwater is a significant contributor to flows. Concentrations of most parameters were noted to increase with distance downstream in the creeks in every watershed sampled in the baseline surface water quality program. This increase was most evident outside of spring freshet. In late summer and winter, groundwater was often observed to be the only significant source of inflows to Peterson Creek in the immediate Project area. Surface and ground water are elevated in dissolved solids and the only significant source of dilution comes from melting snow in the spring (freshet) or storm events. Dissolved solids concentrations were generally lower in surface and ground water samples collected from monitoring locations that were at higher elevations in the various watersheds within the project area and higher at lower elevations, indicating that local scale groundwater recharge is happening in the upper reaches of the smaller project area watersheds and discharge is occurring to nearby lakes, creeks and sloughs.

The baseline water quality study was strategically planned to provide insight into surface water and groundwater quality in the Project area and to provide appropriate coverage both up-gradient and down-gradient of the historical and proposed mine features, and local land uses. The primary objectives of the water quality study were to characterize the complex environment and understand the interactions between surface water and groundwater in the project area, to provide valuable insight into current and potential future stresses on surface and ground water resources and management strategies to address these issues, and to provide a basis for predicting future water quality (baseline comparison and inputs to predictive models). The water quality analytical results

have been compared against an exhaustive list of relevant guidelines as specified in the Application Information Requirements for the Project. The relevant guidelines were based on all potential water users in the project area and include aquatic life, drinking water, agricultural water uses (irrigation and livestock), wildlife, and recreation. Aquatic life guidelines tend to be the most stringent and the report discussion is generally focussed on these guidelines, though the others are discussed to provide context.

6.2 SURFACE WATER QUALITY

Surface waters in the Project area are neutral to basic pH, hard to very hard, and alkaline, with high buffering capacity. Concentrations of most parameters were noted to increase with distance downstream in the creeks in every watershed sampled in the baseline surface water quality program; this increase was most evident outside of spring freshet. Surface water quality within the Project area is highly variable depending on whether the system is a lake, slough, creek, or historical mine site feature and dissolved solids are a key parameter that differentiates these various features within the baseline study program. Inks Lake and Wallender Lake have much higher TDS than the man-made features (Historical Mine Site Features), which in turn have higher TDS than in Peterson Creek, Jacko Lake, Makaoo Lake, Alkali Creek, Anderson Creek, and Cherry Creek. With the exception of upper Cherry Creek, the specific conductance of the water in all of the baseline study area is higher than the normal range for interior streams, which is up to 500 µS/cm (RISC 1998). All of the water bodies show a sharp decrease in TDS and specific conductance in response to dilution from spring freshet flows. The creeks, Makaoo Lake, and Jacko Lake qualify as freshwater sources, with TDS that falls below 1,000 mg/L, the Historical Mine Site Features are slightly to moderately saline (1,000 mg/L to 10,000 mg/L TDS), and Inks Lake and Wallender Lake are saline, though Wallender Lake is verging upon hyper-saline (TDS >50,000 mg/L) (NGWA 2010). It should be noted that Inks Lake, Polygon Pond, and Wallender Lake differ from Jacko Lake and Makaoo Lake, in that the latter have clearly defined outlet channels and multiple inlet streams, whereas, the other lakes are akin to sloughs, with no outlet channels. Wallender Lake, Polygon Pond, Inks Lake and the historical open pits are evaporative basins, in local groundwater discharge zones. As a result of the high evaporation rates and no outlet channels for load removal, the concentrations of the majority of parameters have risen over time and may have reached equilibrium conditions in the natural features, but continue to increase in the man-made features. The parameters in the historical mine facilities and lakes tend to have higher concentrations than the surrounding groundwater and surface water.

Major ion types in surface water are generally similar to the water types observed in groundwater samples collected from the same areas and this convergence is most evident when comparing groundwater chemistry to surface water samples collected under low flow conditions. Bicarbonate and/or sulphate are the dominant anions in all surface waters; however, the dominant cations are less defined but generally magnesium was predominant with significant contributions of sodium and calcium.

Sulphate concentrations are very high in the groundwater in the greater project area and also high in the water samples from the historical mine features, including the pond down-gradient of the historical waste rock pile to the south of Peterson Creek. Sulphate levels in Inks Lake, Polygon Pond, Wallender Lake, and the Historical Mine Site Features are also very high, and generally all exceed the 1000 mg/L livestock water use guidelines. Surface water sulphate concentrations

increased with distance downstream in all of the project area creeks. The BCWQG-30 D for sulphate specifies that site specific toxicity testing is required when hardness exceeds 250 mg/L $CaCO_3$, as was generally the case in the baseline surface water environment in the project area. The toxicity testing, documented in *Testing in support of development of a science based environmental benchmark for sulphate for the Ajax Mine* – Draft Report (Nautilus 2015), resulted in a recommended science based environmental benchmark (SBEB) for a maximum sulphate concentration of 429 mg/L, which is the same as the current BCWQG-30 D, but with the maximum hardness adjusted up to 800 mg/L $CaCO_3$ which is protective of early life stages for trout (present from May through June). An alternative SBEB of 730 mg/L for a hardness of up to 1377 mg/L $CaCO_3$ was recommended for surface waters where early life stages for trout do not occur, or for periods of the year when these life stages are not expected to be present in a given reach of Peterson Creek (July through April). Early life stage for trout are expected to be present in Jacko Lake, Edith Lake, and Peterson Creek and sulphate concentrations were generally below the SBEB, though there were isolated exceedances of the SBEBs lower reaches in Peterson Creek during periods when early life stages of fish would. A more detailed assessment of seasonality in the sites in lower Peterson Creek was required as sulphate concentrations and hardness exceeded the lower benchmark under lower flow conditions (August through April) when early life stages are not expected to be present and these conditions occasionally persisted into May.

Fluoride concentrations were found at concentrations that exceeded the CEQG-PAL (aquatic life) throughout the baseline study area; however, due to elevated hardness, the BCWQG-Max was never exceeded. Chloride concentrations were elevated in baseline surface water samples collected from throughout the study area. Chloride concentrations were highest in samples collected under low flow conditions from Peterson Creek sites PC02, PC-EF-04, and JC03 and Anderson Creek site ANDR-15, all sites that are located in close proximity to highways where road salting would be common practice during the winter months. Chloride concentrations were low in all groundwater samples collected from drilled monitoring wells in the project area, but were elevated in samples collected from residential water supply wells RES-1 and RES-4, which are located in the vicinity of the Davidson Creek aquifer and near the surface water site PC02. These higher concentrations indicate that chloride is elevated in the groundwater system in that reach of Peterson Creek.

Total phosphorus concentrations in the creeks varied significantly on a seasonal basis, resulting in a wide range of trophic classification from eutrophic to hyper-eutrophic. Nutrient loading within the Project area is dominantly phosphorus related and nitrogen based inorganic nutrient (nitrite, nitrate, and ammonia) concentrations were somewhat variable in the creeks and guideline exceedances were infrequent.

