Table of Contents

1.0 INTRODUCTION 1-1

1.1 Project Context 1-7

1.2 Project Overview 1-10

1.3 Project Location 1-12

1.4 Proponent 1-16

1.4.1 Corporate History 1-16

1.4.2 Management Structure 1-17

1.4.3 Key Contact Information 1-19

1.5 Environment Policy 1-20

1.5.1 Health, Safety, Security, Environment and Quality Programs 1-20

1.5.2 Environmental Protection Program 1-21

1.6 Regulatory Framework 1-21

1.6.1 Federal Review Process 1-21

1.6.2 Relevant Standards, Codes and Guidelines 1-22

1.7 Documentation Framework 1-24

1.7.1 Licensing Documentation Interrelations 1-24

1.7.2 Structure of the Environmental Impact Statement 1-28

2.0 PURPOSE OF THE PROJECT AND ALTERNATIVES TO THE PROJECT 2-1

2.1 Introduction 2-1

2.2 CNL's Integrated Waste Strategy 2-1

2.3 Purpose of the Project 2-1

2.4 Project Design Principles 2-2

2.4.1 CNL Design Principles 2-2

2.4.2 Design Principles from External Sources 2-5

2.5 Alternative Means of Carrying out the Project 2-13

2.5.1 Evaluation Approach 2-13

2.5.2 Selection of Assessment Criteria 2-16

2.5.2.1 Technical Feasibility 2-19
2.5.2.2 Economic Feasibility 2-20
2.5.2.3 Safety 2-20
2.5.2.4 Environmental Effects 2-22
2.5.3 Selection of Alternative Means 2-24
2.5.4 Assessment of Alternatives 2-25
2.5.4.1 Alternative #1 – Deferred Dismantling and Removal 2-25
2.5.4.2 Alternative #2 – Immediate Dismantling and Removal 2-32
2.5.4.3 Alternative #3 – In Situ Disposal 2-36
2.5.4.4 Alternative #4 – Partial Dismantling and Removal with In Situ Disposal of the Remainder 2-42
2.5.4.5 Alternative #5 – In Situ Disposal Using Alternative Backfill Materials 2-44
2.5.4.6 Alternative #6 – Rolling Stewardship 2-45
2.6 Comparison of Alternatives 2-45
2.6.1 Technical Feasibility 2-46
2.6.2 Economic Feasibility 2-46
2.6.3 Safety 2-46
2.6.3.1 Worker Safety 2-46
2.6.3.2 Public Safety 2-47
2.6.4 Environmental Effects 2-49
2.6.4.1 Biophysical Environment 2-49
2.6.4.2 Socio-economic Environment 2-50
2.7 Conclusion 2-52
2.8 Sagkeeng's Alternative Means Assessment – Approach and Findings 2-56
2.8.1 Background Information 2-57
2.8.2 Introduction 2-57
2.8.3 Description of Sagkeeng's Alternative Means Assessment Report Results 2-58
2.8.3.1 Test 1 - Revised Scoring with CNL Weighting 2-60
2.8.3.2 Test 2 - Revised Weighting and Revised Scoring 2-62
2.8.3.3 Test 3 - Revised Scoring, Revised Weighting and Technical Uncertainties 2-64
2.8.3.4 Test 4 - Technical with Sagkeeng Preferred Weighting 2-66

2.8.3.5 Test 5 - Sagkeeng Guiding Questions “Pass/Fail Test” 2-67
2.8.3.6 Test 6 - Assessment using 13 Sagkeeng Priority Value-Based Preferences as Criteria ... 2-68
2.8.3.7 Test 7 - Assessment using Indigenous Rights and Interests Factors 2-70
2.8.3.8 Test 8 - Sagkeeng Perspectives on the Overall Ability of Each Alternative to receive the Necessary Consent from Sagkeeng 2-72
2.8.4 Sagkeeng’s Alternative Mean Assessment Conclusion 2-73
2.8.5 CNL Consideration of Sagkeeng’s Alternative Means Assessment 2-74
2.8.5.1 Considerations of Sagkeeng’s Tests 2-74
2.8.5.2 Considerations for an Off-site Disposal in a Purpose-built Facility 2-75
2.8.5.3 Considerations for Sagkeeng’s Preferred Decommissioning Methods - Alternatives 1 and 2 2-75
2.8.5.4 Conclusion of CNL’s Consideration of Sagkeeng’s Assessment 2-76

3.0 PROJECT DESCRIPTION 3-1

3.1 Introduction 3-1
3.1.1 Project Overview 3-1
3.1.2 Project Schedule 3-2
3.2 WR-1 Building Overview 3-3
3.2.1 Major Components in the WR-1 Building 3-5
3.2.1.1 The Reactor Vessel 3-5
3.2.1.2 Shielding 3-5
3.2.1.3 Heavy Water and Helium Systems 3-5
3.2.1.4 Primary Heat Transport System 3-8
3.2.2 WR-1 Auxiliary Systems 3-9
3.2.2.1 Water Supply and Drainage System 3-9
3.2.2.2 Spent Fuel Handling and Storage System 3-11
3.2.2.3 Active Ventilation System 3-14
3.2.2.4 Active Drainage System 3-14
3.2.2.5 Emergency Injection System 3-15
3.2.2.6 Other Supporting Systems 3-15
3.3 Current Status of WR-1 and the WR-1 Building 3-17
3.3.1 Decommissioning Activities Completed to Date 3-17

3.3.2 Remaining WR-1 Systems 3-17
3.3.3 Waste Classification, Inventory and Characterization 3-21
3.3.3.1 Radiological Hazards 3-21
3.3.3.2 Non-radiological Hazards 3-22
3.4 Project Requirements 3-26
3.4.1 Design Requirements 3-26
3.4.2 Strategic Requirements 3-26
3.4.3 Regulatory Requirements 3-27
3.4.4 Guiding Standards 3-27
3.4.5 Project Components 3-27
3.4.6 In Situ Disposal 3-30
3.4.6.1 Preparation for In Situ Disposal 3-30
3.4.6.2 Grouting of Below-Grade Structures and Systems 3-32
3.4.6.3 Removal of Above-Grade WR-1 Building Structures 3-34
3.4.6.4 Installation of Concrete Cap and Engineered Cover 3-34
3.4.6.5 Final Site Restoration 3-35
3.4.6.6 Preparation for Institutional Control 3-35
3.4.7 Temporary Supporting Infrastructure 3-35
3.4.8 Waste Generation and Management 3-35
3.4.8.1 Radiological Wastes 3-36
3.4.8.2 Hazardous Non-radiological Wastes 3-36
3.4.8.3 Clean Wastes and Likely Clean Wastes 3-36
3.4.8.4 Transporting Waste Off-Site 3-36
3.4.9 End-State and Post-closure Activities 3-37
3.4.9.1 In Situ Disposal System 3-37
3.4.9.2 Post-closure Activities 3-45
3.4.10 Human Resource Requirements and Expenditures 3-48
4.0 INDIGENOUS ENGAGEMENT 4-1
4.1 Introduction 4-1
4.1.1 Regulatory Requirements 4-2

4.2 Indigenous Engagement 4-4
4.2.1 Engagement Objectives 4-7
4.2.2 Identified First Nations and the Red River Métis 4-9
4.2.3 Engagement Methods 4-12
4.2.4 Summary of Engagement 4-14
4.2.4.1 Sagkeeng First Nation 4-17
4.2.4.2 Manitoba Métis Federation 4-50
4.2.4.3 Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation (2016 – Autumn 2020) 4-69
4.2.4.4 Wabaseemoong Independent Nations 4-93
4.2.4.5 Shoal Lake #40 First Nation 4-102
4.2.4.6 Iskatewizaagegan No. 39 Independent First Nation 4-103
4.2.4.7 Northwest Angle No. 33 (Treaty No. 3) 4-104
4.2.4.8 Peguis First Nation 4-105
4.2.4.9 Grand Council Treaty #3 4-106
4.2.5 Future Engagement Activities Planned 4-111
4.2.5.1 Short-term Initiatives and Engagements 4-111
4.2.5.2 Long-term Initiatives and Engagements 4-112
4.3 Influence of Traditional Knowledge on the Environmental Assessment 4-113
4.4 Summary of Issues Raised During Engagement Activities that Influenced the Environmental Impact Statement 4-114
4.5 CNL's Long-term Relationship with Indigenous Nations 4-120
5.0 PUBLIC AND STAKEHOLDER ENGAGEMENT 5-1
5.1 Engagement Objectives 5-2
5.1.1 Evaluation 5-3
5.2 Engagement Methods and Activities 5-5
5.2.1 Public Liaison Committee Meetings 5-5
5.2.2 Whiteshell Community Regeneration Partnership Meetings 5-6
5.2.3 Municipal Engagement 5-7
5.2.4 Presentations and Tours 5-7
5.2.5 Public Open Houses 5-8

5.2.6 Virtual Visitor Centre 5-9
5.2.7 Poster Boards 5-9
5.2.8 Webinars 5-9
5.2.9 Breakfast Sessions 5-11
5.2.10 Community Engagement Activities and Conferences 5-11
5.2.11 Employee-Focused Engagement 5-12
5.2.12 Alumni Technical Workshop 5-13
5.2.13 Web Page Content 5-13
5.2.14 External Newsletter – Whiteshell CONTACT 5-13
5.2.15 Email 5-14
5.2.16 Advertising Methods 5-14
5.2.17 Intranet – myCNL 5-14
5.2.18 Internal Newsletters – The Loop and Voyageur 5-14
5.2.19 CNL Social Media 5-15
5.2.20 Media Coverage 5-16
5.2.21 Responding to Information Requests 5-16
5.2.22 Document Repository – November 2017 – July 2024 5-17
5.2.23 Release of Documents – 2017 – September 2022 5-17
5.2.24 Participant Funding 5-17
5.3 Public Feedback and Response 5-17
5.3.1 Public Engagement Feedback 5-18
5.3.2 Formal Public Comments 5-30
5.4 Planned Future Engagements 5-30
5.4.1 Implications of the 2023 Whiteshell Safety Stand Down 5-31
5.4.2 Implications of the COVID-19 Pandemic 5-31
5.5 Conclusions 5-31
6.0 ENVIRONMENTAL EFFECTS 6-1
6.1 Environmental Assessment Approach 6-1
6.1.1 Scope of the Assessment 6-2
6.1.2 Traditional Knowledge and Indigenous Engagement Feedback 6-3

6.1.3 Valued Components 6-3
6.1.4 Assessment Boundaries 6-17
6.1.4.1 Spatial Boundaries 6-17
6.1.4.2 Temporal Boundaries 6-20
6.1.4.3 Assessment Cases 6-22
6.1.5 Description of the Environment 6-23
6.1.6 Project Interactions and Mitigation 6-24
6.1.7 Residual Effects Analysis 6-25
6.1.7.1 Application Case 6-25
6.1.7.2 Reasonably Foreseeable Development Case 6-26
6.1.8 Prediction Confidence and Uncertainty 6-27
6.1.9 Residual Effects Classification and Determination of Significance 6-28
6.1.9.1 Residual Effects Classification 6-28
6.1.9.2 Determination of Significance 6-30
6.1.10 Monitoring and Follow-up 6-32
6.2 Atmospheric Environment 6-31
6.2.1 Air Quality 6-31
6.2.1.1 Scope of the Assessment 6-31
6.2.1.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-32
6.2.1.3 Valued Components 6-33
6.2.1.4 Assessment Boundaries 6-35
6.2.1.5 Description of the Environment 6-41
6.2.1.6 Project Interactions and Mitigation 6-52
6.2.1.7 Residual Effects Analysis 6-58
6.2.1.8 Prediction Confidence and Uncertainty 6-69
6.2.1.9 Residual Effects Classification and Determination of Significance 6-70
6.2.1.10 Monitoring and Follow-up 6-73
6.2.1.11 Conclusions 6-75
6.2.2 Greenhouse Gases 6-79
6.2.2.1 Scope of the Assessment 6-79

6.2.2.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-80
6.2.2.3 Valued Components 6-80
6.2.2.4 Assessment Boundaries 6-81
6.2.2.5 Description of the Environment 6-81
6.2.2.6 Project Interactions and Mitigation 6-82
6.2.2.7 Prediction Confidence and Uncertainty 6-87
6.2.2.8 Monitoring and Follow-up 6-87
6.2.2.9 Conclusions 6-89
6.3 Geological and Hydrogeological Environment 6-91
6.3.1 Geology 6-91
6.3.1.1 Scope of the Assessment 6-91
6.3.1.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-92
6.3.1.3 Valued Components 6-92
6.3.1.4 Assessment Boundaries 6-93
6.3.1.5 Description of the Environment 6-98
6.3.1.6 Project Interactions and Mitigation 6-126
6.3.1.7 Monitoring and Follow-up 6-129
6.3.1.8 Conclusions 6-130
6.3.2 Hydrogeology 6-131
6.3.2.1 Scope of the Assessment 6-131
6.3.2.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-132
6.3.2.3 Valued Components 6-133
6.3.2.4 Assessment Boundaries 6-134
6.3.2.5 Description of the Environment 6-138
6.3.2.6 Project Interactions and Mitigation 6-157
6.3.2.7 Residual Effects Analysis 6-160
6.3.2.8 Prediction Confidence and Uncertainty 6-162
6.3.2.1 Monitoring and Follow-up 6-163
6.3.2.2 Conclusions 6-165
6.4 Surface Water Environment 6-169

6.4.1 Hydrology 6-169
6.4.1.1 Scope of the Assessment 6-169
6.4.1.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-170
6.4.1.3 Valued Components 6-170
6.4.1.4 Assessment Boundaries 6-171
6.4.1.5 Description of the Environment 6-176
6.4.1.6 Project Interactions and Mitigation 6-182
6.4.1.7 Monitoring and Follow-up 6-184
6.4.1.8 Conclusions 6-185
6.4.2 Surface Water Quality 6-187
6.4.2.1 Scope of the Assessment 6-187
6.4.2.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-188
6.4.2.3 Valued Components 6-189
6.4.2.4 Assessment Boundaries 6-190
6.4.2.5 Description of the Environment 6-196
6.4.2.6 Project Interactions and Mitigation 6-214
6.4.2.7 Residual Effects Analysis 6-221
6.4.2.8 Prediction Confidence and Uncertainty 6-235
6.4.2.9 Monitoring and Follow-up 6-236
6.4.2.10 Conclusions 6-239
6.5 Aquatic Environment 6-243
6.5.1 Scope of the Assessment 6-243
6.5.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-244
6.5.3 Valued Components 6-244
6.5.4 Assessment Boundaries 6-246
6.5.4.1 Spatial Boundaries 6-246
6.5.4.2 Temporal Boundaries 6-249
6.5.4.3 Assessment Cases 6-249
6.5.5 Description of the Environment 6-250
6.5.5.1 Methods 6-250

6.5.5.2 Results 6-250
6.5.6 Project Interactions and Mitigation 6-262
6.5.6.1 Methods 6-262
6.5.6.2 Results 6-263
6.5.7 Monitoring and Follow-up 6-272
6.5.8 Conclusions 6-273
6.6 Terrestrial Environment 6-275
6.6.1 Scope of the Assessment 6-275
6.6.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-276
6.6.3 Valued Components 6-277
6.6.4 Assessment Boundaries 6-283
6.6.4.1 Spatial Boundaries 6-283
6.6.4.2 Temporal Boundaries 6-287
6.6.4.3 Assessment Cases 6-287
6.6.5 Description of the Environment 6-289
6.6.5.1 General Overview 6-289
6.6.5.2 Methods 6-292
6.6.5.3 Barn Swallow 6-297
6.6.5.4 Golden-winged Warbler 6-299
6.6.5.5 Bats 6-302
6.6.5.6 Snapping Turtle 6-307
6.6.5.7 Traditional Knowledge 6-309
6.6.6 Project Interactions and Mitigation 6-310
6.6.6.1 Methods 6-310
6.6.6.2 Results 6-311
6.6.7 Monitoring and Follow-up 6-323
6.6.8 Conclusions 6-327
6.7 Human and Ecological Health 6-329
6.7.1 Human Health 6-329
6.7.1.1 Scope of the Assessment 6-329

6.7.1.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-331
6.7.1.3 Valued Components 6-332
6.7.1.4 Assessment Boundaries 6-333
6.7.1.5 Description of the Environment 6-339
6.7.1.6 Project Interactions and Mitigation 6-342
6.7.1.7 Residual Effects Analysis 6-347
6.7.1.8 Prediction Confidence and Uncertainty 6-387
6.7.1.9 Residual Effects Classification and Determination of Significance 6-390
6.7.1.10 Monitoring and Follow-up 6-391
6.7.1.11 Conclusions 6-395
6.7.2 Ecological Health 6-398
6.7.2.1 Scope of the Assessment 6-398
6.7.2.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-400
6.7.2.3 Valued Components 6-401
6.7.2.4 Assessment Boundaries 6-403
6.7.2.5 Description of the Environment 6-406
6.7.2.6 Project Interactions and Mitigation 6-406
6.7.2.7 Residual Effects Analysis 6-410
6.7.2.8 Prediction Confidence and Uncertainty 6-428
6.7.2.9 Residual Effects Classification and Determination of Significance 6-430
6.7.2.10 Monitoring and Follow-up 6-431
6.7.2.11 Conclusions 6-435
6.8 Land and Resource Use 6-437
6.8.1 Traditional Land and Resource Use 6-437
6.8.1.1 Scope of the Assessment 6-437
6.8.1.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-438
6.8.1.3 Valued Components 6-441
6.8.1.4 Assessment Boundaries 6-444
6.8.1.5 Description of the Environment 6-448
6.8.1.6 Project Interactions and Mitigation 6-481

6.8.1.7 Monitoring and Follow-up 6-493
6.8.1.8 Conclusions 6-495
6.8.2 Other Land and Resource Use 6-496
6.8.2.1 Scope of the Assessment 6-496
6.8.2.2 Public Engagement Feedback – Key Interests and Concerns 6-497
6.8.2.3 Valued Components 6-498
6.8.2.4 Assessment Boundaries 6-499
6.8.2.5 Description of the Environment 6-501
6.8.2.6 Project Interactions and Mitigation 6-511
6.8.2.7 Monitoring and Follow-up 6-519
6.8.2.8 Conclusions 6-520
6.9 Socio-economic Environment 6-523
6.9.1 Scope of the Assessment 6-523
6.9.2 Indigenous Engagement Feedback – Key Interests and Concerns 6-524
6.9.3 Valued Components 6-527
6.9.4 Assessment Boundaries 6-530
6.9.4.1 Spatial Boundaries 6-530
6.9.4.2 Temporal Boundaries 6-533
6.9.4.3 Assessment Cases 6-533
6.9.5 Description of the Environment 6-534
6.9.5.1 Methods 6-534
6.9.5.2 Results 6-536
6.9.6 Project Interactions and Mitigation 6-588
6.9.6.1 Methods 6-588
6.9.6.2 Results 6-589
6.9.7 Monitoring and Follow-up 6-600
6.9.8 Conclusions 6-601
7.0 ACCIDENTS AND MALFUNCTIONS 7-1
7.1 Indigenous Engagement Feedback – Key Interests and Concerns 7-1
7.2 Methods 7-2

7.2.1 Hazard Identification 7-2
7.2.1.1 Radiological Hazards 7-4
7.2.1.2 Non-radiological Hazards 7-5
7.2.2 Risk Measurement 7-7
7.2.3 Risk Evaluation 7-8
7.3 Accidents and Malfunctions 7-9
7.3.1 Conventional Occupational Accidents 7-9
7.3.1.1 Hazard Identification 7-9
7.3.1.2 Risk Measurement and Evaluation 7-11
7.3.2 Spills and Leaks 7-11
7.3.2.1 Hazard Identification 7-11
7.3.2.2 Risk Measurement and Evaluation 7-14
7.3.3 Material Handling Accidents 7-14
7.3.3.1 Hazard Identification 7-14
7.3.3.2 Risk Measurement and Evaluation 7-16
7.3.4 Off-site Transportation Accidents 7-16
7.3.4.1 Hazard Identification 7-16
7.3.4.2 Risk Measurement and Evaluation 7-17
7.3.5 System and Equipment Failure 7-18
7.3.5.1 Hazard Identification 7-18
7.3.5.2 Risk Measurement and Evaluation 7-19
7.3.6 Fires and Explosions 7-19
7.3.6.1 Hazard Identification 7-19
7.3.6.2 Risk Measurement and Evaluation 7-24
7.3.7 Aircraft Crash 7-24
7.3.7.1 Hazard Identification 7-24
7.3.7.2 Risk Measurement and Evaluation 7-25
7.4 Summary of Risk Evaluation for Accidents and Malfunctions 7-25
8.0 SUMMARY OF CUMULATIVE EFFECTS 8-1
8.1 Introduction and Approach 8-1

8.2 Reasonably Foreseeable Projects 8-3
8.3 Summary of Cumulative Residual Effects 8-4
8.3.1 Atmospheric Environment 8-4
8.3.2 Physical Environment 8-5
8.3.2.1 Geology 8-5
8.3.2.2 Hydrogeology 8-5
8.3.3 Surface Water Environment 8-6
8.3.3.1 Hydrology 8-6
8.3.3.2 Surface Water Quality 8-6
8.3.4 Aquatic Environment 8-8
8.3.5 Terrestrial Environment 8-8
8.3.6 Human and Ecological Health 8-9
8.3.6.1 Human Health 8-9
8.3.6.2 Ecological Health 8-10
8.3.7 Land and Resource Use 8-10
8.3.8 Socio-economic Environment 8-12
8.4 Summary 8-12
9.0 SUMMARY OF SIGNIFICANCE OF RESIDUAL EFFECTS 9-1
9.1 Introduction and Approach 9-1
9.2 Summary of the Significance of Residual Effects 9-4
9.2.1 Atmospheric Environment 9-4
9.2.1.1 Air Quality 9-4
9.2.1.2 Greenhouse Gases 9-5
9.2.2 Geology and Hydrogeology 9-6
9.2.2.1 Geology 9-6
9.2.2.2 Hydrogeology 9-6
9.2.3 Surface Water Environment 9-7
9.2.3.1 Hydrology 9-7
9.2.3.2 Surface Water Quality 9-8
9.2.4 Aquatic Environment 9-8

9.2.5 Terrestrial Environment 9-9
9.2.6 Human and Ecological Health 9-11
9.2.6.1 Human Health 9-11
9.2.6.2 Ecological Health 9-13
9.2.7 Land and Resource Use 9-14
9.2.7.1 Traditional Land and Resource Use 9-14
9.2.7.2 Other Land and Resource Use 9-15
9.2.8 Socio-economic Environment 9-16
9.3 Summary 9-19
10.0 ASSESSMENT OF EFFECTS OF THE ENVIRONMENT ON THE PROJECT 10-1
10.1 Indigenous Engagement Feedback – Key Interests and Concerns 10-1
10.2 Extreme Weather Events 10-2
10.2.1 Temperature Fluctuations 10-2
10.2.2 Extreme Rainfall Events, Snowmelts and Flooding 10-2
10.2.3 Heavy Snowfall 10-3
10.2.4 Tornado/Extreme Wind 10-3
10.3 Forest Fires 10-4
10.4 Seismic Events 10-5
10.5 Climate Change 10-6
10.5.1 Summary of Climate Change Trends 10-6
10.5.1.1 Climate Change Effects on the Project 10-6
10.5.1.2 Global Climate Change Trends 10-7
10.5.1.3 Current Climate Trends 10-8
10.5.1.4 Future Climate Conditions 10-8
10.5.2 Climate Change Resilience Assessment 10-12
10.5.2.1 Approach for the Climate Change Resilience Assessment 10-12
10.5.2.2 Likelihood, Consequence and Risk Ranking Scales 10-13
10.5.2.3 Climate-Infrastructure Interactions 10-15
10.5.2.4 Climate Change Resilience Profile 10-16
10.5.2.5 Summary of Climate Change Resilience 10-19

10.6 Glaciation 10-19

1.0 INTRODUCTION

The Whiteshell Laboratories (WL) site at Pinawa, Manitoba was established in the 1960s by Atomic Energy of Canada Limited (AECL) to conduct nuclear research. The Whiteshell Reactor 1 (WR-1) provided a facility for engineering tests and scientific studies on alternative fuels, fuel channels and reactor coolants. Whiteshell Laboratories was also home to other significant research programs, including the Nuclear Fuel Waste Management Program, the demonstration reactor, and reactor safety analysis.

The WL site is located in southeastern Manitoba (Figure 1.0-1) and was operated for approximately 40 years under an operating licence issued by the Atomic Energy Control Board. In May 2000, the *Nuclear Safety and Control Act* (NSCA) came into force creating the Canadian Nuclear Safety Commission (CNSC). Since then, the WL site has been operated first under an operating licence and then under a decommissioning licence (since March 2002) issued by the CNSC. WR-1 is housed within the WR-1 Complex, which is located entirely within the WL site main campus (Figure 1.0-2). The WR-1 had a nominal thermal output of 60 megawatts (MW), approximately equivalent to 20 MW electric. The reactor operated from 1965 to 1985. A first phase of decommissioning occurred in the early 1990s and included the removal of easily mobilized radioactive material (e.g., fuel and fluids) and decontamination of the main floor and first sublevel space. Equipment was decommissioned and removed from the main reactor hall floor and one floor below-grade and placed in interim storage. The removal of fuel, liquids and equipment substantially reduced radioactivity. Activated materials and residual corrosion and fission products have been undergoing decay for over 30 years. Currently, WR-1 is under a storage with surveillance program.

In 1998, AECL made a decision to decommission the WL site. A Comprehensive Study Report (CSR; AECL 2001) under the *Canadian Environmental Assessment Act, 1992* was completed for the decommissioning project. The CNSC and Department of Fisheries and Oceans were the Responsible Authorities. The environmental assessment decision to approve the decommissioning project was announced by the federal Minister of the Environment in March 2002 and a decommissioning licence was issued.

In 2013, the Minister of Natural Resources announced plans to restructure AECL and move to a Government-owned, Contractor-operated management model. In 2014, AECL created Canadian Nuclear Laboratories (CNL), a wholly owned subsidiary of AECL, as the Site Operating Company and holder of all CNSC site licences to manage all work performed at AECL sites on behalf of AECL. In September of 2015, a contract was awarded to Canadian National Energy Alliance (CNEA) and ownership of CNL was transferred to CNEA. CNL retained ownership of all CNSC licences and is the operator of all AECL sites.

CNL is a private-sector company that is contractually responsible for the management, operation and decommissioning of nuclear sites, facilities and assets owned by AECL, which is a federal Crown corporation. CNL is performing the decommissioning of the WL site with the planned outcome of complete site closure by 2034. CNL is licensed to perform this work under a CNSC decommissioning licence. Enabled by the CSR approval and the site decommissioning licence, CNL is authorized to decommission WR-1 by means of dismantling and demolition.

CNL is now applying for an amendment to the current decommissioning licence to carry out In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project), rather than dismantling and demolition as previously assessed in the CSR. The in situ disposal (ISD) approach includes partial dismantling and demolition along with passive, permanent disposal of the below-grade portions of WR-1. ISD is a proven decommissioning approach that increases worker safety, provides protection of the environment and the public, reduces interim storage and multiple handling, enables permanent nuclear liability reduction, and utilizes

fewer resources. All other decommissioning activities as outlined in the CSR remain the same and are not the subject of this Environmental Impact Statement (EIS).

CNL is proposing the execution of this designated Project on land that is held in the name of AECL. As such, CNL is the proponent for the Project.

In situ disposal is a departure from the end-states defined in the CSR. As a result, the Project qualifies as a designated project under Section 37(b) of the Regulations Designating Physical Activities (SOR/2012-147) of the *Canadian Environmental Assessment Act, 2012* (CEAA 2012) as a project related to "the long-term management or disposal of irradiated fuel or nuclear waste." A key element of the regulatory approvals process is the completion of an environmental assessment under CEAA 2012, the results of which are documented in this EIS. The environmental assessment is an iterative project planning process, intended to affirm that proposed activities will not cause significant adverse environmental effects. The assessment is completed to demonstrate that proposed activities can be safely completed in compliance with the prescribed protective limits, including radiological doses to workers and members of the public and the releases of contaminants to the surrounding environment. The environmental assessment considers the closure phase (which includes decommissioning and reclamation) and long-term performance during the post-closure phase (which includes institutional control and post-institutional control).

1.1 Project Context

The WR-1 Complex (Figure 1.1-1, also known as Building 100) includes the WR-1 Building, the east annex and the service wing. The east annex and the service wing contain office space and supporting facilities. The WR-1 Building is seven storeys tall, with two storeys above-grade and five below-grade, and contains the WR-1 (Figure 1.1-2). The majority of the remaining contamination in WR-1 is located in the reactor core. Due to its small size, even when it was operating, WR-1 contained considerably less radioactive material than large power reactors.

The approved decommissioning approach for the WL site, as described in the CSR, was to remove all facilities with the exception of low-level waste trenches in the Waste Management Area (WMA), and existing contaminated river sediments, which may be managed through ISD (AECL 2001). The approved decommissioning approach for WR-1 proposed complete removal and remediation of the WR-1 Building (Licence No. NRTEDL-W5-8.00/2024). Prior to demolition of the WR-1 Building, all activated and contaminated components would have been removed, packaged and disposed at off-site facilities (AECL 2001). The facility structure would have been decontaminated and then demolished to achieve unrestricted release criteria. The dismantling and remediation activities previously approved for WR-1 Building included (AECL 2001):

- removal of reactor vault components;
- removal of process piping and equipment;
- transfer of radioactive waste to off-site facilities;
- decontamination of the building structure;
- demolition of the above-grade building structure; and
- remediation of the site to a “natural state.”

AECL's mandate is to manage its radioactive waste and decommissioning liabilities in a safe and environmentally responsible manner. AECL has asked CNL to perform the work, and in keeping with international best practices (IAEA 2004, 2006), the decommissioning timeframe has been accelerated with the goal of completing decommissioning of the WL main campus by 2034. Over the past 10 years, multiple buildings and facilities at the WL site have been decommissioned and the land remediated. In an effort to continue to safely reduce AECL's nuclear legacy liabilities and reduce the need for interim storage of radioactive waste, CNL began to investigate other options that would allow the WR-1 Building to be decommissioned safely. The new proposed approach is ISD, which allows CNL to decommission the WR-1 Building in a safe, compliant manner that reduces the need for interim storage and continued human intervention and provides protection of the public and the environment.

1.2 Project Overview

CNL is proposing an ISD approach to the decommissioning of the WR-1 Building. The ISD system is a permanent, passive decommissioning end-state that uses multiple barriers to contain the waste, providing time for the radioactive materials to decay to safe levels. The below-grade reactor systems, components and structures will be permanently encased in grout. The above-grade structures will be demolished and removed. During decommissioning, consideration will be given to placing some equipment from the primary heat transport system that is currently located on the ground-level reactor floor to a below-grade position for incorporation in the disposal system. A concrete cap and engineered cover will then be constructed over the below grade structure to resist intrusion and divert precipitation and surficial runoff. The final disposal configuration is referred to as the Whiteshell Reactor Disposal Facility (WRDF).

The Project activities assessed in this EIS are limited to ISD of the WR-1 Building. Other decommissioning activities for the WL site, documented in the CSR, have not changed and do not need to be reassessed. Removal of the east annex and service wings of the WR-1 Complex were assessed as part of the CSR and are covered under CNL's existing decommissioning licence for the WL site (Licence No. NRTEDL-W5-8.00/2024). Some activities required prior to ISD, such as isolation of the WR-1 Complex and targeted remediation of hazardous materials, are also covered under CNL's existing decommissioning licence for the WL site.

The decommissioning activities for the WR-1 Building proposed as part of the Project and assessed in this EIS include:

- preparing the building and equipment for ISD;
- establishing temporary and supporting infrastructure;
- grouting of below-grade structures and systems;
- removing above-grade structures and systems, except for the east annex and service wings[1];
- installing a concrete cap and engineered cover over the grouted below-grade structures and systems;
- final site restoration;
- preparation for institutional control; and
- institutional control (includes both passive and active controls).

Details about each of the Project activities and components are provided in Section 3.0 Project Description.

CNL plans to start preparation and implementation of ISD in 2026, which includes grouting of below-grade structures and systems, removal of above-grade WR1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration (pending approval by the CNSC). The Project site will be turned over for institutional control in 2031. Institutional control includes active controls such as environmental monitoring and site surveillance, as well as passive controls such as access restrictions (e.g., physical barriers/fencing, signage, and land title instruments/deed restrictions). It is recognized that institutional control will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer

[1] The removal of the east annex and service wing is included in CNL's existing decommissioning licence for the WL site, which is documented in the CSR, and is therefore not part of the Project.

needed. This is consistent with similar nuclear decommissioning projects completed by the United States Department of Energy such as:

- Feed Materials Production Center in Ohio;
- Mound Plant in Ohio; and
- Rocky Flats Plant in Colorado.

CNL recommends that institutional control continues for a minimum of 100 years. The 100year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. After the institutional control period ends, the post-institutional control period begins and continues indefinitely. The schedule for the proposed decommissioning activities is provided in Table 1.2-1.

Table 1.2-1: WR-1 Decommissioning Project Phases and Schedule

	Description	Planned Schedule[(a)]
Closure Phase		
1	Preparation for ISD	24 months prior to 24 months following EA approval
	WR-1 Deactivation and Segregation Complete	6 months prior
2	Grouting of Below-grade Systems and Structures	12 – 24 months
	In situ Decommissioning Grouting Complete	22 years
3	Removal of Above-grade Structures	6-24 months
	WR-1 Building Demolition and Decommissioning Complete	3 years
4	Installation of Concrete Cap and Engineered Cover	3 years
5	Final Site Restoration	3.5 years
6	Preparation of Institutional Control	3.5-4 years
	Site Turnover for Institutional Control and Monitoring	44 years
Post-closure Phase		
7	Institutional Control	0 – 100 years (minimum)
8	Post-Institutional Control	100 years onwards

(a) Time following EA Approval

For the purposes of the environmental assessment, the temporal boundaries are assumed to be 2026 to 2030 for the Closure Phase and 2031 to 2131 for institutional control. Post-institutional control occurs after 2130 and continues indefinitely. However, it is recognized that these dates are subject to change pending receipt of environmental assessment and licensing approvals.

1.3 Project Location

The WL site is located in southeastern Manitoba, approximately 100 km northeast of Winnipeg (Figure 1.0-1). The WL site occupies 4,375 ha of land that was either privately owned or Crown land before the establishment of Whiteshell Laboratories. Currently, AECL, a federal government Crown corporation, holds the title to the WL site lands. Access to these areas has generally been restricted for security and safety. The WL site is within the boundaries of the Local Government District of Pinawa (Figure 1.0-1). The WL site contains several nuclear facilities, including WR-1, the WMA, and other nuclear and non-nuclear facilities and laboratories. The Winnipeg River passes through the WL site, with a small portion of the WL site located on the west side of the river. The Project is located entirely within the WL site (Figure 1.0-2). The approximate geographic coordinates of the Project are 50°10′ 46″N and 96°03′ 35″W.

The Winnipeg River is the dominant drainage feature in the area. At the WL site, the river is approximately 0.3 km wide, 7 m deep and flows in a northerly direction. Surface water runoff at the WL site drains into the Winnipeg River via natural and engineered drainage features, such as stormwater management system and ditches. The regional surficial geology comprises widespread deposits of till and glacio-fluvial and glaciolacustrine clay and silt materials. In the immediate vicinity of the WL site there are approximately 10 to 20 m of surficial overburden soils overlying Precambrian bedrock. Hydrogeological characterization at the WL main campus has shown overburden thickness in the area is up to 15 m thick. The stratigraphic units in sequence from bedrock upwards are silty sand till, clayey silt till, silty clay and an upper soil complex comprised of laminated clayey silt with minor interbeds of massive silty clay and up to 0.25 m of surface organics. The foundation of the WR-1 Building extends down to the bedrock. Groundwater flow at WR-1 is towards the Winnipeg River.

Terrestrial habitat at the WL site is diverse over short distances. Large tracts of wetland cover the easterly portions of the WL site, with black spruce common. Farther to the west are poorly drained clay plains, forested land including tree species such as ash and poplar, and agricultural areas. Land closer to the Winnipeg River includes gullies and ravines where beaver dams are common.

Nearby communities include the Town of Lac du Bonnet (9 km north of the WL site; population of approximately 1,300); the Local Government District of Pinawa (10 km east of the WL site; population of approximately 1,400); and Seven Sisters Falls (located 3.5 km south of the WL site and part of the rural municipality of Whitemouth; total population of approximately 1,550). The closest permanent residents to the Project reside to the west of the Winnipeg River along Highway 11, approximately 2 km from the WL site.

Aside from the operations and activities undertaken by CNL, other land uses of the WL site are prohibited due to restricted public access. No hunting or fishing is permitted on the WL site. Land use in the region includes forestry, recreation and tourism, hunting, trapping, fishing and agriculture (AECL 2001). Forestry is a strong industry in the region, although little, if any, forestry has occurred in the local area. The WL site is located 7 km northwest of the Whiteshell Provincial Park and 49 km southwest of the Nopiming Provincial Park, both of which are prime outdoor recreation areas in eastern Manitoba. Home and cottage development along the west side of the Winnipeg River suggests that waterways, scenery, trails and wildlife of the region are attracting vacationers and weekend campers. Sport fishing is very popular in the Winnipeg River. Agricultural operations in the region include cereal crop production, hay, flax, canola and alfalfa crops, and dairy and livestock production.

Historic treaties called the Numbered Treaties, which were agreements made between the Government of Canada and Indigenous Nations, cover much of the land in the region and set out continuing treaty rights and benefits. The majority of the WL site is located on Treaty 3 land. A small portion of the WL site that extends west of the

Winnipeg River falls on Treaty 1 land. Communities that are signatories to these Treaties and Treaty 5 have historical and current land use ties with the area. Anishinaabe and Ojibway communities with historical traditional territories in the area, and that have expressed some level of interest in the Project include the Sagkeeng First Nation and Brokenhead First Nations in Treaty 1; Black River and Hollow Water First Nations in Treaty 5; and Wabaseemoong Independent Nations in Treaty 3 (TRCM 2013; Ontario Ministry of Indigenous Affairs 2017). There are no reserve lands located within the WL site.

Indigenous Nations in vicinity to the WL site are described below and additional detail can be found in Section 6.8.1.5.2.2 Traditional Land Use by Indigenous Peoples.

- **Sagkeeng First Nation**, an Anishinaabe community, is the closest Indigenous Nation to the WL site. Sagkeeng reserve land is located 52 km directly downriver from the WL site and includes land parcels on either side of the Winnipeg River.
- **Brokenhead Ojibway Nation** is located near the southern basin of Lake Winnipeg, occupies three reserves: 44 km northwest, 55 km northwest and 73 km southwest of the WL site. Brokenhead is primarily surrounded by the Rural Municipality of St. Clements.
- **Black River First Nation** is an Ojibway community located along the eastern shoreline of Lake Winnipeg at the confluence of the Black and O'Hanly Rivers. The Black River reserve land is 75 km north of the WL site.
- **Hollow Water First Nation**, an Anishinaabe community, is located along the eastern shore of Lake Winnipeg approximately 113 km north of the WL site.
- **Wabaseemoong Independent Nations** is composed of four communities: Whitedog First Nation, serving as the main reserve parcel; One Man Lake; Swan Lake; and Agency 30 (shared with 12 other First Nations). Occupy four reserves: 80 km east, 85 km east, 95 km east and 140 km southeast of the WL site.

The Project is also located in the homeland of the Red River Métis, as represented by the Manitoba Métis Federation. Statistics Canada identified Métis residents in many communities in proximity to the Project. Métis communities that historically emerged in the region include:

- **Bas de la Rivière –**. Situated on both shores of the Winnipeg River and established in 1732, the community served as a wintering post and trading depot. Fishing and agriculture were particularly important in the area. Originally a North West Company outpost, following amalgamation with the Hudson's Bay Company in 1821, the post lost its importance as a provisioning and transportation hub. It became known as Fort Alexander and then eventually Pine Falls.
- **Berens River –** An initial trading post was built at the mouth of the river in 1814 and was a thriving Métis community until fishing was banned on Lake Winnipeg in 1970 as a result of mercury contamination.
- **Fort Alexander –** Built by the Hudson's Bay Company on the Winnipeg River to counter the North West Company's Fort Bas de la Rivière, this post also had ties to the Métis in the area (Barkwell 2016).

The Indigenous peoples within the area have resided at or near their respective reserve parcels since time immemorial (Sagkeeng Anicinabe n.d.). In the nineteenth century, Indigenous peoples living near Fort Alexander, present day Sagkeeng, were nomadic and would make frequent trips north to the Hudson's Bay post to trade and obtain food supplies (Sagkeeng First Nation 2000). The Winnipeg River has historically provided a network of travel routes for local communities (Petch 2005). Present day traditional land and resource use activities, including

trapping and wild rice harvesting, continue to supplement the diet and income of local Indigenous peoples in the region. Wild rice harvesting was originally for domestic purposes, but eventually became a commercial economy (Manitoba Hydro and Golder Associates Ltd. 2012). The following provides a summary of traditional land and resource use activities for each Indigenous Nation, with additional detail found in Section 6.8.1.5.2.2 Traditional Land Use by Indigenous Peoples.

Sagkeeng First Nation (SAFN) reserve is located where the Winnipeg River empties into Lake Winnipeg and their traditional territory encompasses land within Treaty 1 along with land north and west of the Winnipeg River, falling within four Treaty areas (Sagkeeng First Nation 2015): Treaty 1 (1871), Treaty 2 (1871), Treaty 3 (1873) and Treaty 5 (1875). SAFN reserve is located where the Winnipeg River empties into Lake Winnipeg and their traditional territory encompasses land within Treaty 1 along with land north and west of the Winnipeg River, falling within four Treaty areas (Sagkeeng First Nation 2015): Treaty 1 (1871), Treaty 2 (1871), Treaty 3 (1873) and Treaty 5 (1875). Sagkeeng First Nation is a signatory to Treaty 1 and has established Treaty rights throughout Treaty 1 territory, and inherent Aboriginal rights in parts of Treaty 3 Territory, particularly that part of Treaty 3 which is generally within the borders of Manitoba. In 2007, Sagkeeng filed a statement of claim in the Manitoba Court of Queen's Bench asserting unextinguished Aboriginal Title to that part of its traditional territory which is outside of the boundaries of Treaty 1. The Whiteshell facility is situated on that land Sagkeeng's ancestors used and occupied since time immemorial, and which was never ceded or surrendered by Sagkeeng. The site is within the area to which Sagkeeng claims unextinguished Aboriginal title.

The land and waterways have historically been an important part of the economic well-being and transportation system for the Sagkeeng First Nation. In early spring and late fall, fishing was preferred near Catfish Creek and at Point au Mitasse on Lake Winnipeg (Sagkeeng First Nation 2000). Travel in the fall was typically to the Lac du Bonnet area, where the Pinawa Channel meets the Winnipeg River, to harvest wild rice (Sagkeeng First Nation 2000). Family units had preferred hunting areas which included areas close to Fort Alexander and spanned north to Black River First Nation and over 200 km southeast to Dalles and Big Island First Nations in Ontario (Sagkeeng First Nation 2000). Previous studies have documented that Sagkeeng First Nation participates in traditional activities of harvesting wild rice, subsistence fishing (sturgeon), gathering plants and medicines and berry picking (AECL 2001). Sagkeeng First Nation currently uses the Winnipeg River as its source for water supply to the community (J.R. Cousin Consultants Ltd. n.d.).

Brokenhead Ojibway Nation's resource harvesters currently use traditional areas north of the Manigotagan River and as far south as the Rural Municipality of Brokenhead (Brokenhead Ojibway Nation 2015). This traditional use area spans Treaties 1, 3 and 5 (TRCM 2013). Brokenhead Ojibway Nation resource harvesting activities occur within wildlife management areas, parks and reserve boundaries. Resource harvesting sites within this area include locations along the Winnipeg and Brokenhead Rivers (Brokenhead Ojibway Nation 2015). Current resource harvesting activities include, but are not limited to, moose hunting and trapping for muskrat and beaver (Brokenhead Ojibway Nation 2015).

The Black River First Nation's traditional lands are primarily located south of the Manigotagan River, west of the Manitoba-Ontario border, and north of the Winnipeg River in Treaties 3 and 5 (Handkamer 2016; TRCM 2013). Resource use activities include hunting, fish, trapping, wild rice harvesting and plant collection both far afield and near the community (Black River First Nation 2015). Members of Black River First Nation have historically used the Black and Winnipeg rivers most frequently for travel (Handkamer 2016). The Black River served as an access route for resource harvesting in the east, specifically wild rice harvesting and hunting near Nopiming Provincial Park (Handkamer 2016).

Hollow Water First Nation's traditional lands encompass an area south of the Bloodvein River, west of the Manitoba-Ontario border, and north of the Manigotagan River in Treaties 3 and 5 (TRCM 2013). Historically, Hollow Water First Nation's primary food source and economy was based on wild rice harvesting on the Wanipigow and Rice rivers along with Clangula Lake and bays on Lake Winnipeg (Thompson and Bushie 2015). The woodlands were used for hunting and trapping in the winter, fishing along the shores of Lake Winnipeg was popular in the spring, and wild rice was harvested on the shallow rivers and lakes in the fall (Reder 2013). Hollow Water First Nation community members currently maintain the historical tradition of gathering on Black Island to harvest blueberries. Economic activities for the community currently include fishing, hunting, trapping and wild rice harvesting. Fishing is considered the most important of these activities as a majority of community residents are directly employed in the Lake Winnipeg fishery (Manitoba Eco-Network 2010).

Wabaseemoong Independent Nations' traditional land use area is located in Treaty 3 and adjacent to the Manitoba/Ontario border, north of the Town of Kenora (WIN n.d.). The Wabaseemoong Independent Nations have historically used and currently utilize the English and Winnipeg River systems for traditional land and resource use activities (Energy East Project 2016). Water routes from these two systems have provided resource use access to hundreds of kilometres in all directions (WIN n.d.). Previous discussions with Wabaseemoong Independent Nations, have confirmed interest in the area where traditional land and resource use activities regularly occur (AECL 2001).

The Red River Métis have been known by many names throughout history, such as Bois Brûlés, Flower Beadwork People, Otipemisiwak (The People Who Own Themselves), Riel's People, Les Michif, and Manitoba Métis – from the beginning, they have all referred to the same people – the Red River Métis. The Red River Métis possess Aboriginal rights, including pre-existing Aboriginal collective rights and interests in lands recognized and affirmed by section 35 of the Constitution Act, 1982. As affirmed by the Supreme Court of Canada, such rights are "recognize[d] as part of the special aboriginal relationship to the land" (R. v. Powley. 2003) and are grounded on a "communal Aboriginal interest in the land that is integral to the nature of the Métis distinctive community and their relationship to the land" (MMF v. Canada 2013). In particular, the MMF-Manitoba Harvesting Agreement signed in 2012 recognizes that Métis rights include hunting, trapping, fishing and gathering for food and domestic use, including for social and ceremonial purposes and for greater certainty, Métis harvesting includes the harvest of timber for domestic purposes throughout an area spanning approximately 169,584 km² (the Métis Recognized Harvesting Area; MMF-Manitoba Harvesting Agreement).

Recognized Red River Métis Natural Resource Harvesting Areas 36 and Game Hunting Area 26 are situated in the vicinity of the WL site (Manitoba Sustainable Development n.d.). Red River Métis resource harvesters may harvest throughout these areas on "all unoccupied Crown lands in Manitoba and occupied provincial Crown lands, including provincial parks, wherever First Nation Members are allowed to harvest; and on any privately owned lands in Manitoba on which that Red River Métis Harvester has been given permission by the owner or occupant, or Indian Reserve lands with permission of Band Council" (MMF 2013).

According to the Métis Law of the Harvest (MMF 2013), harvest includes hunting, trapping, fishing and gathering for food and domestic use, including sharing, social and ceremonial purposes, of fish, big-game, small game, furbearers, game-bird (upland and migratory), berries, mushrooms, medicinal and other plants including wild rice and firewood or timber. Plant harvesting has been undertaken for food, crafts and medicines and has included birch, cedar, dandelion, milkweed, berries, wood products, roots, nuts and mushrooms. These activities are known to occur in areas southwest of the Project.

Métis citizens documented numerous fishing spots along the Winnipeg River downstream of the Project. Species fished include sauger, pickerel/walleye, jackfish/northern pike, sturgeon, and perch. Historically, populations supported a commercial fishery and prior to construction of the Seven Sisters Generating Station there was an important Lake Sturgeon spawning and nursery area located below the Seven Sisters Generating Station site (COSEWIC 2006). This commercial fishery was important to the Red River Métis into the early 20th century (Shared Value Solutions 2019).

With respect to hunting, the Red River Métis are known to have hunted and currently hunt deer across much of southern Manitoba, which has been documented south of the WL site and east to the Ontario border. Other game known to be harvested include grouse, partridge, ptarmigan, waterfowl and rabbit. The Red River Métis trapping activities, most of which are undertaken for commercial purposes, have focused on beaver, coyote, fisher, fox, lynx, marten, mink, muskrat, otter, rabbit, raccoon, squirrel, weasel, wolf and wolverine. Moose, white-tailed deer and elk are also important game species for the Red River Métis resource harvesters (Manitoba Hydro 2016).

During the public and Indigenous engagement process, the Manitoba Métis Federation noted that its citizens' place of residence did not always correlate with their resource use areas, as the population is mobile and land use tends to be associated with where an individual learned to harvest. As such, Manitoba Métis Federation citizens often travel to other locations across the province when undertaking harvesting activities, which reflects the location in which they learned (e.g., where their grandfather taught them).

1.4 Proponent

AECL, a federal Crown corporation, is responsible for its radioactive waste liabilities, including the waste at the WL site. AECL has contracted CNL to manage and operate its sites on its behalf, including completing the decommissioning of the WL site. As such, CNL is the proponent for the Project.

1.4.1 Corporate History

AECL has a core mandate to enable nuclear science and technology and manage Canada's radioactive waste and decommissioning responsibilities. It fulfils this mandate through a contractual arrangement with CNL for the management and operation of AECL's sites, facilities and assets and the performance of AECL's waste and decommissioning responsibilities, under a Government-owned, Contractor-operated model.

CNL is Canada's leading nuclear science and technology organization and a world leader in developing innovative applications from nuclear technology. Services offered through CNL include research and development, design and engineering to specialized technology, waste management and site decommissioning. CNL is committed to ensuring that Canadians receive energy, health and environmental benefits from nuclear science and technology with confidence that nuclear safety and security are assured. CNL focuses on completing its work activities safely, and meeting the commitments expected of it by its regulators, customers, stakeholders, Indigenous peoples, and the public.

1.4.2 Management Structure

CNL is led by an Executive Team and a Board of Directors. The President and Chief Executive Officer, along with Vice Presidents, are responsible for all aspects of the business. An organizational chart outlining CNL's internal structure relevant to the Project is provided in Figure 1.4-1. A full listing of CNL's Board of Directors and Executive Team can be found online at www.cnl.ca. The following are key roles related to the execution of the Project:

- The CNL President and Chief Executive Officer has overall responsibility for CNL's management of legacy waste at the WL site.
- The Vice President Environmental Remediation Management has overall responsibility for the development of the Project including design, regulatory approvals, and execution. This also includes ensuring the safe conduct of licensed activities associated with the facilities and radioisotope laboratories at the WL site.
- The WL General Manager is accountable to the Vice President Environmental Remediation Management and is responsible for leading and managing the Project and the associated operational activities of the WL site and facilities safely, responsibly and effectively. The WL General Manager is the General Manager of the WL Closure Project and the holder of the WL site Licence (Licence No. NRTEDL-W5-8.00/2024).
- The Head of Decommissioning and Waste Management has overall responsibility for ensuring decommissioning and waste management activities are planned and performed according to the controls and requirements of the WL Decommissioning Quality Assurance Plan. Implementation and maintenance of the WL Decommissioning Quality Assurance Plan is the responsibility of the WL Site Head.

The Director of Reactor Decommissioning has overall responsibility for the safe, cost-effective delivery of projects related to the Project, whilst ensuring program, regulatory and compliance requirements are met. The Director of Reactor Decommissioning is responsible for executing the decommissioning activities at the WL site.

1.4.3 Key Contact Information

The primary contact for the purposes of the EIS for the Project is:

Mr. Mitch MacKay
Director, Communications and Engagement
Canadian Nuclear Laboratories
Chalk River Laboratories
Chalk River, Ontario K0J 1J0
Telephone: 1-800-364-6989
Email: ermstakeholder@cnl.ca

1.5 Environment Policy

For CNL, business and environmental performance go hand in hand. It is important that CNL leads by example in terms of environmental performance. For this reason, CNL has an *Environment Policy* (CNL 2024) that considers the protection of the environment as an integral component of their decision-making in all phases of its business activities, including product development, project planning, project implementation, operations and decommissioning. The Environmental Policy outlines the strategic environmental objectives for CNL sites, including the WL site. CNL also focuses its environmental efforts on limiting nuclear legacy obligations for future generations. The *Environment Policy* (CNL 2024) applies to all aspects of CNL's activities and is outlined below:

- to practice responsible environmental management;
- to be committed to pollution prevention;
- to set environmental objectives and targets to support continual improvement of CNL's environmental performance;
- to set sustainability objectives and targets for energy efficiency, clean energy utilization, waste management and conservation of resources to support continual improvement of CNL performance;
- to comply with environmental laws, requirements and recognized standards and guidelines applicable to CNL's activities;
- to review the impacts of CNL activities, facilities, projects, services and products on the environment;
- to seek to develop and improve technologies to advance environmental protection and clean air solutions; and
- to promote public and employee awareness of this policy and CNL's environmental performance.

1.5.1 Health, Safety, Security, Environment and Quality Programs

To demonstrate compliance with the *Environment Policy* (CNL 2024) and other regulatory commitments related to health, safety and security, CNL has developed a number of programs outlining corporate expectations:

- Occupational Safety and Health Program;
- Radiation Protection Program;
- Environmental Protection Program;
- Waste Management Program;
- Emergency Preparedness Program;
- Human Performance;
- Nuclear Criticality Safety Program;
- Fire Protection Program;
- Security Program;
- Nuclear Materials and Safeguards Management Program;
- Quality Assurance Program; and

- Whiteshell Laboratories Environmental Assessment Follow-up Program.

The Environmental Protection Program, which is most relevant for this EIS, is described briefly below.

1.5.2 Environmental Protection Program

Activities at the WL site have been International Organization for Standardization (ISO) 14001 certified since 2010; during this time, there has been a steady evolution of CNL's Environmental Protection Program (CNL 2023a). A considerable level of effort and vigilance is required to establish, maintain and improve the Environmental Protection Program over time.

CNL's Environmental Protection Program establishes requirements, processes and structure to comply with applicable legal environmental requirements and other requirements CNL has adopted as a matter of policy. The details of CNL's Environmental Protection Program are captured in CNL's document entitled *Environmental Protection* (CNL 2023a). CNL's Environmental Protection Program implements CNL's *Environment Policy* (CNL 2024) described in Section 1.5 (Environment Policy) and provides compliance with legal and other environmental obligations applicable at CNL operated sites in Canada. A comprehensive list of the documentation associated with the Environmental Protection Program is provided in CNL's *Environmental Protection Governing Document Index* (CNL 2023b). Some of the key requirements of the Environmental Protection Program are as follows:

- Identify and evaluate the effects of the environmental aspects associated with CNL's activities.
- Identify and provide access to applicable legal and other environmental requirements and obligations.
- Monitor and measure to verify environmental performance and compliance.
- Manage cultural resources.
- Manage land and habitat.
- Maintain appropriate level of environmental training and awareness.
- Establish and maintain emergency preparedness and response procedures.
- Implement "Green Initiatives" to improve waste management, energy and vehicle usage.

1.6 Regulatory Framework

1.6.1 Federal Review Process

On August 28, 2019, the *Impact Assessment Act* (IAA) came into force, repealing the CEAA 2012. The IAA contains transitional provisions for environmental assessments of designated projects commenced under CEAA 2012 and for which the CNSC is the Responsible Authority. The CNSC has informed CNL that the environmental assessment for the ISD of WR-1 at WL will continue under CEAA 2012. As per the transition provision described in subsection 182 of the IAA, "Any environmental assessment of a designated project by the Canadian Nuclear Safety Commission or the National Energy Board commenced under the 2012 Act, in respect of which a decision statement has not been issued under section 54 of the 2012 Act before the day on which this Act comes into force, is continued under the 2012 Act as if that Act had not been repealed." As outlined in subsection 182, given that this environmental assessment process was commenced under CEAA 2012 and a decision statement has not yet been issued, it will continue to be completed under its current process.

The federal environmental assessment requirements are detailed within CEAA 2012. Designated projects are defined under the Regulations Designating Physical Activities for CEAA 2012 and identify the CNSC as the Responsible Authority for projects that are regulated under the NSCA. As such, the CNSC is responsible for the conduct of the environmental assessment and ensuring that the requirements of CEAA 2012 are met. Following submission of the 2016 Project Description document titled *Environmental Assessment (and/or Environmental Effects Review), In situ Decommissioning of WR-1 Reactor at the Whiteshell Laboratories Site* (CNL 2016), the CNSC issued a *Record of Decision in the Matter of Canadian Nuclear Laboratories* (CNSC 2017) and determined that the Project requires a federal environmental assessment pursuant to CEAA 2012.

As noted in the above sections, CNL holds an existing decommissioning licence for the WL site (Licence No. NRTEDL-W5-8.00/2024). Other permits, licences and authorizations that may be required for the Project are listed below:

- Petroleum storage tank permit(s) from Environment and Climate Change Canada may be required, depending on the size of fuel tanks installed on the site.
- Hazardous waste generator registration will be maintained through Manitoba Sustainable Development (now Manitoba Environment, Climate and Parks) and in compliance with Manitoba's *Dangerous Goods Handling and Transportation Act* (C.C.S.M. c.D12).

The Project is located on federal lands and is regulated by the CNSC. Provincial permits, licences and other authorizations required for the management of hazardous non-radiological wastes will be adhered to. For example, the WL site is registered with the Manitoba Government as a Waste Generator and is required to abide by *The Dangerous Goods Handling and Transportation Act*, Continuing Consolidation of the Statutes of Manitoba 1987, c.D12 and the regulations under the Act. This includes the management of hazardous non-radiological waste under the Hazardous Waste Regulation (195/2015).

Under Section 15 of CEAA 2012, the CNSC is the Responsible Authority for the Project. As documented in the Record of Decision (CNSC 2017), CNSC staff have notified all relevant federal authorities, as well as all relevant provincial authorities in Manitoba with respect to the Project. All notified federal authorities indicated that they possess specialist knowledge with respect to the Project and expertise that could be drawn upon during the environmental assessment process. Federal authorities participating in the environmental assessment process include Environment and Climate Change Canada, Health Canada and Natural Resources Canada. The Manitoba Métis Federation, Sagkeeng First Nation, Black River First Nation, and Hollow Water First Nation joined the CNSC Federal and Provincial Review Team. In addition, the province of Manitoba is participating as a member of the review team during the environmental assessment process for the Project.

1.6.2 Relevant Standards, Codes and Guidelines

It is critical that the environmental assessment be conducted in accordance with relevant standards and codes, while also taking into consideration appropriate guidelines. The environmental assessment has been completed in a manner consistent with direction in the following documents.

Canadian Environmental Assessment Act, 2012

- *Canadian Environmental Assessment Act, 2012*. S.C. 2012, c. 19, s. 52
- CNSC *Generic Guidelines for the Preparation of an Environmental Impact Statement pursuant to the Canadian Environmental Assessment Act, 2012* (Generic EIS Guidelines; CNSC 2021).

- Operational Policy Statement: Assessing Cumulative Environmental Effects under the *Canadian Environmental Assessment Act, 2012* (The Agency 2015a).
- Operational Policy Statement: Addressing the "Purpose of" and "Alternative Means" under the *Canadian Environmental Assessment Act, 2012* (The Agency 2015b).
- Operational Policy Statement: Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the *Canadian Environmental Assessment Act, 2012* (The Agency 2015c).
- Reference Guide: Considering Aboriginal Traditional Knowledge in Environmental Assessments Conducted Under the *Canadian Environmental Assessment Act, 2012* (The Agency 2015d).
- Technical Guidance for Assessing Physical and Cultural Heritage or any Structure, Site or Thing that is of Historical, Archeological, Paleontological or Architectural Significance under the *Canadian Environmental Assessment Act, 2012* (The Agency 2015e).
- Assessing Cumulative Environmental Effects under the *Canadian Environmental Assessment Act, 2012. Interim Technical Guidance* (The Agency 2018).
- Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the *Canadian Environmental Assessment Act, 2012. Interim Technical Guidance* (The Agency 2018).

Canadian Nuclear Safety Acts and Regulations

- *Nuclear Safety and Control Act*. S.C. 1997, c. 9.
- CNSC *REGDOC-2.9.1, Environmental Principles, Assessments and Protection Measures* (CNSC 2020).
- CNSC *REGDOC-3.2.1, Public Information and Disclosure* (CNSC 2018a).
- CNSC *REGDOC-3.2.2, Indigenous Engagement* (CNSC 2019).
- CNSC *REGDOC-2.4.1, Deterministic Safety Analysis* (CNSC 2014).
- CNSC *REGDOC-2.11.1, Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018b).
- CNSC *REGDOC-2.11.2, Decommissioning* (CNSC 2023).

Canadian Standards Association (CSA)

- *CSA N286-12: Management System Requirements for Nuclear Facilities* (CSA Group 2012a).
- *CSA N288.1-14 Guidelines for Calculating Derived Release Limits for Radioactive Material in Airborne and Liquid Effluents for Normal Operation of Nuclear Facilities* (CSA Group 2014a).
- *CSA N288.4-19 Environmental Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2019).
- *CSA N288.5-22 Effluent Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2022).
- *CSA N288.6-12 Environmental Risk Assessment at Class 1 Nuclear Facilities and Uranium mines and Mills*. (CSA Group 2012b).

- *CSA N288.7-23 Groundwater Protection Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2023).
- *CSA N292.3-14 Management of Low- and Intermediate-Level Radioactive Waste* (CSA Group 2014b).

Discipline-specific standards, codes and guidelines used in the assessment of effects are identified as appropriate within each discipline section (Sections 6.2 Atmospheric Environment to 6.9 Socio-economic Environment).

To demonstrate compliance with the Generic EIS Guidelines (CNSC 2021) and REGDOC-2.9.1 (CNSC 2020) and to facilitate access to information within the EIS document, a concordance table (or cross-referencing table) has been prepared (Appendix 1.0-1) that lists the requirements detailed in the Generic EIS Guidelines and REGDOC-2.9.1, and the location for the corresponding information provided within the EIS.

1.7 Documentation Framework

1.7.1 Licensing Documentation Interrelations

CNL is implementing the Project on a high priority basis and has engaged its own project resources and those of engineering and environmental consulting firms. Several related activities, including analyses and report preparation, are being performed in parallel and involve close interaction between and among these resources.

Four documents, in particular, are closely related and contain a degree of overlap in their supporting analyses and content: the EIS, the Decommissioning Safety Assessment Report (DSAR), the Safety Case Report, and the Detailed Decommissioning Plan (DDP). In addition, technical support documents and supplemental supporting documents present information on the existing environment, engagement activities and description of Project components, as well as assessments of the potential effects related to the Project. Much of the information in this EIS has been extracted from the technical support documents and supplemental supporting documents.

An overview of the four key documents is provided below and the interrelations between these reports, technical support documents and supplemental supporting documents are described in Appendix 1.0-2 and illustrated in Figure 1.7.1-1.

- **Environmental Impact Statement –** The purpose of the EIS is to document the assessment and determination of the potential effects of the Project on the environment, including the atmospheric, geological, hydrogeological, surface water, aquatic and terrestrial environments, as well as studying the effects on land and resource use and socio-economic environment. The EIS identifies environmental design features and mitigation to address potential effects. The information and analysis conducted and submitted in the EIS represents the basis against which the environmental, social and human health effects of the Project are evaluated by the regulatory authorities. The EIS for the Project is prepared in parallel with the DSAR, Safety Case Report and DDP and relies on the information available within various technical supporting documents and supplemental supporting documents. The EIS covers the entire lifecycle of the Project from closure to beyond the end of institutional control.
- **Decommissioning Safety Assessment Report –** The DSAR provides the rationale for the ISD strategy, evaluates and provides evidence that the overall performance of the decommissioned WR-1 Building is safe, and identifies institutional controls that will be needed in the long-term to demonstrate protection of human health and the environment. The DSAR assesses safety for both the closure and post-closure periods of the Project lifecycle, including the period beyond institutional control. The DSAR analyzes the normal evolution

of the facility through its lifecycle, as well as disruptive events, such as accidents and extreme weather conditions.

- **Safety Case Report –** The Safety Case Report demonstrates that ISD, post-closure activities and long-term disposal of WR-1 can be safety undertaken. This document provides the safety case (i.e., the argument and provision of evidence to demonstrate that the risk of a contaminant release has been reduced to a level that is as low as reasonably achievable [ALARA]) for the ISD approach and mapping of design and safety documents to the regulatory requirements to demonstrate that the suite of project documents meet all elements of the safety case. This document describes the risks, in terms of hazards presented by the ISD of WR-1, including potential faults and accidents, and those reasonably achievable measures that need to be implemented to prevent or minimize harm to the workers, public and environment. The Safety Case Report is supported by the EIS and DSAR.
- **Detailed Decommissioning Plan –** The DDP describes plans for the decommissioning of WR-1. It is a document that describes the work to be done, lays out the high-level work breakdown structure and provides a high-level hazard assessment. The DDP describes the WR-1 Building, the operational status, and the proposed final end-state for the site. Other key topics such as hazards, regulatory and environmental assessment considerations, waste management plans, program management and quality assurance are also covered in general terms in the DDP.

TECHNICAL SUPPORTING DOCUMENTS / SUPPLEMENTAL SUPPORTING DOCUMENTS

- Hydrogeological Study Report
- Geosynthesis Report
- Reactor Characterization Report
- Building Condition Assessment Report
- Climate Change Assessment
- Environmental Risk Assessment
- Environmental Assessment Follow-up Program
- Groundwater Flow and Solute Transport Modelling Report
- Indigenous Engagement Report
- Stakeholder Engagement Report
- Grout Formulation Report

TERTIARY SUPPORTING DOCUMENTS

DETAILED DECOMMISSIONING PLAN

The DDP describes plans for the decommissioning of the WR-1 Building. It is a bounding scope document that describes the work to be done, lays out the high-level work breakdown structure and provides a high-level hazard assessment.

DECOMMISSIONING SAFETY ASSESSMENT REPORT

The DSAR provides the rationale for the in situ disposal strategy, evaluates and provides evidence that the in situ disposal strategy is safe, and identifies long-term institutional controls to demonstrate protection of human health and the environment.

ENVIRONMENTAL IMPACT STATEMENT

The information presented and the analysis carried out in the EIS are the basis against which the environmental, social and human health effects of the project are evaluated by the regulatory authorities.

SAFETY CASE REPORT

The Safety Case demonstrates that in situ disposal, post-closure activities, and long-term disposal of the WR-1 Building can be safely undertaken.

1.7.2 Structure of the Environmental Impact Statement

The EIS has been prepared following the CNSC Generic EIS Guidelines (CNSC 2021). The EIS is organized into the sections described below and shown in Figure 1.7.2-1.

- **Executive Summary –** contains a description of all key components of the Project and related activities, a summary of all engagement activities, an overview of the results of the environmental assessment and a summary of the conclusions about the residual environmental effects of the Project after considering mitigation and the significance of those effects.
- **Section 1.0 Introduction –** includes the Project context and an overview of the Project and its location, provides an introduction to CNL, outlines the regulatory framework the Project will follow and outlines the organization of the document.
- **Section 2.0 Purpose of the Project and Alternative Means for Carrying out the Project –** identifies the objectives of the Project, the problems or opportunities that the Project is intended to satisfy and the rationale for proceeding with the development. This section also considers the effects of alternative means of carrying out the Project, identifies the economically and technically feasible alternatives and includes environmental and social considerations that were evaluated as means of implementing the Project.
- **Section 3.0 Project Description –** provides a description of all phases of the Project in sufficient detail to allow CNL to predict potential adverse environmental, economic, social and health effects. A timeline for all phases of the Project is provided, as well as a discussion of components and activities, including infrastructure that will be developed as part of the Project.
- **Section 4.0 Indigenous Engagement –** summarizes CNL's engagement activities with Indigenous peoples, including documentation of meetings, discussion topics and outcomes and relevant agreements that were developed.
- **Section 5.0 Public Engagement –** summarizes CNL's engagement activities with the public and regulators, including documentation of meetings, discussion topics and outcomes and relevant agreements that were developed.
- **Section 6.0 Environmental Effects –** outlines the environmental assessment approach, selection of valued components (VCs) and discipline-specific definition of assessment boundaries; describes the Project setting; and presents the results of the environmental assessment (i.e., the predicted residual effects) and determination of significance of environmental, economic, social, heritage and health effects of the Project in each of the following sections:
  - Section 6.1 Environmental Assessment Approach;
  - Section 6.2 Atmospheric Environment;
  - Section 6.3 Geological and Hydrogeological Environment;
  - Section 6.4 Surface Water Environment;
  - Section 6.5 Aquatic Environment;
  - Section 6.6 Terrestrial Environment;
  - Section 6.7 Human and Ecological Health;

- Section 6.8 Land and Resource Use; and
- Section 6.9 Socio-economic Environment.

- **Section 7.0 Malfunctions and Accidents –** presents a description of potential credible malfunctions and accidents that could be associated with the Project, the conditions under which they could occur, and proposed mitigations and contingency plans.
- **Section 8.0 Summary of Cumulative Effects –** contains a summary of residual cumulative environmental, economic, social and health effects predicted to occur as a result of the Project.
- **Section 9.0 Summary of Significance of Residual Effects –** contains an overview of how significance was determined, a summary of the evaluation of significance for the residual environmental, economic, social and health effects predicted to occur as a result of the Project, and a conclusion about whether the residual effect of the Project on each VC was determined to be significant.
- **Section 10.0 Assessment of Effects of the Environment on the Project –** contains the assessment of effects of the environment on the Project including the likelihood and severity of the changes or effects and mitigation planned to avoid or limit the changes or effects. The assessment also includes consideration of effects from climate change.
- **Section 11.0 Summary of Monitoring and Follow-up Programs –** presents the reporting structure and timelines for the various management plans, continuing or follow-up monitoring plans and commitments made for the Project.
- **Section 12.0 Conclusions –** includes a synthesis of the effects assessment, including a summary of residual environmental effects predicted as result of the Project, the determination of significance for the residual effects, the proposed monitoring, and an overall conclusion for the EIS.
- **Section 13.0 References –** includes the references cited throughout the EIS (not illustrated in Figure 1.7.2-1).
- **Section 14.0 Glossary, Abbreviations and Units –** includes a glossary of terms used and list of the abbreviations and units cited throughout the EIS (not illustrated in Figure 1.7.2-1).

2.0 PURPOSE OF THE PROJECT AND ALTERNATIVES TO THE PROJECT

2.1 Introduction

The Whiteshell Reactor 1 (WR1) was permanently shut down in 1985. The first stage of decommissioning of WR1 was consistent with standard practice and involved the removal of liquids and nuclear fuel and decontamination of the main floor (600 level) and first sublevel (500 level) space. All irradiated fuel was removed from the facility and transferred to dry storage at the Concrete Canister Storage Facility adjacent to the Whiteshell Laboratories (WL) Waste Management Area (WMA). Bulk organic coolant was also removed from the reactor cooling circuits and transferred to the WL WMA for incineration. Reactor control systems were isolated and all building service systems were maintained in an operating mode. This initial decommissioning work prepared WR1 for a storage with surveillance period and substantially decreased potential hazards from the facility. Many of the remaining systems for WR1 are permanently shut down, although they remain largely intact. All of the required service systems remain operational to maintain WR1 in a storage with surveillance state.

Canadian Nuclear Laboratories (CNL) is proposing an in situ disposal (ISD) approach to the In Situ Decommission of WR-1 at the Whiteshell Laboratories Site (the Project). The intent of this section is to provide an overview of CNL's overall waste disposal strategy, describe the purpose of the Project as it relates to the overall strategy, provide a list of design principles that the preferred alternative must meet, and present alternative means of carrying out the proposed Project.

2.2 CNL's Integrated Waste Strategy

In Canada, nuclear waste producers and owners are responsible for the funding, organization, management and operation of disposal facilities required for their wastes. CNL has developed an Integrated Waste Strategy that concisely details pathways for all CNL waste streams from generation to final disposition. The Integrated Waste Strategy is based on CNL's waste inventory and forecast data. The strategy is founded on the fundamental principles of waste avoidance, minimization and re-use. It enables the assessment of the quantities and types of waste that CNL manages (e.g., from clean waste to radiological waste). The ISD of the WR-1 meets one of the CNL Integrated Waste Strategy (CNL 2023) objectives by providing a disposal route for the WR-1 components and systems.

2.3 Purpose of the Project

The Government of Canada, through Atomic Energy of Canada Limited (AECL), is responsible for Canada's radioactive waste liabilities. AECL's objective is to reduce risks and costs for Canada in a safe manner, consistent with international best practices (IAEA 2004, 2006a). AECL has contracted CNL to decommission the WL site and reduce Canada's waste liabilities. This work will ensure the long-term safety and security of the public and the environment.

The WR-1 Building is one of the nuclear liabilities at the WL site. The WR-1 Building is approaching 60 years old. Although the building has been well-maintained, it is approaching the end of its useful life.

The purpose of the Project is to safely decommission the reactor in a timely manner that reduces the need for further human intervention. Potential decommissioning strategies were identified through internal CNL discussions and feedback received from the public and Indigenous engagement activities.

CNL evaluated several decommissioning strategies, focusing on the following four main objectives:

1) Ensure protection to the environment (i.e., human and ecological) by:
   a) limiting the need for interim storage if possible;
   b) reducing deferment periods where appropriate;
   c) limiting releases of radiological and hazardous substances from the facility;
   d) meeting applicable regulations;
   e) continuing to meet the obligations committed to in the Comprehensive Study Report (CSR; AECL 2001); and
   f) demonstrating the long-term safety of the selected decommissioning strategy, including implementation of a long-term monitoring and surveillance program.
2) Apply international best practices to safely decommission WR-1.
3) Apply CNL and international safety design principles to minimize radiation exposure to the public and workers (e.g., meeting the As Low As Reasonably Achievable [ALARA] principle).
4) Avoid or minimize industrial hazards during decommissioning activities.

2.4 Project Design Principles

The principles presented in Sections 2.4.1 and 2.4.2 are essential elements in the design of the decommissioning strategy. The alternatives described in Section 2.5.4 were evaluated in the context of these design principles.

2.4.1 CNL Design Principles

The safety principles to be applied to the design and implementation of the decommissioning strategy include:

- defence-in-depth principle;
- ALARA principle; and
- nuclear safety culture.

Defence-in-Depth Principle

The key aspect of defence-in-depth is using multiple layers of protection against abnormal events. When defence-in-depth is applied it provides protection against a wide range of events (e.g., anticipated operational occurrences, accidents, equipment failure, human errors, forest fires, and floods). Defence-in-depth consists of two components: 1) equipment and administrative features that provide protection, and 2) integrated safety management programs that control operations. Section 7.0 and Section 10.0 provide an analysis of potential accidents and malfunctions identified for the Project and effects of the environment on the Project, respectively.

The application of the defence-in-depth concept to abnormal events requires that no single human or equipment failure would result in an unacceptable hazard to the workers in the facility, the public or the environment. This strategy is centred on several barriers of protection with ascending levels of importance: accommodation, mitigation and prevention. The level of application corresponds to the level of risk posed by the postulated event.

To effectively control a hazard, the same basic approach has been taken based on the following sequence of hazard control principles:

- eliminating the hazard;
- reducing/replacing the hazard;
- isolating the hazard;
- controlling the hazard;
- using personnel protective equipment & clothing (PPE&C);
- adhering to policies and procedures; and
- maintaining appropriate documentation.

Of these seven principles, the most effective and preferred method of hazard control is to eliminate the hazard. When a hazard cannot be eliminated, then the remaining principles are implemented to provide an acceptable level of defence-in-depth. The defence-in-depth strategy is used to limit the effects of potential mechanical and human failure and unexpected occurrences. For human errors, prevention is achieved by a combination of process design and administrative controls (e.g., training and procedures), as well as by establishment of a strong safety culture.

As Low As Reasonably Achievable Principle

The ALARA principle requires that the exposures to persons shall be as low as reasonably achievable, social and economic factors being taken into account. CNL's ALARA program (CNL 2018) will be followed and the essential elements include:

- demonstrated management commitment to the ALARA principle;
- implementation of ALARA through design, organization and management, selection and training of personnel, oversight of the Radiation Protection Program, resources and documentation;
- establishment of nuclear safety culture;
- planning and control of all work;
- application of task-specific dose and dose-rate radiological control hold points; and
- regular operational reviews.

In addition to CNL's ALARA program (CNL 2018), the Canadian Nuclear Safety Commission (CNSC) regulatory guide to the ALARA principle (CNSC 2004) is taken into consideration in the design of a decommissioning plan. This document outlines approaches to achieving ALARA through the management control over work practices, qualification and training for personnel, control of occupational and public exposure to radiation, and planning for unusual situations.

The ALARA principle will be achieved by cost-effectively implementing zoning and access control measures, maintaining adequate shielding for structures and waste packages with high radiation fields, providing process equipment segregation, establishment of radiation alarms, continuous monitoring and through operator training and approved procedures. Further reduction in operating staff doses is achieved by limiting releases through periodic inspection and preventive maintenance of equipment. It is important to note that CNL plans to meet regulatory limits for radiation doses to workers at all times.

Nuclear Safety Culture

CNL has adopted the Institute of Nuclear Power Operations' nuclear safety culture definition (INPO 2004)[1]. The following principles and traits are well recognized to contribute to a healthy nuclear safety culture:

- **Personal accountability –** All individuals take personal responsibility for safety.
- **Questioning attitude –** Individuals avoid complacency and continuously challenge existing conditions and activities in order to identify discrepancies that might result in error or inappropriate action.
- **Effective safety communication –** Communications maintain a focus on safety.
- **Leadership safety values and actions –** Leaders demonstrate a commitment to safety in their decisions and behaviors.
- **Decision-making –** Decisions that support or affect nuclear safety are systematic, rigorous and thorough.
- **Respectful work environment –** Trust and respect permeate the organization.
- **Continuous learning –** Opportunities to learn about ways to ensure safety are sought out and implemented.
- **Problem identification and resolution –** Issues potentially affecting safety are promptly identified, fully evaluated and promptly and adequately addressed (corrections are commensurate with the potential consequences).
- **Environment for raising concerns –** A safety-conscious work environment is maintained where personnel feel free to raise safety concerns without fear of retaliation, intimidation, harassment or discrimination.
- **Work processes –** The process of planning and controlling work activities is implemented so that safety is maintained.

The CNSC has issued REGDOC-2.1.2, *Safety Culture* (CNSC 2018a), which provides a definition of safety culture and highlights general safety culture requirements that apply to all licensees. CNL abides by this document that describes the expected and suggested criteria for licensees to self-assess, establish corrective action plans and report on safety culture.

[1] "Nuclear safety culture" is defined as the core values and behaviors resulting from a collective commitment by leaders and individuals to emphasize safety over competing goals to ensure protection of people and the environment.

2.4.2 Design Principles from External Sources

In addition to CNL's design principles, the design and implementation of the decommissioning approach will use Canadian and international best practices and safety fundamentals, including those from the International Atomic Energy Agency (IAEA) and the CNSC.

International Atomic Energy Agency

The IAEA's *Fundamental Safety Principles* (IAEA 2006a) outline and describe 10 safety principles in terms of radiation protection in design:

1) responsibility for safety;
2) role of government;
3) leadership and management for safety;
4) justification of facilities and activities;
5) optimization of protection;
6) limitation of risks to individuals;
7) protection of present and future generations;
8) prevention of accidents;
9) emergency preparedness and response; and
10) protective actions to reduce existing or unregulated radiation risks.

The IAEA has also published *SSG-29: Near Surface Disposal Facilities for Radioactive Waste* (IAEA 2014b). This document gives detailed design guidance on the following:

- containment;
- isolation;
- multiple safety functions;
- passive safety; and
- surveillance and control of passive safety features.

It is noted that as the Whiteshell Reactor Disposal Facility (WRDF) will contain intermediate level waste, SSG-29 is not applicable to the Project; however, where relevant, guidance given in SSG-29 has been taken into account.

Regulating nuclear safety in Canada is the responsibility of the CNSC. The IAEA is a valuable resource to provide guidance for decisions concerning safety related to CNL's plans to decommission WR-1. Current IAEA guidance states that in situ decommissioning should not be the preferred decommissioning strategy for nuclear power reactors, except possibly under exceptional circumstances (IAEA 2014a). As explained in Section 6.3 of the Whiteshell Laboratories Detailed Decommissioning Plan (DDP; CNL 2021), Canada's regulatory framework for decommissioning, according to CNSC REGDOC-2.11.2 (CNSC 2021b), includes ISD as a viable

decommissioning strategy option under specific circumstances or legacy sites. The Project meets all the requirements for a legacy site, as defined in REGDOC-2.11.2:

- WR-1 was a research and a demonstration facility constructed at a time in history when decommissioning was not part of the design;
- All reactor fuel has been removed from the Project site;
- Use of ISD will protect the workers, the public and the environment; and
- Project site will remain under Institutional Controls for a period defined in the safety case.

All four technically feasible alternative means of carrying out the decommissioning of WR-1 assessed in Section 2.5.4 align with IAEA's General Safety Requirements Part 6, *Decommissioning of Facilities* (IAEA 2014a), which lists 15 requirements (which are outlined below) that should be met when selecting a specific decommissioning approach for a facility.

1) **Optimization of protection and safety in decommissioning – Exposure during decommissioning shall be considered to be a planned exposure situation and the relevant requirements of the Basic Safety Standards shall be applied accordingly during decommissioning.**

   National regulations on the protection of the environment shall be complied with during decommissioning, and beyond if a facility is released from regulatory control with restrictions on its future use.

   All decommissioning work at CNL is carried out under the oversight of the CNL Radiation Protection Program, as per the CNSC-issued site decommissioning licence, which provides the framework and constraints for planned exposures during decommissioning work at WL.

   Furthermore, the Project is subject to federal legislation including the *Nuclear Safety and Control Act* and *Canadian Environmental Assessment Act, 2012* (CEAA 2012). The Project is further subject to oversight and approval from the CNSC, which licenses all activities performed by CNL related to decommissioning and waste management. The Decommissioning Licence NRTEDL-W5-8.00/2024 dictates requirements for CNL to comply with and outline what activities CNL is permitted to perform. Regular inspections by the CNSC ensure compliance with the Decommissioning Licence, and all applicable relevant federal legislation. These conditions remain in place until the CNSC deems them no longer necessary for the safety of workers, the public and the environment.

2) **Graded approach in decommissioning – A graded approach shall be applied in all aspects of decommissioning in determining the scope and level of detail for any particular facility, consistent with the magnitude of the possible radiation risks arising from the decommissioning.**

   The conduct and regulatory oversight of decommissioning actions shall be applied in a manner that is commensurate with the hazards and risks associated with the decommissioning of the facility.

   All decommissioning activities carried out by CNL are subject to CNSC oversight under the Decommissioning Licence NRTEDL-W5-8.00/2024. The Decommissioning Licence outlines the activities that CNL is permitted to perform and conditions that must be met while performing it. The Decommissioning Licence further identifies all the relevant CNL policies, programs and procedures that decommissioning activities must be performed in accordance with. The CNSC provides compliance oversight to ensure CNL is following the

specified policies, program and procedures. One such requirement is the adherence to the CSA N286 quality assurance standard for nuclear power plants, which has specific provisions for application of graded approaches to performing work, commensurate with the risk level involved. This graded approach has been implemented in many of the policies, programs and procedures identified in the WL site licence, which have been deemed as satisfactory by the CNSC. The graded approach is reflected in procedures for environmental review, radiation and contamination monitoring, occupational health and safety measures, quality assurance and waste management and minimization, among others. The ALARA principle (As Low As Reasonably Achievable) permeates CNL's safety culture, and the "Reasonably" portion of that is where the graded approach is applied.

The graded approach is also apparent in CNSC oversight of CNL operations. The Decommissioning Licence also outlines which activities CNL may perform without notifying the CNSC, where the CNSC must be notified, or where the CNSC must approve prior to execution. These distinctions are based on the commensurate risk of the activities.

3) **Assessment of safety for decommissioning – Safety shall be assessed for all facilities for which decommissioning is planned and for all facilities undergoing decommissioning.**

The final decommissioning plan shall be supported by a safety assessment addressing the planned decommissioning actions and incidents, including accidents that may occur or situations that may arise during decommissioning.

As part of the ongoing environmental assessment, under CEAA 2012, CNL has prepared this Environmental Impact Statement (EIS), which summarizes the assessed effects of the Project on the environment. This is supported through a detailed *Decommissioning Safety Assessment Report for the WR-1 In Situ Decommissioning of Whiteshell Reactor 1 Project* (DSAR; Golder 2021a), compliant with CNSC's REGDOC 2.11.1, *Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018b). Detailed calculations and modelling that support the assessment in the DSAR are provided in an Environmental Risk Assessment (ERA) report (EcoMetrix 2024), and a Groundwater Flow and Solute Transport Modelling report (Golder 2021b). The DSAR also provides an assessment of accident and malfunction scenarios during decommissioning, and their effect on the environment. All of these documents provide supporting information for the Detailed Decommissioning Plan (DDP) that is prepared in compliance with CSA N294 and submitted for CNSC acceptance as a component of the licence application.

This EIS, the DSAR and the supporting documents focus on the preferred Alternative #3 – ISD. Alternative #1 – Deferred Dismantling and Removal and Alternative #2 – Immediate Dismantling and Removal were shown to be safe in the CSR (AECL 2001). Alternative #4 – Partial Dismantling and Removal with ISD of the Remainder is a combination of Alternatives #2 and #3, both of which have been shown to be safe; therefore, Alternative #4 is deemed safe.

4) **<u>Responsibilities of the government for decommissioning</u> – The government shall establish and maintain a governmental, legal and regulatory framework within which all aspects of decommissioning, including management of the resulting radioactive waste, can be planned and carried out safely. This framework shall include a clear allocation of responsibilities, provision of independent regulatory functions, and requirements in respect of financial assurance for decommissioning.**

The responsibilities of the government shall include:

- *Establishing a national policy for the management of radioactive waste, including radioactive waste generated during decommissioning;*
- *Establishing and maintaining the legal, technical and financial responsibilities for organizations involved in decommissioning, including responsibilities for granting the authorization to conduct decommissioning and for the management of the resulting radioactive waste;*
- *Ensuring that the necessary scientific and technical expertise is available both for the licensee and for the support of regulatory review and other independent national review functions;*
- *Establishing a mechanism to ensure that adequate financial resources are available when necessary for safe decommissioning and for the management of the resulting radioactive waste.*

The Government of Canada provides the legislative framework supporting the CNSC, including defining its mandate and authority as Canada's independent nuclear regulator. The CNSC is responsible for the oversight of all civilian nuclear activities in Canada.

Whiteshell Laboratories is the property of AECL, which is a Schedule III, Part 1 Crown Corporation under the *Financial Administration Act, 1985* and an agent of Her Majesty in Right of Canada. As owner, AECL retains responsibility for the site, financial obligations for decommissioning, and long-term management of the site post-closure. These liabilities have been officially recognized by the Minister of Natural Resources in a letter dated July 31, 2015 (Rickford 2015) and satisfy *CNSC Regulatory Document-3.3.1 Financial Guarantees for Decommissioning of Nuclear Facilities and Termination of Licensed Activities* (CNSC 2021a). AECL has chosen a Government-Owned, Contractor-Operated approach to completing the decommissioning of WL. The tendering process reviewed the proposed approaches to the decommissioning of WL against:

- compliance with AECL mandate, policies and procedures as agent of the Federal Government of Canada;
- adherence to CNSC requirements for the vendor to be the site licence holder and be approved by the CNSC to perform decommissioning work;
- expertise of each vendor in safely performing nuclear decommissioning work; and
- financial commitments of AECL to execute work safely.

5) **Responsibilities of the regulatory body for decommissioning – The regulatory body shall regulate all aspects of decommissioning throughout all stages of the facility's lifetime, from initial planning for decommissioning during the siting and design of the facility, to the completion of decommissioning actions and the termination of authorization for decommissioning. The regulatory body shall establish the safety requirements for decommissioning, including requirements for management of the resulting radioactive waste, and shall adopt associated regulations and guides. The regulatory body shall also take actions to ensure that the regulatory requirements are met.**

The CNSC is the authority having jurisdiction for all nuclear decommissioning work in Canada. The CNSC has a rigorous licencing approach that ensures nuclear safety in all licensed nuclear decommissioning work. The Decommissioning Licence (Licence No. NRTEDL-W5-8.00/2024) currently issued to CNL, and all future licences and licence revisions granted to CNL for decommissioning the WL site, do and will include specific requirements, standards and guidance for maintaining safe decommissioning operations. These requirements are developed with input from regulatory and industry experience and take into consideration international guidance and best practices. As a member state of the IAEA, Canada (and therefore the CNSC) are committed to pursuing the highest standards in nuclear safety through international collaboration and sharing operational experience.

6) **Responsibilities of the licensee for decommissioning – The licensee shall plan for decommissioning and shall conduct the decommissioning actions in compliance with the authorization for decommissioning and with requirements derived from the national legal and regulatory framework. The licensee shall be responsible for all aspects of safety, radiation protection and protection of the environment during decommissioning.**

The responsibilities of the licensee shall include:

- *Selecting a decommissioning strategy as the basis for preparing and maintaining the decommissioning plans throughout the lifetime of the facility.*
- *Preparing and submitting an initial decommissioning plan and its updates for review by the regulatory body.*
- *Establishing and implementing an integrated management system. If the licensee changes during the lifetime of the facility, procedures shall be put in place to ensure the transfer of responsibilities for decommissioning to the new licensee.*
- *Fostering a safety culture in order to encourage a questioning and learning attitude towards safety, and to discourage complacency.*
- *Estimating the cost of decommissioning and providing financial assurances and resources to cover the costs associated with safe decommissioning, including the management of the resulting radioactive waste.*
- *Notifying the regulatory body prior to the permanent shutdown of the facility.*
- *Submitting a final decommissioning plan and supporting documents for review and approval by the regulatory body, in accordance with national regulations, in order to obtain an authorization to conduct decommissioning.*

- *Managing the decommissioning project and conducting decommissioning or ensuring oversight of the actions conducted by contractors.*
- *Managing the remaining operational waste from the facility and all waste from decommissioning.*
- *Ensuring that the facility is maintained in a safe configuration during the period of transition following permanent shutdown and until the approval of the final decommissioning plan.*
- *Performing safety assessments and environmental impact assessments in support of decommissioning actions.*
- *Preparing and implementing appropriate safety procedures, including emergency plans.*
- *Ensuring that properly trained, qualified and competent staff are available for the decommissioning project.*
- *Performing radiological surveys in support of decommissioning.*
- *Verifying that end state criteria have been met by performing a final survey.*
- *Keeping and retaining records and submitting reports as required by the regulatory body.*

CNL performs many of these responsibilities on a daily basis as part of its core business operations. CNL carries out all work at WL in accordance with the Decommissioning Licence (Licence No. NRTEDL-W5-8.00/2024) from the CNSC. The requirements for obtaining and maintaining a licence align with the objectives of the bullet list above. All aspects of the decommissioning work, are subject to CNSC oversight and acceptance prior to any work being performed, including:

- preliminary and detailed planning;
- integrated management systems;
- development of company safety culture;
- cost estimating and financial guarantees;
- safe work execution and oversight;
- waste management, facility maintenance and safety;
- safety assessments supporting decommissioning planning;
- emergency planning, training and qualification of staff; and
- record retention.

The preparation of a DDP by CNL summarizes the pertinent information noted above for CNSC review and acceptance. The CNSC performs regular compliance inspections to verify CNL complies with the requirements of the Decommissioning Licence and the work summarized in the DDP. CNL also develops work plans with additional detail on how work scope of the DDP will be carried. These work plans are provided to the CNSC for information, as a means to assess the plans' compliance with the goals outlined in the DDP. Upon completion of the work, end-state reports are prepared to summarize the work performed against the planned activities, noting discrepancies or changes, for CNSC acceptance.

7) **Integrated management system for decommissioning – The Licensee shall ensure that its integrated management system covers all aspects of decommissioning.**

The prime responsibility for safety shall remain with the licensee.

CNL is the licensee for the overall WL Closure Project, including the decommissioning of WR-1. Under the terms of the Decommissioning Licence, CNL has demonstrated its commitment to safety through both policy and through daily work activities including safe work processes such as work permits, Event Free Tools, and fostering a strong safety culture that permeates the organization.

8) **Selecting a decommissioning strategy – The licensee *shall select a decommissioning strategy* that will form the basis for the planning for decommissioning. The strategy shall be consistent with the national policy on the management of radioactive waste.**

There may be situations in which immediate dismantling is not a practicable strategy when all relevant factors are considered. The selection of a decommissioning strategy shall be justified by the licensee. The licensee shall demonstrate that, under the strategy selected, the facility will be maintained in a safe configuration at all times and will reach the specified decommissioning end state, and that no undue burdens will be imposed on future generations.

CNL has selected ISD as the decommissioning strategy for WR-1. CNL continues to pursue a risk-based approach to radioactive waste management that complies with all CNSC regulations, applicable legislation, and where appropriate aligns with international guidance and best practices. The justification for the selection of this strategy is presented in this section. The EIS, supported by the DSAR (Golder 2021a), the ERA (EcoMetrix 2024) and other technical documents, demonstrates that the effects of this decommissioning strategy do not place an undue burden on future generations of people and the environment. All other alternative means for decommissioning WR1 would have to be justified if they were selected as the preferred decommissioning strategy.

9) **Financing of decommissioning – Responsibilities in respect of financial provisions for decommissioning shall be set out in national legislation. These provisions shall include establishing a mechanism to provide adequate financial resources and to ensure that they are available when necessary, for ensuring safe decommissioning.**

The requirements for financial guarantees are laid out in CSA N294, *Decommissioning of Facilities Containing Nuclear Substances* (CSA Group 2019). Adherence to this standard by CNL is required from national legislation to CNSC regulatory requirements and licence conditions.

10) **Planning for decommissioning – The licensee shall prepare a decommissioning plan and shall maintain it throughout the lifetime of the facility, in accordance with the requirements of the regulatory body, in order to show that decommissioning can be accomplished safely to meet the defined end state.**

CNL has prepared an Overview DDP for the wider WL site closure project. The Overview DDP provides the overall plan for decommissioning of the WL site, including WR-1, and has been periodically revised to include adjustments to the plan. This Overview DDP is part of a larger body work that supports the CNL application for a decommissioning licence for the WL site. It is supported by additional technical information, including but not limited to the Comprehensive Study Report, EIS, DSAR, and CNL policies, programs and procedures. Furthermore, CNL has also prepared a DDP specifically for WR-1 that will be maintained throughout the Project lifetime and is also subject to CNSC review and approval prior to being implemented.

11) **Final decommissioning plan – Prior to the conduct of decommissioning actions, a final decommissioning plan shall be prepared and submitted to the regulatory body for approval.**

The final decommissioning plan and supporting documents shall cover the selected decommissioning strategy; the schedule, type and sequence of decommissioning actions; the waste management strategy applied, including clearance, the proposed end state and how the licensee will demonstrate that the end state has been achieved; the storage and disposal of the waste from decommissioning; the timeframe for decommissioning; and financing for the completion of decommissioning. If the final decommissioning plan includes new technologies and concepts for decommissioning, the licensee shall demonstrate that such methods are safe and effective. Interested parties shall be provided with an opportunity to examine the final decommissioning plan can provide comments prior to its approval.

A DDP has been prepared to address the requirements of a final decommissioning plan including each of the items listed above. Development of the DDP is done in accordance with the WL Closure Project Quality Assurance Manual (CNL 2022) and CSA N294, the WL site licence and the WL Licence Conditions Handbook (CNSC 2020a), and guidance from recent project experience and regulatory input.

12) **Conduct of decommissioning actions – The licensee shall implement the final decommissioning plan, including management of radioactive waste, in compliance with national regulations.**

Decommissioning techniques shall be selected such that protection and safety is optimized, protection of the environment is ensured, the generation of waste is minimized and any potential negative impact on the storage and disposal of waste is minimized.

All operations at CNL, decommissioning or otherwise, are subject to approval by the CNSC. Approval is granted via a site licence that summarizes the policies, programs and key procedures that govern the work processes at WL. All work is performed in accordance with the policies, programs and key procedures identified, including Radiation and Environmental Protection, Occupational Health and Safety, Waste Management, Security Program and Quality Assurance. Any changes to these policies, programs or key procedures are submitted, if required, to the CNSC for review and/or acceptance prior to being implemented to perform work.

CNL has been performing decommissioning work at WL under a CNSC-issued Decommissioning Licence since 2002. Since 2002, the CNSC has verified that CNL is performing its work in a safe and compliant manner. All work necessary to decommission WR-1 will comply with these accepted practices to ensure protection of workers, the public and the environment, safe and optimized waste management and minimization.

13) **Emergency response arrangements for decommissioning – Emergency response arrangements for decommissioning, commensurate with the hazards, shall be established and maintained, and events significant to safety shall be reported to the regulatory body in a timely manner.**

Establishment of appropriate emergency response measures is required per the WL Decommissioning Licence and the Licence Conditions Handbook (Condition 10.1). CNL meets this requirement through the implementation of the WL's Site Emergency Response Plan, as per the CNSC-issued site Decommissioning Licence.

14) **Radioactive waste management in decommissioning – Radioactive waste shall be managed for all waste streams in decommissioning.**

Radioactive waste that remains at the facility and radioactive waste that is generated during decommissioning shall be disposed of properly. If disposal capacity is not available, radioactive waste shall be stored safely in accordance with the relevant requirements.

The safe and effective management of radioactive wastes is mandated through the CNSC Decommissioning Licence under which all activities at WL are performed. Section 11 of the Decommissioning Licence mandates that CNL maintain a waste management program for WL.

CNL maintains a waste management program for WL that controls the management of all radioactive wastes generated at WL, as per the CNSC-issued Decommissioning Licence.

15) **Completion of decommissioning actions and termination of the authorization for decommissioning – On the completion of decommissioning actions, the licensee shall demonstrate that the end state criteria as specified in the final decommissioning plan and any additional regulatory requirements have been met. The regulatory body shall verify compliance with the end state criteria and shall decide on termination of the authorization for decommissioning.**

Upon completion of decommissioning of WR-1, CNL will prepare a WL Remediation Plan, which will document the work performed and the end-state achieved. Further, CNL will implement an Environmental Assessment Follow Up and Monitoring Program (EAFMP) to provide evidence that the system is performing as designed after the end-state has been achieved. The WL Remediation Plan is mandated by the WL Quality Assurance Plan (CNL 2022) and CSA N294. The EAFMP is a mandated component of the environmental assessment process under CEAA 2012. Ongoing environmental monitoring is also a critical aspect of the WL Decommissioning Licence. CNL has previously prepared end-state reports for other work completed on the WL site, to the satisfaction of the CNSC, and will ensure the WR-1 WL Remediation Plan meets the same expectations. CNL has also been performing routine EAFMP monitoring of all decommissioning work, to the satisfaction of the CNSC, to demonstrate their compliance with the criteria of the CSR.

CNL will not adjust or cease monitoring of the WL site without the approval of the CNSC, and any decision to terminate, amend or transfer the Decommissioning Licence for the WL site will be made by the CNSC.

Canadian Nuclear Safety Commission

The CNSC has published REGDOC-2.11.1, *Waste Management Volume III, Assessing the Long Term Safety of Radioactive Waste Management* (CNSC 2018b), which describes the CNSC's licensing philosophy and licensing requirements related to radioactive waste management.

The purpose of REGDOC-2.11.1 Volume III, is to assist applicants for new licences and licence renewals in assessing the long-term safety of radioactive waste management, including:

- long-term care and maintenance considerations;
- setting post-decommissioning objectives;
- establishing assessment criteria;
- assessment strategies and level of detail;
- selecting timeframes and defining assessment scenarios;

- identifying receptors and critical groups; and
- interpretation of assessment results.

REGDOC-2.11.1 Volume III describes the philosophy that underlies the CNSC's approach to regulating the management of radioactive waste and the principles that are taken into account when making regulatory decisions about waste management. CNL considered the CNSC's guidance documents in the design and safety case (i.e., the argument and provision of evidence to demonstrate that the associated hazards and risks have been assessed, appropriate limits and conditions have been defined, and that adequate safety measures have been identified and put into place) for development of the Project.

2.5 Alternative Means of Carrying out the Project

2.5.1 Evaluation Approach

CEAA 2012 requires that federal environmental assessments evaluate alternative means of carrying out the Project that are technically and economically feasible and the environmental effects of any such alternative means. The Canadian Environmental Assessment Agency identifies in its *Operational Policy Statement: Addressing "Purpose of" and "Alternative Means" under the Canadian Environmental Assessment Act, 2012* the overall approach for considering the "alternative means" of carrying out a project (The Agency 2015). "Alternative means" is defined as the "various technical and economically feasible ways under consideration by the proponent that would allow a designated project to be carried out." The environmental effects of each alternative are considered in the assessment, as well as the technical feasibility, the economic feasibility and public and worker health and safety.

The purpose of this section is to present the alternative means of carrying out the Project. The consideration of alternatives is presented in the following three steps:

- identification of technical and economically feasible alternative means;
- identification of effects on valued components (VCs); and
- application of defined assessment criteria (described in Section 2.5.2) and the completion of a comparative evaluation to identify the preferred or most favourable option.

The decommissioning strategy for WR-1 draws upon the experiences and lessons learned from the decommissioning of similar reactors. CNL has conducted extensive research on reactor decommissioning strategies and past projects as part of the planning work for WR-1. CNL has relied on industry experts and has augmented its own team with staff that have been involved in previous reactor decommissioning work. CNL contracted Savannah River National Laboratory to perform a literature review of reactor encasement projects in order to assess techniques and performance results. This is documented in the report titled *Cementitious Materials Applications for Reactor Decommissioning* (SRNL 2016) and includes 12 reactors that have been encased in the USA, Russia, Georgia and Puerto Rico. CNL completed an additional report of 16 nuclear, hazardous, mining and industrial sites that have selected ISD as the strategy for permanent disposal (CNL 2019).

Staff from Savannah River National Laboratory visited both WR-1 and the Nuclear Power Demonstration reactor site in Ontario for the purpose of assessing these reactors and advising the CNL team. Technical considerations included size, condition, remaining radioactive inventory, site hydrogeology, site geology, construction type, integrity and durability of barriers, waste disposal options, site location relative to waste management facilities, site end state and other facility characteristics.

CNL also relied on extensive reactor dismantling experience from the companies that make up the Canadian National Energy Alliance. These companies (initially SNC Lavalin, Energy Solutions, Fluor and CH2M Hill; now SNC Lavalin, Fluor and Jacobs) have vast experience worldwide in nuclear decommissioning. CNL also relied on experience, lessons learned and strategies employed by the United States Department of Energy Office of Environmental Management (US DOE EM) and other international sources. While not a complete list, lessons learned and strategic consideration for ISD that informed the alternatives analysis are readily documented in the following publications:

- IAEA TecDoc 1124 – *Onsite Disposal as a Decommissioning Strategy* (IAEA 1999).
- *Innovations Report from Savannah River National Laboratory* (SRNL 2013).
- *Use of Cementitious Materials for SRS Reactor In-Situ Decommissioning* (Langton et al. 2010).
- IAEA Nuclear Energy Series No. NW-G-2.1 *Policies and Strategies for the Decommissioning of Nuclear and Radiological Facilities* (IAEA 2011a).
- IAEA Technical Report Series No. 446 *Decommissioning of Research Reactors: Evolution, State of the Art, Open Issues* (IAEA 2006b).
- *US DOE EM Strategy and Experience for In Situ Decommissioning*, Office of Engineering and Technology, EM-20, September 2009 (US DOE 2009).
- *In Situ Decommissioning Concepts and Approaches for Excess Nuclear Facilities Decommissioning End State – 13367*, Waste Management 2013 Conference (Serrato et al. 2013).
- *In Situ Decommissioning Lessons Learned 14042*, Waste Management 2014 Conference (Negin et al. 2014).
- *Entombment: A Viable Decommissioning Strategy for Research Reactors?* International Nuclear Safety Journal, Volume 3, Issue 4, 2014 (Laraia 2014).

The information gathered from these sources contributed to the alternatives assessment, particularly with regard to technical feasibility, economic feasibility and environmental effects during closure and post-closure.

WR-1 was defueled during previous decommissioning activities, reducing radioactivity. As a result, most remaining activity is associated with activated metals and contaminated systems and components. The vast majority of the remaining radioactivity is in the reactor core, which includes the calandria (i.e., the reactor vessel) and the fuel channels. This radioactivity must be considered when selecting a technically and economically suitable decommissioning strategy. Another key aspect of WR-1 that must be considered when assessing decommissioning strategies is that the reactor components are primarily located in the five storeys below-grade.

The alternative means evaluated in the EIS are:

- Alternative #1 – Deferred Dismantling and Removal;
- Alternative #2 – Immediate Dismantling and Removal;
- Alternative #3 – ISD;
- Alternative #4 – Partial Dismantling and Removal with ISD of the Remainder;
- Alternative #5 – ISD Using Alternative Backfill Materials; and
- Alternative #6 – Rolling Stewardship.

These alternatives were evaluated in the context of the design principles described in Section 2.4. The full dismantling and removal of the WR-1 Complex is assessed in the CSR and covered under CNL's existing decommissioning licence for the WL site (Licence No. NRTEDL-W5-8.00/2024). As such, the decommissioning alternatives discussed below are specific to the decommissioning of WR-1 Building, which is the central portion of the WR-1 Complex and contains WR-1.

Each alternative was evaluated first for its technical feasibility (e.g., whether the approach has been used elsewhere and can be easily adapted to this application). For those alternatives deemed technically feasible, a comparison of economic feasibility (i.e., cost), safety and environmental effects was completed. The alternatives assessment considered safety (e.g., effects on workers and the public), as well as biophysical (i.e., groundwater, aquatic environment, terrestrial environment and atmospheric environment) and social (i.e., socio-economic and land and resource use) effects.

Public and Indigenous engagement was an important aspect of the decision-making process. A summary of the alternative means being considered was made available to the public at open houses and meetings with Indigenous peoples. The input received is documented in Section 4.0 Indigenous Engagement and Section 5.0 Public Engagement. As a result of these engagement activities, the assessment criteria for evaluating safety and environmental effects were expanded and additional details were added through the development of the EIS.

2.5.2 Selection of Assessment Criteria

Selection of the assessment criteria was based on the requirements of REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures* (CNSC 2020b). Alternatives were screened for technical feasibility. Feasible alternatives were then assessed for economic feasibility and their effects on safety (worker, public and Indigenous safety) and the environment.

The effects were also evaluated against the criteria for each phase of the Project to demonstrate the changing nature of the possible effects of each alternative over time. The Project phases are:

- closure phase – period for decommissioning activities that spans approximately three years (2026 to 2030)
- post-closure phase – comprises two discrete periods:
  - institutional control – Institutional control is estimated to last a minimum of 100 years (i.e., 2031 to 2131) during which long-term monitoring and maintenance activities will continue, to demonstrate compliance with the safety case assumptions. Although institutional control is estimated to last a minimum of 100 years, it is recognized that it will continue until the CNSC agrees institutional controls are no longer needed; and
  - post-institutional control – period beyond the year 2131 that continues indefinitely and during which institutional control is assumed to eventually collapse and knowledge of the facility is lost. There is much uncertainty around when such period may actually begin, if at all. For the purpose of the assessment, it is assumed to occur 100 years after closure of the facility (i.e., at the end of institutional control).

Project phases are discussed in further detail in Section 6.1.4.2 Temporal Boundaries.

The discussion and evaluation of alternatives and assessment criteria were also presented at numerous public and Indigenous engagement events and feedback was solicited. The general feedback indicated the criteria for assessment of safety and environmental effects were not detailed enough. Specific changes as a result of this feedback included the separation of the Safety category into distinct categories for Worker Safety and Public Safety, reducing the perceived importance of transportation risk in the criterion, and defining different criteria for each time phase of the project (closure, institutional control, post-institutional control). Furthermore, the analysis was revised to clarify that this assessment is not intended to try to determine a 'best' alternative, which is highly subjective. It instead considers only alternatives that can all safely achieve the Project goals, and identifies the alternative that makes the most sense given the current circumstances and as per the regulatory guidance [The Agency 2015].

Criteria used to assess each of the alternatives were grouped into four categories: technical feasibility, economic feasibility, safety and environment effects. The criteria are summarized in Table 2.5.2-1, with further rationale provided in the following sections.

Table 2.5.2-1: Criteria for Assessing Alternative Means of Carrying out the Project

Category	Project Phase		Criteria
Technical Feasibility	Closure		***Is the alternative an approach and/or technology that has been successfully deployed elsewhere?*** ***Does the alternative require any tools, equipment or technologies that cannot be easily adapted to the current application (e.g., climate, location, waste type)?***
	Post-closure	Institutional Control	***Does the alternative rely on development of new facilities or technologies that do not yet exist (environmental monitoring or waste processing technologies, storage or disposal facilities)?***
		Post-institutional Control	***Does the alternative require physical human intervention/support beyond the institutional control period?***
Economic Feasibility	Closure		***Are the costs of activities for each alternative supportable within the current funding framework?*** ■ Ongoing storage and surveillance ■ Decommissioning of the WR-1 Building ■ Transportation of waste off site
	Post-closure	Institutional Control	***Are the costs during the institutional control period well defined and sustainable for a reasonable period of assumed institutional control?*** ■ Post-closure environmental monitoring ■ Construction and maintenance of additional interim or final storage facilities
	Post-closure	Post-institutional Control	***Does the alternative require an economic commitment beyond the duration of a reasonable assumed institutional control period?*** ***Are the long-term costs well defined?***
Safety	Closure and Post-closure		**What are the effects on Worker Safety?** ■ Radiological hazards during decommissioning ■ Non-radiological hazards during decommissioning ■ Industrial safety during decommissioning ■ Waste handling and transport hazards ***What are the effects on Public and Indigenous Safety?*** ■ Exposure risks to public near the WL site during closure ■ Transportation hazards
Environmental Effects	Closure and Post-closure		***What is the significance of potential effects on***: ■ Groundwater ■ Aquatic environment ■ Terrestrial environment ■ Atmospheric environment ■ Socio-economic environment

The technical feasibility criteria were not given a specific weight, but were given a "go, no-go" decision. All feasible alternatives were then assessed for economics and effects on worker, public and Indigenous safety, as well as environmental effects. Safety and environmental effects were weighted as follows:

- 30% worker safety;
- 30% public and Indigenous safety;
- 30% biophysical (groundwater, aquatic, terrestrial and atmospheric) environment; and
- 10% socio-economic environment.

Worker safety, public and Indigenous safety, and biophysical environment were given equal weight (30%) because it is recognized that they are inter-related (i.e., one can affect the other), and the assessment does not value the safety of one group of people over another. Socio-economic factors were given a lower weight as physical health and safety are a higher priority than socio-economic health, although, both are important in the decision-making process. While CNL did receive and consider alternative weighting from Sagkeeng First Nation (Sagkeeng), it did not result in changes to CNL's weighting, as CNL believes its weighting to be reasonable and balanced. Additional discussion can be found below.

In their Alternative Means Assessment, Sagkeeng, described in further detail at Section 2.8, provided criteria and tests that are meaningful to their community and represented their community values and interests, as represented by the Chief and Council. CNL re-evaluated its own work based on the information in Sagkeeng's alternative means assessment and deliberated whether changes should be made to their alternative means assessment.

CNL also acknowledges that the weighting of each criterion is a somewhat subjective exercise. Study results in their Alternative Means Assessment reflected Sagkeeng's priority values and associated criteria and weighting for assessing alternatives. Different perspectives and understandings will value different criteria more or less in their decision making. CNL believes the categories, weighting, and scoring it applied to each criterion is fair and balanced. It assumes that impacts to the public and Indigenous peoples, and the environment in which they live and practice their rights, make up 60% of the evaluation. Impacts on the health and safety of workers who live in the local community are 30%, and impacts to the socio-economic interests of the area are given 10%. CNL feels this adequately places the most emphasis on the safety and health of all people, and the environment.

The alternatives were qualitatively ranked. The total score was calculated by adding up the weighted criteria score in each criteria (i.e., worker safety, public and Indigenous safety, biophysical environment, and socio-economic environment). The weighted criteria scores were determined by adding up the scores in each time period (i.e., closure phase + institutional control period + post-institutional control period), and multiplying the sum by the criteria weighting (a percentage) for that criteria score.

$$Total\ score = (CS_{WS})W_{WS} + (CS_{PS})W_{PS} + (CS_{BE})W_{BE} + (CS_{SE})W_{SE}$$

$$CS_{XX} = R_{XX,C} + R_{XX,IC} + R_{XX,PIC}$$

CS_{XX} = Criteria score
W_{XX} = Criteria weighting
$R_{XX,YY}$ = Ranking score
WS = Worker Safety
PS = Public and Indigenous Safety
BE = Biophysical Environment
SE = Socio-Economic Environment
C = Closure Phase
IC = Institutional control period
PIC = Post-institutional control period

Results are summarized in Section 2.6. If an alternative had a high chance of successfully addressing a particular criterion, it was rated most favourable. If an alternative had a moderate likelihood of addressing a criterion, it was rated as favourable, and if an alternative was assessed as having a low likelihood of success with a particular criterion, it was rated as least favourable. More than one alternative could be given the same ranking. The results, which are summarized in Table 2.7-1, were illustrated based on the relative preference of each feasible alternative as depicted below.

2.5.2.1 Technical Feasibility

The following criteria were developed for the technical feasibility category:

- **Closure Phase**
  - **Is the alternative an approach and/or technology that has been successfully deployed elsewhere?** This criterion looks for previous examples to demonstrate that the work to complete the closure phase of the Project can be completed safely with existing technologies. Feasible alternatives will have a demonstrated previous implementation and well-defined process for completion.
  - **Does the alternative require any tools, equipment or technologies that have not previously been implemented elsewhere?** This criterion looks to establish if the approach requires any specialized equipment or tools that, while used in previous applications of the alternative, pose a challenge to implementation, such as climate, safety standards or other factors that affect the ability to implement them. Feasible alternatives will have limited need for undeveloped or underdeveloped technologies, and will show how the technologies have been similarly adapted for the current application.
- **Post-closure Phase – Institutional Control**
  - **Does the alternative rely on development of new facilities or technologies that do not yet exist (environmental monitoring or waste processing technologies, storage or disposal facilities)?** This criterion looks to determine the technical needs of the alternative during the institutional control period. It seeks to identify the needs for monitoring equipment and technologies, and the needs for new facilities to support monitoring and storage of wastes. Feasible alternatives will have a well-defined scope of work and utilize existing or readily adapted technologies to implement them. They will also not rely on future development of undefined advanced technologies.
- **Post-closure Phase – Post-institutional Control**
  - **Does the alternative require physical human intervention/support beyond the institutional control period?** This criterion looks to identify whether the alternative requires human intervention for a period of time beyond that considered a reasonable timeframe to rely on institutional controls. Feasible alternatives will not rely on a perpetual, or undefined long-term, human presence to safely implement the approach.

2.5.2.2 Economic Feasibility

The following criteria were developed for the economic feasibility category:

- **Closure Phase**
  - **Are the costs of the alternative supportable within the current funding framework (ongoing storage and surveillance, decommissioning of the WR-1 Building, transportation of waste off site)?** This criterion looks to identify if the costs associated with the closure phase of each alternative are well defined and within the current funding framework.
- **Post-closure Phase – Institutional Control**
  - **Are the costs during the institutional control period well defined and sustainable for a reasonable period of assumed institutional control (post-closure environmental monitoring, construction and maintenance of additional interim or final storage facilities)?** This criterion looks to identify the economic needs to support each alternative during the institutional control period. Feasible options will have well-defined costs for the associated activities and defined periods over which they will occur. Feasible options must also be within the current funding framework.
- **Post-closure Phase – Post-institutional Control**
  - **Does the alternative require an economic commitment beyond the duration of a reasonable institutional control period?** This criterion looks to identify the long-term economic commitment required for each alternative. Feasible alternatives will have a well-defined limit on financial or economic commitments required to implement the Project.

2.5.2.3 Safety

The safety of the workers, Indigenous peoples and the public is of upmost importance. The evaluation of the potential hazards is separated into time phases to address the evolving nature of hazards. The following criteria were developed for the safety category:

- **Closure Phase**
  - **Worker safety** – The defense-in-depth principle and ALARA principle were considered when alternatives were evaluated for worker safety. For the criteria considered, it is often not possible to completely eliminate the hazard, but all alternatives include appropriate mitigation to reduce the hazard and protect workers.
    - **Radiological hazards during decommissioning** – All alternatives would involve some level of radiation exposure to workers during decommissioning; however, appropriate mitigation (e.g., temporary shielding and ventilation, PPE&C) could be put in place for all alternatives so that worker dose limits would not be not exceeded. The amount of mitigation required would vary among the alternatives due to different types of exposure and radiation levels among the alternatives. Alternatives that minimize the need for mitigation the most were considered most favourable, while alternatives that require more mitigation were considered proportionately less favourable.

- **Non-radiological hazards during decommissioning** – The WR-1 Building also contains non-radiological hazards such as lead, polychlorinated biphenyls (PCBs) and asbestos-containing materials such as pipe insulation. Appropriate mitigation (e.g., PPE&C and ventilation) could be put in place for all alternatives to ensure the protection of worker health. The degree to which mitigation would be needed determined the level of favourability of each alternative. Alternatives requiring the least amount of mitigation were considered most favourable and alternatives requiring the greatest amount of mitigation were considered proportionately less favourable.
- **Industrial safety during decommissioning** – Decommissioning of the WR-1 Building would introduce standard worker industrial safety hazards (e.g., working at heights, confined spaces, congested workspaces and hoisting/rigging). These hazards would be more prevalent in some alternatives. Alternatives with the lowest exposure to these worker safety issues, compared to the other alternatives, were considered most favourable. Alternatives with the highest potential exposure to these worker safety issues, compared to the other alternatives, were considered proportionately less favourable.
- **Waste handling** – The transport of waste off site would require additional handling by workers. Appropriate mitigation (e.g., temporary shielding and ventilation, PPE&C) could be put in place for all alternatives to ensure that worker dose limits would not be exceeded during waste handling and packaging for transport. However, as an appropriate facility does not yet exist for waste disposal, interim storage of wastes would be necessary and double handling of the waste would be required for final disposal at an unspecified future date. Alternatives that would not require the double-handling of wastes were considered most favourable. Alternatives that would require double-handling of wastes and interim storage were considered proportionately less favourable.

Public safety

- **Exposure risk to public at WL site during closure** – The potential radiological risk to the public at the WL site would vary depending on the nature of the decommissioning work being performed. Alternatives with the most invasive activities (e.g., cutting, vibrating, heating) would have a higher risk of emissions, while less invasive techniques (e.g., less cutting, vibrating, heating) would have a lower risk. An alternative was considered most favourable if lower emissions were expected during the closure phase. An alternative was considered proportionately less favourable if higher emissions were expected during the closure phase.
- **Transport of hazardous waste** – While transport of waste is routine and safe, transporting WR-1 wastes off site would introduce the additional risk of vehicle accidents. For low-level wastes, the effects of an incident would not be significant from a radiological perspective; however, intermediate level wastes would present a higher risk to the public during transport and would require more safety measures. Alternatives with the lowest volume of wastes shipped off site for disposal were considered most favourable. Alternatives with the highest volume of wastes shipped off site for disposal were considered proportionately less favourable.

- **Post-closure Phase – Institutional Control**
  - **Worker safety –** All alternatives must be able to meet regulatory limits for exposures to workers and the public, plus the occupational health and safety standards during the institutional control period. An alternative was considered most favourable if the risks (radiological, non-radiological, industrial waste handling and transport) to workers were well defined and smaller compared to the risks of the closure phase (showing an overall risk reduction). An alternative was considered proportionately less favourable if the risks were not well defined, or if there was not an overall reduction in risk to workers.

    Public safety – Alternatives that would reduce the potential for public exposure (emissions, intrusion, transport on public roadways) were considered most favourable. Alternatives that would require repackaging, relocation or other ongoing emissions management were considered proportionately less favourable.
- **Post-closure Phase – Post-institutional Control**
  - **Public safety –** In the post-institutional control period, it was assumed that that there would be no workers present. All people would be considered the public. The primary risk to the public would be from emissions of radiological and non-radiological contaminants over time. All alternatives must be able to demonstrate long-term safety, at or below regulatory limits established by the CNSC. An alternative was considered most favourable if radiological and non-radiological materials were appropriately contained, thereby reducing the risk to the public during the post-closure phase to orders of magnitude below acceptable levels. An alternative was considered proportionately less favourable if the final method was not defined, or if it just met CNSC standard for exposure to the public (1 millisievert per year [mSv/a]).

2.5.2.4 Environmental Effects

The evaluation of environmental effects is based on a qualitative comparison of biophysical and socio-economic effects on VCs. Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Indigenous peoples or the public (The Agency 2018). The selection of appropriate VCs allows the assessment to be focused on those aspects that are of greatest importance to society.

The list of VCs selected for the evaluation is described in Section 6.1 Environmental Assessment Approach. CNL considered a number of factors when selecting the VCs including:

- presence, abundance and distribution within, or relevance to, the area associated with WR-1;
- potential for interaction with WR-1 and potential vulnerability to the effects of WR-1;
- species conservation status or concern (e.g., rarity, sensitivity and uniqueness);
- ecological and socio-economic value to communities, government agencies and the public;
- traditional, cultural and heritage importance to Indigenous peoples;
- legally recognized and afforded specific protection by law, policy, or regulation; and
- experience with similar projects.

To facilitate comparison of potential environmental effects on VCs between the alternatives, effects were described by discipline. For example, VCs for the terrestrial biodiversity discipline include numerous wildlife and vegetation species. For the alternatives assessment, environmental effects were evaluated for the terrestrial biodiversity discipline as a whole.

The following criteria were developed for the environmental effects category:

- **Closure Phase:**
  - **Groundwater, Aquatic, Terrestrial and Atmospheric Environment –** All alternatives would involve some level of emissions to the environment during decommissioning. The type (radiological/non-radiological), magnitude and emission route would vary among alternatives. In general, more invasive decommissioning activities (e.g., cutting, drilling, heating, vibrating) would result in larger potential emissions. Generally, these emissions could be effectively mitigated so that there are no significant effects on the environment. Alternatives that are expected to produce the lowest emission levels were considered most favourable, while alternatives expected to produce higher emission levels were considered proportionately less favourable.
  - **Socio-economic Environment –** During the closure phase, each alternative could have various socio-economic benefits or drawbacks, both directly and indirectly, including the financial benefit, experience and development of the employees and companies participating in the work, and the demands or investments in local infrastructure to support work. Alternatives were considered more favourable if they would provide benefits to the local region and province of Manitoba in the form of employment and investment in local infrastructure. Alternatives were considered proportionately less favourable if the benefits would be more readily realized outside of the local region and province of Manitoba, or if the work created additional demands on local infrastructure.
- **Post-closure Phase – Institutional Control:**
  - **Groundwater, Aquatic, Terrestrial and Atmospheric Environment –** The potential effects on aquatic, terrestrial and atmospheric environment would vary among the different alternatives. In all cases, emissions would be monitored and regulated to an approved standard. An alternative was considered more favourable if the expected releases during the institutional control period could be effectively managed and would not have any significant effect on the environment. An alternative was considered proportionately less favourable if the expected releases during the institutional control period could not be effectively mitigated.
  - **Socio-Economic Environment –** The potential socio-economic effects during the institutional control period include effects on continued employment, land use/availability, the availability of the land for alternate uses or economic development, any changes in the municipal funding arrangement, and ongoing effects or demands on local infrastructure. Alternatives that would provide local employment, encourage economic development and use of the site, and would not impose ongoing demands on local infrastructure were considered more favourable. Alternatives that would have restrictions on future use of the land, deter or limit economic development and require ongoing demands on local infrastructure were considered proportionately less favourable.

- **Post-closure Phase - Post-Institutional Control:**
  - **Groundwater, Aquatic, Terrestrial and Atmospheric Environment –** The potential effects on the environment during the post-institutional control period assumed that institutional control would have been lost. All alternatives must meet regulatory standards for releases to the environment under normal conditions. Alternatives that would be purpose built to provide protection without the need for human intervention were considered more favourable. Alternatives that would require ongoing human intervention in order to remain effective were considered proportionately less favourable.
  - **Socio-Economic Environment –** Socio-economic effects were not evaluated for the post-institutional control period. This phase assumes that all knowledge and control of the site has been lost, so the site could not influence the actual or perceived socio-economic benefits or drawbacks.

2.5.3 Selection of Alternative Means

Alternative means to decommission WR-1 were identified through internal CNL discussions and from public and Indigenous engagement activities.

CNL focused on first identifying the possible end-states for WR-1:

1) radioactive contamination is not present at WR-1 above unrestricted clearance levels; and

2) radioactive contamination is present at WR-1 above unrestricted clearance levels.

In order to achieve the first end-state (no contamination remaining at WR-1), the only possible decommissioning strategy is:

- Complete dismantling of the reactor and removal of wastes to an off-site facility for interim storage or disposal.

The second end-state, where radioactive contamination will remain at the WR-1, can be achieved with any one of three decommissioning strategies.

- **Status quo –** The building and equipment remains in its current storage with surveillance state and is decommissioned following a deferment period.
- **On-site storage –** Radioactive waste is collected into storage containers, moved to the WMA and stored and monitored indefinitely.
- **On-site disposal –** Radioactive waste is placed into a safe final disposal configuration. Disposal can be provided for all or some of the WR-1 components.

On-site storage was eliminated from the assessment because it is contrary to the ALARA principle. It exposes workers and the public to the highest potential exposures during the decommissioning work and does not remove the wastes from the site. Interim storage would require substantial additional storage infrastructure to be constructed at the WL site, which would increase the scope, hazards and costs of the work, again without providing any reduction of on-site liabilities. Without a final disposal facility identified at this time, there is a risk that interim storage methods will require ongoing maintenance for an unidentified period of time.

Table 2.5.3-1 lists the alternative decommissioning strategies that CNL chose to include in this evaluation.

Table 2.5.3-1: Alternative Means Evaluated for the Project

Decommissioning Parameter	Alternatives Evaluated in the EIS
Decommissioning Strategy	■ Alternative #1 – Deferred Dismantling and Removal ■ Alternative #2 – Immediate Dismantling and Removal ■ Alternative #3 – ISD ■ Alternative #4 – Partial Dismantling and Removal with ISD of the Remainder ■ Alternative #5 – ISD Using Alternative Backfill Materials ■ Alternative #6 – Rolling Stewardship

EIS = Environmental Impact Statement.

Feedback on alternatives from the public and Indigenous peoples (see Sections 4.0 Indigenous Engagement and 5.0 Public Engagement) focused on full dismantling as originally assessed and approved in the CSR (Alternative #1), thereby preserving the status quo.

Other comments were related to being able to retrieve or remediate the disposed reactor at an unspecified future date should monitoring show that environmental effects are not acceptable. A specific suggestion was the use of sand instead of grout as a backfill material, with the expectation that the sand could be more easily removed in the event that retrieval or remediation efforts were undertaken; thus Alternative #5 was added to the assessment.

The concept of "Rolling Stewardship," where wastes are packaged and stored in an accessible location and monitored on site in perpetuity, was proposed both through the public and Indigenous (specifically by Turtle Lodge, located on Sagkeeng First Nation) review of the Project's Draft Environmental Impact Statement (Golder et al. 2017); thus Alternative #6 was added to the assessment.

Another suggestion was to create a geologic repository on the WL site. This option was not considered separately by CNL as it would be included in Alternative #4, which considers partial ISD with alternate disposal of the reactor core components in another facility.

2.5.4 Assessment of Alternatives

2.5.4.1 Alternative #1 – Deferred Dismantling and Removal

Alternative #1 is deferred decommissioning with complete dismantling and removal of the WR-1 Building. This alternative is currently approved under the existing decommissioning licence for the WL site as described in CNL's DDP for Building 100 (CNL 2015). This decommissioning strategy assumes an additional prolonged period of storage and surveillance (more than 30 years) prior to completing decommissioning activities.

The major tasks during the closure phase include monitoring and surveillance during the deferment period and then the complete removal of the reactor and the building as follows (CNL 2015):

- removal of non-contaminated asbestos-containing materials and disposal at an appropriate facility;
- removal of contaminated asbestos-containing materials and disposal as radioactive waste;
- removal, segmentation, packaging and transport of the reactor fuel channels;

- removal, segmentation as required, packaging and transport of reactor thermal shields, the reactor vessel and components;
- removal, segmentation, packaging and transport of reactor process systems and equipment;
- decontamination of the building to meet the release criteria;
- final radiological surveys to verify that release criteria are met;
- removal of the building structure to 3 m below ground level;
- backfilling of the site to return it to a state that blends with the surroundings; and
- transport the radioactive waste to a disposal facility.