In Peterson Creek (and tributaries), Anderson Creek, Cherry Creek and Alkali Creek aluminum, copper, and iron frequently exceeded the aquatic life guideline limits and molybdenum and manganese concentrations frequently exceeded the guidelines for irrigation and/or livestock water uses. Exceedances of the drinking water aesthetic objectives for iron and manganese were also common. With the exception of manganese and molybdenum, these parameters were generally elevated in response to freshet flows and dissolved concentrations were significantly lower than total concentrations. Manganese and molybdenum concentrations are elevated in local groundwater, and as such, the surface water concentrations were higher during non-freshet periods when surface water flows were predominantly sustained by groundwater inflows. Molybdenum within Peterson Creek is only elevated in water samples collected downstream of the historical mine rock pile to the

south of the creek and backfilled Ajax East Pit to the north of the creek. Elevated molybdenum concentrations were noted in the water quality samples associated with all of the Historical Mine Site Features, indicating that there is a high likelihood that the local mineralized geology is enriched in this parameter. Molybdenum concentrations decreased with distance downstream in Peterson Creek; which is atypical as the majority of the parameters increase in concentration with distance downstream in each watershed. Cadmium and selenium aquatic life guideline exceedances were also noted within the project area creeks in association with freshet flows, though less frequent than the parameters listed above. In Jacko Lake, only selenium, zinc, and aluminum were reported at concentrations that exceeded the aquatic life guidelines, though exceedances were infrequent. Metal concentrations were low in Makaoo Lake and guideline exceedances were seldom observed.

The Historical Mine Site Features water quality samples revealed elevated concentrations of arsenic, antimony, cadmium, copper, molybdenum, selenium, and uranium, and aquatic life guideline exceedances were frequent. Elevated TDS in the samples from these locations resulted in the inability to obtain MDLs that were below guideline limits for some parameters.

In Inks Lake and Wallender Lake several parameters tested had MDLs that were greater than or equal to the guidelines as a result of sample dilution required to analyze samples with high TDS. MDLs for the following parameters exceeded guideline limits during one or more sampling events: aluminum, beryllium, cadmium, chromium, cobalt, copper, lead, manganese, selenium, and thallium. Of these parameters, analytical resolution was achieved on occasion for aluminum, copper, and selenium and guidelines were generally exceeded for each true measured concentration. Those parameters that were detected and regularly exceeded guideline limits with no elevated MDL exceedances were arsenic and boron, which are also elevated in the project area groundwater samples.

6.3 GROUNDWATER QUALITY

Regional groundwater quality in the Thompson River watershed is described as having high levels of total dissolved solids (TDS) (>500 mg/L) and elevated sulphate concentrations (Zubel 2001). Groundwater quality in the Aberdeen area of Kamloops was reported by Golder Associates (2008) to be alkalinity dominated with major anions ranging from sulphate to bicarbonate and major cations typically ranging from sodium or magnesium. Groundwater was reported to generally increase in TDS and sodium with depth and nitrate concentrations were elevated in the samples from springs and seeps in the area. The groundwater quality analysis for the local study area is consistent with the description of these regional groundwater references.

Groundwater quality in the project area is characterized as alkaline, hard to very hard, and high in dissolved solids. Groundwater physical parameters typically display consistent trends with depth; at groundwater monitoring locations where wells were installed at multiple depths, samples from the deeper wells were generally observed to have higher pH than the shallower wells and hardness and alkalinity concentrations were observed to decrease with depth. The shallow wells were typically completed in overburden and the deeper wells were completed in either the Iron Mask Hybrid or Nicola Volcanics bedrock unit. Groundwater TDS concentrations were typically lower in samples collected from monitoring wells in the upper reaches of catchments (local groundwater recharge areas) and higher in samples from wells at lower elevations in the project area (local groundwater discharge areas such as sloughs and creeks), suggesting that TDS increases along the groundwater

flow path. Based on total dissolved solids concentrations, the majority of the project area monitoring wells (52%) produce freshwater, though typically with TDS near the upper end of this classification, and the remaining monitoring wells produce slightly saline (35%) to moderately saline (12%) water.

Sulphate was the dominant anion in the project area (82% of the monitoring wells) and bicarbonate or intermediate bicarbonate-sulphate anions were dominant in samples form the remaining wells. The dominant cation was sodium, typically in association with sulphate, though intermediate geochemical facies were identified. Magnesium was also a dominant cation but generally with significant proportions of sodium and calcium and rarely as a major contributing cation (typically never greater than 60% of the total cation contribution). Calcium was proportionally dominant in samples from a few monitoring wells installed immediately east of Jacko Lake, but typically only slightly greater than magnesium and/or sodium.

Hydrochemical signatures were not distinct for the specific bedrock or overburden lithological units but were more easily distinguished by location in the project area. The water types observed for specific lithological units are general described as follows:

- Overburden materials (colluvium, fluvial/glaciofluvial, glacial till, and lacustrine) - sulphate was typically the dominant anion and magnesium or sodium were the dominant cations.
- Iron Mask Hybrid - dominantly sulphate type and sodium was the dominant cation in the samples from wells in the vicinity of Jacko Lake and the Open Pit/historical mine features, while magnesium was the dominant cation in wells located further east in the vicinity of the proposed EMRSF (North Peterson Creek watershed).
- Nicola Volcanics - Sodium was also the dominant anion; though bicarbonate was dominant in samples from a few monitoring wells completed in this unit and the remaining samples were intermediate bicarbonate-sulphate type. The major cations were sodium or magnesium, though samples from two of the monitoring wells completed in this unit were weakly dominant in calcium.

Sulphate concentrations were elevated in groundwater samples collected from throughout the baseline study area and the highest sulphate concentrations were noted for those wells that are in the vicinity of local groundwater discharge areas, such as the Ajax West open pits, sloughs, Inks Lake, and Peterson Creek. Groundwater samples from monitoring wells in these areas frequently exceeded the livestock guidelines (BCWQG-Livestock and CEQG-Livestock; both 1,000 mg/L) and most of the samples exceeded the more stringent drinking water guidelines (BCWQG-DW and HC-DW of 500 mg/L). The lowest sulphate concentrations were in samples from monitoring wells in the Keynes Creek and Humphrey Creek watersheds and guideline exceedances were less frequent. This SBEB (aquatic life) was exceeded regularly in groundwater samples collected from the baseline study area, particularly in the open pit area, Peterson Creek aquifer, and the north Peterson Creek watershed.

Fluoride concentrations were elevated in groundwater samples collected from monitoring wells throughout the project area though locally enriched in the vicinity of the proposed Open Pit, where concentrations were often greater than the livestock and irrigation water use guideline limits.

Trace metal and metalloid concentrations in groundwater were not always well correlated with the major ions and the distribution appears to be more strongly influenced by local geological enrichment in specific minerals and by proximity to the open pit area. The majority of the wells in the open pit area are completed in overburden and those that are installed in bedrock tend to be in the Nicola

Volcanics. Arsenic, boron, iron, manganese, molybdenum, and selenium were metals that were elevated in the groundwater quality baseline study area and regularly exceeded guidelines, though the spatial extent varied somewhat by parameter. More sporadic or infrequent exceedances were observed for aluminum, chromium, cobalt, copper, mercury, uranium, and zinc. Arsenic, boron, manganese, and selenium concentrations tend to be higher in the open pit area, where monitoring wells are predominantly completed within the overburden units, though some wells are completed in the Nicola Volcanics bedrock unit that underlies this area. Arsenic, molybdenum, and selenium are specifically elevated in samples collected from the monitoring wells that were installed in the waste rock backfill in the historical Ajax East Pit. Manganese and iron concentrations were also elevated in samples from monitoring wells installed in the vicinity of the proposed EMRSF and in the lower reaches of the Humphrey Creek watershed.

Aquatic life guideline exceedances for groundwater quality were most common through the majority of the baseline groundwater quality study area for fluoride, sulphate, and arsenic, less common for boron, copper, iron, manganese, molybdenum, and selenium, and rare for aluminum, antimony, cadmium, chromium, cobalt, mercury, uranium, and zinc.

The groundwater in the project area is generally not suitable as a raw drinking water source and drinking water quality guideline exceedances are common for pH, TDS, sulphate, fluoride, manganese and sodium, and are less common for nitrate, ammonia, arsenic, selenium, and uranium.

Livestock water use guideline exceedances are common throughout the Project area for specific conductance, TDS, and molybdenum, and less common for sulphate, fluoride, and arsenic. Irrigation water use guideline exceedances are common for specific conductance, TDS, manganese and molybdenum, and less common for chloride, selenium, and uranium.

6.4 ON-GOING WATER QUALITY BASELINE PROGRAM

The water quality baseline data collection program is on-going through the Environmental Assessment and permitting phases of the Project schedule. The surface water quality program will sustain the monthly sampling frequency through this period and lake sampling will continue monthly through the open water period and two samples will be collected during the winter months (through the ice, provided conditions are safe for sampling). Lake sampling is intended to capture fully mixed (spring and fall turn-over) and stratified (summer and winter) conditions. Surface water sample collection in the local creeks will be conducted twice monthly until a full year of samples has been collected from all of the sites that were added into the program in 2014. The purpose of this sampling frequency is to provide a more thorough program in the limited time available to aid in characterization of the local surface water quality.

The groundwater quality program will continue with a seasonally representative sampling frequency, targeting seasonally high (post-freshet) and low (late winter) groundwater elevations and with two events during periods of intermediate groundwater elevations. A more frequent sampling schedule has been maintained for the wells that were installed in 2014 and these wells will be sampled monthly until a full year of data has been obtained. Water level monitoring will continue at all sites.

The basis for this continued program is to establish a robust database of water quality conditions prior to the establishment of the proposed Project that will provide sufficient statistical power to

detect, with greater certainty, changes to water that result from natural variability versus those that result from the Project.

APPENDIX A

QUALITY ASSURANCE/QUALITY CONTROL

(Pages A-1 to A-54)

APPENDIX A

2013 QUALITY ASSURANCE AND QUALITY CONTROL ANALYSIS

1 – OVERVIEW

The quality assurance and quality control (QA/QC) analysis includes a review of all groundwater and surface water data collected prior to October 2014. This appendix builds on the previous QA/QC report generated as an appendix to a previous baseline water quality report for the Project, which included water quality data collected prior to October 2012 (VA101-246/8-7).

The quality of the data obtained for a project is assessed via adherence to a set of pre-defined data quality objectives (DQOs) for the project. DQOs provide a means of assessing whether the data in question are precise, accurate, representative, and complete. The QA/QC analysis in this appendix covers three areas of operations: field data collection, laboratory analysis and office data management.

The results from QA/QC samples are reviewed to determine if sample contamination occurred. The data for any contaminated samples are then reviewed to determine if the contamination occurred during collection, handling, storage, shipping, or analysis.

The QA/QC Protocol and DQOs were compiled with reference to the following Canadian guidance documents:

- Guidance Document for the Sampling and Analysis of Metal Mining Effluents (Environment Canada, 2011).
- Canadian Council of Ministers of the Environment (CCME) Protocols Manual for Water Quality Sampling in Canada (CCME, 2011). This document is based on the Alberta and British Columbia sampling manuals (Alberta Environment, 2006; BC MWLAP, 2003).

Procedures for each area of operations are summarized in Section 2 and are described in detail within the internal manuals and during staff training to ensure the proper collection, analysis, and management of data that will meet the DQOs. A summary of the results obtained during the QA/QC analysis are provided in Section 3.

2 – PROCEDURES

Standard data collection procedures for the water quality data that meet the DQOs are described in the following subsections. In the QA/QC results section (Section 3), the actual procedures used to collect water quality data for the Ajax project are compared against the standard data collection procedures and any discrepancies are investigated to determine the validity of the data collected.

2.1 FIELD DATA COLLECTION QA/QC PROCEDURES

2.1.1 Equipment

Field water quality meters (YSI6820 or YSI6920) for measuring *in situ* parameters are rented from Pine Environmental, where they are maintained and calibrated between water sampling events. Each YSI is calibrated daily for dissolved oxygen and, in cases where water quality sampling events take more than two days, each YSI is recalibrated every three days for other *in situ* parameters using

standard solutions specific to each parameter (i.e. pH, turbidity, conductivity, and ORP). The YSI is recalibrated more often if parameter readings are suspect (ex. pH values that are inconsistent with the rest of the data).

All equipment used in water quality sampling is rinsed or cleaned with a shop towel between sites. Each YSI is rinsed with distilled water between sites or is rinsed with site water (ground- or surface water) prior to recording *in situ* parameters. The YSI is stored overnight in a sheltered environment. Equipment used for processing samples (i.e gloves, filters, and syringes) is disposable and new packaged equipment is used at each site.

2.1.2 Field Procedures

Specific work instructions are provided in KP sampling manuals, which are based on the CCME Protocols Manual for Water Quality Sampling in Canada (CCME, 2011), as well as office presentations, and on-the-job training. All staff members engaged in this work are required to read the sampling manuals prior to conducting any water or sediment quality work on-site. Staff members are also required to work with more experienced personnel during their first site visit.