As described in CNL's DDP for Building 100 (CNL 2015), the WR-1 Building would be decontaminated to allow the bulk of the construction material to be reused, rubblized and used to backfill the WR-1 void or transferred to an inactive landfill. Decontamination and size reduction of materials and equipment would be performed where practicable. Decontaminating techniques that would not produce liquid wastes were preferred to avoid discharge of contaminants to the environment. Decontamination could produce contaminated concrete rubble and other building components, which would be transferred to another facility for interim storage or directly to a final disposal facility. Following removal and decontamination, the facility would be subjected to a radiological survey to confirm that facility release criteria have been met. The remaining building components could be reused or recycled, transferred to an inactive landfill site, or remain in-ground and backfilled over. Once decommissioning is complete, the area would likely be designated for industrial land use, with no restrictions.

During the institutional control period, the wastes were assumed to be kept in interim storage before being transferred to an undefined final disposal facility. The institutional control period would include the institutional control period established for the final disposal facility.

The post-institutional control period occurs after institutional control ends for the disposal facility.

2.5.4.1.1 Technical

The goal of this alternative is to allow radioactive components remaining in the WR-1 Building to decay to safer levels to reduce radiation exposure of workers and the public during decommissioning. There are numerous examples of complete decommissioning projects of nuclear reactors in the United States, United Kingdom, Japan, France and Germany. Canada has not performed a reactor dismantling project yet, other than simple SLOWPOKE reactors. Lessons learned from previous decommissioning work would be used to prepare and execute this decommissioning plan, including the World Association of Nuclear Operators, Institute of Nuclear Power Operations and CNL. There are no foreseeable technical complications to applying those techniques and lessons learned to WR-1.

The complete removal of the facility would require the off-site disposal of wastes. It was assumed that an approved disposal facility would exist or be imminent at the time of decommissioning (i.e., in 30 years), and that it would have the capacity to accept the wastes to be generated from WR-1. Therefore, interim storage of wastes would not be required for deferred decommissioning, or only required for a short time. In the event that off-site disposal would not yet be available, additional interim storage capacity would be required. Interim storage facilities already exist, and expansion would not be technically challenging. The requirement for human support or intervention would end once the final disposal state is reached.

Delayed decommissioning means that the radioactive components within WR-1 would stay on site for a longer period of time. CNL would continue its surveillance and monitoring programs. These programs have been in place for over 20 years at the WL site and are effective at monitoring releases to the environment. Once decommissioning is complete, monitoring would be completed to confirm that the non-radiological and radiological clearance and release criteria meet the target end-state (industrial land-use). Long-term monitoring requirements during the institutional control period are expected to be relatively straightforward and include verifying that release criteria continue to be met.

The technical feasibility of this alternative hinges on the expectation that an off-site disposal facility would exist in the near future. The technical feasibility of the Project would diminish over time if delays to the construction of a final waste disposal facility occur. The technical feasibility of final disposal is not assessed here, as facility design has not been chosen. A key consideration would be whether the facility is dedicated to WR-1 wastes or accepts wastes from other customers. The assumption that a disposal facility would be available is reasonable as several different types of waste disposal facilities have been constructed successfully worldwide to date.

In summary, Alternative #1 (deferment) does meet the technical feasibility criteria as set out in Section 2.5.2.1. The technology for Alternative #1 is proven, and the monitoring programs currently in place at the WL site would continue until decommissioning is complete. Monitoring during the institutional control period could be developed that meets national and international requirements. The assumption that an off-site waste disposal facility would be available in the future is realistic, and thus the alternative is technically feasible and carried forward for further assessment.

2.5.4.1.2 Economic

Alternative #1 would require a prolonged deferment period (more than 30 years) and additional costs associated with ongoing storage with surveillance. As long as WR-1 and the WR-1 Building remain in their current state, the required costs include ongoing security, fire and radiation protection, environmental monitoring, regulatory compliance programs, and maintenance and repairs to necessary infrastructure. The projected annual cost to support these ongoing activities for the WL site is between $9 million (M) and $20 M during decommissioning and $4 M in the final year after all major decommissioning has been completed. Assuming that the overall cost of storage and surveillance remains at 2018 levels, the annual cost is $4 M. Deferring decommissioning a further 30 years results in an additional storage with surveillance cost of about $120 M (Table 2.5.4-1). This would be in addition to the cost of full dismantling and removal of WR-1 at the end of this deferment period. The cost associated with the deferred decommissioning is anticipated to be marginally lower because of the decreased levels of radioactivity for shorter-lived radionuclides such as cobalt-60, hydrogen-3 (tritium) and iron-55, as compared to immediate decommissioning. However, these savings would be largely offset by the costs of a lengthy storage and surveillance period and increased costs due to escalation.

The cost and risk associated with packaging and transporting waste from Whiteshell Laboratories to Chalk River Laboratories has been evaluated as part of the overall CNL integrated waste strategy. This assessment determined a cost estimate of $24 M (see Table 2.5.4-1) to package, transport and store wastes from decommissioning WR-1 using Alternative #1.

Monitoring requirements were based on the assumption that 10 years of monitoring would be completed following decommissioning to verify that non-radiological and radiological clearance and release criteria defined in the WL Closure Land-Use and End-State Plan would be in accordance with the target end-state.

Table 2.5.4-1: Alternative #1 Estimated Cost

Project Component	Activities	Cost ($ Million)
Storage and Surveillance	Includes ongoing security, fire and radiation protection, environmental monitoring and regulatory compliance programs	120
Decommissioning of WR-1 Building	Includes the complete dismantling and removal of the WR-1 Building	>120
Transportation and Storage of Waste	Waste handling, packaging and transportation of wastes to an off-site disposal facility	24
Monitoring Requirements	Includes environmental monitoring after decommissioning is complete	1
	Total	265

The costs of construction of a final disposal facility are not estimated or included in this comparison, as the costs could vary depending on the facility design chosen.

There are no post-institutional control activities on site associated with Alternative #1. Any post-institutional control activities associated with off-site disposal are not included in this evaluation.

The estimated costs of Alternative #1 are feasible within recent and current funding arrangements. As such, Alternative #1 is deemed economically feasible and carried forward for further assessment.

2.5.4.1.3 Safety

2.5.4.1.3.1 Worker Safety

For Alternative #1, the deferment period is considered to be part of the closure phase. The risks to workers during this phase are essentially the same as they are currently and are well understood. There is some uncertainty about the extent of building maintenance that would be required to maintain the current level of safety for workers as the facility continues to age during the deferment period. Over the course of the deferment period, the risks to workers from failing or damaged equipment, and the risks associated with correcting those failures, would generally increase until decontamination and demolition of the WR-1 Building begins. However, these risks are still considered very small and have been well managed to date.

After the deferment period, full dismantling and removal would require sectioning of the fuel channels and reactor vessel, which represent the areas of highest radioactivity. Proper sectioning and bundling of all below-grade materials for safe hoisting would also require substantial work within the WR-1 Building. As described previously, the goal of this alternative is to allow radioactive components remaining in the WR-1 Building to decay to safer levels to reduce radiation exposure of workers during decommissioning. Even though full dismantling and removal would require workers to be present below-grade for prolonged periods of time, dose controls requirements (e.g., shielding and distance) would be less onerous for deferred decommissioning as compared to immediate dismantling and removal (i.e., Alternative #2). However, even with the deferment period, there are aspects of the work that would still require effort to mitigate radiological exposures during removal of the reactor components.

Equally important are the non-radiological hazards present in WR-1, such as asbestos, which do not decay over the course of the deferment period. All asbestos would have to be remediated prior to removing piping and equipment. The extensive remediation efforts may be further hindered by the ongoing degradation of the asbestos during the deferment period. Lead paint, PCBs and mould are also potential hazards that must be addressed and

mitigated during demolition work. More extensive and intrusive decommissioning work would create more risk of exposures to and releases of these materials.

Other industrial hazards are also associated with the dismantling and removal of WR-1. Because much of the contaminated equipment and materials are located below-grade, removal would require considerable cutting to properly section and bundle materials for safe extraction. This would increase worker exposure to risks associated with cutting tools, working at heights, confined spaces and hoisting/rigging. Therefore, additional safety controls would be required to protect workers in these areas.

While the construction and operation of an off-site disposal facility is outside the scope of this project, the effects of that work were considered when assessing the alternatives. Off-site disposal would require workers to dismantle WR-1 at the WL site, package the wastes and transport them on public roads to a waste storage or disposal facility. It would also require workers to construct, operate and decommission additional capacity at a waste disposal facility in addition to decommissioning WR-1. This would involve many standard transportation and construction hazards and risks.

The deferment period has one additional limitation that could affect the level of risk to workers and the public: the loss of experienced personnel over the 30-year deferment. Few employees remain with extensive knowledge of the facility. Delaying decommissioning would very likely result in the loss of the ability to draw from that knowledge during decommissioning work. This could exacerbate existing hazards further.

The institutional control period for Alternative #1 has two components:

1) monitoring of the WL site to verify that end-state conditions have been met; and

2) monitoring the removed wastes in their off-site storage/disposal configuration.

On-site monitoring would continue for a period of time to verify that site end-state conditions have been met. This monitoring would be relatively low risk for workers and would involve collection of various water, soil, flora and fauna samples. This work is currently being performed at the WL site as part of ongoing operations, but is expected to decrease over time. The institutional control period is estimated to last 200 years for Alternative #1 (CNL 2015).

Off-site monitoring during the institutional control period is less defined. It is assumed that a disposal facility will exist, but the location and type of facility are yet to be determined. As such, it is assumed that any facility built would have a similar level of monitoring as Alternative #3 (ISD).

After the institutional control period, it is assumed that there would be no workers present at the site. As such, worker safety is not discussed for the post-institutional control period.

Overall, Alternative #1 would involve intensive decommissioning work and put workers at the highest risk of injury compared to all other alternatives during the closure phase. It would also require off-site construction work for additional storage or disposal capacity. The radiological hazard would be slightly reduced in Alternative #1 compared to Alternative #2 (no deferment), but all other non-radiological hazards would remain largely the same. The loss of experienced workers over the deferment period would further exacerbate these risks. The risks to workers during the institutional control period are well understood and are lower than during the closure phase. This alternative assumes that safe final disposal of the waste would occur before the end of the institutional control

period. The only assumption that can be made about monitoring at the disposal facility is that it would be done in accordance with safety standards of the time.

2.5.4.1.3.2 Public Safety

For Alternative #1, the deferment period is considered to be part of the closure phase. The risks to the public during this phase are essentially the same as they are currently and are well understood. After the deferment period, full dismantling would occur, requiring intrusive decommissioning activities. These activities have the potential to increase both radiological and non-radiological emissions to the air and water, though any such increases would be planned, mitigated and monitored so that emissions remain ALARA and within the safe limits established through the existing decommissioning licence for the WL site. Once the wastes are removed from the WL site, the risk to the public would be reduced from the already benign levels seen during the deferment period. As such, there is not expected to be any remaining risk to the public following the closure phase. Dismantling of WR-1 would require volumes of waste, including the reactor core components, to be transported from the WL site to an approved interim storage location. The materials would likely be transported by road, resulting in an additional risk of a transportation incident. Transporting hazardous materials (both radioactive and non-radioactive) is routine and the risks are well understood. The risks are transferred to the public along the transport route, as well as in the vicinity of the interim storage location. These risks are considered to be very low.

During the institutional control period, the wastes are assumed to be in a waste storage or disposal facility that is routinely maintained and monitored to prevent releases to the environment. This presents a low risk to the public in the vicinity of the new facility, unless additional handling or transportation of the waste were required at some point prior to final disposal. Again, those risks would be small due to the extensive experience in waste handling and transportation. Additional risks related to the construction of the new facility, including increased construction traffic and fugitive dust emissions, could be effectively managed.

In the post-institutional control period, it is assumed that a final disposal facility will exist for the wastes. The type of facility and its location would be socio-economic factors at the time of construction. With such uncertainty, it cannot be assumed that a future disposal facility would pose a lesser risk to the public than any such facilities that exist today or that are currently proposed. CNL assumes that the risks to the public from such a future disposal facility are at least equivalent to the risks associated with the proposed ISD method (Alternative #3).

2.5.4.1.4 Environmental

For Alternative #1, the deferment period is considered to be part of the closure phase. The risks to the environment during this phase are essentially the same as they are currently and are well understood. Dismantling and removal of WR-1 would require extensive and intrusive decommissioning activities (e.g., dismantling, cutting, hoisting). These more intrusive activities would likely result in increased air emissions from the following sources:

- increased use of vehicles and equipment that combust fuel and emit indicator compounds;
- more vehicles travelling on roads that emit fugitive dust; and
- additional release of radioactive compounds during cutting and dismantling of equipment for transport off site; however, the release of radioactive compounds would still be expected to be within applicable release limits (AECL 2001).

Increased air emissions, both radiological and non-radiological, present potential risks to the public, vegetation and wildlife. Effective mitigation could be implemented so that the release of radioactive compounds would be within applicable release limits (AECL 2001). These measures are described in detail in CNL's DDP for Building 100 (CNL 2015). In addition, deferred decommissioning would take place after a period of natural radioactive decay, thereby reducing the risk of radionuclides being released during decommissioning.

The increased vehicle use during decommissioning and the transporting of wastes off site would also result in increased greenhouse gas emissions. An air quality assessment was completed as part of the CSR for the entire WL site (AECL 2001). The CSR assessed the removal of WR-1 (Alternative #1). The assessment determined that appropriate mitigation could be implemented so that air emissions would not result in significant effects.

During the institutional control period, residual radiation may still be present, but it is expected to be at very low levels (below the clearance levels). There would be no risk to the environment at the WL site in the post-closure phase. Removal of WR-1 would eliminate the potential risk of radioactive contaminants entering and potentially affecting human health and the environment.

Alternative #1 has the WR-1 liability and associated risks transferred to another off-site facility for interim storage, and then to a final disposal facility. It is not yet known what environmental effects would be associated with these new facilities.

In the post-institutional control period, the potential effects on the groundwater, aquatic, terrestrial and atmospheric environment would be comparable to other long-term waste disposal options. CNL conservatively assumes that the risks to the environment from a future disposal facility would be at least equivalent to the risks associated with the proposed ISD method (Alternative #3).

From a socio-economic perspective, the extended deferment period and full dismantling approach provides the most man-hours of employment and direct economic benefit to the region of any of the alternatives. The direct economic benefit would be limited to the closure phase, as there would be little work performed at the WL site during the institutional control period since all wastes would have been transferred off site. That economic benefit from monitoring and surveillance work would be transferred to the host community of the interim waste storage facility and the future disposal facility. The complete removal of materials from the WL site would result in an increased level of traffic and wear on local, regional and national roads. The nature of the transportation may also necessitate additional infrastructure upgrades, repairs or temporary closures along the transport route.

In the institutional control period at the WL site, the removal of WR-1 would improve the availability of the site for future business ventures. In addition, complete removal may allow this portion of the site to be released with no restrictions on use, although this would need to be verified against site clean-up criteria. This could result in more diverse commercial or industrial opportunities for the site and additional traditional land use activities (e.g., hunting and berry picking, cultural practices). It is expected that the interim storage facility would be located on a site that has already been allocated for storage of nuclear materials and thus would not necessarily be negatively affected by the interim storage of WR-1 wastes. In addition, the Community Regeneration Partnership, which is intended to help the communities affected by decommissioning, is developing a socio-economic plan for the participating communities and rural municipalities, which could support future economic development and promote the viability of the regional economy. No additional work is expected to occur at the WL site in the institutional control period, and thus there is no expected effect on local infrastructure.

Beyond the institutional control period, it is assumed that prior knowledge of the site and its history would be lost. There should not be any socio-economic effects after the institutional control period.

2.5.4.2 Alternative #2 – Immediate Dismantling and Removal

Alternative #2 would involve the dismantling and removal of WR-1 and the associated building without a deferment period. Similar to Alternative #1, this alternative would involve the removal of all equipment and materials from the WR-1 Building, decontamination of building structure, and demolition and removal of the building structure to 3 m below-ground level. Following removal and decontamination, the site would be subjected to a radiological survey to confirm that the release criteria defined in the WL Closure Land-Use and End-State Plan have been met. The remaining building components could be reused or recycled, transferred to an inactive landfill site, or remain in situ and be backfilled over. Once decommissioning is complete, the area would likely be classified as industrial land use, with no restrictions.

2.5.4.2.1 Technical

The technical feasibility of Alternative #2 (immediate dismantling) is identical to that of Alternative #1. The only difference is the timing of the work. Alternative #2 has the dismantling work beginning immediately, without additional time for radiological hazards to decay. Alternative #2 would require additional procedural and engineered mitigation so that worker exposure to radiological hazards remains ALARA. During and after the latter half of the institutional control period, the radiological hazards would have decayed sufficiently to be considered equivalent to Alternative #1. In summary, Alternative #2 does meet the technical feasibility criteria as set out in Section 2.5.2.1. The technology for Alternative #2 is proven. The monitoring programs currently in place at the WL site would continue until decommissioning is complete. Monitoring during the institutional control period can be developed that meets national and international requirements. The higher radiological hazards for workers are well within a range that has been successfully mitigated in decommissioning projects. The assumption that a off-site waste disposal facility would be available in the future is realistic, and thus the alternative is technically feasible and carried forward for further assessment.

2.5.4.2.2 Economic

The economic feasibility of Alternative #2 is similar to that of Alternative #1. Because Alternative #2 is immediate, the costs associated with a deferment period (e.g., building maintenance and licence requirements) can be avoided. Alternative #2 has an increased radiological risk to workers, with an increased cost to mitigate those hazards. Preliminary estimates put the cost of the work required around $120 M (Table 2.5.4-2). This estimate is at the lower end of costs experienced for dismantling other reactors, which have ranged from $32 M to $1.1 billion.

CNL has prepared a detailed cost estimate of $24 M for the packaging, transportation and waste storage for the WL site. This is the basis for the waste costs associated with dismantling WR-1 (see Table 2.5.4-2).

Monitoring requirements are based on the assumption that 10 years of monitoring would be completed following decommissioning to verify that non-radiological and radiological clearance and release criteria continue to be met.

Table 2.5.4-2: Alternative #2 Estimated Project Cost

Project Component	Activities	Cost ($ Million)
Storage and Surveillance	Includes ongoing security, fire and radiation protection, environmental monitoring and regulatory compliance programs	0
Decommissioning of WR-1 Building	Includes the complete dismantling and removal of the WR-1 Building	120
Transportation and Storage of Waste	Waste handling, packaging and transportation of wastes to an off-site disposal facility.	24
Monitoring Requirements	Includes environmental monitoring after decommissioning is complete	1
	Total	145

As with Alternative #1, the costs of construction of a final disposal facility are not estimated or included in this comparison, as the costs could vary substantially depending on facility design chosen.

There are no on-site post-institutional control activities associated with Alternative #2. Any post-institutional control activities associated with off-site disposal are not included in this evaluation.

The estimated costs of Alternative #2 are feasible within recent and current funding arrangements. As such, Alternative #2 is deemed economically feasible and carried forward for further assessment.

2.5.4.2.3 Safety

2.5.4.2.3.1 Worker Safety

In the closure phase, just like Alternative #1, full dismantling and removal would require sectioning (e.g., cutting and dismantling) of the fuel channels and reactor vessel, which represent the areas of highest radioactivity. Proper sectioning and bundling of all below-grade materials for safe hoisting would also require substantial work within the WR-1 Building. Without the deferment period, the mitigation required to protect workers from radiological hazards would be more onerous than for Alternative #1.

Equally important are the non-radiological hazards present in WR-1, such as asbestos. In the case of non-radiological hazards, not having a deferment period is generally beneficial. The condition of non-radiological hazardous materials usually degrades over time, increasing the potential risk to workers. Immediately dismantling would probably reduce the worker risks from hazardous materials such as asbestos or PCBs.

Industrial hazards are associated with the dismantling and removal of WR-1. Because much of the contaminated equipment and materials are located below-grade, removal would require considerable cutting and dismantling to properly section and bundle materials for safe extraction. This would increase worker exposure to risks associated with powered cutting tools, working at heights, confined spaces and hoisting/rigging.

In contrast to Alternative #1, eliminating the deferment period would reduce the loss of key personnel with valuable operational and personal experience. Few employees would remain with extensive knowledge of the facility, and their expertise and experience would be valuable tools for further reducing risks to workers.

Just as with Alternative #1, the removal of WR-1 would require the off-site disposal of wastes, which would require additional handling by workers for waste packaging and transporting. It is assumed that an approved waste management facility will exist at the time of decommissioning and that it would have the capacity to accept the WR-1 wastes. While the construction and operation of such a facility is outside the scope of the Project, the effects of that work are considered when assessing the alternatives. Off-site disposal would require workers to dismantle, package and transport WR-1, and to construct, operate and decommission additional capacity at a waste disposal facility. Just as in Alternative #1, this would involve many standard transportation and construction hazards and risks.

The institutional control period for Alternative #2 is nearly identical to Alternative #1 (i.e., 200 years). The only difference for Alternative #2 may be a slightly higher radiological risk to workers monitoring the wastes at the off-site storage facility for the first 30 years. However, the increased risks are small and manageable.

In the same way as Alternative #1, after the institutional control period, it is assumed that there would be no workers present at the WL site. As such, worker safety is not discussed for the post-institutional control period.

Overall, Alternative #2, is nearly identical to Alternative #1. It would involve intensive decommissioning work and put workers at a risk of injury or exposure during the closure phase. It would also require additional off-site

construction work to build additional storage or disposal capacity. The radiological hazard is slightly increased in Alternative #2, compared to Alternative #1, and all other non-radiological hazards remain largely the same. The elimination of the deferment period provides the benefit of access to experienced and knowledgeable staff that would not be available in the near future. The risks to workers during the institutional control period are well understood and are lower than the closure phase. Alternative #2 assumes that safe final disposal of the waste occurs before the end of an institutional control period, but CNL cannot define how that would be accomplished, other than to assume it would be done in accordance with safety standards of the time.

2.5.4.2.3.2 Public Safety

The activities expected for Alternative #2 have the potential to increase both radiological and non-radiological emissions to the air and water. These emissions can be planned, mitigated and monitored so that emissions remain ALARA, and within the safe limits established through the existing decommissioning licence for the WL site. Once the wastes are removed from the WL site, there is not expected to be any remaining risk to the public. Dismantling WR-1 would require that the volumes of waste, including the reactor core components, be transported to an approved interim storage facility for long-term management. The materials would likely be transported by road, resulting in an additional risk of a transportation incident. Transporting hazardous materials (both radioactive and non-radioactive) is routine and the risks are well understood. The risks are transferred to the public along the transport route, as well as in the vicinity of the interim storage location. These, risks would be considered to be very low.

During the institutional control period, the wastes are assumed to be in a waste storage or disposal facility that is maintained and monitored to prevent releases to the environment. This would present a low risk to the public in the vicinity of the new facility, unless additional handling or transportation of the waste were required at some point prior to final disposal. Again, those risks would be small due to the extensive experience in waste handling and transportation. Additional risks related to the construction of the new facility, including increased construction traffic and fugitive dust emissions, can be effectively managed.

In the post-institutional control period, it is assumed that a final disposal facility will exist for the wastes, though the location and type of facility are unknown. The type of facility and its location would be a product of the socio-economic factors at the time of construction. With such uncertainty, it cannot be assumed that a future disposal facility would pose a lesser risk to the public than any such facilities that exist today or that are currently proposed. CNL assumed that the risks to the public from such a future disposal facility would be at least equivalent to the risks associated with the proposed in situ disposal method (Alternative #3).

2.5.4.2.4 Environmental

For Alternative #2, the risks to the environment are essentially the same as for Alternative #1. The complete removal of WR-1 would require extensive and intrusive decommissioning activities (e.g., dismantling, cutting, hoisting). These intrusive activities are more likely to result in increased air emissions from the following sources:

- increased use of vehicles and equipment that combust fuel and emit indicator compounds;
- more vehicles travelling on roads that emit fugitive dust; and
- additional release of radioactive compounds during cutting and dismantling of equipment for transport off site; however, the release of radioactive compounds is still expected to be within applicable release limits (AECL 2001).

Increased air emissions, both radiological and non-radiological, could present potential risks to the public, vegetation and wildlife. Effective mitigation could be implemented so that the release of radioactive compounds would be within applicable release limits (AECL 2001). These measures are described in detail in CNL's DDP for Building 100 (CNL 2015). The increased vehicle use during decommissioning and the transport of wastes off site would also result in increased greenhouse gas emissions.

An air quality assessment was completed as part of the CSR for the entire WL site (AECL 2001). The CSR assessed the dismantling and removal of WR-1. The assessment determined that appropriate mitigation could be implemented so that air emissions would not result in significant effects.

During the institutional control period, residual radiation could still be present, but it is expected to be at very low levels (below the clearance levels as stipulated in the Nuclear Substances and Radiation Devices Regulations). There would be no risk to the environment at the WL site in the post-closure phase. Removal of WR-1 would eliminate the potential risk of radioactive contaminants entering and potentially affecting human health and the environment.

Alternative #2 has the WR-1 liability and associated risks transferred to another off-site facility for interim storage, and then to a final disposal facility. It is not yet known what environmental effects would be associated with these new facilities.

In the post-institutional control period, the potential effects on the groundwater, aquatic, terrestrial and atmospheric environment would be comparable to other long-term waste disposal options. CNL conservatively assumed that the risks to the environment from a future disposal facility would be at least equivalent to the risks associated with the proposed in situ disposal method (Alternative #3).

From a socio-economic perspective, during the closure phase, the full dismantling approach provides potentially substantial man-hours of employment and direct economic benefit to the region. The direct economic benefit would be limited to the closure phase, as there would be little work performed at the WL site during the institutional control period since all wastes have been transferred off site. That economic benefit from monitoring and surveillance work would be transferred to the host community of the interim waste storage facility and the future disposal facility. The complete removal of materials from the site would result in an increased level of traffic and wear on local, regional and national roads. The nature of the transportation may also necessitate additional infrastructure upgrades, repairs or temporary closures along the transport route.

In the institutional control period at the WL site, the removal of WR-1 would improve the availability of the site for future business ventures. In addition, complete removal may allow this portion of the site to be released with no restrictions on use, although this would need to be verified against site clean-up criteria. This could result in more diverse commercial or industrial opportunities for the site and additional traditional land use activities (e.g., hunting and berry picking, cultural practices). It is expected that the interim storage facility would be located on a site that has already been allocated for storage of nuclear materials, and thus would not necessarily be negatively affected by the interim storage of WR-1 wastes. In addition, the Community Regeneration Partnership is developing a socio-economic plan for the participating communities and rural municipalities, which could support future economic development. No additional work is expected to occur at the WL site during the institutional control period, and thus there is no expected effect on local infrastructure.

Beyond the institutional control period, it is assumed that prior knowledge of the site and its history would be lost. No socio-economic effects are expected after the institutional control period has ended.

2.5.4.3 Alternative #3 – In Situ Disposal

Alternative #3 would involve ISD of WR-1, where below-grade WR-1 systems, components and structures would be permanently encased with grout. Most of the above-grade structures and all above-grade equipment would be demolished and removed. A small section of the primary heat transport system that is currently above-grade would be removed and placed below-grade with the remainder of the primary heat transport system. After grouting, a concrete cap and engineered cover would be constructed over the below-grade structure. After the closure phase, the remaining structure would be called the WRDF. Institutional control is expected to be maintained for at least 100 years. For the purpose of the assessment, the post-institutional control period is assumed to start 100 years after closure (i.e., once the institutional control period ends).

CNL considered Alternative #3 for WR-1 for three key reasons:

- It allows CNL to safely address the nuclear liability associated with the WR-1 Building.
- CNL does not have a suitable facility available in Canada to accept either the intermediate-level radioactive waste or the organic-contaminated low-level waste expected from dismantling the reactor.
- Alternative #3 is not costlier than the original proposed approach of complete dismantling and removal.

There is no timeline for when a suitable facility might be available in Canada. To ensure that CNL continues to meet its mandate to protect the public and the environment, CNL needed to assess an approach that did not depend on a proposed future disposal facility. The approach for Alternative #3 does not depend on such a facility, does not defer the waste disposal responsibility to future generations, and allows CNL to continue to protect the environment and the public.

2.5.4.3.1 Technical

The US Nuclear Regulatory Commission has recognized ISD as an acceptable decommissioning and disposal strategy since the 1970s (US DOE 2013). The CNSC and the Canadian Standards Association (CSA) also both recognize ISD as an acceptable approach for legacy nuclear facilities such as WR-1, which are remnants of the dawn of the nuclear industry in Canada, and for which decommissioning was not planned as part of the design (CNSC 2021b; CSA 2019).

In situ disposal has already been used for several prototype reactors around the world (Laraia 2014), including:

- **Heavy Water Components Test Reactor, Savannah River, South Carolina** – The Heavy Water Components Test Reactor was an underground reactor built in in 1958. It was 480 times larger than WR-1. ISD was completed in 2011.
- **Lucens Reactor, Lucens, Vaud, Switzerland** – Lucens was a 6 megawatt (MW) experimental reactor (similar physical size to WR-1) that was shut down after an accident in 1969. After 30 years of storage with surveillance, the reactor building was grouted. The site was released from regulatory oversight in 2003 and is now a museum.
- **Boiling Water Reactor Experiment-1 (BORAX-1), National Reactor Testing Station, eastern Idaho** – This test reactor was initially destroyed in 1954. The reactor was placed in a landfill in the mid-1950s. In 1997, an engineered long-term barrier, designed to last 320 years, was installed over the BORAX-1 landfill.
- **R-Reactor and P-Reactor, Savanah River, South Carolina** – The R-reactor was removed from service in 1964. The P-Reactor was shut down in 1990. ISD was completed for both reactors in 2011.

- **Uranium Fueled Graphite-Moderated Reactors, Krasnoyarsk Mining Chemical Plant, Krasnoyarsk, Russia** – Two below-grade reactors (AD and ADE-1) were taken out of service in 1992 and 2010, respectively. In 2009, ISD was selected to decommission the reactors. The decommissioning program is now ongoing.
- **IRT-M Reactor, Tblisi, Georgia** – The reactor was taken out of service in 1988. ISD was completed around the reactor core in collaboration with the IAEA (Project GEO/4/002) in the late 1990s.
- **Below-grade portion of several small reactor facilities at Idaho National Laboratory** – Five Reactors Complexes (Engineering Test Reactor, Materials Test Reactor, Power Burst Facility Reactor, Zero Power Physics Reactor and the Experimental Breeder Reactor II) were all decommissioned at the Idaho National Laboratory. All of the reactors have been removed and disposed of.

Decades of environmental monitoring against design specifications, showed that ISD is a safe, cost-effective decommissioning option (US DOE 2013).

Grout would be used for ISD because it can be pumped into void spaces easily. Filling the void spaces in the below-grade WR-1 Building would stabilize the structure. The introduction of grout would also impede infiltration of water and limit access to intruders (US DOE 2013). Various compounds could be added to the grout formulation to enhance the immobilization of contaminants (US DOE 2013) or to adapt them to local conditions. The properties required for the grout would be achieved using locally available materials that limits water infiltration, minimizing the migration of contaminants to underlying aquifers. In addition, the concrete cap and engineered cover would prevent a person that might inadvertently enter the area from being able to contact buried contamination (US DOE 2013). At the WL site, the concrete cap and engineered cover could also provide insulation from freeze-thaw cycles and reduce degradation of the grouted structure below.

The majority of radiological wastes from WR-1 would be filled as practical with grout and disposed of in situ at the WL site. Only limited quantities of radiological wastes would require packaging and transport to an interim storage facility pending final disposal. Much of the building waste is expected to be clear of contamination. This waste would be handled with standard commercial waste disposal and recycling processes, requiring no additional monitoring or controls.

The institutional control period for the WRDF would involve regular collection of samples and visual inspections of the site. A monitoring program is already in place for the WL site. The monitoring for the WRDF would be added to the existing EAFMP. Institutional control is expected to be at least 100 years long. This monitoring would confirm that the WRDF is operating as expected, isolating the waste from the environment and the public.

The post-institutional control period is defined as the time when a major event (such as government collapse or global-scale natural disaster) causes all knowledge of the WRDF to be lost. For the purpose of the assessment, it is assumed to happen 100 years after closure (i.e., once the institutional control period ends).

The safety of the WRDF is provided by means of passive features (e.g., concrete cap and engineered cover) (IAEA 2011b). The performance of the multiple barriers assure that the WRDF remains safe. The monitoring program would verify long-term safety of the public and the environment.

In summary, Alternative #3 addresses all of the relevant technical feasibility criteria set out in Table 2.5.2-1. The technology for Alternative #3 has been implemented successfully in other jurisdictions. The technology can be easily adapted to suit the local conditions. Alternative #3 does not rely on the development of new technologies or facilities and does not rely on institutional controls for long-term safety. As such, Alternative #3 is deemed technically feasible and is carried forward for further assessment.

2.5.4.3.2 Economic

Alternative #3 does not require the dismantling of the WR-1, and therefore does not result in a large volume of waste material to be packaged and transported to an off-site disposal facility. Current estimates indicate costs associated with ISD activities would be about $35 M (Table 2.5.4-3). CNL assumed 100 years of institutional control during which active monitoring would be completed to verify that non-radiological and radiological clearance and release criteria continue to be met. For Alternative #3, it is anticipated that initial monitoring costs would be high and would decrease over time as monitoring becomes more focused.

Table 2.5.4-3: Alternative #3 Estimated Project Cost

Project Component	Activities	Cost ($ Million)
Storage and Surveillance	Includes ongoing security, fire and radiation protection, environmental monitoring and regulatory compliance programs	0
Decommissioning of WR-1 Building	Includes the ISD of the WR-1 and the associated building	35
Transportation of Waste	Waste handling, packaging and transportation of wastes to an off-site disposal facility	<1
Monitoring Requirements	Includes environmental and performance during institutional control (i.e., 100 years)	7
	Total	43

As with Alternative #1, the costs to dispose of the limited amounts of radioactive waste above-ground at a future disposal facility, or monitoring at that future facility, are not included in this comparison.

There are no on-site post-institutional control activities associated with Alternative #3. Any post-institutional control activities associated with off-site disposal are not included in this evaluation.

Alternative #3 does not cost more than Alternative #1, which has already been previously agreed to as economically feasible. Alternative #3 is therefore considered economically feasible and carried forward for further assessment.

2.5.4.3.3 Safety

2.5.4.3.3.1 Worker Safety

In the closure phase, Alternative #3 provides worker safety benefits. Although some demolition and dismantling are still required with the ISD alternative, the number and complexity of tasks is much less, reducing the safety risks to personnel (US DOE 2013). Due to the less frequent and less intrusive nature of the work, the exposure risk to all potential hazards, both radiological and non-radiological, is reduced with ISD.

The ISD would limit the potential radiation exposure to workers because it would reduce the handling and movement of material, and the grouting of the facility prevents migration of contaminants and radioactive emissions (US DOE 2013). Removal, size reduction and packaging of contaminated process equipment could be an intensive operation. Under the ISD alternative, much of this equipment and material would be left within the structure and grouted in place, thereby requiring minimal handling and subsequent exposure to personnel.

Alternative #3 could leverage the experience and knowledge of current senior staff to improve safety. Deferring the Project, such as for Alternative #1, could result in a loss of operational experience and knowledge that cannot be replaced.

Alternative #3 could introduce construction hazards and risks, such as handling raw materials, operating a batch concrete mixing plant, building and placing concrete forms, pouring grout, construction of the concrete cap and engineered cover and final site grading and landscaping. None of these hazards is unique to WR-1; they are standard for medium to large construction projects. The hazards and risks associated with that work would be well within acceptable limits and can be effectively mitigated.

The institutional control period for this alternative has two components:

- monitoring of the WRDF to verify end-state conditions and observed performance criteria are met; and
- monitoring the removed wastes in their off-site storage/disposal facility.

Monitoring of the WRDF would continue for at least 100 years to verify that the WRDF is performing as expected. This monitoring would be low risk for workers and would involve collection of various water, soil, flora and fauna samples, as well as visual inspection of the concrete cap and engineered cover for indications of premature failure.

Monitoring of wastes removed from the site to an off-site disposal facility during the institutional control period is less defined. It is assumed that a disposal facility would exist, but the location and type of facility are yet to be determined. As such it is assumed that any facility built would have a similar level of monitoring as the WRDF. This assumption is supported by the similarities in existing monitoring plans for the WL and Chalk River Laboratories sites and the various waste storage facilities they operate.

After the completion of the institutional control period, it is assumed that there would be no workers present at the WL site. As such, worker safety is not discussed for the post-institutional control period.

Overall, Alternative #3 (ISD) would present a reduced hazard to workers from radiological exposure and industrial hazards during the closure phase due to the less intrusive nature of the decommissioning work. It would still require off-site disposal of some wastes, though the quantity would be greatly reduced as compared to other alternatives. The risks to workers during the institutional control period are well understood and are lower than during the closure phase. There would be no risks to workers in the post-institutional control period.

Alternative #3 would require the transport and disposal of a small volume of waste off site, reducing the risk to handlers.

2.5.4.3.3.2 Public Safety

For Alternative #3, full dismantling would not occur, requiring fewer intrusive decommissioning activities. These activities have the potential for both radiological and non-radiological emissions to the air and water. Such releases would be planned, mitigated and monitored so that emissions remain ALARA, and within the safe limits established through the existing decommissioning licence for the WL site.

The demolition of the above-grade structure would require limited volumes of waste to be transported from WL to an approved interim storage facility. The materials would likely be transported by road, resulting in an additional risk of a transportation incident. The risks associated with transportation of hazardous materials are well understood, and hazardous materials (both radioactive and non-radioactive) are routinely transported. The risks would be transferred to the public living along the transport route, as well as in the vicinity of the interim storage facility. These risks would remain very low.

During the institutional control period, the WRDF would be routinely monitored to identify any releases to the environment. The risk of releases during the institutional control period would be low. The wastes removed from the site for interim storage or disposal would also be monitored. Such monitoring is expected to be equivalent to the WRDF and other waste management facilities currently in operation. The risk from WR-1 related wastes in this facility would be very low since WR-1 waste would likely make up only a very small portion of its inventory.

In the post-institutional control period, the long-term effects of the WRDF on the public are through potential contamination of groundwater, surface water, soils and air near the WRDF. Contamination may be leached from the grouted structure into the groundwater and transferred to surface water, air and soils near the WRDF. The majority of the contamination would remain or decay away within WRDF, and the risks from any emissions to the groundwater would be well below regulatory limits established by the CNSC. Such losses are expected from any type of waste management facility, constructed at any location.

In the post-institutional control period, it is assumed that a final disposal facility will exist for the off-site wastes, though the location and type of facility are unknown. The type of facility and its location would be socio-economic factors at the time of construction. With such uncertainty, it cannot be assumed that a future disposal facility would pose a lesser risk to the public than any such facilities that exist today or that are currently proposed. CNL assumed that the risks to the public from such a future disposal facility would be at least equivalent to the risks associated with future disposal of a fully dismantled WR-1 (Alternative #1 and Alternative #2).

2.5.4.3.4 Environmental

During the closure phase, as decommissioning work begins, ISD would require limited intrusive decommissioning activities (e.g., dismantling, cutting, hoisting) compared to the full removal option. These activities may result in increased air emissions from the following sources:

- increased use of vehicles and equipment that combust fuel and emit indicator compounds;
- more vehicles travelling on roads that emit fugitive dust;
- additional release of radioactive compounds during cutting and dismantling of equipment in preparation for grouting; however, the release of radioactive compounds is still expected to be within applicable release limits; and
- additional fugitive dust from storage and handling of raw materials for grout and from operation of the batch mixing plant or similar equipment.

Increased air emissions, both radiological and non-radiological, could present potential risks to the public, vegetation and wildlife. Effective mitigation can be implemented so that the release of radioactive compounds would be within applicable release limits. The applicable programs to mitigate these hazards are described in detail in CNL's DDP for Building 100 (CNL 2021). The increased vehicle use during decommissioning and the transport of wastes off site would also result in increased greenhouse gas emissions.

An air quality assessment was completed as part of the CSR for the entire WL site (AECL 2001). The CSR assessed the dismantling and removal of WR-1. The assessment determined that appropriate mitigation could be implemented to ensure that air emissions would not result in significant effects. Alternative #3 would require less demolition work but more construction and preparation work, resulting in a likely equivalent level of potential fugitive dust emissions.

During the institutional control period, routine monitoring would reduce the likelihood of any effects on the environment as a result of the WRDF. The WRDF would have a concrete cap and engineered cover that protects against burrowing animals and deep rooting plants. Any releases to the environment during the institutional control period would be monitored and mitigated as needed to ensure there are no significant effects on the environment. The same would be true for the wastes that were removed from the site and stored/disposed of elsewhere. Alternative #3 has the WR-1 liability remaining at the WL site.

In the post-institutional control period, the potential effects on the groundwater, aquatic, terrestrial and atmospheric environment would be comparable to other long-term waste disposal options. Over long periods of time, the facility would degrade and contamination could be released to the environment through the groundwater. The release of contaminants would pose very little risk to the environment because of the very slow rate at which contaminants migrate out of the WRDF. This is typical of most waste management systems, including any future radiological waste disposal facility expected to be built in Canada with existing technology.

For the wastes that were removed from the WL site, since the final disposal location and configuration is not yet known, a detailed qualitative assessment of potential effects could not be made. The type of facility and its location would be socio-economic factors. CNL conservatively assumed that the risk to the environment from such a future disposal facility would be at least equivalent to that from the proposed ISD (Alternative #3).

From a socio-economic perspective, during the closure phase, the duration of the increased staffing for the closure phase work would likely be shorter than for full dismantling (Alternatives #1 and #2) but would involve the purchase and installation of a substantial amount of raw materials, off-setting some of the cost of work not performed to remove the facility. The direct economic benefit would be highest in the closure phase, but would be substantially reduced during the institutional control period. The economic benefit of employment from monitoring and surveillance work over 100 years would be small compared to staffing levels prior to the closure phase. The installation of grout and the reduced volume of wastes removed from the WL site would result in a similar level of additional traffic and wear on local and regional roads, but would not likely affect infrastructure beyond the local region. The nature of the transportation may also necessitate additional infrastructure upgrades, repairs or temporary closures along the transport route.

In the institutional control period, unlike Alternatives #1 and #2, the presence of the WRDF would result in restrictions on WRDF land use for a period of at least 100 years. The WRDF could affect the availability of the site for future use. This may limit potential commercial and industrial opportunities for the WL site in the future and may limit future traditional land use activities (e.g., hunting and berry picking, cultural practices). As part of the WL Closure Land-Use and End-State Plan being developed, CNL would make efforts to effectively identify and implement a path forward for economic development in the local area. The Plan defines the post-closure

end-states, the post-closure land-use classifications and allocation, and the physical release criteria that must be met at the site closure. While the role of the WL site may change, economic and community development are expected to continue. In addition, the Community Regeneration Partnership is developing a socio-economic plan for the participating communities and rural municipalities, which could support future economic development. The ongoing monitoring at the WL site during the institutional control period would likely be limited to the point where no substantial demands were imposed on local infrastructure, including roads.

It is expected that the interim storage or disposal facility for the removed wastes would be located on a site that has already been allocated for storage of nuclear materials. The facility would benefit economically from storing WR-1 wastes.

Beyond the institutional control period, it is assumed that prior knowledge of the site and its history would be lost. There would be no socio-economic effects beyond this point except those related to environmental effects.

2.5.4.4 Alternative #4 – Partial Dismantling and Removal with In Situ Disposal of the Remainder

Alternative #4 entails the dismantling and removal of select WR-1 systems and the ISD of any remaining WR-1 components. It is effectively a combination of the previous alternatives. A series of partial ISD scenarios were examined, including:

1) removal of fuel channels prior to ISD;

2) dismantling and removal of fuel channels and reactor vessel prior to ISD; and

3) dismantling and removal of fuel channels, reactor vessel and additional contaminated systems (e.g., primary heat transport system and/or moderator systems) prior to ISD.

The majority of the activity in WR-1 is located in the calandria and the fuel channels. All other components are considered low-level waste and have little effect on the safety of the WRDF. The change in overall safety case for the WRDF was also negligible when CNL considered removing just the fuel channels. Therefore, the partial dismantling evaluation focused on removing both the fuel channels and the calandria, and leaving all other systems in place for ISD.

Once removed, the reactor core components would be moved to an interim storage or disposal facility.

2.5.4.4.1 Technical

Alternative #4 is a combination of Alternative #2 and #3, both of which have been deemed technically feasible. No additional work is proposed as part of Alternative #4, and it is therefore deemed technically feasible and carried forward for further assessment.

2.5.4.4.2 Economic

Preliminary estimates indicate that Alternative #4 would cost between $10 M and $30 M to plan and execute the sectioning, removal and packaging of the fuel channels and calandria; however, these costs do not include the long-term storage of the core components once they are removed. An additional $35 M base cost for completion of the ISD is also required (Table 2.5.4-4). The packaging, transportation and storage of wastes are estimated at $10 M for fuel channel removal and $15 M for the calandria. The cost of this decommissioning alternative is still lower than the estimated cost for Alternative #2 (Table 2.5.4-2).

Monitoring requirements are conservatively based on the assumption that approximately 100 years of monitoring would be completed following decommissioning (i.e., during institutional control) to verify that non-radiological and radiological clearance and release criteria in accordance with the target end-state. For Alternative #4, it is anticipated that initial monitoring costs would be higher and would decrease over time as monitoring becomes more focused.

Table 2.5.4-4: Alternative #4 Estimated Project Cost

Project Component	Activities	Cost ($ Million)
Storage and Surveillance	Includes ongoing security, fire and radiation protection, environmental monitoring and regulatory compliance programs	0
Decommissioning of WR-1 Building	Includes the partial ISD of the WR-1 Building	45 to 65
Transportation and Storage of Waste	Waste handling, packaging and transportation of wastes to an off-site disposal facility	25
Monitoring Requirements	Includes environmental monitoring during institutional control (i.e., 100 years)	7
	Total	77 to 97

The cost estimates for Alternative #4 fall between the costs of Alternatives #2 and #3, which have both been deemed economically feasible. Therefore, Alternative #4 is deemed economically feasible and carried forward for further assessment.

2.5.4.4.3 Safety

2.5.4.4.3.1 Worker Safety

During the closure phase, this alternative is generally a combination of the various risks and hazards described for Alternatives #2 and #3. Alternative #4 has a similarly high radiological risk to workers, as the removal, handling and transport of the reactor core presents the largest radiological exposure risk of all the work that would be performed. While the expectation to the leave the remaining systems in place would have a lower risk of exposure to non-radiological hazardous materials and industrial hazards, as described in Alternative #3, the grouting of those systems would introduce the additional construction risks associated with ISD. These risks have been shown to be within acceptable limits and could be effectively managed and mitigated through standard safety practises.

In the institutional control period, Alternative #4 would require monitoring of two sites much like Alternative #3: the on-site WRDF and the off-site interim storage/disposal facility for the removed reactor core components. In this case, the more stringent monitoring program would likely be at the off-site facility simply due to the relative hazard of the reactor core to the remaining reactor systems.

In the post-institutional control period, it was assumed that both the WRDF and the removed reactor core components would be disposed of in a passive safe facility and workers would no longer be present.

2.5.4.4.3.2 Public Safety

In the same ways as worker safety above, Alternative #4 combines the risks to radiological exposure and construction hazards from Alternatives #2 and #3. Any work to remove the reactor core components presents a potential for radiological releases to the environment and potential exposure of the public. Similarly, the construction activities associated with ISD of the remaining systems presents a potential increase in

fugitive dust and noise pollution, among other pollutants common from large construction projects (e.g., greenhouse gases). The reduction in intrusive decommissioning of the remaining reactor systems does not substantially reduce any risk to the public, as the primary risk reduction from ISD is in the industrial hazards workers are exposed to.

2.5.4.4.4 Environmental

Similar to all other alternatives, Alternative #4 would generate air emissions, both radiological and non-radiological, during decommissioning-related vehicle use and the release of radioactive compounds as equipment is removed or prepared for ISD. Alternative #4 would also require the operation of batch mixing plant (or similar equipment) for grout production and hauling of the cement and aggregate. These activities would generate air and greenhouse gas emissions; however, these emissions are anticipated to be minor and short term in duration and mitigation would be implemented to limit effects (e.g., use of enclosure for raw material handling).

In the institutional control and post-institutional control periods, there would be contaminants disposed of at both the WRDF and an off-site facility. In both cases, groundwater leaching through the disposal facility could migrate to surface water and adversely affect human and ecological health. The design of the ISD and off-site waste facility would be important to minimize groundwater leaching and to protect the environment. The level of risk during the institutional control period would be relatively small, as monitoring would be in place to identify any releases and mitigation would be implemented to reduce or prevent effects on the environment. In the post-institutional control period, the WRDF and future disposal facility for the reactor core components would not be actively monitored. The facilities would be designed to be passively safe to ensure long-term effects on the environment would not be significant. As with Alternative #2, removing the reactor core components from the WRDF would not eliminate the potential effects from them, but instead transfer the risk to a new location. Since it cannot be assumed what the future disposal facility for the reactor core components would be, it is assumed that it would provide at least a similar level of protection as the WRDF.

The socio-economic effects of Alternative #4 would be a combination of the effects of both Alternative #2 and #3. The direct economic benefit of employment during closure would likely be larger than in Alternative #3, but less than Alternative #2 simply due to the expected costs of the work performed.

In the institutional control period, the direct economic benefits and drawbacks of the monitoring work would be roughly the same as Alternative #3, though it is unclear if there would be any additional direct economic benefits as a result of the off-site storage or disposal of the reactor core components.

In the post-institutional control period, because there is assumed to be no knowledge of the facility, there would be no predicted socio-economic effects.

2.5.4.5 Alternative #5 – In Situ Disposal Using Alternative Backfill Materials

Alternative #5 is identical to Alternative #3 and #4 with only one key difference: the use of an easily removable material in place of grout as the backfill for the below-grade structure. A specific example is the use of sand instead of grout as a backfill material, with the expectation that the sand could be more easily removed in the event that retrieval or remediation efforts were undertaken.

2.5.4.5.1 Technical

During the closure phase, the use of sand or other materials is technically feasible as it is technology that is currently available and can be implemented for WR-1. During the institutional control period, the concept is also technically feasible as it would not differ from Alternative #3 in terms of what monitoring would be required. During the post-institutional control period, the concept is no longer feasible. The purpose of the alternate backfill is to make the wastes easily retrievable by humans that are monitoring the wastes. In a post-institutional control period, the human component is no longer present and the retrievability is no longer valid. The concept was deemed not technically feasible as intentionally retrievable wastes with no human controls is not considered a passively safe condition, and not considered further.

2.5.4.6 Alternative #6 – Rolling Stewardship

Alternative #6 is the concept of "Rolling Stewardship," where wastes are packaged and stored in an accessible facility and monitored in perpetuity. It was proposed both through the public and Indigenous (specifically by Turtle Lodge, located on Sagkeeng First Nation) review of the Project's Draft Environmental Impact Statement (Golder et al. 2017). The concept is presented as an alternative to disposal or "abandonment" of wastes, rather than an alternative means to reach final disposal. The concept centres on the transfer of knowledge of, and responsibility for, the wastes from generation to generation through periodic ceremonies. In these ceremonies, wastes may be recharacterized, repackaged and passed symbolically to the next generation, over and over, until a "solution" to the radiation hazard is found. The concept is not explicit in what an acceptable solution would be.

2.5.4.6.1 Technical

During closure and the institutional control period, Alternative #6 is technically feasible, as CNL currently monitors all radiological wastes and maintains records to convey the knowledge of the wastes to the next responsible persons.

The entire concept is predicated on the assumption that some sort of organization would always exist to administer the stewardship. The criteria for technical feasibility requires that an alternative be safe and perform its intended function without human intervention. This alternative would require human intervention to maintain safety, therefore it is not considered technically feasible. The concept was, therefore, not considered further.

2.6 Comparison of Alternatives

As described in Section 2.5.2, the alternatives were qualitatively ranked according to the criteria listed in Table 2.5.2-1. Results are summarized in Table 2.7-1 and 2.7-2 illustrating the relative preference of each feasible alternative, as shown below.

2.6.1 Technical Feasibility

The alternatives assessment considered the relevant technical feasibility criteria set out in Section 2.5.2.1. The technologies for each proposed alternative are proven and have been successfully deployed at other sites. Monitoring requirements for Alternatives #3 and #4 would be more extensive than for Alternatives #1 and #2 but can be developed to meet national requirements. All alternatives require at least some wastes be transported for storage or disposal. Alternative #5 (using sand as an alternative backfill material) is not easily adaptable for use in WR-1 because of the issue of the material settling with time and being a poor barrier to water movement. Alternative #6 (rolling stewardship) did not meet the feasibility criteria for being passively safe, as it required an undefined long-term human intervention period to be safe.

Alternatives #1 to #4 were all considered technically feasible and carried forward for further assessment. Alternatives #5 and #6 were not considered technically feasible and were dropped from the assessment.

2.6.2 Economic Feasibility

Alternative #1 was approved as the strategy for decommissioning WR-1 as part of the original plan for decommissioning the WL site. The estimated costs have not changed substantially and were considered economically feasible. As such, an alternative that does not cost more than Alternative #1, and achieves the goal of decommissioning WR-1 is considered economically feasible. The costs of each alternative are summarized in Table 2.6.2-1.

Table 2.6.2-1: Summary of Estimated Project Cost for Alternatives

Project Component	Alternative #1 – Deferred Dismantling and Removal ($ Millions)	Alternative #2 – Immediate Dismantling and Removal (no deferment) ($ Millions)	Alternative #3 – ISD ($ Millions)	Alternative #4 – Partial Dismantling and Removal with ISD of the Remainder ($ Millions)
Storage and Surveillance after 2024	120	0	0	0
Decommissioning of WR-1 Building	>120	120	35	45 to 65
Transportation and storage of waste	24	24	<1	25
Monitoring Requirements	1	1	7	7
Total	**265**	**145**	**43**	**77 to 97**

All four alternatives were deemed economically feasible and carried forward for further assessment.

2.6.3 Safety

2.6.3.1 Worker Safety

2.6.3.1.1 Closure Phase

In the closure phase, Alternative #1 has a slightly lower radiological hazard due to decay during deferment, as compared to Alternatives #2, and #4. Alternative #3 however has the lowest radiological hazard as the most hazardous materials (reactor core) are left in place and not accessed for removal. Alternatives #1 and #2 have the highest risk of exposure to non-radiological hazardous materials (such as asbestos) due to the more intrusive

nature of the decommissioning work, as compared to Alternatives #3 and #4. Alternatives #1 and #2 also have the highest risk of injury to workers from standard decommissioning hazards such as working at heights, confined spaces, cutting, hoisting and rigging hazards. Alternative #3 would involve the least amount of intrusive decommissioning and therefore offers the lowest risk of injury to workers from standard decommissioning hazards. Alternative #4 falls between Alternatives #2 and #3.

All alternatives have construction risks associated with physical work such as demolition of structures, excavation of soil around the building, fabricating and installing the grout (Alternative #3 and Alternative #4), construction of temporary storage facilities or future disposal facility.

Alternatives #2, #3 and #4 all utilize existing staff with many years of operational knowledge of the facility to enhance planning and safety measures. Alternative #1 cannot reasonably rely on that expertise being available due to the deferment period.

All four alternatives can be safely executed with appropriate mitigation in place.

Overall, for worker safety during the closure phase, Alternative #1 is ranked as least favourable, Alternatives #2 and #4 are favourable, and Alternative #3 is most favourable, based largely on the lower risk of exposure to radiological and non-radiological hazardous materials and standard decommissioning hazards.

2.6.3.1.2 Institutional Control Period

In the institutional control period, Alternatives #1 and #2 are the same and Alternative #4 is the combined effect of both Alternatives #2 and #3. Comparing Alternatives #2 and #3 shows that the risks to worker safety are largely the same for both alternatives. Both require ongoing regulatory control, which is not affected by geographical location, with no expected safety issues for workers. Both alternatives require that sampling and visual inspections be done, and decades of experience at the WL site have shown that this work can be carried out safely. In the case of Alternative #2, monitoring requirements are likely to be less comprehensive for the interim storage of the wastes because they would be above-ground, requiring less below-grade sampling. Once the wastes are moved from storage to disposal, the monitoring requirements become at least equivalent to Alternative #3.

Since Alternative #4 would require both on- and off-site monitoring, the effect on worker safety in the institutional control period is effectively doubled.

Overall, in the institutional control period, Alternatives #1, #2 and #3 are largely equivalent and rated as most favourable. Alternative #4 is rated as favourable.

2.6.3.1.3 Post-institutional Control Period

In the post-institutional control period, it was assumed that there would be no ongoing monitoring and control and no workers present at the site. As such, the effects on workers in this period were not evaluated.

2.6.3.2 Public Safety

2.6.3.2.1 Closure Phase

During the closure phase, the primary risk to the public is exposure to airborne and waterborne emissions of both radiological and non-radiological contaminants. The likelihood and magnitude of emissions are driven by the level of intrusive decommissioning work. Alternatives #1 and #2 are largely the same risk, except for a slight increase in radiological risk associated with Alternative #2. Alternative #3 would require the least intrusive decommissioning

work and presents the lowest risk of emissions to air and water. Alternative #4 falls between Alternatives #2 and #3.

All four alternatives can be executed safely, which has been demonstrated by recent decommissioning and demolition experience at the WL site.

Overall, Alternative #3 was rated as most favourable, Alternative #4 as favourable, and Alternatives #1 and #2 as least favourable.

2.6.3.2.2 Institutional Control Period

In the institutional control period, the primary risk to the public is exposure to airborne and waterborne emissions of radiological or non-radiological contaminants. In Alternatives #3 and #4, the contaminants are sealed below-grade and emissions are routinely monitored. The same is true for Alternatives #1 and #2, though the wastes are sealed in appropriate storage containers instead of below-ground. In all cases, the routine monitoring verifies that the waste disposal facilities are operating properly. For Alternatives #1, #2 and the off-site portion of Alternative #4, there is access to the wastes to sample for emissions more easily than if the wastes were sealed below-ground. However, access or the need to relocate the stored wastes creates additional opportunities for emission of contaminants. In all cases, WL has demonstrated experience in effectively and safely monitoring wastes stored both above- and below-grade at the WL site, and all four alternatives can be executed safely.

Overall, all four alternatives were rated as favourable.

2.6.3.2.3 Post-institutional Control Period

In the post-institutional control period, the primary risk to the public is exposure to radiological or non-radiological contaminants emitted from the final waste disposal facility. All four alternatives were assumed to have an acceptable decommissioning strategy for the WR-1 waste. It was assumed that each decommissioning strategy was defined before the end of institutional control.

Alternatives #1, #2 and #4 rely on the assumption that a future disposal facility would be constructed, and that it will provide a greater degree of safety to the public than Alternative #3. This assumption is based on experience that safety standards and risk management improve with time. However, this assumption also must consider that any future disposal facility would also reflect the socio-economic conditions at the time of disposal. As such, there is no certainty that a future disposal facility would provide a substantially safer disposal method for WR-1 than ISD. It was assumed that each of the four alternatives would meet the applicable Canadian standards and regulations.

Alternative #3 would not rely on a future disposal facility. It has been shown that it would meet the safety standards currently in place.

Overall, because of the uncertainty around the future design of a final waste disposal facility, or the future changes to current safety standards, each alternative was assumed to provide at least an equivalent level of long-term safety for the public. Each alternative was rated as favourable.

2.6.4 Environmental Effects

2.6.4.1 Biophysical Environment

2.6.4.1.1 Closure Phase

In the closure phase, the primary risk to the environment is the emission of radiological or non-radiological contaminants from WR-1 to air and water. The primary cause of the emissions is from intrusive decommissioning work that disturbs such materials during removal.

Alternatives #1 and #2 would involve the most intrusive decommissioning work and the highest risk of emissions of contaminants into the air and water. Alternative #3 would require the least amount of intrusive decommissioning work and has the lowest risk of emissions. Alternative #4 falls between Alternatives #2 and #3.

Secondary risks are from increased greenhouse gas emissions, nuisance dust, noise pollution and habitat destruction. These are generally produced by the use of heavy equipment, trucks and loud machinery. Each alternative would require demolition of at least the above-grade structures of WR-1. This would use heavy machinery, portable power generators and trucks to transport equipment to site, and waste materials off site. There is potential for dust generation and noise pollution from the demolition work. Both of these can be mitigated through dust suppression techniques and timing of the work to minimize effects on locally nesting wildlife.

Alternative #1 and #2 would require transporting more radiologically contaminated waste, generating additional greenhouse gases and fugitive dust. Alternative #3 would require transporting of raw materials for grouting and the operation of a batch mixing facility or similar equipment. Both of these activities would also generate greenhouse gas emissions and fugitive dust. The use of dust suppression methods and active air monitoring would mitigate any effects from dust. It is likely that the greenhouse gas emissions would be higher for Alternative #3 as the transport of raw materials to the site likely outweighs the transport of waste off the site in Alternatives #1. Alternative #4 would require both the additional dismantling and shipping of waste, and also includes transporting raw materials for grouting, likely producing the highest greenhouse gas emissions.

In Alternatives #1, #2 and #4, additional interim waste storage capacity may be required. These facilities would likely be constructed on an existing nuclear licensed site in Canada, limiting the risk of habitat disturbances during construction.

In each alternative, the potential effects on the environment could be effectively mitigated through adherence to industry best practices and procedures. CNL has a demonstrated record of performing nuclear demolition and construction activities in adherence to environmental protection programs and limits as per the CNSC-issued site decommissioning licence. As such, all four alternatives can be considered safe for the environment with appropriate mitigation in place.

Overall, each alternative has the potential to affect the biophysical environment. The effects of Alternate #3 are limited to the WRDF, while the other alternatives also have potential effects at an undetermined new interim storage facility. As such, Alternative #3 was rated as most favourable, Alternatives #1 and #2 were rated as favourable, and Alternative #4 was rated as least favourable.

2.6.4.1.2 Institutional Control Period

In the institutional control period, the primary risk to the environment is exposure to airborne and waterborne emissions of either radiological or non-radiological contaminants. In Alternatives #3 and #4, the contaminants are sealed below-grade and emissions are routinely monitored. The same is true for Alternatives #1 and #2, though the wastes are sealed in appropriate storage containers instead of below-ground. In all cases, the routine monitoring for emissions quantifies any releases. For Alternatives #1 and #2, and the off-site portion of Alternative #4, there is easier access to the wastes to sample for emissions than if the wastes were sealed below-ground. However, access or the need to relocate the stored wastes creates additional opportunities for emission of contaminants. In all cases, WL has demonstrated experience in effectively and safely monitoring wastes stored both above- and below-grade at the WL site, and all four alternatives can be executed safely.

The only real difference between the alternatives during the institutional control period is effects of human presence at the disposal or storage site. The WRDF would require very little human presence. An interim storage facility may require more frequent inspection of both the waste and facility support systems. The increased human presence can contribute to an increase in overall risk from vehicle strikes, animal control or noise pollution. In all cases, WL has demonstrated experience in monitoring and mitigating effects of CNL operations on the surrounding environment, and each alternative can be executed without significant adverse effects on the environment.

Overall, Alternative #3 was rated as most favourable, and all other remaining Alternatives were rated as favourable.

2.6.4.1.3 Post-Institutional Control Period

In the post-institutional control period, the primary risk to the environment is exposure to either radiological or non-radiological contaminants that are released into the environment. The waste from each alternative was assumed to be disposed of in an approved facility. It is possible that the future facilities would provide more effective containment of the wastes than the WRDF. However, CNL assumed that each alternative would have its waste in a disposal facility that meets the current Canadian standards and regulations.

As each alternative is expected to meet the safety standards of the time, they are all safe and were all rated as favourable.

2.6.4.2 Socio-economic Environment

2.6.4.2.1 Closure Phase

In the closure phase, the primary risk to socio-economic environment is in the available employment opportunities and their duration. All four alternatives require substantial financial resources for labour. Generally, the higher the cost, the more potential benefit to the local and regional economy. Alternatives #1 and #2 would have higher labour costs and more direct employment benefits due to the larger scope of work to be performed. Alternative #3 would utilize new materials purchased from local suppliers, providing a benefit both from direct employment and purchase of raw materials locally. In all cases, the work to be performed provides valuable experience to current employees, contractors and vendors who participate in the Project. That experience carries value to future employment opportunities.

Alternative #1 is expected to take the longest, and therefore would likely have the longest lasting employment benefit. Alternative #2 would follow as second longest, with Alternative #3 and #4 having the shortest direct employment benefit.

Another benefit from each alternative is related to supplementary work required off site such as construction of additional interim storage capacity, transportation of wastes and regulatory support for project activities. Alternatives #1, #2 and #4 all provide substantial related employment opportunities that are not as prominent in Alternative #3.

The Project site would not be available for development during the closure phase, so there are no expected effects on the suitability of the site for redevelopment during this phase.

Overall, Alternatives #1 and #2 were rated as most favourable, Alternative #4 was rated as favourable, and Alternative #3 was rated as least favourable during the closure phase.

2.6.4.2.2 Institutional Control Period

In the institutional control period, the primary factors affecting the socio-economic environment are ongoing employment opportunities and suitability of the WRDF area for new economic development, and access to the lands for traditional uses.

In each alternative, there would be employment opportunities for ongoing monitoring and surveillance work, such as field staff performing inspections, laboratory staff analyzing samples and safety staff reporting to regulatory authorities. It cannot be assumed that the opportunity would be local to the WL site. Work could be performed by staff based in another part of the country (e.g., Chalk River Laboratories), so the benefits cannot be compared for regional benefit.

All or part of the WL site is expected to be made available in the future for new development, or for cultural or traditional uses. In each alternative decommissioning strategy, there is the potential for residual radiological contamination on the site that could affect the availability of the site for future uses. Radioactive contamination, even at the low levels expected at the WL site, would usually be considered a detriment to development or other future use. However, there are niche industries (e.g., power generation, medical isotope production) for which a previously affected site would be an opportunity to reduce their own potential effect on the environment by not developing unaffected land. Such industries are typically large employers with high paying employment opportunities. The potential benefit from a niche developer is difficult to compare to general market suitability of the site. Due to the uncertainty and for conservatism, it is assumed that such an industry would not want to develop the site because of the overall unavailability of the site for future use.

While all four alternatives are expected to enable a large portion of the WL site to become available for traditional uses by the Red River Métis and the First Nation, the perception of usability for traditional purposes may be negatively impacted by residual radioactivity or waste. While much of the site will be suitable for other uses, including traditional uses, Alternatives #3 and #4 will likely result in a small overall portion of the site remaining undesirable for traditional uses. Alternatives #1 and #2 are expected to have the most positive impact on the suitability of the site for traditional uses.

The wastes from Alternatives #1, #2 and #4 were assumed to be transferred to an existing nuclear site, so no adverse effects on the socio-economic environment near the interim storage or disposal facility would be expected. Alternative #3 leaves the most radioactivity at the WL site, followed by Alternatives #4 and #1/#2.

CNL would make efforts to effectively identify and implement a path forward for economic development, no matter how WR-1 is decommissioned. In addition, the Community Regeneration Partnership is developing a socio-economic plan, which is expected to support future economic development and community development.

Overall, Alternatives #1 and #2 were rated as most favourable, Alternative #4 was rated as favourable, and Alternative #3 was rated as least favourable.

2.6.4.2.3 Post-institutional Control Period

In the post-institutional control period, there was assumed to be no remaining knowledge of the facility. The socio-economic effects of the alternatives are only related to the potential environmental effects from each alternative. Since it was assumed that each alternative would provide a safe long-term disposal option, each alternative was deemed equivalent and should not have any socio-economic effects.

Each of the four alternatives were rated as favourable.

2.7 Conclusion

Tables 2.7-1 and 2.7-2 present a summary of the evaluation for each alternative. Table 2.7-1 summarizes the feasibility screening of the six presented alternatives and which criteria they passed and failed. Table 2.7-2 summarizes the evaluation for each feasible alternative and the Total Score for each.

This page intentionally left blank

In consideration of all factors including Indigenous engagement, the assessment of the alternative decommissioning strategies for WR-1 shows that each alternative evaluated can be executed safely. The recommended alternative for the decommissioning of WR-1, based on the alternative means analysis, is Alternative #3 (ISD). The selection of ISD was based on the safety, environmental, technical and economic factors. ISD is a safe option, reducing the risk to workers compared to dismantling and providing long-term safety to the public and the environment. The ISD approach also has the least reliance on undefined future disposal options or technologies.

Based on an understanding of the hazards associated with WR-1, CNL believes that the WRDF can be built to meet CNSC regulations, considering the recommendations from the IAEA related to radiological waste disposal. CNL also believes that the safety case has been made that this dedicated facility can be used to permanently dispose of the waste, rather than temporarily store it.

CNL recognizes that each Indigenous Nation would prefer to see other alternatives exercised. All engaged First Nations and the Manitoba Métis Federation have expressed a varying level of concern over the Alternative #3 (ISD) or have expressed a preference for Alternative #2 (Immediate Dismantling and Removal). Sagkeeng provided the most extensive feedback of all Indigenous Nations. CNL has strongly considered Sagkeeng's views, opinions and interests and have ongoing engagements and commitments that reflect their input on Alternative Means; especially in the area of trauma informed engagement and risk-informed communications to address psychosocial effects. CNL is of the view that all parties have had an adequate and fair opportunity to present their interests on the Alternatives and that conducting additional Alternative Means Assessments will not yield any additional insights that haven't already been made.

CNL will continue to listen, and consider all feedback on the Project, and work with Sagkeeng through the technical working group table to address any interests and concerns that remain outstanding through dialogue and further engagement. CNL has invested and is committed to ongoing engagement with the First Nations and the Manitoba Métis Federation to discuss all ongoing issues and concerns.

2.8 Sagkeeng's Alternative Means Assessment – Approach and Findings

This sub-section provides a summary of Sagkeeng's independent Alternative Means Assessment Report and explains how CNL considered and utilized the report. For a complete detailed description of Sagkeeng's assessment, refer to Sagkeeng's Alternative Means Assessment Report, included as a supporting document to CNL's WR-1 EIS (Sagkeeng Anicinabe and Firelight Research Inc. 2020). For details on CNL's engagement with Sagkeeng refer to Section 4 in CNL's Indigenous Engagement Report (CNL 2024) and Section 4.0 in the EIS.

CNL values engagement with Sagkeeng and strived to address Sagkeeng's concerns related to the Project. Sagkeeng's Alternative Means Assessment Report and subsequent engagements on the topic have helped CNL understand Sagkeeng's concerns about the Project. We recognize that not all of Sagkeeng's concerns are within scope of the decommissioning Project of WR-1 but our commitments to Sagkeeng demonstrate our resolve to build a strong working relationship that extends beyond the environmental assessment process for the decommissioning Project of WR-1.

2.8.1 Background Information

Since 2018 January, Sagkeeng has raised concerns that their community values and distinct perspective on criteria, weights and scoring were not included in CNL's Alternative Means Assessment. In response to Sagkeeng's concerns, CNL funded and participated in a 3-day workshop on 2019, February with Sagkeeng Chief and Council, Elders, other community members and Sagkeeng's technical consultants to discuss CNL's alternative means and to consider Sagkeeng's viewpoint on the alternatives, considering their community values. The staff of the CNSC and employees of AECL participated as observers in the workshop. During the first day, CNL presented the CNL Alternative Means Assessment results to Sagkeeng and engaged in dialogue on their questions and concerns. Sagkeeng terminated the workshop before lunch on the second day. In their remarks, Chief Henderson and Elder Dave Courchene stated Sagkeeng needed to take some steps back in the process and use ceremony to help guide the community on the Project and educate CNL about the critical role of spirit and ceremony in Sagkeeng decision-making. Sagkeeng invited CNL, CNSC and AECL to participate in a ceremony at Turtle Lodge International Centre for Indigenous Education and Wellness in 2019, March as part of the next steps taken by Sagkeeng on considering the proposed Project and the other technically and economically feasible options.

During CNL's March 2020 meeting with Chief and Council, Sagkeeng again raised their concerns that CNL's alternative means did not adequately consider Sagkeeng's views. To further provide Sagkeeng an opportunity to meaningfully express their concerns and preferred alternatives, CNL provided funding to support a Sagkeeng-driven alternative means assessment that incorporated Sagkeeng's distinct perspectives and values.

2.8.2 Introduction

Sagkeeng's alternative means assessment was prepared by Sagkeeng Chief and Council with support from, and facilitation by, Firelight Group, with technical support from Tony Brown, an environmental consulting engineer. This included a two-day workshop with CNL in February 2019. Sagkeeng's Chief and Council also worked with CNL and Firelight to better understand CNL's four alternatives for decommissioning the WR-1 Reactor. The purpose of the workshop was to:

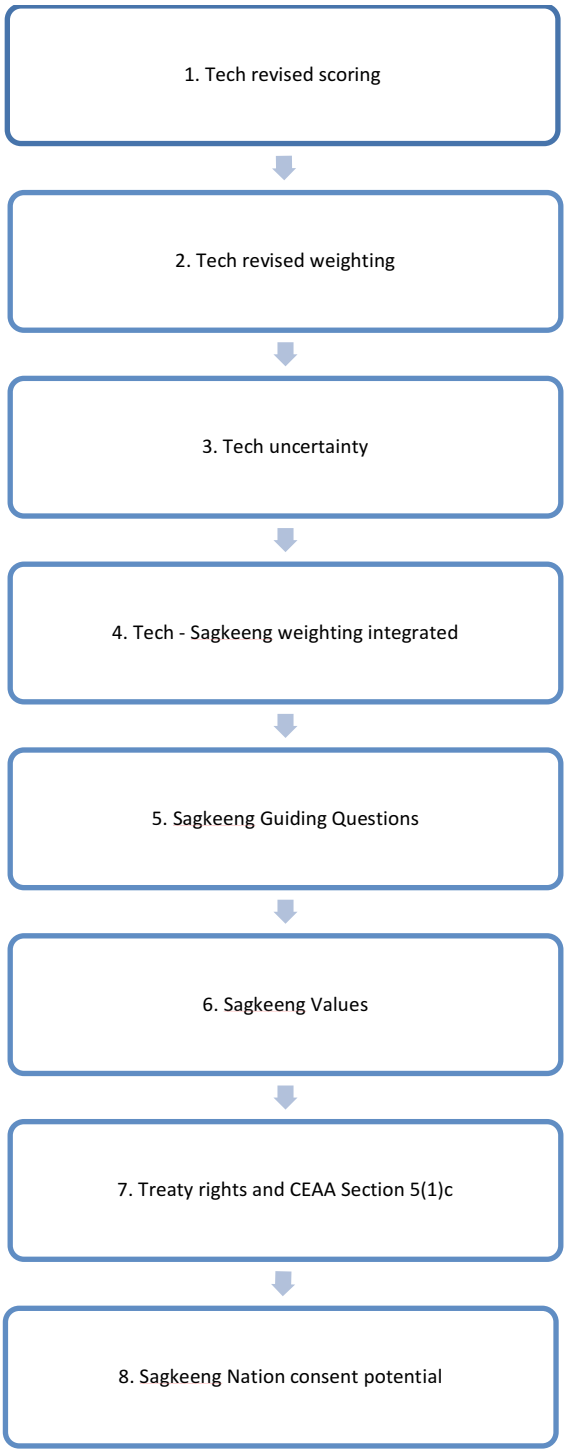
- Identify and prioritize Sagkeeng's values;
- Identify guiding questions and principles that could help protect those values, concerning the WR-1 decommissioning;
- Develop a series of tests/tools to assess the different alternatives and criteria; and
- Assess preference/acceptability of the four alternatives using the tests and report on them.

2.8.3 Description of Sagkeeng's Alternative Means Assessment Report Results

Sagkeeng delivered their Alternative Means Assessment Report to CNL on October 19, 2020, followed by a presentation to CNL, CNSC, and AECL on November 19, 2020. This section summarizes the Sagkeeng process and results, as understood by CNL.

Mr. Brown and Sagkeeng's Chief and Council, with the support of the Firelight Group, developed eight different tests to see which of CNL's four technically and economically feasible alternative ways to decommission the WR-1 Reactor was preferable from an independent technical perspective that used CNL's methodology as a starting point (Tests 1 to 3) and from the perspective of Sagkeeng Chief and Council in Tests 4 through 8 (Figure 2.8.3-1, reproduced from Sagkeeng Anicinabe and Firelight Research Inc. 2020. Presentation of Results of Sagkeeng Anicinabe Alternatives Assessment for WR-1 Reactor Decommissioning, November 19, 2020, here for information).

Figure 2.8.3-1: The Eight Tests of Sagkeeng's Alternative Means Assessment



Sagkeeng requested Mr. Brown independently conduct a technical review of CNL's decommissioning alternatives for the WR-1 Reactor that was based on his professional opinion and experience of previous alternatives assessment processes. Mr. Brown took the CNL alternative means assessment and modified the scoring and weighting of criteria based on Sagkeeng values. In test three, Mr. Brown added additional criteria and further redistributed the weighting. These are described in the Sagkeeng Alternative Means Report as "Tests 1 to 3" (Sagkeeng Anicinabe and Firelight Research Inc. 2020).

Sagkeeng Chief and Council also developed five tests (i.e., Tests 4-8) that reflect Sagkeeng's understandings and values regarding the alternative means to decommission the WR-1 Reactor. These Tests and their results are summarized below.

2.8.3.1 Test 1 - Revised Scoring with CNL Weighting

In Test 1, Mr. Brown identified three areas in the CNL alternative means assessment that resulted in changes to scoring methodology: design methodology, mitigation, and ranking instead of scoring. Regarding design methodology, Mr. Brown questioned the assignment of scores based on the assumption that the retrofit of a 50-year-old facility would perform as effectively as a new, built for purpose facility. Mr. Brown suggested that this assumption does not account for the superior performance of a purpose-built facility. Regarding mitigation, CNL's alternative means assessment is based on potential impacts, prior to the implementation of standard mitigating measures. Mr. Brown indicated that this approach downgrades alternatives that pose theoretical risks, even when they can be effectively mitigated. Finally, ranking relative to the other alternatives, rather than assessing each alternative's performance against the criteria, was identified as a concern. In Mr. Brown's opinion, the CNL approach tended to overemphasize minor differences that skewed the selection process.

Mr. Brown revised CNL's scoring to address these concerns, without changing CNL's criteria weighting. The results of this test indicated Alternatives 1 and 2 (each involving the complete dismantling and full removal of radioactive wastes from WR-1 to an external facility) are preferred over Alternatives 3 and 4. CNL's preferred Alternative 3, In-Situ Disposal (ISD) rates last among the four alternatives (Figure 2.8.3.1-1 as reproduced from the report).

Figure 2.8.3.1-1: Mr. Brown's Revised Scoring with CNL's Weighting (as reported in Sagkeeng Anicinabe and Firelight Research Inc. 2020)

Indicates a higher score was assigned
Indicates a lower score should be assigned

	CNL Scoring					Independent Scoring (with rationale for any changes)

Alternatives #1 and #2 are now preferred.
Alternative #3 has the lowest score.

2.8.3.2 Test 2 - Revised Weighting and Revised Scoring

The assessment of alternatives performed by CNL applied different weights to the various criteria that were considered. During their review of CNL's alternatives assessment, Sagkeeng expressed concern that the weights used in the assessment were established by CNL without consulting Sagkeeng on their appropriateness. Specifically, Mr. Brown believed that CNL's assessment placed excessive emphasis on the potential need for mitigation of occupational risks, even though precedent (and CNL's own assessment) indicates that all technically and economically feasible alternatives can be implemented safely. He suggested that this resulted in insufficient emphasis on the assessment of the primary purpose of the remediation Project, which is to protect people and the environment from impacts associated with a hazardous site. CNL weighted worker safety, public safety and environmental safety as equal in their assessment, accounting for 90% of the total.

In Test 2, Mr. Brown revised CNL weighting with the emphasis moving from worker safety to protection of the public and the environment (Table 2.8.3.2-1). While Mr. Brown agreed the protection of worker safety should be a mandatory requirement of any project, he questioned the relative emphasis on the need for mitigation of Worker Safety since CNL has indicated that all alternatives can be implemented safely (i.e., they will comply with the requirements of appropriate occupational authorities, including the CNSC). Further, Mr. Brown noted the following unique attributes for worker risks: 1) they have a short duration; 2) they can be fully mitigated; 3) they are highly regulated; and 4) workers are fully informed, trained, and compensated, as appropriate.

Table 2.8.3.2-1: Mr. Brown's Revised Weighting (as reported in Sagkeeng Anicinabe and Firelight Research Inc. 2020)

Criteria	CNL's Weighting	Mr. Brown's Weighting in Test 2
Worker Safety	30%	20%
Public Safety	30%	35%
Biophysical	30%	35%
Social	10%	10%

The revised weighting was added to Mr. Brown's prior revisions to the scoring of the alternatives. The result of the revised scoring and weighting showed Alternatives 1 and 2 still preferred and Alternative 3 still the least preferred (Figure 2.8.3.2-1).

Emphasis shifted from Worker Safety to Public Safety and Biophysical. No change to Social at this time.

Alternatives #1 and #2 are still preferred. The performance of Alternative #3 decreases relative to other alternatives.

2.8.3.3 Test 3 - Revised Scoring, Revised Weighting and Technical Uncertainties

Mr. Brown identified his concern that excluding technical uncertainties overlooked important technical differences between the alternatives. In Test 3, two new weighted factors representing technical uncertainties were added; the reversibility of proposed alternatives and confidence in the predicted results of each alternative. He described reversibility as intending to address situations where a selected alternative fails to perform as intended and follow-up mitigations are necessary. For example, in the case of in situ decommissioning using cementitious grout (i.e., Alternatives 3 and 4), the removal of radioactive wastes in the future (if required) would be particularly challenging and could result in elevated occupational risks. Confidence in the predicted results considers the fact that there is a greater degree of certainty regarding the long-term performance of some alternatives.

As shown in Table 2.8.3.3-1, Mr. Brown added a new criterion to address these considerations and the weights of the other criteria were redistributed. Based on scoring using the revised methodology, Alternatives 1 and 2, deferred decommissioning with complete dismantling, and removal and immediate decommissioning with complete dismantling and removal, were preferred and the performance of Alternative 3, complete in-situ decommissioning, decreased relative to the other alternatives (Figure 2.8.3.3-1).

Weightings revised to include new criterion

2.8.3.4 Test 4 - Technical with Sagkeeng Preferred Weighting

Test 4 incorporated Sagkeeng's preferred weighting, which was established by Sagkeeng's Chief and Council. The weighting placed less emphasis on worker safety (10% versus 30% by CNL). Sagkeeng agreed with Mr. Brown's estimation that worker safety issues are extremely well regulated and minimal in relation to the nuclear decommissioning sector. The Sagkeeng weighting placed more emphasis on social factors (30% versus 10% by CNL) (Table 2.8.3.4-1).

Sagkeeng noted that social considerations such as community health and well-being, mental health, and food security are in pre-existing conditions of high constraint/vulnerability among Sagkeeng members, and therefore, is a much higher priority criterion for Sagkeeng when considering the preferability of different alternative means to decommission the WR-1 Reactor.

Table 2.8.3.4-1: Technical with Sagkeeng Preferred Weighting *(reproduced from* Sagkeeng Anicinabe and Firelight Research Inc. 2020*)*

Criteria	CNL Weighting	Mr. Brown's Weighting from Test 2	Sagkeeng Weighting from Test 4
Worker Safety	30%	20%	10%
Public Safety	30%	35%	30%
Biophysical	30%	35%	30%
Social	10%	10%	30%

Table 2.8.3.4-2 below, shows the results when Sagkeeng's preferred criterion weighting was applied to two separate scenarios:

- Test 4.1 - Sagkeeng's preferred weighting with CNL's scoring; and
- Test 4.2 - Sagkeeng's preferred weighting with Mr. Brown's scoring.

The first row in Table 2.8.3.4-2 represents Mr. Brown's conversion of CNL's preferred scoring and weighting to quantitative data, and is here for comparative purposes only; it is not a Sagkeeng test.

Table 2.8.3.4-2: Sagkeeng Test #4.1 and 4.2 Results – Sagkeeng Weighting Preference Added

	Alternative 1 – Deferred Decommissioning w/ Complete Dismantle	Alternative 2 – Immediate Complete Dismantle	Alternative 3 – Complete ISD	Alternative 4 – Partial Dismantle and Removal/ Partial ISD
CNL Scoring (converted by Mr. Brown to quantitative)	5.9	6.2	7.3	5.7
4.1 CNL Scoring with Sagkeeng weighting	6.3	6.4	6.5	5.7
4.2 Mr. Brown's scoring with Sagkeeng weighting	8.4	8.4	6.9	7.7

When Sagkeeng's preferred criteria weighting is applied to the two different sets of technical scoring, the relative performance of Alternative 3 declines in both instances, but it is preferred based on CNL Scoring, and by CNL scoring with Sagkeeng weighting. While in Test 4.1 ISD remains the preferred alternative, its relative score in comparison with other alternatives is lower with only a 0.1 point difference between Alternative 3 (ISD) and Alternative 2 (full, immediate removal). When Mr. Brown's scoring is applied, Alternatives 1 and 2 (full removal) are preferred and the performance of Alternative 3 (full ISD) decreases relative to other alternatives, becoming the least preferred alternative means of decommissioning the WR-1 Reactor. The report suggests that when social considerations are prioritized, ISD becomes the least preferable alternative.

2.8.3.5 Test 5 - Sagkeeng Guiding Questions "Pass/Fail Test"

In test 5, Sagkeeng developed a set of 18 guiding questions identifying overarching key considerations applied by Sagkeeng Chief and Council in their reassessment of alternatives to the Project. Sagkeeng representatives then graded CNL's four alternative means on a "pass/fail/unknown" basis against the guiding questions. For a full list of questions, please review Sagkeeng's Alternative Means Assessment Report (Sagkeeng Anicinabe and Firelight Research Inc. 2020). Sagkeeng's questions focused on:

- **Technical feasibility:** Sagkeeng focused on whether technical performance was proven for each phase of the Project, and confidence that physical human intervention would not be required long-term at the Project site.
- **Economic feasibility:** Sagkeeng focused on longer term costs (e.g., construction, future remediation or mitigations, monitoring costs) and whether there was confidence that those funds would be available in the future.
- **Worker safety:** Sagkeeng focused on whether the alternative could be conducted in a safe manner for workers and worker risks, now and if future intervention was required.
- **Public safety:** Sagkeeng focused on the acceptability of risks associated with the alternative, based on perspectives from local public and other Indigenous Nations.

- **Environmental effects:** Sagkeeng focused on whether radiation risks are As Low As Reasonably Achievable (ALARA), and the ability to identify effects over time.
- **Social and Culture:** Sagkeeng focused on whether the alternative lives up to Canada's commitments to Indigenous nations and people (e.g., UNDRIP, Truth and Reconciliation Commission *Calls to Action*), fear and stigma reduction, and increased access for Sagkeeng members to the Traditional Territory.

These questions were posed in relation to three time frames; closure phase, institutional control phase and post-institutional control phase, respectively.

Graded against Sagkeeng's guiding questions, Alternative 2, immediate decommissioning with complete dismantling and removal was most preferable, while Alternative 3, complete in-situ decommissioning, was the least preferred. Specifically, Sagkeeng's Chief and Council found that Alternative 3 rates poorly in relation to the following:

- The amount of risk left in situ on Sagkeeng Traditional Territory;
- The length of time that active controls will need to be in place on Sagkeeng Traditional Territory;
- Fear and stigma associated with the area, now and into the far future, by Sagkeeng members;
- Confidence that the technology used (concreting/grouting radioactive materials in place underground near the Winnipeg River) will be effective, especially long-term, and that malfunctions will be avoided;
- Confidence that should a malfunction occur, that the cleanup will be easy, safe and effective, and that monies will be available long-term to conduct that cleanup process; and
- Living up to Canada's prior commitments and permitted plan to remove all radioactive materials from the WR-1 facility.

Sagkeeng's Chief and Council also expressed the opinion that even with the bulk of radioactive waste removed from the WR-1 Reactor, fear and stigma would still be associated with the small amount of radioactive material remaining underground in Sagkeeng Traditional Territory and therefore Alternative 4 also rated poorly.

2.8.3.6 Test 6 - Assessment using 13 Sagkeeng Priority Value-Based Preferences as Criteria

Test 6 assessed each alternative against values that Sagkeeng considered to be central to decision-making on preferred futures. The key question at the heart of this test was "Which alternative or alternatives are preferable to Sagkeeng when considering what matters most to Sagkeeng members?" (Sagkeeng Anicinabe and Firelight Research Inc. 2020, pg. 28). Thirteen preferences were selected by Sagkeeng Chief and Council, which represented priority values and preference statements (in italics below), that included:

1. Protect and Heal the Water - *Sagkeeng prefers alternatives that can demonstrate that in the near to long-term, that waters, especially in Winnipeg River, will be protected and will be perceived to be safe by Sagkeeng members*;
2. Protect and Promote Sagkeeng Culture/Spirit - *Sagkeeng prefers alternatives that are respectful of the spiritual balance of people with the earth, and allow at least the potential for greater access to territory for cultural purposes in the future*;

3. Territorial Integrity - *Sagkeeng members prefer alternatives that reduce hazards and result in a net benefit toward restoration of territorial integrity*;
4. Food Security and Faith in Traditional Foods - *Sagkeeng prefers alternatives that will increase trust in traditional foods and water sources over time, increase the amount of potential territory to access country foods in, and reduce risk of wildlife contamination and health risks;*
5. Reduced Mental Stress, Fear, Stigma - *Sagkeeng's preference is for alternatives that will reduce mental stress, fear, and stigma, now and into the future, at and around the Whiteshell facility and at the wider Sagkeeng territory scale*;
6. Reduced Long-Term Risks in Sagkeeng Territory - *Sagkeeng prefers alternatives that reduce long-term risks in Sagkeeng territory and result in reduced long-term human population health risks, reduced long-term risks on the Winnipeg River waters and fish, and lowest amount of in situ risks at the Whiteshell Labs site;*
7. Address the Hazard Sooner and Reduced Future Management Requirements - *Sagkeeng prefers alternatives that address the hazard at WR-1 sooner, require less future management, and leave less risk on Sagkeeng lands for future generations*;
8. Flexibility to Adapt to Contingencies; *Sagkeeng prefers alternatives that either include the flexibility to alter management plans at the site in the future (even possibly future reversal and removal of radioactive materials) or remove the risks entirely from the site altogether*;
9. Impact Equity - *Sagkeeng prefers alternatives that do not put a disproportionate burden of impacts on Sagkeeng members, now and in the future*;
10. Higher Affected Public/Sagkeeng Acceptability **-** *Sagkeeng prefers alternatives that are acceptable to Sagkeeng Anicinabe members and land users*;
11. Protection and Promotion of Treaty Rights - *Sagkeeng prefers alternatives that have the least potential for adverse impacts or infringements on Treaty rights in as much of Sagkeeng territory as possible, and prefers also for alternatives that could have the most beneficial effects on members' ability to meaningfully practice their rights into the future*;
12. Adherence to Ancestral Laws and Norms - *Sagkeeng prefers alternatives that adhere to or are otherwise are not likely to conflict with these ancestral laws*; and
13. Sagkeeng Territory Free of Radioactive Waste - *Sagkeeng prefers alternatives that do not result in a permanent nuclear waste disposal facility in Sagkeeng territory*.

CNL's alternatives were assessed against each preference and scored on a range from 1 to 3 by Sagkeeng Chief and Council. A score of 3 represented a very good alternative when assessed against the preference statement, while a score of 1 represented a poor alternative. Detailed descriptions of how each alternative scored against each preference statement, and supporting rationales, are provided in Section 2.6 of Sagkeeng Anicinabe and Firelight Research Inc. (2020).

The results are summarized in the table below.

Table 2.8.3.6-1: Summary of Sagkeeng Test #6: Values-based Preference Statements

Sagkeeng Values-based Preference Statement	1 – Deferred Full Removal	2 – Immediate Full Removal	3 - ISD	4 – Partial ISD, partial removal
Total Score	29.5	39	15	25
Preference Ranking	2nd	1st	4th	3rd

In every instance in this test, Alternative 2, immediate decommissioning with complete dismantling and removal, scored highest, and Alternative 3, complete in-situ decommissioning, was scored lowest.

2.8.3.7 Test 7 - Assessment using Indigenous Rights and Interests Factors

This test was largely derived from the question “Which alternatives will have the least potential for adverse impact on the ability of Sagkeeng members to meaningfully practice their treaty rights, and the most potential for beneficial impacts on Sagkeeng rights? (Sagkeeng Anicinabe and Firelight Research Inc. 2020, pg. 46).”

These tests were an assessment based on each alternative’s potential beneficial or adverse implications in relation to Sagkeeng’s treaty rights which included but are not limited to the following:

- Test 7.1 treaty Rights: hunting, fishing, trapping, gathering, use and navigation of water, travelling and staying on the land; and
- Test 7.2 CEAA (2012) Section 5(1)(c) factors: health and socio-economic conditions, physical and cultural heritage, current use of lands and resources for cultural purposes, and structures or sites of historical, archaeological, paleontological, or architectural significance.

In the end, the results for Tests 7.1 and 7.2 were the same qualitative responses from Chief and Council and so are pooled together in Table 2.8.3.7-1 below.

Table 2.8.3.7-1: Summary Results of Sagkeeng Test #7

Criteria	Alternative 1 – Deferred Decommissioning w/ Complete Dismantle	Alternative 2 – Immediate Complete Dismantling	Alternative 3 – Complete In-Situ Decommissioning	Alternative 4 – Partial Dismantling and Removal/ Partial ISD
Preference Ranking	**2nd**	**1st**	**4th**	**3rd**
Key Differences	Lower score than Alternative 2 due to deferral of full removal and thus slower potential for improvement in conditions for Treaty rights.	Full removal of all nuclear materials would see both the least real and perceived risks at the site, thus most improved conditions for practice of Sagkeeng Treaty rights.	Minimal to no removal of perceived risk through keeping the waste on site, thus low likelihood of restored Sagkeeng confidence and Treaty rights practice.	Despite 99% of radioactive materials removed, perception of risk could still alienate Treaty rights.

When considered against Sagkeeng treaty rights and CEAA (2012) Section 5(1)(c) factors, Alternative 2, immediate decommissioning with complete dismantling and removal, was most preferable, while Alternative 3, complete in-situ decommissioning, was the least preferred. Sagkeeng have consistently indicated that early and full removal of nuclear materials from Sagkeeng territory is preferred in part because, in their view it brings higher potential for the meaningful recovery of treaty rights and use of lands and resources in and around Whiteshell Laboratories; this result is only achieved by Alternative 2. Alternative 1 scores second highest because it would achieve this eventually, but not as quickly as Alternative 2. ISD (Alternatives 3 and, to a lesser degree, 4) maintain nuclear materials at the WR-1 Reactor site in perpetuity and, the report suggests, this does not restore the necessary conditions for increased expression of treaty rights. Alternative 4 scores higher as it lowers the volume of radioactive materials, however Sagkeeng suggest that this is not likely to have a significant positive effect on the recovery of treaty rights in and around the Whiteshell area due to sustained perceived risk.

The study states that the results are consistent with recent studies related to the proposed WR-1 decommissioning, in which Sagkeeng members noted that ISD would result in reduced confidence in water quality in the Winnipeg River, which is inextricably linked to the future practice of Treaty rights such as fishing, harvesting wild rice, hunting, and collecting drinking water (e.g., Olson et al. 2019). Existing Sagkeeng use and occupancy data shows that numerous values and Treaty rights-based practices – including fishing sites for several species, fish spawning, berry and medicinal plant gathering locations, hunting and trapping values, sacred and ceremonial places, and campsites, among others – are already impacted or at risk in the immediate vicinity of Whiteshell, and Sagkeeng members have expressed that a decision to move forward with ISD would sustain this impact and risk in perpetuity (Olson et al. 2019). Sagkeeng members prefer Alternatives 1 and especially 2 because they would remove the hazard and improve the prospects of future access to the site for the practice of Treaty rights and reconnection to the land.

2.8.3.8 Test 8 - Sagkeeng Perspectives on the Overall Ability of Each Alternative to receive the Necessary Consent from Sagkeeng

Test 8 was based on the assumption that Sagkeeng is involved in all decisions that potentially affect them and that final decisions need to be supported by Sagkeeng free, prior and informed consent, as per Canada's commitments under the *United Nations Declaration on the Rights of Indigenous Peoples*. This test assessed each alternative against the likelihood that CNL would receive consent from Sagkeeng Anicinabe and members.

The following Table shows the results from Test 8 with Sagkeeng's supporting rationales.

Table 2.8.3.8-1: Summary Results of Sagkeeng Test #8

Criteria	Alternative 1 – Deferred Decommissioning w/ Complete Dismantle	Alternative 2 – Immediate Complete Dismantle	Alternative 3 – Complete ISD	Alternative 4 – Partial Dismantle and Removal/ Partial ISD
Sagkeeng Consent Likely?	Uncertain	Yes	No	No
Why?	Deferred complete removal addresses Sagkeeng's main concern, which is removal of all radioactive materials from their lands.	The rationale is the same as Alternative 1, however the benefits are achieved more quickly by immediate removal.	ISD leaves risk in the ground in perpetuity for future generations; Sagkeeng suggest that the land and waters cannot heal; the land will not become more accessible to Sagkeeng members and they will not be able to use the land; fear and stigma related to Whiteshell will continue into the future.	While partial dismantle and removal will heavily reduce the risk for future generations, partial ISD leaves some risk in the ground at the Project site and Sagkeeng claim access is still impacted well into the future, and perceived risk remains high.

Alternative 2, immediate decommissioning with complete dismantling and removal, is acceptable under this scenario while Alternatives 3 and 4, complete in-situ decommissioning with partial dismantling and removal, and partial in-situ decommissioning, respectively were rejected by Sagkeeng Chief and Council. Alternative 1 is identified as "uncertain" for its ability to secure Sagkeeng consent due to the time Treaty rights would be subject to infringement as a result of radioactive materials being removed further in the future.

Sagkeeng's Alternatives Assessment states (pg. 51) "It is important to note that the results of this test are preliminary and do not imply blanket consent for any alternative. Any proposal would need to show evidence that it is planned and undertaken in such a way that will not harm Sagkeeng lands, waters, rights, and people. Any final Sagkeeng consent decisions will need to be through proper Sagkeeng Anicinabe protocols."

2.8.4 Sagkeeng's Alternative Mean Assessment Conclusion

Table 2.8.4-1 provides a summary of Sagkeeng's preferred and least preferred alternatives for all 8 tests conducted.

Table 2.8.4-1: Sagkeeng's Preferred and Least Preferred Alternatives (Sagkeeng Anicinabe and Firelight Research Inc. 2020).

Sagkeeng Test	Most Preferred	Least Preferred
1. Technical revised scoring	1 and 2	3
2. Technical revised scoring and revised weighting	1 and 2	3
3. Technical with revised scoring, revised weighting, and uncertainty integrated	1 and 2	3
4. Technical with Sagkeeng weighting	4.1 - 3 4.2 - 1 and 2	4.1 - 4 4.2 - 3
5. Sagkeeng guiding questions	2	3
6. Sagkeeng values-based preferences	2	3
7. Treaty rights	7.1 – 2 7.2 - 2	7.1 – 3 7.2 - 3
8. Likelihood of Sagkeeng consent	2	3 and 4

Based on the results of Sagkeeng's eight tests in their Alternative Means Assessment report, the most preferred option for decommissioning of the WR-1 Reactor is Alternative 2, immediate full removal of WR-1 Reactor. The second most preferred alternative is Alternative 1, deferred full removal. The least favourable decommissioning for WR-1, according to Sagkeeng's assessment, is Alternative 3, in-situ disposal. The report concludes that (pg. 54), "Sagkeeng's alternatives assessment convincingly demonstrates that ISD (Alternative 3) performs poorer against virtually all Sagkeeng values and preferences, especially against "full removal" Alternatives 2 and 1 (in that order of preference). This assessment also shows that ISD is less preferred relative to full removal options on both a technical (Sagkeeng Tests 1 through 3) and a non-technical (Sagkeeng Tests 4 through 8) basis."

Sagkeeng's Alternatives Assessment concludes with the following synopsis and recommendations (pg. 56):

> "Sagkeeng is not saying its values are the only values that need to be considered in the alternative means assessment. They are very important values, however, that have not been considered by the Proponent's work or Canada's environmental assessment to date. Specifically, they have not been considered in the Proponent's alternatives assessment. Those Sagkeeng values are also tied to Constitutionally-enshrined Treaty and Aboriginal rights that must be considered meaningfully in this decision-making process.
>
> As early as January 2018, Sagkeeng recommended the Proponent engage in a multiple accounts evaluation to identify a preferred alternative means to decommission the WR-1 Reactor. The Proponent

has declined to do so to date. Sagkeeng has herein provided strong inputs to fuel a multi-party, multiple accounts evaluation of alternative means. It shows from a technical and a Sagkeeng values and impacts perspective, that full removal is preferable to ISD. That suggests CNL, AECL and CNSC should stick with the currently approved plan for full removal.

A true multi-party and multiple accounts evaluation would look at differing perspectives and findings, and try to find a jointly preferred, or at minimum a jointly acceptable, solution. Sagkeeng has opened the door with this work, we look forward to Canada and CNL engaging us to take the opportunity to work together toward a more meaningful, collaborative alternative means assessment for this important nuclear decommissioning Project on our Traditional Territory. The results of this report, as well as the forthcoming Sagkeeng psycho-social effects study (Narratives Inc. 2020), can be used to fuel these further discussions and collaborative efforts."

2.8.5 CNL Consideration of Sagkeeng's Alternative Means Assessment

In environmental assessments, proponents engage with interested Indigenous and public parties first on descriptions of feasible alternatives for consideration and then on the details that the proponent built into the analysis. Under CEAA 2012, a qualitative analysis is acceptable, but CNL has integrated some quantitative components and divided the analysis into three main project phases – decommissioning (e.g., closure), institutional control period, and post institutional control period. CNL engaged on the four considered alternatives with Sagkeeng on several occasions, including at the Alternative Means Workshop and through the provision of written information. Sagkeeng accepted the four proposed alternatives as the only alternatives to consider for the purposes of the alternatives assessment, accepting CNL's finding that each alternative was economically and technically feasible.

At one time, Sagkeeng, representatives, through Turtle Lodge, put forward a fifth alternative, called Rolling Stewardship, for consideration. As described by Sagkeeng at the Turtle Lodge ceremony in March 2019, Rolling Stewardship would leave the reactor facility as is, defer decommissioning until another decommissioning approach was developed, and maintain knowledge about the facility during the rolling stewardship period. The duration of the period was undefined by Sagkeeng. CNL considered this alternative. Rolling stewardship is similar to SafeStore, where the reactor is prepared for long-term storage, typically with no staff at the site except to conduct occasional maintenance and monitoring. CNL incorporated this Sagkeeng proposed approach into the alternative means. It was ultimately screened out because it did not include a defined endpoint, and was not sustainable over a long period of time. Subsequently, Sagkeeng used only the four alternatives deemed by CNL to be technically and economically feasible in developing its Alternatives Assessment.

Sagkeeng and their consultants invested significant effort to produce criteria and tests that are meaningful to their community, as represented by the Chief and Council. Sagkeeng developed an alternative means approach that represents their community values and interests. CNL re-evaluated the alternative means assessment based on the information in Sagkeeng's alternative means assessment. Upon much consideration, CNL chose not to make further adjustments to the alternative means and provides an explanation below.

CNL has documented Sagkeeng's preferred alternative in Section 4.0 of the EIS and Section 4 of the Indigenous Engagement Report (CNL 2024).

2.8.5.1 Considerations of Sagkeeng's Tests

CNL disagrees with the revised scoring presented by Sagkeeng in Test 1. This is based on the difference in understanding of how the scores should be applied to each alternative. CNL believes its scoring appropriately

assesses differences in alternatives and screens out differences that are small enough that they should not sway the assessment.

CNL also acknowledges that the weighting of each criteria is a subjective exercise. Different perspectives and understandings will value different criteria more or less in their decision making. The revised weightings discussed by Mr. Brown in tests 2 and 3 reflect his perspective and understanding of the Project. Overall, CNL believes the weighting it applied to each criteria is fair and balanced. It assumes that impacts to the public and Indigenous peoples, and the environment in which they live and practice their rights, make up 60% of the evaluation. Impacts on the health and safety of workers who live in the local community are 30%, and impacts to the economic interests of the area are given 10%. CNL feels this adequately places the most emphasis on the health and safety of all people and the environment.

CNL values Sagkeeng's perspective outlined in the results of tests 4-8. They were developed based on Sagkeeng's community values, Aboriginal and Treaty rights, and the likelihood of each alternative receiving Sagkeeng's consent. CNL has committed to documenting Sagkeeng's preferred alternative in the Indigenous Engagement Report (CNL 2024) and Section 4.0 of the EIS, and will continue to work together with Sagkeeng's Chief and Council to find common ground and areas of mutual benefit and opportunity regarding the decommissioning of WR-1.

2.8.5.2 Considerations for an Off-site Disposal in a Purpose-built Facility

CNL has considered the results of Sagkeeng's assessment and believes that Sagkeeng's assessment overemphasizes the assumed benefits of off-site disposal in a 'purpose-built' facility. This is primarily because a 'purpose-built' facility currently does not exist, nor is proposed to exist for decades, and as such, no direct comparison of the benefits of such a facility can be made with certainty. The only information that can be assumed about such a facility is that it will be required to meet at least the same standards for the protection of workers, the public and the environment as the WR-1 Disposal Facility. CNL believes that a more appropriate assumption is that an off-site facility would meet the same regulatory requirements that in situ disposal is required to meet, and thus all options should be given equal credit for the level of protection they provide over the long term. Waiting for a future date to pursue off-site disposal increases risks to the Project being completed. Changes in policy that currently enable waste transportation could also impact the ability to perform the work. Uncertainty in the future was a key part of the determination of how the different alternatives were scored.

2.8.5.3 Considerations for Sagkeeng's Preferred Decommissioning Methods - Alternatives 1 and 2

CNL found Sagkeeng's alternative means assessment focused on the impacts and benefits of each alternative on Sagkeeng's community and does not appear to consider the potential impacts on the host community for any off-site storage or disposal of WR-1 waste. Test #1 of the Sagkeeng assessment (and any subsequent tests that use the proposed scoring of Test #1) state that risks disappear or are reduced if removed from the Whiteshell Laboratories site.This may be true for members of the Sagkeeng, but this is not the case for the public and Indigenous peoples overall, and all risks are simply transferred to another location and community However, CNL must consider the risk of each alternative to all potentially impacted communities. The argument that the risks are more significant at the Whiteshell Laboratories site than at another central storage site is contrary to the Linear Non-Threshold (LNT) model for radiation exposure risk, which is the model adopted by the CNSC and the wider international community (CNSC 2013). The LNT model assumes there is no lower threshold at which incremental risks start, and assumes a linear relationship between dose and the health risk. LNT assumes that radiation has the potential to cause harm at any dose level, and the sum of several very small exposures is just as likely to cause a stochastic health effect as a single larger exposure of equal dose value. In other words, the risk from WR-1 would be the same regardless of whether it is the only component in the facility or just a small portion of a larger disposal facility at an off-site location.

2.8.5.4 Conclusion of CNL's Consideration of Sagkeeng's Assessment

The analysis of Sagkeeng's alternative means assessment facilitated a critical review and reflection of CNL's own alternative means assessment and working assumptions. Subsequent engagements also helped CNL better understand Sagkeeng's concern on the alternative means assessment. In review of our alternative means assessment, CNL maintains that the overall approach to assessing Project alternatives was appropriate and reasonable, taking in a broad range of considerations. None of the four options proposed present significant off-site impacts to the public or the environment. In fact, off-site biophysical impacts are negligible. While we defer to the Crown on the matter of rights assessment, CNL is unaware that any alternatives increase or decrease potential impacts on Indigenous rights such as hunting, fishing, gathering and ceremony. Sagkeeng has taken the view that their rights are impacted by this project.

Overall, CNL found that Sagkeeng's priority values and associated criteria and weighting for assessing alternatives are heavily focused on factors that lend support to the complete removal of waste from the Whiteshell Laboratories site. CNL felt Sagkeeng overemphasized the need for and benefit of a purpose-built waste disposal facility. CNL has been clear that full dismantling is not a guarantee of removal of all waste from the Whiteshell Laboratories site. Dismantling will not ensure immediate removal of waste from the site, full access to the lands, and, consequently, a reduction in stigma.

If in situ disposal is not approved, there is not an automatic second alternative that can be readily implemented, other than the status quo (even then this would require ongoing upkeep and maintenance and present increasing risks related to a legacy structure)) Currently, there is no available storage space at Chalk River Laboratories for the reactor components. With full dismantling, the waste could continue to be stored on the Whiteshell Laboratories site in a suitable facility. As best practice would suggest, one of CNL's objectives for this Project is to reduce the decommissioning deferment period and not leave it to future generations. After careful consideration, CNL felt the Sagkeeng's alternative means did not produce a strong technical basis to justify a change to the CNL methodology and scoring. CNL also found the assessment narrowly reflected perceived impacts and benefits to Sagkeeng and did not include other considerations for Alternatives 1 and 2.

CNL has reinforced that all the presented alternatives can be achieved safely and that CNL would not consider any alternative they felt was not safe for the public, the environment, or its workers. This does mean that there are differences in risk to workers for the three options. With increased dismantling and waste handling, the risk increases. CNL has selected its preferred approach of the four safe alternatives. Sagkeeng's specific assessment was informative and it compelled CNL to re-evaluate their assessment and it its outcomes. After thoughtful consideration, while not resulting in changes to the assessment itself, Sagkeeng's assessment has helped deepen CNL's understanding of their historical and contemporary interests in the area. Our learnings are also reflected in some of our next steps.

Sagkeeng has requested a "true multi-party and multiple accounts evaluation", (that) "would look at differing perspectives and findings, and try to find a jointly preferred, or at minimum a jointly acceptable, solution". CNL has strongly considered Sagkeeng's views, opinions and interests and have ongoing recommendations and activities that reflect their input on Alternative Means. CNL is of the view that the Alternatives are relatively fixed and all parties have had an adequate and fair opportunity to present their interests on them. CNL believes that conducting additional Alternative Means Assessments, including by way of another assessment tool such as multiple accounts evaluation, will not yield any additional insights that have been already made clear. While other views are important, Sagkeeng has clearly indicated that their preferred alternative is full dismantling and transportation of waste to another location/territory. CNL has invested and is committed to the establishment of specific and deliberate tables to address all ongoing issues and concerns. In respect of addressing any potential ongoing concerns about in-situ disposal, CNL has committed to holding discussions with Sagkeeng Chief and Council to collaborate in developing long-term environmental monitoring initiatives. CNL is also interested in hosting

workshops and webinars to support information-sharing and understanding, especially regarding the safety of in situ disposal in relation to people and the environment.

CNL believes there are numerous opportunities to work together in the interest of mutual learning and to meaningfully address Sagkeeng's ongoing concerns about in situ disposal and on other matters. These engagements combined with other Traditional knowledge provided by Sagkeeng, formed an important component of Indigenous input into the environmental assessment process. We look forward to our ongoing dialogue with Sagkeeng and other Indigenous Nations, as the Project moves forward.

3.0 PROJECT DESCRIPTION

3.1 Introduction

This section provides a description of the in situ disposal (ISD) strategy for the In Situ Decommissioning of Whiteshell Reactor 1 (WR-1) at the Whiteshell Laboratories Site (the Project). ISD is a safe technique that reduces the risk to workers, compared to full dismantling, while providing long-term safety for the public and the environment. The proposed design of the Project is based on current engineering practices and precedents, and the experience of the engineering and environmental assessment teams and third-party experts. Where there remains uncertainty around the design, conservative assumptions or options have been presented to provide a conservative assessment of potential effects of the Project in the environmental assessment. The final design will adhere to these assumptions and concepts.

3.1.1 Project Overview

Canadian Nuclear Laboratories (CNL) is proposing an ISD approach to decommission Whiteshell Reactor 1 (WR-1). The below-grade reactor systems, components and structures will be permanently disposed of in situ. This approach relies on multiple barriers that passively resist the release of contaminants. Most of the above-grade structures will be demolished and the wastes will be recycled or disposed of in appropriate waste disposal facilities. Some above-grade components may also be placed below-grade for disposal within the WR-1 Building. A concrete cap and engineered cover will then be constructed over the below-grade structure to protect the structure from water. ISD is a permanent, passive decommissioning end state.

The Project activities assessed in this Environmental Impact Statement (EIS) are limited to ISD of WR-1 and the associated building. Removal of the above-grade portion of the WR-1 Building and the east annex and service wings of the WR-1 Complex were assessed as part of the *Whiteshell Laboratories Decommissioning Project Comprehensive Study Report* (CSR; AECL 2001) and are covered under CNL's existing decommissioning licence for the Whiteshell Laboratories (WL) site (Licence No. NRTEDL-W5-8.00/2024). Activities required to prepare for ISD, such as isolation of the WR-1 Building and targeted remediation of hazardous materials, are also covered under CNL's existing decommissioning licence for the WL site. CNL is not proposing any changes to these decommissioning activities.

The decommissioning activities proposed as part of the Project and assessed in this EIS include:

- preparation for ISD;
- grouting of below-grade structures and systems;
- removal of above-grade structures and systems;
- installation of a concrete cap and engineered cover over the grouted below-grade structures and systems;
- final site restoration;
- preparation for institutional control; and
- institutional control (includes both passive and active controls).

3.1.2 Project Schedule

CNL plans to start decommissioning activities for the WR-1 Building in 2026. Once decommissioning and grouting work is complete, the Whiteshell Reactor Disposal Facility (WRDF) will be turned over to institutional control in 2031, which is assumed to last for a minimum of 100 years during which environmental monitoring and surveillance activities will be carried out. This timeframe is consistent with requirements for other near surface disposal projects (range 100 to 300 years), including similar projects under Canadian Nuclear Safety Commission (CNSC) jurisdiction and United States Department of Energy projects. However, it is recognized that institutional control will continue until the CNSC agrees it is no longer needed. The proposed overall schedule for the Project is provided in Table 3.1.2-1.

Table 3.1.2-1: Project Schedule

	Description	Planned Schedule
Regulatory Schedule		
	EIS submitted to the CNSC for review	September 2017
	Detailed Decommissioning Plan submitted to CNSC	September 2017
	Public Review Period of EIS	October-December 2017
	Updated EIS submitted to the CNSC	June 2022
	CNSC, Federal and Provincial Review of updated EIS and responses to information requests/comments	March 2025[(a)]
	Final EIS submitted to the CNSC	2 months[(a)]
	CNSC review and acceptance of Final EIS and preparation of CNSC Environmental Assessment Report	2 to 5 months[(a)]
	CNSC Licence Hearing (tentative)	7 months (Part 1) and 9 months (Part 2) [(a)]
	Environmental Assessment Decision (tentative)	12 months[(a)]
Decommissioning Schedule		
Closure Phase		
1	Preparation for ISD	24 months prior to EA approval to 24 months following EA approval
	WR-1 Deactivation and Segregation Complete	6 months prior
2	Grouting of Below-Grade Systems and Structures	12 to 24 months
	ISD Grouting Complete	2 years
3	Removal of Above-Grade Structures	6 to 24 months
	WR-1 Building Demolition and Decommissioning Complete	3 years
4	Installation of Concrete Cap and Engineered Cover	3 years
5	Final Site Restoration	3.5 years
6	Preparation of Institutional Control	3.5 to 4 years
	Site Turnover for Institutional Control and Monitoring	4 years
Post-closure Phase		
7	Institutional Control	0 to 100 years (minimum)
8	Post-institutional Control	100 years onwards

Note: Dates are subject to change pending receipt of environmental assessment and licensing approvals.

(a) Time following acceptance of the updated EIS and responses to information requests/comments

(b) Time following EA approval

EIS = Environmental Impact Statement; CNSC = Canadian Nuclear and Safety Commission.

The Project phases are:

- **Closure phase** – Preparation and implementation of ISD, which includes grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2030.
- **Post-closure phase** – The post-closure phase has two discrete periods: institutional control and post-institutional control. Institutional control is estimated to last a minimum of 100 years during which long-term monitoring and maintenance activities will continue, to demonstrate compliance with the safety case assumptions. Although the duration of institutional control is estimated at a minimum of 100 years, it is recognized that it will continue until the CNSC agrees institutional controls are no longer needed. It is assumed that institutional control eventually collapses, and knowledge of the facility is lost. There is much uncertainty around when this would occur, if at all. For the purposes of the assessment, it is assumed to occur 100 years after closure of the facility. Post-institutional control occurs after year 2131 and continues indefinitely; however, the timeframe defined for the assessment of potential effects, as part of the normal evolution of the Project's safety assessment is 10,000 years. This timeframe (i.e., 10,000 years) encompasses the phase in which peak effects are anticipated (Golder 2021a).

3.2 WR-1 Building Overview

The WR-1 Building consists of seven floors (Level 100 [bottom floor] to Level 700 [top floor]) (Figure 1.1-2), five of which are below-grade (Levels 100 to 500). Level 100 is located approximately 18.5 m below the main floor level (Level 600), which is located at approximately the ground level. All reactor systems are located below-grade, except for the primary coolant pumps and heat exchangers, which are contained in a shielded room on the reactor hall floor. Access is restricted to the lower four levels, while the upper three floors provide office space and laboratory space. A portion of Level 500 also has restricted access.

The general arrangement of the WR-1 Complex is shown in Figure 3.2.1. The building footprint at ground level measures 63.9 m by 52.7 m and includes the main reactor building and east annex and the service wing. The east annex is a two-storey extension that housed various systems, such as an experimental loop, a mechanical maintenance shop and a chemical laboratory. The service wing is a single-storey extension that contained offices and the reactor control room. The east annex and service wing will be decommissioned and demolished following the original decommissioning plan (AECL 2001).

3.2.1 Major Components in the WR-1 Building

3.2.1.1 The Reactor Vessel

The reactor vessel, also known as the calandria (shown in Figure 3.2.1-1), is a cylindrical stainless steel tank approximately 5 m high and 2.75 m in diameter. The calandria contains 54 calandria tubes; each calandria tube surrounds a pressure tube (also known as a fuel channel). The calandria tubes prevented the surrounding heavy water moderator from coming into contact with the pressure tubes. Between the calandria tube and the pressure tube is an annular space that was filled with carbon dioxide. The pressure tubes contained the fuel and circulating organic coolant. The calandria is surrounded by radial and axial shielding and extensions of the pressure tube beyond the calandria tubes, which provided connections to the coolant circulation above and below the radiation shields. The reactor was permanently shut down and the fuel from the pressure tubes and the circulating organic coolant removed in 1985. Figure 3.2.1-2 shows the location of the reactor vessel within the WR-1 Building.

3.2.1.2 Shielding

The reactor is surrounded by heavy concrete shielding (more than 2 m thick), which forms the reactor vault walls (Figure 3.2.1-2). Heavy concrete (density of 3,500 kg/m^3) was also used in the upper and lower access rooms and the shutdown shields. Piping through the concrete provided access for heavy water and helium lines and for the reactor vault exhaust duct. There are also three penetrations for the ion chambers.

The top deck plates provided an operational shield between the upper access space and the reactor hall and supported the fuel transfer flask. This shielding consisted of two rotating plates and an outer stationary ring. The plates are composed of cast steel (0.45 m thick) topped by wood fibre hardboard (Masonite; 9 cm thick) and a steel cover plate (0.5 cm thick).

3.2.1.3 Heavy Water and Helium Systems

These systems provided heavy water and helium to various reactor components. The heavy water system's main components are a dump tank, a helium accumulator tank, three circulation pumps, a heat exchanger, the calandria vessel, piping and instrumentation. The helium system consists of two helium pumps, two helium control valves, six reactor dump valves, a helium accumulator tank, five heavy water vapour condensers, a recombination unit, oxygen and helium addition stations, a sampling station, system piping and instrumentation. The heavy water and helium systems include the following auxiliary systems.

- **Boron addition system –** The boron addition system consists of two circuits: an initial charge circuit and a continuous addition circuit. The continuous addition circuit includes a 45 L tank, a metering pump, a mixing pump, a sample station, an addition station and a cation purification column.
- **Moderator demineralizer system –** The moderator demineralizer system consists of three mixed bed ion exchangers and, if necessary, a shield flask was available for the removal of highly contaminated ion-exchange columns. The ion exchange resins have been removed.
- **Heavy water collection and leak detection system –** The heavy water collection system consists of a stainless steel tank, a pump, piping and instrumentation.
- **Helium gas chromatograph –** The helium gas chromatograph includes an analyzer, a sample conditioner, a programmer, a stream selector and a recorder.

3.2.1.4 Primary Heat Transport System

The primary heat transport (PHT) system (shown in Figure 3.2.1-3) was designed to remove the heat produced in the reactor core. The system was divided into three circuits (A, B and C circuits; C Circuit in the east annex has already been removed) and the heat removed was dissipated to the Winnipeg River through conventional tube-and-shell heat exchangers using an organic primary coolant and river water for the secondary coolant. With this type of heat exchanger, one fluid runs through the tubes and another fluid flows over the tubes inside the surrounding shell to transfer heat between the two fluids. The PHT system had three similar circuits to achieve flexibility for experimental research.

There were four experimental loops in WR-1 (WR-1L2 and three fast neutron loops) and one out-of-reactor hydraulic test loop (WR-1L1 loop) in the reactor building. Each in-reactor loop consisted of a fuelled test section in a reactor lattice position, with piping equipment and instrumentation located in an adjacent loop room necessary to maintain required operating conditions of flow, pressure and temperature in the test section. A fuel position was converted to a loop by disconnecting the inlet and outlet feeders from the PHT system and connecting the feeders to the loop inlet and outlet piping.

3.2.1.4.1 Out-of-Reactor Hydraulic Test Loop (WR-1L1 Loop)

The WR-1L1 loop was a test facility capable of handling full-sized fuel channels and fuel assemblies, and consisted of a circulation pump, a pressurized pump, three test sections, three electric heaters, a make-up tank/degasifier, a condenser circuit, a purification circuit, a loop cooler, piping and instrumentation. Organic coolant was circulated through the test section(s) at operating conditions determined by the experiment being performed.

The three test sections extended between the hatch in the reactor hall floor and the WR-1L1 loop room. Each test section consisted of an outer insulation carbon steel pipe jacket supported from the building and an inner WR-1 fuel channel. The fuel channel was sealed top and bottom to the jacket similar to the in-reactor seals to the calandria extension tubes. A carbon dioxide annulus between the outer jacket and the fuel channel provided insulation. The test sections were arranged in parallel, enabling multiple tests to be carried out simultaneously.

3.2.1.4.2 WR-1L2 Loop

The WR-1L2 loop provided a light water-cooled research facility in the WR-1 Building. The loop was designed to be operated in either the boiling water or the pressurized water mode. Distilled light water was circulated through the test section by one of two pumps. Five immersion heaters on the inlet flow regulated the temperature of the coolant entering the test section. A surge tank and a separator vessel minimized pressure fluctuations in the circuit. The separator vessel stripped the steam from the outlet flow when the boiler circuit was not in use. The steam was then passed to the degassing vessel.

A reflux boiler was used to simulate the heat removed across the boiler section of a power reactor. The condenser cooling circuit consisted of two circulation pumps and a heat exchanger cooled with standby water. A surge tank was also part of the system.

A small coolant flow was passed through a degassing circuit. A heater was located in the circuit for drying the steam so accurate steam flow measurements could be made. The degassing vessel could be operated with a hydrogen atmosphere. All vent and drain valves and bursting disc/relieve valve outlets were connected to this tank. A pump was provided for sampling the tank contents and pumping the effluent to Building 200. Pumps also supplied make-up and emergency coolant to the loop from the distilled water storage tank. A purification circuit consisting of five parallel ion exchange columns and filters was also part of the loop.

3.2.1.4.3 Fast Neutron Loops

Three fast neutron loops (WR-1L4, WR-1L5 and WR-1L6) consisted of the following main components:

- a reflux boiler;
- three centrifugal circulation pumps;
- one vertical centrifugal pressurizing pump (WR-1L6 has two pumps);
- a surge tank; and
- a test section.

Organic coolant was circulated from bottom to top through the test section and back to the reflux boiler where the heat picked up from the fuel was dissipated to the cooling water. A small bleed flow was taken from the outlet feeder, the A/B degassing tank and pressure control. A similar quantity of degassed coolant was returned to the loop from the A/B circuit degassing pump(s). The pressurizing pump supplied the coolant to the suction of the circulation pumps. The circulation pumps were equipped with flywheels, which provided rundown cooling flow. Small motors were supplied to back up each of the main pump motors.

The WR-1 organic loops were connected to the WR-1 emergency injection system at both the inlet and outlet feeders. Emergency cooling to the test section was assured in the event a pipe rupture occurred at any location in the loop.

3.2.2 WR-1 Auxiliary Systems

3.2.2.1 Water Supply and Drainage System

Water was required as a secondary coolant for the PHT system, experimental loops and auxiliary systems, as well as a primary coolant for various pumps, motors and the WR-1 Building services. Water was also required for fire water, domestic water and distilled water systems. The water supply system is sourced from the Winnipeg River via the pump house. Process and standby water was returned to the Winnipeg River through the process drainage system via the outfall station. An organic trap was provided on the discharge line to precipitate out any organic material carried along in the water being discharged into the river.

3.2.2.2 Spent Fuel Handling and Storage System

The fuel handling and storage systems are shown in Figure 3.2.2-1. Throughout the operation of WR-1, irradiated fuel was removed from the reactor core with the large fuel transfer flask.

3.2.2.2.1 Fuel Storage Block

The fuel storage block provided a facility for storing and washing irradiated fuel, for storing irradiated fuel channels and experimental equipment, and for loading and unloading the fuel transfer flask. When the fuel had decayed sufficiently, it was transferred to the fuel storage bays using the fuel transfer flask. The fuel storage block consists of a concrete shielded, stainless steel lined pool filled with water. A carbon steel operating platform is located 0.3 m above the water level. The operating platform supports storage tubes and an operating walkway. A heavily shielded door controls access to the block with interlocks on the fuel transfer flask to prevent fuelling operations at the block without the door being locked shut. The top shield over the block consists of two carbon steel plates bolted together to form a 0.46 m thick shield, flush with the reactor hall floor.

Twenty-eight holes fitted with shielding plugs penetrate the shield and provide access ports to the storage tubes and the fuel channel storage racks below. Twenty-six storage tubes were provided, twenty-four tubes were for fuel storage, one for fuel washing, and one for loading and unloading the transfer flasks. The storage tubes are equipped with overflow drains and level instrumentation. The organic-filled tubes overflowed to the wash-down system's used-organic coolant tank. The wash tube facility consisted of a xylene filled storage tube.

3.2.2.2.2 Spent Fuel Station

The spent fuel station provided shielding in the reactor hall during fuel transfer operations at the fuel storage block and supported the fuel transfer flask and other equipment over the block. The spent fuel station consists of a carbon steel spigot plate recessed in the reactor hall floor, with a guide tube and a fuel transfer trolley mechanism. The spigot plate was used to position the fuel transfer flask at the station. The trolley was manually powered to move spent fuel between the transfer station and the work bay. The fuel transfer flask was interlocked at the station to prevent fuel being lowered unless the trolley was in position to receive it. The guide tube is a stainless steel tube, extending between the spigot plate and the trolley station in the fuel transfer passage. Any organic dripping from the inner vessel was contained by the tube and collected by a drip tray at the base.

The spent fuel room, located one floor below the reactor hall, contains a concrete-shielded work bay, two fuel storage bays and a fuel transfer passage. An electric crane that was used for spent fuel handling is also located there. The bays are constructed of light concrete with an epoxy lining. The underwater corners and joints were reinforced with fibreglass cloth. The storage bays are separated from the work bay by watertight gates. Inflatable seals on the stainless steel gates provided watertight separation of the bays for draining and maintenance. The spent fuel room crane was used to transfer fuel in the storage bay area. Storage racks were provided in each bay.

The work bay provided a fuel separating mechanism, for removing the hanger rod from the fuel end, and a fuel can holding station. An active fuel hanger storage facility was provided in the spent fuel room, consisting of a stainless steel tank located below floor hatch H-24.

0

The spent fuel bay had a circulation system to remove decay heat from spent fuel and irradiated equipment stored in the spent fuel bays and the fuel storage block. A circulation pump forced water from the change volume tank through a tube-in-shell heat exchanger into the bottom of the storage bays, the work bay and the storage block. A small bypass flow from the supply line was passed through a purification circuit containing a mixed sand and gravel bed filter and an ion-exchange column. The water returned by gravity to a change volume tank. The bay water piping was stainless steel.

3.2.2.2.3 Active Dry Storage System

The purpose of the active dry storage system was to provide a storage facility for irradiated or contaminated hardware. The storage facility consists of a concrete-shielded pit lined with stainless steel. The facility is located in the reactor hall north of the fuel storage block. The top shield consists of an 8.34-tonne carbon steel plate. Twenty-seven stepped access holes with carbon steel lead-filled plugs are provided in three rows.

3.2.2.2.4 Fuel Wash-Down System

The fuel wash-down system was used to encase defective fuel and supply and drain organic coolant used by the fuel transfer flask, the fuel storage block and the spent fuel storage bays. The wash-down system consists of a wash-down station, an organic storage and pumping facility, and an organic drainage facility. The wash-down station is in the floor of the reactor hall. It consists of a top shield, a wash tube and an organic accumulator. The wash tube is a water-jacketed stainless steel tube with a ball valve at the top for sealing it. The external water jacket removed the decay heat from the spent fuel rod being washed.

The wash-down station was designed for washing fuel in organic coolant. Two tanks, located in Room 109, provided a reserve supply of fresh and used organic coolant. A shielded dump tank and filter unit was provided for collecting highly active or contaminated coolant from the wash tube or the fuel transfer flask. The tank contents could also be pumped to Room 635 and drummed.