Field notes and *in situ* data are recorded on waterproof paper. At the end of each day, field personnel are expected to check their field notes and sample labels to ensure that no samples are missing and that notes are complete. The laboratory provides protocols for sample labelling, preservation, and shipment and field staff are expected to adhere to these protocols. Bottles and preservatives are shipped with labels, chain of custody (COC) forms, and specific instructions. Water quality samples are labelled with their actual site name rather than an identification code since the samples are re-labelled by the lab prior to analysis (this procedure is specific to ALS laboratories and may not be relevant for all laboratories).

2.1.3 QA/QC Samples

The repeatability and reliability of sample results is evaluated by submitting duplicate water samples, field blanks, and travel blanks for the same parameters for which the primary samples are analyzed. This allows for the detection and reduction of errors that may occur due to contamination of samples. The QA/QC samples should conform to standard sampling methods, outlined by the CCME and were labelled as QA/QC samples because the laboratory adds their own labels upon sample receipt (CCME, 2011). Details regarding each type of QA/QC sample are outlined below:

Duplicate Samples - The purpose of a duplicate sample is to estimate sampling and laboratory analytical precision. At least one duplicate sample is collected for every sampling event and the total number of duplicate samples is maintained at least 5% of the total number of samples. Duplicate samples are the same as their primary sample in collection and handling and are collected at the same time or a few minutes apart from their primary sample.

Field Blank Sample - The purpose of a field blank is to identify potential sources of contamination with preservatives, field filtration, sample handling or transportation, as well as any potential contamination from analytical procedures. Field blanks are prepared from distilled/deionized (DDI) water provided by the laboratory. The DDI water is filtered and preserved using the same methods as for sampling site water. At least one field blank sample is collected for every sampling event and the total number of field blank samples should be maintained at 5% of the total number of samples collected.

Equipment Blank Sample - The purpose of an equipment blank is to identify potential sources of contamination associated with non-disposable equipment used to collect samples. Equipment blanks are prepared from DDI water provided by the laboratory. The DDI water is exposed to the non-disposable sampling equipment, mimicking the sampling procedure as much as possible. The DDI water is then filtered and preserved using the same methods as for sampling site water. At least one equipment blank is prepared on each site visit where non-disposable equipment is used.

Travel Blank Sample - The purpose of a travel blank is to identify potential sources of contamination associated with sample containers, shipping, storage, and analysis. These samples are prepared by the laboratory with DDI water and are never opened on site. Travel blanks travel with the sample bottles sent from the laboratory to the field site, and back to the laboratory. Travel blank samples are not required for each site visit, but should be collected when shipping, storage, and analytical procedures are altered.

2.2 EXTERNAL LABORATORY ANALYSIS QA/QC PROCEDURES

ALS Environmental (ALS) was retained for the analysis of the samples collected from the project site. ALS is an accredited laboratory for water quality analysis with rigorous internal QA/QC procedures. In the event of a failed internal QA/QC test, both laboratories re-run all analyses affected by the same factors as the failed internal QA/QC sample.

Sample integrity issues are highlighted on the sample receipt confirmation (SRC) reports that are provided to Knight Piésold Ltd. following receipt of samples at the laboratory. Where sample integrity issues are identified, correspondence between ALS and Knight Piésold Ltd. results is used to identify corrective actions or resolve causes of the issues.

2.3 OFFICE DATA MANAGEMENT QA/QC PROCEDURES

The FULCRUM data management system is used to organize and store data received from ALS laboratories. In FULCRUM, data are transferred electronically into the database through the use of electronic data files. Data received from SRC is transferred to a Microsoft Excel spreadsheet electronically to avoid transcription errors. All original lab data files are saved and used to check the database.

Upon receipt of laboratory results, several data validation checks are conducted and any QA/QC issues are recorded in a tracking document. If the QA/QC results do not meet the DQOs, results associated with the QA/QC samples in question are flagged and further inspected. If the issue with the QA/QC sample is determined to compromise the validity of the sample results associated with it, data are rejected. Rejected results are not used in the statistical analysis of the data. The validation checks used to determine whether data should be flagged or rejected are outlined below:

Hold time exceedances – hold time exceedances occur when the time period between the sample collection time and the sample analysis time is greater than the recommended maximum holding time. These time frames range from 0.25 hr to 6 months and represent the maximum length of time that should not be exceeded or sample degradation may occur. Reasons for hold time exceedances are determined and, wherever possible, revised to prevent future exceedances. The validity of the results is determined on a case by case basis.

pH – high groundwater pH values (in situ and laboratory values greater than 10) often indicate grout contamination of the well. Grout contamination may compromise the analysis of all parameters. Groundwater quality samples for which the measured pH is greater than 10 should be rejected and removed from the dataset.

Turbidity – the accepted methods for groundwater quality sampling (MOE, 2012) indicate low turbidity (i.e. less than 50 NTU) as a criterion for representative groundwater samples. Both in situ and laboratory turbidity readings should be compared to the decision flow chart in Figure A.1 (adapted from MOE, 2012). Samples unacceptable turbidity values may be rejected from the dataset or used to interpret parameters other than metals.