3.2.2.2.5 Transfer Flasks

A fuel transfer flask was used to transfer irradiated fuel from the reactor to the storage block, the wash-down station and the spent fuel station. The fuel transfer flask is 10.6 m high and 1.24 m in diameter at the base and weighs approximately 41 megagrams (Mg). It consists of outer shielding with the lifting spider, inner vessel, mechanisms and a cooling system.

The outer shielding provided support for the flask equipment and radiation shielding for active fuel carried in it. The inner vessel is a stainless steel, water-jacketed tube with a ball valve and snout at the lower end. The assembly is suspended from the inner vessel hoist by a yoke attached to the upper end. The yoke travels on two screws, which move the inner vessel in the vertical plane. The stationary tube was connected to the building active ventilation system pit exhaust fan through a flexible connection during fuelling operations to remove any organic or radioactive gas released.

The cooling system consists of a stainless steel water tank mounted on the lower platform of the flask circulation pump, connection lines to and from the inner vessel water jacket, and instrumentation. Steam connections were provided to heat the cooling water or the inner vessel, if desired. In an emergency, process water could be circulated though the cooling system on a once-through basis.

The fuel channel transfer flask was used to transfer irradiated fuel channels between the reactor and the storage block, and to transfer irradiated inserts and other radioactive assemblies not requiring cooling. The fuel channel transfer flask is similar to the fuel transfer flask except that all cable drives were manually operated and no instrumentation or interlocks, cooling, or ventilation were provided.

A smaller transfer flask (19 Mg) was used to transfer fuel between WR-1 and the hot cells in the WL Research and Development Building. This flask consists of a stainless steel pipe (8.1 m long), shielded with lead. Loading and unloading was done in WR-1 in a special site at the fuel storage block using the reactor hall crane.

The flask maintenance station was a facility for washing and maintaining the inner vessel of the transfer flask. It was also used as a decontamination facility for the fuel handling equipment. The station is in the reactor hall northwest of the reactor. The station consists of a base plate on the reactor hall floor to support the flask and a shaft 12 m deep with dimensions of 2.1 m by 1.8 m. A manually operated hoist served the bottom platform area. Special mechanisms were provided at the upper platform for removing the flask shutter and inner vessel assemblies.

3.2.2.3 Active Ventilation System

The active ventilation system delivers forced air circulation throughout the WR-1 Building to provide contamination control, environment control for personnel and equipment, and the needed air exchange.

The active ventilation system was designed so that air flows were always towards the zones having the higher contamination level to prevent the spread of contamination. The active ventilation system was sub-divided into four systems: building, cooling, control room and the building extension active ventilation systems. Each system had a fresh air supply, fans, filters, heating and cooling coils and an exhaust system. All systems normally exhausted to a common stack located east of the WR-1 Building. Air flow and pressure were balanced within the zones by manual volume dampers and grilles.

The incoming air was filtered and heated or cooled by preheat and tempering coils, and distribution fans sent air to various parts of the building. A smoke detector monitored the exhaust duct for smoke in the exhaust gases.

The control and relay room air conditioning system drew air to replace air lost to the building active ventilation system. A circulation fan drew the air through cooling coils and a bank of filters. In the event of airborne contamination entering the control room, fresh air could be supplied to flush the room. A fan was used to exhaust directly to atmosphere through a vent in the service wing roof.

3.2.2.4 Active Drainage System

The active drainage system collects liquid effluent from the various areas of the WR-1 Building and the groundwater from around the building base. The active drainage system includes five sumps:

- **Active Drainage Sump A –** general drainage (1.68 m^3 concrete tank);
- **Active Drainage Sump B –** heavy water drainage (2.73 m^3 concrete tank);
- **Organic Drainage Sump A –** organic coolant leakage (1.68 m^3 concrete tank);
- **WR-1 Extension Active Drainage Sump –** general drainage WR-1 extension (3.63 m^3 concrete tank); and
- **Sub-surface Active Drainage Sump –** groundwater around WR-1 Building basement (15 m^3 concrete tank).

Most of the active drainage piping is welded, seamless carbon steel pipe. The floor traps were equipped with a back water valve, which provided a ventilation barrier to prevent the spread of airborne contamination throughout the building. All rooms near WR-1 (other than those containing heavy water or organic piping and equipment) were drained to Active Drainage Sump A.

Floor drains in the moderator room, boron addition room and moderator demineralization drained into the Active Drainage Sump B concrete tank located in the floor of the moderator room. A sump level monitor was located to provide early warning of water in the sump. A remotely operated sampling pump was used to sample the sump effluent for heavy water. Effluent was pumped from this sump to Active Drainage Sump A for processing or to a drumming station to collect heavy water.

The floor drains in rooms containing organic piping or equipment were connected to Organic Drainage Sump A. The drains were positioned in the rooms to handle coolant spills, and the effluent could be pumped to Active Drainage Sump A. The WR-1 extension active drainage sump collected the effluent from the control laboratory fume cabinets and sinks, the mechanical shop and the areas in the building extension. Sump contents were pumped into the Active Drainage Sump A.

Active Drainage Sump A is pumped out to the low level liquid waste (LLLW) treatment system. The LLLW treatment system consists of two high density polyethylene tanks, a sampling station, and two filtering units. The effluent is held in the tanks until ready for sampling. It is sampled, analyzed, filtered and adjusted as required to meet release criteria.

The sub surface drainage sump is a concrete structure located outside the north wall of the WR 1 Building. The purpose of the Sub-Surface Drainage Sump is to collect groundwater from the weeping tiles located under and around the periphery of the WR-1 Building. A network of perforated pipe, embedded in free-draining crushed stone drains the groundwater from beneath the reactor building slab on ground (bedrock) and from the exterior periphery of the foundation walls into the sump. Since no contamination is anticipated to enter this effluent from inside or outside of the WR-1 Building, this sump is typically emptied to the stormwater management system; however, it is possible to route the effluent through the LLLW Treatment System for sampling and treatment prior to release in the event of a spill outside of the WR-1 Building.

3.2.2.5 Emergency Injection System

The emergency injection system consists of two pressurized tanks containing fresh coolant (HB-40 hydrogenated terphenyl used as reactor coolant, also known as OS-84). Tank PO-TK1 was connected to the inlet headers of the PHT A, B and C circuits and to the experimental loops tank and feeders. Tank PO-TK3 was connected to the outlet feeders of A, B and C circuits through the activity monitoring system supply lines.

3.2.2.6 Other Supporting Systems

The various other ancillary systems required to support the WR-1 Building are described below:

- **Thermal shield and concrete cooling system –** The thermal shield cooling system consisted of two circulation pumps, a tube-and-shell heat exchanger, a storage deaerator head tank, piping, instrumentation and miscellaneous equipment. The concrete cooling system consists of two circulation pumps, a U-tube heat exchanger, head degassing tank, six cooling coils, piping, instrumentation and miscellaneous equipment.
- **Compressed air system –** The compressed air system supplies compressed air to the WR-1 Complex from the powerhouse through a carbon steel underground main sheathed in a polyethylene protective coating.

Two air receiver tanks located in the WR-1 Building provide a reserve of compressed air. Compressed air is distributed throughout the building. Mask air was supplied from the instrument air receiver tank. A pressure-reducing station supplied mask air through a humidifier bank. A second pressure reducing station was available if the pressure regulator could not supply the necessary volume.

- **Heating and cooling system –** This system provides process and building heat to the WR-1 Complex and consists of several closed loop, circulating heated propylene glycol solutions or water through in-duct heater coils, room heater units or wall convectors. The main building glycol system consists of a closed loop in which a propylene glycol solution is circulated by one of two pumps. The system includes a heat exchanger and pre-heater coils. Obsolete equipment associated with the heating and cooling system has been partially removed.
- **Activity monitoring system –** The activity monitoring system provided early detection and identification of failed fuel. The activity monitoring system consisted of 19 Geiger tube detectors that monitored the activity of the outlet coolant from the individual fuel channel outlet feeders and 3 Geiger tube detectors that monitored the activity of the three primary heat-transport circuits. When a fuel failure occurred, the Geiger detector monitoring the affected fuel site would show an activity increase, identifying the suspected failure as one of three fuel rods.
- **Fire protection system –**The fire protection system includes the fire detection and alarm system, the pressurized carbon dioxide fire prevention system, the fire water system and the organic leak and smoke detection system. The fire detection and alarm system and the fire water system remain operational, but the other systems have been permanently shut down.
- **Electrical distribution system –** The electrical distribution system supplies power throughout the WR-1 Building and includes wiring, substations, circuits and busses. Emergency or standby electrical power is provided by four sets of diesel-driven generators located in the powerhouse. Highly reliable direct current (DC) power was supplied by rectifying the normal Class IV alternating current (AC) power or the standby Class III AC power. Lead-acid battery banks provided backup power whenever the AC supply to the rectifiers was lost. Only one battery bank remains in the system.
- **Annunciator system –** The annunciator system is operational and consists of alarm units with lighted, engraved windows and plug-in logic circuit boards mounted in cabinets. A tone generator and associated loudspeaker were mounted in each of the two control rooms to provide audible “alarm” and “clear” annunciator for the alarm units in the respective control rooms.
- **Radiological monitoring system –** The radiological monitoring system is operational and consists of an AEP 2180 fixed radiation monitor that is used in the WR-1 Building to monitor external gamma dose rates in the work area. It provides local indication with an alarm unit mounted in the main control room.
- **Auxiliary organic and gas systems –** The auxiliary organic and gas systems are those systems that supported the operation of the PHT system and included the degassing and particulate removal system, the purification system, the relief exhaust system, the organic supply system and the nitrogen supply system. Each system generally consisted of a storage tank, service piping and instrumentation.
- **Neutron power system –** The neutron power system consisted of the ion chambers, amplifiers, signal cables, power supplies and instrumentation.

- **Protective systems –** There were two reactor protective systems: the main protective system and the independent protective system. The main protective system monitored all parameters in the reactor capable of leading to, or causing, a dangerous reactor accident. The independent protective system monitored only two parameters: the reactor flux (neutron and gamma) and the emergency coolant injection tank pressure.
- **Reactor power regulating system –** The reactor regulating system consisted of two regulating channels, each consisting of six blocks: instrumentation, analog control computer, a control station, a routine start-up circuit, routine test equipment and a control valve.

3.3 Current Status of WR-1 and the WR-1 Building

3.3.1 Decommissioning Activities Completed to Date

WR-1 was permanently shut down in 1985 and decommissioned to a secure state in a reduced site access-controlled area. The first stage of decommissioning commenced in 1989 and was completed in 1995. This preliminary decommissioning of WR-1 (1989 to 1995) included:

- de-fuelling the reactor following shutdown in 1985;
- draining the organic coolant (but not flushing) from cooling circuits and transferring to the Waste Management Area for processing;
- removing heavy water and transferring to Chalk River Laboratories for storage;
- transferring all irradiated fuel stored in the fuel storage bays to storage in the Concrete Canister Storage Facility; and
- decontaminating the main floor (Level 600) and first sublevel (Level 500).

The organic coolant system was not flushed, so some coolant is still present within the system. Reactor control systems were isolated and removed. Building services systems are still maintained in an operating mode. This preliminary decommissioning work decreased potential hazards from the facility, reducing the monitoring and surveillance requirements for the deferment period.

The thermal shield and concrete cooling systems were not designed for easy draining, and portions of the systems within the reactor vault remain filled with cooling water. This will be drained as practicable but has been accounted for within the assessment to remain in place for in situ disposal.

3.3.2 Remaining WR-1 Systems

Many of the remaining systems for WR-1 are permanently shut down but are largely intact. Most of the electrical power has been disconnected and the systems have been placed in a safe shut down state. The only system considered as temporarily shut down is the spent fuel storage bay water circulation system. Decommissioning of spent fuel bays was carried out to a level where the bays were cleaned, and the system drained so that they could be placed in operation if they were required to support future research/business programs.

Table 3.3.2-1 summarizes the operational status of the WR-1 systems and identifies the radiological hazards for each system. All the required service systems remain operational to maintain WR-1 in a safe storage and surveillance state. Routine operation of these systems is documented in currently approved procedures. Building services and systems remaining in operation for the WR-1 Building include:

- water supply and drainage system;
- active drainage system;
- active ventilation system;
- compressed air system;
- fire protection system;
- electrical distribution system;
- annunciator system; and
- contamination monitoring system.

Table 3.3.2-1: Summary of WR-1 Building Systems Status

Systems	System Description	Operational Status[a]	Key Hazardous Materials [b]
Major Components			
Reactor Vessel	Section 3.2.1.1	Permanently shut down	**AP** **H-3**
Shielding	Section 3.2.1.2	Operational	**AP** (primary) – The shielding in close proximity to the reactor core, mainly the thermal and biological shields **FP** – Cross-contamination. Highest levels are expected to be the shielding in the upper and lower access rooms **Lead** **Potassium hydroxide**
Heavy Water System	Section 3.2.1.3	Permanently shut down	**H-3** (Primary) **CP** – Corrosion products possible from activation of structures part of the heavy water system in the vicinity of the reactor core and transported to the rest of the system
Helium System	Section 3.2.1.3	Permanently shut down	**H-3** (Primary) **CP** – Contamination likely in helium sample coolers Other parts of the system have the possibility of being cross-contaminated
Primary Heat Transport (PHT) System	Section 3.2.1.4	Permanently shut down; Circuit C (Room 528) dismantled and removed; other systems partially removed	**FP** (Primary) **CP** **AP** – in the sections that is in the reactor core (i.e., the pressure tubes) **Organic coolant**

Table 3.3.2-1: Summary of WR-1 Building Systems Status

Systems	System Description	Operational Status[a]	Key Hazardous Materials [b]
Out-of-Reactor Hydraulic Test Loop (WR-1L1 Loop)	Section 3.2.1.4.1	Permanently shut down	Some cross-contamination from PHT expected **Organic coolant**
WR-1L2 Loop	Section 3.2.1.4.2	Permanently shut down	**CP** (primary) **FP** – Light water cooled loop. This loop is expected to have high level of corrosion products relative to the rest of the WR-1 systems
Fast Neutron Loops	Section 3.2.1.4.3	Permanently shut down, loop 1L6 removed	**FP** (primary) **CP** – 1L4 and 1L5 are contaminated (Class 1). 1L6 has been removed **Organic coolant**
Auxiliary Systems			
Water Supply and Drainage System	Section 3.2.2.1	Operational	Supply water is a MARSAME Class 3. **FP** – Process drain system is known to be contaminated (contains an organic trap)
Fuel Storage Block	Section 3.2.2.2.1	Permanently shut down	**FP** (Primary) **Organic coolant** **Xylene**
Spent Fuel Station	Section 3.2.2.2.2	Permanently shut down	**FP** (Primary)
Active Dry Storage/ Fuel Wash-Down Systems	Section 3.2.2.2.3	Permanently shut down	**FP** (Primary) **CP** – Fuel wash-down system coolant drainage facility is a MARSAME Class 1. Other related structures are a MARSAME Class 1/2
Fuel Transfer Flask	Section 3.2.2.2.5	Permanently shut down	**FP** – Internal contamination Organic coolant
Fuel Channel Transfer Flask 21 Ton Transfer Flask	Section 3.2.2.2.5	Operational	**FP** – Internal contamination Organic coolant
Moderator Demineralizer System	Section 3.2.1.3	Permanently shut down	**H-3** (Primary) **CP**
Heavy Water Collection System	Section 3.2.1.3	Permanently shut down	**H-3** (Primary) **CP**
Helium Gas Chromatograph	Section 3.2.1.3	Dismantled and removed	**H-3** - Possible cross-contamination.
Boron Addition System	Section 3.2.1.3	Partially removed	**H-3** **Boron**
Ventilation System	Section 3.2.2.3	Operational	Active ventilation system is a MARSAME Class 1; remaining system likely clean
Active Drainage System	Section 3.2.2.4	Operational	**FP** **H-3** **CP** **Mercury**

Table 3.3.2-1: Summary of WR-1 Building Systems Status

Systems	System Description	Operational Status[a]	Key Hazardous Materials [b]
Emergency Injection System	Section 3.2.2.5	Mostly dismantled and removed	**FP** – Possible from cross-contamination from PHT system
Thermal Shield and Concrete Cooling System	Section 3.2.2.6	Permanently shut down	**AP** – Possible due to the close proximity to the reactor core **H-3** – Trace amounts from activation of lithium for pH control
Service Air System	Section 3.2.2.6	Operational	None expected
Instrument Air System	Section 3.2.2.6	Operational	None expected
Mask Air System	Section 3.2.2.6	Permanently shut down	None expected
Heating and Cooling System	Section 3.2.2.6	Obsolete equipment partially removed; system remains operational	Likely clean, possibility of leaks from contaminated systems, most likely coolant leaks in heat exchangers in the process heating system
Activity Monitoring System	Section 3.2.2.6	Permanently shut down	**FP** (Primary) **CP** Likely cross-contamination from PHT **Organic coolant**
Fire Protection System	Section 3.2.2.6	Operational	None expected
Electrical Distribution System	Section 3.2.2.6	Operational	No internal contamination expected
Annunciator System	Section 3.2.2.6	Operational	No internal contamination expected
Radiological Monitoring System	Section 3.2.2.6	Operational	**FP** (primary) **CP**
Degassing and Particulate Removal System	Section 3.2.2.6	Partially removed (C Circuit; other selected equipment)	**FP** (Primary) **AP** **Organic coolant**
Purification System	Section 3.2.2.6	Partially dismantled and removed	**FP** (Primary) **AP**
Relief Exhaust System	Section 3.2.2.6	Mostly dismantled and removed	**FP** (Primary) **CP**
Organic Supply System	Section 3.2.2.6	Partially removed (Bulk Storage Tank S0-TK5)	**FP** (Primary) **CP** – Cross-contaminated from used organic coolant **Organic coolant**
Nitrogen Supply System	Section 3.2.2.6	Mostly dismantled and removed	None expected
Neutron Power System	Section 3.2.2.6	Permanently shut down	**AP** – Portions in the vicinity of the reactor core are likely to be activated **FP** – Possibility of cross-contamination
Protective Systems	Section 3.2.2.6	Mostly dismantled and removed	None expected

Table 3.3.2-1: Summary of WR-1 Building Systems Status

Systems	System Description	Operational Status[a]	Key Hazardous Materials [b]
Reactor Power Regulating System	Section 3.2.2.6	Permanently shut down	Any contaminated parts of this system will remain inside the reactor core

(a) "Partially removed" means some specific equipment has been removed, but some equipment, pumps and motors remain. "Mostly dismantled" usually means equipment removed, but associated piping remains.

(b) Radiological Hazard definitions

- AP = Activation products – Neutron activated structures and components. These will be in close proximity to the reactor core.
- FP = Fission products.
- H-3 = Tritium – a weak beta emitter resulting from the activation of Heavy Water. Has the same chemical characteristics as water.
- CP = Corrosion products possible from activation of particles that pass through the reactor core and then get transported to the rest of the system outside of the core
- MARSAME = Multi-agency Radiation Survey and Assessment of Materials and Equipment.
  Class 1: Class 1 materials and equipment are impacted materials and equipment that have, or had, the following: (1) highest potential for, or known, radionuclide concentration(s) or radioactivity about the action level(s); (2) highest potential for small areas of elevated radionuclide concentration(s) or radioactivity; and (3) insufficient evidence to support reclassification as Class 2 of Class 3 materials and equipment.
  Class 2: Class 2 materials and equipment are impacted materials and equipment that have, or had, (1) low potential for radionuclide concentration(s) or radioactivity above the action level(s); and (2) little or no potential for small areas of elevated radionuclide concentration(s) or radioactivity.
  Class 3: Class 3 materials and equipment are impacted materials and equipment that have, or had, (1) little, or no, potential for radionuclide concentration(s) or radioactivity above background; and (2) insufficient evidence to support categorization as non-impacted.
- PHT = primary heat transport.

Since WR-1 was shut down and preliminary decommissioning activities were completed, many of the areas within the WR-1 Building are no longer designated as controlled areas; this includes most of the WR-1 Building rooms on Levels 600 and 700 (Figure 1.1-2). Some rooms that have been decommissioned and decontaminated at Level 400 and lower may have systems within them that have not been completely decontaminated (some ventilation and drainage systems; WR-1 pipes). Other hazards include asbestos-insulating materials, residual organic coolant in piping and tanks, and building structures and service systems. Administrative controls are in place to restrict access to these areas.

3.3.3 Waste Classification, Inventory and Characterization

The Detailed Decommissioning Plan (CNL 2021a) provides a list of the radiological zoning designation for the rooms in the WR-1 Building, along with a description of the potential for contamination present and an estimate of the contamination level and general dose rates expected in each area. This information will inform the detailed work plans that will be developed specifically to include best industry practices and experience with the aim of limiting risks to workers, the public and the environment from ISD hazards and to be compliant with the site's As Low As Reasonably Achievable (ALARA) policy.

3.3.3.1 Radiological Hazards

The remaining hazards in the WR 1 Building are largely radiological, with asbestos and organic coolant remaining in some reactor components. The available information on the radiological status is primarily based on reactor core modelling from the early 1990s (CNL 2020). Furthermore, a comprehensive characterization campaign was performed during 2017 and 2018 to address data gaps and to provide quantitative estimates of residual radionuclide content remaining within WR-1 systems (CNL 2020).

The majority of the remaining radioactivity in the WR-1 Building is situated in the reactor vessel, including the calandria, fuel channels, thermal shield and biological shield. The radiological hazards in the reactor building include potential exposure to radionuclides associated with irradiated reactor fuel, activated reactor components and tritiated heavy water. Corrosion/activation and fission products may also be found in process equipment.

A summary of the results of the comprehensive characterization campaign is provided in Table 3.3.3-1. Table 3.3.3-1 summarizes and compares both the inventory of WR-1 calculated through the historical work and through the recent sampling and validation work. For conservatism, the more bounding estimates are being used in safety and environmental assessment modelling.

Table 3.3.3-1: Summary of Radiological Inventory in WR-1

System	Pre-2018 (Bq)	Post-2018 (Bq)	Bounding Value (Bq)
Bioshield	4.1×10^{9}	n/a	4.1×10^{9}
Core	1.1×10^{15}	4.77×10^{14}	1.1×10^{15}
Out of Core	1.1×10^{12}	8.45×10^{10}	1.1×10^{12}
Total H-3 Out of Core[(a)]	1.27×10^{14}	2.47×10^{15}	2.47×10^{15}
Total	**1.23×10^{15}**	**2.95×10^{15}**	**3.57×10^{15}**

(a) Tritium estimates are conservative to account for uncertainties in the measurements.

Bq = becquerel; n/a = not applicable; H-3 = tritium, a weak beta emitter resulting from the activation of heavy water that has the same chemical characteristics as water.

3.3.3.2 Non-radiological Hazards

Some hazardous materials remain in WR-1 Building, including:

- asbestos-containing materials (ACMs; friable [contains more than 1% asbestos by weight or area and can be crumbled by the human hand] and non-friable [material that contains more than 1% asbestos and cannot be crumbled under hand pressure] asbestos-containing materials);
- residual organic coolant (HB-40 hydrogenated terphenyl used as reactor coolant, also known as OS-84) in the PHT system, unknown volumes potentially present in some of the tanks and some fuel channels;
- lead-based paint and lead shielding;
- polychlorinated biphenyls (PCBs) in fluorescent light fixture ballasts;
- small quantities of mercury in thermostats and switches;
- mould; and
- other hazardous chemicals as listed in Table 3.3.3-2 (HB-40, Lead, Xylene, Boron, Palladium, Potassium Hydroxide, Cadmium, Chromium, Mercury, Beryllium, Platinum, Magnesium Oxide, Gadolinium Oxide, Ozone Depleting Substances, Ion Exchange Columns).

Hazardous substances removed during preparation of ISD will be managed in accordance with CNL's *Environmental Protection* (CNL 2023) and *Management of Waste* (CNL 2022a) requirements.

3.3.3.2.1 Asbestos

Both friable and non-friable ACM is present in the WR-1 Building. Quantities and locations of ACMs are given in the B100/WR-1 Restricted Area Asbestos Abatement Work Plan (AECL 2015). The term friable is applied to a material that can be readily reduced to dust or powder by hand or moderate pressure. Therefore, ACMs that are friable have a much greater potential for airborne release when disturbed.

In 2014, much of the asbestos was removed from the non-restricted access areas of WR-1. The restricted access areas of the WR-1 Building still contain ACMs that will remain to be grouted within the ISD envelope (i.e., asbestos has been removed from Level 500 and above, and minimal disruption of material will occur during dismantling required prior to grouting).

3.3.3.2.2 Lead

In 2006, Pinchin Environmental Ltd. conducted an industrial characterization of B100 and lead-based paint was found (Pinchin 2007). Later, a more extensive examination was performed for lead (CNL 2018). This examination included a desktop review of documentation, analysis of paint, caulking, and other samples, and a thorough walkthrough of B100.

3.3.3.2.3 Polychlorinated Biphenyls

As part of the B100 industrial hazards characterization, light ballasts in fluorescent light fixtures suspected of containing PCBs were found in the WR-1 Building (Pinchin 2007). All light ballasts will be examined for PCB containing material, with those identified as PCB containing being removed in accordance with CNL's PCB Waste Management at WL (CNL 2021b) prior to grouting and demolition.

A more extensive examination was later performed for PCB containing materials (CNL 2021a). Table 3.3.3-2 provides the locations where PCBs in concentrations above the solid exemption quantity of 50 mg/kg (SOR/2008-273) or suspected of exceeding the solid exemption quantity were found. These PCB containing materials will be removed in accordance with CNL's Waste Management Program (CNL 2021b) prior to grouting or demolition.

Table 3.3.3-2: Polychlorinated Biphenyl Locations

Room	Description
414/601 - Crawlspace/Reactor Hall	Wire in cable trays
516 - Heating & Air Conditioning Room	Flex duct
516 - Heating & Air Conditioning Room	Foam duct insulation
630 - Corridor	Caulking - outer window (glazing tape, black)
651 - Office (outside)	Caulking - outer doors/windows (white)

If additional PCB-suspect materials are encountered, additional samples may be taken to confirm their exemption or identify them for removal. All PCB-containing waste material generated at the WL site will be sent to an off-site hazardous waste processing facility for treatment and disposal. Waste with both radiological and other hazardous properties may require segregation or use of a treatment facility to be acceptable for disposal.

3.3.3.2.4 Mould

Minor amounts of mould were observed within the WR-1 Building, mainly on pipe insulation and on ceiling tiles (Pinchin 2007).

3.3.3.2.5 Organic Coolant

The components of the PHT system, the auxiliary organic and gas systems and the fuel wash-down system are expected to be coated with used organic coolant. Fresh organic coolant is not flammable at ambient temperature but is combustible with a flashpoint of around 170°C. However, the properties of the coolant change during irradiation, with viscosity increasing and the length of flexibility of the molecules decreasing.

The residual organic is expected to be found as viscous liquid, sludge or as a dried coating, particularly in cold spots in pipes and tanks and in system elbows, joints and pumps.

3.3.3.2.6 Other Hazardous Chemicals

A number of hazardous chemical and materials were used during the operation of WR-1, Table 3.3.3-2 provides a list of these materials, their expected locations within the WR-1 Building and the estimated quantity remaining. Some items could not be directly estimated for various reasons. For example, chromium plating was used on many components without any indication of such in available documentation. In such cases, conservative assumptions have been made to provide a reasonable estimate. For several contaminants (e.g., xylene), there is no confirmation of their presence within WR-1 and their inclusion in this inventory is precautionary, to ensure the effects of the discovery of detectable quantities is not significant. Any additional non-radiological contaminants of potential concern identified during decommissioning will be assessed and remediated as needed to ensure there are no significant effects to the environment.

Table 3.3.3-2: Hazardous Chemicals and Materials within WR-1 Building

Chemical / Material	Expected Location	Description	Safety Concern	Quantity (kg)	Form
HB-40	PHT system; auxiliary organic system and gas system; fuel wash-down system, calandria tubes, tanks	Bulk removed from the reactor cooling circuits; however, components expected to be coated with used organic coolant	■ Flammable at flashpoint around 170°C ■ Limited toxicity; standard safety precautions ■ Contamination from fuel failures and corrosion products	87,700	Liquid in system low points
Lead	Throughout the WR-1 Building	Lead shielding, lead-based coatings, lead-glass windows and solder, paint	■ Sanding and grinding activities could mobilize	40,800	Solid, various shielding uses (e.g., sheets, bricks)
Xylene	Spent fuel handling and storage system; wash-down system – trapped in system low points or blockages	Used as a cleaning solvent	■ Moderate hazard and highly flammable ■ Protection – goggles, protective clothing, proper gloves and adequate ventilation	1.9	Liquid/vapour
Boron	Heavy water system; auxiliary systems, including boron addition system – low points / joints where residual solutes collect	Added as boric acid to heavy water to control reactor reactivity	■ Long-term exposure may cause kidney damage and a risk to pregnant workers ■ Protection – goggles, protective clothing, proper gloves and adequate ventilation	0.0009	Solids/solutes

Table 3.3.3-2: Hazardous Chemicals and Materials within WR-1 Building

Chemical / Material	Expected Location	Description	Safety Concern	Quantity (kg)	Form
Palladium	Organic supply system, helium system – low points / joints where residual solutes collect	Palladium(II) chloride bed absorption columns used in system; columns have been removed, but other equipment may be contaminated 5% palladium on pelletized alumina used in a recombiner	■ Finely divided palladium metal can be pyrophoric ■ Acute oral toxicity ■ Serious eye damage/irritation ■ Skin sensitization ■ Flammable solid	15.5	Solids/solutes
Potassium Hydroxide	Chemical addition tank in the concrete cooling system – low points / joints where residual solutes collect	Used for pH control of cooling water	■ Strong base ■ Protection – chemical protection suit, including self-contained breathing apparatus	0.01	Solids/solutes
Cadmium	Ion chamber component and as plating and fuel storage block	Alloy cladding component	■ Carcinogen and development and reproductive toxicant	91.4	Solid/plating
Chromium	Various thermocouples and as plating on various components (e.g., condenser tubes; boiler tubes)	Alloy cladding component	■ Carcinogen and suspected respiratory toxicant	148	Solid/plating
Mercury	Various thermocouples and as plating on various components (e.g., condenser tubes; boiler tubes)	Electric relay switches, industrial lighting bulbs and fluorescent tubes	■ Developmental toxicant; wide range of suspected toxic effects	0.33	Liquid/vapour
Beryllium	WR-1 – fuel elements	Alloy in cladding fuel elements	■ Carcinogen and respiratory toxicant	—	Trace solid residuals
Platinum	Flux detectors	Used as wire in the detector	■ Limited hazard ■ Protection – standard safety precautions	—	Trace solid residuals
Magnesium Oxide	Flux detectors	Used as an insulator	■ Negligible hazard	—	Trace solid residuals
Gadolinium Nitrate	SLOWPOKE demonstration reactor liquid absorber safety system	Gadolinium nitrate solution flowed into the pool to shut the reactor down	■ Moderate hazard ■ Protection – goggles, protective clothing, proper gloves and adequate ventilation	—	Trace solid residuals
Ozone Depleting Substances	Multiple systems	Air conditioning and refrigeration systems	■ Negligible hazard ■ Environmental concern	—	Trace solid residuals

Table 3.3.3-2: Hazardous Chemicals and Materials within WR-1 Building

Chemical / Material	Expected Location	Description	Safety Concern	Quantity (kg)	Form
Multiple Ion Exchange Columns	Heavy water system, distilled water system, spent fuel bay circulation system, thermal shield cooling system, boron addition system, SLOWPOKE demonstration reactor auxiliary systems, WR-1L2 loop, fast neutron loop	Numerous ion exchange columns are incorporated into the systems of WR-1	■ Negligible hazard ■ Specific resin type should be confirmed before removal ■ Protection – standard safety precautions	—	Trace solid residuals

PHT = primary heat transport.

3.4 Project Requirements

Numerous design, strategic and regulatory requirements were considered for the development of the Project. These requirements are discussed in the following sections.

3.4.1 Design Requirements

The objective of the Project is to safely decommission WR-1 and the WR-1 Building, providing a reduction of Canada's long-term nuclear legacy liabilities through permanent, passive disposal. The Project will meet the following design requirements:

- Isolate and contain contamination inside the reactor vault and limit releases of radiological and other hazardous substances from the facility.
- Confirm that the effects on people and the environment, both during and after decommissioning, are within acceptable limits (e.g., dose limits, exposure limits and air quality criteria).
- Doses to members of the public are below 0.3 millisieverts per year (mSv/a)[1] (i.e., all processes other than human intrusion).
- The dose to workers and to the public will be ALARA.
- Demonstrate long-term safety through a combination of site characteristics and engineered design features.

3.4.2 Strategic Requirements

The Project must also meet the following strategic requirements:

- Isolate radioactive contamination such that risk to the public and environment is kept ALARA.
- Comply with CNL's Compliance Program requirements:
  - Radiation Protection Program;
  - Environmental Protection Program;

[1] 0.3 mSv/a dose constraint specified in the CNSC REGDOC-2.11.1, Vol. III (CNSC 2018).

- Waste Management Program;
- Occupational Safety and Health Program;
- Emergency Preparedness Program;
- Nuclear Criticality Safety Program;
- Security Program;
- Nuclear Materials and Safeguards Management Program; and
- Fire Protection Program.

3.4.3 Regulatory Requirements

The Project will:

- comply with federal and provincial regulations, guidelines, acts, standards and codes (see Section 1.6.2: Relevant Standards, Codes and Guidelines, and CNL's *Environmental Protection* [CNL 2023]);
- provide long-term protection of the public and the environment; and
- be designed so that the effective dose rates received by any individual meet the limits in Section 13(1) of the Radiation Protection Regulations (SOR/2000-203) (Table 3.4.3-1).

Table 3.4.3-1: Effective Dose Rates

Item	Person	Period	Effective Dose (mSv)
1	Nuclear Energy Worker, including a pregnant energy worker	(a) One-year dosimetry period	50
		(b) Five-year dosimetry period	100
2	Pregnant Nuclear Energy Worker	Balance of the pregnancy	4
3	A person who is not a Nuclear Energy Worker	One calendar year	1

mSv = millisievert.

3.4.4 Guiding Standards

Regulating nuclear safety in Canada is the responsibility of the CNSC. Therefore, the Project has been designed to be compliant with the CNSC guidance documents. The International Atomic Energy Agency (IAEA) is a valuable resource to provide guidance for decisions concerning safety related to CNL's plans to decommission WR-1. The Project has been designed to be in alignment with CNSC and IAEA safety standards (e.g., REGDOC-2.11.1, *Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* [CNSC 2018], *Disposal of Radioactive Waste* [IAEA 2011] and *The Safety Case and Safety Assessment for the Disposal of Radioactive Waste* [IAEA 2012]).

3.4.5 Project Components

As described in Section 3.2 WR-1 Building Overview, CNL is proposing ISD, for the decommissioning of WR-1. The decommissioning activities proposed as part of the Project include:

- preparation for ISD;

- grouting of below-grade structures and systems;
- removal of above-grade WR-1 Building structures and systems;
- installation of a concrete cap and engineered cover over grouted WR-1 Building area;
- final site restoration;
- preparation for institutional control; and
- institutional control.

A detailed description of these activities is provided in the sections below. Other Project components such as temporary supporting infrastructure, waste generation and management, end-state and post-closure activities, and human resource requirements and expenditures also contribute to the overall containment strategy and are discussed in this section. The revised decommissioning plan for each of the WR-1 Building components described in Section 3.3 are provided in Table 3.4.5-1.

Table 3.4.5-1: Decommissioning Plan for the WR-1 Building Systems

Systems	System Description	Decommissioning Plan
Major Components		
Reactor Vessel	Section 3.2.1.1	Leave in place (within existing shielding below grade).
Shielding	Section 3.2.1.2	Leave in place and grout.
Heavy Water System	Section 3.2.1.3	Leave in place and grout.
Helium System	Section 3.2.1.3	Leave in place and grout.
Primary Heat Transport (PHT) System	Section 3.2.1.4	Above-ground portion: To be relocated below-grade. Below-ground portion: Leave in place and grout.
Out-of-Reactor Hydraulic Test Loop (WR-1L1 Loop)	Section 3.2.1.4.1	Leave in place and grout.
WR-1L2 Loop	Section 3.2.1.4.2	Leave in place and grout.
Fast Neutron Loops	Section 3.2.1.4.3	Leave in place and grout.
Auxiliary Systems		
Water Supply and Drainage System	Section 3.2.2.1	Leave in place and grout.
Fuel Storage Block	Section 3.2.2.2.1	Leave in place and grout.
Spent Fuel Station	Section 3.2.2.2.2	Leave in place and grout.
Active Dry Storage / Fuel Wash-Down Systems	Section 3.2.2.2.3	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed during building demolition.
Transfer Flasks	Section 3.2.2.2.5	To be removed before building demolition
Moderator Demineralizer System	Section 3.2.1.3	Leave in place and grout.

Table 3.4.5-1: Decommissioning Plan for the WR-1 Building Systems

Systems	System Description	Decommissioning Plan
Heavy Water Collection System	Section 3.2.1.3	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed during building demolition.
Boron Addition System	Section 3.2.1.3	Leave in place and grout.
Ventilation System	Section 3.2.2.3	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed before or during building demolition
Active Drainage System	Section 3.2.2.4	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed before or during building demolition.
Emergency Injection System	Section 3.2.2.5	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed before or during building demolition.
Thermal Shield and Concrete Cooling System	Section 3.2.2.6	Drain as practicable. Leave in place. Surround by grout.
Compressed Air System	Section 3.2.2.6	Leave in place and grout.
Heating and Cooling System	Section 3.2.2.6	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed during building demolition
Activity Monitoring System	Section 3.2.2.6	Leave in place and grout.
Fire Protection System	Section 3.2.2.6	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed during building demolition
Electrical Distribution System	Section 3.2.2.6	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed during building demolition
Annunciator System	Section 3.2.2.6	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed during building demolition
Radiological Monitoring System	Section 3.2.2.6	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed during building demolition
Degassing and Particulate Removal System	Section 3.2.2.6	Below-ground portion: Leave in place and grout. Above-ground portion: To be removed during building demolition.
Purification System	Section 3.2.2.6	Above-ground portion: To be removed during building demolition. Below-ground portion: Leave in place and grout.
Relief Exhaust System	Section 3.2.2.6	Leave in place and grout.

Table 3.4.5-1: Decommissioning Plan for the WR-1 Building Systems

Systems	System Description	Decommissioning Plan
Organic Supply System	Section 3.2.2.6	Above-ground portion: To be removed during building demolition. Below-ground portion: Leave in place and grout.
Nitrogen Supply System	Section 3.2.2.6	To be removed during building demolition.
Neutron Power System	Section 3.2.2.6	Leave in place and grout.
Protective Systems	Section 3.2.2.6	To be removed during building demolition.
Reactor Power Regulating System	Section 3.2.2.6	Leave in place and grout.

NOTE: All pipes and conduits penetrating outer walls to be cut away from the wall and the penetration to be sealed prior to grouting.

3.4.6 In Situ Disposal

The following sections describe the general process for ISD of WR-1. While the order of execution may vary, the overall scope of activities is not expected to change considerably throughout the Project.

3.4.6.1 Preparation for In Situ Disposal

Preparation for decommissioning will involve a combination of sealing penetrations in the exterior walls of the WR-1 Building; penetrating internal walls and equipment to provide flow paths for grout, displaced air and dissipated heat; and establishing temporary infrastructure to support grout production and placement.

3.4.6.1.1 Deactivation of the Building

The first stage of decommissioning the WR-1 Building will be to disconnect all building services. Deactivation of these services may require the following steps:

- isolation of building electrical supply;
- draining of all devices containing ozone-depleting substances by qualified personnel and removal of hazardous waste materials, as necessary;
- removal of asbestos and other hazardous material as needed to access pipes and connections;
- removal of radioactive liquids from drain lines;
- removal of remaining surplus equipment (e.g., cabinets, sinks);
- removal of utility services, systems and major components (e.g., heating boilers, chiller);
- characterization, packaging and transfer of radioactive and hazardous waste material for management in an approved waste storage facility or transfer to an off-site storage facility; and
- installation of temporary services to support safe execution of the decommissioning work.

Temporary services may include lighting, emergency signals, ventilation, sump water collection and electrical power for tooling. The goal of this step is to reduce the risk of cutting into pressurized or electrified systems during grout preparation work and allow most building materials to be penetrated, cut or removed as appropriate.

3.4.6.1.2 Seal Building Penetrations

There are several locations where penetrations exist in the exterior walls of the building to allow mechanical and electrical services to enter. All below-grade penetrations in the exterior walls and floor of the building will be sealed with an engineered plug, ensuring a continuous and uninterrupted barrier to isolate WR-1. This activity will include construction of forms as necessary for doorways, hatches, chases, ducts or other openings that must be sealed.

3.4.6.1.3 Create Grout Flow Paths

To permit grout to fill the below-grade systems to the extent practicable, it may be necessary to penetrate interior walls, piping systems or tanks. Pathways may also be created between rooms to allow the flow of grout and air out of all areas of the below-grade structure. For piping systems and tanks, penetrations may also be made at strategic locations to:

1) reduce buoyancy loads from empty tanks and large pipes surrounded by liquid grout; and

2) further improve the grout flow into specific piping systems.

3.4.6.1.4 Supporting Infrastructure

CNL plans to assemble a batch mixing plant or similar equipment on site to provide consistent quality and timely application of grout. Grout produced by the batch plant would be transferred by trucks or pumped from the batch plant through piping to a number of placement points throughout the building. A water tank, piping, power, material silos, staging areas and settling ponds may also need to be constructed for the Project.

3.4.6.1.5 Targeted Remediation

Some hazardous materials will be removed from the building prior to ISD. Materials planned for removal include, for example:

- all PCB-containing materials above exemption quantities;
- easily removable lead that is not currently being used for shielding;
- asbestos as necessary to access systems to perform decommissioning; and
- liquid organic coolant, as practicable.

A survey of the building did not identify any major sources of additional hazardous material, but for environmental assessment purposes it was assumed that a conservative amount of these hazardous materials is left in place when grouting. If additional hazardous materials are discovered during decommissioning, they will be assessed for removal prior to grouting. This step will help to further reduce the levels of hazardous materials left within the structure for ISD.

3.4.6.2 Grouting of Below-Grade Structures and Systems

Grout is used for filling void spaces and because of its flowable nature, it can be introduced into the smaller, less accessible spaces of most structures easier than other fill materials. Filling of structural void spaces for ISD serves the purpose of stabilizing the structure to prevent subsidence and impeding the flow of groundwater through the WRDF. The introduction of grout also limits inadvertent intruder access to the WRDF (US DOE 2013).

The EIS and solute transport modelling are based on target properties of grout. CNL has specified the minimum requirements for the grout that will be used in WR-1 (Table 3.4.6-1).

Table 3.4.6-1: Target Physical Properties of Grout

Property	Target	Basis
Bleed Water after 24 hr (vol.%)	0	Eliminate need for liquid removal
Maximum Temperature Rise during Curing	<25°C difference between grout interior and exterior	Manage effects of heat of hydration
pH	<13.5	Compatible with materials and contaminants in most of the rooms to be grouted
Compressive Strength	>3.4 MPa at 28 days	Non-structural grout, needs only to support its own mass
Effective Porosity (vol.%)	<0.6	Used in solute transport model
Dry Bulk Density (kg/m^3)	2,100	Used in solute transport model
Hydraulic Conductivity (m/yr)	<0.03	Used in solute transport model

vol.% = volume percent; MPa = megapascal.

The grout has been designed to achieve the required physical properties listed in Table 3.4.6-1 to flow easily into the void spaces of the WR-1 below-grade structure. The design takes into account the effects of using local fill materials (e.g., sand) and the materials the grout will interact with in the WR-1 below-grade structure (e.g., aluminium and lead). The grout design includes guidance on appropriate quality control measures to be applied during mixing and placement of the grout.

Detailed performance requirements and a supporting test plan were prepared by Savannah River National Laboratory (SRNL 2018). CNL engaged a vendor to develop a grout formulation that meets or exceeds the requirements specified by SRNL, using locally available materials. A similar grout design process (where an existing formula was adapted to use local materials) has already been successfully performed by CNL (Golder 2018b). The formulations have been tested to validate their performance against the required and assumed properties, to confirm they perform as well as or better than estimated in the solute transport model, prior to the installation of any grout into WR-1 (Golder 2022a).

Preliminary screening of the grout formulation using various combinations of locally available materials was completed, with many of the formulas easily meeting all the key target criteria. The primary candidate for the bulk fill formula was carried forward for a second phase of testing (i.e., Stage 2 testing) and refinement. This bulk fill formula is given in Table 3.4.6-2.

Table 3.4.6-2: Grout Formulation for Stage 2 Testing

Material	Quantity per m^3
Portland Cement	89 kg
Fly Ash	297 kg
Sand	1,570 kg
Gravel	0 kg
Water	232 kg
Polycarboxylate Polymer	1.77 L
Diutan Gum Based Viscosity Modifying Admixture	260 g

The bulk fill formula tested meets the target properties with the exception of dry bulk density (Golder 2022a). As stated in Table 3.4.6-1, the target value for dry bulk density is 2,100 kg/m^3, while the value of the tested bulk fill recipe was 2,007 kg/m^3 (Golder 2022a). The target value reflects a recipe containing both sand and aggregate; however, the tested bulk fill recipe does not contain aggregate since it was determined that the fresh and cured property targets could be achieved through the use of sand alone. Therefore, the results for dry bulk density of the tested bulk fill recipe have been deemed acceptable, as tested, by CNL (Golder 2022a).

Grouting of the below-grade structure will be carried out in stages. The safety case for the WRDF is built on the conservative assumption that the only major aspect of the grout to its function as a barrier is the hydraulic conductivity of grout used in the groundwater flow model. Since there is no expectation for grout to completely penetrate and fill every void space, the existence of voids and cold joints is not detrimental to the overall safety of the system. Instead, the structure will be filled to eliminate as many void spaces as is reasonably achievable. The overall fill design will target the elimination of transport pathways through large diameter pipes or ducts by cutting or “air gapping” the pipes, ducts, and other conduit. The term “Air Gapping” indicates providing a physical space cut in piping so that when grout fill is placed, that space is filled with grout and will provide a “grout break” in the pipe, limiting its potential to be a groundwater pathway. The placement of the grout will be completed using an engineered fill schedule (i.e., grouting plan). Multiple lifts of grout will be poured to systematically fill as practical the reactor building voids.

The safety case of the proposed ISD does not currently require that the reactor vault be grouted. The existing structure provides sufficient barrier to releases, and additional grout would not considerably increase the effectiveness of that barrier. If during grouting it is safe and efficient to allow grout to fill the reactor vault, it may be done. Likely the risks involved to properly install grout in the reactor vault, or within the calandria, will outweigh the benefits of additional grout. This option will be reassessed as more detailed grouting plans are developed and the available technologies and strategies from various vendors can be reviewed.

The maximum lift size (depth of fresh grout) will be determined for each room based on the structural properties of the room, the heat generated by the curing grout, and the presence of equipment that could be crushed, filled or dislodged if grout is poured too quickly. Each lift of grout will be given sufficient time to cure before additional grout is poured. Smaller lifts may be used in specific areas, for example to fill targeted voids, or specific systems. Quality control measures on grouting operations will be implemented to ensure all requirements for the grout are met and the final product will perform as expected. Grout filling via an engineered grout placement plan that relies on delivery of grout pumped through lines is the approach used by other reactor grouting projects. It is not expected that high pressure application of the grout will be required (US DOE 2013).

3.4.6.3 Removal of Above-Grade WR-1 Building Structures

The above-grade WR-1 components and portion of the building will be dismantled and removed after grouting has been completed. The main reactor hall, the concrete room that contains the above-grade portion of the PHT system, the reactor hall bridge crane and the ventilation stack will be demolished. Recyclable materials will be segregated and recycled where practicable. Materials that cannot be separated easily from hazardous materials such as asbestos will be sent for storage/disposal off site. No hazardous material or equipment from outside the WR-1 Building will be disposed of inside the WRDF as part of the Project.

The balance of the WR-1 Building outside ISD is expected to contain minimal radiological contamination. The above-grade building will be decontaminated to the extent practicable to allow the bulk of the construction materials to be reused, recycled, or disposed of in a conventional (non-radiological) landfill. Segregation and radiological surveys (i.e., characterization of material to be disposed of) of the building rubble will be undertaken, as required.

Hazardous substances exceeding release criteria will be removed and managed in accordance with CNL's *Environmental Protection* (CNL 2023) and *Management of Waste* (CNL 2022a) requirements. Radiologically contaminated asbestos, if present, will be packaged for storage at an approved waste management facility. Radiologically clean asbestos will be removed and will be disposed of in accordance with *Occupational Safety and Health and Waste Management* requirements at an approved off-site landfill. Decommissioning activities will be undertaken in compliance with the site decommissioning licence requirements and executed in a manner protecting workers, the public and the environment.

The building will be dismantled and demolished in an orderly manner. For example, the building will be stripped to the bare shell, with all of the wood, plaster and room dividers removed. The roof will then be removed, leaving the steel and concrete structure available for final demolition. If feasible, the building material and structure will be recycled. After demolition, the area will be backfilled and graded as necessary to achieve the required drainage conditions.

Final radiological and environmental clearance surveys will be performed on the soil surrounding the foundation, and subsequent remediation will be completed as required. Soil surrounding the building will be remediated if it exceeds the soil clean-up criteria (CNL 2019). Soil surrounding the building footprint is not expected to exceed the clean-up criteria; however, if soil contamination is encountered, it would be removed using standard excavation equipment and practices. Dust suppression methods (e.g., water misting, use of applicable immobilization agents on the soil surface) will be applied during excavation as required to suppress dust levels. The contaminated soils will be managed through CNL's Waste Management Program and placed in an approved waste management facility.

3.4.6.4 Installation of Concrete Cap and Engineered Cover

After grouting has been completed and the other portions of the WR-1 Complex are demolished, a reinforced concrete cap and engineered cover (AECOM 2020) will be constructed on top of the grouted area. The concrete cap can serve as a deterrent to prevent a person who might inadvertently enter the area from being able to contact building contamination (US DOE 2013). It will also resist animal and plant intrusion into the WRDF. The concrete cap will have a design life of 100 years, aligning with the recommended institutional control period, and require no maintenance.

An engineered cover will be installed over the concrete cap to:

- direct surface water away from the WRDF and limit water infiltration;
- protect the concrete cap from the environmental elements including freezing and thawing cycles; and
- support the growth of native vegetation (grasses, shrubs) where possible.

The engineered cover will also have a design life of 100 years and will manage stormwater consistently with the surrounding topography. It will resist wind and water erosion, as well as burrowing animals and tree root penetrations.

3.4.6.5 Final Site Restoration

Upon completion of the installation of the final concrete cap and engineered cover, a grass seed mixture native to the area will be used to establish vegetative cover. Maintenance of the concrete cap and engineered cover includes restricting weed growth and preventing surface erosion and abrasion. The surrounding grounds that were disturbed during demolition and decommissioning activities will be graded and restored with a grass seed mixture compatible with the surrounding area. Stormwater management features for the reclaimed WL site will have physical characteristics similar to the natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. The Project site and final cover will be graded to promote drainage from the site to the Winnipeg River.

3.4.6.6 Preparation for Institutional Control

The grouted area will be fenced with signage as part of the institutional controls. Routine surveillance of the site will include inspecting the concrete cap and engineered cover for subsidence, erosion and animal or other intrusions. Additional groundwater monitoring wells will be installed, as required, to monitor the performance of the WRDF.

3.4.7 Temporary Supporting Infrastructure

Temporary infrastructure may be required to support the Project during closure activities, including:

- batch mixing plant or similar equipment for preparation of grout;
- construction trailers;
- safety and security fencing; and
- equipment paddock and lay down area.

3.4.8 Waste Generation and Management

The handling and disposal of waste material resulting from decommissioning of WR-1 will be conducted in accordance with CNL company-wide requirements:

- waste characterization and tracking;
- waste minimization requirements;
- management of solid and liquid waste; and
- WL waste materials management.

For a summary of the anticipated waste stream volumes and clearance criteria, refer to the Detailed Decommissioning Plan (CNL 2021a). In accordance with established CNL Off-Site Transportation of Dangerous Goods requirements (CNL 2024), prior to transporting any materials, the owners of the disposal or storage facilities will be contacted to verify acceptance of the materials, and a notification will be sent to the appropriate authorities as required.

3.4.8.1 Radiological Wastes

Radiological wastes will be collected during the Project. The sources of these wastes include:

- **Preparation of reactor systems for ISD** – contaminated tools and personal protection equipment will be generated.
- **Removal of the WR-1 Building above-grade structure** – contaminated equipment and structures will need to be handled, such as active ventilation.
- **Grouting activities** – contaminated personal protective equipment will be generated.

Radioactive wastes from the above-listed activities are not planned for ISD and will be managed through the CNL Waste Management Program. However, waste materials from penetration of structures and systems (e.g., small sections of pipe, wall cores) may be left in place for grouting if they can be made secure and do not interfere with the safe execution of the work.

3.4.8.2 Hazardous Non-radiological Wastes

Some small quantities of non-radiological hazardous wastes may be collected from the WR-1 Building during the Project. Hazardous wastes will be managed in accordance with CNL's waste management practices (CNL 2022a) and Environmental Protection Program (CNL 2023), and will meet all federal, provincial and municipal requirements. The collected wastes will be shipped off site to an appropriate hazardous waste facility. The factors that determine if any material is collected for disposal or remains in the building for ISD, are worker safety and risk to the environment.

3.4.8.3 Clean Wastes and Likely Clean Wastes

Removal of the WR-1 Building above-grade structure and decommissioning of the temporary supporting infrastructure will generate clean and likely clean waste. Likely clean wastes will be monitored for radioactivity in accordance with Radiation Protection and Waste Management Program requirements to confirm that the waste is clean. Any waste not meeting criteria for classification as clean will be managed as radioactive waste. Disposal methods for clean waste materials will meet all federal, provincial and municipal requirements. The disposition options are reuse or recycle, disposal in an off-site landfill or other approved waste management facility as appropriate.

3.4.8.4 Transporting Waste Off-Site

The transport of radioactive waste is regulated under the Packaging and Transport of Nuclear Substances Regulations (SOR/2015-145). Key activities consist of:

- loading the waste into an approved shipping container;
- loading the container onto the vehicle;
- monitoring the vehicle for contamination and cleaning it, if necessary; and

- driving the transport vehicle to an approved facility.

The Waste Management Program (CNL 2022a) defines the process for managing wastes from point of generation to ultimate disposition and provides direct support and oversight to ensure waste generating activities are performed in a manner that protects the workers, the public and the environment. The Transportation of Dangerous Goods Program (CNL 2024) interfaces with the Waste Management Program and is responsible for the coordination and transport of all types of wastes (including radiological, hazardous and non-regulated construction and demolition material) from the Project. Specific requirements in the management of transporting radioactive wastes from the Project to Chalk River Laboratories for long-term storage and/or disposal include liaising with the Chalk River Laboratories Waste Receiver and transportation subcontractors and preparing dangerous goods shipments (including classifying the shipment and/or packages and preparing shipment documentation) in accordance with all applicable regulations. The main function of the Transportation of Dangerous Goods Program is to protect personnel, property and the environment from the effects of radiation and hazardous materials during transport by establishing and maintaining requirements and procedures necessary to facilitate the safe transport of dangerous goods and non-regulated waste materials from the Project.

3.4.9 End-State and Post-closure Activities

The final end-state for WR-1 is a permanent passive waste disposal facility that applies a Defense-in-Depth strategy through the use of multiple barriers, which passively resist release of contaminants (Figure 3.4.9-1). The primary pathway for release of contamination from the structure is by groundwater that has infiltrated into the sub-surface structure, picked up contamination and then carried it out of the sub-surface structure to the surrounding environment. Each of the barriers of the WRDF contributes to containing and isolating the waste from people and the environment. The barriers of defence against contaminant release include reactor system components, grout, internal walls, outer foundation walls, the local geosphere, a concrete cap and engineered cover, and active environmental monitoring. Combined, they form a rigorous system of barriers to provide long-term safety to the public and the environment, with environmental monitoring to be conducted to verify the effectiveness of the barriers.

3.4.9.1 In Situ Disposal System

For the Project, the concept for long-term waste management is based on the passive containment and isolation of the waste within the WRDF. Containment is achieved through robust design based on multiple barriers that includes using combined inherent natural and engineered barriers to provide safety following the decommissioning of WR-1. Systematically, the natural and engineered barriers consist of the reactor core and bioshield, grout fill, building foundation, concrete cap and engineered cover, and finally the geologic surround. This concept is shown schematically on Figure 3.4.9-1. The Project is designed to provide containment by controlling the rate of release of nuclear and hazardous substances from the WRDF, and isolation by limiting access to the waste by people and the environment.

3.4.9.1.1 Reactor Core and Bioshield Components

The majority of the remaining radiological contamination in WR-1 is located in the reactor core components (combined calandria and fuel channels). The radiological contamination is both on the internal surfaces (surficial contamination) and embedded in the material itself (activated components). In some cases, the components themselves are the contaminant (e.g., lead). Although sources of contamination, the reactor core components function as barriers providing contaminant isolation and containment These components are the initial barrier to contaminant migration and must first break down through corrosion and dissolution for contamination to be released to groundwater.

Breakdown of the reactor system components is expected to occur gradually over thousands of years. Corrosion rates for the reactor materials were based on estimates from literature for an aerobic environment and ranged from 1.78E-3 m/yr for aluminum to 1.0E-8 m/yr for Ozhennite and Zr-Nb alloy. Details on the selection of corrosion rates and calculation of times required for complete dissolution of each reactor component are provided in Golder's groundwater flow and solute transport modelling document (Section 4.1.3 of Golder 2021b).

The selection of corrosion rates for the WR-1 components was based on the following information:

- Analogous information of corrosion rates in aerobic humid conditions, which will be similar to the conditions expected in the Project.
- The ISD environment is expected to be alkaline. Steel and other alloys are known to corrode very slowly in alkaline conditions.

The corrosion rates used in the GWFSTMR were validated through the Wasteform Synthesis Report (Arcadis 2021) and it was concluded that the corrosion rates used in WR-1 assessment are generally consistent with the long-term measurements. It was assumed that corrosion would occur on both sides of the reactor components.

Information on barrier (concrete bioshield, grout fill, and foundation concrete) degradation was limited in the sources reviewed (Golder 2020), and the assumed step function used in the WR-1 assessment (based on information provided by Walton et al. [1990]; and Clifton et al. 1995) is considered justified. Simulations were completed as a part of the WR-1 assessment to evaluate the sensitivity of model results to the assumptions on degradation of grout and concrete. Results of these simulations were found to be relatively insensitive to the applied degradation rates.

The following documents were reviewed to support the selected corrosion rates and barrier degradation:

- *High-Performance Cement-Based Grouts for use in a Nuclear Waste Disposal Facility* (AECL 1992)
- *Low-pH Cementitious Materials Design and Characterisation* (Alonso et al. 2007)
- *Moisture Transport Review* (Arnold et al. 2009)
- *Properties of Concrete in the Cover Zone: Water Penetration, Sorptivity and Ionic Ingress* (Carter et al. 1996)
- *Implications of the Use of low-pH Cementitious Materials in High Activity Radioactive Waste Repositories* (Garcia et al. 2008)
- *Electrical Conductivity Sensors for Water Penetration Monitoring in Building Masonry Materials* (Guizzardi et al. 2016)

- *Summary of Laboratory Permeability Testing of Cementitious Backfill Grouts* (Golder 2018a)
- *Long-Term Behaviour of Fly Ash and Slag Cement Grouts for Micropiles Exposed to a Sulphate Aggressive Medium* (Ortega et al. 2017)
- *Long Term Behaviour of Cementitious Materials in the Korean Repository Environment* (Park and Kim 2013)
- *Groundwater and Soil Vapour Containment Design at an Industrial Site* (Schmertmann et al. 2017)
- Natural Analogues in Support of the Canadian Concept for Nuclear Fuel Waste Disposal (Cramer 1994)
- A Natural Analogue Study of Cement Buffered, Hyperalkaline Groundwaters and Their Interaction with a Repository Host Rock II (Linklater 1998)
- On the Chief Methods of Construction Used in Ancient Rome (Middleton 1888)
- A Mineralogical and Stable Isotope Study of Natural Analogues of Ordinary Portland Cement (OPC) and CaO-SiO2-H2O (CSH) Compounds (Milodowski et al. 1989)
- Post-closure Safety Assessment of a Used Fuel Repository in Sedimentary Rock (NWMO 2013)
- The ROMACONS Project: A Contribution to the Historical and Engineering Analysis of Hydraulic Concrete in Roman Maritime Structures (Oleson et al. 2004)
- Chemical, Mineralogical and Petrographic Characterization of Roman Ancient Hydraulic Concretes Cores from Santa Liberata, Italy and Caesarea Palestinae, Israel (Vola et al. 2011)

3.4.9.1.2 Grout

The details of the various levels within the final grouted below-grade structure are shown in Figure 3.4.9-2. The grout fills as practical all the reactor system components, as well as any small amounts of contamination that are present outside of the reactors system components at the time of grouting. The primary purpose of grouting of the facility is to stabilize the structure and resist subsidence over time. But additionally, this has a twofold benefit: 1) it slows down the process which will corrode the system components, extending their lifetime as the initial barrier to containment, and 2) it slows the movement of contamination from outside of the system components, as well as contamination from the degraded system components. The grout will slowly degrade over time, allowing water movement to increase as it degrades, though this is expected to occur gradually over thousands of years.

A literature review was conducted (Golder 2020) as part of the grout formulation study. The hydraulic conductivity of the grout used in the WR-1 assessment (5×10^{-8} m/s) was a factor of five times greater than the highest value cited in the literature reviewed, and a factor of 50 times higher than the grout performance specification of 9.5×10^{-10} m/s (see Section 3.4.6.2). Testing carried out on the preferred bulk fill grout formula (Golder 2022a) indicated an average hydraulic conductivity value of 1.27E-11 m/s, confirming that it is lower than values derived through the literature study and used as the grout performance specification, and is significantly lower than the value used in the solute transport model.

The safety case for the WRDF is built on the conservative assumption that the only major aspect of the grout to its function as a barrier is the hydraulic conductivity used in the groundwater flow model. Sensitivity scenarios completed confirm that variations in hydraulic conductivity of the grout affect the rate of water movement through the WRDF and thus influence the performance of the containment system; however, they do not control the overall safety of the containment system.

3.4.9.1.3 Internal Walls

Internal building walls and floors may provide an additional barrier between sections of grout however, this is not relied on in the safety analysis. While penetrations exist in these interior walls (to allow services to pass between rooms), they are mostly sealed for operational purposes such as fire-stopping. Any remaining penetrations are plugged by grout during the grouting process and are small in relation to the walls themselves. The internal walls and floors are largely painted or otherwise coated to seal the concrete to protect it from wear, to provide traction, or for preventing internal contamination of the concrete. These coatings provide a waterproof barrier in many locations and will limit the speed at which water may move into, and out of, the structure, further limiting the speed at which the system components or grout may degrade and the rate at which the contamination can leave the grouted areas. The coatings on these walls must first degrade to allow more water movement through these materials before degradation of the concrete can begin. Conservatively, this is not relied upon in the assessment. Concrete degradation, similar to the grout, is expected to occur gradually over longer periods.

3.4.9.1.4 Building Walls and Foundation

The below-grade concrete external walls and foundation of the WR-1 Building provide a single, continuous, final barrier to the release of contamination. Penetrations in the exterior walls and the foundation are sealed to ensure long term performance. Like the internal walls, the exterior walls also have coatings that restrict water movement, and were constructed of sulphate resistant concrete to resist sulphate attack, common in Manitoba soils. Degradation of the exterior walls and the foundation is expected to occur gradually over a long period of time.

A literature review of cementitious material degradation rates was conducted (Golder 2020) as part of the grout formulation study. The hydraulic conductivity of the concrete foundation used in the WR-1 assessment (5×10^{-10} m/s) was more than an order of magnitude greater than the highest value cited in the literature reviewed. To validate the results of the literature study and the hydraulic conductivity values used in the assessments, a *Building Condition Assessment* (Golder 2022b) was completed to evaluate the integrity of the existing subsurface concrete foundation and bottom slab of WR-1 prior to grouting the existing structure of the WR-1 Building. Hydraulic conductivity testing was completed on core samples of the concrete as a part of this assessment, which indicated a range in hydraulic conductivity of approximately 1.2×10^{-11} m/s to 9.8×10^{-11} m/s. The hydraulic conductivity used in the WR-1 assessment is therefore conservative compared to values determined from the Building Condition Assessment.

3.4.9.1.5 Local Geosphere

The soil conditions at WR-1 provide an additional barrier to release of contamination into the environment. The local soils are primarily clay-based and provide a natural barrier to groundwater movement. The soils provide a final barrier to groundwater movement, reducing the groundwater speed to less than 5 m per year (CNL 2022b). The soil also chemically sorbs contaminants to further reduce their concentrations in any surface water emissions. A geosynthesis report (CNL 2022b, summarized in Section 6.3.1 Geology) has been prepared to support the groundwater flow and solute transport assessment. It discusses the characteristics of the local and regional geosphere as it pertains to performance of the geosphere as a barrier. Buried or embedded services outside of the WRDF that may provide a preferential hydraulic pathway will be removed or sealed. The requirement to align the decommissioning strategy for buried mechanical services on the WL site will be included in the overall end-state plan for the WL site, outside the scope of this EIS.

3.4.9.1.6 Concrete Cap and Engineered Cover

The concrete cap and engineered cover do not provide a barrier for the release of contamination in the traditional sense; instead, they provide a barrier to keep the environment out of the WRDF since human and animal intrusion, plant ingress and water infiltration all directly or indirectly contribute to the release of contamination. The concrete cap is intended to deter intrusion, while the engineered cover protects the concrete cover and WRDF from frost and limits surface water infiltration. The concrete cap will be made of reinforced concrete. The engineered cover will be sloped to direct surface water away from the WRDF, include a drainage layer for any infiltrating surface water, and include a compacted stone layer to deter burrowing animals and roots. Limiting the amount of water entering the WRDF limits the release of contamination as groundwater is the main transport pathway for contamination. The detailed design (AECOM 2020) of engineered cover was confirmed to limit groundwater recharge through vertical infiltration to 0.8 mm/year. Figure 3.4.9-3 provides a conceptual preview of the concrete cap and engineered cover design.

3.4.9.1.7 Post-closure Monitoring

Groundwater monitoring provides verification that the ISD facility is performing as expected. Monitoring also provides an early warning system in the event that something unexpected has occurred and provides the data necessary to make decisions about mitigating actions required.

3.4.9.2 Post-closure Activities

CNL is developing the WL Closure Land-Use and End-State Plan, along with appropriate criteria for site remediation, including the WRDF associated with the ISD of WR-1. The plan defines the post-closure end-states, the post-closure land-use classifications and allocation, and the physical release criteria that must be met at the site closure. These end-state definitions, land-use classification and allocation, and physical release criteria are applicable to all decommissioning activities being carried out under the WL Restoration Project. Following completion of the work, the lands, including any remaining infrastructure, will enter long-term care and maintenance in accordance with the institutional control requirements. As the proponent of the Project, CNL will be responsible for implementing and managing the proposed Environmental Assessment Follow-up and Monitoring Program (EAFMP). The responsible owner of the site (the Government of Canada through AECL), will be responsible for the provision of funds for the follow-up monitoring program, with these costs included in CNL's submission of a decommissioning financial guarantee and accompanying cost estimate that has been submitted to the CNSC as per the WL site decommissioning licence.

In general, affected areas will be remediated to meet the WL site soil clean-up release criteria. Some lands will have restrictions on future use and/or development to ensure there are no adverse effects to the safety assessment and modelling assumptions associated with the WRDF. These areas will require ongoing institutional controls, including access restrictions and environmental monitoring. These processes will require approvals from the CNSC. Through the regulatory process, stakeholders will also have an opportunity to provide input that could help shape how the WL site is used in the future. Future use of the WL site will depend on the ability to release parts of the site so they have no restrictions on use upon completion of the Project.

The post-closure phase has two separate periods: institutional control and post-institutional control. Institutional controls are requirements placed on the licensee by the CNSC for the long-term safety of a decommissioned facility. During institutional control, long-term environmental monitoring and maintenance active will continue.

CNL will develop a Monitoring and Surveillance Plan for the In Situ Decommissioning of WR1 at the WL Site (the Project) and integrate it into the existing Environmental Assessment Follow-Up Program (EAFP) for the WL site. The Monitoring and Surveillance Plan will document the Environmental Assessment Follow-up Monitoring activities for the Project and will include sufficient information on the type, quantity and quality of information required to reliably verify effects predicted by the environmental assessment and confirm the effectiveness of mitigations. Wherever possible, existing programs (i.e., EMVP, GWMP, and EMP) will be adapted to meet the objectives of monitoring the prediction in the environmental assessment for the Project.

Institutional control will continue until the CNSC agrees that it is no longer needed. This is consistent with similar United States Department of Energy projects such as:

- Feed Materials Production Center in Ohio;
- Mound Plant in Ohio; and
- Rocky Flats Plant in Colorado.

For assessment purposes, a period of 100 years (from 2031 to 2131) of institutional control was selected. This timeframe is based on the results of the groundwater flow and solute transport model, and the expected quantities of contaminants within the WRDF over time. For prominent contaminants of concern, such as tritium (hydrogen-3) and cobalt-60, the total activity of these nuclides remaining in the WRDF after 100 years quickly decreases to zero (Figure 3.4.9-4). During the 100-year period, the peak release rate and dose rate from those contaminants are also expected to have occurred. Sampling during institutional control will verify these short-term results or signal the need for intervention.

It is recognized that institutional control could extend for hundreds of years beyond 2131; however, to assess the effects of an institutional control failure, a duration had to be selected. The 100-year period is a reasonable duration for the failure assessment given the results of the groundwater flow and solute transport model. Post-institutional control phase is assumed to occur after the year 2131.

3.4.10 Human Resource Requirements and Expenditures

The closure and post-closure phases of the Project will require administrative and supervisory staff, engineering and environmental monitoring personnel and construction workers. There are currently about 500 employees on the WL site. CNL anticipates employment to peak at approximately 550 employees during the closure phase. The employment is expected to decline to less than 10 employees by 2035. A large workforce is not required during institutional control.

4.0 INDIGENOUS ENGAGEMENT

4.1 Introduction

Canadian Nuclear Laboratories (CNL) has prepared this stand-alone section to document Indigenous engagement with respect to the In Situ Disposal (ISD) of the WR-1 Reactor at the Whiteshell Laboratories (WL) site (Project). This section was updated and enhanced since the March 2020 draft version of the WR-1 Decommissioning Project Environmental Impact Statement (EIS). This section is intended to document the engagement between the First Nations, the Manitoba Métis Federation (MMF), and CNL with respect to the Project, in particular, interests and relevant mitigations while meeting the requirements outlined by the Canadian Nuclear Safety Commission (CNSC) *REGDOC-3.2.2* (CNSC 2019).

This section of the EIS is divided into five major subsections, each of which are described below:

- **Section 4.1 – Introduction:** This section provides an outline for Section 4.0 and describes how CNL is working with Indigenous Nations to include their interests, Traditional Knowledge, and perspectives in the environmental assessment for the Project.
- **Section 4.2 – Indigenous Engagement:** This section describes engagement by each Indigenous Nation. This section summarizes key interests and concerns and explains how CNL is addressing the interests and concerns. This section also summarizes how CNL has verified with each Indigenous Nation that the interest/concern is adequately captured and identifies next steps. CNL is committed to facilitating opportunities for the Indigenous Nations to continue to be involved in the environmental assessment process for and beyond the scope of this Project. This section describes both short-term and long-term planned engagements and initiatives related the Project and the Whiteshell Laboratories Restoration Project.
- **Section 4.3 – Influence of Traditional Knowledge and Indigenous Feedback on the Environmental Assessment:** This section describes how Traditional Knowledge and Indigenous feedback has influenced the environmental assessment approach, including identification of valued components (VCs), defining spatial boundaries, description of the environment, and identification and evaluation of Project interactions, and inclusion in monitoring programs.
- **Section 4. – Summary of Issues Raised During Engagement Activities that Influenced the Environmental Impact Statement:** This section highlights insights, recommendations, and concerns that led to changes of this EIS.
- **Section 4.5 – CNL's Long-Term Relationship with Indigenous Nations:** This section describes CNL's overall, long-term and whole of corporation approach to undertaking meaningful engagement with the goal of building relationships as an organization with Indigenous Nations and communities.
- **Appendix 4.0-1 – Summary of Engagements and Summary of Interests and Concerns Tables:** This appendix provides a list of all key engagements with the MMF and the First Nations who are engaged on the Project. CNL has indicated which engagements focused on specific Project topics such as VCs, baseline studies, and monitoring. The section also includes a table of summarized interests and concerns for each engaged First Nation and the MMF and proposed next steps to address each topic.

This section of the EIS is supported by CNL's Indigenous Engagement Report (IER; CNL 2024) for the Project, which was updated concurrent with this submission. The IER was prepared in accordance with CNSC's *REGDOC-3.2.2 Indigenous Engagement* (CNSC 2019). The IER outlines CNL's approach to Indigenous engagement to support the environmental assessment process for the proposed Project. The IER is a more detailed version of Section 4.0 and provides additional information and context on CNL's engagement activities for the Project, which are summarized and incorporated in this EIS. The IER remains a living document that will continue to be updated.

CNL has demonstrated its commitment to continue to engage with the MMF and the First Nations about both the Project and also more broadly, the WL site decommissioning and environmental remediation. Consistent with the Government of Canada's approach to reconciliation, CNL is working closely with Atomic Energy of Canada Limited (AECL), a federal Crown corporation and owner of the site, to engage and build long-term relationships with Indigenous Nations, on Indigenous reconciliation as an Industry ally, even in instances where these matters go beyond the scope of this environmental assessment and licence amendment for the Project.

Discussions regarding long-term relationships and on specific aspects of the Project will be ongoing up until and after the CNSC Commission Hearing on the Project. Because of the ongoing nature of these discussions and relationships, CNL intends to provide an updated IER as part of the Commission Member Document package for the CNSC Commission Hearing on the Project. to determine interest in the WL site and/or the Project.

The IER provides background information on the First Nations, the Red River Métis, and/or representative organizations with a potential interest in the Project and includes, where possible, reference to the individual community's elected council, geographic location, population, and associations or memberships. The IER will be revised as these First Nations, the MMF and organizations provide additional information. The information summarized in this EIS reflects a summary of information available to CNL as of July 31, 2024.

4.1.1 Regulatory Requirements

Project information distribution and Indigenous participation are important aspects of the environmental assessment process. CNLs approach to Indigenous engagement complies with the regulatory documents *REGDOC-3.2.1, Public Information and Disclosure* (CNSC 2018) and *REGDOC-3.2.2, Indigenous Engagement* (CNSC 2019). Additional information on REGDOC-3.2.1 is provided in Section 5.1.2 Regulatory Requirements. *REGDOC-3.2.2* notes that when a licensee's activities could adversely affect potential or established Aboriginal and/or Treaty Rights, that the licensee shall identify and engage with potentially affected First Nations and the Red River Métis and develop/maintain any IERs in support of the Project.

Consideration was also given to CNSC's *Generic Guidelines for the Preparation of an Environmental Impact Statement (CNSC 2021)* pursuant to the *Canadian Environmental Assessment Act, 2012*, along with *REGDOC2.9.1, Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2020), which explains that the CNSC determines the requirements for Indigenous and public engagement on a case-by-case basis, including consideration of:

- interests of the public, the Red River Métis, and the First Nations;
- the complexity of the facility or activity and its potential interactions with the environment and the public; and
- additional factors such as other jurisdictional mandates or types of decisions.

Regulatory requirements related to these activities are summarized in Section 2.0 of the IER (CNL 2024). The *Canadian Environmental Assessment Act, 2012* (CEAA 2012) provides a clear description of the environmental effects on Indigenous Nations that are to be considered. The CNSC *REGDOC 3.2.2* (CNSC 2019) provides more detailed information and sets out the "requirements and guidance for licensees" with respect to engagement.

As the CNSC *REGDOC-3.2.2* provides specific requirements and guidance on consideration of Treaty Rights and activities (i.e., hunt, trap, fish, gather, or conduct ceremonies), results of CNL's review are specifically addressed in the IER and this EIS. In accordance with *REGDOC-3.2.2*, the scope of CNL's Indigenous engagement includes:

- identify Indigenous Nations for engagement (through consultation with the CNSC);
- gather information on Indigenous engagement activities that have taken place up to the date of writing and a proposed schedule for interim reporting on these activities to the CNSC; and
- plan Indigenous engagement activities through closure and post-closure of the Project and continue to engage with Indigenous Nations.

CNL also enhanced the scope of this section by adding the following:

- a section demonstrating compliance with regulatory requirements;
- a narrative of engagement activities for each First Nation and the MMF;
- an enhanced summary of each First Nation and the Red River Métis to demonstrate CNL's understanding of the historical, legal, socio-economic, traditional use, and other characteristics, including documenting (where available) their interests in the vicinity of the Project;
- a section providing a summary of engagement outcomes;
- a description of CNL's approach to long-term relationships with Indigenous Nations; and
- a section describing the influence of Traditional Knowledge on the environmental assessment (EA).

Interests and concerns raised through the Indigenous engagement process were considered for inclusion in the EA. For example, the Winnipeg River was identified by First Nations and the MMF as a critically important feature of their Aboriginal and Treaty Rights and culture. As such, the Winnipeg River was identified as a valued component (VC). Indigenous concerns and interests are described in tabular format at the outset of subsections of Section 6.0 Environmental Effects (Sections 6.2 Atmospheric Environment through 6.9 Socio-economic Environment) and a compiled summary table is provided in Section 4.4. The table also identifies the corresponding section of the EIS that was changed or altered as a result of Indigenous input.

4.2 Indigenous Engagement

This section summarizes CNL's engagement objectives and includes a brief description of the First Nations and the MMF, whom CNL has engaged with. It also includes the methods used to meet CNL's Indigenous engagement goals and objectives. This section documents engagement activities that have been undertaken between 2016 and up to July 31, 2024, and was subject to verification efforts with the First Nations and the MMF.

Table 4.2-1 below quantitatively describes and summarizes the various Indigenous engagement activities undertaken for the Project. The table is intended to demonstrate two key points:

- CNL has used a wide assortment of engagement tools including, information sharing, formal two-way dialogue, supporting detailed investigative studies, providing capacity funding, and the consideration of long-term relationship agreements. The engagement activities in the columns reflect the increasing degree of engagement.
- CNL has reached out to and/or engaged all the First Nations and the MMF and organizations on the list below in the manner as demonstrated. At the same time, CNL has engaged more extensively with those First Nations, the Red River Métis, through the MMF, and organizations that live and practice traditional activities in closest proximity to the WL site, and that have identified an interest to be involved. Each First Nation and the Red River Métis has their specific interest in the type and depth of engagement on the Project. CNL has adapted its engagement activities accordingly.

Table 4.2-1: Project Identified First Nations and the Red River Métis Engagement and Involvement

Project Identified Indigenous Nations and Organizations	Comments submitted via EA (2017 Draft EIS)	CNSC Participant Funding Issued	MOUs & Contribution Agreements[1] (CNL Funding)	TKLUS or Other Studies	Reviewed the 2020 and/or 2022 EIS	Relationship Agreements or similar agreements
Sagkeeng First Nation	YES	YES	YES	■ TKLUS, ■ Harvest Foods Study, ■ Alternative Means Assessment, ■ Psychosocial Assessment	YES	Signed Community Environmental Monitoring Program (CEMP) agreement and multi-year contribution agreement
Manitoba Métis Federation	YES	YES	YES	■ TKLUS ■ Harvest Foods Study	YES	Signed multi-year MOA(Subsequently withdrawn by MMF)
Black River First Nation	YES	YES	YES	■ TKLUS	YES	Signed
Brokenhead Ojibway Nation	YES	YES	YES	■ TKLUS ■ Technical Review of the Project EIS	YES	Not requested
Hollow Water First Nation	YES	YES	YES	■ TKLUS	YES	Signed
Wabaseemoong Independent Nations	YES	YES	Not requested	■ TK and Environmental Impact Assessment	No comments received	Not requested
Shoal Lake No. 40 (Treaty No. 3)	None received	Not requested	Not requested	Not requested	No comments received	Not requested
Iskatewizaagegan No. 39 Independent First Nation (Shoal Lake No. 39 First Nation) (Treaty No. 3)	None received	Not requested	Not requested	Not requested	None received	Not requested

[1] CNL has also funded a number of workshops and community engagement meetings with all First Nations and the Manitoba Métis Federation.

Table 4.2-1: Project Identified First Nations and the Red River Métis Engagement and Involvement

Project Identified Indigenous Nations and Organizations	Comments submitted via EA (2017 Draft EIS)	CNSC Participant Funding Issued	MOUs & Contribution Agreements[1] (CNL Funding)	TKLUS or Other Studies	Reviewed the 2020 and/or 2022 EIS	Relationship Agreements or similar agreements
Northwest Angle No. 33 (Treaty No. 3)	None received	Not requested	Not requested	Not requested	None received	Not requested
Grand Council Treaty #3	None received	Not requested	Not requested	Not requested	None received	Not requested
Peguis First Nation	None received	Not requested	Not requested	Not requested	None received	Not requested

MOU = Memorandum of Understanding; TKLUS = Traditional Knowledge and Land Use Study; EIS = Environmental Impact Statement.

4.2.1 Engagement Objectives

As part of its corporate, environmental and social responsibility, CNL recognizes and encourages the ongoing engagement of the First Nations, and the Red River Métis through the course of the EA for the Project. Through information sharing and engagement activities, CNL seeks to build Project awareness and learn about interests and concerns to strengthen mutual understanding, opportunities for collaboration and long-term relationships. CNL engages with First Nation's Chief and Councils and community members, the Manitoba Métis Federation and Red River Métis Citizens as well as Indigenous Elders, Knowledge Keepers and Youth and other Indigenous representative organizations on the potential impacts and effects of the Project on the environment and on Aboriginal and Treaty Rights including, but not limited to, trapping, hunting, fishing, gathering on traditional ceremonial grounds.

CNL has five overarching Indigenous engagement goals.

- **Build awareness and mutual understanding,** and by supporting and facilitating opportunities for mutual learning, including current and traditional use, and values and perspectives on nuclear decommissioning, environmental remediation and radioactive waste management, demonstrate CNL's long-term commitment and approach to safe and responsible management of AECL's radioactive waste and decommissioning liabilities (e.g., through Project and site monitoring activities).
- **Share information on the Project, including the potential effects on the environment**. This includes co-developing (where possible plain language information and communication products for First Nations and the MMF and provide accessible and current information on Project activities.
- **Seek input and feedback from the MMF and the First Nations** regarding Project related activities, and traditional and current uses of the land surrounding the WL site. Initiate early and meaningful two-way communication channels between CNL and the First Nations and the Red River Métis to determine the best methods for sharing information and to provide opportunities for Indigenous Nations to provide input on project considerations including design, the environmental assessment process, and assessment of effects. This includes action on economic reconciliation through exploring opportunities for Indigenous economic participation.
- **Develop long term relationships with the First Nations and the MMF** to support continued involvement in the Project, community healing and reconciliation. This will extend beyond the scope of the environmental assessment process for Project.
- **Meet or where possible exceed all regulatory-based communication and engagement requirements** and facilitate engagement that reflects current memorandums of understanding and contribution agreements, and that considers the interests, needs and schedule of each Indigenous Nation.

In addition, CNL applies CNSC's guidance on engaging with First Nations and the MMF and appropriate methodologies for assessing environmental effects and impacts on Aboriginal and Treaty Rights. Indigenous engagement activities completed by the proponent will help determine if the activity described in the EA could adversely impact potential or established Treaty Rights and related interests (CNSC 2019). This information is used to inform the CNSC's determination if duty to consult is required, and if so, the approach to conducting its own Indigenous consultation activities.

As the CNSC *REGDOC-3.2.2* provides specific requirements and guidance on consideration of Treaty Rights and activities (i.e., hunt, trap, fish, gather, or conduct ceremonies), results of CNL's review are specifically addressed in the IER (CNL 2024) and the EIS. The potential effects that were considered in EIS included both adverse and positive effects to the current use of land and resources for traditional purposes, hunting, gathering and ceremonial, and environmental, health, social, and economic conditions of Indigenous Nations potentially affected by the designated Project, including interferences of the Project with the following:

- quantity and quality of resources available for harvesting (e.g., species of cultural importance, traditional and medicinal plants);
- access to culturally important harvesting areas or resources of importance;
- experiences of being on the land (e.g., changes in air quality, noise exposure, effects of vibrations from blasting or other activities);
- current and future availability and quality of country foods (traditional foods);
- the use of travel ways, navigable waterways, and water bodies;
- commercial and non-commercial fishing, hunting, trapping and gathering, and cultural or ceremonial activities and practices;
- commercial, non-commercial, and trade economies; and
- cultural heritage, and structures, sites or things of historical, archaeological, paleontological or architectural significance to the First Nations or the Red River Métis, including, but not limited to:
  - the loss or destruction of physical and cultural heritage;
  - changes to access to physical and cultural heritage;
  - changes to the cultural value, spirituality, or importance associated with physical and cultural heritage;
  - changes to sacred, ceremonial or culturally important places, objects, or things, including languages, stories, and traditions; and
  - changes to visual aesthetics over the life of the Project and post-project abandonment or decommissioning.

To meet these objectives, CNL developed specific strategies to increase the effectiveness of engagement activities so Indigenous engagement objectives and requirements for the Project are met. These strategies include:

- presenting information in plain language formats (e.g., webinars, infographics, one-pager summary documents);
- engaging technical experts to communicate information through a variety of formats;
- accomplishing all required activities in a timely manner;
- providing various means for the First Nations and the Red River Métis to access information (e.g., presentations, infographics, site tours, website information, and community visits);
- support and capacity funding for meaningful and timely engagement and the development of longer-term relationship agreements with the First Nations and the MMF; and

- support the First Nations and the MMF's review of the EIS documentation to allow them to validate if CNL has documented their interests and concerns accurately.

Over the course of the environmental assessment for the Project, CNL has evolved in its approach to Indigenous engagement and grown its relationship with several Indigenous communities both in the context of the Project and at a corporate level. CNL has retained the above objectives, and the understanding and wording of these objectives continues to develop as our relationships develop. Therefore, the way CNL meets and measures these objectives is also evolving to match the unique engagement with each community.

4.2.2 Identified First Nations and the Red River Métis

A list of the Indigenous Nations with a potential interest in the Project was identified by CNL and included in the IER. Identification of the First Nations and the Red River Métis was based on consultation with the CNSC, through CNL's previous Indigenous engagements, and through the use of publicly available sources of information including:

- First Nation and the Red River Métis and organization websites;
- the Aboriginal and Treaty Rights Information System (ATRIS; Government of Canada and INAC 2016); and
- Crown-Indigenous Relations and Northern Affairs Canada First Nation community profiles.

The list was based on the identified potential or established Aboriginal and/or Treaty Rights of the First Nations and the Red River Métis in the vicinity of the Project (Table 4.2.2-1) along with a brief rationale for inclusion. The inclusion of specific Nations considers the nature of the established and/or claimed Treaty Rights and potential effects on those Treaty Rights caused by the proposed Project based on a preliminary assessment of existing and available information. As such, the working list is subject to change based on information and dialogue with the identified First Nations and the MMF.

Table 4.2.2-1: The Indigenous Nations Identified as Having Potential Interest in the Project

First Nations, the Red River Métis and/or Representative Organizations	Identification Rationale and Proximity to the WL site*
Sagkeeng First Nation (Sagkeeng) (Treaty No. 1 and 3)	■ Asserted and/or established Aboriginal and Treaty Rights exist in the vicinity of the WL site. ■ Occupy one reserve located 52 kilometres (km) north of the WL site, and downstream along the Winnipeg River. ■ Existing relationship and interest in the WL site. ■ Sagkeeng has asserted Treaty Rights throughout Treaty 1 territory, and inherent Indigenous Rights in parts of Treaty 3 Territory, particularly that part of Treaty 3 which is generally within the borders of Manitoba. The WL site is situated on that land which Sagkeeng's ancestors used and occupied since time immemorial, and which was never ceded or surrendered by Sagkeeng. ■ The site is within the area to which Sagkeeng claims unextinguished Indigenous title, a proceeding for which is ongoing in the Manitoba Court of King's Bench.

Table 4.2.2-1: The Indigenous Nations Identified as Having Potential Interest in the Project

First Nations, the Red River Métis and/or Representative Organizations	Identification Rationale and Proximity to the WL site*
Brokenhead Ojibway Nation (Treaty No. 1)	■ Asserted and/or established Aboriginal and Treaty Rights exist in the vicinity of the WL site. ■ Occupy three reserves: 44 km northwest, 55 km northwest and 73 km southwest of the WL site respectively. ■ Interest expressed via comments on Project Description.
Red River Métis represented by the Manitoba Métis Federation	■ The MMF is the official democratic and self-governing political representative for the Red River Métis Community. The MMF is considered the government of the Red River Métis. Potential asserted and/or established Métis harvesting Rights in the vicinity of the WL site. ■ Interest expressed via comments on Project Description.
Black River First Nation (Treaty No. 5)	■ Asserted and/or established Aboriginal and Treaty Rights exist in the vicinity of the WL site. ■ Occupy one reserve 75 km north of the WL site.
Hollow Water First Nation (Anishinaabe (Ojibwa)) (Treaty No. 5)	■ Asserted and/or established Aboriginal and Treaty Rights exist in the vicinity of the WL site. ■ Occupy one reserve, 113 km north of the WL site.
Shoal Lake No. 40 (Treaty No. 3)	■ Potential asserted and/or established Aboriginal and Treaty Rights exist in the vicinity of the WL site. ■ Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. ■ Occupy three reserves: 94 km southeast, 110 km southeast and 140 km southeast of the WL site, respectively.
Iskatewizaagegan No. 39 Independent First Nation (Shoal Lake No. 39 First Nation) (Treaty No. 3)	■ Potential asserted and/or established Aboriginal and Treaty Rights exist in the vicinity of the WL site. ■ Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. ■ Occupy four reserves: 93 km southeast, 102 km southeast, 110 km southeast and 140 km southeast of the WL site, respectively.
Northwest Angle No. 33 (Treaty No. 3)	■ Potential asserted and/or established Aboriginal and Treaty Rights exist in the vicinity of the WL site. ■ Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. ■ Occupy three reserves: 111 km southeast, 140 km southeast and 176 km southeast of the WL site, respectively.
Wabaseemoong Independent Nations (also known as Wabaseemoong Independent Nations of One Man Lake, Swan Lake and White Dog) (Treaty No. 3)	■ Potential asserted and/or established Aboriginal and Treaty Rights exist in the vicinity of the WL site. ■ Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. ■ Occupy four reserves: 80 km east, 85 km east, 95 km east and 140 km southeast of the WL site, respectively.

Table 4.2.2-1: The Indigenous Nations Identified as Having Potential Interest in the Project

First Nations, the Red River Métis and/or Representative Organizations	Identification Rationale and Proximity to the WL site*
Grand Council of Treaty 3 (specific to this Project includes: Shoal Lake No. 40 First Nation, Iskatewizaagegan No. 39 Independent First Nation (Shoal Lake No. 39 First Nation), Northwest Angle No. 33, Wabaseemoong Independent Nations, and Sagkeeng First Nation)	■ Treaty organization which represents 28 First Nations and 5 with potential interest in the Project. ■ Treaty 3 territory includes parts of eastern Manitoba, including the WL site.
Chiefs of Ontario (specific to this Project includes Shoal Lake No. 40 First Nation, Iskatewizaagegan No. 39 Independent First Nation (Shoal Lake No. 39 First Nation), Northwest Angle No. 33, and Wabaseemoong Independent Nations)	■ First Nations umbrella organization that represents 133 First Nations and 4 with potential interest in the Project.
Peguis First Nation	■ In 2023 Peguis First Nation reached out to CNL with interest in the Project and WL site.

* Two applications were used in the calculation of distances (Arc GIS 10.4 and Google Earth Pro). Distances were measured as a straight line from the WL site to the approximate centre of each reserve.

Each of the Nations listed in Table 4.2.2-1 were provided written notification regarding the Project and efforts were made to follow up with each via telephone to determine their relative interest in participating in engagement activities. A record of communication with regional Indigenous Nations is provided in Appendix 4.0-1 and a summary narrative of engagement with each identified First Nation and the MMF is provided in Section 4.2.4 Summary of Engagement.

Although efforts were placed on reaching out to all the Indigenous Nations and Indigenous organizations identified, particular effort was placed on outreach to the Nations and organizations who expressed interest or provided comments during the federal Project Description process. These Nations were Sagkeeng First Nation (Sagkeeng), Black River First Nation, Brokenhead Ojibway Nation, Hollow Water First Nation, Wabaseemoong Independent Nations and the Red River Métis.

In the fall of 2020, CNL received two verbal confirmations from Brokenhead Ojibway Nation that they were no longer available to engage with CNL on this Project due to other community priorities. CNL offered to fund a community liaison position to enable ongoing engagement, but the community declined. CNL will continue to keep Brokenhead Ojibway Nation informed about the Project and is prepared to re-engage as desired by the community. While there was limited feedback from Shoal Lake No. 40, Iskatewizaagegan No. 39 Independent First Nation, and Northwest Angle No. 33 in CNL's initial outreach on the Project, CNL has contacted these First Nations in February 2021 to provide a Project status update and to determine their interest in meeting to discuss the Project further.

In addition, CNL and Peguis First Nation, have had some dialogue on the Project. Peguis First Nation is a Treaty 1 First Nation, located approximately 163 km from the WL site and is the largest First Nation community in Manitoba. CNL is committed to continuing to connect with Peguis.

4.2.3 Engagement Methods

Section 4.2.4 describes the engagement that CNL has undertaken with the identified Indigenous Nations: Sagkeeng First Nation, the MMF; Black River First Nation, Brokenhead Ojibway Nation, Hollow Water First Nation, Wabaseemoong Independent Nations, Shoal Lake 40, Iskatewizaagegan No. 39, Northwest Angle No. 33, Grand Council Treaty #3 and Peguis First Nation. CNL recognizes the importance of seeking direction from the First Nations and the Red River Métis (through engagement with the MMF), on how they want to engage on the Project. CNL also recognizes and respects that each Indigenous Nation is unique and may have different approaches, needs, and interests for engagement on this Project. For example, some Nations have indicated they would prefer to establish funding agreements in the form of Contribution Agreements that outline specific engagement activities of interest to the Nation.

The Contribution Agreements signed by CNL and the First Nations or the MMF have supported participation in environmental monitoring activities, funding for community liaison positions, and further participation in the EA process, including technical reviews of CNL's responses to the Nation's comments on the draft EIS. Contribution Agreements have also funded Traditional Knowledge studies conducted by the First Nations and the MMF, food intake studies, and an Alternative Means Assessment that incorporated Sagkeeng's community values, alternative weighting, and additional criteria for consideration. These efforts have assisted CNL in understanding the potential impacts of this Project to Aboriginal and Treaty Rights. The CNSC provided funding for the MMF and Wabaseemoong Independent Nations to conduct their Traditional Knowledge studies. The CNSC has also provided funding to Sagkeeng to conduct a Psychosocial Impact Assessment to help inform the CNSC's Rights Impact Assessment and to inform the CNSC assessment of effects of this EIS.

Various engagement methods were designed to share information with and receive input, while fulfilling CNL's corporate and regulatory objectives. The methods CNL has used to date or plans to undertake, are highly diverse and vary based on expressed community need and desired methods. This includes general information activities focused on community meetings, workshops and long-term relationship building. Section 4.2.4 describes engagement activities for each community, in general using the methods summarized in Table 4.2.3-1 below. Project-specific examples are included; however, relationship-building engagements and funding are also key activities.

As CNL is undertaking closure of the WL site in addition to the Project, it is important to the First Nations and the Red River Métis and CNL that these relationships endure, grow, and adapt to future activities. As such, CNL worked in collaboration with AECL, the MMF, and local First Nations to determine whether an Indigenous Advisory Committee could be established. The intention was that Indigenous Advisory Committee could become an additional mechanism for engagement and would not replace or impede ongoing bilateral engagements with each First Nation or the MMF. In 2021, CNL held workshops on an Indigenous Advisory Committee. Based on feedback received from several First Nations and the MMF, this initiative has been put on hold in favour of bilateral engagement. Canadian Nuclear Laboratories would reopen dialogue on the Indigenous Advisory Committee if there is new interest in revisiting this initiative. For more information on the Indigenous Advisory Committee, refer to Section 4.2.5.2 Long-term Initiatives and Engagements. CNL is also developing and executing relationship agreements, that include liaison positions, to help address each Nation's unique interests and concerns related to the Project and the Whiteshell Laboratories Restoration Project.

Starting in March 2020, the COVID-19 pandemic impacted in-person engagement activities. CNL followed public health requirements and guidance throughout and adapted to restrictions providing online platforms for virtual meetings with First Nations and the MMF. In accordance with local health authorities, and as the World Health Organization declared that COVID-19 is no longer a public health emergency (WHO 2023) CNL has held some in-person meetings and workshops, although virtual meetings have remained the preference in some instances.

Table 4.2.3-1: Engagement Methods and Example Activities

Engagement Method	Example Activities
Contribution Agreements and Relationship agreements	■ Project-specific Agreements (e.g., Contribution Agreements) ▪ Provision of funding to assist in resource capacity development, including peer review studies and engagements with Indigenous organization consultants and staff, review of the draft EIS and review of CNL's responses to community comments on the EIS, community liaison positions ▪ Capacity assistance, as appropriate, including costs to support meetings such as hall rental or production of printed materials, in-kind access to the technical expertise of CNL staff, reimbursement for some expenses to participate in engagement activities such as site visits, and tours. ■ Broader relationship agreement discussions with CNL
Meetings and Workshops *(Learning, dialogue and engagement)*	■ Virtual and/or in-person meetings/workshops ■ Community meetings/open houses ■ Presentations ■ Targeted community initiatives (e.g., environmental monitoring and youth event) ■ Technical meetings to provide an opportunity to discuss more detailed information concerning the Project ■ WL site visits, including WR-1 Building tours ■ Benchmarking trip to a site that underwent a similar disposal technique
Communications Activities and Information Sharing	■ Letters to First Nations, and the Red River Métis (through the MMF), and/or organization representatives (accompanied by follow-up calls) ■ Email correspondence and/or phone ■ Distributing the IER for review prior to submission ■ Distribution of specific sections of the EIS for review ■ Distributing copies of maps, technical studies or reports upon request ■ Invitations to attend informational webinars ■ Distribution of community newsletter on the Project ■ Project notifications and newspaper advertisements ■ Public information sessions, including display materials and handouts ■ Media notifications/releases ■ Webpage content ■ Presentations on environmental monitoring on site ■ Indigenous Ceremony on site
Site Visits	■ Facilitation of visits to the WL site for a variety of activities/purposes including: ▪ Meetings and tours ▪ Indigenous ceremony onsite ▪ Involvement in monitoring activities independently through the Niigan Aki program Niigan Aki program and/or in collaboration with CNL's Environmental Protection team

4.2.4 Summary of Engagement

This section provides a summary of engagement that CNL has undertaken with each Indigenous Nation. The engagement activities captured in this section cover engagements as of July 31, 2024. For each Indigenous Nation, the following subsections are discussed:

- **Engagement.** This subsection summarizes the engagement CNL has had with the First Nation and the MMF or organization.
- **Interests and Concerns.** This subsection addresses each of the interests/concerns identified under feedback. CNL has also provided a narrative discussion that describes:
  - CNL's understanding of the interest or concern raised, a summary of CNL's response to the interest/concern and discussions on the topic;
  - where CNL has verified or has attempted to verify, with the First Nations and the MMF that their interest/concern has been addressed; and
  - where CNL is as of July 31, 2024, with each First Nation, the MMF or organization and how CNL plans to address outstanding interests and concerns (i.e., next steps), including identification of commitments.

    Supporting this narrative section, CNL has also included within Appendix 4.0-1 the Tables of Interests. The Tables of Interests describe how CNL is addressing the interest/concern (Column 3) and impacts on the EIS (Column 4).
- **Verification.** The purpose of the verification section is to describe the steps taken to confirm CNL has correctly understood the Indigenous Nation's interest and concern. The purpose of the verification process at this stage is to confirm that CNL has documented all the interests and concerns, VC, information provided by the Indigenous Nation, and that the Nation's position is correctly described and captured in the revised EIS and supporting documents. CNL has worked and is continuing to work, with the First Nations and the MMF to verify that their interests and concerns have been addressed. This work will continue after the submission of the revised EIS. Verification means that CNL has received verbal or written confirmation from the First Nation, MMF or organization, that how CNL has addressed or responded to the Indigenous Nation's or organization's interests or concerns have either been accepted or in cases where CNL is unable to fully address interests or concerns, this is understood and acknowledged by the First Nation, the MMF or organization. Based on the CNSC's guidance, as well as practices commonly employed in EIS work by other proponents, verification includes:
  - Consolidating all interests and/or concerns raised to confirm accuracy in reporting and tracking. Where applicable this has been done through sharing a summary of interests and concerns with each First Nation, the MMF or organization.
  - Providing a summary of how interests or concerns has led to a change in this EIS and providing an opportunity to review the consolidated material in the context of the EIS. Specific sections of the EIS where Traditional Knowledge was incorporated or where changes occurred due to a particular interest and/or concern were provided to each Indigenous Nation for their review and feedback.
  - Responding to all comments on the 2017 draft EIS, 2020 draft EIS and/or the 2022 draft EIS and sharing responses to the respective First Nation, the MMF or organization. In some cases, the interest/concern

raised has been resolved. However, there are also other issues where there may be a difference in opinion and the First Nation, the MMF or organization may have not confirmed that the response by CNL is deemed acceptable. In this case, the acceptable verification is an acknowledgement and understanding of the differing positions of CNL and the First Nation, the MMF or organization.

- Where direct submissions or comments from specific First Nations, the MMF, and organizations were received, including targeted technical comments on the 2017 draft EIS and comments on the 2022 revised draft EIS, CNL has provided written responses to the First Nations, the MMF, and organizations indicating where changes have been incorporated in this EIS.
- CNL requested feedback from all identified First Nations, the MMF, and organizations on assumptions CNL had made in this EIS with respect to traditional land use around the WL site. CNL has incorporated information from traditional land use and knowledge studies that have been completed by the Sagkeeng, the MMF, Black River First Nation, Brokenhead Ojibway Nation, Hollow Water First Nation, and Wabaseemoong Independent Nations and has asked these Indigenous Nations for verification that the studies were reflected accurately in this EIS.
- CNL provided the tables of interests and concerns to all First Nations and the MMF that have voiced interests and concerns related to the Project and requested feedback (1) that CNL had captured accurately the interests and concerns; and (2) where possible, verification that the Indigenous Nation or organization was satisfied with how the interests or concerns have been addressed by CNL. CNL incorporated proposed changes that were recommended by the First Nations and the MMF to the table of interests and concerns.
- CNL consolidated issues and concerns and identified appropriate next steps in the context of and beyond the EIS that have been verified (or every attempt made to verify) with the Indigenous Nations and filed as commitments lists.

- **Next Steps.** This subsection describes the key next steps for engagement both from a relationship building and EA perspective. It also discusses how CNL plans to address outstanding issues of concern and interest. CNL is aware that not all issues can be quickly or easily resolved as some issues go beyond the scope of the Project or there remain a difference of opinion on certain issues. CNL will continue to listen, respond to, and, where possible, address all issues raised.

CNL has developed a system to gather, document, and verify information in this EIS for the MMF and each First Nation. In general, CNL followed the below process:

Process Step #1 – Receive feedback identifying particular interests or concerns from a First Nation, MMF, or organization through one or more of the following sources:

- Ongoing engagement and information sharing with the First Nations and the MMF;
- Comments on the 2016 Project Description or any draft revision of the EIS;
- Traditional Knowledge and Land Use Studies (Sagkeeng, the Red River Métis, Black River First Nation, Brokenhead Ojibway Nation, Hollow Water First Nation, and Wabaseemoong Independent Nations); and

- Additional studies completed concerning the Project (i.e., Sagkeeng First Nation's Psychosocial Impact Assessment [Narratives 2020] and Alternative Means Assessment [Sagkeeng and Firelight 2020]; and two harvester consumption surveys).

Process Step #2 – Shared this EIS (directing to applicable sections informed by Indigenous engagement), asked for additional feedback, offered support to assist the process, and offered to meet to discuss how Indigenous interests and concerns have been incorporated:

a) If the offer to meet with CNL was accepted, where applicable, CNL completed one or more of the following: targeted engagement on a particular interest or concern, shared draft responses to comments provided, supported additional studies, incorporated additional feedback, and supported further participation in the EA process.

b) If CNL did not receive a response from the Indigenous Nation or the offer for further discussions on a topic or interest was declined, CNL shared draft responses to comments on this EIS or specific topic of interest and outlined future opportunities to engage should the community like to re-engage in the future.

Process Step #3 – Acknowledgement that CNL had adequately documented the Indigenous Nation's position, interest, or concern. Where applicable, CNL incorporates any additional feedback from the Indigenous Nation by revising responses and/or EIS documentation. Where applicable, CNL provides a rationale for any feedback CNL could not incorporate.

Process Step #4 – Shared each finalized summary of interests and concerns and verification status (as understood by CNL) for confirmation by each First Nation, MMF, or organization to confirm whether CNL had adequately captured their interest or concern:

a) The First Nation, the MMF, or organization responds and confirms that the summary was a sufficient representation of their interests and concerns and wished to further discuss how interests and concerns have been incorporated, and/or clarified/revised summary of interests and concerns. Alternatively, acknowledgement and understanding that CNL has not adequately addressed an interest/concern and an agreement on the difference of opinion.

b) If no response or no confirmation of summary of interests and concerns was received, CNL offered further discussion on how to revise summary of interests and concerns with First Nation, the MMF or organization.

Process Step #5 – Finalized the draft EIS.

One of the key outcomes of the engagement verification process is the development of tables that summarize interests and concerns for each Nation. These tables of interests and concerns identify the specific comments that have been formally submitted as part of the engagement process or identify the concerns and comments that have been raised orally or in direct submissions to CNL. These tables are dynamic and continue to reflect the latest identification of interests, concerns and their status. These tables identify CNL's response to the feedback and document next steps. CNL continues to engage with each Indigenous Nation and is working to develop commitments to address concerns. The tables are located in Appendix 4.0-1. Appendix 4.0-1 also provides a list of engagements and identifies engagements relevant to the EIS.

In addition to the summary of engagement for each Indigenous Nation in the sections below, Section 4.3 provides an overview of how Traditional Knowledge has influenced the EA, and Section 4.4 provides a specific list of all the changes to the EIS based on feedback from First Nations and the MMF.

4.2.4.1 Sagkeeng First Nation

is an Anishinaabe First Nation, with traditional territory that extends across the lands and waters which make up Treaties 1, 3, and 5. Sagkeeng's residential reserve is located on both shores of the Winnipeg River, where it meets Lake Winnipeg, which is where the Nation's name comes from: Sagkeeng means "mouth of the river." Sagkeeng's reserve is directly downstream of WL. Sagkeeng has an existing relationship with CNL and has expressed Treaty Rights, Title, and interests in the WL site.

The WL site is located within Sagkeeng's traditional territory, to which Sagkeeng claims unsurrendered Indigenous title. The community articulated to CNL that Sagkeeng's members have been impacted by the WL site since it opened. Located on the WL site, the Project is therefore within Sagkeeng's traditional territory. A map of Sagkeeng First Nation's location in relation to the Project is provided in the IER Appendices (CNL 2024).

Sagkeeng occupies one area of reserve lands: Fort Alexander 3 Reserve No. 06362. The Reserve is situated approximately 52 km north of the WL site, at the southeastern tip of Lake Winnipeg, and along the shores of the Winnipeg River. The reserve covers an area of 8,771.3 ha. Sagkeeng has a total registered population of 8,037 (as of September 2019). Roughly 56 per cent of the registered population resides on off-reserve lands (4,471; INAC 2019a).

Since 2016 when CNL started engaging with Sagkeeng on the proposed Project, Sagkeeng's position has remained that complete removal and remediation of WR-1 and associated waste should be selected as the decommissioning method for WR-1.

In 2020, Sagkeeng undertook an independent Alternative Means Assessment, which assessed and measured the alternatives for decommissioning the WR-1 based on Sagkeeng values. The Sagkeeng assessment found the current in situ disposal approach ranked lower than other approaches, supporting Sagkeeng's position that all waste should be removed from the WL site.

Throughout the EA process, CNL has engaged Sagkeeng to share information and build awareness about the proposed in situ disposal of WR-1, and understand Sagkeeng's Aboriginal and Treaty Rights and main concerns and interests regarding the Project to determine how CNL and Sagkeeng can work collaboratively to address Sagkeeng's concerns. A main component of this engagement is to identify Sagkeeng's concerns and potential impacts from the Project on their Treaty Rights and identify ways to help address the community's concerns. Sagkeeng has asserted their Aboriginal and Treaty Rights based on the location of the Project in their traditional territory, to which they claim unceded Aboriginal Title, where their members use the land around the site for hunting, fishing, and other cultural purposes, have used it in the past, and desire to use it in the future provided the environmental conditions are appropriate for meaningful practice of Sagkeeng's Treaty Rights.

Over time, CNL has increased and strengthened engagement with Sagkeeng on the Project to better understand Sagkeeng's concerns, potential impacts, collaborate on ways to help address these concerns, and to build a lasting working relationship. CNL continues to learn and adapt its approaches based on feedback and direction from the community. Since 2021, CNL has worked closely with AECL and has shifted towards a relationship-based engagement approach to support addressing Sagkeeng's concerns related to the Project, the Whiteshell Laboratories Restoration Project, and the historical siting and operations of the WL site.

CNL, AECL, and Sagkeeng have established a technical working group table to identify, develop, and implement initiatives that will help to address Sagkeeng's interests and concerns related to the WL site. From this working group, Sagkeeng, CNL, and AECL have signed an agreement to support an independent Sagkeeng Community Environmental Monitoring Program (this program is called Niigan Aki, meaning "Land First"). Sagkeeng, CNL, and AECL have also established a community liaison committee to enhance community engagement, build trust, and strengthen relationship-building.

Ongoing discussions with Sagkeeng will include participation and input into CNL's Environmental Monitoring Program, economic development and procurement opportunities, future land use including closure and end state planning, the development of a Sagkeeng-led risk communication program, a relationship agreement and other areas of collaboration and interest to the community. Sagkeeng has expressed its interest in continuing to develop the relationship along these terms, and has emphasized that for engagement to be meaningful, it must be ongoing and beyond the scope of the Project. CNL understands and appreciates Sagkeeng's desire for engagement to be sustained and substantive. To this end, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship. Sagkeeng, CNL and AECL continue to work closely through the technical working group table to strengthen their relationship and implement existing initiatives to help address Sagkeeng's concerns.

It is important to note that while CNL calls this a verification process. Sagkeeng does not view it has verification process when not all revisions and recommendations from Sagkeeng have been adopted into the content. CNL strove to represent the feedback from Sagkeeng as accurately as possible however Sagkeeng has been clear that this feedback, even when incorporated, should not be taken as an endorsement of the EIS or IER or the Project more broadly. Sagkeeng intends to review and comment on the whole EIS, including on the adequacy of incorporation of Sagkeeng inputs, when it comes out formally, and report Sagkeeng's findings to the Federal Provincial Indigenous Review Team.

4.2.4.1.1 Engagement

In relation to the Project, engagement began in April 2016, when CNSC initiated a teleconference with Sagkeeng, CNL, and AECL to discuss the proposed decommissioning of WR-1. In May of that year, CNL and Sagkeeng had an introductory meeting to discuss the preliminary concerns of Sagkeeng and how they would like to be engaged moving forward. In August 2016, CNL sent out formal letters to identified First Nations and the MMF requesting their input on the proposed Project.

In 2017, CNL continued to engage with Sagkeeng, meeting with community representatives in January to present an overview of the Project, as well as hosting a Sagkeeng First Nation Open House on January 25, 2017, featuring overview information on the Project, which three Sagkeeng representatives attended. In May, CSNC led a meeting with Sagkeeng, Wabaseemoong Independent Nations, CNL, and AECL, to discuss engagement and to present on CNSC's role as regulator and the Project. Later in July, Sagkeeng's Chief and Council and summer students from Sagkeeng participated in a WL site tour followed by a dialogue on WL site activities. This included presentations and opportunity for discussion on the Environmental Protection Program at the WL site, an overview of Radiation Protection, as well as a bus tour of the site, including the Waste Management Area WMA).

In September 2017, CNL provided an opportunity for five members from each First Nation community and the MMF to attend a full day workshop to both learn and share on how CNL and First Nations and the MMF collectively protect and care for the environment. The goal was to provide some hands-on experience coupled with ample discussion, learning, and dialogue on opportunities moving forward both as a career option and as a relationship between the site and the First Nations and the MMF. On October 31, 2017, CNL shared the Annual Safety Reports

with each Indigenous Nation including, the Environmental Monitoring in 2016 at Whiteshell Laboratories report (CNL 2017a), and the 2016 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories (CNL 2017b). CNL also provided an invitation to engage on these documents. In November 2017, CNL mailed hard copies of community specific reports along with the draft EIS Executive Summary and had a teleconference with Sagkeeng representatives to discuss how to move forward with the community.

On January 3, 2018, CNL and Sagkeeng signed a Memorandum of Understanding (MOU) and entered into a participation funding agreement in support of Sagkeeng conducting a Traditional Knowledge Land Use Study (TKLUS). The agreement also was supportive of Sagkeeng's review and community engagement on the environmental assessment for the Project. As outlined in the MOU, CNL also committed to continuing to work with Sagkeeng in the development of a Contribution Agreement. In early 2018, Sagkeeng's Chief and Council, other Sagkeeng representatives, CNL, and the CNSC met to discuss Sagkeeng's comments on the draft EIS and requests for additional engagement on the Alternative Means Assessment, concerns about existing and potential Project Case psychosocial impacts, and other key issues.

In April, 2018, CNL supported representatives from all participating First Nations, including Sagkeeng, and the MMF, to participate in a benchmarking trip to Hallam, Nebraska, the site of a reactor that underwent ISD in 1969. The trip was intended to provide First Nations and the MMF with additional information on ISD and provide them with the opportunity to see what a site could look like after in situ disposal. Sagkeeng members were invited but could not attend; Sagkeeng's consultant attended the trip and reported back to the community.

In August 2018, CNL met with Sagkeeng to discuss Sagkeeng's TKLUS (Sagkeeng and Firelight 2020) and also invited Chief Henderson to dine with CNL's Board of Directors. In the fall of 2018, CNL met with Sagkeeng to discuss their comments on the 2017 draft EIS. Following this, CNL had a subsequent meeting with Sagkeeng to discuss action items. CNL also partnered with Sagkeeng to conduct a food consumption survey of their members. The results of the survey were compiled in a summary memo that was shared with Sagkeeng in November 2018. The survey helped validate the assumptions for the Harvester receptor modelled in the human health risk assessment (Section 6.7 Human and Ecological Health).

In response to concerns expressed by Sagkeeng on the draft EIS Alternative Means, CNL and Sagkeeng met in January 2019 for two preparatory meetings for a three-day Alternative Means Workshop planned for February. In February, CNL and Sagkeeng met to conduct the Alternative Means Workshop where Sagkeeng was to present their community perspectives on the Project and alternatives considered. CNSC and AECL participated as observers at this workshop; however, due to poor weather, CNSC participated by teleconference. The workshop's purpose was to provide an opportunity for Sagkeeng to present their community values and preferred weighting of criteria with respect to the Project alternatives, and for CNL to present the proponent's four assessed alternatives and associated weighting and assessment. The workshop was also an opportunity for parties to openly share their thoughts and seek a path forward. Day one started with a cultural water ceremony and traditional drum following which both CNL and Sagkeeng's consultant presented on their respective Alternative Means Assessment and weighting criteria. After lunch on day two, Chief Henderson informed participants that there would be a change in the agenda. Sagkeeng ended the workshop, citing the need to take a cultural pause, and invited all the participants to attend a ceremony at Turtle Lodge prior to continuing this discussion. An Elder also addressed the participants at the workshop before it ended and spoke to the importance of ceremony to help guide the process.

As requested, CNL, AECL, CNSC, and Sagkeeng convened in March 2019 at Turtle Lodge, an internationally recognized Indigenous education and wellness center, located in Sagkeeng, for a ceremony. Turtle Lodge also provided a presentation on radioactive waste issues to the participants. CNL also hosted Turtle Lodge on site in July 2019 for a tour of the WL sire to discuss Project updates, and plan for a ceremony on the WL site.

CNL provided a Project update to Sagkeeng and the CNSC in September 2019 and hosted a ceremony on the WL site. The ceremony was an opportunity to reconnect with the land and to conduct ceremony of importance to Sagkeeng. A sacred fire was lit on the WL site. The ceremony included Chief Henderson, Sagkeeng Councillors, Elders from Sagkeeng and other invited First Nations. A traditional drum group performed, and water and smudging ceremonies were conducted. CNL staff participated and observed the ceremony, providing an important opportunity for growth and cultural learning. Representatives from the CNSC and AECL participated in the day's events. CNL continued to engage with Sagkeeng by participating in a meeting in September 2019 where CNL provided an overview of WL's licencing renewal, the Project, and radiation protection.

On December 11, 2019, CNL and Sagkeeng met in Winnipeg to discuss feedback Sagkeeng provided through the site licence intervention, in-person meetings, email, and submitted comments on the draft EIS. In addition, this meeting was to explore what the possibility of a long-term relationship agreement could look like as well as discuss establishing an Indigenous Advisory Committee, and other areas of interests (e.g., environmental monitoring and end state planning). The purpose was to develop concrete actions to address items of interest to both Sagkeeng and CNL and continue to grow their relationship. Sagkeeng's Chief and full Council attended the meeting. Key topics that were discussed included the EIS, Indigenous Advisory Committee, Indigenous Liaison position, environmental monitoring, capacity building, end state engagement, and asset donations. Several action items were identified and continue to be reviewed and updated by Sagkeeng and CNL.

In February 2020, CNL received a letter from Sagkeeng regarding their position on the Alternative Means Assessment and providing Sagkeeng's opinion on the adequacy of the revised draft EIS and identifying specific opportunities in the EIS for improvements. In the letter, Sagkeeng clearly stated that:

- Sagkeeng's position remains that the assessment of alternatives has not been adequately completed since it did not incorporate Sagkeeng's specific views and community values; and
- Sagkeeng is opposed to leaving the WR-1's radioactive materials in the ground and focused on finding the most preferred alternative that can be consented to by Sagkeeng.

The letter also clarified Sagkeeng's position: *"It remains Sagkeeng's position that all radioactive materials should be removed from WR-1, as committed to under the [2002 Comprehensive Study Report]. Unless and until the Proponent is able to demonstrate that ISD is objectively better than the 'full removal' option, including when examined against Sagkeeng's priorities and criteria provided…"*

Accompanying the letter was a comment table, in which Sagkeeng raised specific concerns and asked specific questions about the EIS, along with a number of other supporting technical documents, reflecting Sagkeeng's position on the then-draft EIS. In reply to the email accompanying that letter, CNL requested a meeting with the Sagkeeng consultation team on February 19, 2020.

In March 2020, CNL and Sagkeeng met to discuss the February letter from Chief Henderson. CNL had also intended to discuss the long-term relationship agreement. However, CNL and Sagkeeng did not align on the purpose of the meeting and this matter was postponed. CNL responded to the questions during the meeting and also provided detailed responses in a letter to Sagkeeng the following month.

In response to the numerous discussions with Sagkeeng regarding the Alternative Means Assessment, CNL and Sagkeeng signed an MOU in June 2020 where CNL supported the completion of Sagkeeng's Independent Alternative Means Assessment that would incorporate Sagkeeng's community values, alternative weight criteria and other key elements. CNL has included details of Sagkeeng's final report in Section 4.2.4.1.3 of the EIS. CNL and Sagkeeng continued to meet monthly from June 2020 to August 2020 to discuss topics of interest to Sagkeeng, including the Project, environmental monitoring, an Indigenous Liaison position, and the long-term relationship agreement.

In September 2020, Sagkeeng and CNL signed another MOU to fund a Sagkeeng Community Liaison position. CNL provided on-site training to the Liaison and met with Sagkeeng to review and discuss action items. Sagkeeng also participated in a tree survey on the WL site and a workshop to initiate the development of a work plan for Sagkeeng's Liaison. CNL and Sagkeeng's Liaison have been in discussions and are working towards completing a work plan.

On October 19, 2020, CNL received Sagkeeng's Alternative Means Assessment report outlining several tests for a preferred alternative means to decommission WR-1, using criteria and their weights as developed by Sagkeeng. Their alternatives assessment incorporated Sagkeeng's values in five tests and included an additional three independent technical tests and weighting provided by Sagkeeng's technical Consultant. Overall, full removal was preferred for, and ISD preferred against, based on Sagkeeng's Alternative Means Assessment. More information on Sagkeeng's Alternative Means Assessment is provided in Section 4.2.4.1.3.

CNL hosted a multi-community event at the WL site on October 20, 2020. The purpose of the half-day site visit was to discuss CNL's Environmental Protection Program and to observe CNL's fish processing, which is part of CNL's routine Environmental Monitoring Program. Participants included Sagkeeng's Liaison Officer, a representative from MMF, and two representatives from Black River and Hollow Water First Nations. A presentation was provided by CNL's environmental specialist on CNL's environmental protection program. Participants also made a number of recommendations on how to incorporate species of interest to the First Nations and the MMF into CNL's monitoring program. Afterwards, CNL and the participants made their way to the environmental lab where participants observed CNL processing fish they had caught that morning. Participants asked CNL's environmental technicians a number of questions about where the fish were caught and the method for catching them. A workshop report was produced and circulated to participants for review and comment. CNL did not receive any feedback on the report from the participants.

On October 20, 2020, CNL and Sagkeeng also signed an MOU to support Sagkeeng's review of CNL's responses to Sagkeeng's comments on the 2017 and 2020 draft EIS. Later that month, on October 28, CNL received Sagkeeng's Psychosocial Assessment report (Narratives 2020). The report describes the historic and intergenerational trauma that Sagkeeng experienced from a variety of sources including Residential schools, Child and Family Services, the former upstream pulp mill and the WL site, including the Project. The report also described potential psychological, social, and cultural impacts of each alternative means of decommissioning WR-1. It found that Alternative 2 – Immediate Full Removal – is the most psychosocially healthy option. The assessment was conducted to inform CNSC's Indigenous Rights Impact Assessment and the overall environmental assessment. Further information on the study is provided in Section 4.2.4.1.4, Sagkeeng's Psychosocial Impact Assessment. CNL had a brief check-in with Sagkeeng's Liaison Officer on November 2, 2020, and discussed a few potential engagement initiatives. The next step was to seek Chief and Council's direction on these engagement initiatives.

On November 3, 2020, CNL provided Sagkeeng with a briefing note highlighting monthly engagement activities with Sagkeeng. The monthly briefing notes were designed to provide Project and engagement updates to Sagkeeng's Chief and Council. This briefing note highlighted engagement activities that took place in September and October, provided Project updates, as well as a detailed Project timeline.

CNL, the CNSC, and Sagkeeng met on November 12, 2020, to discuss Sagkeeng's Psychosocial Assessment. During the meeting, Sagkeeng and Narratives Inc. presented an overview of their psychosocial assessment and highlighted key findings and recommendations from the report.

CNL received Sagkeeng's feedback on CNL's responses to Sagkeeng's comments on the draft EIS on November 16, 2020. CNL began their review of Sagkeeng's feedback and worked with Sagkeeng to schedule a time to discuss the comments on the EIS. Sagkeeng presented the Alternative Means Assessment on November 19, 2020, to the CNSC and CNL. CNL and Sagkeeng's Liaison Officer met on November 25, 2020, to discuss future engagement initiatives. Meeting notes were provided to Sagkeeng's Liaison Officer.

Later that month, on November 26 and December 1, 2020, Sagkeeng's consultation engagement team met with CNL to review and discuss Sagkeeng's comments on the EIS in order to seek clarification and discuss CNL's proposed next steps for addressing Sagkeeng's comments. AECL and the CNSC were present at both meetings as observers. As part of the evolution and learning from our earlier engagement, CNL and Sagkeeng discussed Sagkeeng's comments on the EIS by theme. Each theme was associated with several comments from Sagkeeng. These themes included: psychosocial effects; seeking consent for in situ disposal; the Alternative Means Assessment and alignment with International Atomic Energy Association (IAEA) guidance; community engagement; considering the Project under the *Impact Assessment Act* (IAA) 2019 versus CEAA 2012; consideration for historical land use and past grievances; and future land use. For each theme, CNL indicated its perspective on what was in scope of the EIS and what was out of scope of the EIS and provided a summary of CNL's understanding of Sagkeeng's concern to verify they understood Sagkeeng's concern correctly. CNL also provided for each theme, a summary of activities CNL has undertaken in an effort to address Sagkeeng's concern and outlined proposed next steps to test with Sagkeeng. During the meetings, Sagkeeng raised concerns about fear and stigma not being considered as a primary pathway in the EIS.

On November 30, 2020, CNL had a teleconference with the CNSC and Sagkeeng's lawyer to discuss Sagkeeng's funding needs going forward to continue with environmental assessment involvement.

On December 22, 2020, CNL sent a letter in response to Sagkeeng's Alternative Means Assessment report and a letter of response to Sagkeeng's Psychosocial Impact Assessment report. These letters propose recommended next steps on how CNL could work to address Sagkeeng's concerns. CNL also requested a meeting with the Chief and Council to better understand their concern and discuss CNL's recommendations.

On January 13, 2021, CNL sent Sagkeeng responses to Sagkeeng's comments on the draft EIS. On January 18, CNL sent a copy of the new sections of the EIS that discussed the considerations given to Sagkeeng's Alternative Means Assessment and psychosocial assessment reports. CNL followed up from the response letters on February 2, 2021.

In February 2021, AECL hosted a leadership teleconference with representatives from Sagkeeng, CNL and the CNSC to discuss the principle of Free, Prior and Informed Consent (FPIC) in relation to the Project. During the meeting, Sagkeeng clearly expressed that according to its Anishinaabe law, and its understanding of international law, its consent is required for the Project to proceed. CNL and AECL acknowledged Sagkeeng's perspective but

disagreed, and indicated their willingness to work collaboratively with Sagkeeng, understanding that while consent is the preferred outcome, the Project will benefit from greater collaboration even where consent is not achieved. CNL and AECL believe that meaningful engagement and participation in decisions that affect Sagkeeng members, their community, and territory is critical to fostering understanding and identifying mutually acceptable opportunities in respect of the Project. The meeting led to further discussions between CNL and Sagkeeng in March 2021 regarding capacity funding to support more direct engagement with Sagkeeng members.

On February 20, 2021, CNL provided Sagkeeng with updated material attempting to integrate Sagkeeng's Alternative Means Assessment write up into Section 2 of the EIS that incorporated Sagkeeng's feedback (see Section 2.8 for more information). On February 26, 2021, CNL shared back the write-up indicating how CNL had incorporated Sagkeeng feedback into the revised copy for their review. This included feedback on the table structure, which CNL incorporated. Where Sagkeeng and CNL had differences of opinion, CNL strove to provide fairness in describing the issues and concerns that Sagkeeng had raised. On the same day, Sagkeeng also provided feedback on the Psychosocial Impact Assessment summary that is in Section 4.2.4.1.4. CNL incorporated Sagkeeng's feedback into the EIS Section 4.2.4.1.4.

In March 2021, CNL met with Sagkeeng's Chief and Council via teleconference to review Sagkeeng's engagement proposal to establish a community Liaison committee made up of select Sagkeeng members to be involved in the environmental assessment process for the Project.

On April 6, 2021, senior leadership from CNL, AECL, and Sagkeeng's Chief and Council met to discuss Sagkeeng's Psychosocial Impact Assessment Report. During the call, CNL offered a sincere apology for its approach and response to the report.

CNL and AECL recognized the findings of Sagkeeng's Psychosocial Impact Assessment Report and the trauma experienced by Sagkeeng members in relation to the historical siting and operations of the WL site. CNL and AECL also recognized Sagkeeng as stewards of the land and waters and committed to working with Sagkeeng to develop and implement recommendations arising from the report and the April 6, 2021, dialogue.

The meeting marked a turning point in CNL's and Sagkeeng's relationship as both CNL and AECL recognized the findings of the Sagkeeng Psychosocial Impact Assessment Report and the trauma experienced by members in relation to the historical siting of the WL site. CNL, AECL, and Sagkeeng's leadership agreed to work collaboratively to develop and implement key initiatives recommended by Sagkeeng to help address the Nation's concerns regarding the Project and the Whiteshell Laboratories Restoration Project. Sagkeeng recommended a Technical Working Group be developed to oversee the development of these initiatives.

Later in the month of April, Sagkeeng's Liaison Officer visited the WL site to pick up new infographics regarding the Project for distribution around Sagkeeng's community. During the site visit, Sagkeeng's Liaison's Officer also participated in a refresher course on the Project. The infographics were distributed in central locations in Sagkeeng. On April 20, 2021, CNL invited Sagkeeng to participate in a Project information webinar focused on the protection of the environment before, during, and after the Project.

In June 2021, Sagkeeng's consultation team and representatives from CNL and AECL participated in the first Technical Working Group meeting. The purpose of the Technical Working Group is to identify, develop, and implement initiatives that will help to address Sagkeeng's interests and concerns in a way that is meaningful to Sagkeeng. Four initiatives were identified including:

1. Establishing a community liaison committee.
2. Developing a healing and resiliency action plan to address recommendations in Sagkeeng's Psychosocial Impact Assessment Report.
3. Developing an Indigenous-led CEMP.
4. Coordinating a formal leadership table between Sagkeeng, AECL, and CNL.

Through the Technical Working Group, Sagkeeng, CNL, and AECL drafted a Contribution Agreement to support the development of these initiatives. CNL and Sagkeeng also developed a subcommittee to work together to review and update EIS-related documents to accurately reflect Sagkeeng's position, interests, and concerns.

On June 24, 2021, CNL provided Sagkeeng with a summary table of CNL's interpretation of Sagkeeng's interests and concerns and a list of the community's VCs that may be subject to effects from the Project. On July 14, 2021, Sagkeeng provided feedback on the list of VCs and on July 16, 2021 Sagkeeng provided feedback on the summary of interest and concerns table. After CNL sent Sagkeeng a revised table which incorporated their feedback, Sagkeeng provided additional feedback on July 26, 2021, on the summary of interests and concerns table. CNL met with Sagkeeng on July 28, 2021, to review their summary of interest and concerns table and list of VCs. CNL incorporated Sagkeeng's feedback and sent the updated summary of interests and concerns table, the updated VC table and resent the Psychosocial Impact Assessment write-up for the EIS to reflect sentiments shared at the leadership meeting discussion. Specifically, CNL recognizes that Sagkeeng has experienced a great deal of trauma and that the alienation between Sagkeeng and their traditional territory caused by the siting of the WL site and subsequent lack of engagement through the operations of the site has contributed to that trauma. Sagkeeng provided feedback on all three documents on August 23, 2021.

On the same day, Sagkeeng also provided substantial feedback on Section 2.0. After receiving this information, CNL and Sagkeeng met via teleconference on August 24, and September 7, 2021, to discuss Sagkeeng's comments on the reviewed EIS documentation. On August 31, 2021, CNL provided Sagkeeng with a marked-up copy of Section 2.0, at Sagkeeng's request. The first review meeting, on August 24, 2021, focused on discussing Sagkeeng's feedback on the Summary of Interests and Concerns table and the list of Sagkeeng's VCs. During the meeting, CNL demonstrated to Sagkeeng that CNL had incorporated Sagkeeng's recommended changes to the list of VCs. Sagkeeng did not have any additional edits to make on the list of VCs. Sagkeeng also recommended the VCs list be a topic of discussion with their Community Liaison Committee (CLC) once established. CNL committed to engage with the CLC on Sagkeeng's list of related species and topics of interests. Any revisions to this table will be reported in future updates of the IER for the public record. The second meeting, on September 7, 2021, focused on discussing Sagkeeng's feedback on the Psychosocial Impact Assessment Write-up and general feedback on Section 2.0.

On September 14, 2021, Sagkeeng's Consultation Team and representatives from AECL and CNL held a Technical Working Group meeting to establish next steps to develop the priority initiatives to help address Sagkeeng's concerns on the Project. These initiatives include a healing and resiliency action plan, a community liaison committee, and an Indigenous-led CEMP that includes country foods monitoring and connects with the development of a community-led risk communications program.

On September 20, 2021, following the discussion with Sagkeeng's consultation team on the EIS sections, CNL provided an updated copy of the summary of interests and concerns table and Psychosocial Impact Assessment write-up that reflected Sagkeeng's additional feedback from the meetings on August 24 and September 7, 2021.

As a precursor to developing a healing and resiliency action plan , CNL, AECL, a representative from the CNSC, and Sagkeeng's Liaison Officer participated in a two-day trauma-informed engagement training session on September 22 and September 23, 2021. The training was hosted by Narratives Inc., the author of Sagkeeng's Psychosocial Impact Assessment Report, and took place in Winnipeg. The training in trauma-informed principles and methods of engagement included overview of the types of trauma(s). This included an understanding of the types of traumas, the symptoms of trauma, the impacts of trauma, the relationship between trauma and neurobiology, and responding to expressions of trauma. The training also highlighted the importance of being trauma-informed as well as trauma-informed principles, tools, and strategies. The training was customized to the unique needs of CNL, AECL, the CNSC, and Sagkeeng. By taking this training, CNL, AECL, and CNSC attendees broadened their lens of what trauma means, gained a deeper understanding of the prevalence of trauma and its impact on Indigenous Nations, as well as understanding the importance of being trauma-informed and its relevance in organizational policies and procedures. Eleven participants from CNL, four participants from AECL, one participant from the CNSC, and Sagkeeng's Liaison officer participated in the training. Participants included senior site officials, engagement and communication officers, managers, and directors.

Afterwards, CNL hosted a debrief (November 1, 2021) on the trauma-informed engagement training with Sagkeeng, and the trainer and principle from Narratives Inc. After Narratives Inc. provided an overview of the training, CNL and Sagkeeng discussed how to use these teachings to help develop a healing and resiliency action plan.

On September 29, 2021, Sagkeeng recommended, via email, that CNL proceed with submitting the revised draft EIS with the most current version of the summary of interests and concerns table with the caveat that CNL confirm that Sagkeeng's feedback on the most recent version of the table had been incorporated. On October 6, 2021, CNL sent final copies for the summary of interest and concerns table and the list of VCs to Sagkeeng's leadership for their information and thanked Sagkeeng for their participation in ensuring CNL was accurately documenting Sagkeeng's interest and concerns and list of VCs.

Through the months of October through December, CNL continued to verify information in the EIS related to Sagkeeng was adequately documented and a path forward is clearly defined. On October 13, 2021, Sagkeeng's consultation team confirmed that the latest version of CNL's write-up of Sagkeeng's Psychosocial Impact Assessment adequately captured Sagkeeng's position to the extent possible at this time. Sagkeeng confirmed that their findings and suggestions were incorporated. On the same day, CNL provided Sagkeeng with a final version of EIS Section 11.0 for their review. Sagkeeng provided their feedback on Section 6.7 and Section 11.0 on November 1, 2021.

General engagement and outreach activities continued with Sagkeeng. On October 14, 2021, CNL provided Sagkeeng's Liaison Officer with a copy of a Sagkeeng's fall engagement newsletter for review prior to sending it to Sagkeeng leadership. In addition, CNL provided Sagkeeng with a revised version of EIS Section 6.7 for review and verification that CNL had adequately incorporated Sagkeeng's interests and concerns related to environmental and human health. Sagkeeng flagged a number of outstanding gaps within EIS Section 6.7, these gaps include:

- insufficient consideration of the holistic impacts on health beyond physical health, in particular, Sagkeeng suggested renaming the section to "Physical Human and Ecological Health";
- use of damaged baseline;
- lack of consideration of past impacts from the WL site; and
- need for consideration and incorporation of the following:
  - Psychosocial Impact Assessment (2020);
  - Sagkeeng Anicinabe Land Use and Occupancy Study (February 2019); and
  - Sagkeeng Anicinabe Alternative Means Assessment (October 2020).

During this time, CNL, AECL, and Sagkeeng began discussing and developing a Technical Working Group; a mechanism where the parties can discuss and resolve issues of mutual interest and concern. On October 20, 2021, CNL provided Sagkeeng with a copy of the Contribution Agreement that was developed to support the Technical Working Group, for their review and feedback. CNL also sent Sagkeeng's leadership a fall engagement update newsletter on October 20, 2021.

On November 3, 2021, CNL provided Sagkeeng with a copy of the revised Section 2.0 to show how CNL had incorporated Sagkeeng's feedback. Where integration was not possible, CNL provided a detailed explanation for why CNL was not able to incorporate Sagkeeng's comment. On November 4, 2021, CNL received confirmation from Sagkeeng to proceed with incorporating Section 2.0 into CNL's submission package. At this time, Sagkeeng had not endorsed the draft EIS and had indicated that Sagkeeng would review and comment on the whole refiled EIS, including on the adequacy of incorporation of Sagkeeng inputs, when it comes out formally, and report Sagkeeng's findings to the Federal Provincial Indigenous Review Team.

Since then, Sagkeeng has provided feedback on sections of the draft EIS, including those related to Indigenous Engagement, Alternatives Means, Land and Resource Use and Human and Ecological Health. CNL has incorporated feedback as possible and shared sections back for Sagkeeng's feedback. A meeting of the Technical Working Group was convened on Nov 10, 2021 and the focus was on environmental monitoring with the intention of better understanding how a Sagkeeng-led community environmental monitoring program could be facilitated in and around the WL site. CNL delivered a presentation on the site's environmental protection program and Sagkeeng delivered a presentation on the proposed Guardian Program.

The EIS review continued through this period. On November 15, 2021, Sagkeeng and CNL met with the EIS subcommittee of the Technical Working Group to discuss Sagkeeng's comments on Section 6.7 and Section 11.0. On November 18, 2021, CNL asked Sagkeeng to review Section 6.8 to make sure that CNL had documented Sagkeeng's information correctly. CNL sent Section 4.0 on November 26, 2021 and requested that Sagkeeng review to confirm CNL had documented Sagkeeng's interests and concerns correctly. CNL provided Sagkeeng

with Section 6.9 on November 30, 2021 and requested Sagkeeng review to confirm CNL had documented Sagkeeng's information correctly.

On November 30, 2021, CNL, AECL, and Sagkeeng signed an MOU, which supported the development of a liaison committee, the development of scopes of work for a community environmental monitoring program, a healing and resiliency action plan, and a leadership table.

December focused on receipt of EIS feedback and further discussion and exploration of an independent Sagkeeng Guardianship Program. On December 8, 2021, Sagkeeng provided feedback on Section 6.8 and on December 14, 2021, CNL received feedback from Sagkeeng on Section 6.9. On December 15, 2021, Sagkeeng presented on Indigenous-led community environmental monitoring programs and how CNL and Sagkeeng could incorporate similar elements into monitoring at the WL site.

A teleconference was held by CNL on January 5, 2022, to go over Sagkeeng's comments on Section 4.0 and to confirm that the list of interests and concerns was complete. On January 31, 2022, CNL sent Sagkeeng a revised copy of Section 4.0 and Section 6.7. Both copies were provided in track changes with detailed responses to each of Sagkeeng's comments.

On February 2, 2022, CNL sent an Indigenous Advisory Committee terms of reference to Sagkeeng's consultation team for their review and input. On that same day, Sagkeeng provided CNL with drafts of Sagkeeng's independent CEMP scope of work and their healing and resiliency action plan. The development of the CEMP would become a priority for CNL and Sagkeeng for coming months. On February 22, 2022, the Technical Working Group discussed Sagkeeng's scope of work for a CEMP and on March 2, 2022, Sagkeeng provided an overview of the healing and resiliency action plan. On March 3, 2022, CNL and AECL provided Sagkeeng with written feedback on the CEMP scope of work.

On March 9, 2022, CNL, AECL, and Sagkeeng held further discussions on Sagkeeng's scope of work for the CEMP. CNL and AECL provided Sagkeeng with formal written feedback on the scope of the CEMP on March 15, 2022. Meanwhile, on March 22, 2022, two CNL representatives met with Sagkeeng's community liaison committee to get to know each other and learn a bit more about the Project.

The period of April, May, and June 2022 focused on EIS updates to the interests and concerns tables and further understanding and development of the Sagkeeng's independent CEMP. On April 6, 2022, CNL and Sagkeeng discussed Sagkeeng's scope for the CEMP and repackaging of Sagkeeng's interest and concerns table. On April 11, 2022, CNL sent Sagkeeng their repackaged interests and concerns table for review. On May 10, 2022, CNL and Sagkeeng went through Sagkeeng's revised interest and concerns table and discussed an upcoming in-person workshop on the CEMP. On May 20, 2022, CNL and Sagkeeng met to discuss the coordination of the workshop. On June 9, 2022, CNL and Sagkeeng discussed the interest and concerns table as well as the agenda for workshop. On June 13, 2022, CNL asked Sagkeeng to confirm that they had reviewed and confirmed accurate representation of their interest and concerns table.

The efforts to develop a collaborative CEMP were further explored in a workshop held on June 15 and 16, 2022, in Winnipeg. CNL and Sagkeeng representatives met in-person to negotiate an agreement that would increase Sagkeeng's role (and the role of Anicinabe Traditional Knowledge) in the monitoring of the WL site and surrounding areas, supporting the reduction of fear and stigma at and around the site. The two-day meeting culminated with an agreement in principle to support the development and execution of an independent CEMP over the next five years. The parties determined that they would implement workshop action items and reconvene the Technical

Working Group in the fall. On June 16, 2022, Sagkeeng confirmed during the workshop, that the 2022 interests and concerns table reflected the community's interest and concerns, as well as the status of those concerns.

On July 11, 2022, CNL provided a draft copy of the Contribution Agreement for the Sagkeeng-led CEMP and Sagkeeng's lawyers, provided a revised copy of the draft Contribution Agreement for CNL and AECL's review. On July 19, 2022, CNL continued to develop their relationship with Sagkeeng's Community Liaison Committee by hosting an on-site tour of the WRDF and the WL site, lunch, and a general discussion. CNL followed up with material requested by the Committee. Subsequently, the parties continue to refine the Contribution Agreement for the Sagkeeng CEMP.

In August and early September, CNL held teleconferences with Sagkeeng to discuss the renewal of the Technical Working Group budget and develop a path forward for invoicing. On August 20, 2022, Sagkeeng asked CNL if they would have any objections to Sagkeeng communicating to community members that an agreement in principle has been reached on the Sagkeeng -led CEMP. CNL responded that day, supporting sharing this news with the community. On August 25, CNL met with Sagkeeng representatives to discuss Sagkeeng's revised Technical Working Group budget and specifically the Line Item 9 the Negotiation of a healing and resiliency action plan. At that time CNL expressed an interest to defer discussions until it was better understood and instead, focus efforts on the CEMP. Sagkeeng representatives indicated that the development of the CEMP was a community priority. The parties agreed to discuss the earlier provided healing and resiliency action plan with at an upcoming Technical Working Group meeting. CNL sent a copy of CNL's Environmental Monitoring Program schedule on August 30, 2022, and requested Sagkeeng to identify any potential activities they want to participate in.

CNL held teleconferences with Sagkeeng in August and September 2022 to discuss the renewal of the Technical Working Group budget and develop a path forward for invoicing. CNL and Sagkeeng discussed invoicing at the Technical Working Group meeting on September 7, 2022, and agreed that CNL would provide seed funding to support execution of the Contribution Agreements, and that Sagkeeng would invoice subsequently.

September focused on finalizing Sagkeeng's CEMP. On September 6, 2022, CNL sent Sagkeeng the revised Contribution Agreement to support CEMP for their review and feedback. Discussion of the CEMP budget and supporting scope of work document also occurred at the Technical Working Group meeting on September 7, 2022, where clauses of the agreement and funding structure were discussed. On September 13, 2022, CNL transmitted their final comments and changes to Sagkeeng on the scope of work and a Contribution Agreement for Sagkeeng's CEMP. On September 20, 2022, CNL received an email from Sagkeeng indicating their acceptance of CNL tracked changes and providing notification that the document will be forwarded to Chief and Council for execution. At the next monthly meeting in October, Sagkeeng and CNL discussed the CEMP, the Sagkeeng healing and resiliency action plan and the environmental assessment for the Project. Following this meeting CNL shared key sections of from the revised EIS for the Project, as well the updated appendices for Sagkeeng's review and verification on October 21, 2022. On November 15, 2022, Sagkeeng provided their comments on these revised EIS sections. Three days later, on November 18, CNL shared back a copy of the key EIS sections and the appendices with Sagkeeng's edits incorporated where possible.

At November's monthly meeting (November 2), Sagkeeng and CNL discussed the CEMP, land use and end state and the healing and resiliency action plan.

At December's monthly meeting (December 7) Sagkeeng and CNL discussed the CEMP (including a signing ceremony), land use and end state, the healing and resiliency action plan and budget. On December 12, 2022, Sagkeeng's Chief and Council, AECL President and CEO and other staff, and, CNL's President and CEO, as well

as CNL, Indigenous relations and Communications staff all participated in a signing ceremony for the CEMP agreement at Sagkeeng First Nation. On December 16, 2022, CNL emailed Sagkeeng to share that CNL had submitted the updated revised draft EIS and to thank Sagkeeng for providing their edits on the EIS sections to help support this submission.

In mid-January 2023, CNL shared with Sagkeeng that the CNSC had accepted the EIS for technical review (January 16) and provided Sagkeeng with the 2023 Environmental Monitoring Field Sampling Schedule (January 17). Around this time, CNL's Human Resources team coordinated with Sagkeeng to share CNL job postings (January 17, 2023). At the January monthly meeting Sagkeeng and CNL discussed the Federal Indigenous Technical Review Process, Sagkeeng CEMP, Sagkeeng Community Liaison Committee, the healing and resiliency action plan, land use and end state and CNL Procurement. Following this meeting, CNL provided environmental information, including a draft of the Environmental Assessment Follow-up Program (EAFP), which had been amended with Project-specific information in December 2018.

In February 2023, representatives from CNL and Sagkeeng met in South Beach to discuss the GCT #3 Nuclear 101 Guidebook (as an example of an effective method of communications about nuclear), a land use end state work shop being planned for later in the year at CNL's Regional Leaders Gathering and coordination of other engagements. Another key engagement in February 2023 was CNL's participation in the Sagkeeng Community Liaison Committee Gathering and Feast on February 28.

CNL also shared a report with SFN on elevated levels of manganese detected in the outfall on February 17, 2023. In response to this report, Sagkeeng requested further discussion and plain language information on this topic. Elevated levels of manganese were discussed at the next working group meeting and CNL took the action to send a plain language summary, which was shared with Sagkeeng on March 30. In late February, Sagkeeng Elders and Sagkeeng Community members attended the WL site with CNL Communications Officer for a WL site tour.

The March working group meeting was held virtually on March 1, 2023 and important topics of discussion included elevated levels of manganese, land use and end state, and procurement. Towards the end of the month, Sagkeeng and CNL representatives met two more times. On March 23, they met virtually to discuss the Environmental Protection Plan for the WL site and on March 27 the CNL Indigenous Relations Advisor was invited to, and attended, a Pipe Ceremony at Sagkeeng.

The April working group meeting was held on April 5, 2023 and focused on land use end state, CEMP updates, the CLC, CNL's Indigenous Relations Procurement Strategy and the CNSC's Federal Provincial Indigenous Review Team for the Project, the latter of which Sagkeeng would be a participating in. Another important engagement occurred on April 18, 2023, when Sagkeeng community members Sagkeeng Elders, the Sagkeeng community liaison and the Niigan Aki (formerly the CEMP) program manager presented a lunch and learn for CNL staff on Indigenous Knowledge.

In early May 2023, Sagkeeng and CNL exchanged emails following the Whiteshell Safety Stand Down. One outcome of this, was that the Sagkeeng's planned site visit to the WL site was cancelled. Instead, on May 16, 2023, the Sagkeeng CEMP manager and CNL's Indigenous Relations Advisor met in the parking lot at the WL site. Later that month, Sagkeeng and CNL met in community in follow-up to this meeting at the WL site and to discuss having a CNL float for the Sagkeeng Treaty Days Pow Wow. On May 30, 2023, a representative from Sagkeeng attended CNL's Regional Leaders Gathering at the South Beach Casino in Brokenhead Ojibway First Nation.

Discussions at the June 7, 2023, monthly meeting focused on the Project, land use and end state, the healing and resiliency action plan, and updates from the Niigan Aki program. The other key engagements for June 2023 were CNL's participation in two community tree planting events.

On July 5, 2023, the monthly working group meeting included discussions on the Project, CNL's Indigenous Procurement, land use and end state, CEMP updates, an upcoming leadership meeting, and the healing and resiliency action plan. On July 7, 2023, CNL's IR advisor and Sagkeeng's Niigan Aki program member met in community to discuss CNL's participation in Sagkeeng Treaty days. On July 19, 2023, CNL and Sagkeeng met to discuss the CNSC information requests from Sagkeeng's submission on the Project's EIS, as well as how Sagkeeng could be involved in land use end state. In follow-up to this meeting CNL provided Sagkeeng with the information requests. On July 28, 2023, CNL attended the 2023 Sagkeeng First Nation Treaty Days Parade with the Sagkeeng CEMP manager.

August's working group meeting (August 2, 2023) focused on the Information Requests and the Commitments List CNL was proposing to the Sagkeeng for the Project. Representative from Sagkeeng and CNL also discussed land use end state, updates on the CEMP and the planning for the upcoming Sagkeeng-AECL-CNL leadership meeting. On August 9, 2023, Sagkeeng provided their initial comments on CNL's responses to the CNSC Information Requests for the Project. Sagkeeng's CEMP manager, Sagkeeng consultant and CNL also held the Quarterly meeting update between CNL and the Niigan Aki program about the program on August 17, 2023.

August 24, 2023, marked the in-person leadership meeting between the newly elected Sagkeeng Chief and Council and CNL and AECL staff, including the President and CEO of each organization and other members of both organizations' leadership teams. At this meeting, a signing ceremony was held for the most recent contribution agreement between the three parties. This agreement enables engagement on several items of interest of all three parties, including participation in the EA. At the end of the month, the Sagkeeng CEMP manager attended the 5th Canadian Conference on Waste Management, Decommissioning and Environmental Restoration for a panel on Indigenous engagement within the nuclear industry through the lens of the CEMP.

The September working group meeting (September 06, 2023) between Sagkeeng and CNL focused on the information requests and commitments, land use and end state, updates from the CEMP, an upcoming site tour for the Sagkeeng Chief, the community liaison committee and a proposed benchmarking trip related to the Project decommissioning. In mid-September, Sagkeeng and CNL met in Pine Falls to introduce staff.

On October 4, 2023, Sagkeeng and CNL held the monthly working group meeting virtually. Discussions revolved around commitments and information request, a possible benchmarking trip to a Department of Energy site that was decommissioned in-situ, land use and end state and updates from Niigan Aki program. On October 11, 2023, CNL had a tour for the Sagkeeng Niigan Aki program manager of the WR-1 Disposal Facility (WRDF), the waste management areas, the counting lab and the pump house. In follow-up to the meeting, CNL provided information on the culturally significant plants that were found in the bush and grasslands in 2022. Later, on October 20, CNL also provided the 2023 environmental monitoring field sampling schedule.

On November 01, 2023, the monthly working group between Sagkeeng and CNL focused on land use and end state, the CNL Indigenous Relations Procurement Strategy, updates from Niigan Aki and the November 29, 2023 Chief and Council WL site tour. Mid-month, CNL met with Sagkeeng again to discuss further the Sagkeeng feedback on the Indigenous Relations Procurement strategy. At the end of November, 2023, the Sagkeeng Chief and Council came to the WL site to meet with senior leadership and tour the WL site. The tour included the WMAs, the Winnipeg River, and WDRF.

In early December 2023, CNL shared their initial draft of the EIS Commitments List for Sagkeeng. The December monthly working group meeting was held on December 6, 2023. The focus of this meeting was a presentation and discussion on the low-level waste trenches. A highlight of engagement in December was the Sagkeeng CEMP manager's presentation at an AECL-CNL alumni event in Pinawa. This was an important presentation to share the work being done by the CEMP at and around the WL site.

The January working group meeting, held on January 17, 2024, focused on updates from Sagkeeng, including Niigan Aki, the Community Liaison Committee, and CNL. Towards the end of January, Sagkeeng and CNL coordinated a meeting in mid-February to have a tabletop discussion on the EIS Commitments List for the Sagkeeng, which CNL had drafted and shared in December 2023. On the last day of January 2024, Sagkeeng participated in the in-person meeting and site tour at WL site as a part of the Black River and Hollow Water First Nations' Core Engagement Team meeting. Sagkeeng shared a presentation on the Niigan Aki program, which came out of a request from Black River and Hollow Water First Nations.

In February 2024, CNL, Sagkeeng and AECL began a series of meetings to address relationship level interests and concerns beyond the scope of the Project. These meetings continued through July 2024. On February 12, Sagkeeng and CNL met virtually to discuss the EIS Commitments List. CNL was seeking to make to Sagkeeng. Sagkeeng provided feedback on how CNL should revise the commitments to better address the Sagkeeng interests and concerns, including developing more substantive and focused commitments. The following day, February 13, representatives from Sagkeeng and CNL met with Chief and Council and CNL had the opportunity to present on the Low-Level Waste Trenches at the WL site and the options for managing this waste area.

On February 12, 2024, Sagkeeng and CNL met virtually to discuss the EIS commitments List. CNL was seeking to make to Sagkeeng. The following day, February 13, representatives from Sagkeeng and CNL met with Chief and Council and CNL had the opportunity to present on the Low-Level Waste Trenches at the WL site and the options for managing this waste area. Monthly Technical Working Group meetings also continued in 2024 with a focus on Sagkeeng's participation in the environmental assessment, land use and end state, planning for community engagement activities (including community tree planting days at Sagkeeng First Nation planned for the spring of 2024) and the possibility of a benchmarking trip to a nuclear site that had been decommissioned in-situ. In February 2024, the Sagkeeng Niigan Aki Program Manager participated on a panel at the Waste Management Symposia conference regarding Indigenous Relations.

In March, CNL shared information on the 2024 WL site licence renewal hearing via email, including the licence amendment application, the CNSC Notice of Hearing and information on the CNSC Participant Funding Program. CNL also offered to support for Sagkeeng's participation in the hearing. CNL also shared two batches of responses to the Federal Provincial Indigenous Review Team comments on the Project with Sagkeeng for the First Nation's review this month, on March 4 and March 20. On March 8 CNL shared the summary of engagement section for the Project's IER with Sagkeeng for their review. On March 15, representatives from Sagkeeng and CNL met virtually to discuss procurement, which had been flagged as an outstanding issue of concern in the relationship between Sagkeeng and CNL in Sagkeeng's feedback on the CNL's Indigenous Relations Procurement Strategy.

Sagkeeng and CNL also met twice in March to discuss the Sagkeeng Vision for Long-Term Land Use of WL site, an initiative that Sagkeeng is conducting, which came out of ongoing discussions related to Sagkeeng's feedback on future land use and end sate at the WL site. The Sagkeeng Vision for Long-Term Land Use of WL site, is a study conducted by Sagkeeng with support of a third party and financial support by CNL. It will explore future land use and end state at the WL site through the perspective of Sagkeeng using Indigenous values. Towards the end

of the month, on March 26, CNL shared revised draft commitments in follow-up to the feedback that Sagkeeng shared at the February commitments meeting.

In April 2024, CNL invited Sagkeeng to the second Regional Leaders Gathering, which would be held in June 2024. On April 18, Sagkeeng sent back comments on this draft section, which CNL incorporated into the IER and this EIS. On Earth Day, April 22, the Niigan Aki program manager attended the WL site to facilitate a lunch and learn presentation about the Niigan Aki program for CNL staff. Later in the month, Sagkeeng representatives and CNL representatives met in-person for engagement planning and introduction of new staff.

Throughout May 2024, ongoing communication between CNL and Sagkeeng included logistics for the Niigan Aki mushroom collection fieldwork, coordination of the Tree Planting activities at Sagkeeng First Nation and Sagkeeng attendance at the CNL Regional Leaders Gathering. CNL supported the tree Ppanting activities led by Sagkeeng's Niigan Aki program on May 13 and helped facilitate the Niigan Aki mushroom collection work at the WL site on May 22. During the mushroom collection work, CNL staff had the opportunity to work alongside Niigan Aki Guardians to learn about the cultural practices and uses for mushrooms, as well as species of cultural significance. This visit also included a visit to WL's collections analysis lab to facilitate knowledge sharing between Sagkeeng and CNL. On the last day of May 2024, CNL received two important reviewed documents back from Sagkeeng: their comments on the draft EIS commitments and their comments on CNL's responses to information requests.

Early June 2024 Sagkeeng representatives, including the Chief, an Elder and the Niigan Aki program manager, attended CNL's second annual Regional Leaders Gathering in Beausejour. The Regional Leaders Gathering facilitated discussions amongst leaders from Indigenous and non-Indigenous communities with CNL. The focus was on CNL projects, including this Project, environmental monitoring, and gathering feedback on Trenches and Land Use End State.

On June 11, CNL shared the Indigenous engagement section of the draft Commission Member Document with Sagkeeng as an opportunity for their review. Sagkeeng shared back minimal concerns on the document noting that earlier feedback from the IER review had been incorporated. The June monthly meeting included an update on the Project to keep everyone apprised of CNL's plans for EIS submission in 2024.

On June 25, the Sagkeeng Niigan Aki program manager also attended one of CNL's public webinars on a similar in-situ project undergoing an environmental assessment in Ontario – the NPD Closure Project. Afterwards, the Niigan Aki program manager followed up with several questions about the NPD Closure Project. In July, CNL's Indigenous Engagement Advisor called the Niigan Aki program manager to discuss these questions and to coordinate a meeting to discuss the NPD Closure Project further. Another highlight of June was Niigan Aki participation in milkweed field monitoring and mapping activities at the WL site.

In July, Sagkeeng participation in monitoring activities at the WL site continued with establishment of a seven-week summer student initiative and participation in a bat exit survey, which three Sagkeeng members, enabled through Niigan Aki, participated in on July 17. Two CNL summer students from Sagkeeng, who were on CNL's environmental monitoring team, as well as two members of the Sagkeeng Beautification Team, participated in this survey. Relationship building activities in July 2024 included Sagkeeng's invitation for CNL to participate in their Treaty Days at the end of the month. CNL attended on both July 30 and July 31, with a float on the first day and a booth on the second day.

The above section should make clear that there has been growth in Sagkeeng and CNL's relationship. Sagkeeng and CNL are engaging in many ways on multiple issues, such as ongoing monitoring through the extensive

engagement of the Niigan Aki program and longer-term issues, like the future land use and end state of the site. Though CNL understands that there are still ongoing issues where there is not a clear path to resolution yet, such as Sagkeeng's feedback on CNL's Indigenous Relations Procurement Strategy and preferred decommissioning strategy for WR-1, CNL believes the relationship is on solid footing to continue dialogue and seek solutions where there is disagreement.

4.2.4.1.2 Summary of Interests and Concerns

Sagkeeng and CNL have been engaging on the Project since 2016, which has led to the identification of the interests and concerns held by Sagkeeng. This subsection is a summary of the interests and concerns and describes CNL's understanding based on written submissions and oral discussions with Sagkeeng. The full table of interests and concerns can be found in the IER Appendices.

Sagkeeng provided 38 formal comments on the 2017 and 2020 draft EIS. Sagkeeng also provided feedback during engagements including the Technical Working Group where Sagkeeng has shared their position on topics related to the Project and the Whiteshell Laboratories Restoration Project and through the subcommittee where Sagkeeng shared feedback on sections of the EIS. Sagkeeng has also provided feedback via their Traditional Knowledge and Land Use and Occupancy Study (Firelight 2018), the Harvester Consumption Survey (CNL 2018), their Alternative Means Assessment Report (Sagkeeng Anicinabe and Firelight 2018), and their Psychosocial Impact Assessment Report (Narratives 2020). CNL has made its best efforts to document and verify Sagkeeng's interests, concerns and perspectives.

Relationship Building

Sagkeeng and CNL are working together toward developing a positive and lasting relationship. Sagkeeng requested a meeting with CNL and AECL leadership to discuss concerns regarding CNL's response to Sagkeeng's Psychosocial Impact Assessment Report. This meeting took place on April 6, 2021. During the call, CNL offered a sincere apology for its approach and response to the report. CNL and AECL recognized the findings of Sagkeeng's Psychosocial Impact Assessment Report and the trauma experienced by Sagkeeng members in relation to the historical siting and operations of the WL site. CNL and AECL also recognized Sagkeeng as stewards of the land and waters and committed to working with Sagkeeng to develop and implement recommendations arising from the report and the April 6, 2021, dialogue.

CNL received a follow-up letter from Chief Henderson on April 22, 2021, stating the leadership meeting was productive, and the apology and acknowledgements provided in the meeting were meaningful to Sagkeeng. The letter reiterated Sagkeeng's preferred path forward for working together with CNL and AECL. This included establishing a Technical Working Group between AECL, CNL, and Sagkeeng to implement the following initiatives:

- development of a community liaison committee;
- development of a healing and resiliency action plan;
- development of a leadership table among Sagkeeng, AECL and CNL; and
- development of a meaningful Sagkeeng Indigenous monitoring program at and around the WL site.

The Technical Working Group meets monthly to support ongoing, constructive dialogue to develop and implement the above initiatives. The Technical Working Group progressed a contribution agreement that initially supported Sagkeeng's participation in the environmental assessment. Later amendments helped to formalize the relationship between Sagkeeng and CNL allowing for meaningful engagement on issues of interest and concern, including

those brought forward on the Project and also beyond the scope of environmental assessment. The most recent contribution agreement amendment to that effect was signed in August 2023.

Sagkeeng and CNL also signed a separate agreement in December 2022 to support and resource Sagkeeng's Niigan Aki program.

CNL's relationship with Sagkeeng has improved since a CNL, AECL, and Sagkeeng leadership meeting on April 6, 2021. The relationship is growing positively and is currently being managed through tripartite discussions at the technical working group. Sagkeeng has expressed that the relationship needs to be ratified through meaningful long-term commitments to Sagkeeng monitoring and management roles in relation to the Project and the WL site, and to support for healing and resiliency improvements and evidence of benefit to offset long-term and likely future impacts at and around the WRDF.

Site Management Structure/Roles and Responsibilities

In their review on the 2017 and 2020 draft EIS, Sagkeeng requested CNL provide information on the nature of the contractual relationship between Canada and Canadian National Energy Alliance (CNEA), and the financial terms between Canada and CNEA, with emphasis on any incentives or penalties related to the schedule and budget of the proposed undertaking. Sagkeeng also requested information on the respective responsibilities of Canada, CNL, CNEA, and other parties for the environmental liabilities at the WL site, both now and in the future, and the respective responsibilities of Canada, CNL, CNEA, and other parties to fulfill the fiduciary obligations of Canada to Sagkeeng as they pertain to the proposed undertaking.

Sagkeeng expressed the position that the current application fails to meet both of these requirements and is inconsistent with the federal government's commitment to meaningful reconciliation with Indigenous Nations. Sagkeeng indicated that Canada cannot waive its fiduciary duties to: a) honour its prior commitment to remove the radioactive wastes from Sagkeeng lands; and b) provide that Indigenous interests and Aboriginal and Treaty Rights are fully considered and protected. Sagkeeng expressed an interest in the history of CNL and how CNL relates to AECL and the WL site.

CNL has shared formal responses to these questions and concerns in January 2020, October 2020, and January 2021. In those responses, CNL explained that information on the financial terms of the CNEA contract could not be shared, as it is commercially sensitive. At this time, Sagkeeng does not accept CNL's position that the financial terms of the CNEA contract cannot be disclosed.

CNL provided an overview of the history of the site and explained that the WL site is within a government-owned and contractor-operated facility. The WL site, including all assets and liabilities, is owned by AECL, a federal government Crown corporation. AECL contracted CNL to operate the facility and perform the decommissioning work. While the ownership of CNL may change (CNEA is the current owner of CNL), CNL will remain the operator and licensee for all AECL sites. For questions related to the duty to consult and reconciliation, CNL referred Sagkeeng to the CNSC as the Crown who holds the duty to consult in relation to the EA for the Project. CNL has also shared that AECL has particular responsibilities as the Crown when it comes to the site as a whole and CNL as a corporation, such as next land use end state and the CNL Indigenous Relations Procurement Strategy.

At this time Sagkeeng does not accept CNL's position that the financial terms of the CNEA contract cannot be disclosed. Sagkeeng has proposed entering into confidentiality agreements and other arrangements to allow for the confidential and "for-purpose" disclosure of the requested information. CNL has taken steps to address this

area of interest to the extent it believes is possible. Should this matter remain a priority area of concern for Sagkeeng, CNL would be open to re-engage. SAFN and CNL have differing perspectives on this matter.

Sagkeeng has expressed appreciation for the information provided about present and future nuclear liability responsibility, and has noted that the question of what degree of harm to Sagkeeng's Treaty Rights and interests has already occurred prior to the Project, and how much harm will occur in a future with and without the Project, remains an open issue.

Engagement

In January 2018, Sagkeeng had expressed concerns with the lack of meaningful and responsive engagement by CNL and requested a greater role in reviewing draft documentation related to the draft EIS. Sagkeeng also requested greater involvement in the implementation of the decommissioning plans for the Project and into the institutional control period. The community noted that technical results are difficult to understand and that CNL should consider methods so that future updates about the Project will be in a form that is easily understandable for Sagkeeng. Sagkeeng suggested that CNL work with the Chief and Council to promote future engagement activities with the community. In addition, it would make sense to invite on-reserve members by going door to door.

Sagkeeng requested CNL commit funding to support the development and implementation of an Indigenous-led risk communication program designed to improve Indigenous understanding of the site and vicinity risk to the health and edibility of country food and water sources (including radiation, impact pathway identification, monitoring results, and plain language reporting about the safety of country food and water sources), as well as sharing CNL's annual reports with the community.

To help facilitate greater engagement with Sagkeeng, CNL, Sagkeeng, and AECL have established a Technical Working Group to resolve outstanding concerns and work collaboratively on areas of interest by developing and implementing initiatives that will help address Sagkeeng's concerns on the Project. An agreement was drafted to support Sagkeeng's continued engagement on the Project. CNL will continue to engage meaningfully with Sagkeeng Chief and Council, community members, their engagement team, and their Liaison through the lifecycle of this Project. CNL and AECL have also affirmed their commitment to engage beyond the Project and are already engaging with Sagkeeng on issues regarding the WL site and CNL as a corporation more broadly.

During the COVID-19 pandemic, CNL continued to engage Sagkeeng through their consultation team using teleconferences. As circumstances permit, CNL has expanded its engagement focusing on engaging with more of Sagkeeng's membership. CNL and Sagkeeng have also engaged through a subcommittee focused on verifying that EIS documentation accurately reflects Sagkeeng's interests and position.

CNL will continue to engage meaningfully with Sagkeeng Chief and Council, community members, their engagement team, and their Liaison through the lifecycle of this Project. Sagkeeng acknowledges that CNL has meaningfully engaged with it on the Project, enabling Sagkeeng's participation in the environmental assessment and licensing process and expects that engagement to continue. Sagkeeng has expressed that for engagement to be meaningful, it must be ongoing.

Sagkeeng recognizes that CNL has entered into a formal, funded agreement to support a Community Environmental Monitoring Program with Sagkeeng. Sagkeeng views this as a positive development. In addition, Sagkeeng notes that questions of Sagkeeng's role in planning and assessment of the Project and the WL site have yet to be addressed through concrete commitments by CNL or AECL.

Historical Siting and Operations of the Whiteshell Laboratories Site and Consideration of Cumulative Effects

Sagkeeng identified concerns regarding the lack of engagement during the siting and operations of the WL site. Sagkeeng has also expressed concern that CNL does not adequately consider associated cumulative effects in the draft EIS. More specifically, Sagkeeng has asked CNL to integrate into the baseline, information on the pre-existing cumulative effects context, especially for Sagkeeng's Treaty Rights, cultural practices, and traditional land and resource use, Sagkeeng believes that cumulative effects should include historical changes to their territory and potential impacts to Sagkeeng's Treaty Rights.

CNL and Sagkeeng are working through a subcommittee to review EIS documentation. CNL's position is that it has to incorporated Sagkeeng's feedback as much as possible. Regarding Sagkeeng's concern on historical cumulative effects, the issue remains outstanding and unresolved as Sagkeeng disagrees that adequate steps have been taken on this issue. From CNL's perspective, this concern is out of scope of the EA but commits to supporting a dialogue on historical siting of the WL site between AECL and Sagkeeng, through the Technical Working Group.

CNL has taken steps to address this concern by incorporating feedback from Sagkeeng on historical siting issues and committing to discussions between AECL, Sagkeeng, and CNL on the historic siting of the WL site and will continue to engage Sagkeeng on the Project and closure of the WL site. Sagkeeng disagrees that adequate steps have been taken on this issue, as no facilitated discussions between AECL and Sagkeeng on historic effects or past practices have occurred, or discussions on accommodations and reconciliation have occurred to date.

Free Prior and Informed Consent (FPIC)

Sagkeeng's view is that the Project must adhere to FPIC and requested that CNL agree to a positive Sagkeeng consent requirement into the Project, which could be provided in the form of a community vote or other form of consent provision process to be determined by the Sagkeeng community. Sagkeeng's position is that Article 29(2) of the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) creates a legally binding requirement to secure Sagkeeng's free, prior and informed consent prior to proceeding with the proposed Project, which will convert the WRDF to a permanent hazardous waste disposal facility.

In February 2021, AECL hosted a leadership teleconference with representatives from Sagkeeng, CNL and the CNSC to discuss the principle of FPIC in relation to the Project. During the meeting, CNL and AECL acknowledged Sagkeeng's perspective and indicated their willingness to work collaboratively with Sagkeeng, understanding that while consent is the preferred outcome, the Project will benefit from greater collaboration even where consent is not achieved. CNL and AECL believe that meaningful engagement and participation in decisions that affect Sagkeeng members, their community, and territory is critical to fostering understanding and identifying mutually acceptable opportunities in respect of the Project. The meeting led to further discussions between CNL and Sagkeeng in March 2021 regarding capacity funding to support more direct engagement with Sagkeeng members.

CNL shared with Sagkeeng that while CNL believes consent is not required, CNL is working towards achievement of that principle to the extent possible. CNL and Sagkeeng have signed a Contribution Agreement to support Sagkeeng's engagement in the environmental assessment process. CNL continues to seek direction from the community, and work closely with the Liaison, to strengthen engagement with Sagkeeng community members. CNL has made efforts to address this area of interest to the extent possible. CNL is prepared to continue discussing and responding to Sagkeeng's concerns on this issue.

This issue remains outstanding as Sagkeeng continues to maintain its position that Article 29(2) of UNDRIP creates a requirement to secure Sagkeeng's free, prior and informed consent prior to proceeding with the proposed Project. CNL maintains that this issue remains with the CNSC and AECL as bodies of the Crown.

Rights Impact Assessment

Sagkeeng expressed concern that there was a lack of assessment of potential impacts on their Aboriginal and Treaty Rights, and their ability to practice their Rights in the future. CNL has documented Sagkeeng's concerns and preferred method of decommissioning the WR-1 and defers to the results of CNSC's and Sagkeeng's joint or separate Treaty Rights impact assessments for a conclusion on whether Aboriginal and Treaty Rights are impacted by this Project. The next step is to engage with Sagkeeng through the Technical Working Group to resolve outstanding concerns and work collaboratively on areas of interest.

Sagkeeng's position remains that the EIS and the approach to engagement should be held to the highest current standard of impact assessment, which is now the *Impact Assessment Act*. Further, Sagkeeng notes that what it considers to be inaccurate findings re: impacts from the Project on traditional land and resource use is an outstanding issue that is pertinent to the CNSC's Indigenous Rights Impact Assessment.

Psychosocial Impact Assessment

Sagkeeng has expressed in their Psychosocial Impact Assessment Report (Narratives Inc. 2020) that the ISD option is likely to have incremental adverse psychosocial effects on Sagkeeng's membership, greater than those from other alternative decommissioning means. Sagkeeng's Psychosocial Impact Assessment Report states that CNL must address impacts resulting from past trauma, including the 1960s construction of the WL site, the perception of environmental effects, and the perception that illnesses may be connected with environmental effects.

CNL's leadership held a teleconference with leadership from Sagkeeng and AECL to discuss Sagkeeng's Psychosocial Impact Assessment Report. During the call, CNL offered a sincere apology for its approach and response to the report. CNL and AECL recognized the findings of Sagkeeng's Psychosocial Impact Assessment Report; more specifically, that the current proposal for ISD is Sagkeeng's least preferred option from a psychosocial impact perspective. In addition, both parties recognized the trauma experienced by Sagkeeng members in relation to the historical siting and ongoing presence of the site. Finally, CNL and AECL recognized and acknowledged Sagkeeng as stewards of the land and waters and committed to working with Sagkeeng to develop and implement recommendations arising from the report and the April 6, 2021, dialogue. CNL has summarized the psychosocial impact assessment write-up in Section 4.2.4.1.4.

CNL is committed to working collaboratively with Sagkeeng on developing and implementing the initiatives that will help address Sagkeeng's concerns. These initiatives include the development of a healing and resiliency action plan, which can include or be closely tied to a community-driven risk communication program focused on the health of country foods and waters; an independent Sagkeeng Community Environmental Monitoring Program; a community liaison committee; and a leadership table. CNL, AECL and Sagkeeng have entered discussions on the parameters of their future relationship with the implementation of an Indigenous-led risk communications program a priority. CNL, AECL, the CNSC, and Sagkeeng's Liaison Officer took trauma-informed engagement training as a precursor to developing a Healing and Resiliency Action Plan. The next step is to engage with Sagkeeng through the Technical Working Group to discuss the healing and resiliency action plan and what is within scope to resolve outstanding concerns and work collaboratively on areas of interest.

Sagkeeng remains concerned that the results of the Psychosocial Impact Assessment Report have not been adequately integrated into the effects assessment for human health, well-being and current use of lands and resources for traditional purposes, nor has it altered CNL's preferred alternative to decommissioning.

Further, Sagkeeng notes that CNL has made a nominal commitment to support a healing and resiliency action plan. However, the scope and duration of that program that CNL and AECL are willing to support has yet to be defined.

Valued Components

Sagkeeng suggests that the draft EIS has neglected to consider the full scope of Sagkeeng's VCs within its assessment, which are necessary for the continued practice of Sagkeeng culture and livelihoods.

The VCs identified within the Sagkeeng Traditional Knowledge and Land Use Study (TKLUS; Firelight 2018) are: water; medicine, berries and other food plants; hunting and trapping; and Anicinabe Pimatiziwin. As detailed in the TKLUS in Section 3.1 (p. 22), "the VCs were chosen to represent the critical conditions or elements that must be present for the continued practice of Sagkeeng culture and livelihoods, and that may be impacted by the Project. As such, VCs can range from the direct presence of traditionally hunted animals and gathered plants, to continued habitation, travel, and cultural activities on the land."

CNL collected Sagkeeng species and topics of interest from their TKLUS, Alternative Means Assessment, Psychosocial Impact Assessment, general engagement, and verification discussions. It should be noted that Sagkeeng does not feel that the verification process is an accurate name as CNL has not accepted all recommendations and revisions that Sagkeeng has made on the EIS, IER and Interests and Concerns Table. The collected information regarding VCs helped CNL assess whether they had considered the effect pathway to those specific VCs in the assessment for the Project. CNL worked with Sagkeeng to verify the list of VCs below accurately captures, to the extent possible, Sagkeeng's species and topics of interest. Sagkeeng provided two rounds of feedback and met with CNL on July 28 and August 24, 2021, to revise the list based on Sagkeeng's feedback. Any revisions to this table will be reported in the IER for the public record.

The following list is CNL's understanding of related Sagkeeng species and topics of interest:

- grouse, geese;
- food (e.g., wild rice, wild ginger, blueberries, plums, raspberries, strawberries, pin cherries, Saskatoon berries, low-bush cranberries, gooseberries, chokecherries) and Traditional Medicines (names not included at Sagkeeng's request);
- furbearers, marten, rabbit, squirrel, weasel;
- white-tailed deer, moose, elk;
- sturgeon and sturgeon spawning grounds, sucker, catfish, pickerel, goldeye, sunfish, whitefish, perch, carp, pike, bass, and fish habitat including the Winnipeg River;
- water resources and the Winnipeg River;
- beaver, muskrat, otter;
- groundwater and groundwater interaction with surface waters in the Winnipeg River;

- water resources; drinkable water (i.e., Sagkeeng willingness to drink water directly from the land); Winnipeg River;
- employment and business opportunities; community psychological well-being; environmental and community safety; sense of safety and security on the lands and waters; risk perception regarding the consumption of country foods;
- hunting and trapping;
- Sagkeeng Anicinabe governance and stewardship, including in relation to protecting and monitoring the land, land tenure and future use; culture and archaeological sites;
- Anicinabe Pimatiziwin (a complex value which includes tangible, semi-tangible and intangible elements including but not limited to connectedness to land and waters;
- spirit and spiritual practices/ceremony, knowledge of Sagkeeng territory, inter-generational knowledge transfer, among other cultural continuity factors);
- Winnipeg River; traditional harvesting of country foods; and
- traditional harvesting of country foods.

CNL has revised subsection of Section 6.0 to clearly reflect how VCs from First Nations and the MMF were considered for each effects assessment, where applicable. Sagkeeng has reviewed and provided feedback on this section, which was incorporated into the current version of the EIS.

Business and Employment Opportunities

Sagkeeng expressed an interest to know more about CNL's procurement policies and potential economic participation opportunities associated with the Whiteshell Laboratories Restoration Project, including qualifications. Priority employment and contracts were identified as an important concern and area of interest for Sagkeeng. Sagkeeng also raised the possibility of a certain percentage of the work going to Indigenous companies.

Sagkeeng requested first preference for new or vacant positions and requested a commitment for training to enhance the skills of community members.

CNL adjusted the evaluation criteria for competitive bids to encourage economic participation by contractors that are Indigenous owned or have Indigenous employees or subcontractors. CNL has also sent job postings to Sagkeeng since approximately the mid-1990s. Sagkeeng has provided new contact information (December 12, 2019) and this has been provided to CNL Human Resources for use effective immediately. CNL would welcome applicants from Sagkeeng and will work with Sagkeeng to see how CNL can improve interest and success in recruiting. CNL sent a listing of current and potential future external vacancies as well as criteria for security clearances to Sagkeeng. To help facilitate information sharing, capabilities and opportunities, CNL also supported three "Industry Days" events to connect businesses with invited First Nations and the Manitoba Métis Federation. The industry days were held in Winnipeg, another at the WL site, and a third at the Sagkeeng First Nation Arena.

In 2023, CNL developed and shared a draft Indigenous Relations Procurement Strategy with Sagkeeng. Sagkeeng provided feedback on the strategy and CNL and Sagkeeng met on November 15, 2023, to discuss Sagkeeng feedback. Sagkeeng's feedback on this strategy included recommendation that CNL review the CNL Indigenous

Relations Procurement Strategy within the context of the Sagkeeng-CNL Procurement Policy Discussion Paper-Precedent Analysis Document, which Sagkeeng had provided to CNL. Sagkeeng found that CNL's corporate strategy did not meaningfully enhance Indigenous participation in CNL Procurement, or adequately consider the relationship with Sagkeeng, the future of the WL site and CNL's intention to complete the closure of the site within the decade. While CNL views this feedback as going beyond the scope of the Project, CNL is continuing to work with Sagkeeng to determine an adequate path to addressing this feedback. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship. CNL also shared the Indigenous Vendors Portal in the fall of 2023 and discussed this at the November monthly meeting within the context of the Project and the WL site.

Sagkeeng, and AECL have established a Technical Working Group to resolve outstanding concerns and work collaboratively on areas of interest. This issue remains outstanding.

Future Land Use and Tenure (End State Planning for the Whiteshell Laboratories Site)

Sagkeeng requested more information regarding future compensation for the Local Government District of Pinawa and the First Nation. Sagkeeng also requested that all site clean-up and release criteria and deviation of the desired end-state(s) for the WRDF be developed collaboratively with Sagkeeng. Sagkeeng confirmed their interest in participating in a Whiteshell end-state workshop and in 2023 a representative from Sagkeeng participated in the Regional Leaders Gathering hosted by CNL on Brokenhead Ojibway First Nation.

Sagkeeng has continued interest on the potential impact that small modular reactors might have on the site. As well, Sagkeeng reinforced the importance of an Indigenous Liaison or Monitor to provide information back to the community on how the legacy low-level waste trenches will be decommissioned. In addition, Sagkeeng requested to be more involved, regardless of what decommissioning plan proceeds, in the drafting and implementation of plans for the duration of decommissioning and into the institutional control period, including the participation in the development and/or review of documents such as the Environmental Risk Assessment, Detailed Decommissioning Plans and final safety assessment for the remediation of the trenches, as well as an appropriate institutional control framework. CNL explained that the liability and land remain the long-term responsibility of AECL. CNL and AECL continue to engage Sagkeeng to discuss potential future uses of the WL site.

CNL committed to engaging bilaterally with Sagkeeng and other First Nations, the MMF, local communities and stakeholders to co-develop future land use objectives, as well as engage on the end-state of the WL site as part of Whiteshell Laboratories Restoration Project. CNL, Sagkeeng, and AECL have established a Technical Working Group to resolve outstanding concerns and work collaboratively on areas of interest. CNL will continue to engage meaningfully with Sagkeeng Chief and Council, community members, their engagement team, and their Liaison through the lifecycle of this Project. CNL and AECL have also affirmed their commitment to engage beyond the Project and are already engaging with Sagkeeng on issues regarding the WL site more broadly and land use and end state.

In particular, in early 2024 Sagkeeng informed CNL that they would be working on the Sagkeeng's Long-term Vision for the WL site, which will be the avenue to address the concerns around the site's future land use.

Sagkeeng has also noted that there is no evidence of benefit to the First Nation from employment and business opportunities, or evidence that there are "mitigations in place to enhance benefits for Indigenous Nations" with the closure of the WL site.

Waste Management

Sagkeeng raised concerns and questions regarding how much radioactive waste would remain on the WL site and where and how that radioactive waste was being transported off-site. In response, CNL informed Sagkeeng that all waste materials (radioactive and non-radioactive) are sorted, verified, and transported using licensed containers, depending on the waste type, to a licensed hazardous waste management facility. CNL expects that approximately 2000 truckloads will need to be shipped throughout the Whiteshell Laboratories Restoration Project. CNL has shared how the used fuel baskets contained in the concrete canisters will be placed in a transportation flask and transported by truck. CNL also shared that radioactive material has been transported between CNL's WL site and Chalk River Laboratories site for many decades without a single radiological incident. Transportation of radioactive materials is a highly regulated activity that must meet the stringent requirements of both Transport Canada (Transportation of Dangerous Goods) and the Canadian Nuclear Safety Commission (Packaging and Transport of Nuclear Substances Regulations) prior to approval. CNL's approved Radioactive Material Transportation Program (CNL 2021) is in place to protect persons, property, and the environment from the effects of radiation during the transport of radioactive material. CNL also provided details on site waste management and waste characterization in response to Sagkeeng's comments on the 2017 and 2020 draft EIS.

Through the Sagkeeng Alternative Means Assessment, Sagkeeng expressed that it would be best if all waste from the WRDF were removed from the WL site. In general, Sagkeeng expressed substantial and consistent concerns regarding deviation from the Comprehensive Study Report (AECL 2001), which proposed full removal of WR-1.

CNL has taken steps to address this area of interest however, Sagkeeng and CNL disagree on the preferred approach to decommissioning for WR-1, based on the findings of their respective Alternative Means Assessments. While CNL, Sagkeeng, and AECL have established a Technical Working Group to resolve outstanding concerns and work collaboratively on areas of interest, CNL has found no resolution to this Sagkeeng concern. CNL will continue to engage meaningfully with Sagkeeng Chief and Council, community members, their engagement team, and their Liaison through the lifecycle of this Project. CNL and AECL have also affirmed their commitment to engage beyond the Project and are already engaging with Sagkeeng on issues regarding the WL site more broadly.

Future Monitoring

Sagkeeng expressed an interest in learning about future monitoring of the site, including the duration of monitoring activities and where monitoring would occur. In particular, Sagkeeng thought that there should be monitoring at locations where members fish, and monitoring locations closer to the community. Sagkeeng also expressed concern that a lack of Traditional knowledge informed environmental monitoring and explained that Indigenous environmental monitoring was a critical element of Sagkeeng stewardship and Indigenous-led risk communication with members. Sagkeeng requested a commitment from CNL regarding an independent, long-term future monitoring program to be designed and led by Sagkeeng (a CEMP).

CNL and Sagkeeng have both agreed that Sagkeeng's involvement in monitoring could help address other concerns including reducing fear and stigma of the site regarding the proposed ISD for WR-1 and improved faith in country foods and understanding of the environment and effects from the WL site, through collection of baseline and trend-over-time Traditional Knowledge in a dedicated, continuous fashion. CNL committed to establishing a CEMP with Sagkeeng.

Sagkeeng and CNL worked together to establish the Sagkeeng-led Niigan Aki program (a CEMP), which was officially launched in 2022. CNL has committed to sharing annual environmental monitoring field sampling

schedules with the Sagkeeng Niigan Aki program and is working closely with Niigan Aki staff to support Indigenous-led monitoring in and around the WL site. Niigan Aki staff began initial onsite monitoring activities in 2023.

Sagkeeng has also noted that this issue is related not just to monitoring but also to the different approaches preferred by Sagkeeng (full removal) and CNL (ISD) for WR-1 decommissioning, which have differential long-term effects on real and perceived risk of contamination of fish and the Winnipeg River.

Fish, Fish Habitat, and the Winnipeg River

Sagkeeng expressed concern about the perceived deterioration of fish quality in the Winnipeg River. This included the observation of unusual sores on some fish. Sagkeeng also expressed an interest in being more involved in water quality and fish monitoring on site.

In late 1994, the Winnipeg River Task Force was created. Representatives from Indian and Northern Affairs Canada, Environment Canada, Health Canada, and Sagkeeng took part in the Task Force. The objective of the Task Force was to look at potential sources of Winnipeg River water quality degradation near the community of Sagkeeng. The Task Force report concluded that the drinking water quality met Canadian guidelines and that it was unlikely that the WL site had ever posed or would pose a significant threat to the health of Sagkeeng community members.

CNL committed to the development and execution of a CEMP with Sagkeeng. CNL also committed to sharing annual environmental monitoring field sampling schedules with the Sagkeeng-led CEMP program (now named Niigan Aki) and working closely with CEMP staff to support Indigenous-led monitoring in and around the WL site.

CNL and AECL supported the establishment of Sagkeeng's Niigan Aki program, which began in late 2023. CNL and the Niigan Aki program staff are now working closely to facilitate the program's Indigenous-led monitoring within the WL site and beyond. As of July 2024, CNL is sharing environmental monitoring field sampling schedules with the Niigan Aki program staff every few months.

Regulatory Process

Sagkeeng expressed concern regarding limited funding provided by CNSC for review and participation in the Project. In addition, Sagkeeng expressed an interest in further opportunities for involvement in the Project.

To provide meaningful engagement on the Project, CNL provided capacity funding and support to Sagkeeng beyond the funding provided by CNSC and committed to providing funding to Sagkeeng as needed throughout the environmental assessment process.

CNL considers this concern addressed to the extent possible at this time and will work with Sagkeeng should funding concerns arise.

CNL and Sagkeeng continue to disagree on the approach taken on the regulatory approval process for the project and no resolution is imminent. The Project will continue under CEAA 2012 while working to exceed requirements and work collaboratively with Sagkeeng to address their concerns.

Sagkeeng continues to consider this issue as outstanding because several aspects of the assessment did not meet requirements that would have been required had it been conducted using requirements of the Impact Assessment Act.

In Situ Disposal Design of WR-1

Sagkeeng expressed that they are not confident that the proposed decommissioning method for the Project is adequate, acceptable, or preferable. Sagkeeng's position is that WR-1 should be dismantled and the radiological wastes removed from Sagkeeng territory as described in the 2001 Comprehensive Study Report (AECL 2021).

Sagkeeng expressed an interest in understanding how the grouted encapsulation would maintain its integrity into the future. Topics of interest to Sagkeeng included the potential for climate change and natural disasters to affect the integrity of the grouted encapsulation and how it would be constructed to provide that it is safe. Participants at the community open house were interested in various aspects of the Project. Questions were asked regarding the existence of similar projects, the differences in costs between the original removal decommissioning plan and the ISD and the safety of ISD in connection with the environment. CNL discusses the cost of all the alternatives in more detail in Section 2.6.2 (Economic Feasibility).

CNL provided a detailed response on how the different barriers of the in situ design provide that the waste is properly contained and isolated from the environment. This was done through written responses, in January 2020, October 2020, and January 2021, to Sagkeeng's draft EIS comments, through presentations to community members and consultants, and through dialogue at community and leadership meetings. CNL also provided additional information on the safety case as well as the grout formulation and process.

CNL supported Sagkeeng to undertake their own Alternative Means Assessment; one that assessed and measured the alternatives based on Sagkeeng values, weighting and scoring. On October 19, 2020, Sagkeeng provided a copy of their Alternative Means Assessment. Sagkeeng's Alternative Means Assessment is discussed below in Section 4.2.4.1.3.

This issue remains outstanding. CNL respects that Sagkeeng has a different opinion on the most suitable decommissioning approach for WR-1 and Sagkeeng's preferred approach to decommissioning is articulated in the EIS. CNL will continue to submit the EIS for the Project through the environmental assessment process while supporting Sagkeeng's continued participation in the environmental assessment process. CNL and Sagkeeng recognize this difference of perspectives.

Traditional Knowledge and Land Use and Cultural Heritage

Sagkeeng expressed an interest in conducting a traditional use study as they identified specific traditional uses in proximity to the Project study area and the larger WL site. Specifically, Sagkeeng identified that wild rice and medicinal plants are collected by Sagkeeng members in the area near the WL site. CNL and CNSC agree that a Traditional Knowledge study is an important input to the EIS and the Indigenous Rights Impact Assessment (led by CNSC and Sagkeeng). Therefore, CNL supported Sagkeeng's TKLUS and incorporated findings into the revised draft EIS. CNL also partnered with Sagkeeng to complete a traditional food consumption study, of which 35 members of the community responded, helping CNL confirm that the Harvester model is a conservative model for modern day Indigenous people that rely on harvesting for some of their food.

Sagkeeng suggested that the draft EIS was inadequate based on a lack of meaningful engagement with Sagkeeng in establishing a baseline or conducting an effects assessment or in considering Sagkeeng VCs. Sagkeeng noted that the way the draft EIS was completed was not in keeping with the expectations for acceptable practice established by the Crown in the manner of assessing traditional land use and the assessment should have considered historic/cumulative issues. Sagkeeng expressed the position that the spatial boundaries of the assessment are inappropriate for assessing potential impacts to the current use of lands and resources for

traditional purposes). Sagkeeng expressed the position that CNL effectively ignored critical factors that influence decisions by land users, relying entirely on biophysical factors while ignoring Indigenous observations and perceptions critical to use (and loss of use) of areas of traditional territory.

In response to Sagkeeng's above feedback, CNL collected Sagkeeng species and topics of interest from their TKLUS (Firelight Research and Sagkeeng 2018), Alternative Means Assessment (Sagkeeng and Firelight 2020), Psychosocial Impact Assessment (Narratives 2020), general engagement and verification discussion. The collected information regarding VCs helped CNL assess whether they had considered the impact pathway to those specific VCs in the assessment for the Project. CNL worked with Sagkeeng to verify the list of VCs accurately captures, to the extent possible, Sagkeeng's species and topics of interest. Sagkeeng provided two rounds of feedback and met with CNL on July 28 and August 24, 2021, to revise the list based on Sagkeeng's feedback. CNL will engage with the Sagkeeng Community Liaison Committee once established on Sagkeeng's list of related species and topics of interests. Any revisions to Sagkeeng's VCs will be reported in future updates for the public record. CNL has revised each subsection of Section 6.0 to clearly reflect how VCs from Indigenous communities were considered for each effects assessment. CNL has also revised Section 6.8 to include information from Sagkeeng's TKLUS.

In Sagkeeng's review of Section 6.8 (Land and Resource Use), Sagkeeng stated the use of a "Base Case" tied to current damaged conditions rather than prior conditions or a desired condition set for decommissioning, led CNL to find no adverse effects pathways. Sagkeeng also is concerned in regard to Section 6.7 (Human and Ecological Health) stating the use of a damaged baseline and the lack of any reference to the proper base case to compare the Project against, which is the commitment made by Canada to remove all the radioactive components from WR-1, as per the Comprehensive Study Report (AECL 2001). In Sagkeeng's review of section 6.9 (Socio economic Environment), Sagkeeng raised concerns regarding the socio-economic assessment including but not limited to how CNL defines community well-being in a way that leaves out quite a number of elements that Sagkeeng use to characterize community well-being.

Sagkeeng also noted that CNL defined spatial areas by administrative boundaries as opposed to where impacts are expected; the clearest example of this is that the people of Fort Alexander are among the populations most likely to be subject to adverse socio-economic effects, and most deserving (through the principle of impact equity) of benefits from the Project, but Sagkeeng is put only in the regional study area for the socio-economic assessment, not the local study area. Sagkeeng stated this is inappropriate as the distance of residence is not the sole defining element of local and regional study areas for socio-economic assessment, especially for Indigenous Nations with Treaty Rights in the immediate Project affected area. Indigenous Nations have the right to travel to, through and use, all areas of their traditional territories. Specifically, CNL's assessment does not disaggregate down into sub-populations and/or differential effects on different groups within communities. Sagkeeng expressed concern that CNL only consider Sagkeeng members in Fort Alexander, not off-reserve populations.

Sagkeeng stated that CNL's baseline on Sagkeeng perspective and observations lacks depth and that CNL's assessment on the socioeconomic environment does not capture Sagkeeng's psychosocial concerns or the results of Sagkeeng's psychosocial impact assessment. For more information on Sagkeeng's psychosocial impact assessment report refer to Section 4.2.4.1.4. More specifically Sagkeeng stated the absence of Indigenous indicators of well-being, even when some of those factors were clearly mapped in the Sagkeeng Psycho-social impact assessment, is highly problematic.

Sagkeeng expressed concern that the absence of trend-over-time data for a variety of indicators makes it impossible to determine whether the "health" of an indicator is getting better or worse over time in CNL's

socioeconomic environment assessment. Sagkeeng did not find it acceptable for CNL not to have identified Indigenous determinants of health and verified them with Sagkeeng.

This issue remains outstanding as Sagkeeng has indicated that CNL's EIS does not adequately capture all impact pathways (primary and secondary) on Sagkeeng traditional use and cultural values in the EA, and that the EIS underestimates the magnitude and significance of likely impacts on these values in the Project Case. This interest remains outstanding until the mitigations and commitments are in place.

Alternative Means Assessment

Sagkeeng continues to have strong reservations with ISD and the way in which CNL conducted its Alternative Means Assessment. Sagkeeng states that ISD is not preferred over the previous full removal plan and has called for CNL to re-engage Sagkeeng on Alternative Means Assessment in a collaborative forum. This concern remains outstanding. Sagkeeng's most preferred decommissioning method for WR-1 is immediate full removal and Sagkeeng's least preferred decommissioning method is ISD, based on community input and the findings of Sagkeeng's Alternatives Means Assessment (Sagkeeng and Firelight 2020) and Psychosocial Impact Assessment (Narratives 2020). Sagkeeng's position is that as a result of Article 29(2) of UNDRIP and customary international law, the Project is not permitted to go forward without Sagkeeng's free, prior and informed consent. CNL recognizes that Sagkeeng considers this issue to be outstanding, given Sagkeeng has predicted residual adverse effects on traditional land and resource use and culture in the Project case, which have not been incorporated into the EIS. In addition, Sagkeeng has noted that commitments made with respect to healing and resiliency require more detail before their value as mitigation for impacts on SAFN values can be stated with confidence.

While this issue remains outstanding, CNL has committed to including the Sagkeeng perspective within the EIS as a standalone Section 4.2.4.1.3.

4.2.4.1.3 Sagkeeng's Alternative Means Assessment

Below is a summary of CNL's engagement with Sagkeeng with respect to Sagkeeng's Alternative Means Assessment. A complete description of CNL's considerations of Sagkeeng's Alternative Means Assessment is included in Section 2.8 of the EIS.

Sagkeeng submitted 22 comments on the draft EIS on the Alternative Means Assessment conducted by CNL and has indicated the importance of engaging on Project alternatives in a meaningful way. Additional comments were submitted at the Sagkeeng Alternative Means workshop in February 2019, in a letter in June 2019, a letter from Sagkeeng in February 2020, and reinforced during a meeting in March 2020. Sagkeeng remains critical of the approach taken under CEAA, 2012 by CNL to evaluate Project alternatives, particularly concerning a lack of Sagkeeng's perspectives included in the Alternative Means Assessment. CNL respects the importance of this issue to Sagkeeng and subsequently supported Sagkeeng to undertake their own Alternative Means Assessment; one that assessed and measured the alternatives based on Sagkeeng values, weights and scoring.

On October 19, 2020, Sagkeeng provided a copy of their Alternative Means Assessment (Sagkeeng and Firelight 2020). The Sagkeeng assessment draws the conclusion that based on results of their assessment, the ISD option ranked lower than the other alternatives for 7.5 of the 8 tests they conducted, and that it "…brings into question the appropriateness of CNL's preferred alternative for remediation of WR-1". In the document, Sagkeeng is calling for CNSC to "reject the proposal to change the decommissioning plan to ISD". CNL respects the independent view of Sagkeeng on potential alternatives for the Project.

A copy of the Alternative Means Assessment is included as a separate attachment to the EIS package submitted to the CNSC. For more information on Sagkeeng's Alternative Means Assessment see Section 2.8 of the draft EIS.

4.2.4.1.4 Sagkeeng First Nation's Psychosocial Impact Assessment

This subsection provides an overview of CNL's understanding and considerations of Sagkeeng First Nation's Psychosocial Impact Assessment (Narratives 2020). For details on CNL's engagement with Sagkeeng refer to Section 4.2.4.1 of the EIS and Section 4 in CNL's IER (CNL 2024).

4.2.4.1.4.1 Introduction and Context

An important element of the EIS submission is documenting feedback and information supplied by Sagkeeng that is relevant to the proposed Project. While CNL defers to the results of the Indigenous Rights Impact Assessment process for a conclusion on whether Aboriginal and Treaty Rights are impacted by this Project, Sagkeeng's Psychosocial Impact Assessment report is an important contribution of technical data and Traditional knowledge that contributes to the overall body of information of interests and concerns that Sagkeeng has expressed through engagement.

To better understand Sagkeeng's concerns regarding the psychosocial impacts that Sagkeeng associates with the WL site and predicts may result from the Project, the CNSC supported Sagkeeng's preparation of a psychosocial impact assessment. Sagkeeng commissioned Narratives Inc. to conduct the Psychosocial Impact Assessment of the Project (Narratives 2020). The study includes an account of experienced historical impacts, psychosocial impacts from WL's presence in the area, and psychosocial impacts expected to occur from each alternative[2] currently in consideration. The four alternatives considered as decommissioning options for WR-1 include the four identified by CNL as technically and economically feasible: *Alternative #1 – Deferred Dismantling and Removal*; *Alternative #2 – Dismantling and Removal; Alternative #3 – In Situ Disposal; and Alternative*; *#4 – Partial Dismantling and Removal with In Situ of the Remainder.* Sagkeeng's psychosocial impact assessment gathered information through a literature review and twenty-six semi-structured interviews with community members. In addition, thirteen Sagkeeng members participated in a psychological assessment conducted by a clinical psychologist.

The interviews conducted included prompting questions about the WL site. The overwhelming sentiment shared was regarding the confusion and fear related to nuclear in general; the expressed concerns about the use of a nuclear reactor and waste in Sagkeeng's territory; and the lack of engagement with Sagkeeng on the siting and operations of the WL site (Narratives 2020). One community member succinctly drew the connection between the secrecy and historic lack of consultation or engagement surrounding the WL site on the one hand, and negative feelings of self-worth, family cohesion, and traditional lifestyle on the other (Narratives 2020).

The study recommended that addressing psychosocial impacts of any of the Project Alternatives should focus not only on mitigating past harm but also on preventing future harm. It was assessed that Alternatives #1, #3, and #4 neither mitigate past harm nor prevent future harm, and thus sustain the status quo. If appropriate measures were in place and the fear associated with potential risks during the process of dismantling was addressed, Alternative #2 offers an opportunity to prevent further harm, and allow the community to start healing. Alternative #3 does offer some immediate waste removal action that would be beneficial from a psychosocial

[2] For more information on CNL's Alternative Means Assessment and each of the four alternatives considered technically and economically feasible, please refer to Chapter 2.0 of the EIS.

perspective, but the presence of radioactive material in the long term will continue to be a source of significant distress. Similar sentiments were expressed in the report for Alternative #4. Overall, the study found that Alternative #3 (In-Situ Disposal) was the least preferable option from a future trauma reduction perspective.

The study recommended that the following actions would contribute to a reduction in Sagkeeng's psychosocial impacts:

1. building a trauma-informed decision-making model
2. building a healing and resiliency action plan
3. building a long-term monitoring program with "extensive involvement" for Sagkeeng members
4. providing capacity and access to independent expertise on an ongoing basis
5. actively investing in improving the psychological wellbeing of Sagkeeng members

4.2.4.1.4.2 CNL's Considerations of the Report

CNL has engaged Sagkeeng's leadership, consultation team, and the psychosocial impact assessment author as well as carefully reviewed the findings of Sagkeeng's Psychosocial Impact Assessment (Narratives 2020). CNL's understanding of potential impacts of the Project and understanding of Sagkeeng's perspectives has evolved over time with support and guidance from Sagkeeng. Sagkeeng's concerns include the potential for ongoing fear and avoidance for land use if in situ decommissioning is conducted instead of full dismantling and complete removal of all waste from the land.

CNL acknowledges and accepts the findings in the report and recognizes that Sagkeeng community members have experienced psychosocial impacts that stem from the presence of the WL site in Sagkeeng's traditional territory and other sources of trauma. Based on the study and the separate findings of Sagkeeng's Alternative Means Assessment (Sagkeeng and Firelight 2020), Sagkeeng believes that the best option for community healing arises from complete and immediate removal of all waste from the site and that the proposed ISD option for WR-1 is likely to continue to contribute to psychosocial trauma for Sagkeeng members.

CNL recognizes that members of Sagkeeng are stewards of the lands and waters of their traditional territory, which includes the area now covered by the WL site, which was established by the federal government in the early 1960s. Sagkeeng states this alteration to the land reduced access and created alienation effects at and around the WL site, reducing Sagkeeng's access to and enjoyment of portions of its traditional territory up to the present day, and impacting Sagkeeng's Treaty and Indigenous Rights. CNL also recognizes that the establishment of the WL site, while compliant with regulatory standards at that time, would not meet the engagement and consultation standards that exist today. Sagkeeng has stated, and CNL and AECL recognize that, this process disconnected Sagkeeng from its traditional territory and the lack of engagement throughout the operations of the site, particularly around spills into the river, perpetuated fear and stigma around the WL site. This resulted in a mistrust in the management of the site.

CNL is committed to building trust and maintaining open, transparent communication with Sagkeeng's leadership and members, particularly around issues that arise on the WL site that may influence the water quality of the river. CNL understands that ceremony is a very important part of Anicinabe way of life and is seeking guidance from

Turtle Lodge and the Sagkeeng Anincinabe First Nation on how best to incorporate ceremony into the decommissioning and engagement plans for the Project and for the WL site.

The study recommends that addressing psychosocial impacts of any of the alternatives for the Project should focus not only on mitigating past harm, but also on preventing future harm. CNL recognizes that the proposed in situ option for decommissioning WR-1 does not support optimum healing, and that additional support to Sagkeeng is required to adequately address their concerns regarding the Project.

CNL acknowledges that its actions and engagement alone may not improve perceptions of the proposed Project and WL site, and remains committed to ongoing engagement, cultural training and learning from Sagkeeng about how best to reduce fear and stigma and address any potential impacts from the site. CNL recognizes the role it needs to play in supporting the reduction of fear and stigma associated with the nuclear industry, the WL site, and helping Sagkeeng reduce any potential trauma among its members in relation to the proposed the Project.

4.2.4.1.4.3 Addressing Sagkeeng Psychosocial Impacts

The Psychosocial Impact Assessment Report (Narratives 2020) attributes psychological trauma with each alternative, with the least amount of trauma associated with Alternatives #1 and #2. As stated above, the report indicates that Alternative #3 offers some immediate removal action that would be beneficial from a psychosocial perspective, however according to the report the presence of radioactive material in the long term would continue to be a source of significant distress. CNL believes Alternative #3 is the best option from a technological, practicable, safety to workers, and economic perspective; and provides protection to the public and the environment. Recognizing Alternative #3 is the least favoured option from Sagkeeng's perspective; CNL is committed to working collaboratively with Sagkeeng to develop and implement mitigation measures that are meaningful to Sagkeeng and will help to address Sagkeeng's concerns and ongoing/residual trauma.

As a starting place, Sagkeeng's consultation team, CNL, and AECL have established a Technical Working Group to work together to develop and implement initiatives that will help address Sagkeeng's concerns regarding the Project. The Technical Working Group has agreed to move forward on the following initiatives to help address Sagkeeng's concerns:

- a healing and resiliency action plan;
- a community liaison committee;
- a leadership table between Sagkeeng, AECL, and CNL;
- development and execution of Sagkeeng's CEMP that will include country foods monitoring; and
- a community-led risk communications program that is co-developed by Sagkeeng, CNL, and AECL.

In September 2021, CNL coordinated trauma informed engagement training for Sagkeeng, CNL, AECL and CNSC representatives to support the development of a healing and resiliency action plan . Following the training, CNL shared trauma informed training materials with Sagkeeng representatives. When the parties agreed to support the development of an independent CEMP Sagkeeng acknowledged that the program is part of a recommended approach to addressing fear and stigma.

Sagkeeng and CNL worked together to establish the Sagkeeng Niigan Aki CEMP program, which officially launched after the CEMP agreement was signed in late 2022.

4.2.4.1.5 Verification

CNL incorporated feedback through engagements with Sagkeeng on the Project, their TKLUS, Psychosocial Impact Assessment Report, Alternative Means Assessment Report, and country foods harvest survey. To confirm CNL has adequately captured Sagkeeng's interests and concerns, position, and knowledge, CNL and Sagkeeng underwent a review process whereby CNL provided EIS documentation, which included a summary of interests and concerns table, a list of Sagkeeng's Valued Components, and sections of the EIS, to Sagkeeng for their review and feedback. Upon receiving feedback on a document, CNL and Sagkeeng's Consultation Team met to confirm CNL's understanding of Sagkeeng's feedback, seek clarification where needed, and review CNL's proposed responses. Through this process, Sagkeeng has reviewed and provided feedback from their summary of interests and concerns table, list of VCs, Alternative Means Assessment write-up, psychosocial impact assessment write-up, Section 2.0, Section 4.0, Section 6.0, and Section 11.0. While not all of Sagkeeng's concerns were addressed by this process, CNL made every effort to verify that Sagkeeng's position, interests, and concerns were adequately characterized. Sagkeeng has indicated that it will further review the EIS when filed against comments made by Sagkeeng during this pre-filing period and will report to the CNSC thereafter. Sagkeeng is also part of the CNSC's Federal Provincial Indigenous Review Team. CNL continues to work with Sagkeeng to address their concerns through the Technical Working Group.

Sagkeeng and CNL are also working to co-develop a list of commitments for the EIS that will be specific to the Project. This commitments list was first shared in December 2023, with Sagkeeng providing written and oral feedback in January 2024. CNL and Sagkeeng met again and shared correspondence on the commitments list throughout 2024. Sagkeeng and CNL are in agreement that this list should remain a work in progress at this time.

For specific engagement related information on the verification process, see Section 4.2.4.1.1 Engagement, or see Appendix 4.0-1.

It is important to note that while CNL calls this a verification process, Sagkeeng does not view it has verification process when not all revisions and recommendations from Sagkeeng have been adopted into the content. CNL strove to represent the feedback from Sagkeeng as accurately as possible however Sagkeeng has been clear that this feedback, even when incorporated, should not be taken as an endorsement of the EIS or IER or the Project more broadly. Sagkeeng intends to review and comment on the whole EIS, including on the adequacy of incorporation of Sagkeeng inputs, when it comes out formally, and report Sagkeeng's findings to the Federal Provincial Indigenous Review Team.

4.2.4.1.6 Next Steps

CNL values how the relationship between Sagkeeng and CNL has grown and believes CNL's collective engagement efforts and collaboration through the Technical Working Group table have contributed positively to the environmental assessment of the Project and the Whiteshell Laboratories Restoration Project more broadly.

CNL will continue to work with Sagkeeng on the environmental assessment for the Project to address their concerns in a way that is meaningful to Sagkeeng. As determined through the leadership meeting in April 2021, this included establishing a Technical Working Group between AECL, CNL, and Sagkeeng to implement the following initiatives:

- Development of a community liaison committee
- Development of a Sagkeeng-led risk communications strategy
- Development of a healing and resiliency action plan

- Development of a leadership table among Sagkeeng, AECL and CNL
- Development of a meaningful Sagkeeng Indigenous monitoring program at and around the WL site

Through the persistent efforts of the Technical Working Group, CNL, AECL, and Sagkeeng have made significant progress towards successful implementation of three of the four initiatives listed above. CNL has supported the development of the Community Liaison Committee and has now moved into moved into a support role. On July 18, 2022, CNL hosted Sagkeeng's Community Liaison Committee for an on-site tour of the WRDF and the WL site. CNL and Sagkeeng have agreed to coordinate leadership tables as necessary and when key relationship milestones are reached. In September 2022, CNL and AECL agreed to provide funding support for the development and execution of an independent Sagkeeng CEMP, to the development of a meaningful Sagkeeng community driven monitoring program at and around the WL site. By the end of 2022, the Niigan Aki (CEMP) had officially launched.

Sagkeeng, CNL and AECL continue to discuss the healing and resiliency action plan, and where AECL and CNL may fit within the scope of what is proposed.

CNL will continue engagement with Sagkeeng to address or resolve outstanding issues or concerns to the extent possible regarding the Project and has demonstrated its commitment to ongoing engagement and relationship-building to support discussions regarding the future land use of the WL site.

4.2.4.2 Manitoba Métis Federation

The MMF is the democratically elected self-government representative of the Red River Métis. The Red River Métis are a distinct Indigenous people whose Treaty Rights have been recognized and affirmed as protected by section 35 of the *Constitution Act, 1982*, as well as by the courts, and through agreements with the Crown. The MMF represents and advances the interests of Red River Métis Citizens and harvesters that rely on and use the lands, waters, and resources of their traditional territory throughout the province of Manitoba and across the National Homeland.

The President functions as the Federation leader, spokesperson, and Chief Executive Officer. This position oversees day-to-day Federation operations and is elected through a province-wide election every four years. The President and Cabinet, comprised of 23 democratically elected Ministers, provides guidance, leadership, and management toward Federation (and its subsidiaries) policies, objectives and strategic direction. Seven Regions across Manitoba are administered by a vice-president and two executive officers, who are also of the Federation's Cabinet, and who administer programs and services independently to their specific geographic area. Each Region comprises various Locals. These Locals are administered by a chairperson, a vice-chairperson and a secretary-treasurer, and have a minimum of nine members that meet at least four times a year. Each Red River Métis Citizen belongs to a Local. Specific Locals determine the timing of election of their respective Local representatives, while Regional officers are elected every four years (MMF 2018).

Since 2016 when CNL started engaging MMF on the proposed Project, MMF's position has remained that complete removal and remediation (i.e., CNL's Alternative #2) of WR-1 should be selected as the decommissioning method.

It is MMF's position that, WR-1 was constructed and operated near the heart of the National Homeland of the Red River Métis without consultation. The effect of past decisions has been that the lands and waters which surround the WL site, and the ability of Red River Métis Citizens to use them, has been altered for generations. It is the MMF's end land use vision for the WL site to be restored to a completely functional environment achieving a state

where all lands and waters can function without restriction, a future which is incompatible with the proposed ISD approaches. Additionally, the MMF remain of the position that ISD, as a decommissioning approach, is only appropriate in exceptional instances (such as in the case of a nuclear incident), where complete removal and remediation is not possible - as ISD maintains a possible burden for future generations to manage.

Throughout the EA process for the Project, CNL has engaged with the MMF to determine how CNL and the MMF can work collaboratively to address the MMF concerns by:

- sharing information and build awareness about the proposed ISD of WR-1
- seeking to understand the Manitoba Métis Federation's Aboriginal and Treaty rights and main concerns and interests regarding the Project.

Over time, CNL has strengthened its relationship with the MMF, which has led to more engagements on the broader Whiteshell Laboratories Restoration Project and better understanding of the MMF's concerns, potential impacts, and how to collaborate on ways to help address these concerns of the Project.

In 2021, the MMF and CNL participated in a series of technical workshops on specific areas of interest to the MMF on the Project. Workshops included an overview of the ISD design, proposed groundwater monitoring program, the broader site's environmental protection program, the Alternative Means Assessment, and opportunity for collaboration. The workshops facilitated greater understanding of the concerns and interest of the MMF. As a result of the workshops, CNL committed to incorporating an additional ground monitoring station between the Project and the river as part of its post-closure monitoring program.

Through ongoing discussions CNL and the MMF identified initiatives that would help address the MMF's concerns of the Project. As a culmination of these discussions, in August 2023, the MMF and CNL signed a multi-year contribution agreement. This agreement established a series of ongoing engagement activities to improve communications between the parties, including an annual leadership meeting, the creation of an MMF liaison position, and invitation for Red River Métis participation in an Indigenous Advisory Committee. Other initiatives include the development of a communications protocol for reportable events, the development of plain language materials on CNL activities, and support to enable MMF participation in environmental monitoring and economic activities at the WL site.

It should be noted that in February 2024 the MMF notified CNL of the MMF's decision to end the 2023 agreement, citing a failure by CNL to maintain the confidence of the MMF in ensuring that its interests will be appropriately represented and considered by CNL. CNL respects the MMF's decision while continuing to share information. CNL remains open and interested in discussion with the MMF. CNL aspires to rebuild a productive partnership with the MMF to enable full participation of Red River Métis Citizens in the various projects, licensing, economic benefits, and environmental protection opportunities.

4.2.4.2.1 Engagement

CNL first reached out directly to the MMF in November 2016 after sending a formal letter requesting MMF input on the Project. The MMF and CNL had an introductory meeting in November where CNL provided an overview of their proposed change to the decommissioning of WR-1.

In 2017, CNL and the MMF continued to engage in discussions about the Project via teleconferences, site tours, and by attending MMF's Annual General Assembly. CNL set up a booth at MMF's Annual General Assembly and spoke directly to Red River Métis Citizens about the Project. CNL sent notification of the public comment period

on the draft EIS for the Project and invited the MMF to engage. The MMF participated in a site tour and discussion on the Project, and environmental risk assessment.

In September 2017, CNL provided an opportunity for five members from each First Nation community and the MMF to attend a full day workshop to both learn and share on how CNL and Indigenous Nations protect and care for the environment. The goal was to provide some hands-on experience coupled with ample discussion, learning and dialogue on career opportunities at CNL and on a relationship between the site and Indigenous Nations.

On October 31, 2017, CNL shared the Annual Safety Reports with each Indigenous Nation, including the "Environmental Monitoring in 2016 at Whiteshell Laboratories" report (CNL 2017a), and the "2016 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories" (CNL 2017b). CNL also provided an invitation to engage on these documents.

In 2018, the MMF, CNL, and CNSC set up a monthly recurring meeting to provide updates and discuss topics of interest. In 2018, there were seven update meetings. The MMF also participated in the Benchmarking trip to Hallam, Nebraska, to learn more about ISD. In March 2018, CNL and the MMF signed a Contribution Agreement to further support the MMF's' continued engagement in the environmental assessment process for the Project. At the end of 2018, the MMF participated in a tour of WRDF.

In 2019, the MMF completed their Traditional Knowledge, Land Use, and Occupancy Study, which was shared with CNL (TKLUOS; SVS 2019). Over the course of 2019, CNL, CNSC, and the MMF met eight times as part of their monthly meeting updates. In March 2019, CNL and the MMF discussed actions identified in the TKLUOS.

In August 2019, the MMF and CNL signed a Contribution Agreement for the MMF to observe environmental monitoring activities. One of the MMF's recommendations on CNL's environmental protection program was to include mushroom collection into their sampling program. CNL has since adjusted its environmental protection program to include mushroom collection based on that recommendation.

The MMF also participated in fall monitoring activities. At the MMF's 2019 Annual General Assembly, the MMF Minister of Energy & Infrastructure, spoke about CNL and indicated that it was an example of a positive relationship with the MMF and acknowledged CNL's work with the MMF on environmental monitoring.

In 2020, the MMF, CNL, and CNSC participated in six monthly update meetings at the start of the year, discussing interests including: participating in an Indigenous Advisory Committee, environmental monitoring, and developing a long-term relationship agreement.

In July 2020, the MMF observed a waste shipment from pre-job to completion of loading. In August 2020, CNL provided responses to the MMF's comments on the draft 2017 and 2020 EIS. The MMF and CNL also met that month to introduce CNL's new Indigenous Engagement Officer and discuss the MMF's comments on the Indigenous Advisory Committee Participation Agreement.

In September 2020, CNL provided a list of all fall monitoring activities and invited the MMF to participate. Following this email, the MMF participated in mushroom sampling at the WL site alongside CNL's environmental technicians.

On October 14, 2020, CNL received Métis Cultural Awareness Training provided by the Louis Riel Institute. While this was not a direct engagement with the Red River Métis, the training increased CNL, AECL and CNSC participants' knowledge on Métis history, culture, and the role of the Métis in the formation of Manitoba. Later that month, a Red River Métis representative visited the WL site and observed CNL's environmental technicians

process fish. During this visit, CNL's environmental specialist also provided an overview of CNL's environmental protection program.

At the end of the month on October 26, 2020, CNL hosted a teleconference with the MMF to discuss their comments on the draft EIS. The purpose of the meeting was to seek clarification on the MMF's comments and have a discussion on how CNL can address their concerns. During the meeting, a number of technical and non-technical workshops were suggested. The purpose of these workshops was to try to resolve outstanding concerns presented in the MMF's EIS comments.

Over the course of the next several months, the MMF and CNL planned this series of four workshops as well as an additional technical wrap-up meeting. The workshops focused on topics such as exploring opportunities for collaboration, in situ design and the Alternative Means Assessment, ground water flow and ground water well placement, and CNL's environmental protection program. The workshops were to create space between the Project's technical team and the MMF's technical team to ask questions and support a greater understanding of the CNL's consideration of the ISD design.

During a teleconference on November 12, 2020, the MMF made a few suggested edits to the workshops following which CNL sent out the revised draft agendas and scheduled a follow-up meeting to verify the changes made to the agenda.

On November 25, 2020, CNL invited the MMF to participate in CNL's 2020 virtual industry day being held December 9, 2020. The event was in partnership with the Organization of Canadian Nuclear Industries.

On November 26, CNL and the MMF held the first workshop to discuss the environmental initiatives and identify possible areas for collaboration, by teleconference. The purpose of this workshop was to identify areas of collaboration and mutual interest. The majority of the discussion was on the MMF's environmental and monitoring initiatives.

On December 17, 2020, CNL sent the MMF responses to their EIS comments, which identified any comment or concern that was out of the scope of the EIS and proposed clear next steps to help address the MMF's concerns.

On January 13 and 14, 2021, CNL had teleconferences with the MMF to plan for the upcoming workshops. On January 25, CNL sent the MMF an advance copy of the draft EIS.

CNL had two additional planning meetings on January 27 and February 2, 2021, to discuss the goals, objectives, and agendas for the next workshop. The ground water and groundwater monitoring wells workshop with the MMF was held on February 9, 2021. The main topics of this workshop included surface water and groundwater movement over the WL site and the placement and number of the planned ground monitoring wells around the Project. In particular, the MMF had raised concerns around intervals water monitoring planned for the Project and current monitoring and mitigation. During this workshop, the MMF made a recommendation to put a well closer to the river. CNL suggested that installation of a new well close and asked if that would help address the concerns about groundwater. Representatives from the MMF emphasized the importance of understanding the current quality of the groundwater to the reactor would provide faster and potentially more accurate detection of any movement of contaminants.

As a result of this feedback and discussion at the workshop, CNL has included an additional ground monitoring well into their proposed follow-up monitoring program, which is to be located between the Project and the Winnipeg River.

CNL and the MMF held a follow-up teleconference on February 15, 2021, to discuss action items for the meeting and the outcomes of the workshop. At this meeting, CNL reaffirmed their commitment to adjusting the follow-up monitoring program to include an additional groundwater monitoring well.

On February 18, 2021, CNL and the MMF met via teleconference 2021, to explore opportunities for collaboration in areas of mutual interest including environmental monitoring and environmental sustainability. During this meeting, CNL learned about the multiple green initiatives the MMF was developing and leading.

CNL and the MMF created a list of long-term opportunities for collaboration specifically in site-wide tree planning, river erosion protection, and future land use. CNL and the MMF also created a list of possible short-term objectives to be completed by the end of the fiscal year, which included support for one of MMF's green initiatives such as the Red River Métis' commitment to plant two million trees, their environmental monitoring program, and Citizen science program. Both CNL and the MMF took away the list to discuss internally.

In the meantime, the series of technical workshops continued with a workshop on the Project's Alternative Means Assessment and methodology for choosing Valued Components (VC) on March 2, 2021. Most of the questions posed by the MMF's technical team during the meeting centred on international and federal regulations, oversight, and guidance as well as how the Project considered and adhered to those federal regulations, oversight, and guidance. Note that Section 6 details VCs, including methodology and how VCs from Indigenous Nations are accounted for in the environmental assessment.

On March 9, 2021, CNL and the MMF met via teleconference to discuss the development of the relationship agreement and liaison position for the Project. CNL and the MMF held a final workshop to discuss CNL's environmental protection program and opportunities to incorporate Traditional Knowledge into CNL's current environmental monitoring practices. CNL and the MMF created action items to discuss further opportunities for participation of Métis Citizens in environmental monitoring on site and to discuss supporting the MMF's green initiatives.

As a result of all the engagement that took place in the first half of 2021, CNL created an infographic to illustrate the engagement that had taken place. The infographic included a list of engagements plus a brief description about each engagement. CNL sent the infographic to the MMF on April 12, 2021.

On May 11, 2021, CNL, the MMF held a wrap-up workshop to:

- review the four technical workshops (i.e., topics covered, associated comments/concerns, action items, current commitments);
- discuss the status of comments/ concerns, associated commitments, and appropriate ways to address any outstanding concerns and how the information will be reflected in the EIS; and
- chart a path forward on remaining environmental assessment reviews and next steps.

The commitments, which evolved out of the workshop series, were to address the MMF's concerns involved having the MMF involved in all aspects of current and future environmental monitoring on site. Commitments included participation in CNL's annual environmental monitoring activities, the MMF's involvement in the development and implementation (including participation) of post closure environmental monitoring, and an additional groundwater monitoring well.

As a follow-up to the wrap-up workshop, CNL and the MMF met on May 25, 2021, to discuss their involvement in the 2021 environmental monitoring field season. During the meeting, the MMF identified what field monitoring they would be interested in participating in and activities they would want to have Métis Citizen scientists participate in. CNL and the MMF also briefly discussed the types of support the MMF would need to participate in on site monitoring.

With the technical workshops complete, the MMF and CNL met on June 2, 2021, to discuss the relationship agreement. The MMF and CNL developed the main elements of an agreement and discussed the process to help develop and implement the relationship agreement in a timely, mutually beneficial manner.

On June 2, 2021, CNL sent the MMF a letter requesting their review of the summary table of interests and concerns, which CNL had developed based on engagements and the MMF's TKLOUS (TKLUOS; SVS 2019). CNL had also developed a list of VCs for the MMF based on feedback from past engagement, the MMF's harvester consumption survey, and the MMF's TKLUOS. Note that Section 6 details how VCs from Indigenous Nations are accounted for in the environmental assessment.

In that same June 2 letter, CNL asked the MMF to verify whether CNL had adequately characterized the MMF's interests and concerns. In the letter, CNL offered to provide capacity funding and to meet with the MMF to discuss the interests and concerns table and list of VCs.

On July 26, 2021, the MMF sent CNL feedback on the summary of interests and concerns table and list of VCs. At this time, CNL accepted all tracked changes for both documents from the MMF and sent back the two revised documents on August 19, 2021, which reflected how CNL had incorporated the MMF's feedback. CNL sent a final thank you letter to the MMF on August 24, 2021, thanking the MMF for their participation in verifying CNL had adequately captured their summary of interests and concerns and their list of VCs. It should be noted, that since then, CNL has shared updated versions of the interests and concerns table, with the most recent being shared in October 2024, and the MMF has also shared more recent feedback, which was incorporated into the final version of the interests and concerns table.

With almost all the engagement focused on the Project, CNL and the MMF felt it was timely to discuss the progress made for the Whiteshell Laboratories Restoration Project. Therefore, on June 3, 2021, CNL provided the MMF with an overview of building decommissioning that had been completed to date and planned decommissioning for the next fiscal year. During the meeting, CNL asked the MMF whether they had reviewed the summary table of interests and concerns and list of VCs and whether they required any capacity support. The MMF stated they need to have an internal discussion first and would get back to CNL.

On June 8, 2021, CNL and the MMF held a teleconference to continue their discussion on their participation in CNL's environmental monitoring. The MMF identified which activities they wanted to participate in and which they would like their Citizen scientists to participate in.

Following this discussion, on June 14, 2021, the MMF staff participated in ground water monitoring, a turtle search along the plant road, and a songbird survey. As a part of participation in the turtle search, the MMF staff suggested setting up trail cameras along the Plant Road to better assess whether turtles were in the area.

On June 22 and 23, and July 13 and 14, 2021, the MMF staff and Métis Citizen scientists participated in evening bat surveys for Building 100 where WR-1 is located. The purpose of the survey was to help assess whether bats were roosting in the building. On June 29, 2021, the MMF and CNL signed an MOU to support the MMF's involvement in environmental monitoring on site. In particular this was to support the MMF participation in the 2020

and 2021 summer field seasons and for the MMF to share Métis specific knowledge to enhance CNL's existing monitoring program.

On June 23, 2021, CNL and the MMF met to continue their progress on developing a relationship agreement. This meeting focused on fine tuning the language for the main initiatives identified to help to address the MMF's concerns on the Project, including monitoring participation.

On July 6, 2021, CNL and the MMF met via teleconference to confirm the language in the revised draft relationship agreement and discuss specific edits required to move forward. On July 12, 2021, the MMF provided feedback on the relationship agreement.

On July 26, 2021, CNL and the MMF signed an MOU to support the Manitoba Métis Federation's participation in the environmental assessment process for the Project.

On August 9, 2021, CNL sent a revised copy of the relationship agreement to the MMF for their review and feedback. On August 12, 2021, the MMF participated in a tour of the WR-1 Building and the waste management area. On August 16, 2021, the MMF came to site and observed river sediment, soil, and vegetation sampling.

On August 19, 2021, the MMF, the CNSC, and CNL participated in a trilateral meeting to discuss that status of interests and concerns and the relationship agreement. The MMF and the CNSC were going to meet and do a cross reference between the CNSC table of concerns and the table that CNL had developed. After submission of the revised draft EIS, CNL would assess the summary of interests and concerns and clearly state the responsible party to address the MMF's concerns. On that same day, CNL and the MMF met to discuss the relationship agreement. CNL and the MMF finalized the major initiatives and then turned to discuss the budget for each item. CNL also met with the MMF on August 19, 2021, to discuss support for the Red River Métis' green initiative and begin to identify which green initiative project required the most support. It was identified that the Red River Métis' initiative to plant two million trees needed the most support and after the meeting CNL held internal discussions on how to best support the initiative. On August 30, 2021, CNL sent the MMF a revised budget for the relationship agreement for their review and feedback.

After a few follow-up emails between the MMF and CNL, the MMF and CNL signed a MOU on September 8, 2021, to support the Red River Métis' purchase of 5,000 tree saplings. On September 9, 2021, the MMF staff came to site to participate in mushroom collection on site and in the surrounding area. The MMF recommended CNL cut the mushrooms at the stem when they collect the mushrooms so that the mushroom has an opportunity to grow up. CNL has adopted this method into their environmental practices.

On September 21, 2021, CNL and the MMF held a teleconference to discuss the draft budget, and economic participation and opportunities section in the relationship agreement. CNL sent a revised draft budget and relationship agreement to the MMF on September 29, 2021. CNL reached out to the MMF on September 29, 2021, to provide and confirm the updates made to the budget of the relationship agreement based on the previous meeting.

The month of November of 2021, saw many discussions and engagement activities with the MMF. On November 15, 2021, the MMF completed a technical review of CNL's annual compliance monitoring reports for the WL site and provided CNL with a copy. CNL hosted a teleconference with MMF on November 17, 2021, to discuss CNL's alpha targeted therapy project, which was an action from the MMF, CNL, and AECL Leadership Meeting. Active discussions on the relationship agreement occurred in November. On November 18, 2021, CNL revised the relationship agreement to include both the MMF's and CNL's legal review and sent the revised agreement to the

MMF. On November 22, 2021, CNL met by teleconference with the MMF to review the changes recommend by both party's legal counsel. CNL and the MMF discussed additional revisions that were still required related to the topic of procurement.

CNL sent the MMF several EIS sections (Section 4.0, Section 6.7, Section 6.8, and Section 11.0) on November 26, 2021, with the request for MMF review of these sections and confirmation that CNL has adequately addressed the MMF's concerns and correctly captured the MMF's information. CNL sent Section 6.9 to the MMF on November 30, 2021 and asked the MMF to review to confirm CNL had documented the MMF's information correctly.

On December 7, 2021, CNL sent a revised copy of the relationship agreement to the MMF. This included additional revisions from the teleconference and further revisions on the procurement language. CNL sent the MMF a signed copy of an MOU on December 13, 2021, to support the MMF's technical review of the EIS sections. The MMF returned feedback on Sections 4.0, Section 6.7, Section 6.8, and Section 11.0 on December 19, 2021. On December 28, 2021, MMF sent feedback on the draft relationship agreement.

A meeting with the MMF was held on January 6, 2022, to discuss the relationship agreement, where feedback was provided, and revisions were discussed. On February 17, 2022, CNL sent a revised copy of the relationship agreement to the MMF for review and feedback. On the same day, CNL sent the MMF revised copies of the sections of the EIS that the MMF reviewed and highlighted where any changes were made based on their feedback. CNL also provided a table to show how CNL addressed each of the MMF's concerns. Additional sections of the EIS were provided if they were referenced in CNL's responses. CNL highlighted specific passages in these sections to help the MMF in their review of this information.

There were many engagement activities between CNL and the MMF in March of 2022. On March 2, 2022, with a meeting between CNL and the MMF's communication director to discuss co-developing an infographic in preparation for the MMF's Annual General Assembly. On March 15, 2022, CNL informed the MMF that CNL would be repackaging their interests and concerns table and on March 16, 2022, the MMF confirmed they would review the repackaged table. CNL participated in the MMF's Annual General Assembly from March 24 to 27, 2022. CNL had a booth at the event and engaged with Red River Métis Citizens on the Whiteshell Laboratories Restoration Project. On March 29, 2022, CNL held a teleconference and walked the MMF and their consultants through the repackaged interests and concerns table and discussed their review and timeline. CNL and the MMF also discussed Red River Métis Rights, claims, and interests. CNL sent the MMF the repackaged interests and concerns table on March 31, 2022, for the MMF's review and feedback.

On April 16, 2022, CNL received the MMF's revised relationship agreement for CNL's consideration. CNL held a teleconference on April 25, 2022, with the MMF and their technical consultants to go over the MMF's repackaged interests and concerns table before their review. On May 18, 2022, CNL walked through the MMF's interests and concerns table and the MMF's feedback on the table. CNL focused on items where they would need to revise the MMF's proposed language and provided an explanation. Later in May on May 25, 2022, CNL and the MMF discussed the relationship agreement and Indigenous economic participation. On May 27, 2022, the MMF provided an additional round of feedback on the interests and concerns table. CNL sent back the revised interests and concerns table on May 30, 2022, to show that the MMF's revisions were incorporated.

On June 7, 2022, CNL welcomed the MMF's new coordinator at the WL site to collect mushrooms with CNL's environmental team. CNL asked the MMF on June 13, 2022, to confirm that they have completed the verification of their interests and concerns table. On June 16, 2022, the MMF provided confirmation that the table was reflective of their interests and concerns.

CNL met with the MMF on July 6, 2022, to discuss the status of the relationship agreement, environmental monitoring activities on site, and future engagement activities. CNL sent the revised relationship agreement back to the MMF on July 13, 2022, for their review and feedback. Also, in July on July 28, 2022, CNL hosted the MMF on-site to participate in ground water sampling around the main campus.

August 2022 saw further focus on the relationship agreement. At the monthly meeting on August 8, 2022, the discussion between CNL and the MMF focused on the relationship agreement. CNL presented at the MMF Community Consult Meeting in Lac du Bonnet on August 10, 2022. CNL shared information on their environmental monitoring program and answered questions from Red River Métis Citizens. Red River Métis Citizens participated in a bat survey at the WL site in the evening of August 17, 2022. On August 30, 2022, CNL sent a copy of CNL's environmental monitoring program schedule and requested the MMF identify any activities of interest.

On September 7, 2022, at the monthly meeting, CNL and the MMF discussed the status of the relationship agreement, environmental monitoring and future engagement activities on the Project. CNL provided revisions to the relationship agreement for the MMF's review and feedback on September 9, 2022; these revisions are believed to have addressed any outstanding issues or concerns. On September 11, 2022, CNL confirmed with the MMF that CNL would sponsor and participate in the trade show at the MMF Annual General Assembly from October 14-16, 2022. On September 16, 2022, CNL provided formal written responses to the MMF's comments on CNL's 2020 Compliance Reports for the WL site.

Throughout the last quarter of 2022, there was ongoing communication and engagement between the MMF and CNL. On September 22, 2022, there were emails between the parties regarding the participation in scheduled CNL monitoring activities. On September 26, 2022, CNL sent an email to the MMF inquiring on the status of the relationship agreement.

There was no monthly meeting in October 2022, however, CNL and the MMF met on October 19 to discuss CNL’s responses to the MMF comments on past annual compliance and monitoring reports.

At the November monthly meeting on November 22, 2022, the MMF and CNL discussed the MMF reviewing updates to Section 4 of the EIS prior to the submission of the EIS. In follow-up to this meeting, later in the month and again in December, CNL reached out to confirm the MMF’s verification of CNL’s incorporation of the MMF’s review of sections of the EIS. On December 7, the MMF confirmed their review and noted that the MMF had no further changes to make.

On December 1, 2022, the MMF Energy and Infrastructure Coordinator, and MMF Water Resources Specialist attended the WL site to participate in environmental monitoring. CNL followed up on this activity by reaching out to the MMF within a week with a summary of environmental monitoring activities. In this follow-up, CNL’s Indigenous Relations Advisor also inquired whether the MMF shared information about MMF involvement in environmental monitoring with the Red River Métis Citizenship and if the MMF did, CNL was interested in discussing how CNL could support enhancing these types of reports and activities.

Another meeting happened a few days later on December 7 when the MMF and CNL met to discuss expanding the MMF’s monitoring program, the relationship agreement, addressing MMF’s feedback on the Regulatory Oversight Report and the priorities for engagement in 2023.

The next monthly meeting was held on January 12, 2023. Topics of discussion included the relationship agreement, expanded MMF monitoring, developing a commitments list related to the Project and land use and end state.

A few days later, CNL shared with the MMF that the CNSC had accepted the EIS for technical review (January 16) and provided the MMF with the 2023 Environmental Monitoring Field Sampling Schedule (January 17). This information was to facilitate environmental monitoring throughout 2023. Around this time, an HR staff person from CNL also coordinated with the MMF to share CNL job postings (January 17, 2023), which was in response an ongoing interest in employment.

The February monthly meeting was held on February 5, 2023 and was a continuation of discussion on topics from the January monthly meeting including relationship agreement, expanded MMF monitoring, developing a commitments list related to the Project and land use and end state.

On March 1, 2023, CNL and the MMF held their monthly meeting continuing discussion on the above items as well as an update on the Project and more specifically, the monitoring discussion focused on an MMF-led Harvester Sampling Plan. In March CNL also provided the MMF a draft copy of the CNL Indigenous Relations Procurement Strategy for review, as well as a plain language fact sheet on the elevated levels of manganese that had occurred at the WL site.

On April 4, 2023, the MMF and CNL signed a Memorandum of Agreement (MOA) contribution agreement. This agreement established a series of ongoing engagement activities to improve communications between the parties, including an annual leadership meeting, the creation of an MMF liaison position, and Red River Métis participation in an Indigenous Advisory Committee. Other initiatives include the development of a communications protocol for reportable events, the development of plain language materials on CNL activities, and support to enable MMF participation in environmental monitoring and economic activities at the WL site.

On April 4, 2023, CNL also shared a preliminary table of commitments sought by MMF through engagements and comment responses for the Project.

Discussions at the April monthly meeting, held on April 5, 2023, included the CNL Indigenous Relations Procurement Strategy, the 2023 Regulatory Oversight Report, developing the contribution agreement and monitoring. Mid-April of 2022, MMF representatives attended the WL site for spring sampling at the lagoon as well as a meeting and site tour.

On May 3, 2023, the MMF and CNL held their monthly meeting where discussion focused on the recent Whiteshell Safety Stand Down, the Federal Provincial Indigenous Technical Review and the developing agreement. On May 25, 2023, the MMF emailed CNL to confirm the MMF's preferred mushroom sampling method in advance of the MMF's first harvest sample collection activity, planned for May 31, 2023. This was the first sampling event coming out of the MMF's interest in expanded sampling and monitoring through an MMF-led Harvester Sampling Plan.

The June monthly meeting was held on June 21, which was a continuation of the topics of discussion from the May meeting.

The next monthly meeting was held on August 2, 2023. The focus of discussion here was the Safety Stand Down at Whiteshell, the MMF liaison position and a general round table. Of importance to the Project, CNL and the MMF met in twice in August (on August 17 and August 25) to discuss the Interests and Concerns table and the MMF commitments list.

On August 29, 2023, CNL requested a meeting with MMF to review and discuss the commitments list. Again, on September 28, 2023, CNL emailed MMF requesting availability of dates for a meeting to review and discuss the commitments list.

The October monthly meeting on October 4, 2023, was a discussion on fire protection and the Safety Stand Down, as well as plans for a site tour and CNL attending the MMF AGA. Later that month CNL had a booth at the 2023 MMF AGA from October 13 to October 15.

On October 17, 2023, the draft commitments list was emailed to MMF in preparation for the meeting scheduled for October 18, 2023. On October 18, 2023, CNL met with MMF in-person at the MMF offices located at 90 Sutherland in Winnipeg, Manitoba to discuss the commitments list. On October 18, 2023, the MMF also sent key edits for the WR-1 EIS to CNL, which CNL has since incorporated. On October 20, 2023, CNL sent an email of thanks to MMF for hosting the October 18 in-person meeting. A brief synopsis of the discussion points was noted in the email. On October 24, 2023, CNL sent an email to MMF as a request for a follow-up meeting from the October 18 in-person meeting, to continue the discussions on the work toward the co-development of the commitments list based on the feedback received from MMF at the October 18 CNL-MMF meeting.

On November 3, 2023, CNL emailed MMF the revised commitments list based on the feedback CNL received from MMF during the in-person meeting on October 18, 2023. The MMF and CNL met twice on November 6, one meeting was held virtually to discuss the MMF's feedback on the CNL Indigenous Relations Procurement Strategy and the other was a tour involving monitoring at the WL site. On November 7, 2023, the MMF emailed CNL confirming they received the revised commitments list document.

On November 14, 2023, CNL and MMF met to review the updated commitments list. On November 16, 2023, CNL emailed MMF the revised commitments list based on the feedback CNL received from MMF during their meeting on November 14, 2023. On November 29, the MMF and CNL met and discussed the MMF feedback on this email, CNL requested MMF verify that CNL and the MMF have jointly discussed and verified the commitments list and that the MMF agreed that the list captured the commitments CNL has made to the MMF. Later the same month, the MMF attended the WL site to participate in the WMA well field sampling.

On December 6, 2023, MMF sent CNL confirmation that CNL and MMF have jointly discussed and verified the CNL-MMF commitments list and MMF agreed that the list captured the commitments CNL has made to the MMF. And further, MMF verified that CNL and MMF will work together on formalizing a CNL-MMF communications protocol (including engagement, plain language documentation, reportable events), intellectual property on MMF monitoring data that can be shared with CNL, and MMF recruitment and procurement processes. MMF also noted that these commitments have been identified as requiring further work so that there are protocols and processes that address the commitment and the MMF is comfortable with the status of the commitment and the process to move the items forward.

In January 2024, the MMF and CNL emailed back and forth on a number of items including leadership change at the WL site, a company wide community information bulletin, the MMF's invitation for CNL to participate in the 2024 Climate Symposium and a job posting for a new Indigenous Engagement Officer at the WL site.

On January 8, 2024, CNL sent an email to MMF confirming that the upcoming recurring monthly meeting scheduled for January 15, 2024, with an agreed upon agenda consisting of review of the information requests and outstanding commitments sought and discussion of a draft workplan that will inform and guide the completion of the outstanding commitments sought. The monthly meeting was held on January 15 and discussion was focussed around the CNSC information requests for the Project, as well as the commitments. Another meeting between the MMF and CNL was held on January 24 and was a touch base on the MMF Workplan, MMF harvesting samples, the MMF Climate Symposium and the decommissioning conference in California that both CNL and the MMF were attending.

On January 29, 2024, CNL sent an email to MMF attaching CNL's draft workplan documents meant to be a starting point to flesh out action items and key leads on the work that will address the outstanding commitments sought by the MMF. In this email, CNL sought confirmation on the February 7, 2024, scheduled monthly touch base meeting for MMF and CNL. On February 7, 2024, MMF emailed CNL cancelling that day's meeting scheduled with CNL to review the draft workplan documents for the outstanding commitments. CNL responded the same day indicating that CNL would work with MMF to reschedule the meeting.

In February 2024 the MMF notified CNL of the MMF's decision to end the 2023 agreement, citing a failure by CNL to maintain the confidence of the MMF in ensuring that its interests will be appropriately represented and considered by CNL. CNL respects the MMF's decision while continuing to share information. CNL remains open and interested in discussion with the MMF. CNL aspires to rebuild a productive partnership with the MMF to enable full participation of Red River Métis Citizens in the various projects, licensing, economic benefits, and environmental protection opportunities.

Information shared between the MMF and CNL between February 2024 and the end of July 2024 have included:

- CNL sharing information on how to participate in the CNSC's public hearing for the WL site licence renewal, which is to be held in October 2024;
- CNL inviting the MMF to participate in the 2024 Regional Leaders Gathering and CNL's April and June public webinars (note that one April webinar topic was the Whiteshell Fire Program);
- CNL providing the engagement section of the IER for MMF review (March 2024);
- CNL sharing information on the CNSC's Indigenous and Stakeholder Capacity Fund (April 2024), on student job opportunities (May 2024) and staffing changes (June 2024);
- CNL inviting the MMF to review the engagement section of CNL's Commission Member Document for the 2024 licence renewal hearing and CNL sharing this section in June 2024; and
- The MMF providing comments back on the engagement section for the Commission Member Document in June, which suggested that CNL should update language to reflect the current status of the relationship.

Note that CNL incorporated the suggested changes on the Commission Member Document (CMD) for the 2024 WL site licence renewal hearing and shared these back with the MMF, who came back with further comments in July 2024, which CNL also incorporated into the CMD.

While engagement was not ongoing with the MMF as of July 31, 2024, CNL aspires to rebuild a productive partnership with the MMF to enable full participation of Red River Métis Citizens in the various projects, licensing, economic benefits and environmental protection opportunities.

4.2.4.2.2 Interests and Concerns

The MMF and CNL have had extensive engagement on the Project. Through a variety of engagement forums including technical workshops, webinars, and meetings, the MMF has raised issues, concerns and questions that were initially focused on the 2017 and 2020 draft EIS. These engagements have led to the development of the interests and concerns table. This subsection is taken from the tables of interests and concerns from Appendix 4.0-1 and describes CNL's understanding based on written submissions and oral discussions with the Red River Métis Citizens. CNL continues to work on responding to the Red River Métis' 24 formal comments on the 2017 draft EIS, which the MMF shared with the CNSC during the public comment period on the draft EIS; to date the MMF has fully accepted 14 comments and considers 9 to be partially addressed. The MMF has since

joined the Federal Provincial Indigenous Review Team for the environmental assessment and further comments are expected through that avenue, which CNL will be required to address as a part of the environmental assessment process.

See Appendix 4.0-1 Tables of Interests and Concerns for a list the Red River Métis' concerns. The MMF have also provided feedback during engagements including the technical workshops where the MMF and CNL and their technical experts discussed key topics of interest related to the Project including the in situ design, Alternative Means Assessment, and post closure follow-up monitoring. The MMF has also provided feedback through their Traditional Knowledge and Land Use and Occupancy Study and the harvester consumption survey. CNL has made its best efforts to document and verify the position the MMF has taken on each interest/concern. See Section 4.4 for a summary of issues raised during engagement activities that influenced the scope of the environmental assessment.

The topics in the Table of Interests and Concerns are briefly summarized below:

Long Term Relationship

The MMF and CNL have invested in the development of a positive and collaborative relationship since 2017. A relationship agreement will support implementation of commitments to address the Red River Métis' interests and concerns, including providing appropriate capacity.

On April 4, 2023, CNL and MMF signed the MOA between the MMF and CNL. This agreement established a series of ongoing engagement activities to improve communications between the parties, including an annual leadership meeting, the creation of an MMF liaison position, and Red River Métis participation in an Indigenous Advisory Committee. Other initiatives include the development of a communications protocol for reportable events, the development of plain language materials on CNL activities, and support to enable MMF participation in environmental monitoring and economic activities at the WL site.

Also during 2023, CNL and the MMF worked together on the commitments sought by the MMF on the EIS. On December 6, 2023, the MMF sent CNL confirmation that CNL and MMF jointly discussed and verified the CNL-MMF commitments list and the MMF agreed that the list captured the commitments CNL had made to the MMF. Further, the MMF verified that CNL and the MMF would work together on formalizing a CNL-MMF communications protocol (including engagement, plain language documentation, reportable events), intellectual property on MMF Monitoring data that can be shared with CNL, and MMF recruitment and procurement processes. The MMF also noted that these commitments had been identified as requiring further work so that there would be protocols and processes that addressed the commitment and the MMF was comfortable with the status of the commitment and the process to move the items forward.

Based on MMF's direction in December 2023, CNL drafted a workplan on the outstanding commitments identified as requiring further work and on January 29, 2024, CNL sent the draft workplan to MMF which was a document meant to be a starting point to flesh-out action items and key leads on the work that would address the outstanding commitments sought by the MMF. In this email, CNL sought confirmation of the February 7, 2024, scheduled monthly touch base meeting for the MMF and CNL.

While the agreement has dissolved by the MMF in February 2024, CNL has continued sharing Project information with the MMF and in August 2024 engagement channels reopened to support work between the MMF and CNL, and CNL is still dedicated to the commitments it made to the MMF.

The Health of the Winnipeg River and Confidence in Métis Harvesting near the Whiteshell Laboratories Site

The MMF indicated that the health of the environment, plants, and wildlife relied on for harvesting activities as well as the risk to people in the area of the Project site are of great concern to the Red River Métis Citizens. The MMF also had a series of questions on the WL site's discharge to the Winnipeg River, including the potential for CNL's discharge licence to trigger an environmental assessment and if the site's discharge has any effects on Manitoba Hydro operations. The MMF have indicated they want to be able to share factual and timely information about the WL site with Métis harvesters so they have confidence to conduct their Métis Harvest Rights. The MMF also raised concerns that the MMF be notified within 21 days of construction activities so Métis harvester's Rights would not be affected as a result of construction related activities, which may disturb or displaced wildlife.

During the 2020 Regulatory Oversight Report meeting, the MMF provided recommendations on how CNL can continue to progress its relationship with the MMF through more active involvement in environmental monitoring activities on site. The MMF would like to see more opportunities for participation in environmental monitoring program development and implementation, beyond simply observation.

To help to address these concerns, CNL has committed to collaborating on a MMF wildlife and environmental monitoring program for the WL site, during a technical wrap up meeting on May 11, 2021, to address concerns regarding the health of the environment. CNL also committed (May 2021) to funding a liaison position and supported the Red River Métis' participation in the Indigenous Advisory Committee. These initiatives will improve communication about site activities and support alleviating concerns about the Project. In addition, CNL has committed to establishing a communication protocol for reportable events with the MMF so that Métis harvesters are notified in the unlikely event of any off-site effects such as noise or other activities that may impact harvesting activities. This commitment was affirmed during a workshop in November 2020.

In 2023 the MMF began expanded sampling and monitoring at the WL site through the MMF-led Harvester Sampling Plan. Engagement and monitoring/sampling with the MMF will continue to inform environmental protection for the Project and at the site.

The parties will consider these concerns to be fully addressed once the MMF and CNL assess the success of the implemented commitments and confirm they address the MMF's concerns.

Regulatory Process

The MMF expressed a concern regarding participant funding from the CNSC within the Environmental Assessment process for the Project to date. Participant funding is granted by the CNSC to enable participation in environmental assessments and other projects where Treaty Rights are potentially impacted. The MMF wanted to confirm that they had capacity, resources, and opportunity to exercise their Right to be consulted on and participate in projects that might adversely impact their Section 35 Treaty Rights.

With respect to capacity, CNL has committed to ongoing capacity funding to MMF beyond the funding provided by CNSC. Since the beginning of the Project, to support MMF participation in the environmental assessment for the Project, CNL has provided capacity for technical reviews, studies, general engagement (including meetings, staff time, and consultant support), and environmental monitoring participation through several agreements. CNL has an open offer of capacity funding for different areas of MMF interest related to consultation on the environmental assessment for the Project. CNL is committed to involving the MMF so that are engaged in a respectful and meaningful manner on the environmental assessment for the Project and that the MMF have the capacity to be meaningfully engaged about their Treaty Rights, claims and interests on the Project. CNL will

continue to engage the MMF on the Project and closure of the WL site throughout the licensing process and Project implementation.

Another aspect of the environmental assessment where the MMF expressed interest was in the VC list for the Project. The MMF provided a list of requested additions to the VC list as a method of ensuring the Treaty Rights, Interests, and claims of the Red River Métis were appropriately considered in the assessment for the Project. These additional VCs were important for the MMF to see included in the EIS as a method for ensuring that factors that could impact the both the Treaty Rights and well-being of the Red River Métis were considered as part of the assessment. In addition, the MMF also want to confirm that the exercising of Treaty Rights by Métis Citizens is avoided, Métis specific mitigations implemented, or Métis specific accommodation are provided.

CNL, with support from the CNSC, funded the Whiteshell Reactor #1 Decommissioning: Manitoba Métis TKLUOS (SVS 2019). CNL has incorporated information from the TKLUOS into the draft EIS. CNL has subsequently revised the draft EIS and included elements of the TKLUOS in Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations.

In June 2021 CNL provided a list of VCs for the Project to the MMF. CNL then proceeded to draft a list of the MMF's VCs based on information from engagement activities with the MMF, the MMF's MTKLUOS, and the Red River Métis's harvester consumption survey. CNL verified the VCs with the MMF and for each VC, either:

- Confirmed it was encompassed by the assessment.
- Added it to the assessment.
- Added it to the model to be assessed.
- Did not add it to the assessment, with rationale provided.

CNL confirmed that potential impacts to the environment that could impact Aboriginal and Treaty Rights and claims are considered under the Traditional Land and Resource Use VC in Section 6.8.1.3.

Specific to the Aboriginal Treaty Rights, interests, and claims, CNL has indicated that the CNSC is responsible for making determinations on and assessing any impacts to Aboriginal and Treaty rights. As the CNSC develops the Indigenous Rights Impact Assessment for the Project, there is an opportunity for the MMF to work with the CNSC on that assessment of Treaty Rights.

CNL's view is that the steps CNL has taken adequately addresses this area of interest to the extent possible, while acknowledging that the MMF may not feel the same way.

In Situ Disposal Option

The MMF has indicated that they do not view the ISD as compatible with the MMF's end land use state goals/vision, in part because ISD will not allow for the full restoration of the landscape that enables the River Métis Citizens to fully exercise their unrestricted Treaty Rights to the land. In addition, it is MMF's position that CNL's decision to move forward with ISD further burdens future generations of Red River Métis who will shoulder the same concerns and encroachments of Treaty Rights as presented by MMF.

CNL recognizes that the Red River Métis' preferred decommissioning approach for WR-1 is full removal. CNL's view is that the steps CNL has taken adequately addresses this area of interest to the extent possible at this time.

While CNL and the MMF do not agree on the method of decommissioning, the parties have agreed to continue to work collaboratively so that any outstanding concerns are resolved to the extent possible.

Traditional Land Use

The MMF noted that regulators may notice and flag the absence of Traditional Knowledge in the EIS. The MMF has a catalogue of Traditional Knowledge but does not have the capacity to analyze it for gaps and relevance to the WL site. The MMF notes that a TKLUOS should be undertaken as neither the previous Comprehensive Study Report nor the current monitoring reports consider Métis harvesting. The MMF indicates that CNL should also include monitoring and follow-up programs for potential effects to culturally important terrestrial species, like Moose. The MMF recommends that CNL complete a thorough effects assessment on species of traditional importance to the MMF identified in a Project-specific TKLUOS, as the MMF wants to ensure the Red River Métis' Section 35 Treaty Rights to use lands and resources near the WL site are considered by CNL and not impacted by site and Project activities.

To help address this concern, CNL drafted the EIS to clearly state that Red River Métis Citizens conduct traditional activities and land use near the WL site. CNL funded a traditional food consumption study of which 21 Red River Métis Citizens of the community responded. The MMF carried out the survey and the data was provided back in the community feedback report. CNL has used the data to confirm that the Harvester model is a conservative model for modern day Indigenous people that rely on harvesting for some of their food. The results confirmed that the intake rates assumed in the Harvester model in the EIS are conservative compared to the MMF survey and the post closure safety assessment is also conservative.

CNL undertook research on Red River Métis traditional land use when preparing the draft EIS, however, the MMF indicated in meetings with CNL and CNSC, Métis specific knowledge of the region does not necessarily exist in written documents and needed to be obtained first-hand. As such CNL, with support from the CNSC, funded the Whiteshell Reactor #1 Decommissioning: Manitoba Métis TKLUOS (SVS 2019). CNL has incorporated information from the TKLUOS into the draft EIS. CNL has subsequently revised the draft EIS and included elements of the TKLUOS in Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations. CNL's view is that the steps CNL has taken adequately addresses this area of interest to the extent possible.

CNL has also used the TKLUOS to verify the Project's VCs and created a list of VCs for Red River Métis. The MMF has verified that these VCs adequately capture the species and areas of interest and concern to the Red River Métis. The following list is CNL's understanding of related species and topics of interest to the MMF:

- food and medicines;
- furbearers;
- marten;
- rabbit, squirrel;
- weasel;
- white-tailed deer;
- moose;
- pike, walleye, other fish;
- grouse, geese, ducks, waterfowl;

- groundwater and groundwater interaction;
- Winnipeg River;
- land tenure and future use;
- cultural and archaeological sites;
- traditional harvesting of country foods;
- psychosocial and perceptions-based health and Treaty Rights impacts;
- employment and business opportunity;
- community well-being; and
- environmental and community safety.

CNL has partially addressed this matter within the Project context through the incorporation of TKLUOS information and will continue to respect the MMF and Red River Métis values, interests, and traditional knowledge are meaningfully incorporated into the Project. One way this is being done is through the implementation of the MMF-led Harvester Sampling Plan which was enabled through the 2023 MOA. The parties will consider these concerns to be fully addressed once the MMF and CNL can assess the success of the implemented commitments and confirm they address the MMF's concerns.

Monitoring and Control of the Proposed WR-1 Disposal Facility and the Decommissioned WL site

The MMF raised a concern about monitoring and control of the WL site over the long-term. Specifically, they raised issue that the rationale for ISD relies on maintenance and monitoring of the installation for 300 years and that "control" will last "indefinitely". The MMF indicates that it is not clear how CNL is prepared to make this commitment for the post-closure phase after 2126 or, in particular, after 2326. The MMF notes that environmental regulations change with each government, and it is possible that future governments may choose not to allocate funding to maintaining and monitoring the WL site. The MMF argues that there is no way to guarantee future commitment of resources. The MMF has raised concerns about the containment of waste in the disposal facility, monitoring of the ground water in the vicinity of WR 1 and the Winnipeg River, overall. The MMF stressed the importance of ongoing monitoring and accountability for the WRDF. The MMF requested the opportunity to work alongside CNL in the development of a wildlife mortality monitoring and adaptive management program to address impacts to wildlife important to the MMF.

CNL has committed to supporting the MMF's participation in environmental monitoring and will be collaborating with the MMF so that CNL aligns with the MMF's expectations and interests. CNL and the MMF held a teleconference on March 23, 2021, to discuss a relationship agreement including funding a Liaison position, and participation in annual environmental monitoring. CNL committed to developing a relationship agreement with the MMF and provided a revised draft of the relationship agreement for the MMF's review and feedback on April 22, 2021. The relationship agreement would help support the MMF's continued engagement on the reactor decommissioning and site environmental monitoring activities. CNL and the MMF hosted a workshop and discussed post closure ground water monitoring February 9, 2021, and a workshop on the site wide environmental protection program. Following the workshops, CNL provided the MMF with additional information on upcoming monitoring activities at CNL and invited them to participate.

On May 11, 2021, CNL committed to establishing a MMF wildlife and environmental monitoring program on the WL site. CNL and the MMF agreed to fund this initiative through signing a relationship agreement. During the meeting, the MMF confirmed the implementation of this initiative would address this area of interest. CNL will also use adaptive management practices in the post-closure monitoring program for the Project.

CNL's view is that the steps CNL has taken adequately addresses this area of interest to the extent possible, with the implementation of the MMF-led Harvester Sampling Plan, which was enabled through the 2023 MOA.

The parties will consider these concerns to be fully addressed once the MMF and CNL can assess the success of the implemented commitments and confirm they address the MMF's concerns.

WL site Environmental Remediation and Incorporation of Métis Information

The MMF has expressed interest in providing Red River Métis input into the grass seed mix proposed for site remediation areas, so that species of importance to the Red River Métis are considered and to avoid species that may conflict with Red River Métis harvest practices. The MMF expressed interest in site remediation with respect to bush and tree planting. The MMF would like to see species of importance to the Red River Métis used on site.