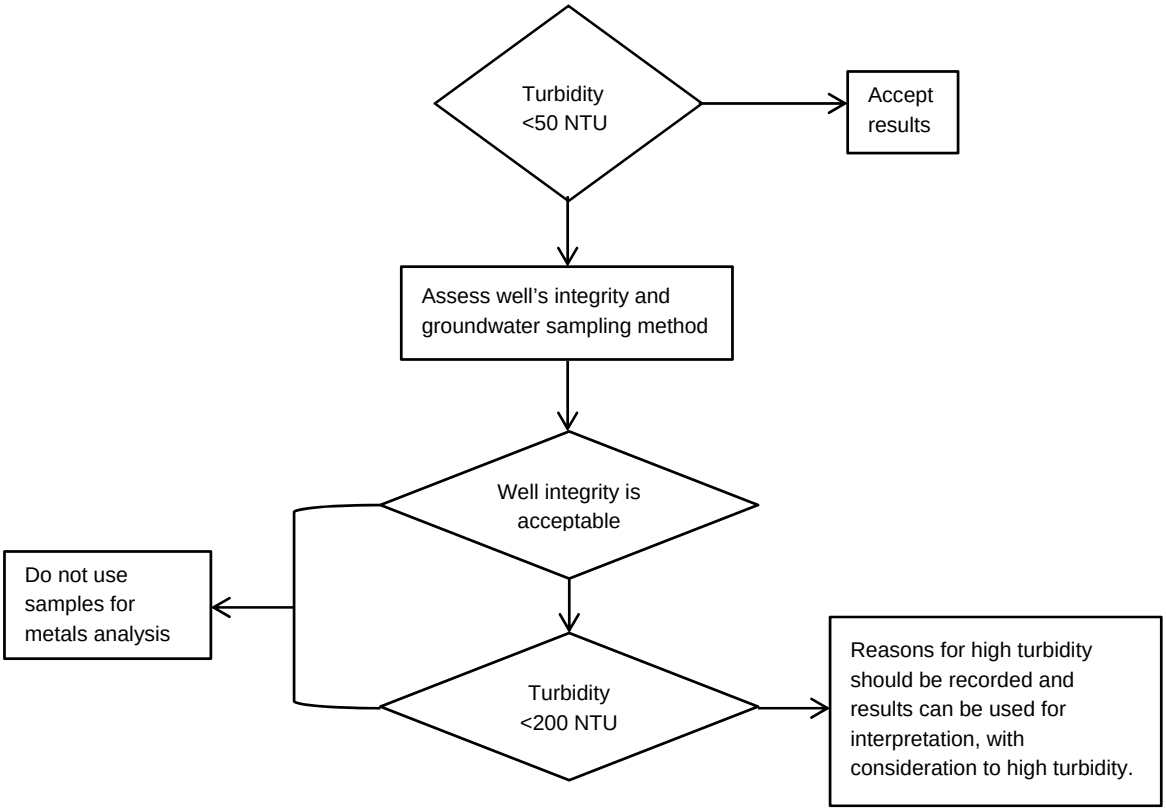

Figure A.1 Decision Flow Chart for Turbidity in Groundwater Samples (adapted from BC MOE, 2012)

Sample Blanks – results of blank samples are used to assess the potential sources of contamination associated with the sample containers, preservatives, and sample handling and transportation, as well as any potential contamination from the analytical procedures. Blank sample results are highlighted if any analyte exceeds the method detection limit (MDL) and are flagged if the result exceeds five times the MDL. Following an investigation to determine the source of error, field sampling and handling procedures may be modified to prevent similar errors from occurring in future sampling events. Highlighted blank sample results that are greater than the MDL, but lower than five times the MDL may not always indicate potential contamination because of the uncertainty of results near the MDL. Common occurrences of these results should prompt in discussions with the lab about uncertainty. Flagged blank results also may or may not indicate sample contamination and

should be assessed in detail to determine the likely cause of the result exceeding five times the MDL. The assessment of these results is summarized in the decision matrix shown in Table A.1.

Table A.1 Decision Matrix for the Assessment of Flagged Blank Samples

Case	Travel Blank	Field Blank (unfiltered)	Field Blank (filtered)	Likely Cause	Actions Taken
1	>5xMDL	>5xMDL	>5xMDL	Contamination during transport, storage, or analysis of samples.	If the results were greater than 10% of the average of the results for samples collected on site, data were rejected.
2	>MDL	>MDL	>MDL	Some uncertainty associated with the MDL and the analysis.	Data were accepted, but the lab was consulted for a discussion on the uncertainty.
3	>5xMDL	-	-	Contamination at the laboratory or contamination of DDW	Discussions with laboratory on potential contamination of DDW. Results were accepted.
4	-	>5xMDL	-	Contamination due to sampling procedures or leaching from bottles.	See Case 1
5	-	-	>5xMDL	Contamination due to filters or filtering process.	See Case 1
6	>5xMDL	>5xMDL	-	Potential contamination of DDW, contamination from the bottles, or a combination of contamination sources.	See Case 1
7		>5xMDL	>5xMDL	Contamination due to sampling methods or contaminated DDW water.	See Case 1
8	>5xMDL		>5xMDL	Contamination from two sources.	See Case 1

Duplicate Samples – duplicate samples are used to estimate sampling and laboratory precision. Analytical results obtained for two samples collected from the same site at the same time are flagged if the relative percent difference (RPD) is greater than 20% and one or both of the measured concentrations are greater than five times the MDL. The RPD is the absolute difference in concentrations of the two duplicate samples divided by the average of the two values. Flagged results are further reviewed to determine whether the high RPD is a result of naturally variable conditions or sampling error. If the latter case is suspected, efforts are made to prevent similar errors from occurring in the future and results associated with the result in question may be rejected. If the high RPD is most likely a result of natural variability in the water body from which the duplicate samples are collected, flagged data are noted as a point of discussion, but are not rejected.

Detection Limits – detection limits are examined on a regular basis to ensure that they coincide with guideline limits. If detection limits exceed the guideline limits, the laboratory is contacted and efforts are made to adjust the analytical procedures to achieve lower detection limits. Detection limits are often increased due to sample matrix interference and efforts are made to adjust laboratory methodology, although lower detection limits are not always possible.

Cation/Anion Balances – ion balances are calculated to detect error associated with the analysis of the major ionic species in the groundwater samples. The major cations in water are calcium, magnesium, potassium, and sodium. The major anions in water are bicarbonate, sulphate, and chloride. The error between the sum of the cation species and the sum of the anion species should

be less than 10%. An error greater than 10% could indicate an analytical error or an unaccounted major ionic species.

Dissolved and Total Metals Concentrations – dissolved and total metal concentrations in all site samples are compared and highlighted if the reported concentration of a dissolved metal is greater than reported concentration of the total metal. Samples are flagged if the RPD between the total and dissolved concentrations of the highlighted sample is greater than 20% and one or both results exceed five times the MDL. Analytical results between one and five times the MDL may be affected by analytical error. Flagged analyses for metals are further investigated and may be rejected if the flagged result is an outlier, exceeds guidelines, or is very different from the expected results, given other samples collected at the same site or in the same area.

2.3.1 Data Analysis

An online database and data management tool (FULCRUM) is used for data storage and statistical calculations. Results that are below the MDL are set to equal half the MDL for all statistical analyses. *In situ* and laboratory results are compared with previous results for the same sites and with expected data trends. Any data outliers are confirmed with the laboratory for validity. Results that do not fit within the expected range, relative to other samples collected from the same or similar sites, are flagged and may be rejected if the likely cause of the discrepancy is determined to be a methodology error. For all analytes, annual statistics and monthly mean values are calculated. Several of the calculations are checked at random using a calculator to proof the Excel spreadsheet calculations.

3 – RESULTS

QA/QC results have been used to verify data and identify any data that should be rejected and also to identify where procedural improvements should be made. These results include procedural results and results of the analysis of QA/QC samples. Procedural results summarize the detailed qualitative review of all data and of field, laboratory, or office procedures that could affect the validity of the data collected. As part of a standard QA/QC protocol, any results that appeared suspicious for any reason were flagged and evaluated in a QA/QC tracking document. Results of the analysis of the QA/QC samples are quantitative results that have been used to identify specific data that did not meet the DQOs.

3.1 FIELD PROCEDURES ANALYSIS

3.1.1 Field Equipment

Field equipment was maintained either in the field or at Pine Environmental, where equipment was rented. *In-situ* probes (YSI 6920 and YSI 6820) were calibrated at Pine Environmental prior to shipping to site. Calibration records have been stored with the field notes. Dissolved oxygen was calibrated on site at the beginning of each sampling event and every time the atmospheric pressure or elevation of the sampling site changed significantly. Other parameters were recalibrated every three to five days, or when the probes detected readings that were unexpected and did not fit within the range of other samples collected from the same site. Multi-parameter probes, groundwater pumps, and lake depth samplers were rinsed with DDI water between sampling sites or with site

water prior to use. All other equipment used in sampling (ex. syringes, filters, gloves) was disposable and new equipment was used at each site.

3.1.2 Field Procedures

Site-specific challenges, namely low surface water flow rates and low groundwater recharge rates, sometimes resulted in the use of alternative sampling methods. In the case of surface water samples, samples were sometimes collected using a syringe rather than submerging the bottle. Groundwater collection often required the use of the low-recharge method for groundwater sampling, described in Appendix B. The alternative methods for both surface- and groundwater sampling are acceptable methods; however, the use of these methods was considered in the interpretation of the data.

Groundwater and surface water samples have been collected by various consultants and sub-consultants since the program began in 2007 and groundwater sampling methods have changed over time as research regarding the validity of methods has been altered. The current acceptable methods for collecting groundwater involve the use of a submersible low-flow pump and are outlined in Appendix B. The acceptable groundwater sampling methods have been used to collect groundwater samples, under the direction of KP, since 2008; samples collected prior to 2008 were collected using bailers or foot valves, both of which are not considered acceptable methods for collecting representative samples. The validity of the analytical results collected using such methods have been evaluated based on turbidity and comparisons with other samples from the same dataset. Data were not rejected on the basis of unacceptable sampling methods alone; rather, samples collected using outdated sampling methods were evaluated more rigorously and were accepted or rejected on the basis of turbidity.

3.1.3 Turbidity

Samples were evaluated for validity based on laboratory and *in situ* turbidity readings using the framework shown on Figure A.1. Samples with turbidity greater than 200 NTU were rejected for all analyses. Sixteen such samples were identified (Table A.2), most of which were collected in 2007 and 2008, using outdated sampling methods (i.e. foot valves, which cause elevated turbidity) and are not expected to be representative of the groundwater. Samples with turbidity higher than the acceptable 50 NTU, but lower than the unacceptable 200 NTU were further investigated, but were not rejected entirely; rather, the metals analyses of such samples were compared with those of other samples collected from the same well and were rejected if the concentrations were outside the expected range. Rejected analyses are listed in Table A.3.

Table A.2 Sample Turbidity in Exceedance of the DQO (>200 NTU)

Site	Date	Turbidity (NTU)
AJGW01-D	Sep-07	*N/A*
AJGW01-D	Dec-07	>4000
AJGW01-D	Jul-08	1040
AJGW01-D	Sep-08	772
AJGW02-D	Sep-07	*N/A*
AJGW02-D	Dec-07	>4000
AJGW02-D	Mar-08	241
AJGW02-D	Sep-08	294
AJGW02-S	Dec-07	543
AJGW03-D	Sep-07	*N/A*
AJGW03-D	Dec-07	1180
AJGW03-D	Mar-08	>4000
AJGW04-D	Apr-08	1610
AJGW04-D	Jul-08	327
AJGW05-S	Jul-08	323
BGC14-006S	May-14	277

NOTES:
1. N/A INDICATES THAT TURBIDITY WAS NOT MEASURED, BUT IS SUSPECTED TO BE HIGH BASED ON THE TURBIDITY OF OTHER SAMPLES COLLECTED FROM THE SAME WELL DURING THE SAME YEAR.
2. ALL TURBIDITY MEASUREMENTS ARE LABORATORY MEASUREMENTS; *IN SITU* MEASUREMENTS WERE NOT REPORTED FOR ALL HISTORIC SAMPLES.

Table A.3 Analyses Rejected Based on High Turbidity (50 NTU to 200 NTU)

Site	Date	Turbidity (NTU)	Analyses	Notes
AJGW04-D	Sep-08	93.4	Dissolved Manganese	The dissolved manganese result for this sample (2.9 mg/L) was much higher than the lower turbidity sample collected from the same site (0.65 mg/L) and was rejected.
MW11-05D	Aug-12	50.9	Dissolved Chromium	The dissolved chromium result for this sample (0.0016 mg/L) was ten times higher than the lower turbidity samples collected from the same site and was rejected.
MW11-10D	Dec-11	68.1	Dissolved Selenium Dissolved Uranium	The dissolved selenium and uranium results for this sample were higher than the lower turbidity samples collected from the same site and were rejected.
AJGW03-D	Jul-08	128	Dissolved Aluminum Dissolved Cadmium	The dissolved aluminum and cadmium results for this sample were higher than the lower turbidity samples collected from the same site and were rejected.

NOTES:
1. ALL TURBIDITY MEASUREMENTS ARE LABORATORY MEASUREMENTS; IN SITU MEASUREMENTS WERE NOT REPORTED FOR ALL HISTORIC SAMPLES.

3.1.4 Measured pH

Seven samples were rejected on the basis of pH values greater than 10, which is indicative of grout contamination of the well. These samples, listed in Table A.4, may not be representative of baseline groundwater and should not be included in the data interpretation.

Table A.4 Analyses Rejected on the Basis of High pH

Site	Date	*In Situ* pH	Laboratory pH
AJGW02-D	Sep-07		11
AJGW02-D	Dec-07	11.8	11.4
BGC14-008D	May-14		12.4
KAX-14-121	May-14		11.6
MW11-01D	Oct-11	10.3	9.48
MW11-04D	Aug-11	11.1	10.8
MW11-04D	Oct-11	10.8	10.2

NOTES:

1. UNITS ARE pH UNITS.

3.2 ION BALANCE RESULTS

Almost all groundwater samples met the DQO for the ion balance criterion of 10%. Several samples collected in August 2012 were not analyzed for calcium and magnesium and were not included in the ion balance; rather, the ion balance of other samples collected from the same sites was used to provide an overview of the validity of the entire dataset. The ion balance results that did not meet the DQO are listed in Table A.5 and the results for all samples are listed in **Error! Reference source not found.**. Three of the samples flagged for ion balances were collected from BGC14-017S (maximum error 15%), which had high magnesium and calcium concentrations relative to samples collected from the deeper well in the same location, making the sum of common cations greater than that of anions. The highest ion balance error observed in the dataset was for a sample collected from AJGW02-S (21.8%) which had a very high sulphate concentration (2020 mg/L), causing a high sum of common anions. A second sample collected from the same well indicated a lower sulphate concentration (1260 mg/L), but still higher than the samples collected from other sites.

Table A.5 Ion Balance Exceedances of the DQO

Site ID	Date	Cation				Anion				Cation					Anion					Error

3.3 LABORATORY OPERATIONS ANALYSIS

ALS has their own internal QA/QC methods for verifying data. Laboratory QA/QC results were reported for matrix spikes, method blanks, laboratory control samples, reference materials, and duplicates/replicates. ALS laboratory reports also provided details regarding sampling hold times and sample integrity issues, a summary of major sample integrity issues are listed below.