To help address Red River Métis' concerns in this area, CNL shared the current seed mix with the MMF to seek their feedback on it. CNL committed to providing the MMF with the detailed site revegetation plan once it has been drafted. CNL committed to only using native seeds in our revegetation efforts. CNL held discussions in fall 2020 with the MMF on input to tree species for site re-forestation. CNL held discussions with the MMF on how to procure trees and bush plants from an appropriate source. The MMF is currently exploring the establishment of a tree nursery.

In addition, CNL and the MMF participated in a workshop on CNL's environmental protection program on March 17, 2021. Afterwards, CNL also provided a list of environmental monitoring activities and invited the MMF to participate in monitoring. A workshop that included tree planting on site was held in late 2020. CNL will continue to engage with the MMF on input to and potential sourcing of seeds, bushes, and trees for site re-vegetation activities. During a teleconference on May 11, 2021, CNL committed to establishing a MMF wildlife and environmental monitoring program for the WL site.

CNL's view is that the steps CNL has taken adequately address this area of interest to the extent possible. Next steps are for CNL and the MMF to begin the implementation of CNL's commitments to the MMF for the Project.

Economic Opportunities

The MMF raised an interest in capacity building for their Citizens and participating in the economics of the Project. The MMF expressed a desire for Métis businesses to be involved in contract work on the Project. In addition, the MMF recommends that CNL provide opportunities to the MMF to build capacity and knowledge in decommissioning activities and reclamation of project components. CNL hosted three industry days to facilitate a dialogue with interested Métis contractors. CNL worked to enhance options to better match Métis businesses' capabilities with their contracting needs, including adding provisions to its procurement process that encourages the use of Indigenous and local small and medium sized businesses. CNL introduced Métis N4 Construction to Golder Associates to provide the possibility of the organizations forming a teaming agreement to support contracting opportunities. CNL exhibited at the 2018 and 2019 MMF Annual General Assembly in order to meet Métis businesses and share employment and contracting opportunities with the Whiteshell Laboratories Restoration Project. CNL integrated these socio-economic considerations into the updated EIS and provided MMF with a copy for their review and feedback to verify these concerns were addressed in the EIS.

Additionally, in 2023 CNL developed and shared the Indigenous Vendors Portal and a draft Indigenous Relations Procurement Strategy with the MMF. The MMF provided feedback on the strategy and CNL and the MMF met on November 14, 2023, to discuss MMF feedback. MMF shared concerns that the Indigenous Relations Procurement Strategy required a change in language that reflected Red River Métis Citizens when recruiting at CNL and a communications protocol be developed so that CNL job postings be shared directly with MMF and in-turn MMF would share with Red River Métis Citizens. In addition, MMF wanted CNL recruitment materials (that promote CNL as an employer) to be adapted to Red River Métis Citizens. In January 2024, CNL developed a draft workplan addressing these concerns raised by MMF. As well, the MMF and CNL have co-developed a list of commitments in relation to the Project. Fulfilling these commitments is a binding aspect of the EA as they are submitted to the CNSC as a part of the final EIS package.

4.2.4.2.3 Verification

CNL incorporated feedback through engagements with the MMF on the Project, their TKLUOS, and the Traditional Foods Harvest Survey. To confirm CNL has adequately captured the Red River Métis' interests and concerns, position, and knowledge, CNL and the MMF underwent a verification process whereby CNL provided EIS documentation to the MMF for their review and feedback. Through this process, the MMF has reviewed and provided feedback from their summary of interests and concerns table, list of VCs, and Section 4.0 Indigenous Engagement. While not all of the Red River Métis' concerns were mitigated by this process, CNL made every effort to verify that the Red River Métis' position, interests, and concerns were adequately characterized. CNL continues to work with the MMF to address their concerns through on-going discussions. And as stated above, CNL and MMF continue to work towards having a relationship agreement in place in the near term.

On June 2, 2021, CNL sent the MMF a letter requesting their review of the summary of interests and concerns CNL had developed based on engagements and Red River Métis' TKLUOS (SVS 2019). CNL also developed a list of VCs for the MMF based on feedback from past engagement, Red River Métis' harvester consumption survey, and Red River Métis' TKLUOS. CNL asked the MMF to verify whether CNL had adequately characterized Red River Métis' interests and concerns. In the letter, CNL offered to provide capacity funding and to meet with MMF to discuss the table and list of VCs.

On July 26, 2021, the MMF sent CNL feedback on the summary of interests and concerns table and list of VCs. On the same day, CNL and the MMF signed an MOU to support Red River Métis' technical review of the summary of interests and concerns and list of VCs. CNL accepted all track changes for both documents from the MMF and sent back the revised two documents on August 19, 2021. CNL sent a final thank you letter to the MMF on August 24, 2021, thanking the MMF for their participation in verifying CNL had adequately captured their summary of interests and concerns table and list of VCs.

Further verification efforts were made to updates to the EIS. Community specific portions of Section 4.0, Engagement Logs, and Interests and Concerns Tables were sent to the MMF to review EIS updates with 2022 and 2024 submissions. The MMF expressed concern for CNL so they are referencing MMF and Red River Métis. The MMF confirmed in an email to CNL on December 7, 2022, that they have no further comments on EIS updates on the 2022 revised EIS.

For the 2024 EIS update, CNL emailed MMF on September 23, 2024, asking for comments on the updated Section 4.0 of the EIS. CNL emailed MMF on October 3, 2024, asking for comments on the updated Section 4.0 of the EIS and the accompanying interests and concerns tables that was to be included in the 2024 EIS submission. On October 9, 2024, the MMF emailed CNL with initial comments on Section 4.0, and on October 25, 2024, the MMF emailed CNL with further comments on Section 4 and the interests and concerns table, which CNL

incorporated into the 2024 draft EIS submission. CNL emailed the MMF on November 11 with the updated Section 4.0 and table of interests and concerns, with both rounds of MMF feedback incorporated, stating that this would be included in the 2024 draft EIS submission.

4.2.4.2.4 Next Steps

In mid-February of 2024, the MMF notified CNL of the MMF's decision to end the 2023 agreement, citing a failure by CNL to maintain the confidence of the MMF in ensuring that its interests will be appropriately represented and considered by CNL, which resulted in the loss of the MMF's confidence that CNL would be working to meaningful consider and address the interests and concerns of the Red River Métis. Canadian Nuclear Laboratories respects the MMF's decision while continuing to share information. Canadian Nuclear Laboratories remains open and interested in discussion with the MMF. Canadian Nuclear Laboratories aspires to rebuild a productive partnership with the MMF to enable full participation of Red River Métis Citizens in the various projects, licensing, economic benefits and environmental protection opportunities.

Since August 2024, CNL and the MMF have reopened engagement channels, particularly related to participation in environmental monitoring, including site visits. The next steps for CNL are to rebuild the relationship to the point where the MMF and CNL can progress with the commitments CNL has made in relation to the Project.

4.2.4.3 Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation (2016 – Autumn 2020)

Black River First Nation, Hollow Water First Nation, and Brokenhead Ojibway Nation are three very unique First Nations that all have asserted or established Aboriginal and Treaty Rights in the vicinity of the Project. Their reserves are also within proximity to the WL site, and the communities have expressed an interest in the Project.

The three First Nation communities have worked together to submit a joint TKLUS report and have worked together to submit questions on the 2017 draft of the EIS and it is for those reasons CNL has put these three communities in one section for engagement from 2016 – autumn 2020 as during this time, CNL engagement with these first Nations were conducted together. See the IER Appendices for more background information on each First Nation community.

Based on discussions between CNL and Brokenhead Ojibway Nation in fall 2020, CNL understood from Brokenhead's representatives at that time that the Nation had more urgent priorities than active engagement with CNL on the Project. CNL acknowledged this position and information-sharing between Brokenhead Ojibway Nation and CNL is ongoing.

4.2.4.3.1 Engagement (2016 – Autumn 2020)

In August 2016, CNL sent the Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation each a letter to introduce the proposed Project, which included a request for community input on any potential adverse impacts from Project activities. In December 2016, CNL invited all three communities to meet and discuss the Project. CNL met with Black River First Nation and Brokenhead Ojibway Nation to discuss how they would like to be engaged and to provide an overview of the proposed alternative to ISD.

In early February 2017, CNL and AECL held a two-day meeting with the three communities to discuss the Project and reviewed a proposed student job description. See the IER for this job description.

On the second day, community representatives were given a tour of WR-1 Building and of the WL site. CNL HR staff were also present to discuss job advertising. In June, CNL and the Brokenhead Ojibway Nation had a follow-

up meeting where CNL presented their proposed ISD and addressed community concerns. In fall 2017, CNL sent a letter to all Indigenous communities notifying them of the public comment period on the draft EIS and invited them to engage. CNL also mailed hard copies of the draft EIS executive summary.

In September 2017, CNL provided an opportunity for five members from each First Nation and the MMF to attend a full day workshop to both learn and share on how CNL and Indigenous Nations collectively protect and care for the environment. The goal was to provide some hands-on experience coupled with ample discussion, learning and dialogue on career opportunities at CNL and on a relationship between the site and Indigenous Nations. On October 31, 2017, CNL shared the Annual Safety Reports with each Indigenous Nation, including the Environmental Monitoring in 2016 at the WL site (CNL 2017a), and the 2016 Progress Report on the Environmental Assessment Follow-up Program for the WL site (CNL 2017b). CNL also provided an invitation to engage on these documents.

In 2018, CNL organized a trip to Hallam, Nebraska with engaged Indigenous communities to visit a site that had implemented ISD. Collectively, Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation sent representatives from Black River First Nation and Brokenhead Ojibway Nation. In September, CNL and Black River, Brokenhead and Hollow Water First Nations had a follow-up meeting to discuss the Hallam trip and the communities introduced the Project Coordinator for the three communities. See the IER Appendices for information on the benchmarking trip.

In February 2019, CNL provided a site tour to the Southeast Resource Development Council (SERDC) and have enabled a potential collaboration with a CNL supply chain contractor for the purpose of economic benefit resulting from the Whiteshell Laboratories Restoration Project. The SERDC, incorporated and recognized in 1978, represents the formal unification of eight (8) member First Nations in the southeastern portion of Manitoba, including Brokenhead, Hollow Water and Black River First Nations. The Tribal Council is accountable to approximately 12,000 members under the leadership of its eight First Nation Councils.

As a political and administrative organization, the SERDC is designed and mandated to facilitate the development of local control and responsibility of programs and services to member First Nations by:

- Providing a mechanism whereby the SERDC can develop the administrative and managerial skills necessary to assist each First Nation institute and deliver local services at its own pace and in tune with each First Nation's level of development.
- Providing a mechanism whereby the SERDC can confirm that services are equitably and effectively delivered to each First Nation.
- Providing a mechanism whereby the SERDC can assist the First Nations to develop a capacity for local services, making them less dependent on Aboriginal Affairs and Northern Development Canada (AANDC) or the Tribal Council in matters of local concern and responsibility.

In March 2019, CNL supported a Councillor from Black River First Nation to attend the Waste Management Symposia in Phoenix, Arizona. This conference is hosted by a not-for-profit organization dedicated to providing education and information exchange on global radioactive waste management. This trip was intended to provide a cooperative learning opportunity for Black River First Nation. A Councillor was able to attend conference presentations and interact with regulators, government representatives and contractors. The Councillor also participated on a panel session regarding Indigenous engagement in nuclear projects.

CNL also hosted all three communities for a two-day meeting in June 2019. The first day, CNL provided a site tour. On the second day, CNL provided a Project update, followed by a Traditional Knowledge study workshop with the three communities held at Brokenhead Ojibway Nation. In September, the communities invited CNL to participate in a meeting to discuss the Traditional Knowledge study wrap-up. In December, CNL, AECL, the communities, and their consultants met to discuss roll-out of a TKLUS.

In March 2020, CNL and Black River First Nation had a teleconference to discuss the next steps as well as setting up a meeting to review the communities' thoughts on CNL's responses to the communities' comments on the EIS. In April 2020, CNL provided an update to the communities and Canadian Nuclear Safety Commission (CNSC) on the decommissioning activities. In August 2020, Brokenhead Ojibway Nation confirmed they did not want to participate in the Indigenous Advisory Committee, nor did they want to have an Indigenous liaison position in their community, despite CNL's offer to provide them with capacity funding. Brokenhead stated they were content to continue to engage through the regulatory process and CNL continues to respect their decision. CNL also continues to send Brokenhead updates. In September 2020, CNL, Black River First Nation, Hollow Water First Nation and their consultant met by teleconference to discuss the Indigenous Advisory Committee and Black River and Hollow Water First Nations' engagement organizational framework.

In fall of 2020, CNL received verbal confirmation from Brokenhead Ojibway Nation that they had no interest in further engagement on the Project. CNL continues to share information with Brokenhead Ojibway Nation and is open to returning to more in-depth engagement with Brokenhead in the future if the community chooses.

4.2.4.3.2 Brokenhead Ojibway First Nation (Autumn 2020 – July 31, 2024)

The Brokenhead Ojibway Nation is an Anishinaabe (Saulteaux/Ojibwa) First Nation. The First Nation is a signatory to Treaty 1. The Brokenhead Ojibway Nation occupies three areas of reserve lands. Brokenhead 4 Reserve No. 06361 is the largest and is situated approximately 44 km northwest of the WL site. This main reserve is largely surrounded by the Rural Municipality of St. Clements and contains the settlement of Scanterbury. The land base for this reserve is 5,412.8 ha. One of two additional smaller reserves is the Birch Landing Reserve No. 09800 (272 ha) to the north of Brokenhead 4 Reserve, and 55 km northwest of the WL site.

A map of Brokenhead Ojibway First Nation is provided in the IER Appendices. See the IER Appendices for more background information on each First Nation community.

See Section 4.2.4.3.3 for information on Black River First Nation and Hollow Water First Nation, as well as engagement between CNL and Black River First Nation and Hollow Water First Nation from Autum 2020 – 2024 July 31.

In March 2020, CNL and Black River First Nation had a teleconference to discuss next steps as well as setting up a meeting to review the communities' thoughts on CNL's responses to the communities' comments on the EIS. In April 2020, CNL provided an update to the communities and CNSC on the decommissioning activities. In August 2020, Brokenhead Ojibway Nation confirmed they did not want to participate in the Indigenous Advisory Committee, nor did they want to have an Indigenous liaison position in their community. Brokenhead stated they were content to continue to engage through the regulatory process and CNL continues to respect their decision. CNL also continues to send Brokenhead updates. In September 2020, CNL, Black River First Nation, Hollow Water First Nation and their consultant met by teleconference to discuss the Indigenous Advisory Committee and Black River and Hollow Water First Nations' engagement organizational framework.

In fall of 2020, CNL received verbal confirmation from Brokenhead Ojibway Nation that they had no interest in further engagement on the Project. CNL respects this position and remains interested in future engagement with Brokenhead if the community chooses to re-engage.

On February 8, 2021, CNL sent out a letter to Brokenhead Ojibway Nation to notify Indigenous communities who had indicated they did not wish to engage of the status of the EIS submission and to offer to meet to discuss their interest and concerns in relation to the Project. On March 11, 2021, CNL reached out to Brokenhead Ojibway Nation via telephone asking to see whether they wanted to re-engage on the Project.

On May 11, 2021, CNL sent a letter to the communities requesting verification of the draft table of interests and concerns as well as the VCs CNL had developed from past engagements and the communities' TKLUS.

CNL met with HTFC Planning & Design and lead representatives from each community on August 19, 2021, to go through the feedback received on the summary of interests and concerns table and list of species and topics raised in the TKLUS and engagement. CNL incorporated the feedback and on August 26, 2021, CNL provided a revised copy to the communities to show how their feedback was incorporated. The communities provided additional feedback on September 2, 2021. CNL incorporated the additional feedback and sent the final copy back the community on September 9, 2021, along with a thank you letter, thanking the communities for participating in the verification process for their summary table of interests and concerns and list of species and topics raised in the TKLUS and engagement.

CNL provided the updated copies to Brokenhead Ojibway Nation and throughout the summer of 2021 reached out by phone, email, and fax. CNL had not heard from the community and while CNL sent an updated copy of the summary of interests and concerns table to include specific references with Brokenhead Ojibway Nation's technical review of the 2020 draft EIS on October 6, 2021, CNL did not received a response from the community. On October 18, 2021, CNL issued a letter to the Brokenhead Ojibway Nation informing them that CNL would be incorporating the table into the EIS and move forward with submission. In the letter, CNL informed Brokenhead Ojibway Nation that CNL would be proceeding with incorporating the summary of interests and concerns table and list of VCs but that there remained opportunities to review and provide feedback in the EIS and throughout the environmental assessment process.

In an email on November 26, 2021, CNL asked Brokenhead Ojibway Nation to review Section 4.0 of the EIS to make sure that CNL had documented information correctly. On November 30, 2021, CNL followed-up via email to confirm Brokenhead Ojibway Nation had received Section 4.0 and were planning to review. Further, on December 1, 2021, CNL followed up via phone to confirm Brokenhead Ojibway Nation had received Section 4.0 and were planning to review the document.

On July 13, 2022, CNL sent out a letter of notice to Brokenhead Ojibway Nation's Chief informing them that CNL has submitted a draft EIS and requested a meeting to engage on the project.

CNL forwarded an invitation to Brokenhead Ojibway Nation on September 20, 2022, to join a webinar on September 28, 2022.

On October 21, CNL emailed Brokenhead Ojibway Nation Chief to provide a letter to update on the status of the EIS for the Project located, which is located near Pinawa Manitoba. CNL proposed a meeting to discuss further.

In mid-November, CNL shared a letter to Brokenhead Ojibway Nation Chief and Council outlining next steps for land use end state engagement.

On December 19, CNL emailed Brokenhead Ojibway Nation to share that the EIS had been resubmitted and to thank Black River First Nation and Hollow Water First Nation for their work on it.

On January 16, CNL emailed to share that the EIS for the Project had passed the initial completeness check and was moving on to the technical review.

On March 10, CNL shared the CNL Indigenous Relations Procurement Strategy. CNL noted that in response to Call to Action #92 in the Truth and Reconciliation report to actively promote economic opportunity for Indigenous Businesses, CNL had developed the Indigenous Relations Procurement Strategy. Atomic Energy of Canada Limited, the federal Crown corporation that provides oversight of CNL, had reviewed and endorsed the Strategy. CNL offered a meeting to discuss this further.

On May 30, representatives from Brokenhead Ojibway Nation attended the Regional Leaders Gathering hosted by CNL at the South Beach Casino on Brokenhead Ojibway First Nation.

In early July CNL shared a draft of the land use end state plan for comment.

On July 21, CNL shared an invite them to the September 7, 2023, Industry Day at the CRL site.

On September 19, CNL shared a link to the new CNL Indigenous Vendors Portal, a part of CNL's Indigenous Relations Procurement Strategy.

On October 20, CNL the important notice of CNL's Administrative Penalty from the CNSC. CNL attached a link to the CNSC Public disclosure and provided information in a PDF.

In early November, CNL emailed Brokenhead Ojibway Nation inviting them to coordinate a review meeting to provide the 6-month update/ feedback on the CNL Indigenous Relations Procurement Strategy.

In January 2024, CNL provided Brokenhead Ojibway Nation with three updates: CNL shared the posting for the role of Indigenous Engagement officer, CNL also notified Brokenhead Ojibway Nation of the change in leadership at the WL site, and, on January 31, CNL shared the link for a CNL Public disclosure Notice.

On February 9, 2024, CNL shared an information bulletin with all engaged Indigenous Nations, which contained information on maintenance work restarting at the WL site.

CNL also shared an invitation to the February public webinar this month.

In March 2024, CNL shared information on how to participate in the CNSC's public hearing for the WL site licence renewal, scheduled for October 2024.

On March 22, 2024, CNL shared the engagement summary section to be included in the IER with BON for review and verification. CNL asked for any feedback on this document to be shared back to CNL by April 19. CNL also followed up in mid-April. CNL did not receive any feedback from BON.

In April 2024, CNL invited BON to participate in the 2024 Regional Leaders Gathering in June 2024 and to attend CNL's April public webinar, which focussed on the Whiteshell Fire Program. This month, CNL also shared information on the CNSC's Indigenous and Stakeholder Capacity Fund.

On May 2, CNL followed up with further information on the Regional Leaders Gathering and on May 15, CNL invited review on the engagement section of CNL's Commission Member Document for the 2024 licence renewal

hearing. On June 10, CNL shared this section, offering capacity for review and requesting any feedback be shared by July 5, 2024. CNL followed up on June 24, 2024, to see if BON was interested in reviewing the Commission Member Document. CNL did not receive feedback from BON on the IER or CMD and no representatives from BON attended the Regional Leaders Gathering.

4.2.4.3.3 Black River and Hollow Water First Nations (Autumn 2020 – July 2024)

Black River First Nation is an Anishinaabe community and signatory to Treaty No. 5. Black River First Nation traditionally spoke Ojibwe and occupy one area of reserve lands: Black River 9. The community is situated approximately 75 km north of the WL site, along the eastern shore of Lake Winnipeg. The Reserve covers an area of approximately 2000 acres. Total membership is approximately 1,650, with over half residing outside of the main Reserve.

A map of Black River First Nation is provided in the IER Appendices. Hollow Water First Nation is an Anishinaabe (Ojibwa) First Nation and signatory to Treaty No. 5, with land cessions within the settlement boundary identified in the IER. In addition, a map of Hollow Water First Nation is provided in the IER Appendices. Both First Nations have potential, asserted, and/or established and Treaty Rights in the vicinity of the Project. See the IER Appendices for more background information on each First Nation community.

CNL, Black River First Nation, and Hollow Water First Nation have collaborated on engagement about the decommissioning project since 2016. CNL and the two Nations have entered a contribution agreement, as of April 2021, to support engagement with the broader community members. Key initiatives in the relationship agreement include establishing a core engagement team made up of community members from each Nation, holding community events and activities such as barbeques and community open house events. The agreement also includes funding for a part-time liaison position to support greater engagement with the two communities.

A summary of engagement from 2016 – Autumn 2020 between CNL and Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation can be found in Section 4.2.4.3.1.

In March 2020, CNL and Black River First Nation had a teleconference to discuss next steps as well as setting up a meeting to review the communities' thoughts on CNL's responses to the communities' comments on the EIS. In April 2020, CNL provided an update to the communities and CNSC on the decommissioning activities. In August 2020, Brokenhead Ojibway Nation confirmed they did not want to participate in the Indigenous Advisory Committee, nor did they want to have an Indigenous liaison position in their community, despite CNL's offer to provide them with capacity funding. Brokenhead stated they were content to continue to engage through the regulatory process and CNL continues to respect their decision. CNL also continues to send Brokenhead updates. In September 2020, CNL, Black River First Nation, Hollow Water First Nation and their consultant met by teleconference to discuss the Indigenous Advisory Committee and Black River and Hollow Water First Nations' engagement organizational framework.

In fall of 2020, CNL received verbal confirmation from Brokenhead Ojibway Nation that they had no interest in further engagement on the Project. CNL continues to share information with Brokenhead Ojibway Nation and is open to returning to more in-depth engagement with Brokenhead in the future if the community chooses.

CNL hosted a multi-community event at the WL site on October 20, 2020. The purpose of the half-day site visit was to discuss CNL's environmental protection program and to observe CNL's fish processing, which is part of CNL's routine environmental monitoring program. Participants included Sagkeeng's Liaison Officer, a representative from the Red River Métis, and two representatives from Black River and Hollow Water First Nations.

A presentation was provided by CNL's environmental specialist on CNL's environmental protection program. Participants also made a number of recommendations on how to incorporate species of interest to the communities into CNL's monitoring program. Afterwards, CNL and the participants made their way to the environmental lab where participants observed CNL processing fish they had caught that morning. Participants asked CNL's environmental technicians several questions about where the fish were caught and the method for catching them. A workshop report was circulated to participants for review and comment. CNL did not receive any feedback on the report from the participants.

On October 27, 2020, HTFC Planning & Design, consultants supporting Black River and Hollow Water First Nations, met with CNL to discuss a two-year engagement plan that would support engagement with both communities on the Project. CNL and HTFC Planning & Design met via teleconference again on November 2 and November 12, 2020, to discuss HTFC Planning & Design's revised proposal. On November 25, 2020, CNL invited Black River and Hollow Water First Nations to participate in CNL's 2020 virtual Industry Day held December 9, 2020.

On December 14, 2020, CNL hosted a teleconference with Black River and Hollow Water First Nations and their consultants, HTFC Planning & Design, to discuss funding needs for the two communities. On January 11, 2021, CNL provided CNL's final responses on their draft EIS comments and on January 19, CNL provide a copy of their proposed Contribution Agreement. CNL also provided an advanced copy of the IER.

In February 2021, CNL met with Black River and Hollow Water First Nations' consultants to review the communities' proposed changes to the Contribution Agreement. This Contribution Agreement was to fund the communities' participation in the Indigenous Advisory Committee as well as a Community Liaison to support engagement between CNL and Black River and Hollow Water First Nations.

On April 6, 2021, Black River First Nation, Hollow Water First Nation, and CNL signed a 2year relationship agreement to support the development of a community liaison position and a community advisory committee and participation in the environmental assessment process for the Project. On April 12, 2021, CNL provided a list of environmental monitoring activities for the 2021 field season and invited the communities to set up a meeting to discuss which activities the communities wanted to participated in. On April 20, 2021, CNL invited the communities to participate in a public webinar to learn more about the Project.

On May 11, 2021, CNL sent a letter to the communities requesting verification of the draft table of interests and concerns as well as the VCs CNL had developed from past engagements and the communities' TKLUS. On May 13, 2021, CNL held a meeting to introduce the new liaison officer to the CNL team and provide some initial background information on the WL site and WR-1. During the meeting, the participants also discussed developing an onboarding program. On May 19, 2021, CNL met with Black River First Nation and Hollow Water First Nation's Liaison Officer to review and finalize the onboarding process and begin to schedule the site tours and presentations.

On May 20, 2021, at the request of Black River First Nation, CNL gave a presentation on the Project to members of the Lake Winnipeg Collective. Black River First Nation and Hollow Water First Nation's Liaison Officer visited site and took a tour of the WR-1 Building on May 25, 2021. On June 1, 2021, the Liaison Officer participated in a radiation 101 course.

In June 2021, CNL sent out invitations to communities to participate in the Indigenous Advisory Committee. On June 23, 2021, CNL met via teleconference with Black River First Nation and Hollow Water First Nation to discuss

how they would like to participate in environmental monitoring. On July 6, 2021, CNL and the communities had a follow-up discussion on which environmental monitoring activities the communities wanted to participate in.

On July 12, 2021, CNL received feedback from Black River First Nation and Hollow Water First Nation on their summary of interests and concerns and list of species and topics raised in the TKLUS and engagement. On July 14, 2021, the communities' Liaison Officer participated in a bat survey for Building 100, which houses WR-1.

The communities' Liaison Officer visited site and participated in a WR-1 Building and Waste Management Area tour on August 11, 2021. On the following day, August 12, 2021, Hollow Water First Nation participated in an exploratory discussion on the formation of an Indigenous Advisory Committee for the WL site. During the meeting the participants worked on key elements of a terms of reference for the committee. On August 16, 2021, the communities' Liaison Officer observed river sediment sampling, soil, and vegetation surveys on site.

CNL met with HTFC Planning & Design and lead representatives from each community on August 19, 2021, to go through the feedback received on the summary of interests and concerns table and list of species and topics raised in the TKLUS and engagement. CNL incorporated the feedback and on August 26, 2021, CNL provided a revised copy to the communities to show how their feedback was incorporated. The communities provided additional feedback on September 2, 2021. CNL incorporated the additional feedback and sent the final copy back the community on September 9, 2021, along with a thank you letter, thanking the communities for participating in the verification process for their summary table of interests and concerns and list of species and topics raised in the TKLUS and engagement.

On November 10, 2021, CNL, Black River First Nation, and Hollow Water First Nation held a teleconference to go over the budget for the relationship agreement and to set next milestones and target dates for key activities within the relationship agreement. In an email on November 26, 2021, CNL asked Black River First Nation and Hollow Water First Nation, to review Section 4.0 of the EIS to make sure that CNL had documented information correctly. On November 30, 2021, CNL followed-up via email to confirm Black River First Nation, and Hollow Water First Nation, had received Section 4.0 and were planning to review. Further, on December 1, 2021, CNL followed up via phone to confirm Black River First Nation, and Hollow Water First Nation had received Section 4.0 and were planning to review the document.

On December 8, 2021, CNL received feedback from Black River First Nation and Hollow Water First Nation on Section 4.0. In a phone conversation on December 13, 2021, Black River First Nation provided an update on the first Black River First Nation and Hollow Water First Nation Liaison Committee Meeting.

On February 8, 2022, CNL met with Black River First Nation to discuss the status of the EIS submission and next steps for engagement in the environmental assessment process. CNL also discussed priority engagement items for the community. Later, on February 16, 2022, CNL met with Black River First Nation to discuss the development of community specific communications material. Black River First Nation provided a list of topics that they would like to communicate to the community.

On March 15, 2022, CNL informed the communities that CNL would be repackaging their interests and concerns table because of CNSC feedback on a similar CNL project. The communities confirmed they would like to review the table prior to submission. During a teleconference on April 13, 2022, CNL, Black River First Nation, and Hollow Water First Nation discussed setting up a site tour with the core engagement team and CNL's environmental monitoring team.

CNL met with Black River First Nation and Hollow Water First Nation on May 11, 2022, to discuss the status of the EIS submission, discuss their revised interests and concerns table, environmental assessment process, development of communication materials, and other areas of interest. On May 25, 2022, CNL, Black River First Nation, and Hollow Water First Nation discussed the logistics for the upcoming site tour, and on June 9, 2022. CNL hosted the Black River First Nation and Hollow Water First Nation Core Engagement Team for their first site tour. Meanwhile on June 13, 2022, CNL requested confirmation from the communities that the table was reflective of their interests and concerns.

CNL, Black River First Nation, and Hollow Water First Nation discussed the upcoming Treaty days via teleconference on July 13, 2022, and how CNL could participate. Later in July, on July 28, 2022, Black River First Nation and Hollow Water First Nation participated in berry picking near the former Underground Research Laboratory site.

August 2022 engagement focused on further discussions regarding the Project and involvement in environmental monitoring. The monthly meeting with CNL, Black River First Nation, and Hollow Water First Nation, on August 17, 2022, focused on upcoming engagements, exploring areas of interest, and updates on the decommissioning work. On August 30, 2022, CNL sent a copy of CNL's monitoring program schedule and requested Black River First Nation and Hollow Water First Nation identify any activities of interest.

On September 8, 2022, Black River First Nation and Hollow Water First Nation participated in mushroom collection from three locations around the WL site. At the September 14, 2022, monthly meeting, CNL, Black River First Nation, and Hollow Water First Nation discussed extending the existing relationship agreement and coordinating future environmental monitoring activities. There was also an invitation extended to Black River First Nation and Hollow Water First Nation to accompany CNL to the Waste Management Symposium in Phoenix in 2023 and be a panelist to discuss risk communication matters.

CNL forwarded an invitation to Black River First Nation, and Hollow Water First Nation on September 20, 2022, to join a Webinar on September 28, 2022. There was much coordination and communication during the week of September 25, 2022, culminating in a fall medicinal plant walk at the WL site with Elders and members from Black River First Nation and Hollow Water First Nation on September 29, 2022.

At the October monthly meeting CNL and the Black River First Nation and Hollow Water First Nation representatives discussed the Project, including the technical review process, the Federal Provincial Indigenous Technical Review kick-off meeting, finalizing commitments and EIS updates. General relationship discussions were also had on the agreement extension, upcoming school engagement activities and a monitoring work plan.

In late October and early November 2022, Black River First Nation and Hollow Water First Nation provided their feedback on the following aspects of the EIS:

- Parts of section 4 (October 31, 2022)
- Commitments list (November 02, 2022)

Following this, on November 3, their consultant emailed confirmation that the 2022 draft EIS submission reflected the Black River First Nation’s and Hollow Water First Nation’s input. Mid-November, CNL’s Indigenous Relations Advisor met with the Black River First Nation and Hollow Water First Nation Chief and Council to discuss land use end state engagement.

On December 19, 2022, CNL emailed Black River First Nation and Hollow Water First Nation to share that the EIS had been resubmitted and to thank Black River First Nation and Hollow Water First Nation for their work on it.

On January 11, 2023, Black River First Nation and Hollow Water First Nation and CNL held their monthly meeting where discussions continued on the Project's environmental assessment, including the finalization of commitments and the Federal Provincial Indigenous Technical Review kick-off meeting. Other ongoing engagement initiatives were also discussed including land use end state and a monitoring workplan. On January 16, 2023, CNL emailed to share that the EIS for the Project had passed the initial completeness check and was moving on to the technical review.

Early February 2023 brought an opportunity for the Black River First Nation and Hollow Water First Nation to participate in monitoring at the WL site on February 1. Several water samples were collected and sent off-site for analysis. The monthly working group meeting was held on February 9, 2023. Discussions were ongoing from the meeting in January. The next day CNL's HR emailed the Black River First Nation and Hollow Water First Nation Project Coordinator to coordinate the sharing of CNL job postings.

On February 17, 2023, CNL also shared a report with Black River First Nation and Hollow Water First Nation on elevated levels of manganese at the WL site. Later in the month, representatives of Black River First Nation and Hollow Water First Nation met with CNL in Hollow Water First Nation for the Quarterly Core Engagement Team meeting. One key outcome was that the commitments list was verified by Black River First Nation and Hollow Water First Nation during the meeting.

On March 7, CNL's Indigenous Relations Advisor emailed the Black River First Nation and Hollow Water First Nation Project Coordinator shared an open invite to community members to come to the WL site. One day later, Black River First Nation and Hollow Water First Nation requested some information on Sturgeon and contact information for CNL's contact with the Provincial government. In relation to this, that same day, CNL requested the contact follow-up on possibly involvement with monitoring activities. The March monthly meeting was held on March 8, 2023, and focused on progressing discussions from the February monthly meeting. A few days after this meeting, CNL shared its Indigenous Relations Procurement Strategy and requested feedback from Black River First Nation and Hollow Water First Nation.

On April 13, 2023, Black River First Nation and Hollow Water First Nation and CNL signed an agreement extension for the MOA. This extension facilitates ongoing engagement and participation in the environmental assessment. At the April monthly meeting on April 19, Black River First Nation and Hollow Water First Nation and CNL followed up on the email enclosing the Indigenous Relations Procurement Strategy with a discussion. Other topics of discussion at the monthly meeting included land use and end state, Black River First Nation's and Hollow Water First Nation's participation in the August 2024 Nuclear Waste Management Decommissioning Environmental Remediation (NWMDER) conference in Niagara Falls, a monitoring workplan and CNL participation in school activities.

On May 1, 2023, CNL shared a memo on the WL site Safety Standdown. CNL also invited Black River First Nation and Hollow Water First Nation to participate with a booth at CNL's Regional Leaders Gathering planned for May 30. This conference and the invitation to Black River First Nation and Hollow Water First Nation was a topic of discussion at the monthly meeting on May 11. Other topics included the CNL Indigenous Relations Procurement Strategy, Land Use and End State and environmental monitoring. In follow-up to discussions on environmental monitoring at the monthly meeting, CNL shared sampling results of key plants including blueberries and mushrooms. On May 30, 2023, representatives from Black River First Nation and Hollow Water First Nation

attended the Regional Leaders Gathering hosted by CNL at the South Beach Casino on Brokenhead Ojibway First Nation.

The June 14, 2023, monthly meeting included follow-up on land use and end state from the Regional Leaders Gathering, a discussion on nuclear waste management and Black River First Nation's and Hollow Water First Nation's attendance at the NWMDER conference as well as education and school initiatives and nuclear waste management in general.

In early July 2023, CNL shared a draft of the land use end state plan for comment. In mid-July Black River First Nation and Hollow Water First Nation and CNL held the July monthly meeting and discussed Treaty Days, the Project, the Whiteshell Safety Stand Down, land use and end state and environmental monitoring. On July 12, CNL shared the CNSC's Independent Environmental Monitoring Program (IEMP) results with Black River First Nation and Hollow Water First Nation. These results confirmed that the environment around the WL site remained protected.

On August 9, 2023, Black River First Nation and Hollow Water First Nation and CNL held their monthly meeting. This meeting was focused on the Project, the Whiteshell Safety Standdown, Environmental Monitoring, land use and end state, progress on building decommissioning at the WL sites and CNL participation in school programming in the community. Towards the end of August 2023, the Project Coordinator representing Black River First Nation and Hollow Water First Nation attended the 2024 NWMDER conference.

On September 19, 2023, CNL shared a link to the new CNL Indigenous Vendors Portal, a part of CNL's Indigenous Relations Procurement Strategy.

On October 3, 2023, CNL's Indigenous Engagement Coordinator and the First Nations' Project Coordinator met to coordinate an upcoming presentation on nuclear science CNL was doing at a school in the community. The monthly meeting for October 2023 was held on the 4th in Hollow Water First Nation. This meeting was also the Quarterly Core Engagement Team Meeting. Discussion focused on a presentation from CNL on the Land Use and End State Plan for Whiteshell, a review of the NWMDER Conference, an update on the upcoming school presentation, an update on CNL's environmental monitoring, School Presentation Update, CNL Environmental Monitoring update, an update on the Project, CNSC's REGDOC 3.2.2 and the Sagkeeng First Nation's Niigan Aki CEMP. On October 6, 2023, CNL shared an email inviting participation in some upcoming fish sampling.

Mid-month, representatives of Black River First Nation and Hollow Water First Nation and CNL held a dinner together. On October 24, CNL representatives, including a Health Physicist and Indigenous Relations Coordinator attended the Black River First Nation elementary school with the First Nations' Project Coordinator. CNL held different sessions for Grade 7 and Grade 8 classes. The presentation included an introduction to CNL, and an introduction to radiation protection.

In early November of 2023, CNL and Black River First Nation and Hollow Water First Nation shared emails back and forth on CNL's Indigenous Relations Procurement Strategy. CNL provided clarification on the Indigenous Business Certification Form. Mid-month a touch base meeting was held to coordinate engagement including the possibility of a community tour, sponsorship and upcoming events. The monthly working group meeting was held on November 20, 2023. The focus of this meeting was the Whiteshell Low Level Waste Trenches, which included discussion on what options CNL was considering for managing these waste trenches.

Towards the end of the month CNL and Black River First Nation and Hollow Water First Nation had another touch base meeting on CNL sponsorship of particular activities in the communities. In follow-up to this late November

meeting, on December 13, 2023, CNL and Black River First Nation and Hollow Water First Nation held another touch base meeting on sponsorship possibilities. Regular meetings, including bi-weekly and monthly meetings between CNL staff and Black River First Nation and Hollow Water First Nation representatives, and quarterly meetings with the core engagement team, have continued throughout 2024 to date.

On January 9, 2024, CNL and Black River First Nation and Hollow Water First Nation held their first touch base meeting of 2024. The focus of the meeting was to discuss the logistics of the upcoming Quarterly Core Engagement Team meeting, which was to be held at the end of the month at the WL site. Two weeks later, on January 23, Black River First Nation and Hollow Water First Nation and CNL met again to confirm the details of the Quarterly Core Engagement Team meeting and discuss other details.

On January 31, 2024, representatives from Black River First Nation and Hollow Water First Nation, including community members, consultants, and staff, met representatives of CNL and AECL at the WL site for the Quarterly Core Engagement Team meeting. The WL site tour included a stop at the river, a tour of the WR-1 Building, the Fire Hall, WMA, and stops at the Lagoon and Outfall. The meeting discussion included updates from Black River First Nation and Hollow Water First Nation, an introduction to the low-level waste trenches, a review of the CNL draft quarterly environmental monitoring report for Indigenous Nations, and a presentation from the Sagkeeng First Nation's Niigan Aki Program Manager. Discussions involved the Project, community involvement in monitoring, communications about monitoring, waste transportation and land use and end state. CNL also introduced a possible format for sharing regular updates on its monitoring with community members.

Throughout February 2024, communications revolved around CNL involvement with tree planting days in the spring, regular communication updates like the maintenance work restart information bulletin and meeting logistics. At the February monthly meeting, participation from the two First Nations in upcoming CNL environmental monitoring was discussed.

In March 2024, CNL shared information on the 2024 licensing hearing via email, including the licence amendment application, the CNSC Notice of Hearing and information on the CNSC Participant Funding Program. CNL also offered support for First Nations to participate in the hearing. At the March monthly meeting, the EIS was a topic of focus along with the October licensing hearing and logistics around tree planting days in the two First Nation communities. On March 22, 2024, CNL provided the engagement summary for the IER for review and verification. CNL also offered capacity for this review. March 2024 also saw emails and dialogue at meetings about a potential benchmarking trip so that community members could see waste management practices at CNL's Chalk River Laboratories site in Ontario.

There was ongoing email correspondence throughout April 2024 between representatives from Black River and Hollow Water First Nations and CNL. Topics of focus included logistics for upcoming engagement events like the tree planting days and monthly meetings. On April 24, 2024, representatives from CNL and Black River and Hollow Water First Nations met in person in Winnipeg to discuss a possible benchmarking trip to Chalk River Laboratories, their feedback on the IER and the tree planting event.

In early May of 2024, members from the CNL team, including the Project Manager and engagement staff attended the Core Engagement Team meeting in Hollow Water First Nation. CNL staff shared overviews on the Project, CNL's Environmental Protection and Monitoring, and the WL Land Use End State program. Throughout the meeting there was dialogue between community members and CNL.

On May 9, 2024, Black River and Hollow Water First Nation provided feedback on the IER engagement summary, which CNL incorporated into that document and this EIS. On May 15, 2024, CNL invited review on the engagement

section of CNL's Commission Member Document for the 2024 licence renewal hearing. And, on June 10, CNL shared this section, offering capacity for review and requesting any feedback be shared by July 5, 2024.

As a result of earlier interest that Black River and Hollow Water First Nations had shared about involvement in monitoring, Elders, community members and consultants with Black River and Hollow Water First Nations participated in the May 22 mushroom collection activities at the WL site, alongside Sagkeeng. This day included a tour of the collection and analysis laboratory at WL.

On June 4, 2024, representatives from Black River First Nation and Hollow Water First Nation participated in the Regional Leaders Gathering hosted by CNL in Beausejour. The Regional Leaders Gathering facilitated discussions amongst leaders from Indigenous Nations and non-Indigenous communities with CNL. The focus was on CNL projects, including the Project, environmental monitoring, and gathering feedback on Trenches and Land Use End State. Participants from BRFN included: Chief Kent, Oral Johnston (Special Projects), Kelsey Boubard (Project Liaison and Lands Manager), Des Abraham (Lands Manager in-Training), Elder Bill Abraham; and from HWFN included: Councillor Wesley Moneas, Nolan Moneyas (Prevention Land Based Coordinator / Core Engagement Team member, Kyle Hardisty (Income Assistance Coordinator / Core Engagement Team member).

In mid-June of 2024 the tree planting days occurred in both communities in addition to a barbeque hosted in Hollow Water First Nation for tree planting participants. On June 19, 2024, alongside Sagkeeng, Representatives from Black River and Hollow Water First Nations participated in field monitoring and mapping for milkweed.

In July of 2024, CNL continued to involve Black River and Hollow Water First Nation in monitoring opportunities with an invitation to the bat exit survey. The July 2024 monthly meeting was held virtually and featured an update on the EIS resubmission, as well as recent and upcoming engagement, and the WL site licence renewal hearing.

4.2.4.3.4 Interests and Concerns

Through a variety of engagement forums, including technical workshops, webinars, and meetings, Black River First Nation and Hollow Water First Nation have raised issues, concerns and questions that were initially focused on the 2017 and 2020 draft EIS. These engagements have led to the development of the interests and concerns table for Black River First Nation, Hollow Water First Nation, and Brokenhead Ojibway Nation. This subsection is taken from the tables of interest and concerns from Appendix 4.0-1 of the EIS and describes CNL's understanding based on written submissions and oral discussions with the Nations. The Nations have also provided feedback through their TKLUS [23] and Brokenhead Ojibway Nation provided addition comments through their technical review of the 2020 draft EIS [24].

CNL has made its best efforts to document and verify the position the Nations have taken on each interest/concern. See Section 3.5 for a summary of issues raised during engagement activities that influenced the scope of the environmental assessment.

Business and Employment Opportunities

Brokenhead Ojibway Nation, Hollow Water First Nation and Black River First Nation raised the possibility of CNL using direct negotiated contracts with First Nations in decommissioning and overall closure processes and expressed an interest in learning more about CNL's Indigenous procurement requirements associated with the Project and employment opportunities that are currently available within the Whiteshell Laboratories Restoration Project. The communities expressed concern that they would not be competitive with larger businesses in the tender process.

To help address this concern, CNL worked to enhance options to better match these First Nations capabilities with their contracting needs including adding provisions to its procurement process that encourages the use of Indigenous-owned businesses or businesses that employ Indigenous Nations. CNL discussed the need for better information sharing regarding the procurement and contracting opportunities and asked for specific capabilities that communities have related to the Project. CNL engaged with the SERDC as it was recommended as the best way to explore First Nation capabilities and CNL procurement opportunities. SERDC has subsequently partnered with Golder to increase their ability to contract to CNL. CNL, Black River First Nation, and Hollow Water First Nation also signed a comprehensive relationship agreement, on April 6, 2021, to support greater community involvement in the Project. The relationship agreement supports the establishment of a community committee, a community liaison position, support to participate in the Indigenous Advisory Committee and provide capacity support so that the communities can continue to participate in discussions on business development opportunities.

In Brokenhead Ojibway Nation's Technical Review of the Revised Environmental Impact Statement for the Project (Technical Report), Brokenhead Ojibway Nation expressed concerns that CNL had not included data on Brokenhead Ojibway Nation's labour force, employment, and income conditions into the regional baseline as well as community well-being as inherently linked to the land in the March 2020 draft of the EIS.

On August 16, 2021, CNL provided responses to questions from Brokenhead Ojibway Nation's Technical Report of the Revised Environmental Impact Statement for the Project. In response to Brokenhead Ojibway Nation's request, CNL has revised the EIS with more current data in Section 6.9.5.2.6, Community Wellbeing, and will include data from Brokenhead Ojibway Nation, where available.

As well, in 2023, CNL developed and shared a draft Indigenous Relations Procurement Strategy with Brokenhead First Nation, Black River First Nation and Hollow Water First Nation. Black River and Hollow Water First Nation reviewed the strategy and requested more information on the Indigenous Business Certification Form, which CNL provided. CNL also shared the Indigenous Vendors Portal in the fall of 2023.

CNL will continue to engage on the matter of contracting and employment with the Nations through the Chiefs and Councils and the Black River First Nation and Hollow Water First Nation Community Liaison. CNL will continue to work to remove the barriers community members may face in applying for positions and seek opportunities to increase Indigenous participation in the project.

Future Land Use and Tenure

Black River First Nation, Hollow Water First Nation, and Brokenhead Ojibway Nation were interested in knowing if the land currently occupied by the WL site would be available for other uses in the future. The communities also noted that the site occupies a large parcel of land that was removed from Treaty 1 territory without adequate consultation and there will need to be discussions with the Federal Government about the future of the WL site and potentially accommodation. There are discussions on using the WL site to build small modular reactors and the communities wanted to know more about small modular reactors and if there will be any First Nation and MMF engagement as part of the process.

CNL explained that the liability and land remain with the federal government (i.e., AECL). Decisions on future uses of the land are not under the scope of the environmental assessment and licence amendment. However, CNL and AECL plan to begin engagement on end state and future land use in 2022. The communities will be invited to participate in that process.

CNL shared that there is a community regeneration partnership that was formed to develop both nuclear and non-nuclear opportunities for the WL site after the site is decommissioned. CNL participates and supports the partnership. CNL invited Indigenous communities to join. Some communities have attended these meetings.

CNL explained that any new project on the WL site such as a small modular reactor would need to go through a licensing process that would include Indigenous engagement.

CNL, Black River First Nation, and Hollow Water First Nation signed a comprehensive relationship agreement, on April 6, 2021, to support greater community involvement in the Project. The relationship agreement supports the establishment of a community committee, a community liaison position, support to participate in the Indigenous Advisory Committee and provide capacity support so that the communities can continue to participate in discussions on future land use of the WL site. On April 13, 2023, the extension agreement of this original agreement was signed.

In their Technical Report, Brokenhead Ojibway Nation identified their Treaty Rights and interests are to maintain a Seven Generations approach to stewardship of their lands and resources. As such, it is imperative that lands are available, healthy, and accessible to future generations. Brokenhead Ojibway Nation requested an engagement and consultation meeting with CNL and AECL to discuss future land use and tenure plans and agreements.

On August 16, 2021, CNL provided responses to questions from Brokenhead Ojibway Nation's Technical Report of the Revised Environmental Impact Statement for the Project. In response to Brokenhead Ojibway Nation's request, CNL invited Brokenhead Ojibway Nation to participate in discussions on future land use and end state when they begin. In response to Brokenhead Ojibway Nation's comments in #51a and #52b, CNL has agreed to develop the post-closure monitoring programs in collaboration with Indigenous communities to support their involvement in site environmental monitoring. CNL updated Section 11.4 Indigenous Engagement and Participation in Environmental Monitoring of the EIS to reflect these commitments.

In 2023, CNL hosted a Regional Leaders Gathering (May 30) in Brokenhead Ojibway First Nation and shared a draft Land Use End State document for input.

While future land use and tenure is out of scope for the assessment for the Project, CNL will be contacting the communities to participate in discussions on site wide end state. CNL has acknowledged the historical lack of engagement on siting the WL site and will continue to facilitate dialogue between CNL, AECL, and the Nations in this regard. CNL will continue to engage the Nations on the Project and closure of the WL site.

Accidents and Malfunctions

The communities expressed concerns about past releases to the environment from the WL site and the potential for future releases of hazardous and radioactive material into the Winnipeg River. Brokenhead Ojibway Nation, Hollow Water First Nation and Black River First Nation were interested in how releases could be contained in the soil. They were also interested in how CNL detects spills.

The history of leaks at the site makes community members even more doubtful about the certainty of predictions related to potential groundwater and environmental contamination in the future.

The communities suggest in their TKLUS that groundwater health and the Winnipeg River are of primary concern. While CNL's scientific models do not predict the levels of these nuclides to be dangerous to human health,

Anishinaabe Traditional Knowledge holders identified that they have seen that when predicting hundreds or thousands of years in the future, it is difficult to be confident in scientific predictions.

CNL provided information on the topic of accidents and malfunctions in writing and at two community meetings at Brokenhead Ojibway Nation. CNL explained that radioactivity levels in WR-1 are similar to other reactors that have gone through the ISD process. When the facility was shut down in 1985, all fuel and liquids were safely removed from the reactor, and what remains in place today are the structural components of the reactor, such as the metal vessel and piping. Radioactivity in the reactor is not easily mobilized. The vast majority is trapped in the walls of tanks and pipes.

With respect to the rest of the WL site, all radioactive waste at the site is safely and securely stored in the site's Waste Management Area. Any events that occurred in the past were reported to the Canadian Nuclear Safety Commission (or previously the Atomic Energy Control Board). No employees or members of the public have been negatively affected by the operation emissions of the WL site.

In addition, CNL provided fact sheets of the Winnipeg River Task Force. Previously, an independent task force was created consisting of Sagkeeng, Indian and Northern Affairs, Health Canada, and Environment Canada. The Winnipeg River Task Force released its report in 1995. The task force concluded that "it is unlikely that the AECL Whiteshell Laboratories has ever posed a significant threat to the health of Sagkeeng residents, nor is there apparently any prospect of such a threat in the future".

CNL explained to the communities during engagements that, as part of the application to the CNSC for a decommissioning licence in 2001, a Comprehensive Environmental Assessment was conducted. This included an investigation of the surrounding environment and the Winnipeg River sediments to look for any radioactive contamination that may have occurred over the history of the site. River sediments were surveyed for radioactivity at hundreds of locations. The assessment concluded that "using the most conservative dose estimation methods, doses to humans and non-human biota are below accepted guidelines." The analysis methodology and results were peer-reviewed, presented in public meetings and are available in the open publication of the Comprehensive Study Report (AECL 2001). CNL continues to monitor the river sediment near the site, and downstream. During tours of the site, CNL demonstrated how environmental monitoring detection tools work.

The CNSC conducted an independent monitoring campaign in 2017 with assistance from Sagkeeng. This independent program included collecting and analyzing fish caught near Sagkeeng. The results of the assessment conclude that the public and the environment in the vicinity of the WL site are protected and there are no expected health impacts. The results of this independent monitoring are publicly available at this link: https://nuclearsafety.gc.ca/eng/resources/maps-of-nuclear-facilities/iemp/whiteshell.cfm. As the CNSC's IEMP is conducted every few years, CNL shared the results of the 2022 IEMP campaign on July 12, 2023.

CNL, Black River First Nation, and Hollow Water First Nation signed a Comprehensive relationship agreement, on April 6, 2021, to support greater community involvement in the Project. The Comprehensive relationship agreement supports the establishment of a community committee, a community liaison position, support to participate in the Indigenous Advisory Committee, and contemplates the provision of capacity support so that the communities and CNL develop infographics specific to the needs of the communities. On April 13, 2023, the extension agreement of this original agreement was signed.

Brokenhead Ojibway Nation expressed numerous concerns through their Technical Report pertaining to accidents and malfunctions. Questions and comments ranged from the safety, condition, and integrity of the concrete barriers to bank stabilization and permanent erosion control measures, to the validity of CNL computer models.

Additionally, in their Technical Report Brokenhead Ojibway Nation re-enforced the importance of water and protecting it and shared many comments and recommendations pertaining to water. Key themes included: protection of water and ensuring the integrity of the Winnipeg River; interests in monitoring and sampling of water; the potential for future groundwater contamination; recommendation for more wells for groundwater testing; concerns about proper sealing of conduits; and that the Proponent develop closure-specific runoff control measures, as well as sediment and erosion control measures, to minimize site surface water and sediment entering the river.

On August 16, 2021, CNL provided responses to questions from Brokenhead Ojibway Nation's Technical Report of the revised EIS for the Project. In response to Brokenhead Ojibway Nation's questions, CNL provide additional rational and clarity on specific topics under this theme. This did not result in any updates to the revised draft EIS.

Recognizing that accidents and malfunctions will continue to be an area of interest for the communities, with the relationship agreement in place, CNL has put in place a forum to discuss and further address this area of interest.

Black River First Nation and Hollow Water First Nation have also indicated interest in participating in environmental monitoring at the WL site and in developing a community environmental monitoring program, perhaps like the Sagkeeng Niigan Aki program. In 2023 Black River and Hollow Water First Nation attended site to participate in environmental monitoring activities and at the January 2024 Quarterly Core Engagement Team meeting, the Niigan Aki Program Manager shared a presentation on the Niigan Aki program. CNL is also working with the Project Coordinator from Black River First Nation and Hollow Water First Nation to develop community materials on environmental monitoring in and around the WL site, which would illustrate how the environment remains protected. In 2023, CNL also shared information on the sampling results for two key plant species – blueberries and mushrooms.

Still, further work is needed so that community members can access information on accidents, malfunctions in the context of environmental protection. CNL will continue to engage the communities on this matter.

Waste Management

The communities were interested to know which material will be sent to Chalk River Laboratories for disposal and how it will be transported. The communities' TKLUS highlighted the tension that many of the community members felt about wanting the waste removed from the WL site while recognizing that this would mean moving it to the lands of other First Nations. One of the communities' questions was to find out more about what, if anything, is being offered in compensation to other First Nations for storing nuclear waste material in their traditional territories.

CNL participated in community meetings where waste management was discussed and provided the following information that all waste materials are sorted, verified, and transported using licensed containers, and depending on the waste type, to a licensed hazardous waste management facility. Radioactive materials will be shipped in licensed waste containers. Depending on what materials are being shipped, sometimes shielded cylinders are used. CNL expects that about 2,000 truckloads will need to be shipped for the Whiteshell Laboratories Restoration Project. A dangerous goods transportation specialization may be required for trucking companies to move some of this waste. The used fuel baskets contained in the concrete silos will be placed in a transportation flask and transported by truck along the highway. CNL explained that radioactive materials are safely shipped around Canada regularly. CNL will be hiring transportation contractors who are qualified to undertake the work and have met the necessary qualifications and have the required safe driving hours logged.

The containers used to transport waste are designed to withstand considerable impact. CNL also has a mobile response unit that can be dispatched if an accident occurred. CNL has an emergency response plan that they are trained and drilled to implement.

CNL committed to asking the closest First Nation to the Chalk River Laboratories site, Algonquins of Pikwakanagan First Nation, about their interest in being contacted by Black River and Hollow Water First Nations to discuss their collective experience with the nuclear industry. CNL committed to sharing the results of their discussion with Pikwakanagan when it occurs. After receiving permission from Pikwakanagan, CNL shared Pikwakanagan's contact information with Black River First Nation and Hollow Water First Nation. CNL is working to facilitate a visit to Chalk River Laboratories, as well, which could help facilitate in-person discussions between representatives of the Algonquins of Pikwakanagan and Black River and Hollow Water First Nations.

Future Communication

The communities expressed a desire for user friendly ongoing communication. CNL continues to send Project updates to the communities and is currently discussing the opportunity to establish an Indigenous Advisory Committee and have committed to fund a community liaison position to support a dialogue between community members and CNL.

CNL, Black River First Nation, and Hollow Water First Nation signed a Comprehensive relationship agreement, on April 6, 2021, to support greater community involvement on the Project. The relationship agreement supports the establishment of a community committee, a community liaison position, supports participation in the Indigenous Advisory Committee, and provides capacity support for meaningful participation and engagement throughout the environmental assessment process. On April 13, 2023, the extension agreement of this original agreement was signed.

Recognizing that matters regarding future communications will continue to be an area of interest for Hollow Water First Nation and Black River First Nation, the relationship agreement establishes a forum to support continuing dialogue on this area of interest, and the parties are seeking to extend this agreement. In September 2020, Brokenhead Ojibway Nation notified CNL via a teleconference on two occasions that they are no longer interested in engaging with CNL on the Project. CNL followed up in an email to confirm. CNL will continue their engagement outreach so that Brokenhead Ojibway Nation is informed as the Project proceeds, or if their interest in the project changes.

Throughout late 2022 and early 2023 CNL and Black River First Nation and Hollow Water First Nation worked on co-developing a list of binding commitments on the Project.

On September 21, 2022, CNL provided a preliminary list of draft commitments to Black River First Nation and Hollow Water First Nation, which was drafted with information from engagements and comment responses for the Project. On November 1, 2022, Black River First Nation and Hollow Water First Nation shared their review of the updated table of commitments. On December 13, 2022, CNL shared an updated list of commitments.

On February 23, 2023, at the Core Engagement Team Meeting between CNL and Black River First Nation and Hollow Water First Nation, representatives from Black River First Nation and Hollow Water First Nation verified the list of commitments.

Monitoring

Brokenhead Ojibway Nation, Hollow Water First Nation and Black River First Nation requested more information about CNL's current monitoring activities, including activities related to the contamination in the riverbed of the Winnipeg River. More specifically, in their TKLUS, the communities identified an interest in further discussion related to the rationale for conducting river sediment sampling at 20-year intervals, believing that more frequent sampling is likely needed. Recommendation #2 of the TKLUS called for funding for the First Nations to contract and conduct independent monitoring of the site using technical and Traditional knowledge.

The communities also wanted further information and discussion about the vegetation, fish, and wildlife sampling taking place at the site, and specifically with respect to the Project. They expressed concern that plants, fish, and wildlife would only be sampled if other parameters raise concern and would like to discuss this further. The communities would also like to be invited to participate in future testing events on the site so that they can ask questions while the testing is in progress.

The three communities expressed an interest in learning more about future monitoring activities that will occur after the WL site is fully decommissioned. Black River First Nation expressed interest in having students involved in monitoring activities.

CNL provided the communities with a list of upcoming monitoring activities and invited them to participate. CNL will continue to send upcoming environmental monitoring activities and seek to host a workshop to discuss CNL's current environmental monitoring programs. In addition, CNL has committed to work with these communities to better understand their monitoring interest, to incorporate Traditional knowledge into existing programs, and develop approaches that encourage the building of trust in the monitoring activities. In addition, CNL has committed to developing Indigenous environmental stewardship initiative.

Through their Technical Report, Brokenhead Ojibway Nation had multiple comments and recommendations related to environmental monitoring. These ranged from concern for how CNL will monitor the performance of the grouted structure and verify that it is operating as predicted, to requests for more detail on CNL pre- and post-closure monitoring programs, from challenges to the CNL monitoring approach, to requests for direct Indigenous involvement and participation in current and post-closure monitoring.

On August 16, 2021, CNL provided responses to questions from Brokenhead Ojibway Nation's Technical Report of the Revised Environmental Impact Statement for the Project. In response to Brokenhead Ojibway Nation's questions and recommendations, CNL has updated Section 11.0 Summary of Monitoring and Follow-Up Programs of the revised draft EIS to include a list of monitoring activities proposed for the Project, which are above and beyond the current monitoring program. The list is provided in Table 11.0-1. CNL has also revised Section 11.4 of the draft EIS to reference CNL's commitment to developing a post-closure monitoring program in collaboration with Indigenous Nations.

Black River First Nation and Hollow Water First Nation have also indicated interest in participating in environmental monitoring at the WL site and in developing a community environmental monitoring program, perhaps like the Sagkeeng Niigan Aki program. In 2023 and 2024 Black River and Hollow Water First Nation attended site to participate in several environmental monitoring activities. At the January 2024 Quarterly Core Engagement Team meeting, the Niigan Aki Program Manager shared a presentation on the Niigan Aki program. CNL is also working with the Project Coordinator from Black River First Nation and Hollow Water First Nation to develop community materials on environmental monitoring in and around the WL site.

Recognizing that environmental monitoring will continue to be an area of interest for the communities, CNL is committed to ongoing Indigenous engagement, in the development and execution of its monitoring programs.

In Situ Disposal

Brokenhead Ojibway Nation, Hollow Water First Nation and Black River First Nation expressed interest in understanding how ISD was chosen as the preferred decommissioning method for WR-1 and wanted to know if nearby communities would have an opportunity to provide input on the chosen decommissioning method. The three communities also wanted to learn and discuss whether climate change or natural disasters could affect the integrity of the grouted encapsulation and how it would be constructed to confirm that it is safe.

The communities suggest in their TKLUS that groundwater health and the Winnipeg River are of primary concern. While CNL's scientific models do not predict the levels of these nuclides to be dangerous to human health, Anishinaabe Traditional Knowledge holders identified that they have seen that when predicting hundreds or thousands of years in the future, it is difficult to be confident in scientific predictions.

In their Technical Report, Brokenhead Ojibway Nation expressed an interest in re-evaluating decommissioning in favour of full removal of waste off-site. They also expressed concerns regarding climate change not being considered in the assessment, and the effects of climate change on VC populations now and in the future. Additionally, in their Technical Report Brokenhead Ojibway Nation re-enforced the importance of water and protecting it and shared many comments and recommendations pertaining to water.

Key themes included: protection of water and ensuring the integrity of the Winnipeg River; interests in monitoring and sampling of water; the potential for future groundwater contamination; recommendation for more wells for groundwater testing; concerns about proper sealing of conduits; and that the Proponent develop closure-specific runoff control measures, as well as sediment and erosion control measures, to minimize site surface water and sediment entering the river.

On August 16, 2021, CNL provided responses to questions from Brokenhead Ojibway Nation's Technical Report of the Revised Environmental Impact Statement for the Project. In response to Brokenhead Ojibway Nation's questions and recommendations, CNL provided additional information on studies and consideration given to the ISD design and climate change. This did not result in any updates to the revised draft EIS.

Recognizing that environmental protection and the integrity of the ISD design will continue to be an area of interest for the communities, with the relationship agreement in place (including its extension), CNL has put in place a forum to discuss and make efforts to address residual areas of concern. Black River First Nation and Hollow Water First Nation have bi-weekly meetings between staff and Quarterly Core Engagement Team meetings involving community members to facilitate discussions.

Consultation, Engagement and Regulatory Processes

Questions were raised about why communities had not been previously consulted when AECL originally chose the WL site. Specifically the communities identified that while this Project is not meant to address historical issues and that the primary duty to consult on this Project lies with the Crown (CNSC) and not CNL, that CNSC and CNL must acknowledge the history of this site, whereby a colonial government was able to establish a nuclear research facility without the permission, engagement, or knowledge of Indigenous communities; one which has created an environmental footprint and had unplanned releases to their traditional territories. They suggested that while the environmental licensing process addresses one project at a time, the dialogue and relationship with First Nations

must take a broader temporal scope. The three communities also raised questions about the duty to consult. Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation expressed a concern about the small amount of participant funding available. The three communities were curious about the CEAA 2012 and its requirements for soliciting information from nearby communities, and Brokenhead Ojibway Nation wanted to understand how the regulator works, and how the independent commission is selected.

In response to the three communities' interests and concerns regarding consultation, engagement, and the regulatory process, CNL confirmed that while historical grievances are outside of the scope of this Project, CNL committed to supporting an open and transparent dialogue on historical concerns between the communities, CNL, and AECL. CNL also has committed to and provided capacity funding for regional Indigenous communities beyond the funding provided by CNSC. CNL also has responded to community requests for capacity and entered into MOUs and contribution agreements for specific scopes of work, such as the TKLUS.

CNL coordinated, and hosted a community benchmarking trip to Hallam, Nebraska, to tour an in situ reactor and CNL has provided support for members and staff to attend nuclear industry conferences, such as the2019 Waste Management Symposia and the 2024 NWMDER conference.

CNL, Black River First Nation, and Hollow Water First Nation signed a Comprehensive relationship agreement, on April 6, 2021, to support greater community involvement on the Project. The Comprehensive relationship agreement supports the establishment of a community committee and a community liaison position, provides support to participate in the Indigenous Advisory Committee, and provides capacity support so that meaningful participation and engagement throughout the environmental assessment process.

The relationship agreement has created a forum to discuss and work to continue to resolve and address residual concerns. On April 13, 2023, the extension agreement of this original agreement was signed.

Black River and Hollow Water First Nation have also worked with CNL to establish a binding set of commitments on the Project that help formalize communications throughout the Project.

CNL continues to share information with Brokenhead Ojibway Nation.

Traditional Knowledge

The communities have identified through the TKLUS that, over time, they have seen changes to the health of the animals that they harvest. They have also seen that hunting and trapping are getting harder to do, as many traditional areas have been converted to other land uses over time. They suggest that the WL site is one piece of the cumulative effects of development that has slowly taken away their traditional way of life. While it is too late to change the fact that the WL site was built on this site within their traditional territory, it is not too late to continue to work with CNL and other partners to discuss their communities' interests in this area as well as the future health of the water, land, fish, and animals.

The communities also noted that some of the spiritual places they had may no longer exist because the land has changed. They emphasized that it is important to protect remaining spiritual places like the petroform sites in the Whiteshell area. Black River First Nation typically held ceremonies in the Whiteshell region in the fall around the period of the Harvest Moon. Here, they also picked wild rice, which was a dietary staple. Brokenhead Ojibway Nation and Hollow Water First Nation also noted the importance of traditional and cultural perspectives about the Project. CNL has offered to Black River First Nation, Hollow Water First Nation and Brokenhead Ojibway Nation the opportunity to conduct ceremony on site in connection to the Project and the WL site.

CNL heard this feedback and confirmed that the EIS properly considered wild rice. Berries were also included as part of the ecological and human health risk assessment, and their consumption, when combined with other activities such as harvesting, did not result in any adverse effects on health. CNL noted that when all the potential pathways from the Project to traditional land and resource use were considered, such as changes to water quality, to fish, to wildlife, to vegetation, or to human health, there were no significant residual effects predicted.

CNL supported the TKLUS that was conducted by the three communities and used the information from the TKLUS to revise sections of the EIS. CNL has also used the TKLUS to verify the Project's VCs and created a list of topics and species of interest and concern for the three communities. The plants, animals, and other species and topics identified below are not intended to be representative of all the Nations' species and topics of interest but are generally representative of aspects of values that have been explicitly flagged through Traditional Knowledge Study and engagement in relation to the Project. They may not reflect an exhaustive list of species and topics of interest. The following list is CNL's understanding of related species and topics of interest to the communities:

- food (e.g., blueberries, raspberries, chokecherries) and Traditional Medicines (e.g., muskeg tea, willow, seneca root, rose hips, cedar, poplar, weekay)
- rabbit, squirrel, porcupine, chipmunks
- white-tailed deer, moose
- fox, lynx, marten, fisher
- sturgeon, pickerel, sunfish, catfish
- geese, ducks, waterfowl
- beaver, muskrat
- wild rice
- seagull eggs
- groundwater and groundwater interaction
- Winnipeg River
- employment and business opportunity
- community well-being
- land tenure and future use
- cultural and archaeological sites
- traditional land use
- traditional harvesting of country foods
- environmental and community safety

In their Technical Report, Brokenhead Ojibway Nation made numerous comments and recommendations pertaining to Traditional Knowledge, culture, and ceremony. Comments on methodology and the need to incorporate traditional values in consideration of seed mix, monitoring and testing on harvested species, and traditional diet considerations.

On August 16, 2021, CNL provided responses to questions from Brokenhead Ojibway Nation's Technical Report of the Revised Environmental Impact Statement for the Project. In response to Brokenhead Ojibway Nation's comments and feedback, CNL has revised Section 11.0 of the draft EIS to reference CNL's commitment to use native grass species for the cap and cover. To provide further clarity on land and resource use, CNL is revising Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations of the draft EIS, as well as the other subsections of Section 6.0, to include up-front tables that explicitly list the interests and concerns of each community and identify exactly how that concern is captured and addressed within the section. These are separated by community so it should be very clear how Brokenhead Ojibway Nation feedback was included and distinguishes Indigenous Nation feedback from public feedback.

Recognizing that Traditional Knowledge, culture and ceremony will continue to be areas of interest for the communities, with the relationship agreement in place with Black River First Nation and Hollow Water First Nation, CNL has put in place a forum to discuss and address any residual concerns on these matters.

CNL will continue to make efforts to engage with Brokenhead Ojibway Nation.

4.2.4.3.5 Verification

CNL incorporated feedback through engagements with the three communities on the Project and their TKLUS. To confirm CNL has adequately captured the communities' interests and concerns, position, and knowledge, CNL and Black River First Nation and Hollow Water First Nation underwent a verification process whereby CNL provided EIS documentation to the three communities for their review and feedback. CNL and Black River First Nation and Hollow Water First Nation met to discuss their feedback on the documents and to inform how CNL incorporated the feedback into the revised draft EIS. Due to the communities' limited capacity to respond during the COVID-19 Pandemic, the information in the summary of interests and concerns table, list of species and topics raised in the TKLUS and engagement, and Section 4.0 of the draft EIS has been reviewed by Hollow Water First Nation and Black River First Nation's technical advisors and one Council representative from each community; however, they may not represent both Nations' whole views. While not all Black River and Hollow Water First Nations' concerns were mitigated by this process, CNL made every effort to verify that the communities' position, interests and concerns were adequately characterized. CNL continues to work with the communities to address their concerns.

On July 7, 2021, technical advisors and lead representatives from Black River First Nation and Hollow Water First Nation provided feedback on the summary of interests and concerns table and list of species and topics raised in the TKLUS and engagement. CNL met with representatives and technical advisors from Black River First Nation and Hollow Water First Nation on August 19, 2021, to go through the feedback received on the summary of interests and concerns table and list of species and topics raised in the TKLUS and engagement. CNL incorporated their feedback and on August 26, 2021, CNL provided a revised copy to the communities to show how their feedback was incorporated. The representatives and technical advisors for the communities provided additional feedback on September 2, 2021. CNL incorporated the additional feedback and sent the final copy back to the communities on September 9, 2021, along with a thank you letter, thanking the communities for participating in the verification process for their summary table of interests and concerns, list of species and topics raised in the TKLUS and engagement. CNL provided the updated copies to Brokenhead Ojibway Nation and throughout the summer of 2021 reached out by phone, email and fax. CNL has not heard from the community and while CNL sent an updated copy of the summary of interests and concerns table to include specific references with Brokenhead Ojibway Nation's technical review of the 2020 draft EIS on October 6, 2021, CNL has not received a response from the community. On October 18, 2021, CNL issued a letter to the Brokenhead Ojibway Nation informing them that CNL would be incorporating the table into the EIS and move forward with submission.

In addition to verifying Indigenous information in the revised draft EIS with the three communities, CNL has also worked on verifying their responses to the three communities' comments on the draft EIS. CNL sent their responses to the communities' draft EIS comments on September 15, 2020, to each individual community and their consultants. In October 2020, the consultant for Black River First Nation and Hollow Water First Nation acknowledged receipt of responses to community comments on the draft EIS and provided additional comments. Prior to submitting additional responses to the communities, CNL met with the communities and their consultants to better understand their concerns and test CNL's proposed responses and next steps. Afterwards, CNL revised its responses based on the feedback received from the communities. CNL sent its responses to each of the communities.

CNL received a letter from the CNSC on August 24, 2022, indicating that three Information requests remained outstanding, including updating the Indigenous engagement narrative and tables. Community specific portions of Section 4.0, Engagement Logs, and Interests and Concerns Tables were sent to Black River First Nation, Hollow Water First Nation, and Brokenhead Ojibway Nation on October 20, 2022. On November 3, 2022, Black River First Nation and Hollow Water First Nation returned an email confirming that changes to the EIS reflected current discussions and understandings. While all efforts were made to communicate changes to the EIS to Brokenhead Ojibway Nation, CNL did not receive any feedback on these latest EIS updates.

CNL has also shared EIS Section 3.4.3 with Black River First Nation and Hollow Water First Nation and Brokenhead Ojibway First Nation for review and comment on X date and incorporated changes from the First Nations prior to submitting the EIS in spring 2024.

CNL also verified the commitments list with Black River First Nation and Hollow Water First Nation. Throughout late 2022 and early 2023 CNL and Black River First Nation and Hollow Water First Nation worked on co-developing a list of binding commitments on the Project.

On September 21, 2022, CNL provided a preliminary list of draft commitments to Black River First Nation and Hollow Water First Nation, which was drafted with information from engagements and comment responses for the Project. On November 1, 2022, Black River First Nation and Hollow Water First Nation shared their review of the updated table of commitments. On December 13, 2022, CNL shared an updated list of commitments.

On October 3, 2024, CNL emailed Black River First Nation and Hollow Water First Nation asking for comments on the updated interests and concerns table to be included in the 2024 EIS submission. On October 25, 2024, Black River First Nation and Hollow Water First Nation emailed CNL with comments on the interests and concerns table, which CNL incorporated.

On September 23, 2024, CNL emailed Black River First Nation and Hollow Water First Nation asking for comments on the updated Section 4 of the EIS to be included in the 2024 EIS. On October 3, 2024, Black River First Nation and Hollow Water First Nation emailed CNL with comments on Section 4, which CNL incorporated.

To confirm the package being submitted for the 2024 draft EIS submission, CNL emailed Black River First Nation and Hollow Water First Nation on November 11, 2024, with the updated Section 4, with Black River First Nation and Hollow Water First Nation's comments incorporated, an updated Table of Key Interests and Concerns, with Black River First Nation and Hollow Water First Nation's feedback incorporated, stating that this would be included in the 2024 draft EIS submission.

4.2.4.3.6 Next Steps

CNL will work with the communities to coordinate recommended next steps and begin to implement commitments.

Black River First Nation and Hollow Water First Nation have been observing and participating on-site monitoring activities. The parties have discussed putting a monitoring plan in place to coordinate these activities.

CNL will also continue engagement with the three communities with the objective of addressing or resolving any outstanding issues or concerns with the Project. CNL, Black River First Nation, and Hollow Water First Nation signed a relationship agreement, which was extended in 2023, that helps increase the communities' capacity and allow for greater participation in the environmental assessment process. The relationship agreement supports a liaison position and the creation of a community liaison committee (the "Core Engagement Team"), among other things.

4.2.4.4 Wabaseemoong Independent Nations

The Wabaseemoong Independent Nations (also known as Wabaseemoong Independent Nations of One Man Lake, Swan Lake, and White Dog) are signatories to Treaty No. 3. The Wabaseemoong Independent Nations (WIN) have potential, asserted and/or established Aboriginal and Treaty Rights in the vicinity of the Project.

A map of Wabaseemoong Independent Nations is provided in the IER Appendices (CNL 2024). See the IER (CNL 2024) for more background information on Wabaseemoong Independent Nations.

The Wabaseemoong Independent Nations have a total registered population of 1,989 (as of September 2018). Approximately half of the community (1,012) reside off reserve lands. The Wabaseemoong Independent Nations occupy four areas of reserve lands, all within northwestern Ontario. Wabaseemoong Reserve No. 06268 has a land base of 8,480 ha. The largest of the four reserves, it is situated approximately 8 km east of the Manitoba-Ontario border and approximately 80 km east of the WL site. At its southern perimeter, the reserve encompasses the community of Whitedog. To the south is Swan Lake 29 Reserve No. 06270 with the second largest land area (2,237 ha), located on the east shore of Swan Lake and approximately 85 km east of the WL site. One Man Lake 29 Reserve No. 06269 is located to the northeast of Wabaseemoong Reserve, on the north shore of One Man Lake and 95 km east of the WL site. This reserve has a land base of 1,117.3 ha. Agency 30 Reserve No. 06240 is the fourth reserve (379 ha), well to the south of the other reserves, and situated in Lake of the Woods, approximately 140 km southeast of the WL site. This reserve is shared with twelve other First Nations, including Shoal Lake No. 40 First Nation, Northwest Angle No. 33 First Nation, and Iskatewizaagegan #39 Independent First Nation.

4.2.4.4.1 Engagement

In August 2016, CNL sent a letter to Wabaseemoong Independent Nations introducing the Project and inviting them to engage on this Project. In May 2017, CNL, AECL, and the CNSC met with Wabaseemoong to discuss the Project. One month later, in June, Wabaseemoong representatives participated in a site tour at the WL site and had a follow-up discussion on the Project. CNL, CNSC, and AECL also met with Wabaseemoong in August 2017 to continue discussions on the Project. In October, CNL sent a letter to Wabaseemoong notifying them of the public comment period for the draft EIS and invited them to review and submit comments. In November, CNL sent a hard copy of the draft Environmental Impact Statement (EIS) executive summary to the community. The same month, CNL invited the community to participate in a site tour.

In September 2017, CNL provided an opportunity for five members from each First Nation community and the MMF to attend a full day workshop to both learn and share on how CNL and the First Nations and the MMF

collectively protect and care for the environment. The goal was to provide some hands-on experience coupled with ample discussion, learning and dialogue on opportunities moving forward both as a career option and as a relationship between the site and the First Nations and the MMF.

On October 31, 2017, CNL shared the Annual Safety Reports with each Indigenous Nation, including the Environmental Monitoring in 2016 at Whiteshell Laboratories report (CNL 2017a), and the 2016 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories (CNL 2017b). CNL also provided an invitation to engage on these documents.

In 2018, Wabaseemoong Independent Nations participated in the Hallam, Nebraska, benchmarking trip. The purpose of the trip was to provide First Nations and the MMF the opportunity to see firsthand what an in-situ disposal (ISD) site looks like post-closure and to provide more information about ISD. Wabaseemoong also submitted a Traditional Knowledge and Environmental Impact Assessment (WIN 2018), which was submitted to the CNSC on January 8, 2018.

In August 2020, CNL submitted CNL's responses to Wabaseemoong's comments on the draft EIS. CNL followed up several times via email and phone requesting an opportunity to discuss CNL's responses and invited them to participate in a site tour. Although Wabaseemoong indicated interest in attending a tour no answer was given for whether the community would like to discuss CNL's responses to their comments. In September, CNL sent an invitation to Wabaseemoong inviting them to participate in CNL's fall monitoring activities. This invitation was sent out to all communities. CNL also sent Wabaseemoong an invitation to participate in CNL's final breakfast session. This was also sent to the First Nations and the MMF. CNL did not receive a response for either invitation.

In October 2020, CNL reached out to Wabaseemoong on a weekly basis requesting to meet to discuss CNL's responses to their comments. The purpose of the meeting would be to determine whether CNL's responses adequately addressed their comments and discuss next steps. Wabaseemoong did not respond to CNL's calls or emails.

On February 8, 2021, CNL sent a formal letter to the community, stating CNL was getting ready to resubmit their draft EIS for the Project and offering to provide a Project update.

On May 11, 2021, CNL sent a letter to Wabaseemoong' s leadership asking for their verification on whether CNL had documented the community's interest and concerns and list of valued components (VC) correctly. On June 6, 2021, CNL sent the community an invitation to participate in an exploratory discussion on developing an Indigenous Advisory Committee at WL. On July 20, 2021, CNL and a representative from Wabaseemoong Independent Nations held a teleconference to go through the table to confirm CNL had addressed their interests and concerns. During the meeting, CNL revised the summary of interests and concerns table and sent back a copy on July 22, 2021, and the revised list of VCs on July 23, 2021. On September 9, 2021, CNL sent a thank you letter to Wabaseemoong, thanking them for verifying that CNL had adequately captured their interests and concerns.

A representative from Wabaseemoong Independent Nations participated in the two exploratory discussions on developing an Indigenous Advisory Committee for the WL site. The two sessions were held on August 12, 2021, and September 28, 2021.

On May 16, 2022, CNL held a teleconference with Wabaseemoong Independent Nations and walked through the revisions to the interests and concerns table and made changes based on Wabaseemoong Independent Nations feedback during the meeting. On June 13, 2022, CNL asked Wabaseemoong Independent Nations to confirm they

have completed verification of their interests and concerns table. On July 12, 2022, CNL and Wabaseemoong Independent Nations had a phone conversation and discussed current events and upcoming availability for a site tour. CNL also confirmed the contact information for the Chief. On the following day, July 13, 2022, CNL sent a letter to Wabaseemoong Independent Nations Chief notifying him that CNL had submitted the draft EIS to the CNSC to determine completeness.

On August 26, 2022, CNL and Wabaseemoong Independent Nations discussed setting up a date for a tour. Wabaseemoong Independent Nations suggested calling in a few weeks to confirm interest in attending a tour. CNL sent a copy of CNL's monitoring program schedule on August 30, 2022 and requested Wabaseemoong Independent Nations to identify any activities of interest. CNL followed up with an email on September 23, 2022, regarding recent discussions about meeting with the Wabaseemoong Independent Nations leadership team and doing a site tour. CNL reaffirmed their interest to meet and coordinate those activities. CNL also requested Wabaseemoong Independent Nations identify any specific monitoring activities that they wish to be involved with, from the list provided to them on August 30, 2022.

On October 4, 2022, CNL sent the 2021 Annual Compliance Monitoring Reports for WL. Later in the month, on October 21, CNL shared relevant sections of EIS Section 4 (related to Wabaseemong Independent Nations) as well as the interests and concerns table, which records the First Nation’s interests and concerns in relation to the Project. CNL also requested a meeting to discuss the EIS Section 4 and the Interests and Concerns table.

Over the course of the next five weeks CNL sent four follow-up emails regarding the EIS Section 4 and the Interests and Concerns table.

On December 16, 2022, CNL wrote to share that they had submitted the revised draft EIS to the CNSC.

On January 16, 2023, CNL emailed Wabaseemoong Independent Nations to share that the EIS had passed its completeness check and that the CNSC had accepted the EIS for technical review.

In March 2023, CNL shared a copy of the draft CNL Indigenous Relations Procurement Strategy with Wabaseemoong Independent Nations for input and discussion.

In April 2023, CNL emailed Wabaseemoong Independent Nations with invitations to CNL’s public webinar on Whiteshell and to confirm that Wabaseemoong Independent Nations was still not interested in engagement with CNL. Wabaseemoong Independent Nations responded that their engagement with CNL was through Grand Council Treaty #3. CNL has been information sharing and met on a monthly basis with Grand Council Treaty #3 throughout 2023. This regular engagement is ongoing.

On July 4, 2023, in follow-up to the CNL-hosted Regional Leaders Gathering, which focussed on Land Use and End State, CNL shared its Land Use End State plan with Wabaseemoong Independent Nations for input. On July 31, 2023, CNL emailed Wabaseemoong Independent Nations to discuss the commitments list for the Project. The Resource Information Officer with Wabaseemoong Independent Nations confirmed that they would meet with CNL on August 9. On August 9, 2023, the Resource Information Officer was not in attendance at the scheduled meeting and so CNL was not able to discuss commitments list at that point.

At the Grand Council Treaty # 3 monthly meeting with CNL in September 2023, CNL heard an update from Wabaseemoong Independent Nations. Later that fall, CNL followed up with Wabaseemoong Independent Nations on the CNL Indigenous Relations Procurement Strategy. CNL also shared the Indigenous Vendors Portal in the

fall of 2023. In November, Wabaseemoong indicated that capacity was an issue for reviewing the Indigenous Relations Procurement Strategy and CNL offered to follow-up in 2024.

On November 20, 2023, CNL requested a meeting to discuss a draft EIS commitments list for the Project.

In January 2024, CNL again followed up requesting a meeting on the draft commitments list for the Project and on January 31 CNL shared a corporate-wide community bulletin.

On February 9, 2024, CNL shared an information bulletin with all engaged Indigenous Nations, which contained information on maintenance work restarting at the WL site. CNL also shared an invitation to the February public webinar this month.

In March 2024, CNL shared information on how to participate in the CNSC's public hearing for the WL site licence renewal, which is to be held in October 2024. On March 22, 2024, CNL shared the engagement summary section to be included in the IER with WIN for review and verification. CNL asked for any feedback on this document to be shared back to CNL by April 19, 2024. CNL did not receive any feedback from WIN.

In April 2024, CNL invited WIN to participate in the 2024 Regional Leaders Gathering in June 2024 and to attend CNL's April public webinar, which focused on the Whiteshell Fire Program. This month, CNL also shared information on the CNSC's Indigenous and Stakeholder Capacity Fund.

On May 2, 2024, CNL followed up with further information on the Regional Leaders Gathering and on May 15, CNL invited review on the engagement section of CNL's Commission Member Document for the 2024 WL site licence renewal hearing. On June 10, 2024, CNL shared this section, offering capacity for review and requesting any feedback be shared by July 5, 2024.

On June 19, WIN's Coordinator replied to the June 10 email, stating that WIN would participate as a part of Grand Council Treaty #3. CNL's Indigenous Relations Officer responded the following day noting that CNL was meeting with Grand Council Treaty #3 and offering to set a call with WIN and encouraging WIN participation in the monthly meetings between Grand Council Treaty #3 and CNL. CNL shared this correspondence with Grand Council Treaty #3 to provide transparency.

4.2.4.4.2 Interests and Concerns

Wabaseemoong Independent Nations submitted three formal comments on the 2017 draft EIS.

Through a variety of engagement forums, including webinars, meetings, and teleconferences, Wabaseemoong Independent Nations has raised a number of issues, concerns and questions that were initially focused on the 2017, 2020 and 2022 draft EIS. These engagements have led to the development of the interests and concerns table for Wabaseemoong Independent Nations. This subsection is taken from the tables of interests and concerns from Appendix 4.0-1 and describes CNL's understanding based on written submissions and oral discussions with the Nations. The Nations have also provided feedback through their TKLUS (WIN 2018). CNL has made its best efforts to document and verify the position the Nations have taken on each interest/concern. See Section 4.4 for a summary of issues raised during engagement activities that influenced the scope of the environmental assessment.

The topics in the table of interests and concerns are briefly summarized below:

Regulatory Process

Wabaseemoong Independent Nations expressed concern with the communication methods used by the CNSC, noting that they were not aware of the Project until Sagkeeng's Chief mentioned it. They also wanted to understand why they were only recently contacted since the WL site was established and began operations in the 1960s. CNL responded directly to community comments and concerns about the timing and communications on the Project. CNL held an information session in the community to provide information on the Project and answer any questions directly from the community members. CNL continues to send updates on the Project. CNL will continue to notify Wabaseemoong Independent Nations about the Project and make itself available to discuss topics of interest to the community.

CNL has adequately addressed this area of interest, based on the steps taken to address this concern with the community and the attempts made to verify this area of interest.

Engaging the Community

Wabaseemoong Independent Nations expressed interest in having an engagement event in their home community with CNL, AECL and CNSC which subsequently occurred August 21, 2017. CNL has invited Wabaseemoong for a site tour and offered capacity funding to support their review of CNL's responses to the community's comments on the draft EIS. CNL continues to look for ways to engage with the community. CNL has adequately addressed this request and area of interest.

Business and Employment Opportunities

Wabaseemoong Independent Nations requested more details about employment opportunities at the WL site, including the availability of seasonal employment and the proportion of the workforce that is Indigenous. Wabaseemoong Independent Nations noted that employment at the WL site may be difficult for members because it is not located within commuting distance of the community. CNL hosted an Indigenous industry day to share information about employment and contracting opportunities with communities. CNL recognized that the commute from Wabaseemoong Independent Nations was long but offered to help any job candidates find appropriate housing in the region.

CNL's procurement department also added provisions to its procurement process that encourages the use of Indigenous and local small and medium sized businesses and has reached out to engage with communities on procurement. CNL believes they have adequately addressed this area of interest, based on the steps taken to address this concern with the community and the attempts made to verify this area of interest.

As well, in 2023, CNL developed and shared a draft Indigenous Relations Procurement Strategy with Wabaseemong Independent Nations. CNL also shared the Indigenous Vendors Portal in the fall of 2023.

CNL believes they have adequately addressed this area of interest, based on the steps taken to address this concern with the community and the attempts made to verify this area of interest.

Traditional Knowledge

Wabaseemoong Independent Nations noted that animals do not obey the same sort of boundaries as humans and could encounter hazardous materials. They expressed an interest in conducting a traditional use study. Wabaseemoong submitted a CNSC funded traditional use study to the CNSC on January 18, 2018. CNL acknowledged this and explained that there were no Project activities or outcomes that would result in a residual adverse effect to wildlife, so species of importance to traditional land and resources use will not be affected.

CNL provided responses to community comments about animals within CNL boundaries limits, and incorporated elements of the traditional use study in Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations of the EIS to the extent possible.

By incorporating Traditional knowledge from Wabaseemoong Independent Nations into the draft EIS, CNL has adequately addressed this area of interest, recognizing that engagement is ongoing and CNL will continue to invite Wabaseemoong to be involved in environmental monitoring on site.

CNL has also used the TKLUS to verify the Project's VCs and created a list of VCs for the community. Wabaseemoong Independent Nations verified that these VCs adequately capture the species and areas of interest and concern to the community to the best of their knowledge at this time. The following list is CNL's understanding of related species and topics of interest:

- Partridge
- Food and traditional medicines
- Rabbit, squirrel, porcupine, chipmunk
- White-tailed deer, moose
- Bear, wolf
- Fish (sturgeon, whitefish, walleye, bass)
- Benthic invertebrate
- Heron
- Mallards, teal, geese
- Mink, beaver, muskrat, otter
- Winnipeg River
- Employment and business opportunity
- Community well-being
- Environmental and community safety
- Land tenure and future use
- Cultural and archaeological sites
- Traditional land.

CNL believes they have adequately addressed this area of interest, based on the steps taken to address this concern and the attempts made to verify this area of interest. CNL also remains open to additional Traditional Knowledge.

Environmental Monitoring

Wabaseemoong Independent Nations expressed an interest in knowing more about monitoring fish, including how fish are tested and if contaminants can accumulate over time. In addition, they asked about air emissions monitoring practices. The community expressed an interest in learning more about CNL's long-term monitoring plan for WR-1 due to the long-term nature of the Project.

CNL environmental protection staff engaged and presented on the WL site environmental protection program, explaining, among many other aspects, the annual monitoring campaign that has been underway since the inception of the site. This included information on fish sampling and air emissions. CNL explained where air monitoring occurs, both on and off site. CNL explained the results and the low impact. CNL pointed to where the results are available annually on their website.

CNL sent Wabaseemoong a list of environmental monitoring activities and invited the community to participate. CNL continues to look for ways to improve its environmental monitoring program. CNL will continue to invite Wabaseemoong to participate in CNL's monitoring activities. CNL has also committed to engagement with each Indigenous community on the development and implementation of a post-closure monitoring plan that will include an Indigenous-led monitoring program.

Recognizing that this is an area of ongoing interest for the community, and CNL's commitment to continued engagement on this topic, CNL believes it has adequately addressed this area of interest.

Future Land Use and Tenure

Wabaseemoong expressed questions about future land use of the WL site, specifically on the proportion of land that would be available post-closure of the WL site. CNL plans to engage with First Nations and the MMF on future land use and end state in 2021. CNL explained and provided information on the size and location of the site. This included posters that had a map and aerial pictures of the site. While out of scope of the environmental assessment for the Project and continues to offer opportunities for engagement on this topic, including providing opportunity for Indigenous input on the draft land use end state plan.

Governance Structure of the Canadian Nuclear Laboratories

Wabaseemoong Independent Nations were interested in the history of the WL site and the functional relationship between CNL and AECL. CNL provided information explaining CNL's governing structure and their relationship with AECL. AECL, CNL, and CNSC have presented on their individual roles in the regulatory process. CNL has adequately addressed this area of interest, based on the steps taken to address this concern with the community and the attempts made to verify this area of interest.

Waste Management

Wabaseemoong Independent Nations were interested in more detailed information about how much radioactive waste would remain on the WL site, where the radioactive waste would be stored, and how it was to be transported off-site. Wabaseemoong Independent Nations also asked about the methods used to transport waste and how it will be communicated to potentially affected communities. CNL hosted Wabaseemoong for a tour of their waste management facilities and answered questions about waste management and transportation of waste. CNL provided information to the community on waste management at the site and proposed plans for waste transportation. CNL has adequately addressed this area of interest, based on the steps taken to address this concern with the community and the attempts made to verify this area of interest.

Accidents and Malfunctions

Wabaseemoong Independent Nations were interested in past releases and the potential for future releases of hazardous and radioactive material into the Winnipeg River. In addition, they were interested in how releases could be contained in the soil, and information on spill detection. As stewards of the land, members of Wabaseemoong Independent Nations have a responsibility to protect ecosystems and maintain ecosystem

function including trophic impacts of contamination. Wabaseemoong Independent Nations expressed the view that potential adverse impacts on fisheries from the Project would negatively impact the ability of Wabaseemoong Independent Nations members to collect these fisheries resources and damage their relationship with them. Moreover, changes to concentrations of contaminants (e.g., nuclear spills) in fish tissues could have negative consequences on human health. CNL continues to provide updates on the decommissioning activities to the community and will continue to seek opportunities to discuss the Project with the community.

CNL responded to Wabaseemoong's questions regarding CNL's detection systems, past spills, and prevention of future spills. CNL developed plain language materials to support their communication of past spills. CNL has committed to involving First Nations and the MMF in the development and implementation of an Indigenous post-closure monitoring program.

CNL has adequately addressed this area of interest, based on the steps taken to address this concern with the community and the attempts made to verify this area of interest.

Project Description

Wabaseemoong Independent Nations expressed a concern about the longevity of the nuclides and the long-term nature of the Project. There was discussion about whether climate change or natural disasters could affect the integrity of the grouted encapsulation and how it would be constructed to confirm that it is safe.

CNL indicated that climate change may have an impact on the site and that potential effects are being studied and reported on in the EIS. CNL also mentioned that extreme events are also being considered including flooding. Wabaseemoong was told that the site is in an area that isn't prone to earthquakes. Seismic activity is extremely low in the Project area and is not expected to result in any damage to the facility. CNL will be examining potential accidents and disruptive scenarios such as a plane crash, animal intrusion, or glaciation.

CNL has adequately addressed this area of interest, based on the steps taken to address this concern with the community and the attempts made to verify this area of interest.

4.2.4.4.3 Verification

CNL incorporated feedback through engagements with Wabaseemoong Independent Nations on the Project and their TKLUS. To confirm CNL has adequately captured the community's interests and concerns, position, and knowledge, CNL and Wabaseemoong Independent Nations underwent a verification process whereby CNL provided EIS documentation to the community for their review and feedback. CNL and Wabaseemoong Independent Nations met to discuss the community's feedback on the documents to inform how CNL incorporated the feedback into the EIS. Through this process, the community has reviewed and provided feedback from their summary of interests and concerns table, list of VCs, and Section 4.0. CNL made every effort to verify that the community's interests and concerns were adequately characterized. CNL continues to work with Wabaseemoong Independent Nation to address their concerns.

In September 2020, Wabaseemoong acknowledged receipt of CNL's responses to their community's comments on the draft EIS. CNL has requested to meet with Wabaseemoong to discuss CNL's responses to their comments, however the community has not yet indicated whether they intend to review CNL's responses. CNL has also offered to provide capacity funding and to host Wabaseemoong for a site tour.

On May 11, 2021, CNL sent a letter to Wabaseemoong' s leadership asking for their verification on whether CNL had documented the community's interests and concerns and list of VCs correctly. On June 6, 2021, CNL sent

the community an invitation to participate in an exploratory discussion on developing an Indigenous Advisory Committee at the WL site. On July 20, 2021, CNL and a representative from Wabaseemoong Independent Nations held a teleconference to go through the table to confirm that CNL had addressed their interests and concerns. During the meeting, CNL revised the summary of interests and concerns table and sent back a copy on July 22, 2021, and the revised list of VCs on July 23, 2021. On September 9, 2021, CNL sent a thank you letter to Wabaseemoong, thanking them for verifying that CNL had adequately captured their interests and concerns.

On October 21, 2022, CNL shared relevant sections of EIS Section 4 (related to Wabaseemong Independent Nations) as well as the interests and concerns table, which records the First Nation's interests and concerns in relation to the Project. CNL also requested a meeting to discuss the EIS Section 4 and the Interests and Concerns table.

Over the course of the next five weeks in fall 2022, CNL sent four follow-up emails regarding the EIS Section 4.0 and the Interests and Concerns table. CNL did not receive a response to these inquiries.

With respect to verification of the binding Commitments, on July 31, 2023, CNL emailed Wabaseemoong Independent Nations to discuss the commitments list for the Project. The Resource Information Officer with Wabaseemoong Independent Nations confirmed that they would meet with CNL on August 9, 2023.

On August 9, 2023, the Resource Information Officer was not in attendance at the scheduled meeting and so CNL was not able to discuss commitments list at that point.

CNL followed up again on November 20, 2023, on January 2, 2024, and on April 5, 2024, regarding a meeting to discuss the commitments.

On September 23, 2024, CNL emailed WIN asking for comments on the updated Section 4.0 of the EIS to be included in the 2024 EIS submission. On October 3, 2024, CNL emailed WIN asking for comments on the interests and concerns tables that is to be included in the 2024 EIS submission.

On October 15, 2024, CNL resent the list of draft commitments, Section 4.0, and the table of interests and concerns, as WIN had noted interest in reviewing the draft EIS content at the monthly meeting between Grand Council Treaty #3 on October 15, 2024.

CNL emailed WIN on November 12, 2024, to share that CNL would be submitting the draft EIS package without WIN's review and that future feedback could inform the final EIS submission. CNL also noted in this email that proposed commitments list was "evergreen" – meaning new commitments could be added when and where WIN and CNL saw the need.

CNL will continue to share information and make efforts to engage with Wabaseemoong Independent Nations.

4.2.4.4.4 Next Steps

CNL will continue to pursue engagement with the Wabaseemoong Independent Nations with the objective of addressing or resolving any outstanding issues or concerns with the Project and establishing a verified commitments list for the Project. CNL will continue to reach out in the interest of improving the relationship between CNL and Wabaseemoong Independent Nations.

CNL also remains open to supporting Indigenous participation in environmental monitoring at the WL site.

4.2.4.5 Shoal Lake #40 First Nation

A map of Shoal Lake #40 First Nation is provided in the IER Appendices.

In August 2016, Canadian Nuclear Laboratories (CNL) sent Shoal Lake #40 First Nation a Project introductory letter and requested the community's input on any potential adverse impacts from the Project activities. CNL did not receive any response from the community. In addition to sending the letter, CNL phoned Shoal Lake multiple times in 2016 to determine whether the community was interested in engaging on the Project. CNL followed up with the Chief who confirmed he had received CNL's letter. In 2017, CNL followed up multiple times with the Lands and Resource Manager and in October 2017, CNL sent a letter to the Chief notifying the community that CNL had submitted the draft Environmental Impact Statement (EIS). Until February 2021, CNL did not reach out to the community. Since CNL had not heard back after multiple attempts to communicate in 2016 and 2017, CNL assumed the community was not interested in engaging on the Project.

Since 2017, CNL has learned a great deal from engaging with First Nations and the MMF on the Project. CNL recognizes the importance of making ongoing efforts to meaningfully engage with communities and has resumed communications with the Shoal Lake #40 First Nation. CNL sent a formal letter in February 2021 to the community, stating CNL was getting ready to resubmit their draft EIS for the Project and offering to provide a Project update.

On July 13, 2021, CNL sent out a letter of notice to the Chief informing him that CNL has submitted a draft EIS and requesting a meeting to engage on the Project. On August 3, 2022, CNL followed up with a phone call and left a detailed message with reception for the Chief regarding receipt of the letter and transmittal email and regarding CNL's interest to discuss and meet.

On November 16, 2022, CNL emailed Shoal Lake #40 First Nation with an update on land use end state and to express interest in community engagement related to the WL site.

In December 2022 CNL shared an update on the revised draft EIS submission to the CNSC. CNL followed up on this email on January 16, 2023, to share that the EIS had been accepted by the CNSC for Technical Review.

On March 10, 2023, CNL shared its Indigenous Relations Procurement Strategy for input. CNL expressed interest in meeting to discuss this strategy further.

In March 2024, CNL shared information on how to participate in the CNSC's public hearing for the WL site licence renewal, which is to be held in October 2024. On March 22, 2024, CNL shared the engagement summary section to be included in the IER with Shoal Lake #40 First Nation for review and verification. CNL asked for any feedback on this document to be shared back to CNL by April 19. CNL did not receive any feedback from Shoal Lake #40 First Nation.

On May 15, 2024, CNL invited review on the engagement section of CNL's Commission Member Document for the 2024 WL site licence renewal hearing. On June 10, CNL shared this section, offering capacity for review and requesting any feedback be shared by July 5, 2024. CNL followed up on June 20 to see if Shoal Lake #40 First Nation was interested in reviewing the Commission Member Document. CNL did not receive feedback from Shoal Lake #40 First Nation.

While CNL has yet to receive a response from Shoal Lake #40 First Nation on the Project, CNL will continue to make efforts to engage and provide regular Project updates.

4.2.4.6 Iskatewizaagegan No. 39 Independent First Nation

A map of Iskatewizaagegan No. 39 Independent First Nation is provided in the IER Appendices.

In August 2016, CNL sent Iskatewizaagegan No. 39 Independent First Nation a Project introductory letter and requested the community's input on any potential adverse impacts from the Project activities. CNL did not receive any response from the community.

In October 2016, CNL called Iskatewizaagegan No. 39 Independent First Nation to gauge interest in the Whiteshell Laboratories Restoration Project. CNL was forwarded to a community representative who requested CNL fax their introductory letter to their community. CNL sent the letter by fax in November 2016. Afterwards, CNL followed-up by phone multiple times with the community that year, with no responses.

In 2017, CNL followed-up multiple times with the community, inviting them to engage on the Project. In October 2017, CNL sent the chief a letter notifying them that CNL had submitted the draft EIS. CNL never received a response from the community and did not reach out again. Since 2017, CNL has learned a great deal from engaging with the First Nations and the MMF on the Project. CNL recognizes the importance of making ongoing efforts to meaningfully engage with the First Nations and the MMF and has resumed communications with the Iskatewizaagegan #39 Independent First Nation. CNL sent a formal letter in February 2021, to the community, stating CNL was getting ready to resubmit their draft EIS for the Project and offering to provide a Project update.

On July 13, 2022, CNL sent out a letter of notice to Chief Lewis informing him that CNL would be submitting a draft EIS and requested a meeting to engage on the Project. On August 3, 2022, CNL followed up with a phone call and left a detailed message with reception for Chief Lewis regarding receipt of the letter and transmittal email and regarding CNL's interest to discuss and meet.

CNL sent a follow-up email on October 21, 2022, with a letter attachment, providing an update on the status of the Project application. CNL will continue to provide regular project updates to Iskatewizaagegan No. 39 Independent First Nation.

On November 16, 2022, CNL emailed with an update on land use end state and to express interest in community engagement related to the WL site.

In December 2022 CNL shared an update on the revised draft EIS submission to the CNSC. CNL followed up on this email on January 16, 2023, to share that the EIS had been accepted by the CNSC for Technical Review.

On March 10, 2023, CNL shared its Indigenous Relations Procurement Strategy for input. CNL expressed interest in meeting to discuss this strategy further. In March 2024, CNL shared information on how to participate in the CNSC's public hearing for the WL site licence renewal, which is to be held in October 2024. On March 22, CNL shared the engagement summary section to be included in the IER with Iskatewizaagegan No. 39 Independent First Nation for review and verification. CNL asked for any feedback on this document to be shared back to CNL by April 19. CNL did not receive any feedback from Iskatewizaagegan No. 39 Independent First Nation.

On May 15, CNL invited review on the engagement section of CNL's Commission Member Document for the 2024 WL site licence renewal hearing. On June 10, CNL shared this section, offering capacity for review and requesting any feedback be shared by July 5, 2024. CNL followed up on June 20 to see if Iskatewizaagegan No. 39 Independent First Nation was interested in reviewing the Commission Member Document. CNL did not receive feedback from Iskatewizaagegan No. 39 Independent First Nation.

While CNL has yet to receive a response from Iskatewizaagegan No. 39 Independent First Nation on the Project, CNL will continue to make efforts to engage and provide regular Project updates.

4.2.4.7 Northwest Angle No. 33 (Treaty No. 3)

A map of Northwest Angle No. 33 First Nation (Treaty No. 3) is provided in the IER Appendices. (CNL, 2024)

After CNL sent the introductory letter to Northwest Angle No. 33, CNL followed up multiple times with the community in 2016 to determine if the community would like to engage CNL on the Project. A community representative informed CNL they had received the letter and that it was provided to Chief and Council, but noted the community recently had an election and people were still getting used to their positions. When CNL followed up they confirmed the letter had been distributed to the Chief and Council but cautioned that the Chief and Council were unlikely to review prior to end of December 2016.

In 2017, CNL notified the Chief of CNL's draft EIS submission and invited them to engage on the Project. After receiving no response on the initial letter or any subsequent follow-up, CNL did not attempt to reach out again. CNL recognizes the importance of making ongoing efforts to meaningfully engage with the First Nations and the MMF and has resumed communications with the Northwest Angle No. #33 First Nation. CNL sent a formal letter in February 2021, to the community stating CNL was getting ready to resubmit their draft EIS for the Project and offering to provide a Project update.

On July 13, 2022, CNL sent out a letter of notice to the Chief informing her that CNL would be submitting a draft EIS and requested a meeting to engage on the Project. On August 3, 2022, CNL followed up with a phone call and left a detailed message with reception for the Chief regarding receipt of the letter and transmittal e-mail and regarding CNL's interest to discuss and meet. While CNL has yet to receive a response from Northwest Angle No. 33 First Nation on the Project, CNL will continue to make efforts to engage and provide regular Project updates.

CNL sent a follow-up email on October 21, 2022, with a letter attachment, providing an update on the status of the Project application. CNL will continue to provide regular Project updates to Northwest Angle No. 33 First Nation.

On November 16, 2022, CNL emailed with an update on land use end state and to express interest in community engagement related to the WL site.

In December 2022 CNL shared an update on the revised draft EIS submission to the CNSC. CNL followed up on this email on January 16, 2023, to share that the EIS had been accepted by the CNSC for Technical Review.

On March 10, 2023, CNL shared its Indigenous Relations Procurement Strategy for input. CNL expressed interest in meeting to discuss this strategy further.

In March 2024, CNL shared information on how to participate in the CNSC's public hearing for the WL site licence renewal, which is to be held in October 2024. On March 22, 2024, CNL shared the engagement summary section to be included in the IER with Northwest Angle No. 33 First Nation for review and verification. CNL asked for any feedback on this document to be shared back to CNL by April 19. CNL did not receive any feedback from Northwest Angle No. 33 First Nation.

On May 15, CNL invited review on the engagement section of CNL's Commission Member Document for the 2024 WL site licence renewal hearing. On June 10, CNL shared this section, offering capacity for review and requesting any feedback be shared by July 5, 2024. CNL followed up on June 20 to see if Northwest Angle No. 33 First Nation

was interested in reviewing the Commission Member Document. CNL did not receive feedback from Northwest Angle No. 33 First Nation.

While CNL has yet to receive a response from Northwest Angle No. 33 First Nation on the Project, CNL will continue to make efforts to engage and provide regular Project updates.

4.2.4.8 Peguis First Nation

Peguis First Nation is a Treaty 1 First Nation, located approximately 163 km from the WL site and is the largest First Nation community in Manitoba.

Peguis First Nation's Director reached out to CNL's Indigenous Relations Advisor on August 24, 2023, inquiring about ongoing and upcoming work at the WL site. CNL responded and looked to coordinate a discussion. After this, CNL began to share regular updates with Peguis. On September 14, 2023, CNL's Indigenous Relations Advisor shared that they were leaving CNL to pursue another role and Peguis reiterated their interest in meeting with CNL.

In February 2024, CNL's Manager of Communications and Engagement reached out via email and telephone to reconnect and coordinate a meeting with Peguis First Nation's Director of Consultation and Special Projects between representatives of CNL and Peguis.

On March 5, 2024, Peguis First Nation, CNL and Atomic Energy of Canada Limited (AECL) met in Winnipeg to discuss CNL, in general, the Whiteshell Restoration Project, the Project, an overview of CNL, reconciliation, engagement, and next steps between Peguis, AECL, and CNL. Later that month, CNL shared information on how to participate in the Canadian Nuclear Safety Commission (CNSC) public hearing for the WL site licence renewal, which is to be held in October 2024.

On March 20, 2024, CNL shared the engagement summary section to be included in the IER with Peguis First Nation for review and verification. CNL asked for any feedback on this document to be shared back to CNL by April 19, 2024. CNL followed up with a phone call from the Manager of Communications and Engagement to Peguis First Nation's Director of Consultation and Special Projects.

On March 28, 2024, CNL's Indigenous Engagement Officer reached out to invite Peguis First Nation representatives to WL site, including a tour to the WR-1 Building on April 23, 2024. Peguis and CNL exchanged several emails with questions about the site and visit in advance of this meeting. CNL followed up on this meeting with telephone calls and invitation to meet and tour at the WL site.

In April 2024, CNL invited Peguis to participate in the 2024 Regional Leaders Gathering in June 2024 and to attend CNL's April public webinar on April 25, which focused on the Whiteshell Fire Program. Note that a Peguis staff member on the Special Projects team on did attend this webinar.

On April 17, 2024, Peguis sent a formal consultation package to CNL for consideration to formalize a relationship and engagement. On April 23, 2024, CNL hosted an in-person meeting at the WL site between Peguis First Nation, including the Lead Consultant, Human Resources Consultant, Human Resources Delegate, a Knowledge Holder, a Knowledge Keeper and Environmental Specialists, and CNL staff, including the Director of End State Strategy, the General Manager and Site License Holder, the Manager of Regulatory Approvals, a Senior Environmental Specialist, an Environmental Analyst, the Communications and Engagement Manager, the Indigenous Relations Advisor, Indigenous Engagement Officers, and the Facility Authority. At the meeting there was a tour of the WR-1 Building and presentation about its decommissioning, a tour of the Waste Management Area sites and a

presentation and discussion on environmental monitoring and land use end state strategy. This month, CNL also shared information on the CNSC's Indigenous and Stakeholder Capacity Fund.

On May 2, CNL followed up with further information on the Regional Leaders Gathering and on May 15, CNL invited review on the engagement section of CNL's Commission Member Document for the 2024 WL site licence renewal hearing. On June 10, CNL shared this section, offering capacity for review and requesting any feedback be shared by July 5, 2024.

Three representatives from Peguis First Nation attended the second annual Regional Leaders Gathering in Beausejour on June 4. The Director of Special Project, the Lead Consultant, an Environmental Lead and an Elder all participated in the event. The Regional Leaders Gathering facilitated discussions amongst leaders from Indigenous and non-Indigenous communities with CNL. The focus was on CNL projects, including the Project, environmental monitoring, and gathering feedback on Trenches and Land Use End State.

On June 18, 2024, Peguis' Lead Consultant emailed CNL to share that Peguis First Nation would not provide comments on the IER or the WL site licence renewal Commission Member Document until a formal consultation was established, noting that CNL had not replied to the consultation package sent in April 2024. The following day, CNL's Indigenous Engagement Officer replied to Peguis' Lead Consultant noting that CNL would be responding to Peguis' proposed workplan and budget with a draft engagement plan.

On July 4, Peguis' Director of Consultation emailed CNL's Whiteshell General Manager to request a leadership meeting on Peguis' involvement in the Whiteshell Laboratories Restoration Project. Towards the end of July, CNL's Indigenous Relations Advisor sent a proposed contribution agreement to Peguis' Director of Consultation and requested a meeting with Chief and Council to share more information on the Whiteshell Laboratories Restoration Project, the Project's environmental assessment and the future of work CNL is performing as the contractor at the WL site.

CNL also followed up by email and phone with Peguis' Lead Consultant to confirm a leadership meeting date involving Peguis Chief and Council for August 23, 2024.

Canadian Nuclear Laboratories continues to be committed to meaningful engagement with Peguis First Nation on the Project and the WL site going forward.

4.2.4.9 Grand Council Treaty #3

A map of treaty #3 is provided in the IER Appendices. (CNL 2024)

Grand Council Treaty #3 (GCT#3) is the Traditional Government of the Anishinaabe Nation in Treaty #3. Grand Council Treaty #3 represents 28 First Nations across the Territory. Grand Council's mandate is to protect the future of the Anishinaabe people by ensuring the protection, preservation, and enhancement of inherent and Treaty Rights. The Territorial Planning Unit (TPU) is a department within the Grand Council that works with the Treaty #3 Leadership to protect the lands, water, and resources within the 55,000 square miles of Treaty #3 Territory. The TPU is guided by the Anishinaabe Inakonigaawin - Manito Aki Inakonigaawin (Great Earth Law) and Treaty #3 Nibi (water) Declaration3.

[3] https://gct3.ca/

Grand Council Treaty #3 (GCT#3) is made up of 28 First Nation communities (two communities in Manitoba and 26 communities in Ontario), which include five member First Nation communities with potential interest in the Project: Shoal Lake 40 First Nation, Iskatewizaagegan 39 Independent First Nation, Northwest Angle 33 First Nation, Wabaseemoong Independent Nations and Sagkeeng First Nation.

Treaty 3 territory includes parts of eastern Manitoba, including the WL site.

More information on Grand Council Treaty #3 can be found in the IER Appendices (CNL 2024) and on the GCT3 website: https://gct3.ca/.

4.2.4.9.1 Engagement

In relation to the Project, engagement began on April 2016, when Canadian Nuclear Laboratories (CNL) sent GCT #3 a Project Introductory Letter and requested for community input on any potential adverse impacts from project activities.

On October 5, 2017, CNL shared the notification of the public comment period on the draft Environmental Impact Statement (EIS) and sent an invitation to engage.

On April 18, 2018, GCT #3 staff attended a tour of the WL site, followed by a Whiteshell Laboratories Restoration Project presentation.

On July 21, 2020, GCT #3 staff attended a tour of the WL site. The tour included a visit to the Waste Management Area and WR-1 Building.

On August 12, 2020, CNL and GCT #3 held an introductory meeting to discuss the Project.

On February 8, 2021, CNL provided notice to GCT #3 that CNL is submitting a draft EIS and requested to engage on the project.

On March 4, 2021, CNL and GCT #3 met virtually to present an overview of the project including end state, valued components, alternative means, site history, and the Project's follow-up monitoring.

On April 19, 2021, CNL invited GCT #3 to attend the CNL webinar on the Project.

On July 7, 2022, CNL contacted GCT #3 to confirm the correct contact information for GCT #3 chiefs. After this, CNL and GCT #3 began to engage more regularly.

On September 23, 2022, CNL and GCT #3 met virtually for CNL to provide an overview of the WL site and a status update for the Project, highlighting engagement with Treaty #3 members. CNL and GCT#3 also discussed future engagements.

In October 2022, CNL sent a letter to GCT #3 titled, CNL Submission of 2021 Annual Compliance Monitoring Report. CNL also followed up in late October to provide GCT #3 a status update of the Project's EIS.

In November 2022, CNL provided GCT #3 with a letter that provides an update and next steps for the land use end-state community engagement for the WL site. CNL also invited GCT #3 to the bi-monthly webinars.

The December monthly working group held on December 15, 2022, focused on land use end-state discussions. In late December, CNL informed GCT #3 that CNL submitted an updated draft EIS for the proposed in situ disposal of WR-1.

On January 16, 2023, CNL informed GCT #3 that CNL received a letter from the CNSC informing them that the EIS for the Project has been accepted for Technical Review. On January 17, 2023, CNL shared the 2023 CNL Environmental Monitoring Field sampling Schedule to see if there was any interest by GCT #3 to come to the WL site to participate in Environmental Monitoring activities.

The March 2023 working group meeting held on March 1, 2023, focused on the Project update, Follow-up topics from previous meetings, additional info on polling survey, land use end state, and Procurement. CNL and GCT #3 also met again on March 8, 2023, for continued discussion. On March 10, 2023, CNL shared the CNL Indigenous Relations Procurement Strategy; CNL offered a meeting to discuss further.

In April 2023, CNL heard from Wabaseemoong Independent Nations, that CNL should be engaging with GCT#3 in addition to Wabaseemoong Independent Nations. CNL has noted this and continues to reach out to Wabaseemoong Independent Nations with information updates about the project and is engaging with GCT#3 with the understanding that GCT#3 is representing Wabaseemoong Independent Nations. The 2023 April working group meeting, held on April 11, 2023, focused on CNL Indigenous Relations Procurement Strategy, Leadership Meeting, and Guardianship Program. On April 11, 2023, CNL shared a CNSC email concerning available funding for Indigenous Nations and communities in reviewing CNSC staff's Regulatory Oversight Report on the Use of Nuclear Substances in Canada: 2022 (Regulatory Oversight Report). GCT #3 also requested a contact at the CNSC, and CNL shared contact information.

On May 1, 2023, CNL sent GCT #3 an email to inform them of the CNL Whiteshell Safety Stand Down. CNL provided additional information on the CNL Whiteshell Safety Stand Down on May 10, 2023. In May, CNL also invited GCT #3 to the land use end-state workshop being held as a part of CNL's Regional Leaders Gathering on May 30, 2023. CNL shared the land use end-state brochure with GCT #3 in advance of the event. GCT #3 Territorial Planning Unit staff attended the CNL Regional Leaders Gathering held in Brokenhead Ojibway Nation on May 30.

The June 2023 monthly meeting, held on June 22, focused on GCT #3 feedback on the May 30 Regional Leaders Gathering, Project updates, and a possible Leadership meeting.

On July 4, 2023, CNL shared the updated Land Use End State Draft 5 copy from the May 30 Regional Leaders Gathering; CNL indicated it would appreciate feedback from communities by the end of August 2023. The July 2023 monthly meeting, held on July 18, focused on Project updates, and land use end state. CNL also provided an update on the CNL Whiteshell Safety Stand Down. In July 2023, CNL also shared a copy of the independent environmental assessment and re-shared a draft of the land use end state from the Regional Leaders Gathering, and the WL Land use end state handout.

On August 8, 2023, GCT #3 invited CNL to join a meet and greet between Sagkeeng First Nation and GCT#3 for the 150-year Treaty #3 celebration. The August 2023 monthly meeting, held on August 15, focused on the Project, land use end state and WL updates. CNL also provided an update on the CNL Whiteshell Safety Stand Down, and Wabaseemoong Independent Nations Project Commitments List.

On September 19, 2023, CNL shared the links to the newly launched CNL Indigenous Vendors Portal, and Indigenous Business network; an initiative that stems from the CNL Indigenous Relations Procurement Strategy.

The September 2023 monthly meeting, held on September 19, focused on CNL Whiteshell Safety Stand Down, Project Update, Land Use and End State Updates, Independent Environmental Monitoring Program, Communities Update, and an update from Wabaseemoong. In September 2023, CNL also shared the job posting for the Director of Indigenous Relations.

On October 5, 2023, CNL sent a meeting request for a 6-month update / feedback session for the Indigenous Relations Procurement Strategy. CNL requested to meet in November to incorporate feedback. CNL and GCT #3 met to discuss GCT #3 feedback on the Indigenous Relations Procurement Strategy on November 6, 2023. The October 2023 monthly meeting, held on October 17, focused on CNL Whiteshell Safety Stand Down, Project Update, Land Use and End State Updates, IMEP, upcoming site tour, discussion around the CNL Indigenous Relations Procurement Strategy, and Communities Update. On October 20, 2023, CNL provided GCT #3 with an important notice of CNL's Administrative Penalty from the CNSC. CNL attached a link to the CNSC Public disclosure and provided information in a PDF.

On November 9, 2023, GCT #3's Policy Manager, and Environmental Monitoring Coordinator attended the WL site for a tour. The tour included a stop at the Waste Management Area, the WR-1 Building, and the Winnipeg River. The November 2023 monthly meeting, held on November 21, focused on feedback from the November 2023 site tour, CNL Whiteshell Safety Stand Down, Down, Project Update, Land Use and End State Updates, IEMP, and Communities Update. On November 21, 2023, CNL invited GCT #3 to the December 19 Public Liaison Community meeting being held virtually.

In December 2023, CNL informed GCT #3 of CNL's intention to begin exploring options and meaningful input on the cleanup of some of the waste facilities in the near future. CNL also follow up on the invite to the CNL Whiteshell Labs Virtual Public Liaison Committee Meeting - CNL 2023 Wrap-Up. CNL Consultant provided the agenda for the meeting on December 19.

In early January 2024, CNL notified GCT#3 of the change in leadership at the WL site. The January working group meeting, held on January 16, 2024, focused on CNL Low-Level Waste Trenches Remediation. GCT #3 had technical difficulties, and the meeting had to be rescheduled to February 2024. On January 31, 2024, CNL shared a link for the CNL Public Disclosure Notice.

At the February 1 meeting CNL and GCT #3 discussed CNL's participation in the upcoming GCT #3 National Environmental Gathering. Later that month, CNL's Director End State Strategy, General Manager, Indigenous Engagement Officer, and Environmental Specialist attended the GCT #3 National Environmental Gathering on February 20 and 21 of 2024. CNL shared a presentation on the Project, Indigenous engagement and Environmental Monitoring at the WL site.

CNL shared information on the 2024 licensing hearing via email on March 11, 2024. This included information on the license amendment application, the CNSC Notice of Hearing and information on the CNSC Participant Funding Program. CNL also offered to support for GCT #3's participation in the hearing. At the monthly meeting on March 14, 2024, GCT #3 and CNL discussed the Project and participation in the relicensing hearing.

On March 22, 2024, CNL shared the engagement summary section to be included in the Project's IER with GCT#3 for review and verification. CNL asked for any feedback on this document to be shared back to CNL by April 19. Ongoing information sharing correspondence occurred throughout March.

The Grand Council Treaty #3 Policy Manager emailed CNL's Indigenous Engagement Officer on April 4, 2024, with a series of questions from a community member regarding waste transportation and fuel consolidation at Chalk River Laboratories.

On April 16 the GCT #3 Policy Manager emailed CNL's Indigenous Engagement Officer with their review of the engagements section of the Project's IER, which CNL incorporated into the IER and this section of the EIS. GCT #3's comments included questions about why particular Nations represented by GCT #3 were identified for engagement and why others weren't. GCT #3 also stated that Wabaseemoong Independent Nations (WIN) had not told GCT #3 to represent them in any way pertaining to engagement on the Project. However, GCT #3 informed CNL that they are not "representing" WIN but are instead keeping WIN updated on the Project when requested by WIN to do so. GCT #3 also informed CNL that CNL still had a duty to consult mandate with WIN that was separate from communication between GCT #3 and CNL. GCT #3 informed CNL that that CNL was still responsible for carry out the duty to consult procedures for all First Nation communities that are involved in the Project.

The same day – April 16, 2024 – CNL and GCT #3 held the April monthly meeting, where representatives discussed the WL site licence renewal hearing, an update on the site tour, and GCT #3's review and feedback of the Project's IER. In this meeting CNL shared more about how the list of identified Indigenous communities had been selected for the environmental assessment. Correspondence in April included information on the CNSC's Indigenous and Stakeholder Capacity Fund and an invitation for GCT #3 to attend the June Regional Leaders Gathering.

On May 2, GCT #3 responded that they could not attend and requested that CNL provide notes from the event. The May monthly meeting was held virtually on May 21. From GCT #3 the Policy Manager, Environmental Manager and Junior Policy Analyst all attended and from and CNL, the Director of End Use Strategy, the Director of Communications & Engagement, the Manager of Communications and Engagement, an Indigenous Engagement Officer, an Indigenous Relations Advisor, and a Senior Communications Officer attended. Discussion included WL relicensing, CNL environmental monitoring updates, invitations to CNL community events and Grand Council's questions for CNL, which had been received from community members on waste.

On May 15, CNL invited review on the engagement section of CNL's Commission Member Document for the 2024 WL site license renewal hearing and on June 10, CNL shared this section, offering capacity for review and requesting any feedback be shared by July 5, 2024.

On June 5, 2024, CNL shared back the Project's IER section with the review and comments from GCT #3 incorporated. Towards the end of June 2024, CNL shared back the questions received on waste transportation and fuel that had been received in April. On June 9, GCT #3's Policy Manager provided their review of the Commission Member Document with no changes noted.

The July monthly meeting, held on July 16, included representatives from CNL, AECL and GCT #3. Discussion included the Project's EIS, the site licence renewal hearing, land use strategy and options for trenches decommissioning. GCT #3 shared community updates and CNL shared their environmental monitoring schedule to facilitate involvement if there was interest. On July 22, Grand Council Treaty #3's Policy Manager emailed CNL's Indigenous Relations Advisor to share that another community member had questions on waste transportation. CNL responded asking for the questions so CNL could provide a response.

4.2.4.9.2 Next Steps

CNL values how the relationship between GCT #3 and CNL has grown and believes CNL's collective engagement efforts and collaboration through the monthly working Group table have contributed positively to the environmental assessment of the Project and the Whiteshell Laboratories Restoration Project more broadly.

CNL will continue to engage with Treaty #3 First Nations as well as GCT #3.

4.2.5 Future Engagement Activities Planned

Canadian Nuclear Laboratories will continue to engage with First Nations and the MMF after submission of the updated draft EIS, throughout the remaining environmental assessment steps, and during the remediation of the WL site. Future activities are expected to focus on continued relationship building addressing ongoing interests and concerns, and monitoring of the site, all of which will be documented into updated revisions of the IER (CNL 2024).

Future engagement activities are broken into short-term initiatives that will take place between now and the final EIS submission, and longer-term initiatives, some of which are relevant to the Project's environmental assessment, and others that extend beyond the scope of the Project.

4.2.5.1 Short-term Initiatives and Engagements

The following list outlines short-term initiatives that apply to all First Nation and the MMF that CNL will take between now and submitting the final EIS. For specific initiatives for each First Nation or the Red River Métis, see the 'Next Steps' subsections in Section 4.2.4.

- **Informational Webinars and Online Open Houses –** CNL has been, and will be, hosting informational webinars on various topics related to the Project including follow-up monitoring, end state for the Project, and baseline conditions. Some of these will be designed to directly address misperceptions and stigma associated with the Project.
- **Commitments Dialogue –** CNL has verified (or made multiple attempts to verify) each Nation's interests and concerns on the Project and commitments list. After submission of the EIS, CNL will continue to work with each Nation to progress commitments to support addressing their concerns related to the Project.
- **Sharing of Job Postings –** CNL will continue to share job postings and opportunities for employment as they become available.
- **Community Liaison and Associated Engagement Plans –** CNL will work with the community liaison officers to develop an engagement plan and other community-specific initiatives to support engagement with community members or MMF Citizens to elevate the level of awareness and knowledge about the Project within the community.
- **Community Specific Information Sessions –** Once CNL has submitted the revised EIS, CNL will send out invitations to the First Nations and the MMF to continue engagement on the key components of the EIS, including baseline studies, Project end state, follow-up monitoring, and other items of importance to that Indigenous Nation.

- **Participation in Environmental Monitoring Activities –** CNL will continue to work with the MMF on MMF-led Harvester Sampling Plan and with Sagkeeng's Niigan Aki program. Additionally, CNL will continue to invite First Nations and the MMF to participate in monitoring activities during the upcoming field seasons.

4.2.5.2 Long-term Initiatives and Engagements

The following is a list of longer-term initiatives that while relevant to the Project's environmental assessment, extend beyond the scope of the Project to address WL site issues, concerns and interests:

- **Supporting Long-term Monitoring** – All the First Nations and the MMF have expressed an interest in being more involved in CNL's environmental protection program. CNL will look for further opportunities to expand First Nation and Métis involvement in monitoring at the WL site and in the area around the site. Specifically, the MMF expressed an interest in actively participating in monitoring both in the environmental protection program and decommissioning activities (outside the scope of the environmental assessment). CNL will work closely with the First Nations and the MMF to support their involvement in environmental monitoring at the WL site. This initiative will extend beyond the timeline and scope of the environmental assessment for the Project and will be a part of the Whiteshell Laboratories Restoration Project. Sagkeeng and CNL signed a multi-year agreement in 2022 to support a Sagkeeng Community Environmental Monitoring Program (CEMP), which Sagkeeng have named Niigan Aki, meaning "Land First". Niigan Aki began monitoring initiatives in 2023.
- **Indigenous Advisory Committee** – CNL had been working in collaboration with AECL, the Manitoba Métis Federation, and local First Nations to determine whether an Indigenous Advisory Committee can be established. Two workshops were held in 2021 to develop a draft term of reference and guide for the Indigenous Advisory Committee. The purpose of the Indigenous Advisory Committee includes but is not limited to foster a working relationship between Indigenous Nations, CNL, and AECL to collaborate and engage with CNL and AECL regarding the Whiteshell Laboratories Restoration Project, and on other topics of mutual interest and concern. Based on feedback received from several First Nations and the MMF, this initiative has been put on hold in favour of bilateral engagement. Canadian Nuclear Laboratories would reopen dialogue on the Indigenous Advisory Committee if there is new interest in revisiting this initiative. CNL notes that the MMF have stated that they are interested in continuing to work with CNL, AECL, and local First Nations through an Indigenous Advisory Committee, however, the MMF cautions CNL from taking a "Pan-Indigenous" approach to addressing concerns raised by a committee like this. The concerns of the Red River Métis, and each individual First Nation at the table, should be considered distinct and reflect those who raised the concern. As a result, while some concerns may reflect the views of multiple or all groups in the Committee, efforts to address these concerns must be tailored to the distinct needs of each community/Nation.
- **Relationship Agreements** - CNL has put in place several agreements for participating in the environmental assessment and for expanded Indigenous-led monitoring with Sagkeeng and the Manitoba Métis Federation. Though, as of November 2024, CNL and the MMF do not have an agreement in place. CNL will continue discussing relationship agreements with each of the involved First Nations and the Manitoba Métis Federation that will likely extend beyond the scope of the environmental assessment for the Project and include engagement, participation, and involvement in the Whiteshell Laboratories Restoration Project. These relationship agreements can also include developing community risk-informed communication tools with direct input from community leaders and include reconnection to the land through access to the site for cultural and ceremony activities. CNL will also discuss implementing long-term relationship agreements.

between AECL, CNL and the First Nations and MMF that will help to confirm the initiatives that are developed and implemented continue into the post-closure phase of the Project and that may also help to address broader concerns.

4.3 Influence of Traditional Knowledge on the Environmental Assessment

Four Traditional Knowledge, Land Use and Occupancy Studies (TKLUOS) for the WL site have been completed. These studies are intended to document traditional use around the Project, local, and regional study areas.

The MMF study, titled “Whiteshell Reactor #1 Decommissioning: Manitoba Métis Traditional Knowledge, Land Use and Occupancy Study” (SVS 2019), was provided to CNL in January 2019 while the Sagkeeng First Nation study, titled “Sagkeeng Anicinabe Land Use and Occupancy Study Specific to Canadian Nuclear Laboratories’ Proposed In Situ Decommissioning of the WR-1 Reactor at Whiteshell Laboratories” (Firelight Research Inc. and Sagkeeng Anicinabe 2018), was provided in December 2018.

The study done jointly by Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation, titled “api migizik pii pa gilot – When Eagles Call Traditional Knowledge and Land Use Study for the WR-1 Nuclear Reactor In Situ Decommissioning Project” (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019), was provided to CNL in November 2019. The study by Wabaseemoong Independent Nations, titled “Traditional Knowledge and Environmental Impact Assessment - Decommissioning of Whiteshell Nuclear Reactor #1” (WIN 2018), was provided to CNL in January 2018.

CNL provided capacity funding to support the commissioning and completion of these studies which provided CNL with a better understanding of modern and traditional land and resource use near the WL site and Aboriginal and Treaty Rights matters. The results of these studies informed the five column interests and concerns table for each Nation (see Appendix A) and list of valued components. CNL also used these studies to support the environmental assessment of the Project documented in Section 6.0. For each interest and concern in Section 1.3 of Appendix 4.0-1, CNL has included a reference to a section of the EIS where CNL made changes based on the Nation’s interest or concern.

Traditional knowledge was considered in the environmental assessment, including identification of VCs, defining spatial boundaries, description of the environment, and identification and evaluation of Project interactions, and participation in monitoring program. Traditional knowledge includes both Traditional knowledge and feedback gathered through engagement and community-led studies. Traditional knowledge was primarily gathered through the TKLUS’s and were completed to further enable opportunities to capture and include Traditional Knowledge into the environmental assessment and the EIS. CNL has supported these studies to better understand modern and traditional land and resource use near the WL site. Four Traditional Knowledge, Land Use and Occupancy Studies for the WL site were completed and shared CNL for inclusion in the EIS. For more information on the Traditional Knowledge and Land Use and Occupancy Studies, see the IER (CNL 2024).

CNL developed and verified a list of VCs for each community based on their TKLUS and feedback during engagement. These VCs were used to validate the Project’s VCs. Where information was provided by the First Nations and the Red River Métis, CNL included a list of relevant Indigenous VCs and demonstrated how they were considered in the discipline assessment. Most of the VCs identified through Indigenous and public engagement activities are already represented by the VCs selected for the environmental assessment. Moose was identified as an important species to Indigenous communities and was subsequently added as a VC in the Ecological Health Assessment (Section 6.7 Human and Ecological Health). In addition, Traditional Knowledge and Land Use and

Occupancy Studies identified that Indigenous Nations harvest wild rice and medicinal plants. As such, weekay was added to the diet of a Harvester in the Human Health Assessment (Section 6.7).

To incorporate input from the First Nations and the MMF, the local and regional study areas for the Land and Resource Use VC was revised to capture Indigenous land and resource use within proximity of the WL site and on either side of the Winnipeg River (Section 6.8.1.4.1 Spatial Boundaries [traditional land and resource use assessment]). As such, updates were also warranted in Section 6.9.4.1 Spatial Boundaries (socio-economic assessment) as the relationship between traditional land and resources use has linkages to well-being. The boundaries for the study areas are designed to quantify baseline conditions at a scale that is large enough to assess to maximum predicted geographic extent of direct and indirect effects from the Project on VCs and the Project in combination with previous, existing, and reasonably foreseeable developments.

The TKLUS's further enabled opportunities to capture and include Traditional Knowledge into the description of the environment. These studies are intended to document traditional use around the Project, local, and regional study areas. The 'Description of the Environment' section in the discipline assessments (Section 6.2 to Section 6.9) has been updated to include a description of how traditional land and resource use activities have changed in response to past historical events and external pressures, where available.

Traditional Knowledge and Indigenous engagement feedback also identified linkages between components of the environment that support traditional way of life, traditional land and resource use, and harvesting Treaty Rights. These linkages provide a more holistic understanding of the environment and relationships between different components, including their continued practice of culture and livelihoods. Feedback from Indigenous engagement also considered in the evaluation of the pathways. For example, a pathway may be evaluated as a secondary pathway due to their importance to Indigenous people even if there are no direct or indicate effects on a VC (Section 6.9.6 Project Interactions and Mitigation).

Indigenous engagement feedback is reflected in CNL's commitments to participation of Indigenous Nations in environmental monitoring (Section 11.4). CNL will be updating the existing WL site Environmental Assessment Follow-up Program to suit the ongoing needs of the Project, stakeholders and Indigenous Nations. CNL recognizes that the First Nations and the MMF are stewards of the land who have a great interest in participating in monitoring at WL site. As such, ongoing engagements and commitments to support meaningful discussion on the monitoring and follow-up program and how each Nation and the MMF wishes to be involved in future monitoring of the site will be included in the program. CNL has committed to engaging with each Nation and the MMF on their specific interest and concerns regarding monitoring for the Project and the existing WL site Environmental Assessment Follow-up Program.

4.4 Summary of Issues Raised During Engagement Activities that Influenced the Environmental Impact Statement

The feedback sections under Section 4.2 Indigenous Engagement describe at a high level the interest, concerns, and comments CNL has heard from each Nation. Some of those concerns are out of scope of the EIS, in CNL's opinion. This section specifically looks at interests and concerns raised during the engagement activities that influence the scope of the environmental assessment (Table4.4-1). For more information on specific interests and concerns of each First Nation and the MMF as well as how these interest and concerns influenced the EIS, see Appendix 4.0-1 – the tables of interest and concerns including how CNL incorporated and considered feedback on mitigation measures for the Project.

Table 4.4-1: Summary of Interests and Concerns Raised During Engagement Activities that Influenced the Environmental Assessment

Interest and Concern	How the Issue was included in the Assessment	Section of the EIS that the Issue is Addressed in
Alternative Means Assessment		
Indigenous Nations expressed interest in understanding how in situ disposal was chosen as the preferred decommissioning method for WR-1 and if nearby First Nations and the MMF would have an opportunity to provide input on the chosen decommissioning method.	As a result of feedback from Indigenous Nations and the public, CNL has revised and improved the alternative analysis section, additional detail to support the selection of the preferred alternative has been included	Section 2.0 Purpose of the Project and Alternatives Assessment: *Section 2.5.4 Assessment of Alternatives*
Sagkeeng First Nation expressed interest in adding an additional alternative of rolling stewardship as an option for consideration in the Alternative Means Assessment.	As a result of this feedback, CNL added Rolling Stewardship (Alternative #6) as a proposed alternative in the alternative means assessment.	Section 2.0 Purpose of the Project and Alternatives Assessment: *Section 2.5.4.6 Assessment of Alternatives*
Sagkeeng First Nation conducted an Alternative Means Assessment to incorporate Sagkeeng's community values and preferred weighted criteria.	CNL included a new section that provides a summary of Sagkeeng First Nation's Alternative Means Assessment and explains how CNL has considered and used the report.	Section 2 Purpose of the Project and Alternatives to the Project: *Section 2.8 Sagkeeng's Alternative Means Assessment – Approach and Findings*
Indigenous communities communicated their preference towards being able to retrieve or remediate the disposed reactor at an unspecified future date should monitoring show that environmental effects are not acceptable. A specific suggestion was the use of sand instead of grout as a backfill material, with the expectation that the sand could be more easily removed in the event that retrieval or remediation efforts were undertaken.	As a result of this feedback, CNL added In Situ Disposal Using Alternative Backfill Materials as a proposed alternative in the alternative means assessment.	Section 2 Purpose of the Project and Alternatives to the Project: *Section 2.5.4.5 Alternative #5 – In Situ Disposal Using Alternative Backfill*

Table 4.4-1: Summary of Interests and Concerns Raised During Engagement Activities that Influenced the Environmental Assessment

Interest and Concern	How the Issue was included in the Assessment	Section of the EIS that the Issue is Addressed in
Existing Conditions		
Concern about the collective effects of historical changes to each Nation's cultural practices, land and resource use, and Aboriginal and Treaty Rights as a result of the establishment of WL site.	The description of the existing environment for Indigenous land and resource use has been updated to include a description of how traditional land and resource use activities have changed in response to past historical events and external pressures, which has been summarized from the Traditional Knowledge and Land Use Studies. A subsection on Indigenous Community Perspectives on Health and Wellness was added to the socio-economic assessment.	Section 6.8.1 Traditional Land and Resource Use: *Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations* Section 6.9 Socio-economic Enviornment: *Section 6.9.5.2.1.1 Indigenous Community Perspectives on and Observataions of the WL site* *Section 6.9.5.2.6.4 Indigenous Health*
First Nations and the MMF initially expressed concern on lack of information on Traditional Knowledge and land use in the EIS.	CNL supported, through funding or other means, four Traditional Knowledge and Land Use Studies with five First Nations (Sagkeeng First Nation, Black River First Nation, Hollow Water First Nation, Brokenhead Ojibway Nation, and Wabaseemoong Independent Nations) and the MMF. Subsequently CNL staff reviewed those documents and sought to integrate information, while improving CNL overall understanding of Indigenous interests and concerns.	The 'Description of the Environment' section in the discipline assessments (Section 6.2 to Section 6.9) has been updated to include a description of how traditional land and resource use activities have changed in response to past historical events and external pressures, where available

Table 4.4-1: Summary of Interests and Concerns Raised During Engagement Activities that Influenced the Environmental Assessment

Interest and Concern	How the Issue was included in the Assessment	Section of the EIS that the Issue is Addressed in
Effects Assessment		
Sagkeeng First Nation was concerned about the spatial boundaries used in the assessment not being reflective of those used in traditional land use studies.	CNL has separated Indigenous traditional land and resource use from other non-Indigenous land and resource use in order to reflect spatial boundaries that more closely reflect the boundaries as identified in traditional land use studies, combined with consideration of where effects are likely to be measurable. Indigenous communities that were previously included as part of the regional study area were revised to be part of the local study area, reflective of the role of traditional land and resources use and its contribution to well-being.	Section 6.8.1 Traditional Land and Resource Use: *Section 6.8.1.4.1 Spatial Boundaries* Section 6.9 Socio-economic Environment: *Section 6.9.4.1 Spatial Boundaries*
Concerns about the extent of Indigenous participation in the assessment of effects to traditional land and resource use (from the identification of pathways to the verification of results)	The assessment has been updated to include a summary of Indigenous community's conclusions about the potential effects of the Project, which has been summarized from the Traditional Knowledge and Land Use Studies.	Section 6.8.1 Traditional Land and Resource Use: *Section 6.8.1.6 Project Interactions and Mitigation*
Concerns from Indigenous Nations on the health of members in the WL site area harvest wild rice and medicinal plants. The MMF requested CNL give consideration to the potential increase in moose harvesting and consumption by its Citizens.	Consumption of local plants and foods was considered as a pathway in the Environmental Risk Assessment (ERA). CNL conducted an Indigenous Food Intake Survey to understand the types and quantities of local food consumed. Based on the results of the surveys, the diet of a Harvester in the human health assessment was updated. Wild rice does not grow close to the Project and therefore, was not included in the assessment; however, the medicinal plant weekay was added to the diet of a Harvester in the human health assessment. Moose was also added to the diet of Harvester in the human health assessment.	Section 6.7.1 Human Health: *Section 6.7.1.7 Residual Effects Analysis*
Concerns from Indigenous communities on the long-term health effects of the Project on plants and wildlife important to Indigenous people. Indigenous communities have seen changes to the health of the animals they harvest.	CNL verified the list of important species identified by each Indigenous community to confirm that each was adequately represented by the selected representative organisms. Based on feedback from Indigenous Nations during engagement activities, moose was added as a VC to the ecological health assessment given the species importance to Indigenous people.	Section 6.7.2 Ecological Health: *Section 6.7.2.7 Residual Effects Analysis*

Table 4.4-1: Summary of Interests and Concerns Raised During Engagement Activities that Influenced the Environmental Assessment

Interest and Concern	How the Issue was included in the Assessment	Section of the EIS that the Issue is Addressed in
Concern that the Project may limit each Nation's participation in land and resource use activities, which would affect their well-being through the ability to express their culture.	The italicized text in the following pathway has been added to the socio-economic pathway: The presence of long-lived radioactive material as part of ISD may affect community well-being for Indigenous communities through the changes to the suitability of the site for future uses, *the continued inability to exercise stewardship and governance over land and resource management decisions* Psychosocial aspects are important to Sagkeeng, and as such CNL has included them in the socio-economic assessment. This pathway was elevated from a no linkage pathway to a secondary pathway due to the importance of it to Indigenous communities.	Section 6.9 Socio-economic Environment: *Section 6.9.6 Project Interactions and Mitigation*
Indigenous Nations requested more information about potential contracting opportunities with CNL, including qualifications and procurement requirements.	Various employment and contracting initiatives were added to the socio-economic assessment including: ■ CNL worked to enhance options to better match the Indigenous Nations capabilities with their contracting needs including adding provisions to its procurement process that encourages the use of Indigenous and local small and medium-sized businesses. ■ CNL discussed the request for information sharing regarding the procurement and contracting opportunities and asked for specific capabilities that communities have related to the Project. ■ CNL facilitated introductions between the communities and the CNL procurement department. ■ To facilitate information sharing, capabilities and opportunities, CNL planned and executed three industry days and invited First Nation communities. ■ CNL created a First Nation and Métis summer student position that was advertised with First Nations and Métis communities interested in the Project. During site visits Human Resources shared information about employment opportunities at the WL site. CNL has been sharing job postings and will continue to share job postings with the First Nations and the Red River Métis.	Section 6.9 Socio-economic Assessment: *Section 6.9.6 Project Interactions and Mitigation* *Section 6.9.7 Monitoring and Follow-up*
Wabaseemoong Independent Nations noted that employment at the WL site may be difficult for members because it is not located within commuting distance of the community.	CNL recognized that the commute from the Wabaseemoong Independent Nations community was long and have made a commitment to help job candidates find appropriate housing in the region. This commitment has been included in the EIS.	Section 6.9 Socio-economic Environment: *Section 6.9.6 Project Interactions and Mitigation*

Table 4.4-1: Summary of Interests and Concerns Raised During Engagement Activities that Influenced the Environmental Assessment

Interest and Concern	How the Issue was included in the Assessment	Section of the EIS that the Issue is Addressed in
Follow-up Monitoring		
After reviewing the placement of the proposed ground monitoring wells, the MMF proposed an additional well be placed closer to the reactor.	CNL has committed to adding additional ground monitoring well(s) between the Project and the Winnipeg River as requested by the Red River Métis.	Section 6.3.2 Hydrogeology: *Section 6.3.2.9 Monitoring and Follow-up* Section 11.0 Summary of Monitoring and Follow-Up and Programs
First Nations and the MMF expressed an interest in being involved in determining the future use of the WL site.	CNL is working in collaboration with AECL and will be engaging local communities to discuss and consider options for the future use of the WL site. A commitment by CNL to determine the future use of the WL site, including collaboration with local stakeholders has been added to the assessment.	Section 6.8.1 Traditional Land and Resource Use: *Section 6.8.1.6 Project Interactions and Mitigation* Section 6.8.2 Other Land and Resource Use: *Section 6.8.2.6 Project Interactions and Mitigation* Section 11.0 Summary of Monitoring and Follow-Up and Programs
First Nations and the MMF expressed an interest in being involved in the development and implementation of the follow-up monitoring program.	In response, CNL has committed to working collaboratively with the First Nations and the MMF to support each Indigenous Nation to participate in environmental monitoring at the WL site. The goal of the initiative is to help address concerns regarding protection of the environment, health of people, confidence in the health of country foods and stigma associated with the Project. CNL and AECL have agreed to support an independent Sagkeeng Guardianship Program.	Section 11.0 Summary of Monitoring and Follow-Up and Programs

4.5 CNL's Long-term Relationship with Indigenous Nations

CNL recognizes First Nations and the Red River Métis as stewards of the land and CNL is working towards developing long-term meaningful relationships with each Nation that occupies and have traditional territories and modern-day interests near its operations. Further, we acknowledge that the WL site was established without consultation with the Indigenous Nations of this area.

CNL recognizes each Nation or community has its own unique set of interests and concerns associated with both the Project and Whiteshell Laboratories Restoration Project and CNL is committed to taking a distinctions-based approach to engagement to confirm that each Nation's interests and concerns are addressed. CNL also takes a holistic, relationship-based approach to engagement with each Nation, working closely with AECL, to help address interests and concerns regarding all aspects of the Project and Whiteshell Laboratories Restoration Project. As the federal Crown corporation with responsibility for the long-term stewardship of the site, AECL is committed to taking meaningful actions to support healing and to advance reconciliation through nation-to-nation dialogue and relationship-building.

This shift in CNL's Indigenous engagement approach from Project-based engagement to a holistic, relationship, and distinction-based approach will support meaningful actions to build foundations for trust, understanding, and mutually beneficial relationships, including addressing broader issues and concerns such as the historical siting of the WL site.

CNL is currently working with each Nation on formalizing these relationships through relationship-building and corresponding agreements. These agreements are intended to help enable greater integration of Traditional Knowledge, ceremony, and cultural and stewardship practices in the decommissioning, and monitoring of the Project and the WL site. These agreements will also enable dialogue and participation through the development of monitoring programs, culturally appropriate communications, and trauma-informed engagement. In addition, they help to enhance community engagement, building trust, and strengthen relationship-building, as well as setting up mechanisms to facilitate Indigenous participation and input into CNL's Environmental Monitoring Program, economic development and procurement opportunities, future land use, and other areas of collaboration.

CNL continues to build relationships with First Nations and the MMF to support overall decommissioning of the WL site, including the Project. CNL is committed to learning about Indigenous values through ceremony and on-going dialogue, and discussing, incorporating, and addressing concerns to the extent possible.

5.0 PUBLIC AND STAKEHOLDER ENGAGEMENT

Public and Indigenous engagement is a key component of the environmental assessment process and reflects the corporate social responsibility of Canadian Nuclear Laboratories (CNL). As part of our corporate, environmental, and social responsibility, CNL is committed to early, open, and ongoing public, Indigenous and stakeholder engagement and participation throughout the environmental assessment process. Through a broad range of information sharing and engagement activities, CNL seeks to build Project awareness and learn about distinct interests and concerns to strengthen mutual understanding, opportunities for collaboration and long-term relationships.

Project information distribution and public participation are important aspects of the environmental assessment process with public engagement guided by the Canadian Nuclear Safety Commission (CNSC) REGDOC-3.2.1, Public Information and Disclosure (CNSC 2018). Public engagement includes external engagement with local communities, industry, local government, interest groups and the wider public. An overview of Indigenous engagement for the In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site Project (Project) at the Whiteshell Laboratories (WL) site is provided in Section 4.0 Indigenous Engagement.

Consideration was also given to CNSC's *Generic Guidelines for the Preparation of an Environmental Impact Statement* (CNSC 2021), along with CNSC's REGDOC-2.9.1, *Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2020). REGDOC-2.9.1 explains that the CNSC determines the requirements for public and Indigenous engagement on a case-by-case basis, including consideration of public and Indigenous interests and concerns, potential impacts and interactions on the environment and the public, and other factors that impact the project.

This section describes past, ongoing, and proposed public and stakeholder engagement activities and events in accordance with the *Generic Guidelines for the Preparation of an Environmental Impact Statement* (CNSC 2021), which states:

> *"…the EIS will describe the ongoing and proposed participation activities that the proponent will undertake or that it has already conducted on the project. It will describe efforts made to distribute project information, as well as information and materials that were distributed during the public consultation process. The EIS will indicate the methods used, where the consultation was held, the persons and organizations consulted, the concerns voiced and the extent to which this information was incorporated in the design of the project as well as in the EIS. The EIS will provide a summary of key issues raised related to the project and its potential environmental effects, as well as describe any outstanding issues and ways to address them."*

In addition, CNSC and Canadian Environmental Assessment Agency (The Agency) guidance documents require that the following topics are to be included as part of public engagement activities:

- Current Project information;
- Alternative Means;
- Valued Components (VCs);
- Spatial and Temporal Boundaries; and
- Environmental Assessment Follow-up and Monitoring Program (EAFMP).

Issues, interests, and concerns raised through the public engagement process were considered as part of the environmental assessment process. For example, the future use of the WL site was identified as important for local and rural municipalities. As such, the importance of continued economic development was considered under the context of community well-being and was included as a VC for the assessment. A summary of the issues, interests, and concerns raised during public engagement and how CNL has responded to them is described in Table 5.3.1-1. Valued components are described near the beginning of each subsection of Section 6.0 Environmental Effects (Sections 6.2 Atmospheric Environment through 6.9 Socio-economic Environment). Section 2.0 Purpose of the Project and Alternatives to the Project also includes information on how public feedback was considered in the alternatives assessment.

This section of the Environmental Impact Statement (EIS) demonstrates how CNL has engaged with local communities that are interested in and potentially affected by the Project, as well as communication initiatives with regulators. The section includes a description of engagement activities, including documentation of meetings, key interests and concerns, discussion topics, outcomes, relevant agreements, and how CNL is addressing comments received. Please refer to the *Environmental Assessment Stakeholder Engagement Report – WR-1 In Situ Decommissioning* (CNL 2024b) for supporting documentation.

5.1 Engagement Objectives

CNL is committed to developing and maintaining solid, long-term relationships with all external parties. This includes the local communities where CNL employees live and work, the companies CNL does business with, as well as the public. CNL is committed to communicating in a timely manner and exchanging information and recognizes the importance of listening and working to resolve concerns. Communication activities are conducted in support of a clean environment and healthy society. CNL's specific communication objectives include:

1. Initiating and maintaining two-way communication channels between CNL and local and regional communities, determining the best methods for sharing Project information, and facilitating input at timely junctures in the Project schedule, so that feedback can be integrated into Project planning and design, as appropriate.

2. Developing meaningful, user-friendly information and communication products for host communities and the wider public, ensuring accessible and current information on Project activities.

3. Demonstrating CNL's long-term commitment and approach to safely and responsibly managing radioactive waste and decommissioning activities for the benefit of future generations.

4. Sharing information, building awareness, and facilitating learning opportunities with host communities and stakeholders regarding nuclear decommissioning, environmental remediation, and radioactive waste management.

5. Meeting all regulatory-based communication and engagement requirements.

CNL has employed a variety of methods and activities to achieve these objectives. The following section outlines these methods.

In March 2020, the COVID-19 pandemic impacted in-person engagement activities; therefore, CNL adapted the engagement in accordance with all public health requirements and guidelines providing virtual platforms for meetings, workshops, webinars, project updates, and open houses. CNL remained committed to ongoing engagement activities, in alignment with pandemic restrictions throughout the COVID-19 pandemic.

Additionally, in 2023, CNL implemented a Safety Stand Down at the WL site, which limited site visits and tours for several months of that year. Throughout the Safety Stand Down, CNL continued to engage with local communities and the general public on the Safety Stand Down and other CNL activities. CNL has developed a Stakeholder Engagement Technical Supporting Document (SER [CNL 2024b]) to support the EIS. Engagement activities from April 2017 to July 2024 are included the report. Engagement activities carried out prior to April 2017 are included in the Section 5 Appendices. The report details the engagement methods and activities that support CNL's engagement objectives. Each method or activity was applied to share information, build awareness, facilitate learning, and discuss the Project. These methods and activities provided valuable feedback for the Project team to incorporate, as presented in Section 5.2 below.

5.1.1 Evaluation

CNL is committed to conducting all operations in a safe and responsible manner in compliance with and under a well-established Quality Program. Through the program, CNL is committed to actively seeking the public feedback to improve public engagement and to find innovative and sustainable solutions to restore and protect the environment. To demonstrate that the Project communications objectives have been met, CNL conducted a self-assessment in 2021, guided by the quality program. The engagement activities were assessed based on the level of participant satisfaction, audience representation, level of engagement with subject matter experts, level of understanding of the Project, and level of increased Project understanding of public issues. A self-assessment, along with public feedback, guided the planning for future engagement activities, including some activities reported within the timeframe of this report. The assessment of the objectives is summarized below.

Assessment of Objectives One and Two

1. Initiating and maintaining two-way communication channels between CNL and local and regional communities and stakeholders, determining the best methods for sharing Project information, and facilitating input at timely junctures in the Project schedule, so that feedback can be integrated into Project planning and design, as appropriate.

2. Developing meaningful, user-friendly information and communication products for host communities and the public, providing accessible and current information on Project activities.

CNL initiated and maintains a progressive number of communication channels between CNL host communities and stakeholders from the early stages of Project planning. As Project planning and preparation of the EIS evolved, regular Public Liaison Committee (PLC) meetings, Public Open Houses, Information Sessions, and Breakfast Briefings have been held in local communities. CNL continues to expand and evolve opportunities so that information is available to a wider audience.

CNL was able to accommodate diverse preferences for engagement methods, through a variety of approaches:

- in-person information sessions;
- WL site tours;

- technical workshops with retirees, former employees, and local experts;
- downloadable technical materials (e.g., infographics about in-situ disposal [ISD] and Project timelines);
- project videos; and
- virtual webinars.

These enabled CNL to engage directly, both in person and virtually, and allowed CNL to develop a substantive mailing list, initiate further dialogue and build and strengthen relationships. Following the 2017 submission of the Draft EIS to the CNSC, CNL began participating in externally hosted events to increase the Project's exposure and provide an opportunity for increased engagement with the Project team. CNL attended events such as the Lac du Bonnet trade fair, Manitoba Métis Federation Annual General Assembly trade show and the Brokenhead Double B agricultural festival. CNL also hosted two webinars that attracted people from across Manitoba and Canada. These events added to CNL's mailing list and introduced the Project to a broader audience.

Over the course of multiple open houses and engagements, CNL received feedback on what the public was interested in and what the public needed to increase/strengthen understanding about the Project. CNL sought to refine its messages based on this feedback. CNL used feedback and input received from the PLC to confirm that public engagement was meeting regional expectations. This approach has helped CNL improve key messages and presentation material.

Adapting to different audiences was an important step in keeping the public engaged; for instance, CNL decided to take a more technical approach with WL retirees and alumni and hosted a full-day workshop on the Project. Another important evolution in engaging the public was tours. CNL hosted several tours with regional representatives and interested members of the public. Once again, through these activities CNL was able to further refine key themes and the information being provided to the public.

CNL continues to receive, track, and assess feedback for future planning.

Assessment of Objectives Three and Four

3. Demonstrating CNL's long-term commitment and approach to safely and responsibly managing radioactive waste and decommissioning activities for the benefit of future generations.

4. Sharing information, building awareness, and facilitating learning opportunities with host communities and the public regarding nuclear decommissioning, environmental remediation, and radioactive waste management.

Public engagement activities routinely include the purpose of the Project and its role in CNL's long-term commitment and approach to safely reducing Canada's nuclear legacy liabilities. CNL continues to evolve Project information based on feedback and to respond to key interests, concerns, and misperceptions, particularly regarding ISD as a permanent, safe, and proven solution for the Whiteshell Reactor Disposal Facility (WRDF).

CNL measured levels of public understanding though various public feedback tools, including exit polls, feedback forms, and public engagement at various events. These measures have demonstrated improved public understanding about decommissioning, environmental remediation, and waste management over the life of the Project.

Assessment of Objective Five

5. Meeting all regulatory-based communication and engagement requirements.

All public engagement activities in support of the Project have adhered to the REGDOC 3.2.1 *Public Information and Disclosure* requirements, CNL's Public Information Program (CNL 2024a), as well as CEAA 2012. Furthermore, communication activities are audited annually through CNL's Environmental Protection Program's ISO: 14001 certification. CNL also looks to third-party expertise to so that CNL is aware of any changing techniques and improvements, this has included training, industry experience, and international lesson learned.

5.2 Engagement Methods and Activities

CNL shares information about the Project with the public through several products and methods including community newsletters, website updates, social media posts, webinars, and more.

The following subsections outline specific engagement methods undertaken for the Project, at the time of preparation of this Section (i.e., up to July 2024). Engagement activities will continue as part of the environmental assessment process for the Project and beyond.

5.2.1 Public Liaison Committee Meetings

Established in 2003, the PLC meets twice annually. The objective of the PLC is to build working relationships and create opportunities for open dialogue between various local communities and CNL. Members include local elected officials and industry members.

During regularly scheduled meetings, PLC members are presented with an update on the Project, information about the Whiteshell Laboratories Restoration Project (WLRP), environmental practices, and are given the opportunity to ask questions and discuss the information presented. The PLC members are also asked to take meeting information back to their respective constituents. Meeting notes are taken at each meeting, recording all questions and actions that occurred during a PLC meeting. Following updates during each meeting, members could seek clarification and raise any concerns they have with both the Project and the WLRP. Guided site tours were provided following many of the meetings.

A WR-1 Environmental Assessment update was an agenda item at all meetings during the period of 2016 to 2024. Other Project-related topics at PLC meetings during this period included:

- a status update on the Draft EIS submission
- a report on a benchmarking trip to an existing ISD reactor in Hallam, Nebraska
- updates on decommissioning, specifically of the Project
- community interests and concerns
- public and Indigenous engagement
- public feedback received to date
- waste management and transportation

The PLC was provided a written update from CNL in May 2020 on CNL's activities during and leading up to COVID. The update provided details on CNL's response to the COVID pandemic, decommissioning updates over the winter and details on the March 2020 submission of the Draft EIS.

The PLC members were invited to a Regional Leaders Gathering, hosted by CNL to facilitate dialogue amongst Indigenous and non-Indigenous leaders, CNL, and AECL in the spring of 2023 and 2024. At the 2023 gathering, leaders learned about the Project, received an overview of the WL Remediation Plan (formerly the Land Use and End State Plan). At the 2024 gathering, leaders learned about the Project, received an update on the WL Remediation Plan and received an overview on options being explored for waste management of the Low-Level Waste Trenches. Both gatherings were an opportunity to ask questions, voice concerns, and provide insight into community priorities.

See Appendix A of the Stakeholder Engagement Report for an example of PLC agenda, meeting notes and presentation.

5.2.2 Whiteshell Community Regeneration Partnership Meetings

The Whiteshell Community Regeneration Partnership (the Partnership) was formed in 2015 by the Local Government District (LGD) of Pinawa and neighboring municipalities. The Partnership addresses the economic concerns of the local municipalities that have historically had residents working at the WL site, and is driven by a desire by both the region and CNL to encourage post-closure economic development. According to the Terms of Reference from October 21, 2015: "The proposed mandate of the Community Regeneration Partnership will be to develop a socio economic plan for the vicinity of the region affected by the WL decommissioning activities, to subsequently implement the plan and to review, update and report on the plan annually" (Skinner 2016). Overall, the goal of the Partnership is job creation, replacing the employment that has been and will continue to be lost as WL site decommissioning is completed. The partnership consists of six municipalities, three economic development organizations, CNL, and the Atomic Energy of Canada Limited (AECL). In addition, and to date, CNL has introduced representatives from Sagkeeng First Nation, Black River First Nation, Brokenhead Ojibway Nation, Hollow Water First Nation, and the Manitoba Métis Federation to the Partnership.

CNL's involvement in the Partnership includes:

- **listening to members** - CNL actively engages with members with the goal of hearing and understanding their priorities and concerns in regard to the WL site.
- **data integration** - CNL will provide requested data to the Partnership to provide the region and the social economic plan with details such as annual and 5–year rolling forecasts of employment levels and external contracting needs.
- **regional educational and outreach programs** - provide CNL employees and the regional workforce an opportunity to improve their employment skills with educational assistance and access to internal CNL training and outside training and reskilling programs, including programs related to (e.g., decommissioning and waste management), and unrelated to the WL decommissioning objectives (e.g., new business incubation).
- **regional purchasing programs** - develop multiple programs to support the regional supply chain so they can benefit from the extensive work scope to be accomplished at the site and to establish a supply chain that will be sustainable after the WL site has been decommissioned.

- **community support** - sponsor specific regional community activities and not-for-profit organizations and individual employees available to support these regional activities and organizations (CNL 2015).

As a result of the Partnership, a regional business incubator program called North Forge East (recently rebranded as Innovate Eastman) has been set up in the LGD of Pinawa and is funded by the Canadian National Energy Alliance. CNL meets and participates in the business incubator activities that have included on-site events, presentations and tours related to the wider WLRP.

The Partnership provides another venue for communication to the public about WL and to receive feedback as well. During meetings, Partnership members are presented with information about the WLRP (including the 2023 WL safety stand-down and potential future land-use), the WR-1 Project, and CNL's environmental practices. They are given the opportunity to ask questions and discuss the information presented. Several guided tours have been provided to the Partnership members since the Partnership's inception.

5.2.3 Municipal Engagement

CNL regularly engages with the rural municipalities, including the Town and the Rural Municipality of Lac du Bonnet and the LGD of Pinawa, the Town of Powerview – Pine Falls, and the Rural Municipality of Alexander. Elected officials from the nearest communities are also members on the Public Liaison Committee, where they receive regular updates and have the opportunity to dialogue with Project staff. Municipal representatives also joined CNL on the Hallam benchmarking trip (see Appendix W of the Stakeholder Engagement Report [CNL 2024b]). For information on tours and presentations involving elected officials, see Section 5.2.4.

CNL hosted a Regional Leader Gathering in May 2023 and June 2024 for non-Indigenous and Indigenous leadership. These events facilitated dialogue on projects and activities at the WL site. Both gatherings were an opportunity to ask questions, voice concerns, and provide insight into community priorities.

On July 30, 2024, the host community of Pinawa coordinated a public meeting on the Project, which CNL, AECL, and the CNSC participated in. CNL was invited by the LGD to the meeting, which was a forum for open discussion on the Project.

Generally, feedback from the municipalities has been similar to other interested parties feedback. Concerns were raised around the protection of the Winnipeg River; clarification on decommissioning and licensing timelines, and interest in participation in the licensing process. Questions have been asked about risk to the public, how the grouting will last against the timeline for radioactivity, and what monitoring and contingencies would be in place. Concern was also expressed around future use of the WL site and economic development, particularly the effect of having a reactor disposed of on-site. CNL's public engagement activities were generally thought of as positive. Some suggestions have been shared on engaging the local media more and the timing of open houses. It was also suggested that CNL develop an easy-to-understand brochure.

See the Stakeholder Engagement Report (CNL 2024b) for details of municipal engagement.

5.2.4 Presentations and Tours

CNL uses presentations and meetings to help share information, build awareness, and facilitate learning about the proposed Project. CNL also hosts tours of the WL site for government representatives, interest groups, and members of the public.

These presentations and tours provide an opportunity for a general Project overview, information sharing, and open dialogue about the Project between CNL and the public. These visits are used as one of several means of engaging and generating discussion that helps to inform the Project throughout the regulatory process.

Updates are also provided through the PLC, the LGD of Pinawa, and the Partnership.

See the Stakeholder Engagement Report (CNL 2024b) for details on presentations and tours, including examples of a meeting agenda and a public presentation.

5.2.5 Public Open Houses

Open houses have been held in regional towns within the vicinity of the WL site. The open houses featured a combination of booths, including storyboards and fact sheets regarding various aspects of the Project and the WL site in general, and comment forms to solicit feedback from participants. CNL staff were available at open houses to address questions and hear feedback from the public.

The key interests shared during the public open houses were:

- the rationale for choosing ISD as the decommissioning method, with requests for additional information on the other decommissioning methods considered, including associated costs;
- the availability of the WL site for future economic activities;
- understanding where used fuel would be stored;
- understanding more about the Project, including the grout, ISD in general, where would the radioactive material be stored and how long it would take to decay, as well as why ISD was chosen (with several participants expressing a preference for complete dismantlement);
- requests for materials, including the Comprehensive Study Report (AECL 2001);
- potential future uses of the WL site and how that would be determined. This concern was expressed by multiple parties, including municipalities, First Nations and the Manitoba Métis Federation, and landowners who had their land expropriated when the WL site was founded;
- water quality in various water bodies with a request for more information on monitoring activities during institutional control and how CNL would respond if there was a release of hazardous/radioactive material;
- water quality monitoring for groundwater and the Winnipeg River, as well as monitoring plans after decommissioning is complete;
- historical releases of contaminants on the WL site and how they were handled;
- the radioactive material currently stored on the site and the amount of material that would be transported to the Chalk River Laboratories site;
- comparable projects, the approval process, and what happens if ISD is not approved; and
- engagement accessibility, including interpret technical reports, and open house locations and times.

See the Stakeholder Engagement Report (CNL 2024b) for open house details, including dates, locations and information on issues and concerns.

5.2.6 Virtual Visitor Centre

The Virtual Visitor Centre is a website that focuses on the WLRP, addresses public concerns and answers questions that came through in the 2022 telephone survey. The site also has ample opportunity for visitors to ask questions and send feedback about the Project.

The website was advertised in local magazines, including Discover Lac du Bonnet and Lac du Bonnet Living, in the LUES brochure, which was handed out at events, and in the Lac du Bonnet Clipper newspaper.

The site can be found at www.engagewithcnl.ca/whiteshell.

5.2.7 Poster Boards

The 15 poster boards listed according to subject in Table 5.2.6-1, were developed with the intent to raise awareness and prompt discussion about the Project within the context of the entire WL Restoration Project. Poster boards are used in community engagement, such as community open houses. The poster boards are also used to keep CNL staff informed on the Project. They are posted throughout the WL buildings and offices.

Table 5.2.6-1: Poster Boards

Environmental Protection	WR-1 In Situ Decommissioning Project	Whiteshell Laboratories Decommissioning
Winnipeg River – Risk Assessment – WR-1 Decommissioning	Hydrology – WR-1 Decommissioning	WL Closure Project Overview
WR-1 Environmental Assessment Valued Components	Understanding Long-term Performance	WL Waste Management Overview
Protecting the Environment – Canadian Nuclear Laboratories	WR-1 Decommissioning – Alternative Means	Regulatory Oversight
Safe by Design – WR-1 Decommissioning	Public Engagement – WR-1 Decommissioning	WR-1 Reactor – Site and Surrounding Area
	Decommissioning Solution – WR-1 Decommissioning Project	
	WR-1 Reactor In situ Decommissioning(two boards)	

WR-1 = Whiteshell Reactor 1

See the Stakeholder Engagement Report (CNL 2024b) for examples of the posters.

5.2.8 Webinars

A webinar is an online, interactive forum that enables information sharing and two-way dialogue between CNL and the public. Webinars have the advantage of allowing people to participate from anywhere. The cost and time associated with travel to an alternative engagement activity is eliminated. Anonymous participation is possible if desired by participants.

In 2022, the WR-1 Project and the Nuclear Power Demonstration (NPD) Closure Project began hosting combined bi-monthly webinars, which has increased visibility of the Project. In 2023 and 2024, several additional webinars focussed on projects, activities and environmental protection at the WL site. All webinars are advertised in local papers and on CNL's social media channels. All webinars are available in both official languages and posted on CNL's YouTube page.

The webinars CNL hosted to provide information related to the Project are summarized in Table 5.2.7-1.

Table 5.2.7-1: WR-1 Webinars

Date	Topic	Peak Concurrent Viewers	Total Number of Views (to October 2024)
January 20, 2017	Whiteshell Laboratories WR-1 Reactor: In Situ Decommissioning	NA	3,900
October 24, 2018	Whiteshell Laboratories Restoration Project: Project update	22	N/A
June 23, 2020	Webinar: An Overview of the Post-Closure Safety Assessment of the WR-1 Disposal Facility	N/A	154
August 25, 2020	Whiteshell Laboratories WR-1 Reactor: In Situ Decommissioning Project webinar	NA	198
April 20, 2021	Whiteshell Laboratories Restoration Project: Environmental Protection	27	194
May 18, 2021	WR-1 Reactor Decommissioning Fact or Fiction Webinar	17	143
September 21, 2021	Whiteshell Laboratories Restoration Project: Project Update	39	149
November 16, 2021	Webinar- Overview of Environmental Protection at Whiteshell Laboratories- 2021 November	51	63
January 18, 2022	Regulatory process for the Nuclear Power Demonstration and WR-1 In Situ Disposal Projects	87	71
March 22, 2022	Nuclear Power Demonstration and WR-1: The design of the WR-1 and NPD reactors and In-Situ Disposal	44	164
May 10, 2022	WR-1 and Nuclear Power Demonstration: Overview of the Environmental Impact Statements	87	75
November 22, 2022	Whiteshell Laboratories: Past, Present & Future	34	450
September 28, 2022	NPD and WR-1: Who Supports and Environmental Assessment	46	56
April 18, 2023	Whiteshell Laboratories Restoration Project: Environmental Monitoring	39	154
February 20, 2024	Restoring the Whiteshell Laboratories site	96	266
April 9, 2024	Whiteshell Laboratories Fire Program	60	200

Watch recorded webinars: https://www.youtube.com/c/CNLCanada%20.

See the Stakeholder Engagement Report (CNL 2024b) for a webinar presentation.

5.2.9 Breakfast Sessions

A series of technical Breakfast Sessions were held late 2019 and early 2020 in person, changing to a webinar later in 2020, as a result of COVID-19 restrictions. These sessions provided an opportunity to share the technical details of the Project with interested participants, as well as respond to questions and receive feedback. Table 5.2.8-1 provides a list of Breakfast Sessions dates and topics.

Table 5.2.8-1: WR-1 Breakfast Sessions

Date	Topic
November 12, 2019	Reactor Characterization
February 4, 2020	Alternatives Analysis
June 23, 2020	An overview of the post closure safety assessment of the WR-1 Disposal Facility
August 25 2020	Defence in Depth - An overview of the WR-1 Disposal Facility containment and isolation barriers
September 29, 2020	Development and test results of the WR-1 Disposal Facility grout

See Appendix H of the Stakeholder Engagement Report (CNL 2024b) for a Breakfast Session presentation.

5.2.10 Community Engagement Activities and Conferences

CNL has extended invitations to the local and regional public to participate in engagement sessions. Table 5.2.9-1 lists all community engagement activities and site tours since engagement on the Project began.

One approach used to share information, build awareness, and facilitate learning opportunities was to have CNL representatives attend community events in communities local to the WL site. CNL representatives were available to answer questions, collect feedback and provide information about the Project at these community events.

CNL brings information to share at community engagement activities, which may include:

- WR-1 Project feedback form;
- WR-1 fact sheet;
- WR-1 Project Description document;
- WR-1 Project and Whiteshell Laboratories Restoration Project poster boards;
- Copies of presentations;
- Hallam trip report;
- WR-1 model;
- Indigenous Engagement Report;
- Environmental Monitoring Program brochure; and

- Land Use End State fact sheet.

See the Stakeholder Engagement Report (CNL 2024b) for a sample tour agenda.

Table 5.2.9-1: Community Engagement Activities

Date	Activity
September 20, 2017	Presentation to American Concrete Association
November 15, 2017	Alumni, Retiree WR-1 workshop technical tour
April 3 – 5, 2018	Community benchmarking tour, Hallam, Nebraska
May 26, 2018	Information booth at the Lac du Bonnet Trade
September 8, 2018	Information booth at the Brokenhead Double B agricultural festival
May 24, 2019	Lac du Bonnet and District Trade Fair
May 31, 2019	Sunrise School Division School Board tour and meeting
November 6, 2019	Take Your Kids to Work Day including tour of WR-1
August 20, 2020	CNL booth at the Lac du Bonnet Night Market
September 5, 2020	CNL booth at the Lac du Bonnet Home and Cottage Expo
May 26, 2021	In situ disposal approach to decommissioning legacy reactors meeting (Sweden)
June 8, 2021	Decommissioning Technology and Experience Workshop (United Kingdom)
June 14- 18, 2021	IAEA International Project on the Completion of Decommissioning
August 6, 2022	Booth at CNL Open House at Chalk River Laboratories
September 8-10, 2022	Booth at FireCon in Thunder Bay, ON
May 6, 2023	Lac du Bonnet Great Outdoors Expo
June 30, 2023	Regional Leaders Gathering (hosted by CNL) in Brokenhead Ojibway Nation
July 16, 2023	Booth at Pinawa's 60th Birthday Celebration event
November 22, 2023	Booth at Manitoba Environmental Industries Association CleanTech Conference
December 7, 2023	Land Use End State Alumni Event in Pinawa (hosted by CNL)
June 1-2, 2024	Lac du Bonnet Great Outdoors Expo
June 4, 2024	Regional Leaders Gathering (hosted by CNL) in Beausejour
June 30, 2024	Float in Lac du Bonnet Parade
July 30, 2024	WR-1 presentation at Public Meeting (hosted by LGD Pinawa) in Pinawa

5.2.11 Employee-Focused Engagement

To reach internal stakeholders (employees), different methods were employed including myCNL TV broadcasts (which are live broadcasts similar to the webinars sent out via CNL's intranet), employee information sessions, "lunch and learns", and content distributed via the intranet (*myCNL*), internal newsletters, in particular the CNL-wide, *Voyageur* newsletter and as of October 2022, there is the Whiteshell-specific, *The Loop* newsletter. As well, in the summer of 2022, CNL began holding weekly all-staff meetings each Thursday to keep staff at site up to date on activities and provide two-way dialogue with leadership.

All new employees also take part in New Employee Orientation where they are introduced to the proposed Project and have the opportunity to ask questions and learn about the Project. Invitations to the bi-monthly webinars are also shared with all staff at the WL site.

See the Stakeholder Engagement Report (CNL 2024b) for examples of employee engagement, including a list of employee engagement events.

5.2.12 Alumni Technical Workshop

Following the first round of open houses, it was recognized that community members in the WL site region have expertise who could independently review certain aspects of the Project. An Alumni Technical Workshop was held November 15, 2017, with 11 invited retirees and regional experts in attendance. The workshop started with a tour of the WRDF and then moved into a focused technical discussion centered on some of the key aspects of the EIS. The workshop was a very productive event with questions asked and feedback/advice provided.

As mentioned above in Section 5.2.10, CNL also hosted a 2023 event in the community for alumni to learn and discuss land use and end state at the WL site.

See the Stakeholder Engagement Report (CNL 2024b) for more information on these workshops.

5.2.13 Web Page Content

CNL has established a Project-specific webpage: www.cnl.ca/wr1. In addition, quick links have been added to the landing page, raising Project visibility and easing access to the appropriate pages. Since April 2017, updated information has been added to the Project webpage, and webpage activity continues to be tracked and analyzed using Google Analytics.

The webpage is updated with new information as it becomes available. Public information session posters, a hyperlink to a revised formal feedback mechanism, the Project timeline, factsheets, and Project infographics have all been added to the Project webpage.

See the Stakeholder Engagement Report (CNL 2024b) for information on Google Analytics and sample webpage content.

5.2.14 External Newsletter – Whiteshell CONTACT

The Whiteshell CONTACT newsletter is published and mailed to more than 7,500 homes in the vicinity of the WL site and is available on https://www.cnl.ca/news-publications/newsletters/. This publication informs the reader on activities undertaken at the WL site and profiles CNL's community activities.

Nine issues of the newsletter have been released. Each issue has some focus on environmental assessment activities, as well as CNL's environmental stewardship. In particular, each issue included an update on the WLRP and the Project, or a separate article on the WRDF, in addition to an update on the overall WLRP.

In the spring of 2019, CNL also published an Environmental Issue, which included articles on environmental stewardship, energy efficiencies, wildlife protection, and waste minimization.

See the Stakeholder Report (CNL 2024b) for an example of newsletter content and when issues have been published.

5.2.15 Email

Emails have been used to connect with internal and external stakeholders, as well as with non-government organizations (NGOs). In particular, emails were sent out to promote different events, to advise of the public comment period on the draft EIS, and to provide responses to questions submitted electronically. Interested members of the public are encouraged to join an email distribution list to receive notices of upcoming events related to the Project (e.g., webinars, breakfast briefings, open houses).

See the Stakeholder Engagement Report (CNL 2024b) for a sample email.

5.2.16 Advertising Methods

CNL uses advertising to announce and increase awareness of the events. Advertising is undertaken in specific regions in the vicinity of the WL site. Different forms of advertising have been used to reach the interested public. For instance, to advertise the Breakfast Sessions and increase public awareness about technical topics, CNL posted ads in local papers for one to two weeks leading up to each session, and sent invitations to local mailing lists. CNL has also run advertisements in local newspapers, on Facebook via targeted advertising, on its website, and through mailouts, including a one-page flyer sent to approximately 7,900 Canada Post mailboxes.

Advertising methods used include:

- advertisements posted on CNL.ca landing page and the Project-specific webpage: www.cnl.ca/wr1;
- advertisements have been included in versions of CNL's Whiteshell CONTACT newsletter, when applicable;
- newspaper advertisements; and
- paid Facebook advertising via "Boosted Posts".

See the Stakeholder Engagement Report (CNL 2024b) for detailed advertising information and a sample advertisement.

5.2.17 Intranet – myCNL

The internal website has been used to communicate with internal stakeholders, providing updates on the Project and publicizing events related to the Project. Posts on the Project are shared on myCNL to educate, inform, and provide updates on the Project to employees.

See the Stakeholder Engagement Report (CNL 2024b) for an example of a myCNL posting.

5.2.18 Internal Newsletters – The Loop and Voyageur

CNL's internal newsletters, Voyageur, and the Whiteshell-specific newsletter, The Loop, are regularly published to update current and former CNL employees. Former employees can sign up as "CNL Alumni" to receive these newsletters via email. There are around 500 individuals on the distribution list for The Loop and for Voyageur, CNL shares via email with around 500 "CNL Alumni" and publishes 300 hard copies for the Chalk River staff. Both newsletters are also available, including archived editions, through CNL's internal website, myCNL.

Since 2017 the following issues of The Loop have been published:

1. January 2019;

2. Fall 2022;
3. Winter 2022-23;
4. Spring 2023;
5. Summer 2023;
6. Fall 2023;
7. Winter 2024;
8. Spring 2024; and
9. Summer 2024

Since 2017, the following articles on the WR-1 Restoration Project were published in the Voyageur newsletter:

1. May 2017 – The Year Ahead in WL;
2. August 2017 – CNL & UOIT Partner on Hydrogen Generation;
3. February 2019 – Technology Developers Advance in SMR Process;
4. June 2019 – Whiteshell Open House a Success!;
5. December 2019 – #Coolthings We Did in 2019;
6. September 2021 – CNEA Donates $240,000 to North Forge East;
7. March 2021 – CNEA Donates $80,000 to North Forge East;
8. September 2021 – Indigenous Advisory Committee Kicks Off;
9. December 2021 – Whiteshell Employee Transition Plan;
10. January 2023 – WR-1 EIS Passes Completeness Check;
11. April 2023 - SBWRS project now in testing phase; and
12. August 2024 – Whiteshell Laboratories Site Relicensing.

See the Stakeholder Engagement Report (CNL 2024b) for a newsletter article.

5.2.19 CNL Social Media

Social media is used to share information and increase awareness about CNL activities, including the Project events and to receive feedback on the Project.

From the various social media platforms, Facebook provides the strongest engagement through “comments, shares and likes” of posts. When CNL wished to raise the profile of Project events or information, “boosted” posts were used to target by location and demographics. “Boosted” posts are paid posts through Facebook. Twitter has not been used as broadly as Tweets have been found to receive very little traction, and comparatively CNL has a much larger Facebook following. While numbers are larger on LinkedIn, the demographics are far more industry based, rather than general public. Therefore, CNL uses LinkedIn, but in a much lower capacity than Facebook to confirm engagement is a balanced approach with general public in comparison to those actively part of the nuclear industry. YouTube has also been used successfully to engage with stakeholders. Webinars have been posted on YouTube for easy access by the public.

To support the WL projects and the WL site, CNL has used social media to promote events, share and receive information, and generally engage with the public. Social media has been an effective tool to reach and engage stakeholders. CNL’s post on April 16, 2020, sharing the support the WL team was giving to the COVID-19 response had a high level of engagement with 363 individuals interacting with the content.

Another example of how social media has supported CNL's transparency on the restoration of the WL site is the Facebook post from October 11, 2019 that showed progress on the physical changes at the site. This post was clicked on 1,922 times.

While Twitter is still used to promote events and engage with different stakeholders, it has not proved as effective a tool for CNL's audiences. Given the bigger following of CNL's Facebook account, it is currently the social media of choice for reaching stakeholders.

More information on CNL's social media can be found the Stakeholder Engagement Report (CNL 2024b).

5.2.20 Media Coverage

CNL engaged in outreach with media organizations as part of the environmental assessment process. Five media outlets were invited to tour the WL site: The Clipper, CBC Radio, CBC Radio-Canada, the Winnipeg Free Press, and the Winnipeg River Advocate. Two organizations participated. Radio Canada toured the WL site. The Clipper toured the WR-1 Building and watched a video on the reactor and a presentation by CNL staff. A total of 46 articles and 16 opinion pieces were written from June 2016 to December 3, 2020, about the Project or referencing the Project.

Media coverage gradually grew over 2016 and 2017 as CNL hosted open houses, peaking in 2018 with the trip to Hallam, Nebraska, and then levelling off again in 2019 and continued through 2021. The majority of the articles were submitted by CNL or written by the paper with the tone of the coverage, neutral or supportive in nature. CNL began actively utilizing a "detect and correct" method in sending in responses to articles that help correct misinformation. This method proved effective in getting more factual information out and overall has led to more balanced coverage. CNL has also had supportive articles published by former AECL and CNL retirees. These positive articles have proved beneficial and present facts related to the Project.

Summaries of Project related media can be found in Section 3.19 and Appendix U of the Stakeholder Engagement Report (CNL 2024b).

5.2.21 Responding to Information Requests

When requests for information were received (e.g., via email, letters, formal comment cards submitted at an open house), they were electronically logged and assigned to appropriate subject matter experts. Once the response was received from the subject matter experts, it was then issued for final internal review. The response was electronically recorded and returned to the originator via the same stream it was received. If the request received was for copies of the EIS supporting documentation, the files were deposited in a Secure File Transfer Protocol site and the login information forwarded to the originator. CNL also delivered hard copies of the EIS, when requested.

5.2.22 Document Repository – November 2017 – July 2024

CNL made four hard copies of the draft EIS publicly available, functionally creating a document repository for the draft EIS volumes. One hard copy of the draft EIS was available at both the Pinawa and Lac du Bonnet Public Libraries. These copies were updated at both libraries in April of 2023.

5.2.23 Release of Documents – 2017 – September 2022

To support interested members of the public's review of Project materials, CNL has responded to requests to provide documents related to the Project. CNL notifies interested members of the public of documents as they become available by email.

5.2.24 Participant Funding

The CNSC offered funding through its Participant Funding Program to assist members of the public, First Nations and the Manitoba Métis Federation, and other stakeholders in participating in the environmental assessment, licence application review, and Commission hearing processes for the Project. Recipients provide value-added and relevant information that contributes to a better understanding of the anticipated effects of a Project. Recipients also participate in the CNSC's proceedings for this Project. The CNSC's decision on who has received funding to participate is available in the CNSC *Participant Funding Program Decision: Canadian Nuclear Laboratories' Whiteshell Reactor No. 1 (WR-1) Decommissioning Project*.

Information on participant funding for the Project is available at: PFP funding opportunities - Canadian Nuclear Safety Commission

CNL considers those that have applied and received funding from the Participant Funding Program as stakeholders that have self-selected as especially interested in the Project. As such, CNL has made particular efforts to reach out to recipients of participant funding with offers to provide information and meet with these individuals and/or organizations.

5.3 Public Feedback and Response

Feedback continues to give valuable insight into issues that are important to the public, enabling the Project team to respond to and incorporate the issues of the local community and the broader public into the planning and the EIS. For example, the future use of the WL site and employment that offsets the loss of jobs at CNL following site closure was identified as important for local municipalities and RMs. As such, the importance of continued economic development was considered under the context of community well-being and was included as a VC in the environmental assessment (Section 6.9 Socio-economic Environment). A summary of the concerns and questions raised during public engagement and how CNL has responded to them is provided in Table 5.3.1-1.

Valued components are described near the beginning of each subsection of Section 6.0 Environmental Effects (Sections 6.2 Atmospheric Environment through 6.9 Socio-economic Environment). Section 2.0 Purpose of the Project and Alternative Means, also includes information on how public feedback was considered in the alternatives assessment.

Throughout the engagement period, CNL continued to review and update communication channels so that CNL was open and reachable by the public. CNL provided user-friendly information and communications products to facilitate sharing information and updates about the Project, and to address concerns and interests, including those identified in Table 5.3.1-1. CNL actively sought feedback through provision of feedback forms at engagement sessions and online, as well as encouraging direct contact with CNL, using this feedback to inform the EIS development.

5.3.1 Public Engagement Feedback

Public feedback from all Project engagement activities described in Section 5.2 Engagement Methods and Activities help CNL to understand public interest in and awareness of the Project, as well as the effectiveness of public communication and methods of sharing information. Key themes raided during engagement activities are summarized in Table 5.3.1-1 and include areas of interest and/or concern that were frequently voiced by the public. Topics and key interests and concerns have been gathered from multiple events.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Regulatory Process	Requested more information on updated timing for the review process, submittal, and commission hearing. During engagement sessions, members of the public requested more information on updated timing for the review process, submittal, and commission hearing. During these sessions, the public was advised that the environmental assessment process requires CNL to generate a thorough analysis of effects on the environment from the Project, including an EIS, a decommissioning safety assessment and a post-closure safety assessment, which are submitted to the CNSC.	CNL is currently working with the CNSC to establish a revised schedule for final regulatory submittals, including the submission date for the final EIS. CNL regularly updates interested members of the public about the environmental assessment process and the Project through the engagement methods discussed in Section 5.2. CNL has received 26 comment submissions from members of the public and regulatory bodies on the EIS. Presently CNL is responding to those submissions and, subject to their acceptance by the CNSC, CNL will update and finalize the EIS. The adjustment to the schedule is being made in order to allow CNL to appropriately address these comments and for the CNSC staff to conduct a fulsome assessment of CNL's proposal. All information will be available to the public and will include a meaningful public and Indigenous engagement process. The proposed Project can only proceed if it receives regulatory approvals for demonstrating safety to the environment and people.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Alternative Means	How was ISD chosen as the preferred option?	CNL presented alternatives that were safe and both technically and economically feasible at all the public engagements. CNL shared how these options were qualitatively assessed for their environmental effect, socio-economic effect, and human health effects. Members of the public asked CNL to provide further detail on how the ISD method was chosen for the Project. In accordance with guidance from The Agency, the original EIS included qualitative assessments of the options considered. In response to requests, CNL revised the assessment of alternatives for clarity, and to incorporate feedback from the public and from First Nations and the Manitoba Métis Federation. This is provided in Section 2.0 of the EIS. The updated assessment clarifies the differences between the alternatives and explains the risks and benefits relative to each alternative. Based on this assessment, ISD is CNL's preferred option and is low risk to the public and the environment when compared to the limits established by Canada's nuclear regulator, the CNSC. Complete removal of the WR-1 following a deferment period was the decommissioning method described in the Comprehensive Study Report. Since then, CNL has re-evaluated that plan considering international best practice to reduce deferment periods. The Canadian regulations have adopted specific conditions for when ISD would be acceptable. WR-1 meets those conditions as: ■ it is a legacy facility from the dawn of the nuclear age in Canada; ■ it was not designed with decommissioning of the facility in mind; ■ all reactor fuel has been removed; ■ the use of ISD will be protective of workers, the public and the environment; and ■ the Project site will remain under institutional control for the period defined in the safety case. The ISD option is a safe decommissioning option for the WR-1 with respect to the environment, workers and the public and has been used successfully for over six decades in other parts of the world. CNL's plans for WR-1 are going through a rigorous licensing approval process by Canada's independent nuclear regulator, the CNSC. If approved, ISD will be undertaken under strict CNSC regulations.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Economics	What is the cost of this option in comparison to alternative methods? Members of the public were interested in knowing the cost of ISD in comparison to alternative methods.	In response, CNL included information on the approximate costs of alternative methods at subsequent open houses. The alternative means assessment (Section 2.0 Purpose of the Project and Alternatives to the Project) presents a high-level cost analysis of the ISD option compared to other alternatives considered. Costs range from approximately $43 million to $265 million. Funding for the Project is provided by AECL, a federal Crown corporation and owner of the WL site. The alternative means assessment that was conducted for the Project did not use cost as an evaluation criterion because only economically feasible options were evaluated.
Lessons Learned	Ensuring that the Project was properly quantifying and incorporating available lessons learned from other similar work already conducted and work done at the WL site. Members of the public wanted assurance from CNL that the Project was properly quantifying and incorporating available lessons learned from other similar work already conducted and work done at the WL site.	CNL has gathered data and lessons learned where available on other ISD projects (Section 2.5.1 Evaluation Approach). CNL has participated in several learning workshops with technical experts that have performed ISD and has used services and advisement from organizations that have performed the ISD method. Development of the grout formulation incorporated lessons learned from the in situ grouting of the Savannah River National Laboratory's reactors, as described in Section 3.4.6.2 Grouting of Below-Grade Structures. Lessons learned documents from previous decommissioning work, including operating experiences were reviewed as part of assessing the potential for accidents and malfunctions (Section 7.0 Accidents and Malfunctions). CNL recognizes the incredible depth of research on nuclear waste disposal that was carried out at the WL site and has been incorporating that research into the Groundwater Flow and Solute Transport Modelling Report (Golder 2021) and the Geosynthesis Report (CNL 2022) supporting the EIS. Gathering and incorporating lessons learned will be an important part of the detailed work planning activities prior to starting the work.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Design and engineering details	What would eventual design look like?	During engagement sessions, many questions were raised on the design of the Project. When CNL submitted the EIS, it had completed a preliminary, conceptual design. Since then, the design process has continued to progress, and more refined designs have been prepared for the re-submission of the final EIS. The final detailed design will equal or surpass the performance of the conceptual design that was assessed in the EIS. The current design of the disposal system is described in Section 3.4.9.1 In Situ Disposal System. Design of the monitoring program will include input from the regulators, the Indigenous Nations, and local municipalities (Section 11.0 Summary of Monitoring and Follow-up Programs). CNL also received questions about the IAEA's safety standard for decommissioning, which states that ISD is not a suitable option for all nuclear facilities and should be considered only under certain conditions. CNL agrees with this assessment, and CNL determined that WR-1 has features that make it suitable for long-term disposal such as: its location below grade, it does not contain substantial quantities of long-lived isotopes, and that it can be monitored post-closure during the institutional control period. CNL is following IAEA safety standards for the decommissioning of the facility and more importantly is also following the IAEA safety standards for waste disposal, since the WRDF – in its end state – would be classified as a disposal site. The Agency and the CNSC require CNL to demonstrate that the proposed Project does not pose an unacceptable level of risk to human health or the environment. The Project is subject to approval by the CNSC, who has established regulations for the management of radioactive materials. They draw input to their regulations from the IAEA but are an independent regulator with the responsibility to verify the information CNL has presented as part of the EIS. The regulatory framework for this Project is provided in Section 1.7 Regulatory Framework, and AECL's and CNL's commitment to international best practices, including the IAEA is provided in Section 1.1 Project Context.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Effectiveness of the Grout	How effective is the grout?	Since CNL has identified ISD as the preferred option for decommissioning the WR-1, and the use of grout to fill the building below-grade has prompted many questions. CNL has developed specially-formulated grout based on the requirements of the WRDF and experience from Savannah River National Laboratory's ISD projects. The grout formulation has been designed and evaluated through a testing program to validate its performance against the required and assumed properties, to confirm it performs, as well as or better than estimated in the solute transport model, prior to the installation of any grout into the WR 1 Building. Properties of the grout are discussed in Section 3.4.6.2 Grouting of Below-Grade Structures and Systems. The primary purpose of grouting the WRDF is to stabilize the structure and resist subsidence over time. The physical presence of grout will also reduce the total amount of groundwater in the WRDF and thus reduce the amount of water available for various chemical and corrosion reactions. In addition, it provide a favourable chemical environment due to its high pH, which will slow down the rates of corrosion of the steel-based components, including the reactor vessel. The safety case for the proposed ISD does not require that the reactor vault be grouted. The existing structure provides sufficient barrier to releases, and additional grout would not considerably increase the effectiveness of that barrier. The safety case for the WRDF is built on the conservative assumption that the primary aspect of the grout to its function as a barrier is the hydraulic conductivity of grout used in the groundwater flow model. Effectiveness of the grout and concrete materials used for the ISD system have been evaluated through the sensitivity analysis evaluated and presented in Section 5.0 of the Groundwater Flow and Solute Transport Modelling Report (Golder 2021).

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Radiological Inventory	Understanding current inventory Confirmation on how the radiological inventory will reduce over time CNL received several requests for details on the current radiological content of the WR-1 and how the levels of radioactivity will reduce over time. It should be noted that the reactor fuel – the most radioactive part of the WR-1 – was removed in 1985. The available information on the radiological status is primarily based on reactor core modelling from the early 1990s (CNL 2024b).	In response to questions, CNL has conducted further radiological characterization of the facility. A comprehensive characterization campaign was performed during 2017 and 2018 to address data gaps and to provide quantitative estimates of residual radionuclide content remaining within WR-1 systems (CNL 2024b). The updated radiological inventory information is provided in Section 3.3.3.1 Radiological Hazards.
Valued Components	Confirming environmental VCs that were identified by the Project, reflect public feedback. Public feedback has included comments and questions about the Winnipeg River VC and the future land use at the WL site.	CNL surveyed attendees at public open house events to get their input into the VCs selected for the Project. Section 6.1 Environmental Assessment Approach of the EIS outlines the process that was followed to develop the list of VCs. The list of VCs was presented on poster boards during all open houses, as well as on CNL's external website. CNL provided information handouts at public open houses, and created posters displaying valued components. The public was given the opportunity to identify new VCs through a questionnaire that was offered to visitors. CNL considered all suggested VCs and either included them in the assessment, determined they were effectively covered by existing VCs or provided rationale for why the VC was included in the assessment. Section 6.1 Environmental Assessment Approach outlines the process that was followed to develop the list of VCs. The feedback collected was used to validate CNL's list of VCs (See Section 4.3 of the Stakeholder Engagement Report (CNL 2024b). The Winnipeg River was a key concern for the members of the public, and CNL confirmed that it was represented in the EIS as a separate VC. Land and resource use is also included as VCs in Section 6.8 Land and Resource Use.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Protecting the Winnipeg River	The continued protection of the Winnipeg River is a key focus of the EIS. Understandably, the proximity of the WRDF to the Winnipeg River prompted many questions about how the final, grouted Project would affect the waterway. The Winnipeg River is a key concern for the members of the public.	CNL confirmed that the Winnipeg River is a VC and that the continued protection of the Winnipeg River is a key focus of the EIS. Understandably, the proximity of the WR-1 to the Winnipeg River prompted many questions about how the Project would affect the waterway. Water quality, flow, recreational use, and fish and fish habitat were considered in the assessment. An Ecological Risk Assessment was completed to evaluate the potential for adverse effects on aquatic health associated with exposure to chemical and radiological contaminants from the Project in the long-term (Section 6.7.2 Ecological Health). There are no exceedances of the radiation benchmark for the aquatic biota in the Winnipeg River and all predicted doses are well below this level. Therefore, it is unlikely there would be significant adverse effects on aquatic populations or communities as a result of radionuclide releases in the long-term during the post-closure phase. CNL will implement an EAFMP for the Project that will be integrated with the existing EAFMP for the WL site (Section 11.0 Summary of Monitoring and Follow-up Programs). The EAFMP for the Project will include sufficient information on the type, quantity and quality of information required to reliably verify effects predicted by the environmental assessment and confirm the effectiveness of mitigations. Wherever possible, existing programs will be adapted to meet the objectives of the EAFMP for the Project.
Effects of the Environment on the Project (Extreme Weather Events, Forest Fires, Seismic Events)	Has the Project examined the potential effects of an earthquake or climate change or other natural disasters on WR-1? Members of the public expressed concerns of the potential effects of an earthquake or climate change or other natural disasters on the WRDF.	CNL has shared that an assessment was completed that evaluated the potential effects of natural hazards (i.e., extreme weather events, forest fires and seismic events) and climate change on the Project (Section 10.0 Effects of the Environment on the Project). The Project design includes environmental design features, management practices and other mitigation to reduce the risks from natural hazards and climate change. In addition, a seismic hazard analysis was completed for the WL site, which concluded that an earthquake would not cause damage to the WRDF. To provide further confidence, CNL modelled a scenario where the concrete foundation of the WRDF failed (WRDF Barrier Failure Disruptive Event; Section 6.7 Human and Ecological Health), which predicted that adverse effects to human and ecological receptors are not anticipated from WRDF barrier failure.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Contingency Planning	Information on how the Project design accounts for the risk that in situ does not operate as planned. What is the contingency plan and who is responsible?	Members of the public requested information on how the Project design accounts for the risk that the WRDF does not operate as planned. CNL explained that the WRDF will include multiple barriers, including the waste form, a specialized grout formulation, the existing WR-1 Facility walls, a concrete cap and engineered cover, and the surrounding geosphere. In the very unlikely case that degradation of these barriers occurs earlier than predicted, the surface and ground water monitoring system will detect contamination migration well before it reaches the Winnipeg River. CNL will implement an EAFMP for the Project that will be integrated with the existing EAFMP for the WL site (CNL 2018). The EAFMP for the Project will include sufficient information on the type, quantity and quality of information required to reliably verify effects predicted by the environmental assessment and confirm the effectiveness of mitigations. If the EAFMP identifies that adverse environmental effects are greater than predicted, then CNL will evaluate the need for revised mitigation actions and management practices to manage effects, with engagement with the public for openness and transparency. Where the need for revised mitigations is identified, they will be developed and implemented. Any proposals on modifications to the monitoring program will be communicated to the CNSC. Section 11.2 Adaptive Management includes CNL commitment to developing environmental mitigation actions under the Environmental Protection Program in case of unexpected monitoring results.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Environmental Monitoring	Information was sought on how the in situ design incorporates ongoing environmental monitoring. Interest was expressed in the depth of monitoring wells. Members of the public requested information on how the ISD incorporates ongoing environmental monitoring.	CNL has shared that the EAFMP developed for the Project will be integrated with the existing EAFMP for the WL site. Section 11.0 Summary of Monitoring and Follow-up Programs was updated to include this commitment. The EAFMP for the Project will include sufficient information on the type, quantity and quality of information required to reliably verify effects predicted by the environmental assessment and confirm the effectiveness of mitigations. Wherever possible, existing programs will be adapted to meet the objectives of the EAFMP for the Project. Table 11.1-1 summarizes the conceptual monitoring programs to be included in the overall EAFMP for the Project. Section 11.2 Adaptive Management was updated with CNL's commitment to engage with the local municipal governments, regulators (including the CNSC), First Nations, and the Manitoba Métis Federation on the monitoring program and incorporate their feedback on the monitoring program, as possible. Interest was also expressed in the depth of monitoring wells. Depths and location of monitoring wells was explained and talked about in public presentations. CNL has committed to adding additional ground monitoring well(s) between the WRDF and the Winnipeg River as requested by the Manitoba Métis Federation.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
Future Land Use and Economic Opportunity	Requested more information on the plans for the WR-1 site after ISD is completed. Members of the public expressed concern with the Project because it would limit the types of businesses and industries that could use the WL site for future operations and therefore reduce the number of economic development opportunities available to them. This is a major concern for local communities who have considered the operation of the WL site as an important economic contributor in the region, as expressed through the desire to recruit a new industry to the site.	CNL is currently working with the communities and RMs in the local area by funding the activities of the Whiteshell Community Generation Partnership (now known as Innovate Eastman). The goal of the Partnership is to develop a socio-economic plan for the region. CNL supported development of the regional socio-economic plan through the provision of access to CNL technical resources and contracting of graphic arts services. The plan lays out the steps needed to facilitate future economic development of the region. The public expressed hope that activities through the Partnership would replace the employment lost at the WL site with stable, high quality employment in the region. Although uncertainty remains about the timing and nature of a new industry being attracted to the site, CNL is encouraged by the interest that has been expressed to develop the site for alternative uses. Future uses and zoning for the WL site have not been determined and will be the responsibility of AECL as the owner of the site. Although a small proportion of the WL site will have restrictions on use because of the Project (i.e., 0.07 ha), it is still anticipated that the majority of the site will be safe and appropriate for unrestricted use, and that future designations will seek to maximize the amount of lands available for other uses. CNL is engaging with the local public and Indigenous Nations on next land use related to the WL. CNL supports robust communication of environmental monitoring results to confirm the safety of the WL site and help address concerns and mitigate concerns about the site's suitability for future uses. These commitments have been included in Section 6.9 Socio-economic Environment.

Table 5.3.1-1 Summary of Feedback and Responses

Topic	Key Interest and/or Concern	Response
IAEA guidance for In Situ Disposal	Participants wanted to ensure that international guidance on in situ design was being properly considered. CNL received questions about the IAEA's safety standard for decommissioning, which states that in-situ disposal is not a suitable option for all nuclear facilities and should be considered only under certain conditions.	CNL agrees with this assessment, and CNL determined that WRDF has features that make it suitable for long-term disposal such as: its location below grade, it does not contain substantial quantities of long-lived isotopes, and that it can be monitored post-closure during the institutional control period. CNL is following IAEA safety standards for the decommissioning of WR-1 and more importantly is also following the IAEA safety standards for waste disposal, since the facility – in its end state – would be classified as a disposal site. The Agency and the CNSC require CNL to demonstrate that the proposed Project does not pose an unacceptable level of risk to human health or the environment. The Project is subject to approval by the CNSC, who has established regulations for the management of radioactive materials. The CNSC draws input to their regulations from the IAEA but are an independent regulator with responsibility to verify the information CNL has presented as part of the EIS. The regulatory framework for the Project is provided in Section 1.7 Regulatory Framework, and AECL's and CNL's commitment to international best practices, including IAEA is provided in Section 1.1 Project Context.

CNL = Canadian Nuclear Laboratories; CNSC = Canadian Nuclear Safety Commission; EIS = environmental Impact Statement; ISD = in situ disposal; WR-1 = Whiteshell Reactor 1; AECL = Atomic Energy of Canada Limited; WL = Whiteshell Laboratories; IAEA = International Atomic Energy Agency; WRDF = Whiteshell Reactor Disposal Facility; VC = Valued Component; EAFMP = Environmental Assessment Follow-up Program; ha = hectare

5.3.2 Formal Public Comments

In addition to the informal feedback that the public engagement outreach activities offer, the environmental assessment process provides an opportunity for formal feedback from the public. This process began with the formal public and Indigenous comment period on the Project Description in May 2016. Followed, by a formal public and Indigenous comment period on the EIS for the proposed Project from May 2017 until August 2017. Comments from members of the public, First Nations and the Manitoba Métis Federation, and NGOs on the EIS were consolidated by the CNSC (as the responsible authority) and received by CNL. CNL prepared responses to the formal comments which will be submitted to the CNSC and posted on the CEAA Registry under project #80142.

Previously identified areas of interest surrounding the Project continue to be prevalent in the 104 formal comments that the Project have received over the period September 2017 to December 3, 2020, including many comments and questions arising from the Alumni Technical Workshop held November 15, 2017, feedback from the April 3-5, 2018 benchmarking trip to Hallam, Nebraska, and the open house on June 8, 2019. For example, economic regeneration, future land use, assessment of the decommissioning alternatives, and contingency plans continued to draw interest from the local public.

5.4 Planned Future Engagements

The summary presented within this section is based on engagement activities up to July 2024. Future engagements will be summarized in the Stakeholder Engagement Report, which will continue to be updated through the environmental assessment process. As the Project schedule evolves, CNL will continue to confirm engagement activities and provide updates to the CNSC through monthly meetings to report on CNL's Indigenous and public outreach. Planned future engagements may include but are not limited to the following:

- site tours;
- community information sessions;
- participation in regular public events such as community events, trade shows, fairs, and street markets;
- regular website review and content update with new information added as it becomes available;
- semi-annual PLC meetings;
- webinars;
- WR-1 Project update letter/invitation to intervenors;
- public polling; and
- semi-annual Whiteshell CONTACT and Kids CONTACT newsletters.

Note that throughout this section, dates and other details are provided where possible. For engagements planned for the near-term, details and dates are present, but subject to change. For engagements planned to occur farther into the future, specific dates, and details of the activity are available closer to the activity, to allow for flexibility and accommodation of the environmental assessment process.

CNL has planned engagements up until the licensing hearing available in the Stakeholder Engagement Report (CNL 2024b).

5.4.1 Implications of the 2023 Whiteshell Safety Stand Down

In April 2023, CNL reported to the CNSC that a self-assessment of the Whiteshell Fire Protection Program had identified gaps in fire responder training qualifications. In response to the findings, CNL took immediate action to pause all non-essential work at the site and to redeploy fire responders and equipment from the Chalk River Laboratories site to the WL site to provide effective site fire protection.

CNL shared that there was no risk to the public, workers, or the environment from the event. At the end of June of 2023, a virtual public meeting was held to discuss the stand-down with the CNSC Commission. For several months, the Whiteshell Safety Stand-down limited on-site engagements, such as meetings and tours.

Throughout the Safety Stand Down, CNL continued to engage local communities and the public. CNL provided regular updates on its activities at the WL site via meetings, email blasts, updates to the external website and media interviews.

In November 2023, CNL returned to hosting tours and meetings at the WL site.

5.4.2 Implications of the COVID-19 Pandemic

In March 2020, the COVID-19 pandemic directly impacted face-to-face and public interactions around the world, including those under CNL's public engagement program. CNL successfully transitioned to virtual activities as the standard for engagements in 2021, ensuring that its engagement strategies were resilient in the face of the challenges presented by the pandemic. CNL continued to host virtual and hybrid events through 2023 and into 2024.

5.5 Conclusions

Methods employed to date have helped to share information and build awareness about the Project and have enabled the public to provide valuable feedback into the Project. CNL will continue engagement efforts to support growth in awareness and understanding of the Project.

The progression of the Project through the environmental assessment process is reflected in the evolution of engagement strategies. This report demonstrates that CNL was able to achieve its engagement objectives from 2020 through 2024 despite the challenges presented by the COVID-19 pandemic and Safety Stand Downs at the WL site.

Through direct conversations with the public, CNL strived to address issues and concerns that the public had about the Project. In-person meetings, print media, and public information sessions facilitated organic conversations between Project staff and the public. These traditional forms of engagement are recognized by CNL to facilitate active relationship-building.

Over the course of the past five years, CNL also had to adapt and evolve its engagement strategies to accommodate a virtual environment. As a result, CNL developed virtual platforms that continued to enable direct conversation (e.g., webinars, virtual open house). The open concept and broad reach of these virtual chat "rooms" (anyone with an internet connection can participate) enabled CNL to engage with a wider audience than before. The evidence of increased participation (attendance and submission of feedback) from the public signifies the popularity and success of these virtual engagement activities. CNL continues to use virtual platforms to provide a variety of flexible means of interacting and conversing with the public.

CNL has proactively addressed the key issues raised by the public, in many cases resolving those concerns. However there remains persistent issues including the perception of a potential negative effect of the WRDF on the Winnipeg River and other off-site effects. CNL will continue to share information with the public in accordance with CNL's Public Information Program (CNL 2024a), including follow-up monitoring being used to verify predictions made in the final EIS.

Continuing to provide current information will reinforce transparency and encourage further feedback which can assist CNL in understanding and incorporating community perspectives into Project planning, future communications, and the environmental assessment process. To reduce the stigma surrounding legacy nuclear waste and remediation, CNL will continue to proactively share information with the public about its waste management practices and projects.

CNL will measure its effectiveness by continuing to self-evaluate against its communication objectives. This is an ongoing process and validation continues regularly through analysis of multiple forms of feedback. Continued success means that CNL will endeavour to assess to what extent members of the public participate in and trust CNL's communication and engagement. This is essential to verify and create the path for CNL's communications and engagement strategy in support of the Project into the future.

6.0 ENVIRONMENTAL EFFECTS

6.1 Environmental Assessment Approach

The environmental assessment process is an important tool that is used to integrate environmental and social factors into project planning and decision-making. The goal of the environmental assessment process is:

- promote sustainable development;
- engage Indigenous peoples, the public and government agencies; and
- reduce the overall biophysical, economic, social, and health effects of the Project.

An environmental assessment:

- identifies potential adverse environmental effects;
- proposes measures to mitigate adverse environmental effects;
- predicts whether there will be significant adverse environmental effects after mitigation is implemented; and
- includes a follow-up monitoring program to verify the accuracy of the environmental assessment and the effectiveness of the mitigation.

This section describes the scope and approach of the environmental assessment implemented for the Canadian Nuclear Laboratories (CNL) In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project). The environmental assessment approach applied to disciplines (e.g., atmospheric environment, hydrogeology, terrestrial biodiversity, human health and socio-economic environment) includes the following main activities (where applicable), with further detail on each provided in Sections 6.2 to 6.9:

- Step 1 – **Define the scope of the assessment**, including input received from regulatory agencies and engagement activities:
  - Identify the valued components (VCs) for each discipline that the assessment will focus on, and the associated measurement indicators and assessment endpoints for VCs.
  - Define spatial (e.g., geographic extent of the Project activities and effects) and temporal (e.g., timelines for the Project phases and effects) boundaries and assessment cases used to evaluate effects.
- Step 2 – **Describe the existing conditions**, including the cumulative effects of previous and existing developments for each VC.
- Step 3 – **Evaluate Project interaction and mitigation** by conducting a pathway analysis to identify Project components or activities with a potential to create a residual effect and describe the mitigation developed for removing pathways or limiting effects. In the assessment for some disciplines, no primary pathways for effects are identified and the assessment proceeds directly to Step 7.
- Step 4 – **Conduct an analysis for each VC to predict residual effects from the Project**. Conduct an assessment for each VC to predict the Project-specific effect, as well as cumulative effects from the Project, other previous and existing projects and activities, and potential future projects that have been proposed but not yet approved (if applicable).

- Step 5 – **Evaluate and describe the level of certainty** that can be placed on predicted residual effects and the methods used to manage uncertainty.
- Step 6 – **Classify and determine the significance of predicted residual effects**, including Project-specific effects, and cumulative effects from the Project and potential future projects that have been proposed but not yet approved (if applicable).
- Step 7 – **Identify monitoring and follow-up programs** to confirm the effects predictions and address uncertainty.
- Step 8 – **Present a consolidated summary of conclusions** and outcomes of the assessment.

Generally, this approach is consistently applied across disciplines, with some modifications, where appropriate. For example, VCs are defined for all disciplines and there is consistency in the determination of spatial and temporal boundaries for the effects analysis. Similarly, the methods for identifying interactions that link the Project to potential effects on VCs are consistent.

In contrast, the methods for analyzing, classifying (e.g., magnitude and duration) and predicting environmental significance of residual effects can differ between discipline components. For example, human effects from a specific project are difficult to isolate from the ongoing processes of interdependent social, cultural and economic change. Evolving social trends, government policy and programming decisions, and individual choice all have effects that will be concurrent with potential effects of the Project. Biophysical disciplines (e.g., hydrogeology, aquatic environment and terrestrial environment) are influenced simultaneously by natural and human-related factors. For many biophysical disciplines, Project -specific effects can be quantified (e.g., incremental changes to ground and surface water quality, air quality, and fish and wildlife habitat). Because the socio-economic status of different communities, subpopulations and individuals may vary, a socio-economic effect may have positive aspects and negative aspects. An effect on a biophysical discipline is typically constrained to being negative or positive.

Each of the steps identified above are described in the following sections; details specific to each discipline are provided in their respective sections of the Environmental Impact Statement (EIS).

6.1.1 Scope of the Assessment

The decommissioning approach for the Whiteshell Laboratories (WL) site as described in the Comprehensive Study Report was to remove all facilities from the WL site with the exception of low-level waste trenches in the Waste Management Area, and existing contaminated river sediments, which may be managed through in situ disposal (ISD) (AECL 2001). CNL proposed in situ disposal of the WR-1 Building, which allows CNL to decommission WR-1 in a safe, cost-effective manner and in a shorter timeframe without interim storage of the waste. The Project activities are limited to ISD of the WR-1 Building (i.e., the Project). Other decommissioning activities for the WL site, documented in the Comprehensive Study Report (AECL 2001), are assumed to be unmodified. Removal of the east annex and service wing of the WR-1 Complex were assessed as part of the Comprehensive Study Report and are covered under CNL's existing decommissioning licence for the WL site (Licence No. NRTEDL-W5-8.00/2024). Activities required to prepare for ISD, such as isolation of the WR-1 Building and targeted remediation of hazardous materials, are also covered under CNL's existing decommissioning licence No. NRTEDL-W5-8.00/2024 for the WL site.

The scope of the environmental assessment incorporates advice provided in guidance documents relevant to environmental assessment practice (Section 1.6.1 Federal Review Process) and input received from regulatory

agencies, Indigenous peoples and the public (Section 4.0 Indigenous Engagement and Section 5.0 Public Engagement). As described in Section 1.6.2, the *Generic Guidelines for the Preparation of an Environmental Impact Statement* (Generic EIS Guidelines) developed by the Canadian Nuclear Safety Commission (CNSC 2021) provides an outline of the information to be included in the EIS, along with a high-level description of the methods to be implemented for the environmental assessment.

6.1.2 Traditional Knowledge and Indigenous Engagement Feedback

Traditional knowledge and Indigenous engagement feedback was integrated into the development of the Project, including the environmental assessment. Four Traditional Knowledge and Land Use Studies for the WL site have been completed. Traditional Knowledge and Land Use Studies were completed to further enable opportunities to capture and include Traditional knowledge into the environmental assessment.

Interests and concerns raised by Sagkeeng First Nation (Sagkeeng); the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement were also considered for inclusion in the environmental assessment. 'Interests and Concerns' tables were developed that summarize the key interests and concerns raised by each Indigenous community to date on the Project (Appendix 4.0-1 Summary of Engagement and Summary of Interests and Concerns Tables). The key interests and concerns raised by each Indigenous community have been assembled from a number of sources provided by the community to CNL. Sources of information include formally submitted comments to the CNSC as part of the environmental assessment process, comments and questions sent to CNL regarding the Project; and summaries of topics that have been discussed between CNL and each Indigenous community at meetings, site tours, workshops benchmarking trips, and the Traditional Knowledge and Land Use Studies.

Traditional Knowledge and Land Use Studies and interests and concerns identified through Indigenous engagement were considered in the environmental assessment, including identification of VCs, defining spatial boundaries, description of the environment, identification and evaluation of Project interactions, and inclusion in monitoring programs. Available sources of Traditional knowledge and feedback from Indigenous engagement were shared with the environmental assessment discipline leads for their review and consideration in their respective assessments. The interests and concerns received from Indigenous communities were summarized in each discipline section, indicating how/if there were changes made to the EIS as a result of the feedback received.

6.1.3 Valued Components

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). The selection of appropriate VCs allows the assessment to be focused on those aspects of the natural and human environment that are of greatest importance to society and species conservation.

The list of VCs selected for the Project considered a number of factors, including:

- presence, abundance and distribution within, or relevance to, the area associated with the Project;
- potential for interaction with the Project and potential vulnerability to the effects of the Project;
- species conservation status or concern (e.g., rarity, sensitivity and uniqueness);
- ecological and socio-economic value to communities, government agencies and the public;
- traditional, cultural and heritage importance to Indigenous peoples;

- legally recognized and afforded specific protection by law, policy, or regulation; and
- experience with similar projects.

Valued components were selected with due consideration of the results of baseline studies and subsequent consultation with regulators, with a focus on criteria used to evaluate the potential significance of residual effects. Since it is generally an impractical task to assess the potential effects of the Project on all the species of biota within a natural ecosystem, and specifically within the ecosystem around the WL site, representative organisms were chosen as VCs for the Project's environmental assessment. These organisms were selected because they are known to exist on the WL site and within the Winnipeg River, are representative of major taxonomic groups or exposure pathways, or have a special importance or value. As per *REGDOC-2.9.1, Environmental Principles, Assessments and Protection Measures*, VC selection focused on providing a "full accounting of effects on species with elevated conservation status and their habitat" (CNSC 2020).

The selection of VCs also considered information collected by CNL through public and Indigenous engagement activities with Sagkeeng, the Manitoba Métis Federation, Brokenhead Ojibway Nation, Black River First Nation, Hollow Water First Nation, and Wabaseemoong Independent Nations. As part of CNL's Public Information Program (CNL 2024), CNL held open house events where the public was given the opportunity to identify new VCs. Traditional Knowledge and Land Use Studies (Firelight Research and SFN 2018, BRFN, BON, and HWFN 2019, and SVS 2019) also identified VCs for consideration in the environmental assessment. The majority of the VCs identified through Indigenous and public engagement activities are already represented by the VCs selected for the environmental assessment. Moose was identified as an important species to Indigenous Nations and was subsequently added as a VC in the Ecological Health Assessment (Section 6.7 Human and Ecological Health). Where VCs identified by Indigenous Nations were not included in the assessment, rationale was provided within the discipline assessments.

CNL also carried out Indigenous engagement activities seeking to understand traditional rights-based activities such as traditional harvesting. CNL partnered with Sagkeeng and the Manitoba Métis Federation to carry out surveys on traditional harvesting and food intake. Traditional Knowledge and Land Use Studies identified that Indigenous peoples harvest wild rice and medicinal plants (i.e., weekay). As such, weekay was added to the diet of a Harvester in the Human Health Assessment; however, wild rice does not grow in close proximity to WR-1 and therefore was not added to the Human Health Assessment (see Section 6.7 Human and Ecological Health).

CNL has chosen traditional land and resource use as a VC, which considers how traditional land and resource uses such as trapping, hunting, fishing, gathering, and culture might be affected by the Project. The traditional land and resource use assessment also considers the different land use practices among the various Indigenous Nations / organizations. For example, Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Peoples has been updated and is segmented by Indigenous community to outline their unique ways of practicing and describing traditional uses.

The final list of VCs that are included in the environmental assessment for the Project, including rationale for their selection, is provided in Table 6.1.2-1.

Table 6.1.2-1: Valued Components Selected for the Environmental Assessment

Discipline	Valued Component	Rationale
Atmospheric Environment	Air Quality	Air quality is selected as a VC as it has been identified as an important aspect of the environment by the regulators. In addition, emissions from the Project activities have the potential to alter the existing air quality regime.
	Climate Change	This valued component, assessed through incremental changes in emissions of greenhouse gases, considers the potential of the Project to contribute to climate change.
Physical Environment	Geology*	Characteristics of geology, such as soil quality and quantity, bedrock and geomorphology, are important components that interact with other VCs (e.g., hydrology and surface water quality) and if changed by Project activities could affect terrestrial and aquatic biodiversity.
	Hydrogeology*	Characteristics of hydrogeology, such as groundwater quantity and quality are important components that interact with other VCs (e.g., hydrology and surface water quality) and if changed by Project activities could affect terrestrial and aquatic biodiversity and human health.
Surface Water Environment	Hydrology*	■ The Project may affect existing availability of the spatial and temporal distribution of water quantity for aquatic and terrestrial biodiversity, which can subsequently affect land and resource use. ■ Public and Indigenous peoples 'concerns regarding changes in water quantity in the Winnipeg River are an important consideration in understanding potential effects of the Project.
	Surface Water Quality*	There is potential for interaction with the Project; species of concern live in the river; river has ecological and socio-economic value to communities, government agencies and the public; and downstream areas have traditional, cultural and heritage importance to Indigenous peoples.
Aquatic Environment	Fish and fish habitat	The Winnipeg River supports a diverse fish community, including species at risk and species that support recreational fisheries. This VC captures the fish species identified by Indigenous Nations. The migration of radionuclides to the Winnipeg River via groundwater and site surface runoff may potentially affect fish and fish habitat.
Terrestrial Environment	Barn swallow	■ Barn swallow (*Hirundo rustica*) has been recently downgraded to Special Concern by COSEWIC, is currently federally listed as Threatened under SARA (as amended February 2022, with potential for downgrading to Special Concern based on COSEWIC re-assessment) and is listed under the MBCA. It currently has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ■ Because the WL site is federally owned, critical habitat of the species will be afforded protection under SARA, once the features of critical habitat have been defined in a federal recovery strategy and described in an order made by the competent minister (in this case, the Minister of Environment and Climate Change). A federal recovery strategy for barn swallow has not yet been prepared. ■ There is the potential for barn swallow to be indirectly and directly affected by the Project through sensory disturbance, habitat loss and mortality. Barn swallows have been observed nesting within the WL main campus.

Table 6.1.2-1: Valued Components Selected for the Environmental Assessment

Discipline	Valued Component	Rationale
Terrestrial Environment (continued)	Golden-winged warbler	■ Golden-winged warbler (*Vermivora chrysoptera*) is federally listed as Threatened under SARA (as amended February 2022) and listed under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under MBCA. ■ As the WL site is federally owned, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has been partially defined for this species in the federal recovery strategy. ■ There is the potential for golden-winged warbler to be indirectly affected by the Project through sensory disturbance (i.e., noise created by decommissioning activities). ■ Avian species with the potential to occur within the WL site (no confirmed observation records to-date), that represents a guild of edge habitat specialists.
	Bats ■ Little brown myotis ■ Northern myotis	■ Little brown myotis (*Myotis lucifugus*) and northern myotis (*M. septentrionalis*) have observation records within the WL main campus. Both bat species are federally listed as Endangered (as amended February 2022) and have legal individual protection provisions under the federal SARA. ■ As the WL site is federally owned, these bat species are afforded protection of critical habitat because they are listed as Endangered on Schedule 1 of SARA. ■ Critical habitat has only been “partially identified”, for one life history requirement and habitat type (overwintering habitat), as the largest threat to these species is associated with that habitat type. No active hibernacula have been identified in the WL site and the geological conditions make the presence of caves or exposed bedrock highly unlikely. ■ Other critical habitat types that are identified, but not yet legally defined and protected as “critical habitat”, include: roosting, foraging and swarming habitat. ■ Maternity roost habitat for little brown myotis and northern myotis is potentially present in the treed areas of the WL site surrounding the WL main campus. There is the potential for both species to be indirectly affected by the Project through sensory disturbance and related habitat avoidance (caused by noise associated with decommissioning activities and potential roost abandonment). ■ Maternity roost habitat for little brown myotis is also potentially present in the WR 1 Building, and little brown myotis have the potential to be indirectly and directly affected by the through disturbance, habitat loss and mortality. ■ Represents small mammal species recorded in the WL main campus that may utilize buildings for part of their life history (maternity roosting, diurnal roosting and evening roosting).

Table 6.1.2-1: Valued Components Selected for the Environmental Assessment

Discipline	Valued Component	Rationale
Terrestrial Environment (continued)	Snapping turtle	■ Snapping turtle (*Chelydra serpentina*) have been observed within the WL site. They are federally listed as Special Concern under SARA (as amended February 2022), but they do not have legal individual protection provisions under the Act, nor do they receive protection of critical habitat. ■ There is the potential for snapping turtle to be indirectly and directly affected by the Project through sensory disturbance (noise) and mortality (i.e., vehicle strike on roads). All snapping turtle observations to-date within the WL site have been on roads. ■ Represents herpetile species that are vulnerable to mortality on roadways.
Human Health	Public Health ■ Farms A and F ■ Harvesters ■ On-site farm	Potential exposure to airborne and waterborne radiological and non-radiological emissions: ■ Farms A and F includes year-round occupants, with livestock, located near the east bank of the Winnipeg River. Farm F being north-northeast of the WL site and Farm A being north of the WL site. ■ Harvesters represent Indigenous or traditional users of the area who may be exposed through harvesting of country foods. ■ In the long-term, during post-institutional control, there is the potential that a farm may inhabit the site.
	Worker Health	On-site workers not involved in performing closure activities may be potentially exposed to both radiological and non-radiological hazards (e.g., asbestos).
Ecological Health	Earthworm	Detritivore. Exposed to atmospheric release through soil.
	American Robin	Observed on-Site. Exposed to atmospheric release through the ingestion of soil invertebrates. A surrogate for insect eating birds including various species at risk under COSEWIC, ESEA or SARA.
	Loggerhead Shrike	Historically observed on-site. Exposure to atmospheric release through the ingestion of soil invertebrates, small mammals and birds. Identified as a Species at Risk under COSEWIC, ESEA or SARA. A surrogate for other predatory birds identified as Species at Risk under COSEWIC, ESEA or SARA.
	Barn Swallow	Observed on-site. Exposure to aquatic release through ingestion of aerial stages of benthic invertebrates. Identified as a Species at Risk under COSEWIC, ESEA or SARA. A surrogate for aquatic insect eating birds including various Species at Risk under COSEWIC, ESEA or SARA.
	Horned Grebe	Present in the area. Exposure to aquatic release through ingestion of water and fish. Identified as a Species at Risk under COSEWIC, ESEA or SARA. Food source for other VCs. Surrogate for other important species such as the common loon and red-necked grebe.
	Trumpeter Swan	Observed on-site. Exposure to aquatic release through ingestion of water and aquatic plants. Identified as a Species at Risk under COSEWIC, ESEA or SARA.
	Mallard	Representative of waterfowl. Exposure to aquatic release through ingestion of water, aquatic plants and benthic invertebrates. Food source for other VCs and human receptors.
	Grass and Shrubs	Present on-site. Exposure to atmospheric release through soil. Food source for other VCs.
	Berries	Present in the area. Exposure to atmospheric release through soil. Food source for VCs.
	Meadow Vole	Common in the area. Exposure to atmospheric release through ingestion of terrestrial plants. A food source for VCs.

Table 6.1.2-1: Valued Components Selected for the Environmental Assessment

Discipline	Valued Component	Rationale
Ecological Health (continued)	Common Shrew	Common in the area. Exposure to atmospheric release through ingestion of soil invertebrates. A food source for VCs.
	Snowshoe Hare	Common in the area. Exposure to atmospheric release through ingestion of terrestrial plants. A game species.
	White-tailed Deer	Common in the area. Over winters on-site. Exposure to atmospheric release through ingestion of terrestrial plants. A game species. An important game species for Traditional Communities.
	Moose	Present on-site to a limited extent. Identified as a game animal of interest for some Indigenous Nations. Exposure to aquatic release through ingestion of aquatic plants.
	Red Fox	Common in the area. Exposure to atmospheric release through the ingestion of small mammals and birds. A surrogate for the Grey Fox identified as a Species at Risk under COSEWIC, ESEA or SARA.
	Mink	Present in the area. Exposure to aquatic release through ingestion of water, waterfowl and fish.
	Little Brown Myotis	Bats observed roosting in forested areas of the WL site. Exposure to atmospheric release through ingestion of soil invertebrates. Exposure to aquatic release through ingestion of aerial stages of benthic invertebrates. Identified as a Species at Risk under COSEWIC, ESEA or SARA. A surrogate for other bats identified as Species at Risk under COSEWIC, ESEA or SARA.
	Common Shiner	Present in the Winnipeg River. Exposure to aquatic release through surface water and sediment. Identified as a Species at Risk under COSEWIC, ESEA or SARA. Small-bodied forage fish. A food source for other VCs.
	Lake Sturgeon	Present in the Winnipeg River. Exposure to aquatic release through surface water and sediment. Identified as a Species at Risk under COSEWIC, ESEA or SARA.
	Walleye	Present in the Winnipeg River. Exposure to aquatic release through surface water. A sport fish. A surrogate for other pelagic fish in the Winnipeg River such as Northern Pike and Mooneye.
	Aquatic Plants	Present in the Winnipeg River. Exposure to aquatic release through surface water. Food source for other VCs.
	Benthic Invertebrates	Present in the Winnipeg River. Exposure to aquatic release through surface water and sediment. Food source for other VCs.

Table 6.1.2-1: Valued Components Selected for the Environmental Assessment

Discipline	Valued Component	Rationale
Traditional Land and Resource Use	Cultural and Archaeological Sites	Cultural and archaeological sites are those sites protected under legislation and administered by the Manitoba Heritage Resource Branch. Cultural and archaeological sites are important for revealing past and present land use, cultural identity and relationships with other cultures and the social and biophysical environments. Potential alteration or loss of cultural and archaeological sites can have an effect on Indigenous people. Consideration of physical and cultural heritage is a requirement under Section 5 of the *Canadian Environmental Assessment Act, 2012*. The cultural and archaeological sites VC is of known importance to Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations as identified through Traditional Knowledge and Land Use Studies, engagement with CNL, and verification discussions. Consideration of physical and cultural heritage is a requirement under Section 5 of the *Canadian Environmental Assessment Act, 2012*.
	Traditional Land and Resource Use by Indigenous Peoples	Traditional Land and Resource Use is defined as the land and resource by Indigenous Peoples for traditional purposes, including hunting, fishing, trapping and gathering. Traditional land and resource use by Indigenous people is important for maintaining meaningful connections with cultural identity and community history, for food security, economic self-sufficiency, and the maintenance of individual and population health. Traditional land and resource use can also promote intergenerational connections within communities as knowledge is passed down from elders to community members, including youth. Potential changes to traditional land and resource use by Indigenous people can have an adverse effect on Indigenous people by preventing them from fully expressing their cultural identity and Treaty rights. The traditional land and resource use by Indigenous people VC is representative of the values identified by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations, as identified through Traditional Knowledge and Land Use Studies, engagement with CNL, and verification discussions. Consideration of current land and resources use for traditional purposes is a requirement under Section 5 of *Canadian Environmental Assessment Act, 2012*.
	Winnipeg River	The public and Indigenous peoples identified the importance of the Winnipeg River. A number of communities depend on the river for drinking water, recreation, cultural vitality, inter-generational knowledge transfer and food security. The river flows into the Lake Winnipeg, one of the largest lakes in the world. The eastern shore of the lake is included in a United Nations World Heritage Site proposal (Manitoba Wildlands 2008). This watershed is valued for many reasons by many people and groups. Indigenous peoples identified the Winnipeg River as a critical resource for traditional and rights-based activities, including harvesting of fish, waterfowl, plants and other animals. The river was identified as a source of drinking water and as a transportation corridor. Further, Indigenous peoples recognize the sacredness of water, the interconnectedness of all life and the importance of protecting water. The Winnipeg River VC is of known importance to Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations as identified through Traditional Knowledge and Land Use Studies, engagement with CNL, and verification discussions.

Table 6.1.2-1: Valued Components Selected for the Environmental Assessment

Discipline	Valued Component	Rationale
Other Land and Resource Use	Land Tenure	Land tenure considers the uses, allocations and ownership of lands in proximity to the Project, including the Whiteshell Laboratories (WL) site itself. The change in decommissioning for the Whiteshell Reactor 1 (WR-1) Building will decrease the proportion of the WL site available for future land tenure by private or public entities. The use of in situ disposal may also change the perceived suitability of land use surrounding the WL site. The land tenure VC is of known importance to Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations as identified through Traditional Knowledge and Land Use Studies, engagement with CNL, and verification discussions.
	Outdoor Recreation and Tourism	The WL site is located in an area with several provincial parks, including the Whiteshell Provincial Park, that offer a variety of outdoor recreation opportunities while also being located near towns and Rural Municipalities (RMs) that rely on cottagers and tourism to contribute to their local economies.
	Winnipeg River	The public identified the importance of the Winnipeg River. A number of communities depend on the river for drinking water, recreation and food. The river flows into the Lake Winnipeg, one of the largest lakes in the world. The eastern shore of the lake is included in a United Nations World Heritage Site proposal (Manitoba Wildlands 2008). This watershed is valued for many reasons by many people and groups.
Socio-economic Environment	Employment and Income	Local communities recognize that the decommissioning of the WL site will result in changes to local employment and income opportunities. There are concerns that the change in approach to decommissioning the WR-1 Building may result in challenges to attracting new businesses to the WL site and creating future employment opportunities. The Sagkeeng First Nation; the Red River Métis; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations also identified employment as important through engagement and verification discussions.
	Business Opportunities	The proposed changes in decommissioning activities for the WR-1 Building create a different set of opportunities for contractors than the previous decommissioning plan. The Sagkeeng First Nation; the Red River Métis; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations also identified business opportunities as important through engagement and verification discussions.
	Government Finances	The LGD of Pinawa relies on a grant-in-lieu of taxes from AECL associated with the presence and operation of the WL site. The proposed changes in decommissioning activities may accelerate changes to the grant-in-lieu of taxes, which would change Pinawa's municipal revenue streams.
	Community Infrastructure and Services	A wide range of essential human needs are fulfilled by infrastructure and services in communities. Projects can place additional demands on them and their ability to meet community needs. The Project may also affect how community infrastructure and services are funded in Pinawa as AECL pays the LGD a grant-in-lieu of taxes, which is used to fund infrastructure and services, including the School District of Whiteshell.

Table 6.1.2-1: Valued Components Selected for the Environmental Assessment

Discipline	Valued Component	Rationale
Socio-economic Environment (continued)	Community Well-being	Community well-being is affected by a variety of factors, including consideration of economic well-being, physical well-being, social well-being and the environment. The change in approach to decommissioning the WR-1 Building may restrict access to more of the WL site than previously anticipated and limit its subsequent use for other activities. Indigenous Nations have expressed concern that the Project may limit their participation in land and resource use activities, which would affect their well-being through the ability to express their culture or exercise Aboriginal and Treaty rights. Communities have also expressed concern that attracting a new business/industry to the WL site is important for their continued viability, both in terms of employment/income and in terms of their long-term sustainability.
	Public Safety	Public Safety has been a concern for the overall decommissioning of the WL site, which included medium-term storage of radioactive waste and eventual transport of radiological waste to permanent disposal facilities. The Project will reduce the amount of radiological waste being transported to disposal facilities, which will reduce one public safety hazard; however, the shift to in situ disposal will create a new public concern that was also identified by Indigenous peoples as some waste will be stored on the WL site permanently. Public safety related to the transportation of radiological waste off-site is considered in this assessment; while concern related to public exposure from in situ disposal is evaluated in Section 6.7 Human and Ecological Health. Psychosocial impacts are not considered a VC; however, due to the significant importance of this concern, and in the spirit of understanding and cooperation, the EIS discusses the psychosocial impacts of perceptions of the project in Section 4, as well as mitigations CNL has and will put in place to address concerns related to fear and stigma associated with the site.

Note: Those valued components denoted with an "*" indicate a valued component that does not have an assessment endpoint.

Farm A = Easting (m): 709547, Northing (m): 5565803; Farm F = Easting (m): 708772, Northing (m): 5564710

VC = valued component; *SARA* = *Species at Risk Act*; COSEWIC = Committee on the Status of Endangered Wildlife in Canada; ESEA = *Endangered Species and Ecosystems Act*; ISD = In Situ Disposal; MBCA = *Migratory Birds Convention Act*; *CEAA* = *Canadian Environmental Assessment Act*; AECL = Atomic Energy of Canada Limited; LGD = Local Government District.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future human generations (i.e., incorporates sustainability). For example, self-sustaining and ecologically effective fish and wildlife populations, continued land use opportunities and protection of archaeological resources may be assessment endpoints for fish and wildlife, land use and tenure, and archaeological resources, respectively.

Assessment endpoints are typically not quantifiable and require the identification of one or more measurement indicators that can be directly linked to the assessment endpoint. Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on assessment endpoints. Measurement indicators may be quantitative (e.g., concentrations of metals and radioactivity in surface water) or qualitative (e.g., movement and behaviour of wildlife from disturbance to habitat). Measurement indicators also provide the primary factors for discussing the uncertainty of effects on VCs and, subsequently, are key variables for study in potential follow-up and monitoring programs.

The significance of effects from the Project on VCs is evaluated by linking **changes** in measurement indicators to **effects** on the assessment endpoints. For example, changes in habitat quantity and quality (measurement indicators) are used to assess the significance of residual effects from the Project on the ability of a wildlife population to remain self-sustaining and ecologically effective (an assessment endpoint).

All VCs have measurement indicators, but not every VC has an assessment endpoint. For example, VCs such as geology, hydrogeology and surface water are considered as measurement indicators for other VCs, and do not have an assessment endpoint (i.e., may be referred to as pathway or intermediate VCs). Intermediate VCs are considered to be important aspects of the natural and human environment, and are evaluated in the EIS to determine how they may influence assessment endpoints. The evaluation includes an analysis of changes in measurement indicators for the intermediate VCs. The results of the analysis are provided to other disciplines (e.g., aquatic and terrestrial environment and human health) for inclusion in their residual effects analysis.

Valued components with no assessment endpoint are still analyzed for Project-specific and cumulative (if applicable) changes in measurement indicators. The changes are characterized in terms of magnitude, duration and geographic extent, but are not classified using rankings for effects criteria. For example, the magnitude of change in hydrological flows may be described as the relative change from baseline; however, this change would not be classified (or ranked) as low, moderate or high. This ranking would be reserved for the classification of residual effects and determination of significance for those VCs with assessment endpoints.

In summary, the same systematic and rigorous approach is applied to VCs with and without assessment endpoints, except that effects on VCs without explicit assessment endpoints are not classified using effects criteria nor evaluated for significance. The environmental assessment approach for VCs with assessment endpoints is illustrated on Figure 6.1.2-1, and the approach for VCs with no assessment endpoints is illustrated on Figure 6.1.2-2. The assessment approach is described further in Section 6.1.3 Assessment Boundaries to Section 6.1.9 Monitoring and Follow-up. Each of the steps identified in Figure 6.1.2-1 and Figure 6.1.2-2 are described in the subsequent sections.

6.1.4 Assessment Boundaries

Assessment boundaries define the geographic and temporal scope or limits of the analysis of effects from the Project on the environment. These boundaries encompass the areas within (spatial boundaries) and times during (temporal boundaries) which the Project, and in combination with previous, existing and reasonably foreseeable developments, is expected to interact with the VCs.

6.1.4.1 Spatial Boundaries

Defining the geographic extent of the study areas for each discipline is a key element of the environmental assessment process. Spatial boundaries are selected to be appropriate for each discipline (i.e., hydrogeology, aquatic environment, terrestrial environment and socio-economics) and associated VCs, using the following criteria:

- physical extent of the Project;
- physical extent of Project-related effects; and
- physical extent of key environmental systems (e.g., watershed boundary of potentially affected streams).

Individuals, populations and communities function within the environment at different spatial and temporal scales (Wiens 1989). In addition, the response of physical, chemical and biological processes to changes in the environment can occur across several spatial scales at the same time (Holling 1992; Levin 1992). The boundaries for the study areas are designed to quantify baseline conditions at a scale that is large enough to assess to maximum predicted geographic extent of direct and indirect effects from the Project on VCs and the Project in combination with previous, existing, and reasonably foreseeable developments. This environmental assessment has adopted a multi-scale approach for describing baseline conditions (existing environment) and predicting effects from the Project on VCs because the responses of physical, biological, cultural and economic properties to natural and human-induced disturbance will be unique and will occur across different scales.

As indicated in the CNSC Generic EIS Guidelines, the following spatial scales will be considered by each discipline.

- **Site Study Area (SSA):** The Site Study Area is the Project footprint (i.e., the footprint of the WR-1 Building, where Project activities would be undertaken including the Project's proposed facilities and infrastructure).
- **Local Study Area (LSA):** The Local Study Area is defined as the area existing outside the SSA, where measurable changes to the environment resulting from the proposed activities may be anticipated. The LSA varies depending on the environmental component assessed and each are described in more detail in their respective sections.
- **Regional Study Area (RSA):** The Regional Study Area is defined as the area within which the potential effects of the Project may interact with the effects of other projects. The RSA varies depending on the environmental component assessed and each are described in more detail in their respective sections.

The spatial boundaries for the study areas considered by each discipline and the rationale for their selection are identified in Section 6.2 Atmospheric Environment through Section 6.9 Socio-economic Environment under the "Assessment Boundaries" heading. The study areas are illustrated on maps of appropriate scale, which are also included in Section 6.2 Atmospheric Environment through Section 6.9 Socio-economic Environment

under the "Assessment Boundaries" heading. A summary of the spatial boundaries for this environmental assessment is provided in Table 6.1.3-1.

Table 6.1.3-1: Spatial Boundaries Selected for the Effects Assessment

Environmental Component	SSA	LSA	RSA
Atmospheric Environment	WR-1 Building (0.07 ha)	Approximately an 8 km by 8 km square that includes the SSA and the WL site (approximately 6,400 ha).	Approximately a 12 km by 12 km square surrounding the LSA (approximately 14,400 ha).
Geological and Hydrogeological Environment	WR-1 Building (0.07 ha)	Western boundary is approximately 800 m west of the WR-1 Building. Northern boundary is approximately 450 m north of the WR-1 Building. Southern boundary is approximately 1,400 m south of the WR-1 Building. Eastern boundary is approximately 700 m east of the WR-1 Building and approximately 500 m east of the WL main campus (approximately 260 ha).	WL site (approximately 4,375 ha).
Surface Water Environment and Aquatic Environment	WR-1 Building (0.07 ha)	Fenced area of the WL main campus (approximately 29 ha)	To the north, east and south the RSA is delineated by the boundaries of the WL site. To the west, the RSA follows the west bank of the Winnipeg River adjacent to WL site. The RSA also includes the first farm located downstream on the east bank of the Winnipeg River (approximately 4,121 ha).
Terrestrial Environment	WR-1 Building (0.07 ha)	Fenced area of the WL main campus (approximately 29 ha)	The portion of the WL site on the east side of the Winnipeg River (approximately 3,710 ha).
Human Health and Ecological Health	WR-1 Building (0.07 ha)	Southern boundary extends from the west shore of the Winnipeg River to the east fence on the property line about 400 m north of Provincial Highway 211. The eastern boundary of the LSA follows the fence on the property line to the north property line. The northern boundary follows the north fence on the property line about 1.6 km and then turns north for about 400 m before turning west and extending to the west side of the Winnipeg River. Western boundary follows the west bank of the Winnipeg River for about 1.5 km and then turns west for 370 m, north for 1.4 km and then turns east for 630 m to the west side of the Winnipeg River (approximately 4,174 ha).	Approximately a 12 km by 12 km square surrounding the LSA (14,400 ha).

Table 6.1.3-1: Spatial Boundaries Selected for the Effects Assessment

Environmental Component	SSA	LSA	RSA
Land and Resource Use	WR-1 Building (0.07 ha)	To incorporate input from Indigenous Nations, the LSA was revised to capture Traditional land and resource use within proximity of the WL site and extends approximately 5 km beyond the WL site boundaries (approximately 11,917 ha)	The south boundary of the RSA extends from the west shore of the Winnipeg River to the east fence on the property line about 400 m north of Provincial Highway 211. The eastern boundary of the RSA follows the fence on the property line to the north property line. The north boundary follows the north fence on the property line about 1.6 km and then turns north for about 400 m before turning west and extending to the west side of the Winnipeg River. To incorporate input from Indigenous Nations, the RSA was revised to include the Winnipeg River from the WL site downstream to Lake Winnipeg with a 100 m buffer on either side of the river to capture Traditional land and resource use activities on either shore of the river. (approximately 14,182 ha).
Socio-economic Environment	—	Contains the Local Government Districts of Pinawa, the Town of Lac du Bonnet and the Town of Beausejour and the Rural Municipalities of Whitemouth, Lac du Bonnet and Brokenhead (approximately 278,031 ha).	Contains the Southeast Region of Manitoba and the City of Winnipeg (approximately 2,271,005 ha).

SSA = Site Study Area; LSA = Local Study Area; RSA = Regional Study Area

6.1.4.2 Temporal Boundaries

The temporal boundary of the assessment includes effects observed under existing conditions, the timeframe during which Project activities are actively occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years).

Baseline studies associated with each VC identify temporal variation (e.g., annual or seasonal changes in water flow or habitat use, or trends over time in populations and employment) and other biophysical constraints relevant

to the assessment of the Project. The final selection of temporal boundaries is discipline-specific and include consideration of the phases described above. For some VCs, residual effects are assessed for all phases of the Project, but not necessarily for each specific phase. For example, effects on wildlife begin during the closure phase with the removal and alteration of habitat (i.e., results in direct and indirect changes) and continue through the post-closure phase and for a period after the post-closure phase until reversed, unless determined to be irreversible or permanent. Therefore, effects on wildlife are analyzed and predicted from closure through to post-closure, which generates the maximum potential spatial and temporal extent of effects and provides confident and ecologically relevant effects predictions.

Alternately, for some VCs, the assessment was completed for those phases of the Project where predicted effects would be expected to peak (e.g., most air quality effects from emissions occur during closure) or at several key points in time. These points in time may include several periods within or among Project phases. Examples include comparing the maximum extent of disturbance to vegetation during closure to the amount that will be reclaimed, or evaluating surface water quality predictions at specific times that represent key milestones throughout the life of the Project. For other VCs, the assessment of effects may continue beyond the post-closure phase.

Similarly, the temporal boundaries identified for cumulative effects assessments are specific to the VCs being assessed. Temporal boundaries include the duration of residual effects from previous and existing developments that overlap with residual effects of the Project and the period during which the residual effects from reasonably foreseeable developments will overlap with residual effects from the Project. The temporal boundaries considered by each discipline are identified in Section 6.2 Atmospheric Environment through Section 6.9 Socio-economic Environment under the “Assessment Boundaries” heading.

The environmental assessment was designed to evaluate the short- and longer-term changes from the Project and associated effects on the biophysical and human environments. Projects are defined by phases, which typically includes construction, operations and reclamation and closure; however, given the nature of this Project, only the closure (which includes decommissioning and reclamation) and post-closure phases are relevant. These phases are described below.

Climate change may result in shifts in the frequency and/or intensity of the extreme weather events and forest fires. The effects of climate change are typically measured over longer periods, with the potential for climate change effects increasing as the period over which they are measured increases. The relatively short timeline for the closure phase (i.e., 2026 to 2031) means that there is smaller potential for interaction with climate change when compared to the more distant timeline of the Post-closure phase. The Closure phase of the Project is considered to be resilient to changing climatic conditions since it occurs during time frames too short to have a high climate change risk outside of those experienced by the large range of seasonal weather conditions. An effect assessment of climate change was completed for the Project and is included in Section 10 Effects of the Environment on the Project.

6.1.4.2.1 Closure Phase

Preparation and implementation of ISD, which includes preparation for ISD, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031.

6.1.4.2.2 Post-closure Phase

The post-closure phase has two discrete periods: institutional control and post-institutional control. The institutional control period is assumed to occur from 2031 to 2131 (i.e., 100 years). The post-institutional control period is assumed to occur after year 2131 and continues indefinitely. However, it is recognized that the institutional control period will continue until the CNSC, or the appropriate regulatory authority at that time, agrees it is no longer needed.

Institutional Control Period

The institutional control period spans a minimum of 100 years (i.e., 2031 to 2131), during which long-term environmental monitoring and maintenance activities will continue to demonstrate WRDF performance is in compliance with the safety case assumptions and performance modelling.

The 100-year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. The WR-1 Groundwater Flow and Solute Transport Modelling report (Golder 2021a) indicates that in the event of a failure of the ISD primary barrier, contaminants would be detectable (albeit at very low levels) within the first 100 years. The results of the 100-year active monitoring period will support the discussions to reduce, or even stop active monitoring in the future, once sufficient data are available to provide further confidence that the ISD system is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon.

Post-institutional Control Period

The post-institutional control period occurs after year 2131 and continues indefinitely. It is assumed that institutional control eventually ends, and detailed knowledge of the facility is lost. There is uncertainty around when such a phase may actually begin. But for the purposes of the assessment, it is assumed to occur 100 years after closure of the facility (i.e., at the end of the institutional control period). The post-institutional control period will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years as described in Section 5.3 (Timeframes) of the Decommissioning Safety Assessment Report (Golder 2021b). This time period encompasses the phase in which peak effects are anticipated. None of the above precludes the option of extending the institutional control period beyond 100 years if the institutions in question have the resources and desire to do so. However, this EIS conservatively assumed that institutional control ends beyond 100 years from closure to assess the potential bounding effects of the ISD system. However, some passive controls will still be in place including the limited footprint, the WRDF composition being relatively impervious and made of material of no economic value, and any remaining land use restriction acting to reduce the likelihood of a human intrusion event.

6.1.4.3 Assessment Cases

This section provides a brief description the assessment cases considered in the EIS. Multiple assessment cases are considered in an EIS to characterize existing conditions, understand the potential effects of a project and to understand how these potential effects may interact with other future projects. The assessment cases are -discipline specific and include the following.

- **Base Case –** This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, and residential and recreational development. Current effects from the

existing WL site facilities and operations, for example, are considered part of the Base Case. In addition, existing conditions of areas not affected by the WL site are also considered as part of the Base Case. For example, Seven Sisters Generating Station is approximately 7.5 km upstream of the WL site and McArthur Generating Station is approximately 26 km downstream. Effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case.

- **Application Case –** This scenario represents predictions of the effects of the Base Case combined with the effects that may result from the Project.
- **Reasonably Foreseeable Development (RFD) Case –** this scenario represents predictions of the cumulative effects of the Application Case, which includes the Base Case, plus projects that are currently under application review or that have officially entered a regulatory application process and are therefore, considered reasonably foreseeable. Effects from the future decommissioning and reclamation activities to be completed at the WL site are also considered as part of the RFD Case. The projects considered as RFDs are described in Table 6.1.3-2.

Table 6.1.3-2: Reasonably Foreseeable Developments Considered for the Effects Assessment

Type of Project	Location	Description	Timeframe	Disciplines in which the RFD was Considered
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes ISD of the low-level waste trenches).	2016 to 2034	■ Section 6.2 Atmospheric Environment ■ Section 6.3.2 Hydrogeology ■ Section 6.4 Surface Water Environment ■ Section 6.5 Aquatic Environment ■ Section 6.7 Human and Ecological Health* ■ Section 6.8 Land and Resource Use
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	■ Section 6.2 Atmospheric Environment ■ Section 6.3.2 Hydrogeology ■ Section 6.4 Surface Water Environment ■ Section 6.5 Aquatic Environment ■ Section 6.7 Human and Ecological Health* ■ Section 6.8 Land and Resource Use

Note: * effects are evaluated as part of the Application Case.

6.1.5 Description of the Environment

To provide a basis for evaluating potential changes of the Project, each discipline assessment includes a description of the baseline conditions in the “Description of the Environment” subsection. The baseline studies are completed to develop an understanding of the existing physical, biological and social conditions that may be

influenced by the Project and are used to prepare a Base Case. The Base Case includes the cumulative effects from all previous and existing developments in the study area of a VC. Existing environment or baseline conditions represent the historical and current environmental selection pressures that have shaped the observed patterns in VCs. Environmental selection pressures include natural (e.g., weather, predation and competition) and human-related factors (e.g., agricultural activities, forestry, traditional and sport hunting and fishing).

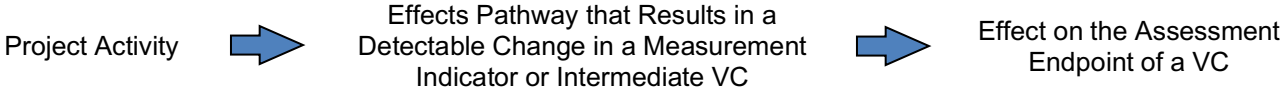
Existing conditions are described recognizing that baseline conditions typically fluctuate within a range of variation through time and space depending on which selection pressures are currently driving changes to the VC and system. The Base Case thus describes the existing environment without the implementation of the Project and is used to provide an understanding of the physical, biological and social conditions that may be influenced by the Project. Information sources included published and unpublished material, consultation with appropriate government staff (e.g., Manitoba Sustainable Development [now Manitoba Environment, Climate and Parks]) and baseline and other monitoring data collected by CNL. The Traditional Knowledge and Land Use Studies completed further enabled opportunities to capture and include Traditional Knowledge into the description of the environment. These studies are intended to document traditional use around the Project, local, and regional study areas. The 'Description of the Environment' section in the discipline assessments has been updated to include a description of how traditional land and resource use activities have changed in response to past historical events and external pressures, where available.

This information is reviewed and analyzed to determine the presence of data gaps. Depending on the degree of the risk that the data gap carries, baseline field studies may be completed to fill the identified gaps. Alternatively, uncertainties in data may be addressed through the development of monitoring programs. Relevant existing data from previous studies and the results of the recent baseline field programs are presented in the discipline-specific sections. Data that are directly relevant to the assessment of Project effects are summarized in the sub-sections in Section 6.2 Atmospheric Environment through Section 6.9 Socio-economic Environment.

6.1.6 Project Interactions and Mitigation

Interactions (linkages) between Project components or activities and the corresponding potential changes to measurement indicators are identified by a pathway analysis that is then used to focus the residual effects assessment for the VCs. The first part of the analysis is to identify all pathways by which a Project component or activity could cause a potential effect. Each pathway is initially considered to have a linkage to potential effects on VCs. Traditional Knowledge and Indigenous engagement feedback also identified linkages between components of the environment that support traditional way of life, traditional land and resource use, and harvesting rights. These linkages provide a more holistic understanding of the environment and relationships between different components, including their continued practice of culture and livelihoods.

The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. For an effect to occur there has to be a Project component or activity that results in a detectable change to the measurement indicators and a correspondent effect on a VC.



The development of the potential pathways is followed by a screening to determine if mitigation is required. If needed, environmental design features and mitigation that can be incorporated into the Project to remove a pathway (i.e., eliminate the potential effect) or limit (i.e., mitigate) adverse effects on VCs, will be developed. Environmental design features and mitigation include engineering design elements, environmental best practices, management policies and procedures and spill response and emergency contingency plans. The description of environmental design features and mitigation will be specific to each discipline and the associated VCs. Any uncertainty associated with the effectiveness of proposed mitigation actions will be noted.

The purpose of the pathway analysis is to focus the residual effects analysis on linkages that require a more comprehensive assessment of effects on VCs, or those pathways that are likely to result in residual effects on a VC. Pathways are determined to have no linkage, a secondary (minor) linkage, or a primary linkage using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features. Feedback from Indigenous engagement is also considered in the evaluation of the pathways. Each potential pathway is evaluated and described as follows:

- **no linkage –** analysis of the potential pathway reveals that there is no valid linkage between the Project and the VC, or the pathway is removed by environmental design features or mitigation so that the Project would not be expected to result in a measurable environmental change and would, therefore, have no residual effect on a VC relative to existing conditions or guideline values;
- **secondary –** pathway could result in a measurable minor environmental change, but would have a negligible residual effect on a VC relative to existing conditions or guideline values, and is not expected to contribute to effects of other existing, approved, or reasonably foreseeable developments to cause a significant effect; or
- **primary –** pathway is likely to result in an environmental change that could contribute to residual effects on a VC relative to existing conditions.

Pathways with no linkage to a VC, either because there was no linkage initially or because environmental design features or mitigation will remove the pathway, are not advanced for further assessment. Pathways that are assessed to be secondary and demonstrated to have a negligible effect on a VC through simple qualitative or semi-quantitative evaluation of the pathway are also not advanced for further assessment. However, a pathway may be evaluated as a secondary pathway due to their importance to Indigenous people even if there are no direct or indirect effects on a VC. In summary, pathways determined to have no linkage to a VC or those that are considered secondary are not expected to result in environmentally significant effects on the assessment endpoint of VCs, individually or cumulatively. Primary pathways require further effects analysis and classification to determine the environmental significance of the Project effects on VCs. A matrix table is included in Appendix 6.1-1 Project-Environment Interactions Matrix summarizing Project interactions for each VC that are determined to be no linkage, secondary, or primary, after consideration of environmental design features and mitigation.

6.1.7 Residual Effects Analysis

A residual adverse environmental effect is an effect that remains, or is predicted to remain, after mitigation has been implemented (The Agency 2015). Therefore, they are the expected consequences of the Project for the selected VCs. The residual effects analysis is based on the Project interactions that are determined to be primary in the pathway analysis. For primary pathways that require a residual effects analysis, assessment cases are applied (see Section 6.1.3.3 Assessment Cases) to estimate the incremental and cumulative effects from the Project. The residual effects analysis is completed for the Application Case and the RFD Case.