- Container broken in transit
- Discrepancy between Chain of Custody (COC) and label
- Extra samples/bottles received but not listed on the COC
- Preservation incompatible with test
- Sample listed on COC but not received
- Temperature > 10 Celsius upon arrival at the lab

3.3.1 Laboratory Qualifiers

Very few of the results reported by the laboratories were categorized as rejected. In most cases where data were flagged by the laboratory, the issue resulted in an adjustment of the MDL and did not result in the exclusion of results from the statistical analysis. Reasons for the MDL adjustment included the requirement of further dilution of samples prior to analysis, the detection of an analyte in the Method Blank, and sample matrix effects. On several occasions, dissolved concentrations exceeded total concentrations; these were confirmed by re-analysis and were flagged, but not removed from the data set.

3.4 DETECTION LIMITS

The method detection limits of the laboratory analytical procedures are generally not higher than the relevant guidelines for any of the parameters except dissolved bromide, beryllium, cadmium, and selenium. Some water quality sites have very high TDS and matrix interference in the samples result in elevated MDL values, which exceed guidelines for some of the other parameters. All elevated MDL values are shown in tables in the data appendices, but are not shown as guideline exceedances. These potential guideline exceedances are specific to individual sites and are discussed in the text of the report. MDL guideline exceedances for bromide, beryllium, and cadmium apply to all samples.

3.4.1 Bromide

The BC drinking water working guideline for bromide and the HC drinking water guideline for bromate are 0.05 mg/L and 0.01 mg/L, respectively, while the MDL was 0.05 mg/L. Water within the project area is not considered a source of long-term drinking water for humans; however, the drinking water guidelines are used for reference but were excluded from the assessment reporting. The high MDL for bromide is currently being investigated and may be in part due to dilutions required because of other parameters that can cause matrix effects, such as chloride and sulphate.

3.4.2 Beryllium

The BC aquatic life working water quality guidelines were recently updated and the beryllium BCWQG-Max was lowered from the previous threshold of 0.053 mg/L to 0.00013 mg/L. The MDL for this parameter generally ranges from 0.0001 mg/L to 0.005 mg/L and many sample-specific MDL

values exceeded the guideline. ALS is currently in the process of refining their laboratory procedures to accommodate for this guideline.

3.4.3 Cadmium

There are both long-term and short-term exposure CEQG cadmium guidelines, which are hardness dependent. The long-term exposure values range from 0.0000679 mg/L up to 0.000170 mg/L and the short-term exposure values range from 0.000283 mg/L to 0.001640 mg/L (both for hardness values that range from 20.2 mg/L $CaCO_3$ to 2700 mg/L $CaCO_3$). The MDL for cadmium results ranged from 0.00001 mg/L to 0.000085 mg/L (total cadmium and dissolved cadmium).

KP has been working closely with ALS to achieve lower detection limits to investigate if the presence of cadmium was not being detected due to sample matrix interference with other analytes. A new method has recently been adopted for the analysis of samples with high non-detected levels of cadmium which have been adapted from “Recommended Guideline for Measuring Metals in Puget Sound Marin Water, Sediment and Tissue Samples” referred to as Puget Sound Protocols, EPA 6020A, Total Metals in Seawater by SPE ICPMS. Directly quoted from the ALS laboratory Certificate of Analysis reports for all samples analyzed by this method: A suspended particulate resin (SPR), consisting of immobilized iminodiacetate (IDA) on a divinylbenzene polymer, is used to chelated and preconcentrate metals in seawater. Instrumental analysis is by inductively coupled plasma mass spectrometry (ICPMS). This method was described through personal communication with Andre Langlais (ALS Environmental, Burnaby, BC) to result in the reduction of conductivity in the sample and leave behind at least 95% of the sample cadmium and results in clear ICPMS resolution of the cadmium signature. Cadmium sample concentrations that have resulted from this method are available for various samples collected between May 2014 and September 2014. The MDL achieved at these sites from 0.00002 mg/L for all sites during all sampling events, which was below both the long-term and short-term exposure guidelines. Cadmium concentrations that were reported by the seawater extract method (SWE) were typically greater than half the high non-detect MDL but less that the value equivalent to the MDL.

3.4.4 Selenium

Prior to October 2011, the MDL for selenium was equal to or half the guideline thresholds (BCWQG of 0.002 mg/L and the CEQG of 0.001 mg/L), depending on matrix interference. During this time, several guideline exceedances were observed that were close to the MDL. These results have not been rejected, but the high MDL has been considered in the interpretation of the data. After October 2011, the MDL was reduced to 0.0001 mg/L.

One outlier analysis for selenium was rejected (JACL-D; September 2008; dissolved and total concentrations of 0.0107 mg/L and 0.0171 mg/L, respectively) because the concentration was over 100 times most of the other detected values in the dataset. This result was reported at a time when elevated MDLs were common and, since it is within five times the MDL, it is considered an uncertain result.

3.4.5 Cyanide

The laboratory method used for cyanide analysis was updated in December 2011 and was fully implemented in May 2012. The main disadvantage of the previous method was that the presence of

thiocyanate and organics caused interference, which could have resulting in false positives. The updated method mitigates interference and increases the certainty in the data. Prior to May 2012, measureable concentrations of total cyanide were sporadically observed in water quality samples in association with samples that were analyzed using the superseded method. No concentrations above the MDL were observed in samples analyzed using the updated method. The concentrations that were measured above the MDL using the superseded method are likely false positives, given that all of the samples analyzed using the new method were below the MDL (ALS, 2015). Suspected false positive data is not discussed in the report; however, since the actual concentrations could not be confirmed, the results are still shown in the appendix tables, with the guideline exceedance highlighting not shown.

3.5 OFFICE DATA MANAGEMENT OPERATIONS

In the office, all *in situ* data and laboratory results from ALS laboratories were entered into FULCRUM. This task was completed by the field personnel who collected the samples and the entered data was checked regularly by other staff members. On the few occasions where an error in data entry was noted, the error was most commonly a unit conversion error. In these cases, the field personnel were informed of the non-conformance and the error was corrected.

3.6 QA/QC SAMPLE RESULTS

3.6.1 Blank Samples

A summary of the field blanks analyses that were flagged (i.e. samples with detectable parameters concentrations in excess of five times the MDL) are summarized in Table A.6 and all results of field blank analyses, including results below the MDL and results between the MDL and five times the MDL, are shown in Table A.6. Equipment blank results are provided in Table A.9.