6.1.7.1 Application Case

This Application Case scenario represents predictions of the cumulative effects of the existing environment combined with the effects that may result from the Project. The residual effects analysis for the Application Case is based on residual Project -specific (incremental) effects that are evaluated to be primary in the pathway analysis. The environmental design features and mitigation identified in Section 6.1.5 Project Interactions and Mitigation will be described in this section. Thus, the residual effects analysis will consider all primary pathways that will likely result in detectable changes in measurement indicators and subsequent residual effects on VCs, after implementing environmental design features and mitigation.

The Application Case represents predictions of the cumulative effects of the developments in the Base Case combined with the effects from the Project. Where relevant, this case was used to identify the incremental changes from the Project that are predicted to occur between the Base Case and the Application Case. The residual effects analysis considers the proposed environmental design features and mitigation identified in Section 6.1.5 Project Interactions and Mitigation.

The temporal boundary of the Application Case begins with the anticipated first year of the Project and continues until the predicted effects are reversed. For several VCs, the temporal extent of some effects likely will be greater than the lifespan of the Project because the effects will not be reversible until beyond closure. For other VCs, the effects may be determined to be irreversible within the temporal boundary of the assessment if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years).

Results of the effects analyses for the Application Case are used to describe the magnitude, duration and geographic extent of the predicted changes to measurement indicators and residual effects on VC assessment endpoints. Expected changes are expressed quantitatively, wherever possible. For example, the magnitude of the effect may be expressed in absolute or percentage values above or below baseline conditions or a guideline value. The duration, including reversibility, of the effect typically is described in years relative to the phases of development of the Project and the spatial extent of effects is typically expressed in area or distance from the Project. In addition, the direction, frequency, reversibility, probability and context of effects are described, where applicable. Rankings, such as -short-term duration or moderate magnitude are not used in the effects analysis. These rankings are applied to the classification of effects and determination of significance, where definitions of these rankings are provided.

Effects on social, economic and cultural properties include positive and negative changes to employment, training and education, family income, traditional land use, family and community cohesion, and -long-term social, cultural and economic sustainability. Some of these measurement indicators can be analyzed quantitatively (e.g., number of jobs created and estimated income levels). Other indicators such as community cohesion and traditional land use are more difficult to quantify and involve information from public engagement, literature, examples from similar projects under similar conditions and scientific knowledge and experience. The effects analysis considers the interactions among the unique and common attributes, challenges and opportunities related to social, cultural and economic measurement indicators.

6.1.7.2 Reasonably Foreseeable Development Case

The RFD Case scenario includes the Application Case plus additional RFDs in the region that have not yet been approved. Developments and activities that are currently under application review, or that have officially entered a regulatory application process were considered reasonably foreseeable. This section describes the general

methods used to predict whether the cumulative effects from the Project, in combination with existing, previous and RFDs and activities are likely to result in environmental, social, economic, heritage and health effects, taking into account the mitigation actions proposed in the EIS. The CEAA 2012 requires that each environmental assessment of a designated project take into account any cumulative environmental effects that are likely to result from the designated project in combination with the environmental effects of other physical activities that have been or will be carried out (The Agency 2018). Cumulative effects are those that are likely from a reviewable project, combined with the effects from prior development, existing activities and reasonably foreseeable future developments that are sufficiently certain to proceed.

The RFD Case includes the predicted duration of residual effects from the Project, plus other previous, existing and future developments and activities. Thus, the minimum temporal boundary for the Application Case and the RFD Case is the expected lifespan of the Project, which like the Base Case, includes a range of conditions over time. The difference between the Application Case and the RFD Case is that the Application Case considers the incremental effects from the Project in isolation of potential future land use activities.

The VCs requiring an analysis under the RFD Case are determined by understanding whether the residual effects from the Project and one or more additional developments (or activities) overlap or interact with the temporal or spatial distribution of the VC. Where potential cumulative effects from the RFD Case are identified for these VCs, these effects will be assessed using the same approach used for the Project-specific effects analysis (Section 6.1.6.1 Application Case).

The analysis for the RFD Case is quantitative, where possible, and qualitative, where necessary. The analysis is quantitative for those future projects that could be assigned a location, a physical footprint (i.e., known or hypothetical) on the landscape and information about project emissions (e.g., to air and water). The analysis is qualitative for developments that did not have this information. For all RFDs, the EIS uses the most current information available for the location, size and type of activity associated with a project.

6.1.8 Prediction Confidence and Uncertainty

The purpose of an environmental assessment is to predict the future conditions of the biophysical and human environments as a result of a proposed project or development using conservative assumptions when dealing with uncertainties. Because the biophysical and human environment changes naturally and continually through time and across space, most assessments of effects embody some degree of uncertainty. In addition, Anishinaabe Traditional Knowledge holders indicate that when predicting hundreds or thousands of years in the future, it is difficult to be confident in scientific predictions.

The purpose of the uncertainty sections of the assessment is to identify the key sources of uncertainty and to discuss how uncertainty is addressed to increase the level of confidence that effects will not be worse than predicted. Confidence in effects analyses can be related to many elements, including the following:

- adequacy of the baseline data for providing an understanding of the existing conditions and future changes unrelated to the Project (e.g., rate and extent of future developments, climate change or catastrophic events);
- model inputs (e.g., changes in chemical concentration in water over time and space);
- understanding of Project related effects on complex ecosystems that contain interactions across different scales of time and space (e.g., how and why the Project will influence wildlife);
- limited knowledge and experience with the type of effect in the system;

- knowledge of the effectiveness of the environmental design features for reducing or removing effects (e.g., environmental performance of the base liner);
- uncertainties associated with the exact location, physical footprint and activity level of a development and the timing and rate of future developments in the RFD Case; and
- uncertainties in the direction, magnitude and spatial extent of future fluctuations in ecological, cultural and socio-economic variables, independent of effects from the Project and other developments.

Uncertainty in these elements can decrease confidence in the prediction of environmental significance. Discipline studies use quantitative methods, such as sensitivity analyses, or qualitative discussion to assess prediction confidence to the extent reasonable. The assumptions for statistical tests and details on models that were used as part of the assessment are discussed within each discipline of study. Where possible, methods are used to reduce uncertainty and increase the level of confidence in effects predictions. For example, the timeframe defined for assessment of potential effects to groundwater as part of the normal evolution of the Project is estimated to be 10,000 years. This time period encompasses the phase in which peak effects to groundwater are anticipated (Section 6.3.2 Hydrogeology). These peak effects were then included in the Environmental Risk Assessment so that doses arising from post-closure have not been underestimated (Section 6.7 Human and Ecological Health). A conservative approach was implemented when information is limited so that effects are typically overestimated (e.g., defining the key input variables so that the result is a conservatively high effects prediction). Other examples include the following:

- using the results from several models and analyses to help reduce bias and increase precision in prediction; and
- using data from effects monitoring programs and literature as inputs for models rather than strictly hypothetical or theoretical values.

Where appropriate, residual uncertainty is addressed by additional mitigation and in monitoring and follow-up programs. Each discipline of study includes a discussion of how uncertainty is addressed and provides a qualitative evaluation of the resulting level of confidence, which is included in the residual effects classification and determination of significance discussions.

6.1.9 Residual Effects Classification and Determination of Significance

6.1.9.1 Residual Effects Classification

The purpose of the residual effects classification is to describe the residual incremental and cumulative adverse effects from the Project and other developments on VCs using a common set of criteria. The classification criteria provide definitions that permit a clear, thorough and unambiguous classification of residual effects such that reviewers and readers can follow and apply the logic used in the assessment and reach the same classification for a given residual effect. The residual effects classification is then used to make significance determinations. The intent of the environmental assessment is to predict if the Project is likely to cause a significant adverse effect on the environment or to cause public concern.

The classification of residual adverse effects and the determination of significance are completed for those VCs that have assessment endpoints, and where residual adverse effects are predicted. The residual effects classification takes into consideration additional mitigation identified (if applicable) in the residual effects assessment. The results of the classification are used to determine the significance of predicted adverse effects.

Effects are classified using the following criteria, which follows the Generic EIS Guidelines provided by the CNSC (CNSC 2021) and the *Operational Policy Statement Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the Canadian Environmental Assessment Act, 2012* (The Agency 2015). Specific definitions for the classification criteria have been developed for each VC or discipline of study.

Direction – Direction indicates whether the residual effect on a VC is negative, positive or neutral (i.e., no change). Neutral and positive changes are not assessed for significance.

Magnitude – Magnitude is a measure of the intensity of a residual effect, or the degree of change caused by the Project (and other developments, if applicable) relative to the Base Case, guidelines or threshold values. Magnitude is typically classified into three scales: negligible to low, moderate and high. The scales of magnitude are specific to each VC or discipline of study and incorporate the geographic extent and duration of residual effects in context of the properties of VC assessment endpoints. Where possible, magnitude is reported in absolute and in relative terms.

Geographic Extent – This criterion refers to the spatial extent of the effect, and is different from the spatial boundary (i.e., study area) for the residual effects analysis. The spatial boundary for the residual effects analysis represents the maximum area used for the assessment and is related to the spatial distribution and movement of VCs. The geographic extent of residual effects can occur on multiple scales within the spatial boundary of the assessment. Geographic extent refers to the area affected, and is often categorized into three scales of local, regional and beyond regional.

Duration – Duration is defined as the amount of time (usually in years) from the beginning of a residual effect on when the residual effect to a VC is reversed and is expressed relative to Project phases. Duration has two components. It is the amount of time between the start and end of a Project activity or stressor (which is related to Project development phases), plus the time required for the residual effect to be reversed.

Reversibility – After removal of the activity or stressor, reversibility is the likelihood that the Project will no longer influence a VC in a future predicted period. Reversibility usually has only two alternatives: reversible or irreversible. The period is provided for reversibility (i.e., duration) if a residual effect is reversible. Permanent residual effects are considered irreversible.

Frequency – Frequency refers to how often a residual effect will occur and may be expressed as isolated, periodic or continuous. Frequency is explained more fully by identifying when the residual effect occurs (e.g., once at the beginning of the Project). If the frequency is periodic, then the length of time between occurrences and the seasonality of occurrences (if present) is discussed.

Likelihood – Likelihood is the probability of an effect occurring and is described in parallel with uncertainty. This criterion may be influenced by a variety of factors, such as the likelihood of disturbance occurring or the likelihood of mitigation being successful. Four classification categories are typically used: unlikely, possible, likely and highly likely.

The specific definitions applied to the above classification criteria for each VC or discipline of study are based on the ecological or socio-economic processes and properties of the VC or discipline of study. Although some professional judgement or experienced opinion is inevitable in determining the scales for effects predictions, the residual effects, to the extent possible, are classified using scientific principles, established guidelines, thresholds or target values and supporting evidence.

6.1.9.2 Determination of Significance

The residual effects classification of primary pathways and the associated predicted changes in measurement indicators provide the foundation for determining the significance of incremental and cumulative effects from the Project and other existing, approved and RFDs on VC assessment endpoints. For some VCs, there may be no RFD Case and the assessment is limited to determining the significance of residual effects from the Project and previous and existing developments (i.e., Application Case). For those VCs that may be influenced by forecasted future developments, the assessment includes classifying and determining the significance of cumulative effects from all previous, existing and future developments, including the Project (i.e., RFD Case). The classification of residual adverse effects and the determination of significance are completed only for those VCs that have assessment endpoints. Although the neutral and positive residual effects associated with the Project are reported in this section, they are not assessed for significance.

Magnitude is the primary criterion used to determine the significance of effects on VCs. Where possible and appropriate, established guidelines, thresholds and screening values are used to support the classification of the predicted amount of change in measurement indicators and associated effects on VC assessment endpoints. For some disciplines and VCs, such as aquatic health effects to fish, guideline or threshold values are known with reasonable certainty, which increases confidence in effects predictions and significance determinations. For other VCs of the biophysical and human environments, social and ecological benchmarks or effects thresholds are not known with reasonable certainty, which decreases confidence in determining the significance of predicted effects. For example, critical thresholds and screening levels for measurement indicators such as habitat quality, quantity and connectivity, and ecologically effective population sizes are frequently not available for plant, fish and wildlife species. Because of the uncertainty regarding the effects of development on VCs, magnitude classification is conducted conservatively to increase confidence that effects will not be underestimated. Furthermore, the determination of significance considers the level of confidence in the effects predictions.

Magnitude also considers the geographic extent and duration of residual effects that are specific to VC assessment endpoints. For example, the magnitude of an effect on a fish or wildlife VC from changes in habitat availability and connectivity depends on the spatial extent (e.g., amount of area or proportion of the population) and duration of the changes in habitat (e.g., how long populations using that habitat may be adversely affected). Duration includes consideration of reversibility; a reversible effect from development does not result in a permanent adverse effect and therefore may be considered to be of lower magnitude. The duration of residual effects to VCs with high resilience (ability to recover from disturbance) would be expected to be shorter relative to VCs with lower resilience to disturbance.

Frequency and likelihood are considered as modifiers when determining significance, where applicable. For example, the magnitude of the effect from the loss of individuals from a wildlife population due to collisions with vehicles will depend partially on how often animal -vehicle collisions occur over the life of a project. For some effects, such as the physical loss of habitat from the WR-1 Building, the likelihood is high and has little influence on the significance of effects (i.e., the decline in habitat is certain and significance depends on the amount of change over space and time [magnitude]). Alternately, the magnitude of an effect may vary from low to high depending on the probability of different projected outcomes of climate change and the degree of success in actions implemented to mitigate effects from climate change.

The evaluation of significance for biophysical VCs considers the entire set of primary pathways that influence a particular assessment endpoint; thus, significance is not explicitly assigned to each pathway. Rather, the relative contribution of each pathway is used to determine the significance of potential adverse effects of the Project and other developments on an assessment endpoint. This approach is known as a "weight of evidence" approach (i.e., an evaluation of the persuasiveness of the collective evidence). For example, a pathway with a high magnitude (which would include a large geographic extent and a -long-term duration) is given more weight in determining significance relative to pathways with smaller scale effects. The relative effect from each pathway is discussed; however, pathways that are predicted to have the greatest influence on effects to assessment endpoints are assumed to contribute the most to the determination of significance. This method is used to identify predicted residual adverse effects that have sufficient magnitude, duration and geographic extent to result in significant adverse effects on VC assessment endpoints.

Classification of residual effects and determination of significance for the human environment generally follow the methods used for biophysical VCs. However, there are some differences in the selection and definition of effects criteria. For socio-economic VCs, direction, magnitude, geographic extent and duration are the criteria used to classify effects and evaluate the significance of changes to assessment endpoints. The assessment of significance considers the scale of these criteria (e.g., low magnitude, regional geographic extent and long-term duration) and scientific knowledge and experience, which is based on the context of the communities involved, and the informed value and judgement of interested and affected organizations and specialists. The level of significance takes into consideration the effectiveness of the proposed mitigation (i.e., policies, practices and investments) and benefit enhancement programs to limit negative effects and foster positive effects on the continued persistence of long-term sustainable social, cultural and economic features of the human environment.

Details on the approach and methods for classifying residual effects and determining significance on VCs of the biophysical and human environments are provided in the applicable discipline sections of the EIS. The definition of a significant effect is specific to each discipline and will be provided in each discipline section. Significance is determined for the residual adverse effects of the Project overall, for the cumulative residual adverse effects from the Project and previous and existing developments (Application Case), and for the Project and previous, existing and RFDs (RFD Case). The following is a summary of some of the key factors considered in the determination of significance on VCs of the biophysical and human environments:

- Results from the residual effects classification of primary pathways and associated predicted changes in measurement indicators.
- Magnitude is the primary criterion used to determine significance, with geographic extent and duration (which implies reversibility) providing important context for assigning magnitude. Frequency and likelihood act as modifiers for determining significance, where applicable.
- The degree of uncertainty in the effects estimates also influences the classification of magnitude and the determination of significance. Where uncertainty was high and the effect might be either significant or not significant, the assessment conservatively identified the effect as significant and provided additional follow-up actions to reduce uncertainty.

6.1.10 Monitoring and Follow-up

In the EIS, monitoring programs are proposed to address the uncertainties associated with the effects predictions and the performance of mitigation. In general, monitoring is used to verify the effects predictions. Monitoring is used to identify any unanticipated effects and provide for the implementation of adaptive management to limit these effects. Typically, monitoring includes one or more of the following categories, which may be applied during the development of the Project.

- **Compliance Inspections –** monitoring activities, procedures and programs undertaken to confirm the implementation of approved design standards, mitigation and conditions of approval and company commitments (e.g., inspecting the installation of a silt fence).
- **Environmental Monitoring** – monitoring to track conditions or issues during the development lifespan of the Project, and to subsequently provide for the implementation of adaptive management (e.g., monitoring of treated wastewater discharge quality and volumes).
- **Follow-up Monitoring** – programs designed to test the accuracy of effects predictions, reduce or address uncertainties, determine the effectiveness of mitigation, or provide appropriate feedback to operations for modifying or adopting new mitigation designs, policies and practices (e.g., monitoring of Winnipeg River for water quality effects). Results from these programs can be used to increase the certainty of effect predictions in future environmental assessments.

Proposed monitoring and follow-up programs are discussed in each discipline section of the EIS and, upon Project approval, will be included in the Whiteshell Laboratories Integrated Monitoring Framework and coordinated with the existing Environmental Assessment Follow-up and Monitoring Program being conducted as specified in the Comprehensive Study Report (AECL 2001), where practical. CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects and determine the effectiveness of mitigation that have or are to be implemented. Where relevant, conceptual monitoring programs will be proposed to deal with the uncertainties associated with the effect predictions and mitigation.

CNL has committed to engaging with each Nation on their specific interest and concerns regarding monitoring for the Project and the existing WL site Environmental Assessment Follow-up and Monitoring Program. CNL has committed to working collaboratively with the engaged First Nations and the Red River Métis to participate in environmental monitoring at the WL site. Each Nation may have different preferences for how to participate in the initiative and CNL commits to development of a program that is flexible to the needs of each Nation.

An annual progress report on the Environmental Assessment Follow-up and Monitoring Program for the Project will be prepared and will include a summary of the environmental monitoring results for the Project. Public and Indigenous information activities required as part of CNL's Public Information Program will be part of the Environmental Assessment Follow-up and Monitoring Program for the Project and will be summarized as part of the annual progress report.

6.2 Atmospheric Environment

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) In Situ Decommissioning of Whiteshell Reactor 1 (WR-1) at the Whiteshell Laboratories Site (the Project) characterizes potential residual effects of the Project on the atmospheric environment. Section 6.2.1 focuses on air quality and Section 6.2.2 focuses on greenhouse gas (GHG) emissions.

A quantitative noise assessment has not been completed for inclusion in this EIS as it is not anticipated that there are sensitive human receptors in the vicinity of the Project that would experience nuisance effects from the closure and post-closure phases of the Project. A qualitative discussion of potential effects from noise (i.e., sensory disturbance) on wildlife is provided in Section 6.6 Terrestrial Environment and on community well-being in Section 6.9 Socio-economic Environment.

6.2.1 Air Quality

6.2.1.1 Scope of the Assessment

The scope of the air quality assessment focuses on predicting changes in indicator compounds emissions and comparison of these changes to the applicable guidelines and standards. The indicator compounds emissions from the Project include suspended particulate matter (SPM), particles nominally smaller than 10 micrometres (µm) in diameter (PM_{10}), particles nominally smaller than 2.5 µm in diameter ($PM_{2.5}$), carbon monoxide (CO), sulphur dioxide (SO_2) and nitrogen oxides (NO_x) expressed as nitrogen dioxide (NO_2). Emissions of particulates (SPM, PM_{10} and $PM_{2.5}$), CO, SO_2 and NO_x have the potential to affect aquatic, human and terrestrial wildlife health. Particulates emissions, which are also referred to as fugitive dust, can also be a nuisance issue over which the public is concerned. The assessment of air quality within Section 6.2.1 Air Quality focuses on predicting changes in the concentrations of above-mentioned indicator compounds emissions. Hazardous radiological and non-radiological air emissions are assessed in the Environmental Risk Assessment technical supporting document (ERA TSD [EcoMetrix 2021) and summarized in Section 6.7 (Human and Ecological Health) of the EIS. The indicator compounds and the hazardous radiological and non-radiological air emissions are assessed in different sections because the hazardous radiological and non-radiological emissions require additional screening and assessment as part of the ERA TSD to meet the requirements for the Canadian Standards Association (CSA) N288.6 Standard on Environmental Risk Assessment for Class I Nuclear Facilities (CSA Group 2012).

Parameters with no established federal or provincial standards or criteria were not considered.

The air quality assessment follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment is completed in the following primary steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Sections 6.2.1.3 Valued Components and Section 6.2.1.4 Assessment Boundaries) for the air quality assessment. The VCs, assessment endpoints and measurement indicators used to assess Project related changes to air quality, the spatial and temporal boundaries at which the assessment occurred, and the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.2.1.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).

- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.2.1.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect air quality are identified and mitigation options are presented to limit or avoid these effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described. Primary pathways that may lead to residual effects to air quality after incorporating mitigation are carried forward to Step 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 6.2.1.7 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to air quality from primary effect pathways. The analysis results are also presented including the characterization of incremental effects from the Project, as well as cumulative effects of the Project in combination with other reasonably foreseeable developments (if applicable). A key outcome of this section is the predicted changes to emissions of indicator compounds that are passed on to other disciplines for their assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 6.2.1.8 Prediction Confidence and Uncertainty). The purpose of this section is to evaluate the available literature, data and models used for the assessment, and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 – Classify and determine the significance of the predicted residual effects** (refer to Section 6.2.1.9 Residual Effects Classification and Determination of Significance). Residual effects predicted from primary pathways are classified using a common set of criteria: direction, magnitude, geographic extent, duration, reversibility, frequency, and likelihood. A determination of the significance of the predicted residual effects from the Project for the air quality VC is made.
- **Step 7 – Identify monitoring and follow-up** (refer to Section 6.2.1.10 Monitoring and Follow-up) required to confirm effects predictions and address uncertainty.
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.2.1.11 Conclusions) of residual effects on air quality.

6.2.1.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation (Sagkeeng); the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement are related to the air quality assessment are summarized in Table 6.2.1-1. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4 Indigenous Engagement.

Table 6.2.1-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Air Quality Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
Air Emissions and Monitoring ■ Downwind effects of air emissions associated with operations at the WL site.	Included in the environmental assessment	Predicted changes in air quality are assessed in Section 6.2.1.7.2 Application Case Results.
Monitoring ■ Air emissions and monitoring practices on the site currently and into the future.	Included in the environmental assessment	Information on monitoring related to air quality is provided in Section 6.2.1.10 Monitoring and Follow-up.

6.2.1.3 Valued Components

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Air quality was selected as a VC as there is a potential for the Project activities to release air emissions that could affect the local air quality (Table 6.2.1-2). Meteorology is also important as it governs the transport, dispersion and deposition of air emissions from the Project. Sagkeeng; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations did not identify additional VCs beyond those included in Table 6.2.1-2.

Table 6.2.1-2: Valued Components for Air Quality Assessment

Valued Component	Rationale for Selection
Air Quality	Air quality is selected as a VC as it has been identified as an important aspect of the environment by the regulators. In addition, emissions from the Project activities have the potential to alter the existing air quality regime.

VC = valued component

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. The assessment endpoint for air quality is performance against the criteria and thresholds for protection of human health and the environment. Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on a VC. Measurement indicators also provide the primary factors for discussing the uncertainty of effects on VCs and, subsequently, are the key variables for study in follow-up and monitoring programs. The assessment of air quality focused on predicting changes in the concentrations of selected non-radiological indicator compounds (Table 6.2.1-3). These compounds are generally accepted as indicative of changing air quality and for which relevant air quality criteria exist. The selected non-radiological indicator compounds fall into the following two categories:

- **particulate matter**: SPM, PM_{10} and $PM_{2.5}$; and
- **combustion gases**: NO_X represented by NO_2, SO_2 and CO.

These indicator compounds are associated with various Project activities. Particulate matter is typically associated with airborne dust from demolition and decommissioning activities including the mobile concrete batching plant, construction equipment and vehicles travelling over on-site paved roads, as well as material handling activities. Products of combustion (NO_2, SO_2 and CO) are associated with the exhaust from on-site vehicles.

While ozone (O_3) is not directly emitted into the atmosphere from the Project, it is associated with the reaction of NO_X and volatile organic compounds (VOCs) to create NO_2 (MOECC 2016). Ozone was assessed as part of baseline conditions, to calculate the NO_2 emissions from the Project. Emissions of ozone are not quantified for the Project's activities as it is not directly emitted into the atmosphere from the Project. The VOCs, while a criteria air contaminant, are not considered indicator compounds for this Project. The VOCs are not expected to be emitted from the decommissioning activities with the exception of some VOC emissions from fuel combustion. There are no provincial or federal standards for total VOCs to compare predicted concentrations, therefore, VOCs were not retained for the air quality baseline assessment. Polycyclic aromatic hydrocarbons (PAHs) and metals are not considered as indicator compounds as their associated emission factors, where applicable, are considerably lower than the assessed indicator compounds (e.g., NOx). It is not expected that PAHs emissions from fuel combustion would result in substantial predicted concentrations. Non-road mobile fuel combustion products may include hydrocarbons; however, the associated emission factors may represent total hydrocarbons or non-methane hydrocarbons.

Components of the residual organic coolant that is in piping in tanks are not considered indicator compounds for this Project. The residual organic coolant has been drained, with the remainder to be filled as practical in place. The material in question is OS-84 and the Safety Data Sheet (AECL 2014) notes that the material's evaporation rate is negligible with a vapour pressure of lower than 0.001 hPa; therefore, the coolant's components are not volatile and are not expected to be released to the atmosphere in measurable amounts.

The measurement indicator used for assessing the effects of the Project on the air quality VC considers a combination of indicator compounds and their associated averaging period(s) where federal and/or provincial air quality objectives and criteria are available. A single measure is used when evaluating effects, namely the maximum predicted concentration resulting from the Project activities. To evaluate the effect of project-related changes to air quality on other VCs, the results of the air quality assessment were provided to the disciplines listed in Table 6.2.1-3.

Table 6.2.1-3: Assessment Endpoints and Measurement Indicators for the Air Quality Assessment

Valued Component	Assessment Endpoints	Measurement Indicators	Discipline Assessments where Effects on Air Quality are Considered
Air Quality	Performance against criteria and thresholds for protection of human health and the environment	Changes to ambient concentrations of criteria air contaminants (SPM, PM_{10}, $PM_{2.5}$, NO_2, SO_2 and CO).	■ Surface Water Quality (Section 6.4.2); ■ Aquatic Environment (Section 6.5); ■ Terrestrial Environment (Section 6.6); ■ Human and Ecological Health (Section 6.7); and ■ Land and Resource Use (Section 6.8).

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; CO = carbon monoxide.

6.2.1.4 Assessment Boundaries

6.2.1.4.1 Spatial Boundaries

The spatial boundaries selected for the air quality assessment are presented on Figure 6.2.1-1 and are described below.

- **Site Study Area (SSA):** is the WR-1 Building and represents the Project footprint (i.e., where Project activities will be undertaken; 0.07 ha).
- **Local Study Area (LSA):** is defined as the area within which there is potential for measurable changes resulting from the proposed Project activities. The LSA is defined to encompass activities and sources of emissions associated with the Project and is equivalent to approximately 8 km by 8 km square that includes the SSA and the WL site (approximately 6,400 ha).
- **Regional Study Area (RSA):** is defined as the area within which the potential effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. The RSA is equivalent to approximately a 12 km by 12 km square surrounding the LSA (approximately 14,400 ha; Figure 6.2.1-1). This area was selected to include the entire Pinawa Provincial Park to support the land use assessment.

The LSA and the RSA were selected to assess the maximum potential effects for the Project. The size of the LSA and RSA capture the maximum potential effects considering that potential effects of the Project are predicted to remain close to the emission sources centered around WR-1 and to decrease with distance. To provide a conservative assessment, the maximum predicted air quality results at the LSA boundary are presented and are considered to be representative of the highest concentrations at ground-level of contaminants expected outside the LSA from Project activities.

6.2.1.4.2 Temporal Boundaries

The temporal boundary of the assessment is the timeframe during which Project activities are actively occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The Project consists of two phases: closure and post-closure.

The stages and associated activities during the closure phase of the Project are presented in Table 6.2.1-4. Project Stages 1 to 3 involve overlapping years of activities and include the following sources of emissions:

- on-road vehicles exhaust and dust from paved roads;
- non-road vehicles exhaust;
- material handling (grouting and demolition);
- batch mixing plant or similar equipment; and
- emergency power generators.

Project Stages 1 to 3 are considered to involve the highest level of emissions compared to the remaining stages as they occur during overlapping years. Project Stages 4 to 6 will include substantially less road and non-road activities and will not include the batch mixing plant or similar equipment, demolition or propane combustion, resulting in lower emissions. Emissions sources for Stage 4 were compiled to verify Stages 1 to 3 as the bounding case for the atmospheric assessment (Golder 2020a). While Stage 4 includes travel on unpaved roads that have a greater emission factor than paved roads, the vehicular travel along the roads is assumed to be substantially less when compared to Stages 1 to 3. The remaining sources of emissions from Stage 4 are also substantially less than in Stages 1 to 3, as a result, no further assessment is required. Therefore, only activities associated with Stages 1 to 3 are considered in the air quality assessment as they represent the most conservative air emission scenario. Details on the sources of emissions are provided in Appendix 6.2-2.

The post-closure phase has two discrete periods: institutional control and post-institutional control. Institutional control is estimated to last 100 years during which long term monitoring and maintenance activities will continue to demonstrate Whiteshell Reactor Disposal Facility (WRDF) performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated. No sources of indicator compound emissions are expected during the post-closure phase as a result of the Project; therefore, has not been evaluated in the air quality assessment.

Table 6.2.1-4: Project Stages and Associated Activities during the Closure Phase

Project Stage	Activity Description	Duration	Number of Years
1	Preparation for In Situ Disposal	2026 to 2029	3
2	Grouting of below-grade structures and systems	2029	1
3	Removal of above-grade WR-1 structures	2028-2029	2
4	Installation of concrete cap and engineered cover	2030	1
5	Final site restoration	2030	1
6	Preparation for Institutional Control	2030	1

6.2.1.4.3 Assessment Cases

The assessment cases considered in the air quality assessment include the Base Case, Application Case and the Reasonably Foreseeable Development (RFD) Case:

- **Base Case:** represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural and residential and recreational development. Current effects from the existing facilities and operations at the WL site, for example, are considered part of the Base Case. In addition, existing conditions of areas not affected by the WL site are also considered as part of the Base Case.
- **Application Case:** represents the effects of the Base Case combined with the predicted effects that from the Project. The Application Case includes Project Stages 1 to 3; the emissions and associated effects during these stages of the Project represent the bounding cases.
- **RFD Case:** represents the predictions of the cumulative effects of the Application Case, plus projects that are currently under application review or that have officially entered a regulatory application process and that overlap with the air quality RSA. Foreseeable developments in the air quality RSA that are expected to overlap with residual effects on air quality from the Project include the decommissioning of the remaining infrastructure and support facilities and remediation of affected lands at the WL site as per the existing decommissioning licence (Table 6.2.1-5). A Comprehensive Study Report (AECL 2001) under the *Canadian Environmental Assessment Act* (1992) was completed for the decommissioning of the WL site. The Environmental Assessment decision to approve the Project was announced by the Minister of the Environment in March 2002 and a decommissioning licence was issued to Atomic Energy of Canada Limited (AECL) and subsequently to CNL.

Table 6.2.1-5: Reasonably Foreseeable Developments considered in the Air Quality and Greenhouse Gas Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes in situ disposal of the low-level waste trenches).	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project

6.2.1.5 Description of the Environment

6.2.1.5.1 Methods

This section documents the methods, data and results that were used to describe the background air quality at the Project and in the LSA and RSA for indicator compounds. For each indicator compound identified in Section 6.2.1.3 Valued Components, the assessment was carried out by:

- identifying and comparing air quality guidelines in Manitoba and/or Canada for the indicator compounds;
- assessing air quality data sources for use in the background air quality assessment; and
- comparing air quality monitored data to the applicable air quality guidelines.

These steps are detailed in the following sections.

Applicable Criteria

The relevant air quality criteria used for screening air quality effects in the region include Manitoba Air Quality Criteria. The Province of Manitoba, Department of Sustainable Development (now Manitoba Environment, Climate and Parks), Climate Change and Air Quality Branch (Manitoba) has set guidelines related to ambient air concentrations and are summarized in *Objectives and Guidelines for Various Air Pollutants: Ambient Air Quality Criteria* (Manitoba AAQC; Government of Manitoba 2005). The Manitoba AAQC are maximum concentration levels set for the protection and preservation of ambient air quality within Manitoba. The criteria are classified as objectives, guidelines or refer to Canada-wide Standards. The Canada-wide Standards were updated in 2012 and are now known as Canadian Ambient Air Quality Standards (CAAQS). The Manitoba AAQC are characterized as maximum tolerable, acceptable, or desirable level concentrations in ambient air, and intend to serve as guidance for air quality assessments.

The Manitoba AAQC state the following:

- Maximum Acceptable Levels are not to be exceeded in any urban centre including areas that are in the vicinity of industries with atmospheric emissions;
- within rural areas, the goal is to maintain concentrations at or below Maximum Desirable Levels; and
- Maximum Tolerable Levels are only for evaluation purposes to identify the severity of an anthropogenic or natural phenomenon to protect human health and institute appropriate corrective action.

As the Project is in a rural area, the Maximum Desirable Levels were used to assess background air quality conditions, if available; where the Maximum Desirable Levels were not available, the Maximum Acceptable Levels were used.

There are two sets of federal objectives and criteria: the National Ambient Air Quality Objectives (NAAQOs) and the CAAQSs. Similar to the Manitoba AAQCs, the NAAQOs are benchmarks that can be used to facilitate air quality management on a regional scale and provide goals for outdoor air quality that protect public health, the environment, or aesthetic properties of the environment (CCME 1999).

The NAAQOs are not regulatory criteria, rather the federal government has established the following levels of NAAQOs (Health Canada 1994):

- the Maximum Desirable Level defines the long-term goal for air quality and provides a basis for an anti-degradation policy for unpolluted parts of the country and for the continuing development of control technology; and
- the Maximum Acceptable Level is intended to provide adequate protection against adverse effects on soil, water, vegetation, materials, animals, visibility, personal comfort and well-being.

The CAAQSs have been developed under the *Canadian Environmental Protection Act, 1999* and include standards for $PM_{2.5}$, NO_2, SO_2 and ozone that must be achieved by 2020, as well as more stringent standards for NO_2, SO_2 and ozone that must be achieved by 2025. In 2015, the standard was phased in, with the final standard phase in date in 2025 (Government of Canada 2013). Similar to the NAAQOs, the CAAQSs are not regulatory limits, but rather, are used as national targets for $PM_{2.5}$, NO_2, SO_2 and ozone, excluding Quebec (CCME 2014).

Monitoring data in Canada periodically exceeds these criteria, objectives, and standards at different locations for different periods of time. Measured concentrations above these values does not necessarily result in immediate adverse effects but serves as a guidance for areas where air quality could potentially be improved and to take actions to reduce or limit exposure.

A summary of the applicable Manitoba and federal objectives and criteria for the Project are listed in Table 6.2.1-6.

Table 6.2.1-6: Summary of the Applicable Manitoba and Federal Objectives and Criteria

Contaminant	Criteria Classification	Averaging Period	Manitoba AAQC[a] (µg/m³)			Canada-wide Standards[b] (µg/m³)	Canadian Ambient Air Quality Standards[c] (µg/m³)	National Ambient Air Quality Standards and Objectives[d] (µg/m³)

Note: Bold indicates which objective or criteria was used in the assessment.

a) Manitoba AAQC (Government of Manitoba 2005).

b) Canada-wide Standard as published in the Manitoba AAQC (2005) (updated in 2012 to CAAQS).

c) CAAQS published in the Canada Gazette Volume 147, No. 21 - May 25, 2013. Final standard phase in date of 2020 used.

d) CCME 1999.

e) The 24-hour CAAQS for $PM_{2.5}$ is based on the three-year average of the annual 98th percentile of the daily averaged monitored data. The annual CAAQS for $PM_{2.5}$ is based on the three-year average of annual averaged monitored data.

f) The 1-hour CAAQS for NO_2 is based on the 3-year average of the annual 98th percentile of the daily maximum 1-hour average concentrations.

g) The 8-hour CAAQS for O_3 is based on the fourth highest 8-hour value annually, averaged over a 3-year period.

h) The 1-hour CAAQS for SO_2 is based on the 3-year average of the annual 99th percentile of the SO_2 daily maximum 1-hour average concentrations.

µg/m³ = micrograms per cubic metre; SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; CO = carbon monoxide; NO_2 = nitrogen dioxide; O_3 = ozone; SO_2 = sulphur dioxide; — = No guideline available.

Baseline Air Quality Data

In Manitoba and throughout Canada, regional air quality is monitored through a network of air quality monitoring stations operated by the Environment and Climate Change Canada (ECCC) National Air Pollution Surveillance (NAPS) program. These stations are operated under strict quality assurance and quality control procedures. Existing air quality was characterized using background air concentrations from monitoring data sources near the Project. The Comprehensive Study Report (see Section 5.4.1 and Section 5.4.2 of AECL 2001) included an air quality baseline assessment that used monitoring stations that are no longer in operation or have been relocated (i.e., Winnipeg's station ID 9119); therefore, the data from these stations was not considered in this assessment.

There are no air quality monitoring stations within the RSA; however, six air quality monitoring stations are located within 1,1100 km of the Project: Winnipeg (65 Ellen Street), Experimental Lakes, Brandon Assiniboine Community College (Assiniboine) and Flin Flon in Manitoba, and Estevan and Buffalo Narrows in Saskatchewan. The 65 Ellen Street station was the only air quality monitoring station located within 100 km of the Project[1]. The 65 Ellen Street station includes indicator compounds with the exception of SPM. The 65 Ellen Street station is located approximately 84 km from the Project, in an urban area and approximately 60 to 70 km away from two large bodies of water.

The second closest station, Experimental Lakes is located approximately 180 km away from the Project and is situated in one of the largest research areas for freshwater lakes that is managed by the International Institute for Sustainable Development (IISD 2016). The data from this station is heavily influenced by the more than 50 surrounding freshwater lakes and the station only monitors ozone, which makes it difficult to compare with the other data sets. The limited data from this station are not considered representative of the air quality within the LSA and RSA, and therefore, were not used in the air quality assessment.

The next closest air quality monitoring station is in Brandon Assiniboine Community College (Assiniboine) and includes all indicator compounds except for CO, SO_2 and SPM. The Assiniboine station is located approximately 280 km from the Project.

The Flin Flon, Estevan and Buffalo Narrows air quality monitoring stations are located approximately 645 km, 512 km and 1,036 km away from the project, respectively. These stations are the three closest stations in proximity to the project location that are located in areas more characteristic of the Project location in terms of population, urbanization, and land use and that include all indicator compounds, with the exception of CO and SPM.

Ideally, an air quality monitoring station would be within proximity of the Project with a similar geographical siting and similar influences; however, the NAPS program focuses on areas that are affected by local sources and not on remote un-affected areas like the WL site. Therefore, for the Project, all six of the stations, except for Experimental Lake, will be considered in the assessment to produce a range of background air quality concentrations that will be used in the assessment.

[1] The second monitoring station in Winnipeg was not selected for this assessment as it monitors fewer indicator compounds.

The relative locations of the five air monitoring stations selected to describe the background air quality for the LSA and RSA (i.e., 65 Ellen Street, Assiniboine, Flin Flon, Estevan and Buffalo Narrows) are provided in Table 6.2.1-7 and the station locations are shown on Figure 6.2.1-2. For this assessment, data from 2009 to 2013 was used for the 65 Ellen Street and Assiniboine stations, which is the most recent five-year period at the time of the original assessment for which all data are available, and quality assured by ECCC. For the Flin Flon, Estevan and Buffalo Narrows stations, data from 2017-2021 was used which is the most recent five-year period at the time of the updated assessment for which all data are available and quality assured by ECCC.

Table 6.2.1-7: Location of Background Air Monitoring Stations Selected for the Project

City	NAPS Station ID	Location	Latitude and Longitude	Distance to the Project[a] (km)	Direction
Winnipeg	70119	Outside Regional Study Area	49.89809, -97.14652	84	Southwest
Brandon	70203	Outside Regional Study Area	49.83918, -99.9206	280	Southwest
Estevan	80502	Outside Regional Study Area	49.132350, -102.98499	512	Southwest
Flin Flon	70301	Outside Regional Study Area	54.76852, -101.87747	645	Northwest
Buffalo Narrows	82002	Outside Regional Study Area	55.834566, -108.403332	1,036	Northwest

a) Approximate distance from Project.

NAPS = National Air Pollution Surveillance.

The air flow into the WL site varies in direction but is predominantly blowing from the south and south-southeast and slightly less predominantly from the north-northwest and northwest. The Project is located in a fairly remote area, with very few industrial emission sources that influence the airshed surrounding the Project. As the 65 Ellen Street and Assiniboine monitoring stations are located in more industrial and urban areas, the air quality data from these two stations can be considered to provide conservative air quality estimates and are likely to be greater than the existing conditions in the RSA. As the Flin Flon, Estevan and Buffalo Narrows stations are located in areas more characteristic of the project location in terms of population, urbanization, and land use, the air quality data from these three stations can be considered to provide representative air quality estimates of the existing conditions in the RSA.

Table 6.2.1-8 provides a summary of the monitoring data available from each of the five selected stations for the period from 2000 through 2021. At the time of the original assessment, complete datasets were available up until 2013, with only partial information available for 2014 and 2015 at the 65 Ellen Street and Assiniboine stations. At the time of the updated assessment, compete datasets were available up until 2021 at the Flin Flon, Estevan and Buffalo Narrows stations. Not all compounds have the same data availability period for a given station, as additional compounds are added to the station at different dates as required by the ECCC (e.g., SO_2 was only monitored starting in 2008).

Table 6.2.1-8: Availability of Ambient Air Quality Data (Years)

Compound	65 Ellen Street Station	Assiniboine Station	Buffalo Narrows Station	Flin Flon Station	Estevan Station
SPM[a]	—	—	—	—	—
PM_{10}	2006 - 2013	2006 - 2013	2017-2021	2002-2021	2017-2021
$PM_{2.5}$	2000 - 2002, 2013	2001 - 2002, 2013	2017-2021	2002-2021	2017-2021
NO_2	2000 - 2013	2000 - 2010, 2012 - 2013	2017-2021	2002-2021	2017-2021

O_3	2000 - 2013	2000 - 2013	2017-2021	2002-2021	2017-2021

a) SPM values may be calculated from the monitored values of PM_{10}.

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_2 = nitrogen dioxide; NO = nitrogen oxide; CO = carbon monoxide; SO_2 = sulphur dioxide; O_3 = ozone; — = data for the parameter were not available at that station.

6.2.1.5.2 Results

Table 6.2.1-9 provides a summary of the existing air quality data for the RSA, which is considered as background air quality. The 65 Ellen Street station is the only air quality monitoring station located within 100 km of the Project, but both the 65 Ellen Street station and the Assiniboine station are located in urban settings that could have elevated background air quality concentrations that are over-conservative for this assessment. The Flin Flon, Estevan and Buffalo Narrows stations are all located in rural areas more characteristic of the project location in terms of population, urbanization, and land use but are each located over 500 km from the Project. As a result, minimum and maximum background concentrations from all five stations were considered to be the most representative background air quality for non-radiological indicator compounds in the RSA. The comparison of the five stations is provided in Appendix 6.2-1.

The background air quality values retained for the assessment are presented below in Table 6.2.1-9 and are based on the minimum and maximum values from all five stations. The existing concentrations are below the respective provincial and federal criteria for each indicator compound, suggesting that the region has generally good air quality.

Table 6.2.1-9: Background Air Quality Values (90th Percentile, Average for Annual Only) [a]

Indicator	Averaging Period	65 Ellen Street (84 km SW)	Assiniboine (280 km SW)	Flin Flon (645 km NW)	Estevan SK (512 km SW)	Buffalo Narrows SK (1,036 km NW)	Background Air Quality (Minimum Base Case)	Background Air Quality (Maximum Base Case)
SPM[b]	24-hour	22.46	81.61	58.38	67.33	32.16	**22.46**	**81.61**

	8-Hour	86.35	88.07	76.05	91.01	88.80	**76.05**	**91.01**

Bolded values represent the Base Case air quality.

a) Data measured in parts per billion (ppb) or parts per million (ppm), were converted to µg/m³ assuming standard temperature and pressure (25°C and one atmosphere of pressure).

b) SPM concentrations were calculated using PM_{10} concentrations

µg/m³ = microgram per cubic metre; SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; CO = carbon monoxide; O_3 = ozone.

6.2.1.6 Project Interactions and Mitigation

6.2.1.6.1 Methods

This section describes the process by which interactions between Project components and activities and air quality were identified and evaluated. Potential effect pathways are identified, and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the Project and the environment by evaluating the different effect pathways to assess if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in Section 6.2.1.7 Residual Effects Analysis. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce effects to air quality. Environmental design features included design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the engineering and environmental teams, combined with input from Project-specific or regional engagement with other interested parties. The design features and/or mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation.

- **No linkage pathway –** pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change to concentrations of indicator compounds relative to Base Case values, and therefore would have no residual effects to air quality.
- **Secondary pathway –** the pathway could result in a measurable minor change to concentrations of indicator compounds, but would have a negligible residual effect on air quality relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway –** the pathway is likely to result in an environmental change to concentrations of indicator compounds relative to the Base Case and/or guideline values that could contribute to residual effects to air quality.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects to air quality were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to air quality through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and/or qualitative effects analysis to characterize the residual effects of the Project on air quality.

CNL's *Management and Monitoring of Emissions* (CNL 2022) outlines the requirements for identification, control and treatment of emissions at CNL sites. Some applicable mitigation methods are described below.

- Facilities shall be designed, operated, decommissioned and abandoned such that radioactive and non-radioactive emissions to the environment remain As Low As Reasonably Achievable (ALARA), economic and social factors being taken into account.
- Radioactive and non-radioactive emissions to the environment from CNL facilities and sites shall be controlled so as to remain below regulatory release limits specified in any applicable legislation, license, permit or approval issued in respect of the operation of that specific facility or site by a regulatory agency having jurisdiction.
- To the extent practical, emissions to the environment should be controlled by proactive prevention of the emission at the source, through means such as:
  - selecting or using such types, quantities, and physical and chemical forms of radioactive and non-radioactive contaminants, or materials that may become contaminated in use, that minimize the potential for and significance of emissions; and
  - implementing preventative maintenance and inspection programs on systems containing radioactive or non-radioactive contaminants.

6.2.1.6.2 Results

The potential pathways from sources of air emissions to air quality are dependent on the presence and relative intensity of the activity over the Project phases. Activities that use vehicles, mobile equipment, or stationary combustion sources would emit indicator compounds. Material handling activities would emit fugitive dust, as would vehicle movements on paved roads. Each activity would have a different level of intensity or use a different amount of equipment depending on the phase in which the activity occurred. Pathways through which the Project may interact with and result in changes to concentrations of indicator compounds is provided in Table 6.2.1-10.

Table 6.2.1-10: Pathways Analysis for the Air Quality Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Closure Phase ■ Stage 1: Preparation for in situ disposal ■ Stage 2: Grouting of below-grade structures and systems ■ Stage 3: Removal of above-grade WR-1 structures and systems	Closure activities will alter concentrations of indicator compounds, including: ■ use of vehicles and equipment that combust fuel and emit indicator compounds; ■ material handling, for grouting, demolition, or soil remediation; ■ vehicles travelling on roads; ■ operation of batch mixing plant or similar equipment for grout production.	■ Implementation of CNL's *Environmental Protection* (CNL 2023b), *Management and Monitoring of Emissions* (CNL 2022), and the WL Open Air Demolition Technical Basis document (CNL 2020), which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Implementation of dust management techniques to control dust generated by the Project, consistent with the Environmental Assessment Follow-up and Monitoring Program for the WL site. ■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. ■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include: ▪ wetting techniques during demolition to limit mobility of dust; ▪ wind restrictions during demolition to stop work or apply wetting techniques; and ▪ hydro seeding during backfilling and landscaping to reduce soil erosion. ■ Road watering and chemical dust suppressant when necessary. Dust suppressant is already used annually at the WL site for select unpaved roads. ■ Removal of accumulations of particulates (e.g., dirt) on road as soon as possible. ■ On-site vehicles and equipment engines will meet Tier 4 emission standards, where possible and be maintained in good working order. ■ Limit idling of vehicles on-site and speed on roads. ■ Use of tarps or 3 sided enclosures for raw material storage.	Primary

Table 6.2.1-10: Pathways Analysis for the Air Quality Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Closure Phase ■ Stage 1: Preparation for in situ disposal ■ Stage 2: Grouting of below-grade structures and systems ■ Stage 3: Removal of above-grade WR-1 structures and systems	Closure activities for the Project will overlap with decommissioning of the remaining infrastructure and support facilities at the WL site as per the existing decommissioning licence.	■ Implementation of CNL's *Environmental Protection* (CNL 2023b), *Management and Monitoring of Emissions* (CNL 2022), and the WL Open Air Demolition Technical Basis document (CNL 2020), which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. ■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include: ▪ wetting techniques during demolition to limit mobility of dust; ▪ wind restrictions during demolition to stop work or apply wetting techniques; and ▪ hydro seeding during backfilling and landscaping to reduce soil erosion. ■ Curtailment of activities during periods of adverse meteorological conditions (e.g., during periods of high winds). ■ Maintenance of on-site access routes. ■ Continued implementation of the Environmental Assessment Follow-up Monitoring Program for the WL site.	Secondary

6.2.1.6.2.1 No Linkage Pathways

There are no pathways identified as having no linkages to effects to the air quality VC.

6.2.1.6.2.2 Secondary Pathways

In some cases, a Project source of effect and an interaction with an assessment endpoint exists but mitigation is expected to cause minor changes to the environment and a negligible effect on air quality relative to the existing Base Case and/or guidelines. The following pathway is expected to result in negligible effects on the air quality VC and is not evaluated further in the EIS.

- **Closure activities for the Project will overlap with decommissioning of the remaining infrastructure and support facilities at the WL site as per the existing decommissioning licence.**

The Comprehensive Study Report (see Section 6.3.1 of AECL 2001) evaluated the effects of physical works/activities on the atmospheric environment from closure of the WL site. Physical work/activities evaluated for indicator compounds included:

- disconnecting of nuclear facility services and maintenance of buildings;
- removal of hazardous materials from facilities;
- methane pollution from organic material that may be in the inactive landfill;
- retrieval and repackaging of waste from existing storage facilities and construction of new storage area;
- demolition of facilities and disposal of rubble as clean fill; and
- site restoration (AECL 2001).

Results of the air quality assessment completed as part of the Comprehensive Study Report indicated that from time-to-time nuisance dust will be generated. Mitigation practices will be implemented to limit potential effects to air quality, including dust control measures (e.g., containment and suppression), curtailment of activities during periods of high winds and maintenance of on-site access routes (see Section 6.3.1 of AECL 2001). In addition, dust monitoring stations have been established on site to collect airborne particulate samples as part of environmental monitoring during decommissioning activities. Special enclosures to cover large areas are currently in use and additional ones may be implemented in the future to contain potential airborne emissions from decommissioning activities (e.g., decommissioning of the Waste Management Area). In addition, temporary ventilated enclosures that implement HEPA filtration are used where airborne contamination is a potential hazard during work. This protects workers and the environment. The evaluation of effects to air quality from decommissioning and reclamation activities for the entire WL site concluded that release of air emissions is negligible; consequently, no significant effects were predicted (AECL 2001).

Radiological, industrial, and environmental hazards will be remediated as practical and required for building demolition. The goal is to remove or remediate radiologically contaminated areas and systems so that the building and non-grouted reactor areas can be released for demolition as clean (non-contaminated). A Radiological Clearance Survey of the building will be performed to demonstrate remaining areas and systems are clean, confirm areas that are contaminated, and/or identify areas that are not feasible to demonstrate as clean. Contaminated areas that are not feasible to remove, remediate, or demonstrate as clean, will be identified and marked for segregation during demolition. An assessment will be done on whether such building areas or systems pose a risk for cross-contamination of clean building areas and the subsequent need to be managed as radioactive waste.

The magnitude of potential dispersion of contamination during demolition and the need to implement contamination controls will be assessed in accordance with the WL Open-Air Demolition Technical Basis Document (CNL 2020).

To control the radiological air emissions, the criteria for moving from enclosed decontamination to open-air demolition will be determined using the WL Open Air Demolition Technical Basis document (CNL 2020). This document outlines the methodology by which the remaining activity that is left in the building for the demolition is correlated to the method of demolition and doses to adjacent receptors are determined. Based on the dose constraints and Derived Air Concentrations a screening level will be assigned to the demolition work, ranging from Level 1 where no additional modeling or special precautions are necessary to Level 3, where in-depth modeling will be required, and demolition controls will be subject to approval by the Radiation Protection and Environmental Protection program managers. Generally, open-air demolition is not performed above Level 3 dose constraint.

The Comprehensive Study Report included consideration of the WR-1 Building in the original evaluation of residual effects to air quality (see Section 6.3.1 of AECL 2001). Although the decommissioning strategy has changed for WR-1 from a complete removal of the facility to in situ disposal, activities related to the decommissioning of the reactor are expected to be less disruptive than those assessed in the Comprehensive Study Report (AECL 2001) for the currently approved decommissioning approach (i.e., complete removal of the facility). Mitigation such as the use of dust suppression methods will be implemented during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation will be implemented to further limit emissions. Consequently, the Project is not anticipated to result in a change in the conclusions of the 2001 Comprehensive Study Report related to air quality (see Section 6.2.1.7.2 Application Case Results for the Project air quality predictions).

As such, the Project is not expected to contribute cumulatively to the effects of decommissioning of the remaining infrastructure and support facilities at the WL to cause a significant effect; consequently, this pathway is considered to be secondary.

6.2.1.6.2.3 Primary Pathways

Project activities completed during Stage 1, 2 and 3 of the closure phase were identified as having a residual effect on the air quality VC, and therefore, are carried forward to the residual effects analysis. Closure activities for the Project include:

- use of vehicles and equipment combust fuel and emit indicator compounds;
- material handling for grouting and demolition emit fugitive dust;
- vehicles travelling on roads emit fugitive dust; and
- operation of batch mixing plant or similar equipment for grout production emits fugitive dust.

6.2.1.7 Residual Effects Analysis

6.2.1.7.1 Methods

Residual effects of the Project are those effects that remain after implementation of all mitigation. The assessment of effects of the Project on air quality involves two steps, namely the calculation of emission rates (which include the implementation of mitigation) and dispersion modelling to predict the resulting concentrations of indicator compounds. These steps are described below.

Emissions Quantification

The method used for calculating and quantifying air emissions resulting from the Project involved the following steps:

- **Identifying emissions sources:** Emission sources were identified based on the Project conceptual design and the Project information provided in Section 3.0 Project Description.
- **Calculating emission rates:** Air emission rates were calculated using accepted methods, such as emission factors, and were based on activity data provided in Section 3.0 Project Description, as well as MOBILE6.2.C modelling results provided in Appendix 6.2-2. Emission rates were calculated for the Application Case scenario.
- **Summarizing overall emissions:** The calculated emissions were summarized by Project stage for the closure phase.

The emission estimation methods used in the air quality assessment follow generally accepted practices for conducting environmental assessments and, where appropriate, guidance in Appendix C of *REGDOC-2.9.1, Environmental Principles, Assessments and Protection Measures* (CNSC 2020). Scientifically accepted by Manitoba Sustainable Development (now Manitoba Environment, Climate and Parks) (Draft Guidelines) and well-documented emission factors, such as AP-42 from the United States Environmental Protection Agency (US EPA 1995) were used to estimate maximum and average emission rates. Details of the specific emission calculation methods and resulting emissions are provided in Appendix 6.2-2.

Dispersion Modelling

The modelling approach used to evaluate the likely environmental effects for the air quality indicators followed generally accepted practices for conducting environmental assessments and modelling guidance. It should be noted that the Manitoba Sustainable Development (now Manitoba Environment, Climate and Parks), Climate Change and Air Quality Branch, has limited dispersion modelling guidance included in the *Draft Guidelines for Air Dispersion Modelling in Manitoba* - Air Quality section (Manitoba Conservation 2006). Therefore, the Draft Guidelines and the following guidance documents were followed as appropriate: *Air Dispersion Modelling Guideline for Ontario* (MOECC 2017), the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012) and in *Modeling Fugitive Dust Sources* (National Stone, Sand and Gravel Association 2004).

The selection of the AERMOD model was based on the following capabilities:

- has a technical basis that is scientifically sound and is in keeping with the current understanding of dispersion in the atmosphere;
- applies formulations that are clearly delineated and are subjected to rigorous independent scrutiny;

- makes predictions that are consistent with observations;
- is recognized by federal and provincial regulators, including Quebec, as a regulatory default mode;
- evaluates the source configurations and indicator compounds associated with the Project;
- the terrain surrounding the Project is relatively simple and can be addressed by the terrain features of the model;
- allows for the use of localised meteorological data;
- incorporates building downwash effects; and
- long-range transport of compounds is not anticipated.

Details regarding the dispersion modelling, including receptor grids and source input parameters are provided in Appendix 6.2-3.

6.2.1.7.2 Application Case Results

Average and Maximum Emission Rates

In accordance with REGDOC-2.9.1 (CNSC 2020), average and maximum emission rates have been provided for the Application Case. Table 6.2.1-11 and Table 6.2.1-12 summarize the average and maximum daily emission rates in grams per second (g/s) for the Application Case. The largest contributors to the emissions of the contaminants are as follows:

- SPM, PM_{10} and $PM_{2.5}$: paved roads;
- NOx (as NO_2) and CO: non-road equipment exhaust; and
- SO_2: emergency power generators fuel combustion.

Details of the specific emission calculation methods and resulting emissions estimates used for dispersion modelling are provided in Appendix 6.2-2.

Negligible Emissions from the Project

There are many activities associated with the Project that produce emissions; however, not all activities produce emissions for any or all compounds that are relevant to the overall emissions assessment. All activities that potentially produce emissions were evaluated to assess their relevance; however, only activities that were considered to be relevant were included in the assessment.

The following lists rationale as to why certain activities and/or emissions of certain compounds can be excluded from the assessment:

- the emission rates of certain compounds are very small relative to the overall emissions at the Project;
- the emissions of certain sources are known to not be relevant due to the type of operations in the assessment; and
- the location of the source relative to the rest of the sources on-site (i.e., the source is located far away from any potential receptors).

Table 6.2.1-13 lists the activities that were not assessed and the accompanying rationale.

Table 6.2.1-13: Emissions Not Included in the Air Quality Assessment

Activity/Compound	Rationale for Excluding from the Air Quality Assessment
Emergency power equipment	Emissions from the emergency power equipment were only included for contaminants with an averaging period of 1 hour (NO_2, CO, SO_2). Other averaging periods for NO_2, CO and SO_2 exclude the generators emissions. Other contaminants with longer averaging periods (particulates) are excluded from the emergency power equipment assessment. The generators only operate periodically during monthly routine maintenance testing and a duration of one hour per month, rather than continuously. Additionally, the emergency power generators will only be used to supply electricity during power outage when other equipment is not in operation. Therefore, only routine maintenance of one hour per month is included in the representative scenario.
Snow removal equipment	Emissions from this equipment occur seasonally and are infrequent (i.e., only during the winter following a snowfall), and therefore, are not included in the representative scenario.
Operations support activities, such as maintenance activities	Emissions from these sources are infrequent, relatively small and do not occur at all times compared to the other activities that are occurring regularly and/or continuously. For example, these activities may include minor vehicles maintenance.
Combustion from Propane Space Heating	At the time of the assessment, it is unknown when the electric building heating systems will be taken offline for the WR-1 Building and replacement heating using propane has not been confirmed. The possible emissions from the combustion of propane used to replace the electric space heating would account for less than 5% of the total emissions from the Project and were not included in the representative scenario.
Removal of the Primary Heat Transport system	Releases from dust or gaseous emissions from removal of the PHT system are expected to be negligible because these particulates are anticipated to be captured in the remnant organics (oil), within the system. In addition, the structure is made of steel not concrete, which also inhibits the collection of dust and particulates on the PHT system. Regardless of the decontamination and dismantling techniques used for the WR-1, best practices will be implemented and will follow the Environmental Protection Plan. Releases of radiological emissions from the removal of the PHT system are evaluated in Section 6.7 Human and Ecological Health.

Table 6.2.1-13: Emissions Not Included in the Air Quality Assessment

Activity/Compound	Rationale for Excluding from the Air Quality Assessment
Non-road nuisance dust	Potential sources of dust not already included in the assessment will be managed through CNL's *Management and Monitoring of Emissions* (CNL 2022).
Non-dust fugitive emissions	■ Materials such as insulating material and asbestos are handled through existing strict procedures outlined in the *Management Control Procedure, Controlling Asbestos Hazards* (CNL 2023a) and are therefore not included in the assessment. ■ The bulk of the residual organic coolant that is in piping and tanks has been drained out, with the remainder to be filled as practical in place. This coolant, OS-84, has a negligible evaporation rate and its vapour pressure is lower than 0.001 hectopascal pressure unit. Therefore, the coolant's components are not volatile and are not expected to be released to the atmosphere in measurable amounts.

NO_2 = nitrogen dioxide; CO = carbon monoxide; SO_2 = sulphur dioxide; PHT = primary heat transport; WR-1 = Whiteshell Reactor 1.

Predicted Modelling Concentrations

Ground level concentrations resulting from the Application Case for the air quality indicator compounds were predicted with the aid of the estimated emission rates (Table 6.2.1-11 and Table 6.2.1-12) and AERMOD dispersion models. For each indicator compound and respective averaging period, maximum POI concentrations at the CNL property boundary were combined with both the minimum and maximum background concentrations and compared to the lowest criteria. The Minimum Scenario predicted ground level concentrations at the LSA boundary for the Application Case are presented in Table 6.2.1-14. The Maximum Scenario predicted ground level concentrations at the LSA boundary for the Application Case are presented in Table 6.2.1-15 (Average Scenario predicted concentrations are not presented as they are lower than the Maximum Scenario).

All indicator compounds were below the applicable criteria at the CNL property boundary, except for SPM and PM10 on the 24-hour averaging period. The SPM result was above the MAAQC Maximum Acceptable Level Concentration but remains below the MAAQC Maximum Tolerable Level Concentration, while the PM10 result was above the MAAQC Maximum Acceptable Level Concentration. Modelling results for SPM greater than 98% of the maximum POI concentration along the CNL boundary is attributable to re-entrainment of dust from vehicles travelling on paved roads, with less than 2% from the decommissioning activities around the Project site. As a result, dust generated from decommissioning activities around the Project site that is dispersed off-site is expected to be negligible. Dust from vehicle re-entrainment generally on paved roads is intermittent that does not produce visible emissions and is not considered a significant source of deposition. For both SPM and PM10, all receptor locations above their respective criteria were located in close proximity to the CNL property boundary along Ara Mooradian Way, north of Hwy 211 and on property controlled by CNL. All sensitive receptors (residences) had POI concentrations below their respective guideline.

Further, the quantity of the dust from the paved roads at CNL is expected to be considerably less than the dust generated by existing roads in the study area. For example, Provincial Trunk Highway 11 (PTH 11) runs west of the site boundary and has recorded annual average daily traffic (AADT) of over 1400 vehicles in 2017. Comparatively, the site access road is expected to have a maximum of 97 vehicles per day during decommissioning, or approximately 7% of the vehicles that travel on PTH 11 daily. As a result, particulate matter deposition modelling is not required for this assessment as the Project is not expected to contribute significantly to dustfall in the area.

Table 6.2.1-14: Concentrations at the Local Study Area Boundary for the Minimum Base Case and Application Case

Contaminant		Chemical Abstracts Service Number	Averaging Period	Applicable Air Quality Guideline or Standard [a] (µg/m³)	Base Case Concentration[b] (µg/m³)	Maximum Scenario Maximum Predicted Incremental Concentration (µg/m³)	Application Case Concentration (µg/m³)	Application Case Concentration Percent of Applicable Air Quality Guideline of Standard
Suspended Particulate Matter	SPM	N/A-1	24-hour	120	22.5	158	181	150%
Suspended Particulate Matter	SPM	N/A-1	Annual	60	12.4	13.5	26.0	43.3%

Sulfur Dioxide	SO_2	7446-09-5	Annual	10.5	0.48	0.0150	0.494	4.7%
Carbon Monoxide	CO	630-08-0	1-Hour	15,000	802	465	1267	8.4%
Carbon Monoxide	CO	630-08-0	8-Hour	6,000	916	171	1087	18.1%

a) Table 13 in Appendix 6.2-1 identifies which guideline or standard was used in the screening of effects to air quality.

b) The 90th percentile background concentrations; values for SPM are calculated from the PM_{10} values as described in Appendix 6.2-1. Data measured in parts per billion (ppb) or parts per million (ppm), were converted to µg/m³ assuming standard temperature and pressure (25°C and one atmosphere of pressure). Although ozone was assessed as part of baseline conditions to calculate the NO_2 emissions from the Application Case, these are not presented in this table as emissions of ozone are not quantified for the Project's activities since they are not directly emitted into the atmosphere from the Project

c) Calculated using the Ozone Limiting Method. Refer to Appendix 6.2-3 for methods.

µg/m³ = micrograms per cubic metre.

6.2.1.8 Prediction Confidence and Uncertainty

Potential sources of uncertainty in the assessment of air quality include:

- the accuracy and representativeness of the activity data and emission factors used to estimate emissions;
- the accuracy and representativeness of the meteorological data used in the AERMOD dispersion model;
- the accuracy of formulations within the AERMOD dispersion modelling system;
- the representativeness of the ambient data used to represent background concentrations; and
- the potential error associated with omitting some emission sources.

Dispersion models employ assumptions that simplify the random processes associated with atmospheric motions and turbulence. While this simplification limits the model's ability to replicate individual events, the strength of the model lies in the ability to predict overall values for a given set of input parameters. Considerable effort was undertaken by the US EPA during the development and testing of the dispersion models, such that the model predictions can be relied on as reasonable estimates of the likely concentrations. AERMOD is based on known theory and proven to reliably produce repeatable results (Section 6.2.1.7.1). To limit the uncertainty associated with emissions input to the model, assumptions that are likely to over predict emissions or concentrations were made where practical. These conservative assumptions were used to manage the above uncertainties and are described as follows below"

- The Application Case (i.e., during the closure phase, Project Stages 1 to 3) were assumed to occur simultaneously. It is conservatively assumed that all non-road equipment is operating simultaneously during the daytime operating hours for Project Stages 1 to 3 and for the entire duration of these three stages. In reality, it is unlikely that all equipment would operate simultaneously and that the same type of equipment will operate simultaneously for different components of these stages. The modelling assessment includes all operations occurring simultaneously and continuous over the entire modelling period.
- It is assumed that all equipment will comply with US EPA Tier 4 emissions standards, where possible. Tier 3 standards have begun being phased-out in Canada (variable depending on the engine sizes) and new equipment is required to comply with interim Tier 4 or Tier 4 emissions standards starting in 2014 (Environment Canada 2012).
- Combustion emissions from the propane-fired boiler were based on an assumed maximum equipment firing rate.
- Project activities were modelled as a volume source. Modelling the emissions as a volume source is conservative since this model source type does not take advantage of favourable dispersion characteristics such as plume buoyancy and initial exit velocity of emissions from the propane-fired boiler, batch mixing plant or similar equipment. Further, the dispersion modelling source dimensions selected for the volume source result in a dispersion modelling source which is smaller than the corresponding real-life source. This is conservative since estimated emissions occur over a smaller area, and thus, are more concentrated (and therefore less dispersed) at the point of release.

- The emission estimates for fugitive road dust from paved roads are conservative and overestimate emissions from facility roadways for the following reasons:
  - The US EPA AP 42 equations were developed from measured emissions from public roadways and as a result will tend to overestimate low speed vehicle traffic from construction and industrial sites.
  - All roadways at the Project were modelled assuming simultaneous and continuous use; however, it is unlikely that this situation will occur in reality.
  - As the dust best management practices are revised through continuous improvements, the emissions from the on-site roadways are likely to decrease.
- The modelling assessment includes all operations occurring simultaneously and continuous over the entire modelling period. Variable emission rates were not used for the material handling activities and vehicle traffic although these activities are planning to only occur during the daytime and weekdays. Seasonal variability for fugitive dust emissions was also not considered in the assessment.
- The influence of natural mitigation from events such as rainfall, snowfall, residual moisture, or snow cover was not considered in estimating fugitive dust emission rates. The modelling will likely yield higher concentrations since contaminants will be deposited from the air by dry or wet depletion and deposition processes.
- The parameters that were required for fugitive dust modelling from paved roads include site geometry inputs, locations and dimension of the roadway segments, worst-case meteorological conditions, receptor locations and vehicle emission rates. This is a conservative approach to estimate the maximum off-property concentrations.

It is assumed that the conservative emission rates, when combined with the conservative operating conditions and conservative dispersion modelling assumptions described herein, are not likely to under predict the modelled concentrations at each of the identified receptors.

6.2.1.9 Residual Effects Classification and Determination of Significance

This section classifies the residual effects from changes to measurement indicators for the Application Case and presents a determination of significance for the air quality VC.

6.2.1.9.1 Residual Effects Classification

Effects from adverse residual changes to measurement indicators were classified using a categorical scale and common words to facilitate the determination of significance. The purpose of categorical classification is to provide definitions that permit a clear, thorough and unambiguous classification of residual effects such that reviewers and readers can follow and apply the logic used in the assessment and reach the same classification for a given residual effect.

Residual adverse effects were classified using the criteria and definitions outlined in Table 6.2.1-16. For air quality, residual effects stop almost immediately when the Project activity stops. It should be noted that reversibility refers to effects to air quality only; how effects to air quality affect other VCs are assessed in their discipline-specific sections.

Table 6.2.1-16: Definitions of Assessment Criteria for Classifying Predicted Residual Adverse Effects to Air Quality

Criteria	Description	Definition
Direction	Direction relates to the "value" of the effect in relation to the environment.	**Positive:** Maximum concentration for an indicator compound represents a decrease from Base Case.
		Negative: Maximum concentration for an indicator compound represents an increase from Base Case.
		Neutral: No change in concentrations of an indicator compound relative to Base Case.
Magnitude	Magnitude is the intensity of the effect or a measure of the degree of change from existing (baseline) conditions or guidelines expected to occur in the criterion.	**Negligible:** Maximum concentration for an indicator compound is <5% of the corresponding criteria[(a)]
		Low: Maximum concentration for an indicator compound is less than 50% of the corresponding criteria[(a)]
		Moderate: Maximum concentration for an indicator compound is between 50% and 100% of the corresponding criteria[(a)]
		High: Maximum concentration for an indicator compound is above the corresponding criteria[(a)]
Geographic extent	Geographic extent refers to the spatial area over which an effect will occur/can be detected (distance covered or range).	**Local:** Effect is limited to within the LSA
		Regional: Effect extends beyond the LSA, but is contained within the RSA
		Beyond Regional: Effect extends beyond the RSA
Duration	Duration is the period of time over which the environmental effect will be present. The amount of time between the start and end of an activity or stressor (which relates to project phases), plus the time required for the effect to be reversed. Duration and reversibility are functions of the length of time a criterion is exposed to activities.	**Short-term:** Effects are not evident beyond Application Case (i.e., closure phase, Project Stages 1 to 3)
		Medium-term: Effects are not evident beyond all project phases
		Long-term: Effects are not evident beyond the completion of all project phases
		Permanent: Effects are not reversible
Frequency	Frequency refers to the occurrence of the environmental effect over the duration of the assessment.	**Infrequent:** Effects are confined to a specific discrete period
		Frequent: Effects occur intermittently, but repeatedly, or continuous over the assessment period
Reversibility	Reversibility is an indicator of the potential for recovery of the criterion from an effect. Reversible implies that the effect will not influence the criterion at a future predicted period in time. For effects that are permanent, the effect is determined to be irreversible.	**Reversible:** Change of state in environment is not permanent
		Irreversible: Change of state in the environment is permanent
Likelihood	Likelihood is a measure of the probability that an activity will result in an environmental effect.	**Low:** Effect is unlikely to occur
		Medium: Effect is likely to occur
		High: Effect is highly likely to occur

a) Table 13 in Appendix 6.2-1 identifies which guideline or standard was used in the screening of effects to air quality.

LSA = Local Study Area; RSA = Regional Study Area.

6.2.1.9.2 Determination of Significance

The residual effects classification of primary pathways and the associated predicted changes in measurement indicators provide the foundation for determining the significance of residual effects from the Project on air quality. Where possible and appropriate, established guidelines, thresholds and screening values were used to support the classification of the predicted amount of change in measurement indicators and associated effects on air quality. For an effect to be deemed significant, the effect on an indicator compound must be adverse (negative in direction), exceed relevant guideline/standard (high in magnitude), extend beyond the local study area (regional in geographic extent) and irreversible or only reversible following completion of the Project phases (long-term in duration). As part of the determination of significance, confidence in the assessment identified in Section 6.2.1.7 was considered for the air quality VC.

As presented in Table 6.2.1-17, the direction is negative for all indicator compounds as there are emissions during the Application Case. The magnitude of changes to indicator compound emissions are predicted to be low to moderate for $PM_{2.5}$, NO_2, SO_2, and CO as the predicted concentrations of each of these indicator compounds from the Application Case are below their relevant guideline/standard. The magnitude of changes to indicator compound emissions for SPM and PM_{10} are predicted to be high as the predicted concentrations for these two indicator compounds from the Application Case are above their relevant guideline/standard. However, the locations of these predicted high concentrations are limited to a small area just outside the LSA and contained within the RSA, along Ara Mooradian Way north of 211 Rd in a restricted area. The predicted effects are limited to the RSA, and therefore the geographic extent of changes to all indicator compounds is regional for the Application Case. Although there are planned stages for the closure phase beyond the Application Case (Phases 4-6), emissions of indicator compounds during these phases will be lower than the Application Case; therefore, the duration of effect is conservatively considered to be short-term. Criteria air contaminants will be emitted continuously or near-continuously during the Application Case, and therefore the frequency of effect is frequent. The likelihood of emissions from the Project changing indicator compound concentrations for the Application Case phases is high.

Based on the low to high magnitude, the regional geographical extent of the effect and the short-term duration, the overall residual adverse effect of the Application Case on air quality is determined to be not significant.

Table 6.2.1-17: Classification of Predicted Residual Adverse Effects on Air Quality for the Application Case

Indicator Compound	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Likelihood
SPM	Negative	High	Regional	Short-term	Frequent	Reversible	High
PM_{10}	Negative	High	Regional	Short-term	Frequent	Reversible	High
$PM_{2.5}$	Negative	Moderate	Regional	Short-term	Frequent	Reversible	High
NO_2	Negative	Moderate	Regional	Short-term	Frequent	Reversible	High
SO_2	Negative	Low	Regional	Short-term	Frequent	Reversible	High
CO	Negative	Low	Regional	Short-term	Frequent	Reversible	High

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; CO = carbon monoxide.

6.2.1.10 Monitoring and Follow-up

CNL's *Environmental Protection* (CNL 2023b) requires air quality concerns related to the Project be addressed. As part of this program, CNL requires contractors to conform to *Best Practices for the Reduction of Air Emissions from Construction and Demolition Activities* (Environment Canada 2005). In addition, this program provides air quality monitoring during decommissioning work to meet the applicable criteria.

Implementation of CNL's *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring, will continue for the Project. In addition, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project with the purposes to:

- verify effects predictions and compare actual with predicted effects;
- confirm effectiveness of mitigation and in doing so evaluate if alternate mitigation is required;
- provide information for use in adaptive management to address potential unforeseen effects; and
- demonstrate compliance with regulatory requirements.

This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical. It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Within this framework, modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS, including the findings from the Environmental Risk Assessment, the frequency of sampling may be increased and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized, or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals for modifications to the monitoring program and the rationale for the modifications will be communicated to the CNSC prior to implementation. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs.

CNL will continue to proactively seek, engage, and support meaningful discussions with First Nations and the Manitoba Métis Federation and communities of interest on issues and opportunities related to the Project, including the monitoring and follow-up program. For example, the Wabaseemoong Independent Nations expressed interest in and concern about air emissions and monitoring practices on the site currently and into the future. In response to this concern, CNL shared on-site and off-site monitoring locations on for the existing operation and indicated that monitoring results will be publicly available on their website. CNL has advanced its plans relative to monitoring and follow-up and has sent Wabaseemoong Independent Nations a list of monitoring activities and invited them to participate. CNL continues to pursue discussions with Wabaseemoong Independent Nations and Indigenous peoples and communities of interest on air quality monitoring and will continue to invite Wabaseemoong Independent Nations to participate in monitoring activities.

CNL has also had discussions with First Nations and the Manitoba Métis Federation on how future monitoring on the WL site could incorporate Indigenous interests, as well as discussion on participation and/or oversight by Indigenous peoples. CNL will continually evaluate both the process and the outcome of the ongoing engagement and communication activities, to address and manage issues as they arise.

Table 6.2.1-18: Monitoring and Follow up Programs for Air Quality

Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Air Quality	**Potential Source(s) of Effects:** ■ Closure activities will result in fugitive dust emissions **Proposed Monitoring:** ■ Application of aggregate to unpaved roads – a record will be kept of the date of each application of aggregate to unpaved roads. ■ Dust Control on Roads – a record will be maintained of dust control treatment for roads. ■ Site inspection – during periods of high dust susceptibility, regular inspections will be carried out to monitor the efficacy of dust mitigation and any potential concerns with regards to fugitive dust, and if required implementation of mitigation will be recommended. Environmental conditions will be recorded. ■ Confirmatory monitoring of total suspended particulates (PM_{10}) and radioactivity will be conducted during demolishing and other dust generating activities. **Trigger for Further Action:** ■ Investigation if parameters above predictions, applicable guidelines, thresholds or limits, or if actual number of vehicles/kilometres travelled exceeds the prediction on which emission estimates were based. ■ If high levels of dust are identified (qualitative), adjust dust suppression measures accordingly.	■ Verify that mitigation are being incorporated as planned and are effective. ■ Verify predictions are within air quality criteria. ■ Demonstrate compliance with regulatory requirements.	Through the closure phase.	■ Captured through the implementation of CNL's *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring and verification monitoring. ■ WL currently conducts industrial hygiene assessments of lead, asbestos and mould within facilities as part of the decommissioning planning process. ■ Emissions associated with NPRI reporting are estimated. Facility to ensure that NPRI reporting includes updated estimates.

PM_{10} = particles nominally smaller than 10 micrometres in diameter; NPRI = National Pollutant Release Inventory

6.2.1.11 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Air quality was selected as a VC as emissions from the Project activities have the potential to alter the existing air quality regime. Sagkeeng; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations did not identify additional valued components beyond air quality. The assessment endpoint for the air quality assessment are performance against criteria and thresholds for protection of human health and the environment. The measurement indicators for air quality include changes in ambient concentrations of indicator compounds in comparison to the provincial or federal ambient air quality criteria.

Residual effects from activities that occur during the Application Case have been identified as the primary linkage to potentially affect ambient air quality. During the Application Case, Project activities will result in emissions associated with the operation of vehicles and equipment, as well as material handling emissions from the demolition and grouting and temporary batch mixing plant or similar equipment. A summary of the predicted residual adverse effects for air quality, including associated mitigation, are provided and examples of mitigation practices implemented to limit predicted residual effects to air quality include:

- implementation of CNL's *Environmental Protection* (CNL 2023b) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring;
- on-site vehicles and equipment engines will meet a minimum of Tier 4 emission standards, where possible, and be maintained in good working order;
- limit idling of vehicles on-site and limit speed on roads; and
- use of tarps or 3-sided enclosures for raw material storage.

The predicted residual effects air quality were estimated to increase because of the Project. Fugitive dust from vehicle movement on paved roads is the largest contributor to SPM, PM_{10} and $PM_{2.5}$ emissions. Non-road equipment exhaust emissions are the largest contributors to NOx (as NO_2) and CO emissions. Finally, the largest contributor to SO_2 is fuel combustion for emergency power generators. Predicted concentrations for the Application Case are below applicable air quality guidelines and/or standards, with the exception of SPM and PM_{10} limited to a small area just outside the LSA and contained within the RSA, along Ara Mooradian Way north of 211 Rd in a restricted area. Following the methods described above, the residual effects from the Project on air quality was determined to be not significant (Table 6.2.1-19). This conclusion applies to the air quality interests and concerns raised by the engaged First Nations and the Manitoba Métis Federation, which were encompassed by the assessment (Table 6.2.1-1).

The *Management and Monitoring of Emissions* (CNL 2022) outlines the key management practices that limit air quality emissions effects, as well as the current monitoring requirements. Current and future monitoring of air quality was of interest to Indigenous peoples. CNL will continue to proactively seek, engage, and support meaningful discussions with First Nations and the Manitoba Métis Federation and communities of interest on issues and opportunities related to the Project, including the monitoring and follow-up program.

Table 6.2.1-19: Summary of Predicted Residual Adverse Effects for Atmospheric Environment Valued Components

Valued Compound	Assessment Endpoint	Residual Adverse Effects	Phase the Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation	Significance
Air Quality	Performance against criteria and thresholds for protection of human health and the environment	Closure activities will alter concentrations of indicator compounds, including: ■ use of vehicles and equipment that combust fuel and emit indicator compounds; ■ material handling, for grouting and demolition; ■ vehicles travelling on roads; ■ operation of batch mixing plant or similar equipment for grout production.	Closure Phase	■ Stage 1: Preparation for in situ disposal ■ Stage 2: Grouting of below-grade structures and systems ■ Stage 3: Removal of above-grade WR-1 structures and systems	■ Implementation of CNL's Environmental Protection Program and *Management and Monitoring of Emissions*, which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Implementation of dust management techniques to control dust generated by the Project, consistent with the Environmental Assessment Follow-up and Monitoring Program for the WL site. ■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. ■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include: ▪ wetting techniques during demolition to limit mobility of dust; ▪ wind restrictions during demolition to stop work or apply wetting techniques; and ▪ hydro seeding during backfilling and landscaping to reduce soil erosion. ■ Road watering and chemical dust suppressant when necessary. Dust suppressant is already used annually at the site for select unpaved roads. ■ Removal of accumulations of particulates (e.g., dirt) on road as soon as possible. Onsite vehicles and equipment engines will meet Tier 4 emission standards, where possible, and be maintained in good working order. ■ Limit idling of vehicles on-site and speed on roads. ■ Use of tarps or 3-sided enclosures for raw material storage.	Not Significant

6.2.2 Greenhouse Gases

6.2.2.1 Scope of the Assessment

Greenhouse gases have the potential to affect future climate as they contribute to the greenhouse effect by absorbing infrared radiation in the atmosphere, increasing temperature and changing weather patterns. The GHG assessment follows the overall environmental assessment approach and methods described in Section 6.1. The assessment is completed in the following primary steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Sections 6.2.2.3 Valued Components and Section 6.2.2.4 Assessment Boundaries) for the GHG assessment. The VCs, assessment endpoints and measurement indicators used to assess Project related changes to GHG, the spatial and temporal boundaries at which the assessment occurred, and, the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.2.2.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.2.2.6 Project Interactions and Mitigation). Project components and/or activities with the potential to release GHG are identified and mitigation options are presented to limit or avoid these effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described. Primary pathways were not identified for climate change; therefore, no residual effects are carried forward for further analysis and characterization.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the GHG assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 6.2.2.7). The purpose of this section is to evaluate the available literature and data used for the assessment and describe the level of certainty that can be placed on estimated emissions. This section will also identify how the uncertainty has been managed.
- **Step 6 – Classify and determine the significance of the predicted residual effects.** This step was not required as no residual adverse effects were identified in the GHG assessment.
- **Step 7 – Identify monitoring and follow-up** (refer to Section 6.2.2.8 Monitoring and Follow-up) required to confirm effects predictions and address uncertainty.
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.2.2.9 Conclusions) for GHG.

6.2.2.2 Indigenous Engagement Feedback – Key Interests and Concerns

While interest in how CNL manages GHG has been evident during engagement, no specific concerns regarding GHG emissions specific to the Project have been identified. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4 Indigenous Engagement.

6.2.2.3 Valued Components

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Climate change was selected as a VC for the GHG assessment as there is a potential for the Project activities to release GHG emissions that could contribute incrementally to climate change (Table 6.2.2-1). The mechanism by which the Project has the potential to contribute to global climate change is by the addition of GHG emissions. Greenhouse gases refer to a group of gases that build up in the atmosphere and have the potential to contribute incrementally to climate change.

Table 6.2.2-1: Valued Components for Greenhouse Gas Assessment

Valued Component	Rationale for Selection
Climate Change	This valued component, assessed through incremental changes in emissions of greenhouse gases, considers the potential of the Project to contribute to climate change.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. The assessment endpoint for climate change is comparison to provincial and national totals. Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on an assessment endpoint. Measurement indicators also provide the primary factors for discussing the uncertainty of effects on VCs and, subsequently, are the key variables for study in follow-up and monitoring programs. The measurement indicators considered in the climate change assessment include changes in concentrations of the following GHG emissions:

- carbon dioxide (CO_2);
- methane (CH_4); and
- nitrous oxide (N_2O).

There are no Project activities that are expected to emit sulphur hexafluoride (SF_6), perfluorocarbons (PFCs) or hydrofluorocarbons (HFCs); therefore, these compounds are not included in the GHG assessment. Greenhouse gas emissions are expressed as tonnes of equivalent CO_2 (CO_2e), calculated by multiplying the annual emissions of each indicator compound by its 100-year global warming potential. A single measure is used when evaluating effects, namely the maximum annual GHG emissions resulting from the Project activities in tonnes of CO_2e. The assessment endpoints and measurement indicators used in the climate change assessment are listed in Table 6.2.2-2.

Table 6.2.2-2: Assessment Endpoints and Measurement Indicators for the Greenhouse Gas Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Climate Change	Comparison of greenhouse gas emissions to provincial and national totals	Changes in greenhouse gas emissions (CO_2, CH_4 and N_2O) compared to provincial and national totals

CO_2 = carbon dioxide; CH_4 = methane; N_2O = nitrous oxide.

6.2.2.4 Assessment Boundaries

6.2.2.4.1 Spatial Boundaries

The spatial boundaries for the GHG assessment are considered to be beyond regional as the predicted residual adverse effect of GHG emissions is considered global in nature.

6.2.2.4.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) establish the timeframe during which Project effects are assessed. The temporal boundaries for the GHG assessment are the same as those defined for the air quality assessment (see Section 6.2.1.3.2 Temporal Boundaries).

6.2.2.4.3 Assessment Cases

The assessment cases are defined in the air quality assessment (Section 6.2.1.3.3 Assessment Cases). The GHG assessment includes evaluation of the Base Case and Application Case.

6.2.2.5 Description of the Environment

6.2.2.5.1 Methods

This section documents the methods, data and results that were used to assess the GHG emissions in the LSA and RSA.

Applicable Criteria

The relevant GHG emissions criteria include the provincial and federal emission levels. These emission levels are calculated using the assessment frameworks summarized below, followed by the baseline GHG emissions levels considered for the Base Case.

Technical Guidance on Reporting Greenhouse Gas Emissions, Environment and Climate Change Canada (November 2015)

The *Technical Guidance on Reporting Greenhouse Gas Emissions* (January 2023; the GHG Reporting Program [GHGRP] Guideline) provides direction in identifying if facilities are required to submit a GHG report to ECCC under the GHGRP, an overview of the reporting process, as well as technical information related to GHG emissions estimations, including identifying GHG emission sources subject to reporting. The GHGRP Guideline references GHG estimation methodologies from the United Nations Framework Convention on Climate Change and was developed by the Intergovernmental Panel on Climate Change. The GHGRP Guideline states that “there are no specific protocols to define how reporting companies must calculate their GHG emissions” and that facilities should choose estimation methods that are most appropriate for their particular industry but are

consistent with the guidelines adopted by the United Nations Framework Convention on Climate Change for preparing GHG inventories. The reporting threshold for the GHGRP is 10,000 tonnes of CO_2e.

There is no GHG regulatory program specific to Manitoba currently in place; however, Manitoba is in the process of developing a regulation for mandatory reporting of GHG emissions (IISD 2015). While the regulation is under development, Manitoba continues to rely on the federal GHGRP to collect GHG data for the large emitters and other GHG sources Manitoba covered through the National Inventory Report for Canada (Environment Canada 2014).

Baseline GHG Emissions Data

Existing GHG emissions are not measured; however, they are routinely estimated. For the purposes of this GHG assessment, federal and provincial reported GHG data is used to describe the GHG emissions.

6.2.2.5.2 Results

In 2015, Canada represented less than 2% of total global GHG emissions (ECCC 2019a). Therefore, any GHG emissions from the Project may be considered negligible on a global scale. The latest available federal and provincial facility reported GHG data were used to describe the background GHG emissions. The latest available federal and provincial data are from the 2017 reporting year (ECCC 2019b). The WL main campus was not required to report GHG emissions in 2014 under the Federal GHGRP; however, these numbers are reported within the CNL Annual Safety Review Report. Total federal and provincial GHG emissions are provided in Table 6.2.2-3.

Table 6.2.2-3: Baseline Greenhouse Gas Emissions

Source	GHG Emissions[a] (tonnes CO_2e)
Canada-wide 2017 GHG Emissions	716,000,000
Manitoba-wide 2017 GHG Emissions	22,000,000

GHG = greenhouse gases; CO_2e = carbon dioxide equivalent.

a) GHG emissions obtained from ECCC National Inventory Report 1990-2017: Greenhouse Gas Sources and Sinks in Canada (ECCC 2019b).

6.2.2.6 Project Interactions and Mitigation

6.2.2.6.1 Methods

This section describes the process by which interactions between Project components and activities and GHG were identified and evaluated. Potential effect pathways are identified, and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the Project and the environment by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce releases of GHG emissions. Environmental design features included design elements, best environmental practices, best available technologies, and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the engineering and environmental teams, combined with input from project-specific or regional engagement with other interested parties. The design features and/or mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage pathway –** pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change to concentrations of GHG emissions relative to Base Case values, and therefore would have no residual effects to climate change.
- **Secondary pathway –** the pathway could result in a measurable minor change to GHG emissions, but would have a negligible residual effect on climate change relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway –** the pathway is likely to result in an environmental change to GHG emissions relative to the Base Case and/or guideline values that could contribute to residual effects to climate change.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects to climate change were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to climate change through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways are carried forward for more detailed quantitative and/or qualitative effects analysis to characterize the residual effects of the Project on climate change.

6.2.2.6.2 Results

Pathways through which all components of the Project may interact with and result in releases of GHG emissions are provided in Table 6.2.2-4. The GHG emissions were estimated by considering the mitigation considered to be integral to the design and implementation of the Project activities. These mitigations, which are typical and consistent with best practices are presented in Table 6.2.2-4.

Table 6.2.2-4: Pathways Analysis for Greenhouse Gas Emissions

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Closure Phase ■ Stage 1: Preparation for in situ disposal ■ Stage 2: Grouting of below-grade structures and systems ■ Stage 3: Removal of above-grade WR-1 structures and systems	Vehicles and equipment used for closure activities combust fuel and emit GHGs.	■ Implementation of CNL's *Environmental Protection Program* and *Standard for Management and Monitoring of Emissions*, which includes operational control monitoring and environmental monitoring. ■ On-site vehicles and equipment engines will be maintained in good working order. ■ Limit idling of vehicles on-site.	Secondary

GHGs = greenhouse gasses.

6.2.2.6.2.1 No Linkage Pathways

There are no pathways identified as having no linkages to effects on climate change.

6.2.2.6.2.2 Secondary Pathways

In some cases, a Project interaction exists, but mitigation is expected to cause minor changes to the environment relative to the existing Base Case and/or guidelines. The following pathway is expected to result in a negligible release of GHG emissions and will not be evaluated further in the EIS.

- **Vehicles and equipment used for closure activities combust fuel and emit GHGs.**

The assessment of effects of releases of GHG from the Project on climate change involves two steps, namely the calculation of emission rates (which include the implementation of mitigation) and comparison to provincial and federal emissions. Details of the specific GHG emission source identification, calculation methods and sample calculations are provided in Appendix 6.2-2; a summary is provided below.

Identification of emission sources was completed by defining a reporting inventory boundary, which frames the GHG emission sources that are included in the assessment for the Project. The reporting inventory boundary is based on the GHGRP; and therefore, all stationary fuel combustion emissions and on-site mobile emissions have been included in the GHG assessment. The source categories included in the GHG assessment are:

- on-site stationary fuel combustion sources (including eight months of propane heating the WR-1 Building once it is disconnected from the grid);
- on-site stationary fuel combustion for generators; and
- on-site mobile fuel combustion sources.

All activities that potentially produce GHG emissions were evaluated to assess their relevance; however, only activities that emit GHGs were included in the assessment. Table 6.2.2-5 lists the activities that were not considered to be relevant (e.g., not included in the assessment) and the accompanying rationale.

Table 6.2.2-5: Emissions Not Included in the Greenhouse Gas Emissions Assessment

Activity/Compound	Rationale for Excluding from the GHG Assessment
Emissions from electricity consumption	Emissions from the electricity consumption from the Project are excluded from the greenhouse gas (GHG) assessment. This is consistent with the Greenhouse Gas Reporting Program (GHGRP) as only direct GHG emissions from sources operating at the facility are reported. Emissions from electricity consumption are considered as indirect emissions.
Emissions from transportation that occurred outside the Whiteshell Laboratories (WL) Site boundary	The transportation emissions to and from the site are excluded and should not be reported in accordance to the GHGRP. Only emissions from machinery used for the on-site transportation of materials or products used in the Project activities are included in the GHG assessment.
Snow removal equipment	Emissions from this equipment occur seasonally and are infrequent (i.e., only during the winter following a snowfall), and therefore, are not included in the representative scenario.
Upstream GHG emissions	A March 19, 2016 Notice in the Canada Gazette presented ECCC's proposed method for estimating the upstream GHG emissions associated with projects undergoing federal environmental assessments. Upstream GHG emissions are those resulting from all industrial activities from the point of resource extraction to the Project. The specific processes will vary by resource but generally include extraction, processing, handling and transportation. The final block volume of 15,000m^3 of grout is not planned to enable new soil or clay extraction or cement production facilities. Rather, the Project will be a customer for existing soil or clay supply and cement facilities and is unlikely to affect the Provincial supply and demand for these materials. Therefore, these indirect and upstream emissions have been excluded from the assessment. However, an upstream GHG assessment has been conducted and the resulting GHG emissions estimates are considerably lower than the ECCC's Strategic Assessment of Climate Change (ECCC 2020) threshold for requiring an upstream GHG assessment, therefore, the upstream GHG assessment (Golder 2020b) has not been included in this report but is available as a standalone document.
Land Clearing (Carbon Sinks)	There is no land clearing associated with the Project and therefore no negative impact on carbon sinks. During the Final Site Restoration stage, the reclaimed WL site will have a vegetative grass cover producing an overall positive impact on carbon sinks for the Project. The area of the reclaimed land will not result in a significant change in GHG emissions, and therefore, an assessment has not been conducted
Emissions from Accidents or Malfunctions	There are no potentially large sources of GHG emissions from accidents or malfunctions associated with the Project, and therefore, are not included in the assessment.
Emissions Intensity	There are no products manufactured as part of the Project to estimate an emissions intensity, and therefore, an intensity estimate is not included in the assessment.
Net-Zero Plan	A Net-Zero Plan is not required as the Project is not planning to operate beyond 2050.

The emission estimation methods follow the following guidance:

- ECCC's Technical Guidance on Reporting GHG Emissions (ECCC 2019a);
- Part 2 of ECCC's National Inventory Report 1990-2013[2] (Environment Canada 2015); and
- ON.20 (General Stationary Combustion) of the Ontario Guideline for Greenhouse Gas Emissions Reporting (MOECC 2015).

Table 6.2.2-6 summarizes the annual emission rates in tonnes per year for each activity at the Project. The global warming potential used to calculate GHG emissions in CO_2e correspond to ECCC's global warming potential (Environment Canada 2015).

Table 6.2.2-6: Summary of Annual Greenhouse Gas Emissions

Source	Annual GHG Emissions (tonnes CO_2e/year)			Annual GHG Emissions (tonnes CO_2e/year)
	CO_2	CH_4	N_2O	CO_2e
Mobile Equipment (Road and Non-Road)	11,886	17	693	12,595
Propane Combustion (including heating)	1,629	0.65	0.77	1,630
Emergency Power Generators	3	0.004	0.13	3
Total	13,517	17	694	**14,228**

Table 6.2.2-7 summarizes the annual overall emissions in tonnes of CO_2e for the Application Case. Project GHG emissions represent less than 0.01% of the Canada-wide total and less than 0.1% of the provincial total.

Table 6.2.2-7: Comparison of Greenhouse Gas Emissions from the Project to Manitoba and Canadian Emission Totals

Source	Annual GHG Emissions (tonnes CO_2e)
Project Emissions	14,228
Canada-wide GHG Emissions 2017 (b)	716,000,000
Manitoba-wide GHG Emissions 2017 (b)	22,000,000
Comparison of Project to Canada-wide GHG Emissions	<0.01%
Comparison of Project to Manitoba-wide GHG Emissions	<0.1%

b) GHG emissions obtained from ECCC National Inventory Report 1990-2017: Greenhouse Gas Sources and Sinks in Canada (ECCC 2019b).

Based on the comparison between the estimated annual emission to both the federal and provincial greenhouse gas emissions, the Project will result in minor releases of GHG emissions but is predicted to have a negligible residual effect on climate change and will not impact Canada's emissions reduction efforts.

[2] The ECCC National Inventory Report (1990-2013) was used as it presents a higher emission factor for N_2O from off-road diesel combustion.

6.2.2.6.2.3 Primary Pathways

No primary pathways are identified for the GHG assessment. Subsequently, there is no further residual effects classification and determination of significance.

6.2.2.7 Prediction Confidence and Uncertainty

The potential sources of uncertainty in the assessment of climate change are the accuracy and representativeness of the activity data and emission factors used to estimate GHG emissions:

- Combustion emissions from the propane-fired boiler based on an assumed maximum equipment firing rate and an assumed operating schedule.
- Combustion emissions from the WR-1 building heating using propane based on as assumed 8 month per year operating schedule. At the time of the assessment, it is unknown when the electric building heating systems will be taken offline for the WR-1 Building and replacement heating using propane has not been confirmed.
- Combustion emissions from diesel-fired emergency power generators based on assumed rating capacities, number of units, and operating schedule.
- Combustion emissions from diesel fueled mobile equipment (trucks, loaders, excavators etc.) based on assumed rating capacities, number of units, and operating schedules.

Uncertainty in the emissions estimates was reduced through continued discussion with knowledgeable personnel, comparison to similar projects, and using current (at the time of the assessment) emission factors.

6.2.2.8 Monitoring and Follow-up

CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects predictions and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical. The GHG monitoring activities will be incorporated into the Environmental Assessment Follow-up and Monitoring Program for the Project. Implementation of CNL's *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, emissions verification monitoring and environmental monitoring, will continue for the Project (Table 6.2.2-8).

In addition, air quality monitoring activities for the Project will be implemented as outlined in Section 6.2.1.9. It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Within this framework, modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS, the frequency of sampling may be increased, and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized, or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals for modifications to the monitoring program and the rationale for the modifications will be communicated to the CNSC prior to implementation. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs.

Table 6.2.2-8: Monitoring and Follow-up Programs for Greenhouse Gas Emissions

Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Climate Change	**Potential Source(s) of Effects:** ■ Closure activities will result in increased greenhouse gas emissions. **Proposed Monitoring:** ■ Fuel Usage – a record will be kept of the fuel usage related to the Project. **Trigger for Further Action:** ■ Investigation if parameters above applicable guidelines, thresholds or limits, or if actual number of vehicles/kilometres travelled exceeds the prediction on which emission estimates were based.	Verify that GHG emission rates used in the assessment are reasonable, but conservative. Monitoring results will be used for GHG reporting requirements.	Annual estimations and GHG reporting, as required during the closure phase.	Monitoring of GHG emissions is already completed as part of CNL's WL Effluent Verification and WL Environmental Monitoring Programs. No new monitoring is required for Project-specific GHG emissions.

6.2.2.9 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Climate change was selected as a VC as there is a potential for the Project activities to release GHG emissions that could contribute incrementally to climate change. The measurement indicator for the assessment includes changes in emissions of CO_2e and comparison to provincial and national GHG totals.

Project activities will result in GHG emissions associated with the operation of vehicles and equipment during the closure phase, the GHG emissions are estimated to be less than 0.1% increase in total provincial GHG emissions and less than 0.01% increase in total national GHG emissions. Based on the comparison between the estimated annual emission to both the federal and provincial GHG emissions, the Project will result in minor releases of GHG emissions but is predicted to have a negligible residual effect on climate change and will not impact Canada's emissions reduction efforts.

6.3 Geological and Hydrogeological Environment

6.3.1 Geology

This section of the Environmental Impact Statement (EIS) examines the potential residual effects of the Project on the geological environment (Section 6.3.1 Geology) and hydrogeological environment (Section 6.3.2 Hydrogeology).

6.3.1.1 Scope of the Assessment

This section focuses on geology, which includes bedrock, soils and geomorphology. The geology assessment follows the overall approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment was completed in the following steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Section 6.3.1.3 Valued Components and Section 6.3.1.4 Assessment Boundaries) for the geology assessment. The VCs and measurement indicators used to assess Project related changes to geology, the spatial and temporal boundaries at which the assessment occurred, and the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.3.1.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.3.1.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect geology are identified and mitigation options are presented to limit or avoid these effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the geology assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the geology assessment.
- **Step 6 – Classify and determine the significance of the predicted residual effects.** This step was not required as the geology VC is an intermediate component, which does not include an assessment endpoint to determine significance.
- **Step 7 – Identifying monitoring and follow-up** (refer to Section 6.3.1.7 Monitoring and Follow-up) required to confirm effects predictions and address uncertainty.
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.3.1.8 Conclusions) for geology.

6.3.1.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the geological environment assessment are summarized in Table 6.3.1-1. Other general concerns and questions raised during Indigenous engagement are documented in Section 4 Indigenous Engagement.

Table 6.3.1-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Geological Environment Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
How releases could be contained in the soil	Included in the environmental assessment	Changes to soil quality from groundwater during the post-closure phase are assessed in Section 6.3.1.6.2 Results.
Spills of contaminants to soil	Included in the environmental assessment	Accidental releases of liquid contaminants and potential to contaminate soil is discussed in Section 7.3.2 Spills and Leaks

6.3.1.3 Valued Components

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous people, or the public (The Agency 2018). Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations did not identify any additional valued components as it relates to the geological assessment. Geology, which includes bedrock, soils and geomorphology, is recognized as an important component of the environment that may be affected by the Project and changes to geology could, in turn, lead to effects on other VCs selected for assessment. For example, changes to the characteristics of geology, such as soil quality and quantity, have a large influence on the local and regional diversity, contributing to the abundance and distribution of plants and animals on the landscape. Changes to these characteristics by Project activities could affect terrestrial and aquatic ecosystem structure and function (Table 6.3.1-2).

Table 6.3.1-2: Valued Components for Geology Assessment

Valued Component	Rationale for Selection
Geology	Characteristics of geology, such as soil quality and quantity, bedrock and geomorphology, are important components that interact with other valued components (e.g., hydrogeology, hydrology and surface water quality) and if changed by Project activities could affect terrestrial and aquatic biodiversity.

Acknowledging that changes to geology are considered to be important aspects of the natural and human environment, geology is referred to as an intermediate component (i.e., it does not have an assessment endpoint). Changes to intermediate component VCs must be understood to facilitate assessment of Project interactions. The geology assessment, therefore, is analyzed for incremental and cumulative (if applicable) changes in the relevant measurement indicators associated with geology (Table 6.3.1-3). The assessment of geology focused on predicting changes in the concentrations of selected non-radiological compounds; radiological parameters are considered in Section 6.7 Human and Ecological Health. The changes are characterized in terms of magnitude, duration and geographic extent, but are not classified using rankings for effects criteria. The geology assessment also does not include the assessment of the significance of these changes; rather, results of the analysis of changes in measurement indicators for geology are provided to other disciplines for inclusion in their assessment (Table 6.3.1-3).

Table 6.3.1-3: Measurement Indicators for the Geology Assessment

Valued Component	Measurement Indicators	Discipline Assessments where Effects on Geology are Considered
Geology	■ Bedrock ■ Soil quality ■ Soil quantity ■ Geomorphology	■ Section 6.4.2 Surface Water Quality ■ Section 6.5 Aquatic Environment ■ Section 6.6 Terrestrial Environment ■ Section 6.8 Land and Resource Use

6.3.1.4 Assessment Boundaries

6.3.1.4.1 Spatial Boundaries

The spatial boundaries selected for the geology assessment are presented on Figure 6.3.1-1 and described below.

- **Site Study Area (SSA)** is the Whiteshell Reactor 1 (WR-1) Building and represents the Project footprint (i.e., where Project activities will be undertaken; 0.07 ha).
- **Local Study Area (LSA)** is defined as the area within which there is potential for measurable changes resulting from the proposed Project activities. The LSA is delineated by the boundaries of the groundwater model for the Project, which were selected based on groundwater elevation data and topography. The western boundary of the LSA is approximately 800 m west of the WR-1 Building and coincides with the inferred groundwater flow divide at the centre of the Winnipeg River. The northern boundary of the LSA is approximately 450 m north of the WR-1 Building and is parallel to the inferred direction of groundwater flow; the location of this boundary was selected as it follows a topographic divide and is south of the Lagoon Area. The southern boundary of the LSA is approximately 1,400 m south of the WR-1 Building and is parallel to the inferred direction of groundwater flow; the location of this boundary was selected as it coincides with a topographic divide and an inferred divide in groundwater flow. The eastern boundary of the LSA is located approximately 700 m east of the WR-1 Building and approximately 500 m east of the Whiteshell Laboratories (WL) main campus; this boundary is perpendicular to the inferred direction of groundwater flow and upgradient of the WR-1 Building (approximately 260 ha).
- **Regional Study Area (RSA)** is defined as the area within which the potential effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. The RSA is delineated by the WL site boundary (approximately 4,375 ha; Figure 6.3.1-1).

6.3.1.4.2 Temporal Boundaries

The temporal boundary of the assessment is the timeframe during which Project activities are occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project.

- **Closure Phase:** Preparation and implementation of in situ disposal (ISD), which includes preparation for ISD, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031.

  Post-closure Phase: The post-closure phase has two discrete periods: institutional control and post-institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue to demonstrate Whiteshell Reactor Disposal Facility (WRDF) performance is in compliance with the safety case assumptions and performance modelling. The 100-year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.3.1.4.3 Assessment Cases

The geology assessment has three assessment cases:

- **Base Case:** represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural and residential and recreational development. Current effects from the existing facilities and operations at the WL site, for example, are considered part of the Base Case. In addition, existing conditions of areas not affected by the WL site are also considered as part of the Base Case. Effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case.
- **Application Case**: represents predictions of the effects of the Base Case combined with the effects that may result from the Project. The Application Case considers potential effects from the Project during closure and throughout the post-closure phase.
- **Reasonably Foreseeable Development (RFD) Case**: represents the predictions of the cumulative effects of the Application Case, plus projects that are currently under application review or that have officially entered a regulatory application process and which overlap with the geology RSA. There are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the Comprehensive Study Report (AECL 2001). The Comprehensive Study Report indicated that existing effects on soils are limited to contaminated soils within affected lands on the WL site (see Section 6.3.4 of AECL 2001). Affected lands and associated contaminated soils will be remediated during the WL site decommissioning. As such, decommissioning of these structures is anticipated to positively affect geology. The end-state plan for the WL site is to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-state. Because RFDs are likely to positively affect the geology, an RFD Case is not presented as part of this assessment (Table 6.3.1-4).

Table 6.3.1-4: Reasonably Foreseeable Developments considered in the Geology Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes in situ disposal of the low-level waste trenches).	2016 to 2034	Yes – however, effects are considered to be positive and therefore, are not assessed
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – however, effects are considered to be positive and therefore, are not assessed

6.3.1.5 Description of the Environment

6.3.1.5.1 Methods

Baseline geology data were collected from the results of recent drilling and core logging at the WL main campus. Four new bedrock monitoring wells were installed in 2016 at depths ranging from 24 m to 42 m below-ground surface (10 m to 30 m below the top of the bedrock surface). Details on the drilling program, monitoring well installation and the borehole logs are described in the WR-1 Hydrogeological Study Report (Dillon 2018). The stratigraphic data collected from these boreholes were supplemented through the review of the following existing reports on the WL site:

- Geosynthesis for WR-1 Environmental Impact Statement (CNL 2022b).
- Load Bearing Test on Glacial Till, Test Pile and Bench Mark Locations, Whiteshell Nuclear Research Establishment, D-901-A-1 (AECL 1961).
- Hydrogeologic Regime of the Environmental Control Area and Vicinity, Whiteshell Nuclear Research Establishment, Manitoba, Preliminary Progress Report (Cherry et al. 1970).
- Hydrogeological Studies at a Subsurface Radioactive-Waste-Management Site in West-Central Canada, (Cherry et al. 1973).
- Review of the Hydrogeology of the Radioactive Waste Management Site (Robertson and Cherry 1985).
- Whiteshell Laboratories Decommissioning Project, Comprehensive Study Report (AECL 2001).
- Hydrogeology of the Waste Management Area, Lagoon and Landfill-Enhanced Monitoring Program, WL Decommissioning (AECL 2008).
- Whiteshell Laboratories Projects Branch Comprehensive Final Report on Installation of 7 Groundwater Monitoring Wells Nests (KGS Group 2016).

Dillon (2018) provides details on recent geological and hydrogeological investigations of the LSA, which (in part) involved drilling and instrumentation of seven monitoring well nests and a single monitoring well (16-8) that encompass a total of 33 monitoring wells. The monitoring well nests are named numerically (i.e., monitoring well nest 1 through monitoring well nest 7). Each monitoring well nest includes between 4 and 6 monitoring wells. Individual monitoring wells are named using the installation year, the monitoring well nest number and a letter indicating the relative depth (with “A” assigned to the shallowest monitoring interval). In the following sections, the term monitoring well nest is used to refer to the conditions observed throughout the group of monitoring wells, while individual monitoring well names are used to refer to conditions at a specific depth interval. The monitoring well names and geological units for each monitoring well nest is summarized in Table 6.3.1-5. Monitoring well nest locations are shown on Figure 6.3.1-2.

General descriptions of the geological setting and hydrostratigraphic units were based on the information contained in these reports along with publicly available literature and subsequently refined based on a review of lithologic descriptions, grain size data, geological surface topography, groundwater elevation data and hydraulic conductivity data to maintain consistency in unit assignments throughout the LSA. Specific refinements are detailed in Section 2.3.4. of the Groundwater Flow and Solute Transport Modelling Report (Golder 2021a). The overall conceptual model presented in the aforementioned documents was unchanged. Borehole logs and cross sections contained in these reports were used to infer stratigraphic boundary points (i.e., contact elevations

between geological surfaces) and construct overburden and stratigraphic unit thickness maps (isopachs), and to construct a cross-section for the RSA (Figure 6.3.1-8).

6.3.1.5.2 Results

6.3.1.5.2.1 Regional Geological Conditions

The region surrounding the RSA is underlain by the Precambrian rock of the Lac du Bonnet Batholith, part of the Superior Province of the Canadian Shield. The Lac du Bonnet Batholith consists of undifferentiated and partly foliated porphyritic granite and granodiorite (Everitt et al. 1996). The batholith trends southwest to northeast. The upper 200 m of the batholith consists primarily of pink hematite-bearing granite, underlain by a grey magnetite-bearing granite (Everitt et al. 1996). The batholith covers an approximate area of 1,400 km² (Chandler 2003). At the northeastern extent of the Lac du Bonnet Batholith (approximately 20 km north of the RSA) there is a sharp contact with the metavolcanic and metasedimentary rocks of the Bird River Greenstone Belt. The southern boundary of the Lac du Bonnet Batholith (approximately 4 km south of the RSA) is a gradational transition to gneisses and migmatites of the Winnipeg River Subprovince of the Canadian Shield. Approximately 25 km west of the RSA, the batholith becomes overlain by Paleozoic sedimentary rocks of the Western Canadian Sedimentary Basin. The batholith extends westward under the Paleozoic rocks of the Williston Basin and to the east, it pinches out to the west of Savant Lake (Beakhouse 1991). Regional bedrock geology is shown on Figure 6.3.1-3.

The batholith is associated temporally and spatially with several other felsic intrusive bodies of roughly the same exposed size and age (approximately 2.65 billion years old) in the Winnipeg River Subprovince including the Betula Lake and Medika plutons to the southeast. The relatively sparsely fractured characteristics of large portions of these bodies and of the Lac du Bonnet Batholith, are attributed at least in part to their intrusion at or near the end of regional deformation, and to prolonged cooling, which delayed the onset of brittle deformation. This was in part due to the size of the intrusive bodies and their proximity to each other and to the distance separating the intrusions regionally from later tectonic events in the Superior Province at the end of the Kenoran Orogeny (Everitt et al. 1996). The batholith intruded at a depth of 10-12 km, based on a comparison of isobaric minima in the normative quartz-albite-alkali feldspar system (CNL 2022b).

Faulting is known in the eastern end of the batholith, which is remote from the LSA. At site of the Underground Research Laboratory (URL) approximately 20 km from the WL site, extensive studies of the rock mass revealed the presence of shallow dipping (25° to 30°) short displacement thrust faults, which were termed fracture zones in the geologic investigations of the URL. Discolouration of the granite to deeper pink and red along with closely spaced subparallel fractures are characteristic of these zones (Brown et al. 1989).

Lineament studies were performed in the 1980s for the Lac du Bonnet Batholith, as was surface mapping of exposed outcrops (McCrank 1985; Tammemagi et al. 1980). Lineaments oriented in a northwest direction are noted to be present on the WL site; due to the amount of overburden it was not possible to discern other lineaments in the bedrock near WR-1. From rock outcrop mapping, the most common fracture set trends north-northeast (010° to 040°) and accounts for 28% of the sample population. The southeast set of fractures is oriented from 120° to 140° and accounts for 19% of the sample population. The east and south-southeast sets are less common and account for 12% and 13% of the sample population, respectively; they comprise fractures oriented from 080° to 100° and 160° to 180°, respectively.

Jointing and fracturing has been observed at various locations within the batholith and additional details are provided in the following sections pertaining to observations made in the LSA, with more detail provided in the Geosynthesis report (CNL 2022b). Observations of outcrops on the Lac du Bonnet Batholith indicates that fracture intensity (based on 7517 mapped fractures, infilled or open) averaged for the entire batholith is 1.5 fractures per metre. The intensity is based on average fracture spacing and number of fractures per metre. Data on fracture spacings was not nearly as complete nor as uniformly distributed throughout the mapped areas as the fracture intensity data. Spacing values show the rock to be less intensely fractured than fracture intensity values. The average spacing value, based on limited data, is 3.5 m between fractures with a standard deviation of 3.4 m. The fracture spacing values range from 0.8 to 22.8 m.

Everitt et al. (1996) noted that subvertical fractures are grouped into those striking north northeast (015° to 020°), those striking east southeast (110° to 130°) and those striking south southeast (160° to 170°). Locally significant groups strike south (180°) and northeast (035°). The first two groups show many characteristics of extension fractures, such as irregularity and lens-shaped infilling. Unequivocal right-hand strike-slip movement is visible on fractures striking south southeast; left-hand strike slip movement occurs on fractures striking northeast. These observations suggest a north northeast-trending compressive stress axis at the time of fracturing, similar to the stress field during the formation of later pegmatite dykes and quartz veins (Brown et al. 1989). In general, subvertical fractures are partially or completely filled with a combination of chlorite, iron oxides, carbonates and clay minerals.

There are no absolute dates between Early Proterozoic faults, pre-dating the epidotal alteration (2350 ± 60 million years [Ma]), and fracture infillings associated with Pleistocene (2.5 Ma to 11 thousand years before present [Ka]) glaciations, however dates from an unpublished report (Gascoyne et al. 1997) indicate dates of 404 ± 64 Ka ago and 475 ± 33 Ka ago. Illite (clay) from Fracture Zone 2 (approximately 400 m deep) at the URL gave an age of formation prior to 832 ± 1 Ma ago and an overprinted age post 510 ± 1 Ma ago.

Uranium dating of calcite contain older (but still largely Pleistocene calcite infillings) in major fracture zones, whereas near surface fractures contain mainly younger (<350 Ka) calcites. Ages commonly range from 20 Ka to 55 Ka but are more recent than 350 Ka ago. This demonstrates the long-term presence of water with elevated calcium levels slowly depositing calcium that lead to formation of calcium in pre-existing fractures.

The near surface mesoscopic fractures follow an orthogonal pattern in the upper tens of metres of the batholith implying a general extension of the ground. Many of the larger extension fractures also show evidence of normal movement, disrupting earlier low-temperature infillings such as calcite to form pathways for groundwater. The amount of water flow in these fractures will vary based of the amount of previous infilling, the degree of disruption of that infilling and local connectivity and local fracture frequency at a particular location on the batholith. As stated in Gascoyne et al (1997), all types of mesoscopic fractures studied appear to act as pathways for groundwater recharge to the main fracture zones at the URL site. It is not unreasonable to assume this is the case for fractures elsewhere within the batholith.

More geologically recent activity may relate to glacial deposition, with some glacial chatter marks having been filled by calcite, probably due to subglacial pressures (Gascoyne et al. 1997).

IF THIS MEASUREMENT DOES NOT MATCH WHAT IS SHOWN, THE SHEET SIZE HAS BEEN MODIFIED FROM: 25mm

This page intentionally left blank

The surficial geology in the RSA consists of glaciofluvial tills and outwash deposits and glacial lacustrine deposits associated with Glacial Lake Agassiz. Surficial deposits have been documented to be up to 25 m thick (AECL 2008). In the area surrounding the Winnipeg River, these deposits have been regionally subdivided into three main stratigraphic units (based on McPherson 1968). The units are listed from the top of bedrock, with the description used in the LSA in parenthesis, as follows:

- Glacial Till (also referred to as Basal Sand and Basal Till);
- Glacio-Lacustrine Clay (also referred to as Clay Till as the lower portion of this unit is derived from the Glacial Till); and
- Transitional Glacio-Lacustrine Clay (Clay) and Glacio-Fluvial and Glacio-Lacustrine Sandy Silt (Interbedded Silt and Clay).

Organic deposits are present at surface over much of the RSA (Figure 6.3.1-4) and range in thickness from 0.25 m to 2 m (AECL 2008). The thickness of the overburden deposits decreases to the east of the RSA where bedrock outcrops become more prevalent (near Pinawa), and glacial till is present at surface in some areas (approximately 15 km east of the eastern boundary of the LSA) (Figure 6.3.1-4). The units described above within the RSA are consistent in composition with those observed during the recent drilling program within the LSA as refined and described in the following sections; however, the thickness of these units can vary as a function of bedrock topography.

6.3.1.5.2.2 Local Geological Conditions

Local geological conditions are described generally for the RSA (based on historical information) to provide context and are described in more detail for the LSA (based on site-specific data from recent boreholes).

Bedrock Geology

Detailed information on bedrock lithology is available from the area adjacent to the Waste Management Area (WMA) and north of the WL main campus. As the bedrock lithology within the LSA is expected to be consistent with the lithology observed near the WMA, this detailed information is presented here to supplement the information from the LSA. In this area bedrock lithology has been generalized based on borehole observations at WN-1 and WN-2 (Figure 6.3.1-3). At these locations the bedrock is predominately a medium to coarse grained pink granite (typical of the upper surface of the Lac du Bonnet Batholith) to a depth of approximately 300 m, where it transitions to a pink granite to granodiorite. At both locations a zone of mixed granodiorite, granite and pegmatite with xenoliths of tonalite was noted between depths of approximately 50 m to 100 m (Lau and Bisson 1980a,b,c; Lau, Bisson and Auger 1982; Lau, Auger and Bisson 1985a,b). Borehole logs for the WN-series wells are shown on Figure 6.3.1-5.

At the WN boreholes, fracture zones were noted between 20 m and 150 m and between 395 m to 400 m. Fracture frequency for the WN-1 borehole is shown on Figure 6.3.1-5. Fractures encountered have dips, which range anywhere from subvertical to subhorizontal. All of the fractures in the interval 150 m to 375 m in WN-1 have dip angles ranging from 10° to 50°, and no subvertical fractures were intersected in this zone (Davison 1980). The decreasing number and frequency of fractures with depth is similar to what was found in investigations into the rock mass at the former AECL URL[1] (Brown et al. 1989). The similarities between the WN and URL portions of the Lac du Bonnet Batholith suggest that similar fracture patterns exist in at least the main portion of the batholith.

[1] The approximate location of the former AECL URL is shown on Figures 6.3.1-3 and 6.3.1-4. The URL has since been decommissioned.

Recent boreholes drilled in the vicinity of WR-1, extended several metres into the underlying bedrock. The core logs indicated that the shallow bedrock near WR-1 is dominated by pink to red-pink granite with mafic granolithic dykes and possibly layered xenolithic structures. Pegmatitic (larger grain size) granite was also encountered. Areas of the pink granite include altered red granite similar to more heavily altered and oxidized fractures similar to those found in fracture zones at the URL (Brown et al. 1989). This indicates some of the fractures encountered underwent hydrothermal alteration in the geologic past and have undergone extensive weathering alteration. The presence of clay infilling and drill core smoothed rock fragments from fractured rock in the cores further suggests potential water bearing fractures exist in the bedrock on the WL site.

Borehole 16-2E is to the east of WR-1, the borehole encountered bedrock at approximately 16 m, the rock type is a pink coloured syenogranite, monzogranite to tonalite with a granodioite dyke present from approximately 17 m depth below surface 20.5 m and a second dyke from approximately 22 m depth to the end of the borehole at 24 m. The upper surface of the rock appears heavily weathered at the unconformity of the rock and overlying sediments.

Borehole 16-4F is to the northwest of WR-1. The borehole encountered bedrock at 16.9 m and the rock type is largely a coarse-grained mafic dyke (identified as diorite) to the bottom of the borehole at approximately 26 m depth. There are approximately 26 fractures, in the 10 m of core, many of the core breaks and fractures are steeply oriented indicating the presence or past presence of sub-vertical fracturing in the dyke. The difference in rock type is an indication of the local variability found elsewhere in the batholith.

Borehole 16-7 is to the southwest of WR-1, the borehole encountered bedrock at 20.78 m. The rock is heavily weathered red-pink granite with red clay and gravel present in fractures. There are heavily fractured zones encountered at 21.13 m, at 22.71 m and 23.12 m depth. It is unknown from current drilling if these represent splays of a larger fracture zone, or are separate fractures, but their relatively close vertical distances suggest that they are part of an interrelated fracture zone structure. Below that the granite is K-feldspar rich with many healed fractures to the bottom of the borehole at 25.81 m. The composition of the fractures reflects similarities to the fracture zones encountered at the URL in terms of appearance and colouration/alteration.

Borehole 16-8A is to the northwest of WR-1, the borehole encountered bedrock at 12.19 m with alkali feldspar granite, red, porphyritic structure, deformation of structures and vertical fractures. The upper few metres of the borehole present vertical fractures and fractures with sand sized particles and clay. At approximately 29 m, the rock is syenogranite, red, medium-grained, with phanertic texture, deformation of structures, microvertical fractures throughout, the presence of vertical fractures decreases and quartz content increases. Borehole bottom is at 42.6 m.

Both open and closed factures were noted throughout the length of core logged for each borehole. Areas of the pink granite include altered red granite similar to more heavily altered and oxidized fractures similar to those found in fracture zones logged in WN-1 and WN-2. This indicates some of the fractures encountered were water bearing in the geologic past having undergone hydrothermal alteration and have undergone extensive weathering alteration. The presence of clay infilling and drill core smoothed rock fragments in the cores further suggests potential water bearing fractures exist in the bedrock on the WL site. The clay may represent alteration of early chlorite and epidote fracture fillings (Gascoyne et al. 1997).

Bedrock Topography

Bedrock topography at the LSA has been determined based on boreholes extended through the full overburden thickness to confirmed bedrock. These boreholes include the BHS 500-series wells in the Lagoon Area (AECL 2008) and the recently drilled boreholes in the WL main campus area (Dillon 2018), supplemented with the historical data (AECL 1961). Depth to auger refusal has not been found to be a reliable surrogate for depth to the bedrock surface at the WL site given the prevalence of large boulders in the basal overburden unit (Robertson and Cherry 1985). Bedrock topography varies from 245 to 257 metres above sea level and is generally gradually sloped towards the south west (and the Winnipeg River). A local bedrock high in the vicinity of boreholes 16-8 and 15-4 has been identified though recent coring. Bedrock topography mapping for the LSA is shown on Figure 6.3.1-6.

Surficial Soils

The LSA and RSA are located largely within the Agriculture Interpretation Block Area of Pinawa and a small portion within the Lac du Bonnet Block Area (MLI 2003). In general, the historical surficial soil distribution within the LSA and RSA is comprised of organics in areas of poor drainage and Glysolic and Chernozemic soils in areas with improved drainage. Soils developed on outwash sands and alluvial materials are typically Luvisolic (MLI 2003). Precambrian bedrock outcrops generally only have partial lichen and moss cover, although peat soil is common in depressions (AECL 2001). Most of the soils within the LSA have been disturbed. A summary of the dominant baseline soil types and substrates within the LSA and RSA are outlined in Table 6.3.1-6 and presented on Figure 6.3.1-7.

Table 6.3.1-6: Baseline Soil Types and Substrates within the Local Study Area and Regional Study Area

Soil Series	Soil Subgroup	Substrate/Parent Material	Area (ha)
Local Study Area			
$ZZ	Undifferentiated	Active Fluvial River Bed	35.0
LEV	Peaty Humic Luvic Gleysol	Moderately Calcareous Lacustrine Clay	98.6

THG	Gleyed Solinetzic Dark Gray Chernozem	Weakly Calcareous Lacustrine Clay	28.5
WHU	Dark Gray Luvisol	Strongly Calcareous, Moderately Fine Textured Alluvial Sediments	83.3
Regional Study Area			
$ZZ	Undifferentiated	Active Fluvial River Bed	16.2
BYH	Typic Mesisol	Deep Organic	1,290.5
FYL	Peaty Rego Humic Gleysols	Weakly to Moderately Calcareous Lacustrine Clay	206.1
LEV	Peaty Humic Luvic Gleysol	Moderately Calcareous Lacustrine Clay	574.2
LTI	Solinetzic Gray Luvisol	Moderately to Strongly Calcareous Lacustrine Clay	27.3
OOK	Terric Mesisol	Shallow Organic	1,084.5
THG	Gleyed Solinetzic Dark Gray Chernozem	Weakly Calcareous Lacustrine Clay	590.8
WHU	Dark Gray Luvisol	Strongly Calcareous, Moderately Fine Textured Alluvial Sediments	491.1
WOG	Orthic Gray Luvisol	Coarse Grained Outwash	60.7

Source: MLI 2003.

Drainage ranges from well-drained, coarse-textured soils to poorly and very poorly-drained organic soils in lower elevation positions. Coarse-textured soils, with higher initial total porosity (e.g., WOG – Orthic Gravy Luvisol), are relatively resistant to compaction compared to finer textured soils (e.g., THG - Gleyed Solinetzic Dark Gray Chernozem, LEV - Peaty Humic Luvic Gleysol, WHU - Dark Gray Luvisol); these soils are, however, prone to wind erosion. Soil erosion risk is a concern for disturbed soils because the sparse vegetation cover exposes soil materials to the elements (e.g., wind and water). In areas of organic soils that are not deep (e.g., OOK - Terric Mesisol) and organic surface horizons are removed and subsurface materials and exposed, the water erosion potential of the underlying material would be low if sandy and moderate if silty. Areas containing organic materials will have a low sensitivity to wind erosion.

Surficial Geology

The surficial geology of the LSA is similar to that observed in the RSA, consisting of (from the bedrock upwards):

- Glacial Till (also referred to as Basal Sand and Basal Till);
- Glacio-Lacustrine Clay (also referred to as Clay Till as the lower portion of this unit is derived from the Glacial Till); and
- Transitional Glacio-Lacustrine Clay (Clay) and Glacio-Fluvial and Glacio-Lacustrine Sandy Silt (Surficial Interbedded Silt and Clay).

A cross-section through the LSA is shown on Figure 6.3.1-8.

Glacial Till (also referred to as Basal Sand or Basal Till)

Bedrock is overlain by a glacial till (referred to also as basal sand, silty sand till or basal till in other WR-1 in situ disposal documents) throughout the majority of the RSA. The till varies from a silty coarse sand till to a clean medium to coarse sand (Cherry et al. 1970) and boulders are common above the bedrock surface. This unit is referred to as the “basal sand” in the area of the WR-1 Building (Dillon 2018) due to the increased sand content observed in this unit in other areas of the SSA (primarily the WMA). Based on its grain-size distribution and hydraulic conductivity characteristics within the area of WR-1 it is not considered to be representative of sand.