The equipment blank collected on Sept 4th, 2013 had a result of 0.301 mg/L for dissolved sodium and 0.373 mg/L for total sodium, both of which are over five times the MDL of 0.05 mg/L. Similarly the equipment blank collected on Sept 24th, 2014 had a result of 0.343 mg/L for dissolved calcium and 0.385 mg/L for total calcium, both of which are over five times the MDL of 0.05 mg/L. Out of the 18 equipment blanks collected, five samples had analytes which were higher than five times the MDL. Analytes that were higher than five times the MDL in the equipment blanks include barium, manganese, calcium, copper, sodium, molybdenum, strontium and selenium. The contamination may have been cause by the improper decontamination of field sampling equipment prior to the collection of the sample.

Since May 2007, 95 field blanks have been collected and a total of seven samples collected had analytes which were higher than five times the MDL. The concentrations in the samples associated with the contaminated blank samples were not higher than the concentrations in other samples in the data set, therefore the results were not rejected.

Table A.6 Flagged Field Blank Sample Analyses

Sample Type	Date	Lab ID	Analyte	MDL	Blank Concentration (mg/L)
FIELD BLANK	9-Jul-08	L653846-3	Turbidity NTU	0.1	0.65
FIELD BLANK	18-May-11	L1007006-5	Manganese	5E-005 to 0.0015	0.00135

FIELD BLANK	19-Nov-13	L1394041-3	Barium	5E-005 to 0.02	0.000086
			Carbon Organic (Dissolved)	0.5 to 5	3.2
			Calcium	0.05 to 0.1	0.067
FIELD BLANK	13-May-14	L1454705-3	Molybdenum	5E-005 to 0.005	0.000417

3.6.2 Duplicate Samples

A summary of duplicate sample results for which the RPD between samples was greater than 20%, where one or both sample concentrations was greater than five times the MDL are listed in Table A.10 and A.11. There are several possible reasons for duplicate sample RPDs exceeding 20%. Natural variability in the water quality in surface water systems is a probably cause. Inconsistent sampling methods are another possibility. Detailed sampling procedure manuals and field staff training were used to minimize the chances of the latter. All data associated with duplicate samples exceeding the acceptable RPD of 20% for analyses higher in concentration than five times the MDL was flagged and further examined, but neither the site sample data nor the site data associated with the flagged duplicates were removed from the dataset used in the statistical analysis of results.

3.6.3 Metals Analysis

Sample analyses were flagged when dissolved concentrations of metals exceeded total concentrations of the same metals and one or both concentrations exceeded five times the MDL. Data were inspected when the difference was greater than 30%. In cases where the analytical result was different from the rest of the dataset (ex. total concentration was lower and dissolved concentration was higher than the other data), both the total and dissolved data were rejected. In certain instances the dissolved metals concentrations were replaced by the total metals concentration. A summary of the sample analyses that were flagged and qualified is shown in Table A.7.

NOTES:

1. UNITS ARE IN mg/L UNLESS OTHERWISE STATED.
2. BRITISH COLUMBIA WATER QUALITY GUIDELINES (APPROVED AND WORKING) - 30 DAY AVERAGE LIMITS (BCWQG-30 DAY AVERAGE) - FRESHWATER AQUATIC LIFE.
3. BRITISH COLUMBIA WATER QUALITY GUIDELINES (APPROVED AND WORKING) - MAXIMUM LIMITS (BCWQG-MAX) - FRESHWATER AQUATIC LIFE.
4. CANADIAN ENVIRONMENTAL QUALITY GUIDELINES - WATER QUALITY GUIDELINE FOR THE PROTECTION OF AQUATIC LIFE (CEQG-PAL) - FRESHWATER.
5. THIS SHADING INDICATES THAT THE VALUE EXCEEDS THE LIMITS OF THE BCWQG - 30 DAY AVERAGE GUIDELINES.
6. THIS SHADING INDICATES THAT THE VALUE EXCEEDS THE LIMITS OF THE BCWQG - MAXIMUM GUIDELINES.
7. THIS SHADING INDICATES THAT THE VALUED EXCEEDS THE LIMITS OF THE CEQG-PAL.
8. THIS SHADING INDICATES THAT THE VALUE EXCEEDS THE LIMITS OF THE BCWQG - 30 DAY AVERAGE AND THE BCWQG - MAXIMUM.
9. THIS SHADING INDICATES THAT THE VALUE EXCEEDS THE LIMITS OF THE BCWQG - 30 DAY AVERAGE AND THE CEQG-PAL.
10. THIS SHADING INDICATES THAT THE VALUE EXCEEDS THE LIMITS OF THE BCWQG-MAXIMUM AND THE CEQG-PAL.
11. THIS SHADING INDICATES THAT THE VALUE EXCEEDS ALL OF THE ABOVE LISTED GUIDELINES.
12. HARDNESS (H) DEPENDENT GUIDELINE LIMIT (DISSOLVED).
13. pH DEPENDENT GUIDELINE LIMIT (*IN SITU* VALUE PREFFERED).
14. TEMPERATURE DEPENDENT GUIDELINE LIMIT.
15. CHLORIDE (DISSOLVED) DEPENDENT GUIDELINE LIMIT.
16. GUIDELINE IS SPECIFIC TO DISSOLVED CONCENTRATION ONLY.
17. GUIDELINE IS SPECIFIC TO TOTAL CONCENTRATION ONLY.
18. GUIDELINE IS SPECIFIC TO LONG-TERM EXPOSURE.
19. GUIDELINE IS SPECIFIC TO SHORT-TERM EXPOSURE.
20. GUIDELINE IS APPLIED ONLY FOR WATERS OF DISSOLVED HARDNESS >250 mg/L AND IS DEPENDENT ON TOXICITY TESTING.
21. GUIDELINE IS APPLICABLE FOR Sb(III) ONLY.
22. ALL SHADING INDICATING EXCEEDANCE OF THE CEQG-PAL GUIDELINE FOR B, Cd, AND Cl REFERS TO THE LONG-TERM EXPOSURE GUIDELINES.

NOTES:

1. UNITS ARE IN mg/L UNLESS OTHERWISE STATED.
2. BCWQG - BC WATER QUALITY GUIDELINES FOR RAW DRINKING WATER (WORKING AND APPROVED).
3. HC - HEALTH CANADA - GUIDELINES FOR CANADIAN DRINKING WATER QUALITY - FTP COMMITTEE ON DRINKING WATER (DECEMBER 2010).
4. THIS SHADING INDICATED THAT THE VALUE EXCEEDS THE LIMITS OF THE BCWQG.
5. THIS SHADING INDICATED THAT THE VALUE EXCEED THE LIMITS OF THE HC - DRINKING WATER GUIDELINES.
6. THIS SHADING INDICATES THAT THE VALUE EXCEEDS THE BCWQG AND HC GUIDELINES FOR DRINKING WATER QUALITY.
7. GUIDELINES IN ITALICS ARE AESTHETIC OR OPERATIONAL GUIDELINES - NOT HEALTH-BASED.