Based on the descriptions provided by McPherson (1968) and Robertson and Cherry (1985), the basal unit is characterized by variability in grain size. Results of grain size analysis on samples of this unit taken from the recently drilled boreholes in the vicinity of WR-1 (KGS Group 2016; plotted on Figure 6.3.1-9) indicated that this unit is primarily comprised of silt (content ranged from 26% to 56%), with most remaining particles categorized as fine sand (15% to 32%) and clay (5% to 24%). Water content for this unit ranged from 9% to 27%.

In the WMA to the north of the LSA, this unit has been found to vary in thickness from 1 m to 7 m thick (AECL 2008). At the LSA, this unit varies in thickness from 3.6 m to 8.3 m. In other areas of the RSA this unit appears to thin towards the Winnipeg River; however, surrounding the SSA this unit appears to be thickest to the southwest and thins to the north. This unit is thinnest over the local bedrock high in the vicinity of monitoring well nest 4 and borehole 16-8. A basal sand isopach is shown on Figure 6.3.1-10.

Glacio-Lacustrine Clay (also referred to as Clay Till)

The basal sand is overlain by a clay till unit containing sand and silty sand seams. The bulk porosity of this unit in the WMA was determined to be 0.23 indicating a high degree of consolidation (Robertson and Cherry 1985). This value is based on three samples of “clay loam” collected near the WMA as documented in Gillham et al. (1981). No porosity measurements have been completed in the LSA. Results of grain size analysis on samples of this unit taken from the recently drilled boreholes in the vicinity of WR-1 (KGS Group 2016; plotted on Figure 6.3.1-9) indicated that this unit is primarily comprised of clay (content ranged from 4% to 76%) and silt (21% to 57%) with most remaining particles categorized as fine sand (6% to 55%). Gravel content in upwards of 7% to 9% was noted in some samples. Water content for this unit ranged from 26% to 59%.

In the WMA, this unit has been found to vary in thickness from 2 m to 5 m (AECL 2008). In the LSA, this unit varies in thickness from 3 m to 7 m. The clay till is generally thinnest in the central portion of the LSA and thickens to the northwest and southwest towards the Winnipeg River. A clay till isopach is shown on Figure 6.3.1-11.

Transitional Glacio-Lacustrine Clay (Clay) and Glacio-Fluvial and Glacio-Lacustrine Sandy Silt (Surficial Interbedded Silt and Clay)

A glacio-lacustrine clay unit has been found to overlie the clay till unit throughout the LSA. This unit is transitional, with the lower portion more laminated with silty interbeds, and the upper portion more massive. A thin surficial interbedded silt and clay unit overlies these clays. These units have been grouped given their similar properties and relative thinness of the surficial unit.

Results of grain size analysis on samples of this unit taken from the recently drilled boreholes in the vicinity of WR-1 (KGS Group 2016; plotted on Figure 6.3.1-9) indicated that this unit is primarily comprised of clay (content ranged from 44% to 92%), with the majority of remaining particles categorized as silt (6% to 55%). In all samples less than 5% of the material was categorized as having a grain size equivalent to fine sand or larger. Water content for this unit ranged from 26% to 59%.

In the WMA this unit has been found to vary in thickness from 2 m to 8 m and is thickest in the Lagoon Area (AECL 2008). In the LSA, this unit is relatively uniform in thickness, varying from 5.5 m to 7.3 m. This unit is inferred to be absent adjacent to the Winnipeg River due to the erosional drop in topography towards the river. An isopach of the clay till and surficial silt and clay unit is shown on Figure 6.3.1-12. Contouring of this isopach is affected by the nature of the Digital Elevation Model for the LSA.

Geomorphology

The surficial deposits in the RSA consist of glaciofluvial tills, outwash deposits and glacial lacustrine deposits that originated from Wisconsin glaciations of the Pleistocene epoch and associated stages of the Glacial Lake Agassiz (McPherson 1968; Cherry et. al 1970). The basal overburden unit was deposited near the glacier front during glaciation, whereas the overlying clay till was deposited during an episode of glacial advance from the northwest (McPherson 1968; Robertson and Cherry 1985). Final deglaciation in the RSA occurred between 12,000 and 13,000 years before present. Glacial Lake Agassiz, which formed during deglaciation, inundated the RSA until approximately 9,500 years before present. The lacustrine clay unit was deposited in an early deep water phase of Glacial Lake Agassiz. Surficial silt, sand and gravel materials were formed during a late shallow water phase of Glacial Lake Agassiz (Robertson and Cherry 1985). After the final drainage of Glacial Lake Agassiz, there has been some aeolian reworking of the uppermost sediments, though the overall stratigraphic sequence remains unchanged.

To the west of the LSA the overburden sequence has been partially incised by the Winnipeg River. Based on the available mapping of surficial geology, fluvial deposits associated with the Winnipeg River are not known to be found in the RSA indicating a relatively consistent lateral position of the river following drainage of Glacial Lake Agassiz. The current river level (which is controlled upstream via the Seven Sisters Generating Station) is approximately 10 m below the top of the adjacent eastern riverbank near the WL site.

Erosion potential for the WL site and surrounding area has been mapped based on the universal soil loss equation as being moderate for the gently sloped region near the Winnipeg River, and negligible for remaining portions of the WL site (Agriculture and Agri-Food Canada 1999). It is noted that this method applies to sheet erosion (i.e., rain-derived) and does not necessarily apply to riverbank erosion. Erosional features have been found along the banks of the Winnipeg River.

The Winnipeg River hosts six hydroelectric dams, as well as many lakes, with flows controlled by the Lake of the Woods Control Board. This watercourse is highly controlled and monitored and will be for the foreseeable future. Thus, the position of the Winnipeg River is assumed to remain close to its current placement on the landscape for the foreseeable future (Golder 2021b).

The uncertainty in future erosional changes in the Winnipeg River was identified in the Geosynthesis Report (CNL 2022b) Table 12 – Geoscience Verification Plan. To address the uncertainty in future geomorphological changes to the river and dam a simulation was completed to evaluate the potential changes to mass loadings resulting from a low river stage condition (i.e., higher hydraulic gradient between the WRDF and Winnipeg River due to lowering of the downstream river head boundary, which controls outflow in the model). The low river stage simulation had a minor influence on the simulated groundwater flow rates through the WRDF and local geosphere, though the change in hydraulic gradient in the bedrock pathway resulted in higher groundwater velocities and increased peak mass loading rates. The increases in peak mass loading rates were greatest for those solutes found outside of the reactor core (i.e., those not released through corrosion). Details of the simulation are provided in Section 6.5 Local Hydrogeology of the Decommissioning Safety Assessment Report (Golder 2021b).

6.3.1.5.2.3 Seismic

The Lac du Bonnet batholith remained distant from tectonic events in the Superior Province at the end of the Kenoran Orogeny (approximately 2.65 billion years ago; Gascoyne et al. 1997). Faulting is known in the eastern end of the batholith, which are attributed to this event and that may contribute to local features and perhaps river orientation; however, there is no recent activity in the region. Based on a detection level of 2.5 on the Richter scale, the WL area and the southern two-thirds of Manitoba are aseismic. Detailed information on earthquakes that have occurred in Canada is contained in publications of Earthquakes Canada of Natural Resources Canada and their predecessor organizations.

A seismic zoning map for Canada has been developed on the basis of these studies and is used in the National Building Code of Canada (NBCC) 2015 (NRCan 2019). The seismic hazard maps are derived from statistical analysis of past earthquakes and from advancing knowledge of Canada's tectonic and geological structure. On the maps, seismic hazard is expressed as the most powerful ground motion that is expected to occur in an area for a given probability level. Contours delineation regions likely to experience similarly strong ground motions. Earthquakes Canada provides information on recent and historical earthquakes. The results support the NBCC classification that seismic activity has not been noted or recorded in Manitoba over nearly a 400-year period.

A seismic hazard analysis was completed for the WL site. In 1995, the NBCC placed the WL site (and all of Manitoba) within a Seismic Zone 0, a zone that has a probability of exceedance of 0.0021. The peak ground acceleration (i.e., the maximum acceleration that a rigid structure would experience if it was located on bedrock) data from NBCC was considered for the years 2005, 2010 and 2015. The trend since 2005 is that for every probability of exceedance, the seismic hazard at the WL site has decreased (NBCC 2015). For the 1 in 10,000-year probability of exceedance, the peak ground acceleration is approximately 0.10. Comparatively, the 0.10 peak ground acceleration represents a light (almost moderate) earthquake for which one wouldn't normally expect structural damage for NBCC designed building and components. There could be some non-structural damage such as fine cracking on non-ductile non-structural elements (e.g., plaster or drywall). Structures that could experience damage due to this size of earthquake are those located on soils that are susceptible to amplification and/or have quite low natural frequencies. These structures man have characteristics that make them susceptible to earthquakes (e.g., tall structures will no bracing or shear walls). Conventionally designed structures using ductile materials (e.g., steel or reinforced concrete) following good engineering practices that incorporate bracing/shear walls, symmetric geometry, low horizontal eccentricity are not likely to be damaged by this level of earthquake (CNL 2022b).

6.3.1.5.2.4 Liquefaction

Liquefaction occurs when vibrations or water pressure within a mass of soil cause the soil particles to lose contact with one another. As a result, the soil behaves like a liquid, has an inability to support weight and can flow down even gently slopes. This condition is usually temporary and is most often caused by an earthquake vibrating water-saturated fill or unconsolidated soil. Liquefaction is possible for cohesionless soils for M=4 to 6 earthquakes, which can produce ground shaking levels up to VIII on the Modified Mercalli Intensity. Liquefaction is therefore not deemed to be an issue for the WL site due to the aseismic conditions of Eastern Manitoba. The soil properties of the WL site also indicate that liquefaction would not be an issue. Cone penetration testing has been completed at site to assess the liquefaction potential of the overburden soils at the WL site. In general, the high plastic clayey overburden soils present at the site are not susceptible to cyclic liquefaction (KGS Group 2019).

6.3.1.6 Project Interactions and Mitigation

6.3.1.6.1 Methods

This section describes the process by which interactions between Project components and activities and geology were identified and evaluated. Potential effect pathways are identified, and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the Project and the environment by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the Project to eliminate and/or reduce adverse effects to geology. Environmental design features included Project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project's engineering and environmental teams, combined with input from Project-specific or regional engagement with other interested parties. The environmental design features and/or mitigation were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage pathway –** pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects to geology.
- **Secondary pathway –** the pathway could result in a measurable minor environmental change, but would have a negligible residual effect on geology relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway –** the pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects to geology.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to geology through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways are carried forward for more detailed quantitative and/or qualitative effects analysis to characterize the residual effects of the Project.

6.3.1.6.2 Results

Pathways through which all stages of the Project may interact with and result in changes to measurement indicators for geology is provided in Table 6.3.1-7. As mentioned previously, geology includes bedrock, soils and geomorphology. Below-ground, no decommissioning activities will extend beyond the outer wall of the WR-1 Building. As such, the Project is not expected to interact with bedrock or geomorphology; therefore, no pathways are identified in Table 6.3.1-7 for bedrock or geomorphology.

Table 6.3.1-7: Pathways Analysis for Geology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Construction of temporary supporting infrastructure during decommissioning (e.g., batch mixing plant or other similar equipment for preparation of grout)	Loss or alteration of soil quantity and quality from construction of temporary supporting infrastructure.	■ Temporary supporting infrastructure will be located within the WL main campus (i.e., previously disturbed and developed). ■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the WL site will be used during decommissioning activities around disturbed areas, where appropriate.	Secondary
General Project activities during the closure phase	Changes in soil quality from changes in air quality. General activities that require the use of vehicles and equipment that combust fuel and emit criteria air contaminants. These activities involve material handling, vehicles travelling on roads and wind erosion of stockpiles that will result in fugitive dust emissions.	Implementation of CNL's *Management and Monitoring of Emissions*, which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Implementation of the dust management techniques for the Project. ■ On-site vehicles and equipment engines will meet a minimum of Tier 3 emission standards, where possible, and be maintained in good working order. ■ Limit idling of vehicles on-site. ■ Use enclosure for the raw material handling.	Secondary
Long-term performance during the post-closure phase	Changes to groundwater quality during the post-closure phase may affect soil quality.	■ The concrete cap and engineered cover to be placed over the decommissioned WR-1 Building is designed to limit infiltration.	Secondary

6.3.1.6.2.1 No Linkage Pathway

There were no “no linkage” pathways identified to effects on geology.

6.3.1.6.2.2 Secondary Pathways

- **Changes to groundwater quality during the post-closure phase may affect soil quality.**

After below-grade grouting has been completed, a concrete cap and engineered cover will be installed over the footprint of the WRDF. The concrete cap and engineered cover design will include an appropriate slope to achieve drainage off the surface, which will limit infiltration, surficial erosion and enhance the stability of the concrete cap and engineered cover. The concrete cap and engineered cover will be designed to mitigate moisture infiltration into the WRDF and hence limit leakage through the grouting to groundwater, and subsequent changes in soil quality. Environmental monitoring will be completed throughout the institutional control period to confirm that the WRDF barriers are functioning as intended. This monitoring will be integrated into the overall CNL WL Groundwater Monitoring Program and will be compliant with *CSA N288.7-23: Groundwater Protection and Monitoring Programs for Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2023). Overall, changes to soil quality from groundwater quality are predicted to have a negligible residual effect on geology.

- **Loss or alteration of soil quantity and quality from construction of temporary supporting infrastructure.**

The Project will require the construction of temporary infrastructure (e.g., batch mixing plant or other similar equipment for preparation of grout) to support the ISD of the WR-1 Building. Temporary infrastructure will be located within the WL main campus that is previously disturbed and developed, limiting potential effects to soil quality and quantity. Erosion and sediment control practices (e.g., silt fences, runoff management) already in place at the WL site will be used during decommissioning activities around disturbed areas, where appropriate. As such, changes to soil quality and quantity from construction outside the WR-1 Building are predicted to have a negligible residual effect on geology.

- **Changes in soil quality from changes in air quality. General activities that require the use of vehicles and equipment that combust fuel and emit criteria air contaminants. These activities involve material handling, vehicles travelling on roads and wind erosion of stockpiles that will result in fugitive dust emissions.**

Deposition of particulates has the potential to affect local soil quality. Decommissioning activities from the Project will generate air and dust emissions such as carbon monoxide (CO), oxides of sulphur (SO_x includes sulphur dioxide [SO_2]), oxides of nitrogen (NO_x includes nitrogen dioxide NO_2), particulate matter ($PM_{2.5}$) and suspended particulate matter (SPM). Air emissions such as SOx and NOx can result from the use of fossil fuels in generators, vehicles and machinery. Vehicle exhaust and fugitive dust from roads is the largest contributor to particulate matter (SPM, PM_{10} and $PM_{2.5}$) during decommissioning activities.

Examples of mitigation practices implemented to limit predicted residual effects to air quality (and subsequently soil quality) include:

- implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022a), which includes operational control monitoring, air verification monitoring and environmental monitoring;
- implementation of the dust management techniques;
- on-site vehicles and equipment engines will meet a minimum of Tier 3 emission standards, where possible, and be maintained in good working order;
- limit idling of vehicles on-site and limit speed on roads; and
- use of tarps or 3-sided enclosures for raw material storage.

With the implementation of CNL's *Management and Monitoring of Emissions* and through the implementation of the dust management techniques for the Project, concentrations of particulate matter (SPM, PM_{10}, $PM_{2.5}$), SO_2, NO_2 and carbon monoxide are all predicted to be lower than applicable air quality guidelines/standards during the closure phase of the Project (Section 6.2.1.6.2 Application Case Results). As such, air and dust emissions and subsequent deposition are expected to result in minor and local changes to soil quality relative to Base Case conditions. Therefore, this pathway was determined to have a negligible residual effect on geology.

6.3.1.6.2.3 Primary Pathways

No primary pathways were identified as having residual effect on geology. As such, the residual effects analysis and determination of significance is not completed for the assessment of geology.

6.3.1.7 Monitoring and Follow-up

CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects predictions and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical. Monitoring and follow-up programs specific to soil quality are not identified for the Project as there are no predicted residual effects to soil quality; rather, monitoring will be implemented for other disciplines to verify effects predictions for soil quality. For example, environmental monitoring will be completed throughout the institutional control period to confirm that the WRDF barriers are functioning as intended. This monitoring will be integrated into the overall CNL WL Groundwater Monitoring Program to verify that changes to soil quality as a result of groundwater are negligible. In addition, CNL's *Management and Monitoring of Emissions* will include monitoring objectives air quality to verify that air emissions during closure have a negligible effect on soil quality.

It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Within this framework, modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS, the frequency of sampling may be increased and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized or has been reduced to a level where it is no longer considered relevant with respect to regulatory requirements or community concerns.

Any proposals for modifications to the monitoring program and the rationale for the modifications will be communicated to the CNSC prior to implementation. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs.

6.3.1.8 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous people, or the public (The Agency 2018). Geology, which includes bedrock, soils and geomorphology, is recognized as an important component of the environment that may be affected by the Project and changes to geology could, in turn, lead to effects on other VCs selected for assessment. Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations did not identify any additional VCs as it relates to the geological assessment. Acknowledging that changes to geology are considered to be important aspects of the natural and human environment, geology is referred to as an intermediate component. Results of the analysis of changes in measurement indicators for geology are provided to other disciplines for inclusion in their assessment.

Potential effects on geology are limited to changes in soil quantity and quality as a result of construction of temporary supporting infrastructure (e.g., batch mixing plant or other similar equipment for preparation of grout) for the Project, and changes to soil quality from air emissions and groundwater transport from the WRDF. Mitigation and environmental design features implemented for the Project are well-understood and include existing practices at the WL site. In addition, monitoring will be implemented for air quality and hydrogeology (groundwater quality and quantity) to verify effects predictions for soil quality. Consequently, no residual effects on geology are predicted as a result of the Project.

6.3.2 Hydrogeology

This section of the Environmental Impact Statement (EIS) examines the potential residual effects of the Project on the hydrogeological environment.

6.3.2.1 Scope of the Assessment

This section focuses on hydrogeology and follows the overall approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment was completed in the following steps:

- **Step 1 – Identify Valued Components (VCs) and defines the spatial boundaries, temporal boundaries and assessment cases** (refer to Sections 6.3.2.3 Valued Components and 6.3.2.4 Assessment Boundaries) for the hydrogeology assessment). The VCs and measurement indicators used to assess Project-related changes to hydrogeology; the spatial and temporal boundaries at which the assessment occurred; and the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.3.2.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.3.2.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect hydrogeology are identified and mitigation options are presented to limit or avoid these effects. A pathways analysis is then used to focus on key interactions between the Project and determine if mitigation, can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described. Primary pathways that may lead to residual effects to hydrogeology after incorporating mitigation are carried forward to Steps 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 6.3.2.7 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to hydrogeology from primary effect pathways. The analysis results are presented, including the characterization of: (i) residual incremental effects of the Project and the effects of the Project in combination with past and present developments on hydrogeology (Application Case); and (ii) residual effects of the Project in combination with past and present developments, as well as other reasonably foreseeable developments (Reasonably Foreseeable Development Case). A key outcome of this section is the predicted effects to hydrogeology that are passed on to other VCs for inclusion in their assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 6.3.2.8 Prediction Confidence and Uncertainty). Evaluate the available literature, data and models used for the assessment, and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.

- **Step 6 – Classify and determine the significance of the predicted residual effects.** This step was not required as the hydrogeology VC is an intermediate component which does not include an assessment endpoint to determine significance.
- **Step 7 – Identifying monitoring and follow-up** required to confirm effects predictions and address uncertainty (refer to Section 6.3.2.9 Monitoring and Follow-up).
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** of residual effects on hydrogeology (refer to Section 6.3.2.10 Conclusions).

6.3.2.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the hydrogeology assessment are summarized in Table 6.3.2-1. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4.0 Indigenous Engagement.

Table 6.3.2-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Hydrogeology Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
Effects on Groundwater ■ Groundwater releases to surface water ■ How groundwater releases could be contained in the soil ■ Long-term effect on surface water quality ■ Future releases of hazardous and radioactive material	Included in the environmental assessment.	Effects on groundwater quality are described in Section 6.3.2.7 Residual Effects Analysis. Long-term effects of groundwater on the Winnipeg River are considered under Surface Water Quality (Section 6.4.2.7 Residual Effects Analysis).
Effects on the Winnipeg River ■ Discharges that relate to the Winnipeg River ■ Potential for future releases of hazardous and radioactive material into the Winnipeg River through groundwater	Included in the environmental assessment.	Effects of groundwater on the Winnipeg River are considered under Surface Water Quality (Section 6.4.2.7 Residual Effects Analysis).
Monitoring ■ Monitoring after decommissioning	Included in the environmental assessment. As a result of engagement on the Project's follow-up monitoring program thus far, CNL has committed to adding additional ground monitoring well(s) between the WR-1 reactor and the Winnipeg River as requested by the Red River Métis.	Information on the monitoring program is available in Section 6.3.2.9 Monitoring and Follow-up. This commitment has been added to Section 6.3.2.9 Monitoring and Follow-up and Section 11.0 Summary of Monitoring and Follow-up Programs.

6.3.2.3 Valued Components

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Hydrogeology is recognized as an important component of the environment that may be affected by the Project. Acknowledging that changes to hydrogeology could lead to effects on other VCs, hydrogeology is referred to as an intermediate VC (i.e., it does not have an assessment endpoint). For example, changes to the characteristics of groundwater quality from release of solutes as the grout and reactor components gradually deteriorate may have a influence on surface water quality, which in turn can affect terrestrial and aquatic biodiversity and human health (Table 6.3.2-2). Indigenous engagement confirmed the importance of effects to hydrogeology. Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations were concerned that the Project may affect groundwater quality.

Table 6.3.2-2: Valued Components for Hydrogeology Assessment

Valued Component	Rationale for Selection
Hydrogeology (groundwater quality and quantity)	Characteristics of hydrogeology, such as groundwater quantity and quality are important components that interact with other valued components (e.g., hydrology and surface water quality) and if changed by Project activities could affect terrestrial and aquatic biodiversity and human health.

Changes to intermediate VCs must be understood to facilitate assessment of Project interactions. The hydrogeology assessment, therefore, is analyzed for incremental and cumulative (if applicable) changes in the relevant measurement indicators associated with hydrogeology (Table 6.3.2-3). The changes are characterized in terms of magnitude, duration and geographic extent, but are not classified using rankings for effects criteria. The hydrogeology assessment also does not include the assessment of the significance of these changes; rather, results of the analysis of changes in measurement indicators for hydrogeology are provided to other disciplines for inclusion in their assessment (Table 6.3.2-3).

Table 6.3.2-3: Assessment Endpoints and Measurement Indicators for the Hydrogeology Assessment

Valued Component	Measurement Indicators	Discipline Assessments where Effects on Hydrogeology are Considered
Hydrogeology	■ Groundwater flow patterns and discharge rates (groundwater quantity). ■ Groundwater table elevations (groundwater quantity). ■ Peak solute mass loadings of contaminants in groundwater to the Winnipeg River (groundwater quality).	■ Section 6.4 Surface Water Environment. ■ Section 6.5 Aquatic Environment. ■ Section 6.6 Terrestrial Environment. ■ Section 6.7 Human and Ecological Health.

6.3.2.4 Assessment Boundaries

6.3.2.4.1 Spatial Boundaries

The spatial boundaries selected for the hydrogeology assessment are presented on Figure 6.3.2-1. These boundaries coincide with those used in the geology assessment and are described below:

- **Site Study Area (SSA)** is the Whiteshell Reactor 1 (WR-1) Building and represents the Project footprint (i.e., where project activities will be undertaken; 0.07 ha).
- **Local Study Area (LSA)** is defined as the area within which there is potential for measurable changes resulting from the proposed Project activities. The LSA is delineated by the boundaries of the groundwater model for the Project, which were selected based on groundwater elevation data and topography. The western boundary of the LSA is approximately 800 m west of the WR-1 Building and coincides with the inferred groundwater flow divide at the centre of the Winnipeg River. The northern boundary of the LSA is approximately 450 m) north of the WR-1 Building and is parallel to the inferred direction of groundwater flow. The location of this boundary was selected as it follows a topographic divide and is south of the Lagoon Area. The southern boundary of the LSA is approximately 1,400 m south of the WR-1 Building and is parallel to the inferred direction of groundwater flow. The location of this boundary was selected as it coincides with a topographic divide and an inferred divide in groundwater flow. The eastern boundary of the LSA is located approximately 700 m east of the WR-1 Building and approximately 500 m east of the WL main campus (approximately 260 ha). This boundary is perpendicular to the inferred direction of groundwater flow and upgradient of the WR-1 Building.
- **Regional Study Area (RSA)** is defined as the area within which the potential effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. The RSA is delineated by the Whiteshell Laboratories (WL) site boundary (approximately 4,375 ha).

6.3.2.4.2 Temporal Boundaries

The temporal boundary of the assessment is the timeframe during which Project activities are occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of in situ disposal (ISD), which includes preparation for ISD, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls, and final site restoration. These activities last from 2026 to 2031.
- **Post-closure Phase:** The post closure phase has two discrete periods: institutional control and post institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue to demonstrate Whiteshell Reactor Disposal Facility (WRDF) performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.3.2.4.3 Assessment Cases

The hydrogeology assessment has three assessment cases:

- **Base Case:** represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural and residential and recreational development. Current effects from the existing facilities and operations at the WL site, for example, are considered part of the Base Case. In addition, existing conditions of areas not affected by the WL site are also considered as part of the Base Case. Effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case.
- **Application Case**: represents predictions of the effects of the Base Case combined with the effects that may result from the Project. The Application Case considers potential effects from the Project during closure through to the post-closure phase.

- **Reasonably Foreseeable Developments (RFD) Case**: represents the predictions of the cumulative effects of the Application Case, plus projects that are currently under application review or that have officially entered a regulatory application process and which overlap with the RSA. Foreseeable developments in the RSA that are expected to overlap with residual effects on groundwater quality from the Project includes the decommissioning of the remaining infrastructure and support facilities and remediation of affected lands at the WL site as per the existing decommissioning licence. A Comprehensive Study Report (AECL 2001) under the *Canadian Environmental Assessment Act, 1992* was completed for the decommissioning of the WL site. The Environmental Assessment decision to approve the Project was announced by the Minister of the Environment in March 2002 and a decommissioning licence was issued to Atomic Energy of Canada Limited (AECL) and subsequently to Canadian Nuclear Laboratories (CNL). There are no other foreseeable developments in the RSA that are expected to overlap with changes to groundwater quality (Table 6.3.2-4).

Table 6.3.2-4: Reasonably Foreseeable Developments considered in the Hydrogeology Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes in situ disposal of the low-level waste trenches).	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project
Environmental Remediation	WL	Remediation of affected lands, with the exception of some low-level waste trenches.	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project

6.3.2.5 Description of the Environment

6.3.2.5.1 Methods

Baseline hydrogeological data were summarized from the review of the following reports:

- Hydrogeologic Regime of the Environmental Control Area and Vicinity, Whiteshell Nuclear Research Establishment, Manitoba, Preliminary Progress Report (Cherry et al. 1970).
- Hydrogeological Studies at a Subsurface Radioactive-Waste-Management Site in West-Central Canada (Cherry et al. 1973).
- Review of hydrogeology of the radioactive waste management site, Final Report, Prepared for: Atomic Energy of Canada Limited (Robertson and Cherry 1985).
- Whiteshell Laboratories Decommissioning Project, Comprehensive Study Report (AECL 2001).
- Follow-Up Program, Summary Report: Hydrogeology of the WMA, Lagoon and Landfill-Enhanced Monitoring Program (AECL 2008).
- Whiteshell Laboratories Projects Branch Comprehensive Final Report on Installation of 7 Groundwater Monitoring Wells Nests (KGS Group 2016).
- Canadian Nuclear Laboratories WR-1 Hydrogeological Study Report (Dillon 2018).

Dillon (2018) provides details on recent geological and hydrogeological investigations of the LSA, which (in part) involved drilling and instrumentation of 7 monitoring well nests and a single monitoring well (16-8A) that encompass a total of 33 monitoring wells. The monitoring wells are named numerically (i.e., monitoring well nest 1 through monitoring well nest 7). Each monitoring well nest includes between 4 and 6 monitoring wells. Individual monitoring wells are named using the installation year, the monitoring well nest number and a letter generally indicating the relative depth (with "A" assigned to the deepest monitoring well within the overburden and the final letter assigned to the bedrock interval). In the following sections, the term monitoring well nest is used to refer to the conditions observed throughout the group of monitoring wells, while individual monitoring well names are used to refer to conditions at a specific depth interval. The monitoring well names and geological units and the inferred top and bottom of each unit for each monitoring well nest are summarized in Table 6.3.2-5 with information from Dillon (2018). The locations of the monitoring wells nests are shown on Figure 6.3.2-2.

Table 6.3.2-5: Monitoring Well Nest Details

Monitoring Well Nest	Monitoring Well	Hydrostratigraphic Unit	Top of Unit Elevation (masl)	Bottom of Unit Elevation (masl)
1	15-1A	Basal Sand	257.23	—
	15-1B	Clay Till	261.90	257.23

	16-7E	Bedrock	246.26	—
8	16-8A	Bedrock	252.83	—

masl = metres above sea level; — = no available measurement.

Groundwater level measurements have been periodically taken from these monitoring wells since December 2015. Groundwater elevation data from December 2015 through November 2016 were initially reviewed to evaluate the groundwater conditions in the vicinity of WR-1 as detailed below. These data were interpreted for the clay, clay till and combined basal sand/upper bedrock units and used to form the basis of the groundwater assessment (the basal sand and upper bedrock units were combined for the purpose of generating potentiometric surface maps due to the similar groundwater elevations and neutral vertical gradients observed between these units). Subsequent groundwater elevation data collected in 2017 and 2018 (that are included in Dillon's 2018 report) have been reviewed and found to be consistent with the 2015-2016 data. As such, the 2015-2016 data were maintained as the basis for interpretation of groundwater conditions. It should be noted that the influence of the other WL main campus buildings on the groundwater flow system (e.g., due to removal of water from building sumps and preferential drainage pathways) was not considered in the interpretation of the groundwater elevations presented herein. While water level measurements collected may have been influenced by these buildings, the monitoring wells are generally located too distant from the known locations of building sumps to confirm this influence. Water levels can be expected to rise to some degree as the existing sumps and storm and sewer drains are removed. This will lead to local variations in groundwater flow direction as the former building basement and crawlspaces gradually become filled in and compacted, and regionally consistent groundwater flow is re-established.

Groundwater samples were collected from each monitoring well in monitoring wells nests 2, 4 and 7 in October 2016 as part of the Dillon (2018) hydrogeological investigation (see Figure 6.3.2-2). These samples were analyzed for select major ions and radiological constituents. Groundwater quality in the LSA is based on the results and interpretation provided by Dillon (2018).

6.3.2.5.2 Results

6.3.2.5.2.1 Groundwater Elevations and Flow Directions

Groundwater flow in the unconsolidated sediments and bedrock within the RSA generally follows topography, with the predominant direction of groundwater flow occurring from east to west. Within the Precambrian bedrock groundwater flow occurs primarily within fractures (AECL 2001). Based on the available information from previous hydrogeological investigations (Robertson and Cherry 1985) groundwater recharge primarily occurs in the local topographic high located approximately 3 km east of the WL main campus (where the geological conditions (a former glacial Lake Agassiz beach structure) at surface allow for greater infiltration) and groundwater discharge ultimately occurs at the Winnipeg River.

The interpreted groundwater elevations for the LSA are illustrated on Figures 6.3.2-2 through 6.3.2-4, based on groundwater elevation measurements from September 2016, which corresponds to the calibration targets used in the groundwater flow modelling assessment (see Section 6.3.2.7). The groundwater elevation data are plotted through time from December 2015 through September 2018 on Figure 6.3.2-5A through Figure 6.3.2-5D, and the measured groundwater elevation data are provided in Table 6.3.2-6. The following observations are made based on a review of these figures and table:

- As shown on Figure 6.3.2-2 through Figure 6.3.2-4, the groundwater flow direction in the LSA was consistent with the existing conceptualization for the RSA in that flow generally occurs from east to west (i.e., towards the Winnipeg River) for all hydrostratigraphic units.
- Groundwater elevations at monitoring well nest 2 were consistently low compared to nearby monitoring wells, potentially indicating an enhanced degree of hydraulic connection between monitoring well nest 2 and the sump in the WR-1 Building (Dillon 2018).
- Groundwater elevations at individual monitoring wells typically varied within 1 m to 3 m over the data record, following a period of recovery data from drilling and instrumentation of the well. At monitoring well 15-4B, 15-5B, 15-5C and 15-6B (situated in the clay and clay till) groundwater elevations varied by approximately 5 m to 6 m, with the highest groundwater elevation occurring on May 27, 2016 and the lowest groundwater elevation occurring in December 2015 and November 2016. Groundwater elevations measured at these wells from August and September 2018 indicate that the groundwater elevation data collected since May 2016 are within the range of seasonal variability at these locations.
- The variability in groundwater levels observed in 2016 at 16-2E, 16-4F and 16-7E (situated in the bedrock) is indicative of recovery following drilling and hydraulic testing. It is inferred that the bedrock in which these wells are screened has a very low hydraulic conductivity, resulting in long periods of recovery from drilling and hydraulic testing. This long recovery time is more apparent for 16-2E. Based on the more recent measurements at these monitoring locations, the groundwater level recovery appeared to be complete by November 9, 2016.
- Groundwater elevation measurements have been periodically taken from the monitoring wells since December 2015. Monthly groundwater level measurements were from March 2016 to September 2016 to evaluate whether stabilization of water levels has been reached in the monitoring wells of the seven nests in the vicinity of WR-1. Water level measurements were subsequently taken at a frequency of twice a year to evaluate the recovery of groundwater in the bedrock wells and to provide a basis for ongoing monitoring of groundwater elevations.

6.3.2.5.2.2 Hydraulic Gradients

Horizontal hydraulic gradients were estimated based on the groundwater elevations in monitoring wells located parallel to the direction of groundwater flow. Relatively neutral gradients were noted for the clay unit, with a maximum estimated gradient of approximately 0.007 metres per metre (m/m) between monitoring well nests 5 and 6. For the clay till unit, the horizontal gradient was approximately 0.012 m/m, as measured between monitoring well nests 3 and 4 and monitoring well nests 1 and 7. Similarly, for the combined basal sand/upper bedrock unit, the horizontal gradient was approximately 0.010 m/m, as measured between monitoring well nests 3 and 4 and monitoring well nests 1 and 7.

Vertical hydraulic gradients were calculated between the various units based on mid-point elevations of monitoring well screens, as summarized in Table 6.3.2-7. At all locations, groundwater elevations were highest in the clay unit and lowest in the combined basal sand/upper bedrock unit, indicating a downward direction of groundwater flow through the overburden. Between the clay and clay till units the vertical gradient ranged from 0.22 m/m at monitoring well nest 1 to 1.39 m/m at monitoring well nest 6, with an average vertical gradient of 0.83 m/m across all locations. Between the clay till and combined basal sand/upper bedrock units the vertical gradient ranged from 0.24 m/m at monitoring well nest 2 to 0.86 m/m at monitoring well nest 5, with an average vertical gradient of 0.52 m/m across all locations.

The principal groundwater gradients in the clay soils above the basal layer and bedrock interface are vertical (i.e., downward flow) and horizontal gradients in the clay are small in comparison. Given the low permeability soils above the basal layer there is no expectation of movement upwards to the surface from the WRDF or downgradient to the river.

Table 6.3.2-7: Vertical Gradients

Monitoring Well Nest	Groundwater Elevation[a] (masl)					Screen Elevation (masl)			Vertical Gradient[c]	
	Clay	Clay-Till	Basal Sand	Bedrock	BS/Br Maximum[b]	Clay	Clay-Till	BS/Br	Clay to Clay-Till	Clay-Till to BS/Br
1	266.69	265.45	261.86	–	261.86	265.81	260.14	254.93	0.22	0.69

3	266.87	264.29	261.63	–	261.63	265.01	260.00	256.00	0.51	0.66
4	265.32	258.51	256.82	256.58	256.82	263.88	257.00	252.21	0.99	0.35
5	264.44	258.59	255.84	–	255.84	261.98	256.40	253.22	1.05	0.86
6	265.69	259.91	–	–	–	264.37	260.21	–	1.39	–
7	266.55	260.02	–	256.27	256.27	264.76	255.44	242.79	0.70	0.30

a) Groundwater elevation measurements taken between September 14, 2016 and September 26, 2016.
b) The maximum groundwater elevation was selected at each monitoring well nest to represent the groundwater elevation for this unit.
c) Vertical gradient calculated based on screen mid-point elevations. Positive values indicate a downward direction of groundwater flow.
"–" indicates no measurement available; masl = metres above sea level; BS/Br = indicates combined basal-sand / bedrock unit.

6.3.2.5.2.3 Hydraulic Conductivity

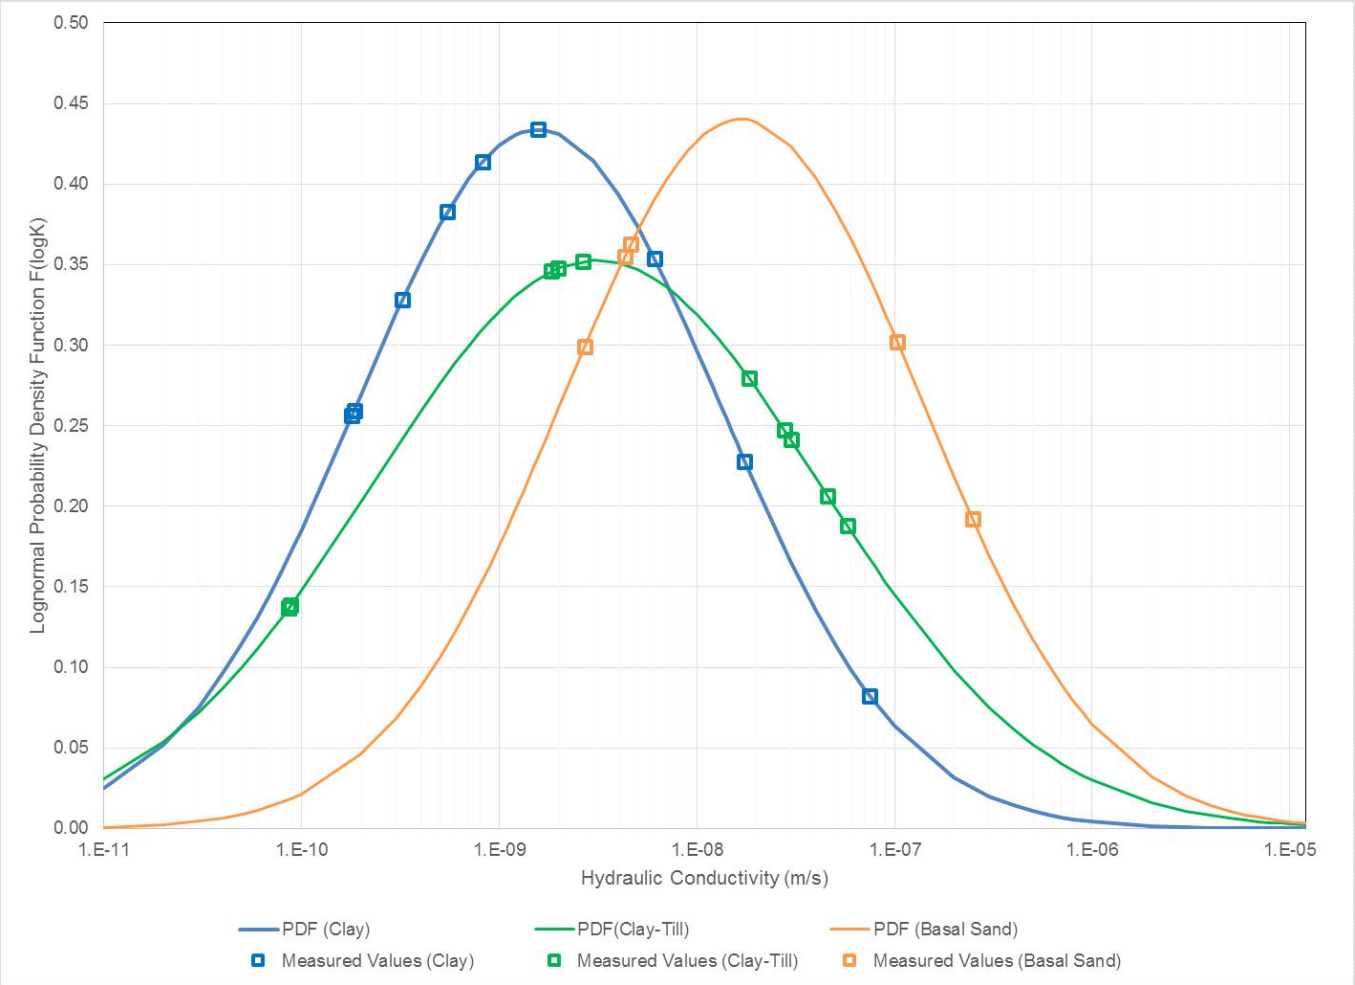
Measurements of hydraulic conductivity of the principal hydrostratigraphic units found within the RSA were available from previous hydrogeological investigations, which focused on the Waste Management Area (WMA). These are summarized below (Dillon 2018):

- Robertson and Cherry (1985) measured the hydraulic conductivity of the overburden in the WMA using both laboratory and field methods (i.e., monitoring well response tests, pumping tests, mass balance methods). The monitoring well response test results suggested that the hydraulic conductivity of the clay (10^{11} to 10^{-6} m/s), clay till (10^{-10} to 10^{-6} m/s) and basal sand (10^{-11} to 10^{-6} m/s) varied over a wide range of values. Pumping test and mass balance estimates suggested that the average hydraulic conductivity of the clay and clay till units ranged from 10^{10} to 10^{9} m/s, and the average hydraulic conductivity of the sand unit ranged from 10^{6} to 10^{5} m/s. The wide range of hydraulic conductivity can be attributed to the presence of fine layers of silt/sand and other features such as fractures in the clay, which imparts secondary permeability to the soils.

Single well response tests (AECL 2008) were completed in most of the BHS 500 series groundwater monitoring wells at the WMA. Most of the hydraulic conductivity values in the clay units from the single well response tests were in the range of 10^{-7} to 10^{-9} m/s. Groundwater flow through the clay/silt units is probably controlled, for the most part, by these lower permeability soils. In the clay till, most of the single well response tests (21 of 26) provided hydraulic conductivity values in the range of 10^{-7} to 10^{-9} m/s. Seventeen hydraulic conductivity tests were completed in the basal sand unit (AECL 2008). These tests generally showed a high range of hydraulic conductivity (10^{-5} to 10^{-7} m/s) compared to the clay and clay till units. Fourteen of the 17 single well response tests completed in the basal sand unit had hydraulic conductivity values in the order of 10^{-6} m/s.

Although the primary focus of the above-mentioned studies was the WMA, Robertson and Cherry (1985) indicate that the basal sand demonstrated a fining trend from east to west, resulting in reduction of hydraulic conductivity of this unit in a westerly direction.

Single well response testing was completed at 29 monitoring wells in the unconsolidated (overburden) deposits within the LSA (KGS Group 2016). Data from 25 of the tests were used to define normally distributed probability density functions of the log hydraulic conductivity estimate for the primary hydrostratigraphic- units in the LSA. Data from the remaining wells (15-2C, 15-5D, 15-6D and 15-7C) were omitted from this analysis due to the anomalous responses (i.e., slow recovery) observed during testing, as noted in KGS Group (2016). For wells situated in the unconsolidated (overburden) deposits the probability density functions are plotted on Figure 6.3.2-6 and the data are provided in Table 6.3.2-8.



Hydrostratigraphic Unit	Hydraulic Conductivity (m/s)			
	Minimum	Maximum	Geometric Mean	Standard Deviation
Clay	1.80E-10	7.49E-08	1.58E-09	2.45E-08
Clay Till	8.61E-11	5.76E-08	3.10E-09	2.07E-08
Basal Sand	2.69E-09	2.48E-07	1.69E-08	1.07E-07

15-6B	Clay Till	8.61×10^{-11}
15-6C	Clay Till	2.99×10^{-8}
15-7A	Clay Till	1.99×10^{-9}
15-7B	Clay Till	1.84×10^{-9}
15-7D	Clay	6.11×10^{-9}

Key observations from Figure 6.3.2-6 and Table 6.3.2-8 are summarized below:

- Consistent with the observations made by others within the RSA, the hydrostratigraphic units exhibited a wide range in estimated hydraulic conductivity values, spanning two to three orders of magnitude.
- Hydraulic conductivity estimates within the LSA were generally within the ranges defined by testing completed at the WMA as noted above, except for the basal sand unit, which was somewhat less permeable. Estimates of basal sand hydraulic conductivity from the LSA were typically an order of magnitude lower than the available estimates from the WMA. This indicates that although the basal sand unit is present in the stratigraphic sequence in both the WMA and LSA, its properties vary spatially. As indicated previously in Section 6.3.1, this unit is referred as a “basal sand” for consistency with previous work completed across the SSA, though within the LSA it does not display the characteristics of a typical sand (e.g., silt content in samples of this unit ranged from 26% to 56%, and clay content was up to 24%).

- Hydraulic conductivity increases with depth on a unit-average basis (i.e., the clay is the least permeable and the basal sand is the most permeable), though this was not always the case at individual monitoring well nests (e.g., the hydraulic conductivity estimate in the basal sand at 15-2A was lower than the estimate in the clay till at 15-2B).
- Single well response (packer) testing was completed in the upper portion of the bedrock at locations within the LSA (Dillon 2018). Interpreted hydraulic conductivity values ranged from less than $1.3x10^{-7}$ m/s at two of the test locations to 2.0E06 m/s at the third location. This is generally consistent with previous assessments completed within the RSA that have interpreted the upper bedrock to be within the range of $5.0x10^{-12}$ m/s to $6.5x10^{-7}$ m/s (Stevenson et al. 1996). Based on these data, the upper portion of the bedrock (in contact with the overburden) is considered the primary aquifer within the LSA.

6.3.2.5.2.4 Groundwater Quality

Ongoing groundwater sampling within the RSA for both radiological and non-radiological contaminants occur at specific facilities as part of the routine environmental monitoring for the WL site. These facilities include the sewage lagoon, the landfill and the WMA, which includes unlined trenches used to dispose of low level radioactive and conventional waste. The monitoring programs differ slightly by facility and are documented in CNL's 2015 progress report on the Environmental Assessment Follow-up and Monitoring Program for WL (CNL 2021b).

Concentrations of metals in groundwater within the RSA are generally low. Slightly elevated concentrations of arsenic (0.017 to 0.025 mg/L) at the landfill and iron (0.2 to 3.0 mg/L) at the WMA were reported in 2015 (CNL 2016a). These metals are known to be naturally elevated in groundwater elsewhere in Manitoba, and concentrations observed in 2015 were attributed to these natural conditions as opposed to anthropogenic sources (CNL 2016a). In 2019, the groundwater quality monitoring indicated iron concentrations at or below the aesthetic objective (0.3 mg/L) at the WMA. Elevated concentrations of chromium were detected in 2019 sampling (0.124 mg/L) and are suspected to be related to issues with sample filtration (CNL 2020a). Volatile organic compounds (VOCs) including benzene, ethylbenzene, toluene and xylene were detected at low concentrations within the WMA and are possibly related to gas powered equipment used during sampling (CNL 2016a), as these compounds were not detected in 2019 (CNL 2020a). HB-40, the primary coolant feedstock for WR-1, was detected at trace concentrations (less than 0.026 mg/L) at four monitoring wells within the WMA in 2015 (CNL 2016a).

The radiological component of the routine environmental monitoring program includes the analysis of gross beta, gross alpha, tritium and uranium in groundwater. In the landfill area, gross beta, gross alpha and uranium activities/concentrations are low (less than 1 Becquerel per litre [Bq/L], 0.5 Bq/L and 0.020 mg/L respectively). Tritium was detected in the in two of the dugouts near the landfill that fill from precipitation and receive shallow groundwater. Tritium at low levels ranging from 41 to 212 Bq/L over the 2015 to 2020 period were measured in the dugout closest to the landfall (CNL 2021a).

At the lagoon, gross beta activity in groundwater is elevated and greater than 1 Bq/L at all monitoring locations within the basal sand unit. Gross alpha activity was also greater than 0.5 Bq/L at half of the lagoon monitoring locations. Uranium concentrations at the lagoon ranged from 0.006 to 0.128 mg/L in 2015 and 0.012 to 0.149 mg/L in 2019. Gamma analysis indicated the presence of naturally occurring potassium-40 and uranium progeny, and the elevated gross beta and gross alpha at the lagoon were attributed to natural conditions as opposed to anthropogenic sources (CNL 2016a, 2020).

Within the WMA, the five-year average gross beta activities in groundwater within the clay and basal sand units are below 1 Bq/L and are slightly above 1 Bq/L within the clay and clay till units (in three samples). The five-year average gross alpha activities within the clay and basal sand units are below 0.5 Bq/L and are slightly above 0.5 Bq/L within the clay and clay till units. In 2019, uranium concentrations in groundwater within the WMA ranged from 0.0001 to 0.136 mg/L, with concentrations being highest in the clay unit, lowest in the basal sand. As with the lagoon area, gamma analysis of groundwater within the WMA indicated the presence of naturally occurring potassium-40 and uranium progeny, and the elevated gross beta and gross alpha are likely related to natural sources (CNL 2020a). Tritium was detected at several wells within the clay and clay till units, with activities ranging from 7.2 to 66.4 Bq/L in 2015 (CNL 2016a) and 29.9 to 83.3 Bq/L in 2019 (CNL 2020a). Tritium was detected at one location within the basal sand in 2015 (at 17.3 Bq/L) and 2019 (at 72.9 Bq/L) in an area of the WMA where transient reversals of recharge/discharge conditions have been noted (CNL 2016a, 2020). These tritium concentrations in groundwater are attributed to the low-level radioactive waste stored in unlined trenches within the WMA (CNL 2020a). Based on the results of the monitoring it was concluded that no significant contaminant migration from the WMA with groundwater flow has occurred (CNL 2021).

Previous studies within the RSA have indicated that the groundwater quality in the overburden and bedrock aquifers is generally considered potable (AECL 2001). Within the LSA, a piper tri-linear plot presented in Dillon (2018) indicates that groundwater within the bedrock and basal sand units was predominately of a calcium-magnesium-sulphate type, while groundwater within the clay unit was predominately of a calcium-magnesium-bicarbonate type.

Samples analysed by Dillon (2018) showed sulphate levels ranging from 180 to 2500 mg/L. The values of sulphate reach levels that are known to promote sulphate attack on concrete. The sulphate, calcium (63 to 461 mg/L), magnesium (88 to 323 mg/L) and pH (7.11 to 8.67) are similar to the chemistry seen in groundwater wells at the WMA (CNL 2015, 2016b, 2018).

Dillon (2018) noted that the measured uranium concentration in the initial sample collected from the bedrock at monitoring well nest 2 was approximately 2 mg/L. Following subsequent sampling and further analysis completed in October 2016, Dillon (2018) concluded that the results indicated the presence of naturally occurring uranium. Similar elevated uranium concentrations have been previously noted in the Precambrian bedrock within the RSA. These concentrations were previously attributed to leakage of natural groundwater from the overlying uraniferous clay (AECL 2001).

Analysis of groundwater samples for radiological constituents completed by Dillon (2018) resulted in the presence of the following parameters at activities above their respective detection limits:

- Actinum-228 (at monitoring well 15-4A);
- Bismuth-214 (at monitoring well 16-2E);
- Lead-210 (at monitoring wells 15-2A, 15-2D, 16-2E, 16-4F and 16-7E);
- Lead-212 (at monitoring wells 15-2A, 15-4A and 15-7A);
- Lead-214 (at monitoring well 16-2E);
- Radium-226 (at monitoring wells 16-2E, 16-4F, 15-7B, 16-7E); and
- Thorium-234 (at monitoring well 16-2E).

There is no notable radiological component in the initial water samples taken on the WL main campus (Dillon 2018). Only one well, 16-6F located to the northwest of WR-1 as part of monitoring well nest 4, showed a slightly elevated alpha reading of 41 parts per billion [ppb]. Slightly elevated alpha readings are to be expected as local well waters within the Canadian Shield contain naturally occurring uranium (less than 100 ppb) and therefore elevated alpha readings are not unexpected (Betcher et al. 1988; Betcher et al. 1995), however, in general as at the WMA (CNL 2018) most uranium values are low.

6.3.2.6 Project Interactions and Mitigation

6.3.2.6.1 Methods

This section describes the process by which interactions between Project components and activities and groundwater quantity and quality were identified and evaluated. Potential effect pathways are identified, and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the Project and the environment by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in Section 6.3.2.7 Residual Effects Analysis. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce adverse effects to hydrogeology. Environmental design features included Project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project's engineering and environmental teams, combined with input from Project-specific or regional engagement with other interested parties. The design features and/or mitigation activities were selected considering their effectiveness for implementation and maintenance and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage pathway –** pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects to groundwater quantity and quality.
- **Secondary pathway –** the pathway could result in a measurable minor environmental change but would have a negligible residual effect on groundwater quantity and quality relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway –** the pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects to groundwater quantity and quality.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to hydrogeology through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and/or qualitative effects analysis to characterize the residual effects of the Project.

6.3.2.6.2 Results

Pathways through which all phases of the Project may interact with and result in changes to measurement indicators for hydrogeology is provided in Table 6.3.2-9.

Table 6.3.2-9: Pathways Analysis for Hydrogeology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Closure of the entire WL site	Decommissioning and reclamation of the entire WL site, including the Project.	■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. ■ The WL site will be graded to promote drainage from the site to the Winnipeg River.	Secondary
Long-term performance during the post-closure phase	Release of solutes into the groundwater as the grout and reactor components gradually deteriorate.	■ Installation of a concrete cap and engineered cover system to mitigate moisture infiltration into the Whiteshell Reactor Disposal Facility (WRDF) and hence limit release of solutes into the groundwater. ■ The planned decommissioning of the WR-1 Building presently involves: ▪ removal the service area and infilling in these areas with compacted clay-based soil; ▪ sealing of open conduits in the building foundation; and ▪ grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation. ■ Monitoring will also be completed throughout the post-closure phase for the Project to confirm that the cover and grout is functioning as intended, and to confirm modelling predictions.	Primary
	Release of chemical and radiological contaminants in the long-term during the post-closure phase from the previous activities completed at the WL site.	■ As part of CNL's licence with the Canadian Nuclear Safety Commission, environmental monitoring around the WL site will continue for the Project. ■ Follow-up monitoring during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.	No Linkage

6.3.2.6.2.1 No Linkage Pathway

The following pathway was assessed as having no measurable environmental change and hence, no linkage to residual effects on groundwater quality.

- **Release of chemical and radiological contaminants in the long-term during the post-closure phase from the previous activities completed at the WL site.**

The Comprehensive Study Report (AECL 2001) indicated that for effects to groundwater quality, the main area of concern was the low-level waste that may be managed in situ in the WMA. The evaluation of contaminant migration from the WMA trenches concluded that the nature of groundwater flow in the area around the WMA limits contaminant migration away from the WMA. There is no downward movement of groundwater flow from the WMA to the underlying permeable sandy zone, which has the potential to act as a transmission zone to the Winnipeg River (see Section 6.3.4 and Appendix C of AECL 2001). Generally, the natural hydraulic head at 10 m depth is higher, meaning that the hydraulic head gradient is upward leading to potential water discharge towards the surface (i.e., artesian conditions).

Contaminant migration, if it were to occur, would be less than 10 cm over 20 years. Testing also provided no evidence of a “bathtub effect” (i.e., flooding of the trenches so that they have a higher conductivity than the trench wall) and associated near-surface lateral movement of contaminants, although further testing was recommended to support a future detailed safety analysis (AECL 2001).

The final safety assessments for these wastes have not been completed. However, both the Project and the WMA are subject to the same regulatory requirements, which require that no member of the public receive a dose greater than 1 mSv/a. A value of 0.3 mSv/a dose limit to public has been established for the WL site. The Project specified a 0.25 mSv/a target dose rate limit for the public, and results of the assessment for the normal evolution indicate that the Project is well below this target. The expectation is that the final assessment of the WMA will demonstrate negligible dose rates compared to these targets. Consequently, there are negligible cumulative effects of the Project.

Consequently, there is no overlap of effects between WR-1 ISD and previous activities at the WL site (i.e., effects from the WMA) and changes to groundwater quality from the Project. Potential for cumulative effects with surface water quality and human health are considered in Section 6.4.2 Surface Water Quality and Section 6.7.1 Human Health and Section 6.7.2 Ecological Health, respectively.

6.3.2.6.2.2 Secondary Pathways

The following pathways were assessed as potentially having a measurable minor change to hydrogeology relative to Base Case.

- **Decommissioning and reclamation of the entire WL site, including the Project.**

The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. Following decommissioning of the building sumps, groundwater levels will approach static conditions similar to the local environment. On the main campus of the WL site, groundwater heads indicate downward flow conditions exist. For the closure and post-closure phases, groundwater will flow downwards through the overburden and westward, ultimately discharging at the Winnipeg River. Overall, cumulative effects from the

Project in combination with the decommissioning of the remaining infrastructure and support facilities and reclamation of the affected areas at the WL site are anticipated to have a negligible effect on groundwater quantity.

6.3.2.6.2.3 Primary Pathways

The Project is expected to have the following primary pathway effects on groundwater quality that are carried forward to the residual effects analysis:

- **Release of solutes into the groundwater as the grout and reactor components gradually deteriorate.**

6.3.2.7 Residual Effects Analysis

The objectives of the groundwater flow and solute transport modelling include estimation of the potential long-term changes to the groundwater flow regime and groundwater quality resulting from the proposed decommissioning of the WR-1 Building. The modelling was completed to provide an estimate of solute mass loadings during the post-closure phase to identify potential solutes of concern within the Environmental Risk Assessment framework.

6.3.2.7.1 Methods

6.3.2.7.1.1 Groundwater Flow and Solute Transport Modelling

Groundwater flow and solute transport modelling was completed in support of an assessment of the Project and is described in detail in the Groundwater Flow and Solute Transport Modelling Report (Golder 2021a). The conceptual model, upon which the numerical model was founded, was developed based on the available information. Primarily, these data included borehole logs, estimates of hydraulic conductivity and groundwater elevations collected during field investigations of the SSA (Dillon 2018). Groundwater elevations and estimates of inflows to the WR-1 Building sump were used as metrics for calibration of the groundwater flow model. A comparison of the simulated to measured data showed that an acceptable model calibration was achieved.

MODFLOW-2005 (Harbaugh 2005) was used to complete the groundwater flow simulations and Visual MODFLOW® (Version 4.6.0.156) was used as the numeric flow engine for the simulations. MODPATH (Pollock 1989), a companion code to MODFLOW, was used to complete the particle tracking analyses necessary to illustrate the flow paths from the WR-1 Building.

An analytical approach was adopted to complete the solute transport modelling. GoldSim® (Version 12.1), a commercially available, flexible, object-oriented computer program, was selected as the software package to complete the analytical calculations. The GoldSim software is fully documented in the Main Users Guide (GTG 2014a) and the Contaminant Transport Module Users Guide (GTG 2014b). Details of the conceptual model development, modelling approach and model assumptions are described in the Groundwater Flow and Solute Transport Modelling Report (Golder 2021a).

6.3.2.7.1.2 Contaminant Release

The planned decommissioning of the WR-1 Building presently involves:

- removal of the service area and infilling in these areas with compacted clay-based soil;
- sealing of open conduits in the building foundation; and
- grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation.

Following the encapsulation of WR-1 and the cessation of pumping from the sumps, the groundwater elevation will gradually become restored to an equilibrium elevation and the majority of the grout (including the remaining components of the reactor) will be situated below the groundwater table. The calibrated groundwater flow model was reconfigured for representation of these conditions at various states of degradation of the encapsulation with respect to the condition of the cover, grout, and foundation materials. The modelling assumed that these materials will experience an increase in hydraulic conductivity as they degrade over time (Golder 2021a). The hydraulic conductivity applied to the building foundation (i.e., the primary barrier) in the model at the beginning of the simulation was specified to be $5x10^{-10}$ m/s. This value is approximately 5 times higher than the highest measured value obtained as a part of testing of the foundation materials that was completed during a recent building condition assessment (Golder 2022). Simulations were completed to estimate the groundwater flow through the components of the decommissioned structure and results of these simulations were used as input to the analytical solute transport model (Golder 2021a).

The solute transport model was defined as a source area (representing the remaining solute mass contained within the decommissioned structure), a barrier for containment (the building foundation), a transport pathway (the upper portion of the bedrock, which receives solute mass loadings from the decommissioned building via advection and diffusion through the barrier and into the surrounding fill material) and a receptor (the Winnipeg River). Solute mass originating from the reactor and lead-containing materials is released gradually over time to represent corrosion of the reactor components that remain following decommissioning; whereas mass originating from other sources was assumed to be present in a dissolved phase throughout the grout at the start of decommissioning. The release of solute mass is therefore a function of the assumed estimated inventory, groundwater flow rates, groundwater chemistry, corrosion rates and degradation rates of the grout and structural concrete. Uncertainty associated with these parameters, as well as other model inputs, was addressed through a sensitivity analysis (see Section 6.3.2.8). Retardation from adsorption of the solutes was considered for the bedrock pathway only, as determined through a review of the available information on sorption-partitioning coefficients. The effect of changes to the surficial geology, for example erosion of the river bank, was also considered through sensitivity analysis. Details are provided in the Groundwater Flow and Solute Transport Modelling Report (Golder 2021a).

6.3.2.7.2 Application Case

The following provides a summary of the key findings from the groundwater flow and solute transport modelling assessment:

- The post-decommissioning groundwater elevation is expected to recover to the top of (or above) the reactor materials. Groundwater seepage (and mass flux) pathways were estimated to occur downwards to the underlying bedrock and then laterally to the west towards the Winnipeg River. The Winnipeg River was identified as the eventual discharge location of seepage from the WRDF.
- Mean advective groundwater travel times to the Winnipeg River were estimated to be on the order 100 years.
- The peak total activity level estimated from the simulations (~2×10^{10} Bq/yr.) occurs after approximately 70 years. The peak activity is principally related to the migration of tritium from the WR-1. Due to dispersion, the finite amount of tritium in the source (grout) and the half-life associated with tritium (approximately 12 years) its peak arrival occurs earlier than the mean advective groundwater travel time.
- Mass flux rates from 56 radiological parameters and 29 non-radiological elements were simulated in the groundwater flow and transport model as shown in Golder (2021a). These parameters and elements were selected based on the expected mass inventory for the WR-1 Building as discussed in Section 4.1.1 of Golder

(2021a). Mass flux estimates for a simulation period of 500,000 years were then provided for incorporation in the Environmental Risk Assessment for an assessment of effects to human and ecological health. Key controls on the magnitude of the peaks and the timing of the peak mass fluxes include adsorption properties for each solute, rates of decay and in-growth for the radiological contaminants, and source release mechanism (i.e., distributed initially within the grout matrix versus released slowly through corrosion of WR-1 components).

6.3.2.8 Prediction Confidence and Uncertainty

The groundwater flow and solute transport results presented in Golder (2021b) are based on currently available best-estimates and assumptions of the input parameters and processes affecting solute transport. Uncertainty in both the groundwater flow and solute transport modelling is recognized and was evaluated through the completion of a sensitivity analysis. The sensitivity analysis included the evaluation of the effect of 18 various model assumptions on model results as discussed in detail in Golder (2021b).

Results of the sensitivity analysis indicated the following:

- Peak mass loading rates and/or earlier arrival of peaks, were found to be most sensitive to: assumptions on where the solute mass initially resides within the grout; the alternative model boundary applied to the cover; the rate of flow through the bedrock pathway (as explored through the preferential pathway simulation, adjustments to the bedrock hydraulic conductivity and lowering of the river stage); the rate of corrosion; the initial mass inventory (for non-radionuclide solutes); the radionuclide source inventory, and adjustments to the solute-partitioning coefficients (for solutes where the upper or lower bound value was significantly different from the base case value).
- Peak mass loading rates and earlier arrival to peaks was found to be less sensitive to: the degradation rate of the engineering components (within the ranges assessed); a local failure of the foundation; increase in the hydraulic conductivity of the backfill; an increase in the rate of degradation of the grout and foundation; and a compromised foundation.
- Negligible Xylene mass was present at the outflow boundary when degradation was applied, indicating the xylene mass loading rate is sensitive to its degradation.

In 2024, groundwater flow and solute transport modelling was completed to evaluate 11 additional sensitivity scenarios (Scenarios 19 through 29) to further assess the peak loadings to the Winnipeg River (WSP 2024). This modelling was done giving consideration to an expanded range of input parameter values that lie outside of the range assessed in the Normal Evolution Scenario and the 18 Sensitivity Scenarios completed in the draft EIS (Golder 2022). Based on this, CNL completed a series of 11 additional groundwater flow and solute transport simulations (Sensitivity Scenarios 19 through 29), some of which included consideration of an enhancement to the hydraulic conductivity of the grout to reflect uncertainty in this input parameter. The specific parameter assignments and results of the additional Sensitivity Scenarios are provided in a separate Technical Memorandum (WSP 2024).

Two additional sensitivity scenarios were completed giving consideration to a fractured flow condition in the bedrock pathway ranging from a parallel set of 5 fractures (Scenario 21) to a parallel set of 10 fractures (Scenario 22) (WSP 2024). Four sensitivity scenarios (Scenarios 23 to 26) were also completed giving consideration to: updated lower bound (Scenario 23) and upper bound (Scenario 24) adsorption co-efficients for

the bedrock geo-pathway (based on additional literature review); and increased diffusivity for the WRDF foundation (Scenarios 25 and 26).

With respect to the performance of the grout, the Normal Evolution Scenario in the draft EIS (Golder 2022) considered a gradual degradation of the hydraulic conductivity over time due to fracturing based on information in the technical literature (Section 4.1.1 of Golder 2021). Two additional sensitivity scenarios were completed giving consideration to a grout hydraulic conductivity at the maximum value from the scale-up testing (i.e., $1.5x10^{-6}$ m/s in Scenario 27; WSP 2024); as well as an extreme upper bound assumption of 1x10-4 m/s for the grout in Scenario 28. This extreme upper bound assumption lies at the upper end of the range of hydraulic conductivities noted for cracked grout in core samples from a recent CNSC research project [Androuet 2024]). In both Scenarios 27 and 28, the higher grout K's were applied at the beginning of the simulation; essentially assuming immediate degradation of the grout to a long-term higher permeability condition.

The results indicate that the expanded set of parameter inputs results in increased mass loading estimates to the environment for some scenarios relative to those assessed in the Draft EIS submitted December 2022. The overall impact of the increased mass loadings are evaluated in an addendum to the Environmental Risk Assessment (EcoMetrix 2024) to determine the potential impact of these results on human and ecological health, as well as in Section 6.7 of this EIS.

6.3.2.1 Monitoring and Follow-up

As part of CNL's licence (NRTEDL-W5-8.00/2024), CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects predictions and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical. For monitoring requirements arising from the Project appropriate procedures will be developed that will meet or exceed federal and provincial regulatory requirements (Table 6.3.210). A post-closure monitoring program will also be developed that will provide the sampling and analysis objectives and procedures for sampling and testing the groundwater quality in the vicinity of the WR1 Building during the institutional control period. The program will include details concerning sampling locations and sampling frequencies, analysis, quality assurance/quality control requirements, and will be compliant with *CSA N288.7-23: Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2023). As a result of engagement on the Project's follow-up monitoring program thus far, CNL has committed to adding additional ground monitoring well(s) between the WR-1 reactor and the Winnipeg River as requested by the Red River Métis.

It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Within this framework, modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS or Decommissioning Safety Assessment Report, including the findings from the Groundwater Flow and Solute Transport Monitoring Report, the frequency of sampling may be increased, and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals for modifications to the monitoring program and the rationale for the modifications will be communicated to the CNSC prior to implementation. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs.

Table 6.3.2-10: Monitoring and Follow-up Programs for Hydrogeology

Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Hydrogeology	**Potential Source(s) of Effects:** ■ Changes to groundwater quality from the release of solutes into the groundwater as the grout and reactor components gradually deteriorate during post-closure phases. **Proposed Monitoring:** ■ Water elevation measurements to determine groundwater flow direction and gradients. ■ Sampling to confirm groundwater quality to detect potential releases of constituents from the WRDF. ■ Initial sampling frequency will likely be twice per year (spring and fall). **Trigger for further action:** ■ If concentrations of dissolved constituents in groundwater are above applicable guidelines or above typical background concentration, conduct groundwater and/or soil sampling and analysis to delineate the extent and identify the source of contaminants of concern. ■ If significant unexpected changes to groundwater flow are interpreted through analysis of groundwater elevation measurements, complete a survey of the integrity of WRDF (e.g., using geophysical methods).	■ Verify effects predictions on groundwater from the Project. ■ Verify the effectiveness of mitigation. ■ Demonstrate compliance with regulatory requirements.	■ Groundwater monitoring will continue through closure and institutional control period. Semi-annual water level measurement and water quality measurements will be included in the Environmental Assessment Follow-Up and Monitoring Program. The frequency of recurrence of water sampling will be reviewed based on performance data. The number and location of wells and parameters measured, may change based on an annual review of the data.	■ Project groundwater monitoring will be integrated into the overall CNL Groundwater Monitoring Program and will be compliant with CSA N288.7-23 Groundwater Protection Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills (CSA Group 2023).

6.3.2.2 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Hydrogeology is recognized as an important component of the environment that may be affected by the Project and changes to hydrogeology could, in turn, lead to effects on other VCs selected for assessment. Acknowledging that changes to hydrogeology are considered to be important aspects of the natural and human environment, hydrogeology is referred to as an intermediate VC. Results of the analysis of changes in measurement indicators for hydrogeology are provided to other disciplines for inclusion in their assessment.

Table 6.3.2-10 provides a summary of the residual adverse effects identified for hydrogeology. Based on the Comprehensive Study Report (AECL 2001), it was determined that the likelihood of contaminant transport beyond the WMA was very low and no effects on groundwater were anticipated from ISD of the trenches; therefore, no overlap with the Project is expected. Changes to groundwater quality from the Project due to the release of solutes into the groundwater as the grout and reactor components gradually deteriorate was identified as having a residual effect on the hydrogeological environment. Environmental design features and mitigation implemented to reduce residual effects on groundwater quality include:

- installation of a concrete cap and engineered cover to mitigate moisture infiltration into the WRDF;
- removal of the service area and infilling in these areas with compacted clay-based soil;
- sealing of open conduits in the building foundation;
- grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation; and
- monitoring will be completed throughout the institutional control period for the Project to confirm that the cover and grout is functioning as intended and to confirm modelling predictions.

Groundwater flow and solute transport modelling was completed to provide estimates of solute mass loadings during the post closure phase. The Winnipeg River was identified by the post decommissioning groundwater flow model as the principal receptor of groundwater discharge. The Winnipeg River is also of high importance to Indigenous peoples.

Mass flux rates from 56 radiological parameters, along with 29 non-radiological elements, were simulated in the groundwater flow and transport modelling. The groundwater flow modelling indicated that the mean advective groundwater travel times to the Winnipeg River were an estimated 100 years. The peak total activity level from the simulations occurs after approximately 70 years and is principally related to the migration of tritium from WR-1. Due to dispersion, the finite amount of tritium in the source (grout) and the half-life associated with tritium (approximately 12 years), its peak arrival to the Winnipeg River occurs earlier than the mean advective groundwater travel time. Results of the groundwater assessment are used in the surface water quality assessment and the Environmental Risk Assessment to determine potential long-term adverse effects from the Project, which is a key concern expressed by Indigenous peoples.

Indigenous peoples have interest in the current and future monitoring proposed for the Project. As part of CNL's licence (NRTEDL-W5-8.00/2024) with the CNSC, CNL will continue to implement the Environmental Assessment Follow-up and Monitoring Program for the WL site to verify the accuracy of environmental effects predictions and determine the effectiveness of mitigation that has or is to be implemented. CNL will provide First Nations and the Manitoba Métis Federation with the opportunity to participate in the implementation and review of mitigation measures. For monitoring requirements arising from the Project, but not covered in the Environmental Assessment Follow-up and Monitoring Program, appropriate procedures will be developed that will meet or exceed federal and provincial regulatory requirements. A post-closure monitoring program will also be developed that will provide the sampling and analysis objectives and procedures for sampling and testing the groundwater quality in the vicinity of the WR-1 Building.

Table 6.3.2-11: Summary of Predicted Residual Adverse Effects for Hydrogeology

Valued Component	Assessment Endpoint	Residual Effect	Phase Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation	Significance
Groundwater Quality	Intermediate VC (i.e., it does not have an assessment endpoint)	Release of solutes into the groundwater as the grout and reactor components gradually deteriorate may cause changes in groundwater quality	Post-Closure Phase	Grout and reactor components gradually deteriorate	■ Installation of a concrete cap and engineered cover to mitigate moisture infiltration into the WRDF and hence limit release of solutes into the groundwater. ■ The planned decommissioning of the WR-1 Building presently involves: ▪ removal the service area and infilling in these areas with compacted clay-based soil; ▪ sealing of open conduits in the building foundation; and ▪ grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation. ■ Monitoring will also be completed throughout the post-closure phase for the Project to confirm that the cover and grout is functioning as intended and to confirm modelling predictions.	Significance is not determined as valued component does not have an assessment endpoint; rather the results provided to other disciplines for inclusion in their assessment.

6.4 Surface Water Environment

This section examines the potential residual effects of the Project on surface water hydrology (Section 6.4.1 Hydrology) and surface water quality (Section 6.4.2 Surface Water Quality).

6.4.1 Hydrology

6.4.1.1 Scope of the Assessment

The hydrology assessment follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment was completed in the following steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Sections 6.4.1.3 Valued Components and Section 6.4.1.4 Assessment Boundaries) for the hydrology assessment. The VCs and measurement indicators used to assess Project-related changes to hydrology, the spatial and temporal boundaries at which the assessment occurred, and the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.4.1.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.4.1.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect hydrology are identified and mitigation options are presented to limit or avoid these effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the hydrology assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the hydrology assessment.
- **Step 6 – Classify and determine the significance of the predicted residual effects.** This step was not required as the hydrology VC is an intermediate component which does not include an assessment endpoint to determine significance.
- **Step 7 – Identifying monitoring and follow-up** (refer to Section 6.4.1.7 Monitoring and Follow-up) required to confirm effects predictions and address uncertainty.
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.4.1.8 Conclusions) for hydrology.

6.4.1.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement that are related to the terrestrial environment assessment are summarized in Table 6.4.1-1. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4.0 Indigenous Engagement.

Table 6.4.1-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Hydrology Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
Effects on the Winnipeg River ■ Importance of the river for drinking water, recreation and food.	Included in the environmental assessment	Effects to the Winnipeg River are addressed in Section 6.4.1.6.2 Results.
Effects on Manitoba Hydro Operations ■ Whether the site's discharge has any effects on Manitoba Hydro operations.	Included in the environmental assessment	Effects to the Winnipeg River are addressed in Section 6.4.1.6.2 Results. Although not explicitly called out in Section 6.4.1.6.2 Results, effects on the Manitoba Hydro operations are predicted to be negligible as changes to the discharge volume to the Winnipeg River is predicted to be within the natural range of variation of the Winnipeg River.

6.4.1.3 Valued Components

Valued components refer to environmental features identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Hydrology, which includes surface water flow and drainage direction, is recognized as an important component of the environment that may be affected by the Project and changes to hydrology could, in turn, lead to effects on other VCs selected for assessment. Acknowledging that changes to hydrology could lead to effects on other VCs, hydrology is referred to as an intermediate VC. For example, changes to the characteristics of hydrology flow rates, direction and riverbed location potentially have an influence on the local and regional biodiversity, contributing to the spatial and temporal distribution of aquatic and terrestrial ecosystems. Subsequently, changes to these characteristics by Project activities could affect fish and wildlife and land and resource use (Table 6.4.1-2). Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations did not identify any additional valued components as it relates to the hydrology assessment (Section 4.0).

Table 6.4.1-2: Valued Components for Hydrology Assessment

Valued Component	Rationale for Selection
Hydrology	■ The Project may affect the spatial and temporal distribution of water quantity for aquatic and terrestrial biodiversity, which can subsequently affect land and resource use. ■ Public, Indigenous concerns regarding changes in water quantity in the Winnipeg River are an important consideration in understanding potential effects of the Project.

Changes to intermediate VCs must be understood to facilitate assessment of project interactions. The hydrology assessment, therefore, is analyzed for incremental and cumulative (if applicable) changes in the relevant measurement indicators associated with hydrology (Table 6.4.1-3). The results of the analysis of changes in measurement indicators for hydrology are provided to other disciplines for inclusion in their assessment (Table 6.4.1-3).

Table 6.4.1-3: Measurement Indicators for the Hydrology Assessment

Valued Component	Measurement Indicators	Discipline Assessments where Effects on Hydrology are Considered
Hydrology	■ Runoff rates and volumes ■ Drainage patterns	■ Section 6.4.2 Surface Water Quality ■ Section 6.5 Aquatic Biodiversity ■ Section 6.6 Terrestrial Biodiversity ■ Section 6.8 Land and Resource Use

6.4.1.4 Assessment Boundaries

6.4.1.4.1 Spatial Boundaries

The spatial boundaries selected for the hydrology assessment are consistent with the surface water quality and aquatic biodiversity, and are presented on Figure 6.4.1-1 and described below:

- **Site Study Area (SSA)** is the Whiteshell Reactor 1 (WR-1) Building and represents the Project footprint (i.e., where project activities will be undertaken; 0.07 ha).
- **Local Study Area (LSA)** was selected in consideration of the SSA and the spatial extent of potential direct effects of the Project on hydrology, surface water quality and the aquatic environment. The LSA was selected to represent an area that is likely to be directly affected by the Project, helping to identify Project-specific (rather than cumulative effects of the Project in combination with other projects in the region). The LSA is represented by the fenced area of the Whiteshell Laboratories (WL) main campus and includes the SSA. The LSA was based on the area of the WL main campus that is currently drained by roadside ditches and storm sewers. All discharges (e.g., sumps, storm, process) flow to the single outfall station discharge. The approximate size of the LSA is 29 ha. The LSA does not include the Winnipeg River as direct effects on hydrology from the Project on the Winnipeg River are not anticipated. For example, direct effects to Winnipeg River as a result of changes in hydrology are anticipated to be negligible as the drainage area of the LSA is several orders of magnitude smaller than that of the Winnipeg River (15,000,000 ha).

- **Regional Study Area (RSA)** is defined as the area within which the maximum geographical extent of potential indirect effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. To the north, east and south the RSA is delineated by the boundaries of the WL site. To the west, the RSA is delineated by the Winnipeg River reach adjacent to WL site. For example, indirect effects on surface water quality from the Project include potential seepage of groundwater into the Winnipeg River. The plume from the discharged effluent during operation was previously assessed to hug the east bank of the river (AECL 1973) and it is assumed that a groundwater seep in relatively the same area will behave similarly. Therefore, the south boundary of the RSA extends from the west shore of the Winnipeg River to the east fence on the property line about 400 m north of Provincial Highway 211. The eastern boundary of the RSA follows the fence on the property line to the north property line. The north boundary follows the north fence on the property line about 1.6 km and then turns north for about 400 m before turning west and extending to the west side of the Winnipeg River. This is to include the first farm downstream on the east bank because this is the most conservative potential water user. The west boundary follows the west bank of the Winnipeg River. The RSA has an approximate size of 4,121 ha.

6.4.1.4.2 Temporal Boundaries

The temporal boundary of the assessment is the timeframe during which Project activities are occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of in situ disposal, which includes preparation for in situ disposal, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031.
- **Post-closure Phase:** The post closure phase has two discrete periods: institutional control and post institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue to demonstrate Whiteshell Reactor Disposal Facility (WRDF) performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.4.1.4.3 Assessment Cases

The assessment cases considered in the hydrology assessment include the Base Case, Application Case and the Reasonably Foreseeable Development (RFD) Case.

- **Base Case:** represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural and residential and recreational development. Current effects from the existing facilities and operations at the WL site, for example, are considered part of the Base Case. Seven Sisters Generating Station is approximately 7.5 km upstream of the WL site and McArthur Generating Station is approximately 26 km downstream. In addition, effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case.
- **Application Case:** represents the effects of the Base Case combined with the predicted effects from the Project. The Application Case includes closure and post-closure activities, and therefore, the associated effects during these phases of the Project represents the bounding case.

- **RFD Case**: represents the predictions of the cumulative effects of the Application Case, plus projects that are currently under application review or that have officially entered a regulatory application process and which overlap with the surface water environment RSA. Foreseeable developments in the surface water environment RSA that are expected to overlap with residual effects on hydrology from the Project includes the decommissioning of the remaining infrastructure and support facilities and remediation of affected lands at the WL site as per the existing decommissioning licence. A Comprehensive Study Report (AECL 2001) under the *Canadian Environmental Assessment Act, 1992* was completed for the decommissioning of the WL site. The Environmental Assessment decision to approve the Project was announced by the Minister of the Environment in March 2002 and a decommissioning licence was issued to Atomic Energy of Canada Limited and subsequently to Canadian Nuclear Laboratories (CNL). There are no other foreseeable developments in the surface water environment RSA that are expected to overlap with residual effects on hydrology from the Project (Table 6.4.1-4).

Table 6.4.1-4: Reasonably Foreseeable Developments considered in the Hydrology Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes in situ disposal of the low-level waste trenches).	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project

6.4.1.5 Description of the Environment

6.4.1.5.1 Methods

Existing hydrological conditions (e.g., flow rates, volumes, velocities and direction) within and surrounding the RSA, including the Winnipeg River, were obtained through a literature review of available baseline information and public information. Regional and local hydrology described in the Comprehensive Study Report (AECL 2001) and hydrology assessment at the WL site (AECL 2000) are summarized in this section. Daily discharge rates were provided by Manitoba Hydro (2016) at the Seven Sisters Generating Station (approximately 7.5 km upstream) and also taken from the Water Survey of Canada (WSC 2016) at McArthur Generating Station (approximately 26 km downstream). Water levels in the Winnipeg River for the intake water were provided by CNL (CNL 2016a).

Rainfall data were sourced from Environment and Climate Change Canada (ECCC) Weather Website (Government of Canada 2016). Runoff volumes generated by rainfall events within the SSA were estimated using the rainfall depths and intensities (i.e., Intensity-Duration-Frequency [IDF] data) recorded at Climate Station 5023233. This is the closest climate station with available rainfall IDF data from ECCC and is approximately 75 km west of the WL site (i.e., Winnipeg St Boniface CS 5023233). The Rational Method was applied to determine the peak runoff rates generated from the SSA (MOE 2003).

The analysis method provides estimates of the total runoff volumes from the SSA for storm events that range in frequency from once in every two years to once in every 100 year (return periods). A 1:100-year was selected as the evaluation event for this study since it is the largest IDF event that is provided by Environment Canada and is the industry standard for evaluating and designing structures for large storm events.

6.4.1.5.2 Results

The following sections present the results of the literature review relating to characterization of the Winnipeg River, local and regional drainage patterns, and estimates of the SSA surface water flows.

6.4.1.5.2.1 General Overview

The dominant hydrological feature of the RSA is the Winnipeg River, which flows on the west side of the RSA (Figure 6.4.1-1). The Winnipeg River flows from the Lake of the Woods and the English River system in Northwestern Ontario and drains to Lake Winnipeg located northwest of the WL site.

The Winnipeg River is classified as a medium-sized low land river. The total drainage basin of the Winnipeg River is approximately 15,000,000 ha. The river flow is determined by hydrologic conditions over the entire upstream drainage area and is not likely affected by localized precipitation events.

A decrease in ground elevation of 83 m from the Manitoba/Ontario border to Lake Winnipeg through a series of falls and rapids has resulted in extensive hydroelectric exploitation of this river. Six electric generating stations are present on the Winnipeg River, whose discharge rate is now largely controlled by these hydroelectric dams, which precludes any short-term correlation between precipitation and river flow. The two most relevant stations are the Seven Sisters Generating Station, which is approximately 7.5 km upstream of the WL site and McArthur Generating Station, which is approximately 26 km downstream.

Near the LSA, the river is approximately 300 m wide, 7 m deep and flows in a northerly direction at a velocity of approximately 0.3 m/s. Flow rates measured at the nearby Seven Sisters Falls Hydroelectric Generating Station (approximately 7.5 km upstream of the WL site) typically vary between 600 and 1,800 m^3/s with a record low at 125 m^3/s and a high at 2,800 m^3/s (CNL 2016b).

The flow of the river is usually lowest in late summer/early fall and highest in late spring/early summer (Figure 6.4.1-2). This follows typical temporal river patterns with water levels affected by spring snow melt and large precipitation events in spring and fall. The dams on the Winnipeg River provide some storage capacity, preventing extreme flooding and extreme low water levels.

A stage-discharge graph compares the river level to river flow. For the Winnipeg River, the water levels were taken at the WL pump house (AECL 2016) and the flows were taken approximately 7.5 km upstream at Seven Sisters Generating Station (Manitoba Hydro 2016). The stage-discharge for the Winnipeg River adjacent to the WL site demonstrates that there is a relationship between flow and water level at higher flow and water levels, but this changes when flow is below 1,200 m^3/s and elevation is below 255 m (Figure 6.4.1-3). As there are no extreme low water levels at low flows, it is inferred that the downstream dam, McArthur, is likely influencing water elevation in low flow conditions. Water levels on Winnipeg River at the WL pump house in 2013 and 2014 were recorded weekly (approximately 4 or 5 times per month).

6.4.1.5.2.2 Drainage Patterns

Surface water runoff generated within the SSA and LSA drains into the Winnipeg River. The SSA area is 0.07 ha and the LSA area is approximately 29 ha. Drainage around the LSA perimeter is accommodated by the use of shallow swales and drainage ditches. The roads, parking pads and roof discharges within the LSA are drained by underground storm drains that flow into the main drainage ditches within the LSA and directed to the Winnipeg River (AECL 2000).

The LSA is a very low-lying area with local elevations of only a few tens of centimetres to a few metres; the elevation difference from the WL main campus to top of the riverbank is approximately 0.5 m. However, there is a 10 m difference between the normal water elevations in the river and top of bank elevation.

Most of the surficial geology in the RSA consists of glacial lacustrine and glacial till deposits (about 20 m thick). Overlying are deposits of organic matter (i.e., wetland, swamp areas) most often about 0.5 to a few metres thick. There are also some localized areas that are well-drained, and these drier soils support mixed hardwood stands (AECL 2000). Most of the runoff from the RSA drains directly into Winnipeg River. A small amount of land from the low-lying eastern area within the WL site drains by ditches and small streams that flow into the Pinawa Channel. The Pinawa Channel, a diversion of some of the Winnipeg River discharge, flows in a roughly south to north direction on the eastern side of the RSA. Drainage within the RSA are directed by roadside ditches. The drainage area and quantity of discharge within the various drainage ditches vary, with some ditches and culverts having only measurable flow following spring melt and after sustained wet periods. Two of the drainage ditches (along Provincial Highway 211) are considered to be important for reducing surface storage and channel surface runoff directly to the Winnipeg River. One major drainage ditch, potentially diverting surface runoff from eastern boundary of the WL site, crosses Provincial Road 520 and drains into Pinawa Channel.

6.4.1.5.2.3 Surface Water Flow Estimation

The runoff rates and volumes generated by the SSA following activities of the Project are expected to decline from the existing conditions. To estimate the runoff rates and volumes generated by the SSA after the decommissioning activities, a runoff coefficient of 0.23 was assumed for the conditions designed for the SSA (average sloped soil and grassed area) based on speciality literature recommendations (i.e., parks; RTAC 1982). The runoff coefficient assumed for the current drainage conditions within the SSA, is approximately 0.83 (i.e., roofs, RTAC 1982), provided by the high percentage of hard surface area and buildings. The lower runoff coefficient for a grass covered area leads to a decrease of approximately 72% in runoff rates and volumes generated by the SSA.

Runoff volumes generated by rainfall events within the SSA were estimated using the rainfall depths and intensities (i.e., IDF data) recorded at the Climate Station 5023233. The Rational Method was applied to determine the peak runoff rates generated from the SSA that has an area of 0.07 ha (MOE 2003).

The Rational Method equation is: $Q = 0.00278\ C\ i\ A$

Where: Q = peak flow (m^3/s)

- C = runoff coefficient (dimensionless)
- i = rainfall intensity (mm/h)
- A = drainage area (ha)

The rainfall intensity used in the Rational Method equation was determined based on the return period at the time of concentration calculated for the SSA drainage area and applying the IDF curves. Rainfall intensities for a range of return periods at the SSA are given in Table 6.4.1-5. Drainage peak flow generated by the SSA for a specific return period and duration of a rainfall event were determined by applying the rainfall intensity values presented in Table 6.4.1-5 to the Rational Method. The resulting runoff volumes generated by the SSA for various return periods and durations are presented in Table 6.4.1-6.

Table 6.4.1-5: Estimated Rainfall Intensities (mm/hr) at the Site Study Area for Various Return Periods

Duration	Return Period					
	2 Years	5 Years	10 Years	25 Years	50 Years	100 Years
5 minutes	99.2	136.9	162.0	193.6	217.0	240.3
10 minutes	75.9	98.6	113.6	132.5	146.5	160.5
15 minutes	63.6	80.7	92.1	106.5	117.1	127.7
30 minutes	45.5	59.9	69.5	81.5	90.5	99.4
1 hr	27.2	36.9	43.4	51.6	57.6	63.6
2 hr	15.8	21.9	26.0	31.1	34.9	38.7
6 hr	6.6	9.2	10.9	13.1	14.7	16.3
12 hr	3.8	5.3	6.4	7.6	8.6	9.5
24 hr	2.1	2.9	3.4	4.1	4.6	5.0

Table 6.4.1-6: Estimated Runoff Volumes (m^3) Generated by the Site Study Area for Various Return Periods

Duration	Return Period					
	2 Years	5 Years	10 Years	25 Years	50 Years	100 Years
5 minutes	2	2	3	3	4	4
10 minutes	2	3	3	4	4	5
15 minutes	3	3	4	5	5	6
30 minutes	3	4	5	6	6	7
1 hr	4	5	6	7	8	9
2 hr	5	6	8	9	10	11
6 hr	7	9	11	13	14	16
12 hr	8	11	13	16	18	20
24 hr	10	14	16	20	22	25

The peak runoff rate from the SSA for a 1:25-year rainfall event is 0.012 m^3/s and, for a 1:100-year event, it is 0.014 m^3/s. The runoff volume generated by the SSA for a 1:25-year; 24-hour event is approximately 20 m^3 and for a 1:100-year event it is 25 m^3. Flow contribution to the Winnipeg River from the SSA is four or five orders of magnitude smaller than the river average flow.

6.4.1.6 Project Interactions and Mitigation

6.4.1.6.1 Methods

This section describes the process by which interactions between Project components and activities and hydrology were identified and evaluated. Potential effect pathways are identified, and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the Project and the environment by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the Project to eliminate and/or reduce adverse effects to hydrology. Environmental design features included project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project's engineering and environmental teams, combined with input from Project-specific or regional engagement with other interested parties. The design features and/or mitigation were selected considering their effectiveness for implementation and maintenance and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage pathway –** pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects to hydrology.
- **Secondary pathway –** the pathway could result in a measurable minor environmental change but would have a negligible residual effect on hydrology relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway –** the pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects to hydrology.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to hydrology through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways

were carried forward for more detailed quantitative and/or qualitative effects analysis to characterize the residual effects of the Project.

6.4.1.6.2 Results

Pathways through which all phases of the Project may interact with and result in changes to measurement indicators for hydrology are provided in Table 6.4.1-7.

Table 6.4.1-7: Pathways Analysis for Hydrology Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Installation of the concrete cap and engineered cover during closure	Installation of concrete cap and engineered cover at the WR-1 Building may alter drainage rates and flow patterns	■ The Project site and the engineered cover will be graded to promote drainage to the Winnipeg River.	Secondary
Closure of the entire WL site	Decommissioning and reclamation of the entire WL site, including the Project, may alter drainage rates and flow patterns	■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ The drainage system for the reclaimed WL site will have the physical characteristics similar to the natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. ■ The WL site will be graded to promote drainage to the Winnipeg River. ■ A stormwater management plan will be developed for the closure of the WL site using best management practices.	Secondary

6.4.1.6.2.1 No Linkage Pathway

There are no pathways identified as having no linkage to effects on hydrology.

6.4.1.6.2.2 Secondary Pathways

- **Installation of concrete cap and engineered cover at the WR-1 Building.**

Drainage from the LSA is to the Winnipeg River. Following the completion of closure activities, the Project site will be graded to promote drainage to the Winnipeg River. Run-off control for the engineered cover is designed to limit erosion and infiltration of water into the grouted structure. This is achieved by sloping the cover surface to maintain a slope toward the edges and the collection of water by the surface water management systems at the WL site. Although the installation of the concrete cap and engineered cover at the WR-1 Building is expected to slightly alter the drainage rates and flow patterns; the changes are expected to be within the natural range of variation. Conclusions on the effect of the concrete cap and engineered cover on the drainage and flow patterns of the Winnipeg River are supported given the footprint of the concrete cap and engineered cover is relatively small (approximately 30 m by 30 m) when considering the drainage area it resides within. Further, the natural variation

flow patterns in the Winnipeg River are a cumulative effect of its drainage basin, which outweigh the plausible flow from the concrete cap and engineered cover.

As such, effects to hydrology from the installation of the cover at closure is predicted to have a negligible residual effect on hydrology.

- **Decommissioning and reclamation of the entire WL site, including the Project.**

The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness, and longevity. The contribution to site runoff from the Project is expected to be minor relative to the entire decommissioned WL site. The WL site will be graded to promote drainage to the Winnipeg River. Although closure of the WL site may slightly alter the drainage rates and flow patterns and discharge volume to the Winnipeg River; the changes are expected to be within the natural range of variation.

As part of the closure of the WL site, a stormwater management plan will be developed using best management practices and taking into consideration the impact of the WL site's drainage following the demolition of the infrastructure (e.g., buildings, roads, catch basins, storm drainage system). The objectives of this management plan will include alternate drainage works (e.g., swales, ditches, culverts) along with aligning the landscaping to existing grades so that proper drainage is achieved. Typically, the stormwater will be directed to the Winnipeg River utilizing existing topography's drainage paths (creeks) to the greatest extent possible. The storm water management plan will evaluate:

- the post-closure topography applying the appropriate runoff coefficients;
- the impacts due to the reduction/elimination of existing drainage works;
- the rainfall event impacts on peak flow rates to the new drainage works; and
- the integration of remedial drainage works with the existing drains and creeks.

As such, effects to hydrology from the closure of the WL site, including the Project, are predicted to have a negligible residual effect on hydrology.

6.4.1.6.2.3 Primary Pathways

There are no primary pathways identified as having a residual effect on hydrology. As such, there is no residual effects analysis and determination of significance completed for the hydrology assessment.

6.4.1.7 Monitoring and Follow-up

Monitoring and follow-up programs are not identified as there are no predicted residual effects to hydrology. However, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as identified for other environmental components to verify the accuracy of environmental effects predictions and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with

that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs.

CNL will continue to proactively seek, engage, and support meaningful discussion on issues and opportunities related to the Project, including the monitoring and follow-up program, with First Nations and the Manitoba Métis Federation and communities of interest. CNL will continually evaluate both the process and the outcome of the ongoing engagement and communication activities, to address and manage issues as they arise.

6.4.1.8 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Acknowledging that changes to hydrology could lead to effects on other VCs, hydrology is referred to as an intermediate VC. Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations indicated the importance of the Winnipeg River for drinking water, recreation, food, and traditional access to land, including transportation. Indigenous peoples did not identify any additional valued components as it relates to the hydrology assessment.

The hydrology assessment considers the potential effects of the Project to the flows and water levels of the Winnipeg River. The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. Following the completion of closure activities, the WL site and engineered cover will be graded to promote drainage from the site to the Winnipeg River. Run-off control for the cover is designed to limit erosion and infiltration of water into the grouted structure. This is achieved by sloping the cover surface to maintain a slope toward the edges and the collection of water by the existing surface water management systems at the WL site. A stormwater management plan will be developed for the closure of the WL site using best management practices. The overall contribution of WL site drainage to the Winnipeg River flow is negligible, thus no effects are anticipated.

Natural runoff from the decommissioned WL site will continue to discharge to the Winnipeg River during the post-closure phase. Overall, the assessment of potential effects determined there are no residual adverse effects on hydrology of the Winnipeg River. This conclusion applies to the interests and concerns about the Winnipeg River hydrology raised by the engaged Indigenous Nations that were encompassed by the assessment (Table 6.2.1-1).

Monitoring and follow-up programs are not identified as there are no predicted residual effects to hydrology. However, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as identified for other environmental components to verify the accuracy of environmental effects predictions and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical.

CNL will continue to proactively seek, engage, and support meaningful discussion on issues and opportunities related to the Project, including the monitoring and follow-up program, with First Nations and the Manitoba Métis Federation and communities of interest. CNL will continually evaluate both the process and the outcome of the ongoing engagement and communication activities, to address and manage issues as they arise.

6.4.2 Surface Water Quality

6.4.2.1 Scope of the Assessment

Section 6.4.2 focuses on surface water quality within the Winnipeg River. It assesses the potential change in water quality attributed to the Project, including parameters relevant to the health of humans, aquatic biota and terrestrial wildlife.

The surface water quality assessment follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment is completed in the following steps:

- **Step 1 – Identifies Valued Components (VCs) and defines the spatial boundaries, temporal boundaries and assessment cases** (refer to Section 6.4.2.3 Valued Components and Section 6.4.2.4 Assessment Boundaries) for the surface water quality assessment. The VCs, assessment endpoints and measurement indicators used to assess Project related changes to surface water quality, the spatial and temporal boundaries at which the assessment occurred, and the assessment cases considered are described.
- **Step 2 – Describes the existing conditions** (refer to Section 6.4.2.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluates Project interactions and mitigation** (refer to Section 6.4.2.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect surface water quality are identified and mitigation options are presented to limit or avoid these effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded to further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described. Primary pathways that may lead to residual effects to surface water quality after incorporating mitigation are carried forward to Step 4 for further analysis and residual effects characterization.
- **Step 4 – Presents the methods and results of the residual effects analysis** (refer to Section 6.4.2.7 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to surface water quality from primary effect pathways. The analysis results are also presented including the characterization of incremental effects from the Project, as well as cumulative effects of the Project in combination with other reasonably foreseeable developments (if applicable). A key outcome of this section is the predicted changes to surface water parameters in the Winnipeg River that are passed to other disciplines for their assessment.

- **Step 5 – Describes the level of certainty and management of uncertainty** (refer to Section 6.4.2.8 Prediction Confidence and Uncertainty). The purpose of the section is to evaluate the available literature, data and models used for the assessment, and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 – Classify and determine the significance of the predicted residual effects.** This step was not required as the surface water quality VC is an intermediate component, which does not include an assessment endpoint to determine significance.
- **Step 7 – Identifies monitoring and follow-up** (refer to Section 6.4.2.9 Monitoring and Follow-up) required to confirm effect predictions and address uncertainty.
- **Step 8 – Presents a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.4.2.10 Conclusions) of residual effects on surface water quality.

6.4.2.2 Indigenous Engagement Feedback – Key Interests and Concerns

Information and concerns raised specifically by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the surface water quality assessment are summarized in Table 6.4.2-1. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4 Indigenous Engagement.

Table 6.4.2-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Surface Water Quality Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
Effects on the Winnipeg River ■ The containment of waste in the disposal facility and long-term effects of the site and the Project on water quality. ■ Past releases and potential future discharges of hazardous and radioactive material	Included in the environmental assessment	The Winnipeg River was included in the Regional Study Area for the assessment of water quality. See Section 6.4.2.4.1 Spatial Boundaries. Effects on water quality are described in Section 6.4.2.7 Residual Effects Analysis.
Spills of Hazardous Materials ■ How CNL detects spills	Included in the environmental assessment	CNL's Emergency Preparedness Program is summarized in Section 7.3.2 Spills and Leaks.
Water Quality Monitoring	Included in the environmental assessment	Information on the monitoring program is available in Section 6.4.2.9 Monitoring and Follow-up.

6.4.2.3 Valued Components

Valued components refer to environmental features that may be influenced by the Project and that have been identified to be of importance by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Surface water quality is recognized as an important component of the environment that may be affected by the Project. Subsequently, changes to surface water quality by Project activities could affect human health, fish and wildlife and land and resource use (Table 6.4.2-2). Indigenous engagement confirmed the importance of surface water quality. Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations were concerned as the Project may indirectly discharge water into the Winnipeg River.

Table 6.4.2-2: Valued Components for Surface Water Quality Assessment

Valued Component	Rationale for Selection
Surface Water Quality	There is potential for interaction with the Project; species of concern live in the river; river has ecological and socio-economic value to communities, government agencies and the public; and downstream areas have traditional, cultural and heritage importance to Indigenous peoples.

Acknowledging that change to water quality is considered to be an important aspect of the natural and human environment, surface water quality is referred to as an intermediate VC (i.e., it does not have an assessment endpoint). Changes to intermediate VCs must be understood to facilitate assessment of project interactions. The surface water assessment, therefore, is analyzed for incremental and cumulative (if applicable) changes in the relevant measurement indicators associated with surface water quality (Table 6.4.2-3).

Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on a VC. Measurement indicators also provide the primary factors for discussing the uncertainty of effects on VCs and, subsequently, are the key variables for study in follow-up and monitoring programs. The changes are characterized in terms of magnitude, duration, and geographic extent, but are not classified using rankings for effects criteria. The surface water quality assessment also does not include the assessment of the significance of these changes; rather, results of the analysis of changes in measurement indicators for surface water quality are provided to other disciplines for inclusion in their assessment (Table 6.4.2-3).

Surface waters interact with other environment features, including humans, aquatic biota, and terrestrial wildlife. The results of the surface water quality assessment therefore extend to other disciplines as listed in Table 6.4.2-3.

Table 6.4.2-3: Measurement Indicators for the Surface Water Quality Assessment

Valued Component	Measurement Indicators	Discipline Assessments where Effects on Surface Water Quality are Considered
Surface Water Quality	Changes to ambient levels of surface water contaminants (turbidity, radionuclides, metals)	■ Aquatic Environment (Section 6.5) ■ Terrestrial Environment (Section 6.6) ■ Human and Ecological Health (Section 6.7) ■ Land and Resource Use (Section 6.8)

6.4.2.4 Assessment Boundaries

6.4.2.4.1 Spatial Boundaries

The spatial boundaries selected for the surface water quality assessment are consistent with hydrology and aquatic environment, and are presented on Figure 6.4.2-1:

- **Site Study Area (SSA):** is the Whiteshell Reactor 1 (WR-1) Building and represents the Project footprint (i.e., where project activities will be undertaken; 0.07 ha).
- **Local Study Area (LSA):** was selected in consideration of the SSA and the spatial extent of potential direct effects of the Project on hydrology, surface water quality and the aquatic environment. The LSA was selected to represent an area that is likely to be directly affected by the Project, helping to identify Project-specific (rather than cumulative effects of the Project in combination with other projects in the region). The LSA is represented by the fenced area of the WL main campus and includes the SSA. The LSA was based on the area of the WL main campus that is currently drained by roadside ditches and storm sewers. The approximate size of the LSA is 29 ha. The LSA does not include the Winnipeg River as direct effects to surface water quality from the Project on the Winnipeg River are anticipated to be negligible (e.g., there is no direct discharge to the Winnipeg River). Conversely, indirect effects to the surface water quality of the Winnipeg River may occur as a result of changes to groundwater quality resulting from the Project. As such, the Winnipeg River is considered as part of the RSA (see description below).
- **The Regional Study Area (RSA)** is defined as the area within which maximum geographical extent of potential indirect effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. For example, indirect effects on surface water quality from the Project include potential seepage of groundwater into the Winnipeg River. The plume from the discharged effluent during operation was previously assessed to hug the east bank of the river (AECL 1973) and it is assumed that a groundwater seep in relatively the same area will behave similarly. Therefore, the south boundary of the RSA extends from the west shore of the Winnipeg River to the east fence on the property line about 400 m north of Provincial Highway 211. The eastern boundary of the RSA follows the fence on the property line to the north property line. The north boundary follows the north fence on the property line about 1.6 km and then turns north for about 400 m before turning west and extending to the west side of the Winnipeg River. This is to include the first farm (Farm A) downstream on the east bank because this is the most conservative potential water user. The west boundary follows the west bank of the Winnipeg River. The RSA has an approximate size of 4,121 ha.

6.4.2.4.2 Temporal Boundaries

The temporal boundary of the assessment includes effects observed under existing conditions, the timeframe during which Project activities are actively occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of in situ disposal, which includes preparation for in situ disposal, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031.
- **Post-closure Phase:** The post closure phase has two discrete periods: institutional control and post institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue to demonstrate Whiteshell Reactor Disposal Facility (WRDF) performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.4.2.4.3 Assessment Cases

There are three assessment cases considered in this EIS: the base case; application case; and reasonably foreseeable developments (RFD) case:

- **Base Case:** represents existing conditions and characterized combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining, and residential and recreational activities. Current effects from the existing facilities at the WL site such as effluent discharged to the Winnipeg River are considered. These include the ditch drainage system of the Waste Management Area (WMA) and sewage lagoon. Sediment near the effluent outfall has elevated levels of radionuclides due to historical discharge and fallout (AECL 2001a) and is also considered as part of the Base Case. Levels of caesium-137 in soil and sediment are elevated in the WL area (latitude 40 to 60 degrees) due to above average deposition from world-wide nuclear weapon testing during the cold war (AECL 2001a; NRCC 1983). In addition, existing conditions of areas not affected by the WL site are also considered as part of the Base Case. For example, Seven Sisters Generating Station is approximately 7.5 km upstream of the WL site and McArthur Generating Station is approximately 26 km downstream. Effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case.
- **Application Case:** represents the effects of the Base Case combined with the predicted effects from the Project. The Application Case includes closure and post-closure activities. Surface water runoff during closure and the groundwater seep during post-closure represent the bounding cases.
- **RFD Case:** represents the predictions of the cumulative effects of the Application Case, plus projects that are currently under application review or that have officially entered a regulatory application process and which overlap with the surface water quality in the RSA. Foreseeable developments in the surface water environment RSA that are expected to overlap with residual effects on surface water quality from the Project includes the decommissioning of the remaining infrastructure and support facilities and remediation of affected lands at the WL site as per the existing decommissioning licence. A Comprehensive Study Report (AECL 2001b) under the *Canadian Environmental Assessment Act, 1992* was completed for the decommissioning of the WL site. The Environmental Assessment decision to approve the Project was announced by the Minister of the Environment in March 2002 and a decommissioning licence was issued to Atomic Energy of Canada Limited (AECL) and subsequently to Canadian Nuclear Laboratories (CNL). There are no other foreseeable developments in the RSA that are expected to overlap with changes to surface water quality (Table 6.4.2-4).

Table 6.4.2-4: Reasonably Foreseeable Developments considered in the Surface Water Quality Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes in situ disposal of the low-level waste trenches).	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project

6.4.2.5 Description of the Environment

6.4.2.5.1 Methods

This section documents the methods, data and results that were used to describe the background surface water quality in the SSA, LSA and RSA for surface water parameters. The assessment was carried out by reviewing documents and collecting data from government agencies.

Background, or ambient water quality for the Winnipeg River exclusive of any potential WL site related influence is represented herein by two sampling locations – the WL Intake and the Powerview Dam. The WL Intake is located in the river at the WL site, upstream of any potential site-associated influence. Sampling at WL is completed by CNL. The Powerview Dam site is located on the river at the community of Powerview-Pine Falls approximately 26 km downstream of WL, well beyond the influence of the WL site. Sampling at the Powerview Dam is completed through a provincial government initiative by the Department of Sustainable Development. Water quality data collected over the period 2011 through 2019 (where available) at these two locations are summarized in Table 6.4.2-5 and Table 6.4.2-6. The data are associated with monthly sampling events and are summarized on a yearly basis. In the tables, data for the WL Intake station are prioritized over the Powerview Dam site - that is, where available, the data for the WL Intake are shown. The Powerview Dam data are provided to supplement the WL Intake data for specific constituents that are not captured in the WL Intake sampling program, in order to present a broader characterization of background conditions in the river. Notes provided with the tables identify the origin of the data shown for each constituent.

Where possible, surface water parameters were compared to federal or provincial standards, objectives, or guidelines. Where guidelines from the federal or provincial jurisdictions were missing, guidelines from other provinces or toxicity tests were used. Acute toxicity tests were divided by 100 and chronic toxicity tests were divided by 10 to adjust the values to a no observable adverse effects level guideline.

Some sediment samples downstream of the outfall had elevated levels of radionuclides so a more detailed investigation was conducted in 2000 (AECL 2001a). The sediment surface was surveyed with a gamma survey probe and gamma spectroscopy probe. Sediment samples were also collected for laboratory analysis of radionuclides. In 2006, sediment cores were taken as part of the Environmental Assessment Follow-Up and Monitoring Program (AECL 2008). This program involves sampling in Lake Sylvia and upstream and downstream of the waterbody Lac du Bonnet every 20 years. The objective is to characterize sediment adjacent to the WL site by age dating with lead-210 methods. As part of the routine monitoring at the WL site, water, sediment, and biota are sampled regularly (CNL 2012, 2013, 2014, 2015 2016a, 2017a, 2018a, 2019a, 2020a). Radionuclides

measured in liquids are reported as Becquerel per litre (Bq/L) and radionuclides measured in solids are reported as Becquerels per kilogram (Bq/kg).

Daily discharge rates were provided by Manitoba Hydro (2016) at the Seven Sisters Generating Station 7.5 km upstream and were also taken from the Water Survey of Canada (WSC 2016) at McArthur Generating Station. Water levels in the Winnipeg River and water chemistry for the intake water was provided by CNL (CNL 2016b, 2020b). Water quality was also provided by the Manitoba Water Quality Management Section (WQMS 2016; 2020) from Pine Falls.

6.4.2.5.2 Results

6.4.2.5.2.1 General Overview

The Winnipeg River is considered to be a medium-sized lowland river (AECL 2001b). Its drainage area is approximately 15,000,000 ha, originating in Ontario at Lake of the Woods (Figure 6.4.2-2). The Winnipeg River and its chief tributary, the English River, drain a 150,000 km^2 area contained almost entirely within the Precambrian Shield. Two thirds of the basin lie within northwestern Ontario. From Ontario, it extends south into northern Minnesota, and west from the head of the Great Lakes through the Whiteshell Provincial Park. In eastern Manitoba, Lake of the Woods is the largest single lake in the Winnipeg River drainage basin. Lake of the Woods and its major tributary, the Rainy River, form a system that drains the southern portion of the area. The northern portion is drained by the English River and Lac Seul systems.

There are nine hydroelectric dams within the watershed, the closest approximately 7.5 km upstream of the WL site. These dams have extensively modified flow patterns in the river (AECL 2001b). Dams store water during periods of high precipitation and release water during periods of low precipitation. This regulates the downstream flow (Section 6.4.1.4.2, Figure 6.4.1-3). Adjacent to the WL site, the river is approximately 0.3 km wide and 7 m deep and flows northerly between 436 and 1,842 m^3/s (2010 to 2015 average at Seven Sisters Generating Station; Manitoba Hydro 2016) to Lake Winnipeg.

The flow of the river is usually lowest in late summer/early fall and highest in late spring/early summer (Section 6.4.1.4.2, Figure 6.4.1-2). This follows typical temporal river patterns with water levels affected by spring snow melt and large precipitation events in spring and fall. The dams on the Winnipeg River provide some storage capacity, preventing the extreme flooding and extreme low water levels. For the Winnipeg River, the water levels were taken at the WL pump house (CNL 2016b) and the flows were taken approximately 7.5 km upstream at Seven Sisters Generating Station (Manitoba Hydro 2016). The stage-discharge for the Winnipeg River adjacent to the WL site demonstrates that there is a relationship between flow and water level at higher flow and water levels, but this changes when flow is below 1,200 m^3/s and elevation is below 255 m (Section 6.4.1.4.2, Figure 6.4.1-3).

An extensive wetland area is situated in the middle to eastern portion of the RSA (AECL 2001b). Surface water drainage from the wetland area generally flows from the east towards the Winnipeg River (Section 6.4.1.3).

6.4.2.5.2.2 Surface Water and Sediment Quality

Liquid effluent from the active liquid waste treatment systems at the WL site discharged to the Winnipeg River via the Process Sewer at the sewer outfall located about 8 m offshore in approximately 5 m of water (AECL 2001b). The Winnipeg River Task Force (WRTF 1995) looked at potential sources of Winnipeg River water quality degradation near Sagkeeng First Nation. The Winnipeg River Task Force found that the WL site has not had an adverse effect on water quality in the Winnipeg River for downstream communities (AECL 2001b). The Winnipeg River Task Force included members from the Sagkeeng First Nation, Environment Canada, Indian and Northern Affairs Canada and Health Canada. The concentration of the dominant radionuclide associated with the discharge, caesium-137, in downstream river water (K11 on Figure 6.4.2-3) was an average of 0.005 Bq/L in 2015 and 0.014 Bq/L in 2019 compared to the Canadian Drinking Water Quality Guideline of 10 Bq/L.

The monthly average of water chemistry for 2011 to 2019 for the intake water for WL site had concentrations of copper, iron and lead exceeding the Manitoba Water Quality Standards, Objectives and Guidelines (WQSOG). Copper and lead also exceeded the Canadian Council of Ministers of the Environment Water Quality Guidelines (CCME WQG; Table 6.4.2-5; Figure 6.4.2-2, Figure 6.4.2-3), although concentrations have decreased starting in 2016, and lead concentrations have been under the WQSOG and CCME WQG since 2017. Concentrations of mercury exceeded the WQSOG in 2016 but not in any other years. Phosphorous concentrations in the river also exceeded the WQSOG between 2014 and 2017 but have since decreased to below guideline levels. The intake water quality is considered to be uninfluenced by the WL site because it is located upstream of discharges from the WL site. Recently, the Winnipeg River has been classified as meso-eutrophic (at Pointe du Bois; ECCC 2015). This indicates that nutrient levels are moderate, which may lead to plant growth and reduced water clarity.

The provincial water sampling location at Powerview Dam Forebay (shown as Pine Falls on Figure 6.4.2-2) exceeded the aquatic life guideline for barium. Dissolved oxygen levels (Table 6.4.2-6) were usually around 12 mg/L, but were occasionally below 4 mg/L in the morning. Water quality does not comply with the WQSOG if the dissolved oxygen goes below 4 mg/L more than three times per year (MWS 2011). Temperatures varied seasonally, with extremes of 0.8°C and 25°C. The lowest and highest hardness measured was 43.2 and 58.5 mg/L, respectively, since 2011. Samples collected upstream of the WL site (Pinawa) has consistently had caesium-137 and strontium-90 concentrations below the federal drinking water standard (Table 6.4.2-6).

During the 2000 sediment investigation, the sediment downstream of the outfall was determined to be erosional, with a clay bottom covered in parts with sand, gravel, cobble, and boulders (AECL 2001a). Figure 6.4.2-4 presents the results from the 2000 gamma sediment survey. The y- and x-axis are distance on the bottom of the river in relation to the shore and outfall pipe of WL. The colouring indicates the gamma count rate (Becquerel, equivalent to counts per second), where the redder the peak, the higher the count rate, the higher the disintegration of the radionuclides. The z-axis (up axis) indicates the relation of the disintegration to background, where the very top of the axis is 350-fold above background, which is considered a threshold for environmental exposure (AECL 2001a). AECL (2001a) determined that 350-fold above background or lower was acceptable for the protection of aquatic life (i.e., expected no effect value from Environment Canada and Health Canada 2000 a,b). The highest count rate was 54 times background and the area averaged approximately 7 times background. The sediment core samples taken in this area had the highest activity in the top 1 cm. A small area adjacent to the outfall had elevated radionuclide levels, but these levels were below the threshold that would cause adverse effects to human or ecological health. Therefore, during the discharge of the 1990s and 2000s, the accumulation of radionuclides in sediment had negligible environmental effects.

Notes:
WQSOG = Manitoba Water Quality Standards, Objective and Guidelines (MWS 2011). 43 mg/L was used for hardness from Pine Falls (WQMS 2016).
CCME WQG = CCME Water Quality Guidelines for the protection of aquatic life (CCME 1999a).
CDWG = Canadian Drinking Water Guidelines (Health Canada 2009).
Other - Other guidance used where ecological or human health values not provided by sources above.
* Guideline is hardness-dependent.
<Value is less than detection.
1 - Secondary Chronic Value from Suter and Tsao (1996) divided by 10.
2 - LC_{50} from Borgmann et al. (2005) divided by 100.
3 - Ontario Provincial Water Quality Objective (MOEE 1994).
4 - British Columbia Water Quality Guidelines (BC MOE 2009).
WQMS 2016; 2020 indicates water quality from the provincial water sampling location at Pine Falls on the Winnipeg River located downstream of the WL site.
CNL 2016b, 2017b, 2018b, 2019b, 2020b indicates water quality from the Whiteshell Laboratories intake on the Winnipeg River located upstream of the process outfall station.
NA – Not applicable; NV – No value; —- = no guidelines or no value

Notes:
WQSOG = Manitoba Water Quality Standards, Objective and Guidelines (MWS 2011). 43 mg/L was used for hardness from Pine Falls (WQMS 2016).
CCME WQG = CCME Water Quality Guidelines for the protection of aquatic life (CCME 1999a).
CDWG = Canadian Drinking Water Guidelines (Health Canada 2009).
Other - Other guidance used where ecological or human health values not provided by sources above.
* Standard is hardness-dependent.
<Value is less than detection.
‡ For cool water, not more than once each 3 years below 5.5, 6.0, 4.0, 5.0 and 3.0 mg/L for 30 days, 7 days, 7 day minimum, instantaneous minimum and instantaneous minimum, respectively. For cold water not more than once each 3 years below 6.5, 9.5, 5, 8 and 4 mg/L for 30 days, 7 days, 7 day minimum, instantaneous minimum and instantaneous minimum, respectively.
1 - Lowest IC_{25} from HB-40 Toxicity Testing (EcoMetrix 2017) divided by 10.
2 - British Columbia Water Quality Guidelines (BC MOE 2007).
WQMS 2016 and 2020 indicates water quality from the provincial water sampling location at Pine Falls on the Winnipeg River located downstream of the WL site.
CNL 2016b and 2019a,b, 2020b indicates water quality from the Whiteshell Laboratories intake on the Winnipeg River located upstream of the process outfall station.
µS/cm = microSiemens per centimetre; Bq/L = Becquerel per litre; NTU = Nephelometric Turbidity Units; NA = Not applicable; NV=– No value

Sediment core sampling as part of the Environmental Assessment Follow-Up and Monitoring Program was completed in 2006 and is planned to occur every 20 years following. The top 10 cm in each area was below the caesium-137 *Nuclear Substance and Radiation Devices Regulations (*SOR/2000-207) (NSRDR) Clearance Level of 100 Bq/kg (AECL 2008). Caesium-137 activity increased with depth in all cores (AECL 2008). For the upstream cores this was attributed to the preferential fallout in the area during global weapons testing in the 1960s. The downstream cores increase in activity was attributed to a combination of the weapon's testing and WL discharges in the 1970s and 1980s. Sediments at depths dating to before 1990 had caesium-137 activities that exceeded the NSRDR Clearance Level (AECL 2008).

As part of the routine monitoring at the WL site, river bottom sediments were collected from twelve locations along the Winnipeg River, ranging from 0.8 km upstream to 13.1 km downstream of the Outfall (Figure 6.4.2-3). In 2019, the gross alpha activity detected in the samples ranged from 167 to 633 Bq/kg (CNL 2020a). In five years prior, average minimums and maximums activities ranged from 214±173 to 534±255 Bq/kg. The alpha activity in these samples is due to naturally occurring isotopes such as uranium-238 or thorium-232 and their progeny, as both upstream and downstream samples contain similar levels. All radionuclides measured in sediment in the Uranium-238 and Thorium-232 decay chain were below detection limits. All samples are below the NSRDR Clearance Level for naturally occurring uranium-238 or thorium-232 of 1,000 Bq/kg (CNL 2020a).

Gamma spectrometry of the samples identified the presence of caesium-137 and potassium-40. The gross beta activity in sediment ranged from 333 to 1133 Bq/kg in 2019 at the twelve sampling locations (CNL 2020a). The previous five years average minimums and maximums ranged from 283±119 to 1,504±206 Bq/kg. The gross beta activities measured in 2019 for most sediment samples are higher than averages for the previous five years, with no trends observed. Beta activity includes contributions from naturally occurring potassium-40 and from caesium-137. Aliquots of samples collected in 2019 were submitted for strontium-90 analysis, and results indicated that strontium-90 makes an insignificant contribution to radioactivity in sediments. The majority of the beta activity for all locations continues to be from naturally occurring potassium-40 (CNL 2020a). The NSRDR Clearance Level for potassium-40 is 10,000 Bq/kg.

The highest measured Cs-137 level in a sediment sample during the 2000 study was 2,610 Bq/kg (AECL 2001a). This exceeds the NSRDR Clearance Level of 100 Bq/kg for caesium-137. Although the activity level in the sediment at the K03 location is above NSRDR unconditional clearance level, it is well below a human external exposure level of concern of 2.8×10^{6} Bq/kg. It is also well below the Tier 2 estimated no-effects value for benthic invertebrates' of 1.5×10^{5} Bq/kg. The caesium-137 levels detected in the samples collected during routine monitoring at locations OFL, K03, K05, K14 and K23 from 2010 to 2019 were one to two orders of magnitude lower than the highest 2000 sample (Table 6.4.2-7; CNL 2016a, 2020a). Caesium-137 levels at all locations except OFL, K03 and K05 were below the NSRDR Clearance Level of 100 Bq/kg. With exception of samples from K19, K23 and K30, all caesium-137 activity levels in 2019 were below the lower limit of detection of 20 Bq/kg (CNL 2020a). The activity at OFL has historically varied from less than 5 Bq/kg to 75,500 Bq/kg (CNL 2016a). Variation of activity is not unexpected for all samples due to the highly localized and spotty nature of the contamination in the river sediments. This variability is the likely reason for the unusually high caesium-137 activity noted in the K05 sample in 2015 (Table 6.4.2-7; CNL 2016a).

6.4.2.5.2.3 Traditional Knowledge

This section summarizes observations and concerns shared by Indigenous Nations in their Traditional Land Use and Occupancy Studies related to the existing conditions of the Winnipeg River. The following are quotes relevant to surface water quality as it pertains to the existing conditions of the Winnipeg River and the ability to obtain drinking water.

From the Sagkeeng First Nation:

> *"You know what, drinking water was no problem … You know, just dig a hole, just dig a hole there, there'd be nothing, right, maybe two, three feet and then just leave it, you know, you keep picking your blueberries or whatever you're doing. And then you fill up your container and by the time you go and, by the time you go and fill it up, by the time it's filled up and then you go and check your water, your hole then it's full of water already. So, there was always water filled by, flowing under, you know what I mean."* (Firelight Group Inc and Sagkeeng Anicinabe 2018)

From Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation:

> *"Years ago, the water was clean…My husband said he remembered the river clear or blue and you could dip your dipper in and see it. He used to go out paddling with his grandmother to get medicine. And she would dip her dipper in and drink it."* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019)

> *"Something is happening in our water reservoir of Lake Winnipeg. Our lake is bad now and getting worse. Fishermen are having a hard time catching our limits. We were out 3 weeks and caught only 200 kilograms of pickerel. Now the dirty water in the lake is contaminated. Need to go further to do more testing on the lake to clean it up like they did in the North Basin. Not only fishing – we drank from there, too. We're*

> *hearing stories about deformed fish with growths on their scales. Winnipeg River has something to do with it too."* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019)

From the MMF:

> *"One participant noted two drinking water sources from within the 25 km Study Area. GISID 5202-16 indicates a pump in the Lee River which is the drinking water source for the participant's household. The participant explained that they used to drink water straight from the Lee River, but since moving back to the area in 2003, they have had to install multiple filters and reverse osmosis on their water coming from the Lee River. These filters have to be changed roughly every week and a half. The participant noted the high cost of these filters as well as costs associated with ongoing water quality testing (Shared Value Solutions 2019)."*

For further information on how CNL incorporated Traditional knowledge into the EIS refer to Section 4.3 Influence of Traditional Knowledge on the Environmental Assessment and to Section 5.0 Traditional Land and Resources Use of the Indigenous Engagement Report (CNL 2024b).

6.4.2.6 Project Interactions and Mitigation

6.4.2.6.1 Methods

This section describes the process by which interactions between Project components and activities and surface water quality were identified and evaluated. Potential effect pathways are identified and mitigation developed to eliminate and/or reduce effect is presented. A pathways analysis is then used to focus the assessment on key interactions between the Project and the environment by evaluating the different effect pathways to assess if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in Section 6.4.2.6 (Residual Effects Analysis). As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce effects to surface water quality. After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation.

- **No linkage pathway –** pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change to concentrations of parameters relative to Base Case values, and therefore would have no residual effects to surface water quality.
- **Secondary pathway –** the pathway could result in a measurable minor change to concentrations of parameters but would have a negligible residual effect on surface water quality relative to Base Case and/or

guideline values and is not expected to contribute cumulatively to other past, present, or reasonably foreseeable developments to cause a significant effect.

- **Primary pathway –** the pathway is likely to result in an environmental change to concentrations of parameters relative to the Base Case and/or guideline values that could contribute to residual effects to surface water quality.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects to the aquatic environment were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect on the aquatic environment through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways are carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the Project on the aquatic environment.

6.4.2.6.2 Results

Pathways through which the Project may interact with and result in changes to concentrations of surface water parameters are provided in Table 6.4.2-8.

Table 6.4.2-8: Pathways Analysis for Surface Water Quality Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

General Project activities during the closure phase	Non-radiological air emissions and dust emissions (including sulphur dioxide, nitrogen oxides [NO_X/NO_2] and particulate matter) and subsequent deposition.	■ Implementation of CNL's *Environmental Protection* (CNL 2021a) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring.
		■ Implementation of CNL's Environmental Monitoring Program (CNL 2020a).
		■ Implementation of dust management techniques to control dust generated by the Project, consistent with the current Environmental Assessment Follow-up and Monitoring Program.
		■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures.
		■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include:
		  ■ wetting techniques during demolition to limit mobility of dust;
		  ■ wind restrictions during demolition to stop work or apply wetting techniques; and
		  ■ hydro seeding during backfilling and landscaping to reduce soil erosion.
		■ Road watering and chemical dust suppressant when necessary. Dust suppressant is already used annually at the site for select unpaved roads.
		■ Removal of accumulations of particulates (e.g., dirt) on road as soon as possible.
		■ On-site vehicles and equipment engines will meet Tier 3 emission standards, where possible, and be maintained in good working order.
		■ Limit idling of vehicles on-site and speed on roads.
			Secondary

Table 6.4.2-8: Pathways Analysis for Surface Water Quality Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
		■ Use of tarps or 3-sided enclosures for raw material storage.	
General Project activities during the closure phase	Closure activities will result in the atmospheric release of radiological compounds from the WR-1 Building	■ Implementation of CNL's Radiation Protection Program and Procedure, which includes Radiation Safety Zones, detailed work planning to limit doses to As Low As Reasonably Achievable (ALARA), dose monitoring and contamination control procedures (e.g., stabilizing and immobilizing agents). ■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Implementation of CNL's Environmental Monitoring Program (CNL 2020a).	Secondary
General Project activities during the closure phase	During closure activities, there is the potential for the transport of site runoff to the Winnipeg River.	■ Wastewater from decommissioning activities is collected and tested, and based on the results, is directed either to the waste treatment center, domestic drain, processed drain or ditch systems, or is sent for evaporation and/or solidification and disposal. ■ Existing surface water management systems at the WL site will remain in place to manage site runoff. ■ As per CNL's Management of Land, Habitat and Wildlife (CNL 2024a), any work within 30 metres of rivers, streams and lakes will have preventative and mitigation measures in place.	Secondary
Installation of concrete cap and engineered cover over grouted structure and final restoration	Installation of concrete cap and engineered cover may alter drainage rates and flow patterns.	■ The WL site and engineered cover will be graded to promote drainage from the site to the Winnipeg River.	Secondary
Closure of the entire WL site	Decommissioning and reclamation of the entire WL site, including the Project, may alter drainage rates and flow patterns as current precipitation management is removed.	■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. ■ The WL site will be graded to promote drainage from the site to the Winnipeg River.	Secondary
Post-closure Performance (Project-related)	Release of chemical and radiological contaminants in the long-term during the post-closure phase from the Project.	■ The planned decommissioning of the WR-1 Complex presently involves: ▪ removal the service area and infilling in these areas with compact soil; ▪ sealing of open conduits in the building foundation; and ▪ grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation. ■ As part of CNL's licence with the Canadian Nuclear Safety Commission (CNSC), environmental monitoring around the WL site is required and will continue for the Project during institutional control. ■ Follow-up monitoring will be completed during institutional control to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Primary

Table 6.4.2-8: Pathways Analysis for Surface Water Quality Valued Component

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Post-closure Performance (Other activities at the WL site)	Release of chemical and radiological contaminants in the long-term during the post-closure phase from the previous activities completed at the WL site.	■ As part of CNL's licence with the CNSC, environmental monitoring around the WL site will continue for the Project during the institutional control. ■ Follow-up monitoring will continue during institutional control to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Secondary

6.4.2.6.2.1 No Linkage Pathway

No pathways were identified between the Project and the aquatic environment as being 'no linkage' to residual effects on surface water quality.

6.4.2.6.2.2 Secondary Pathways

The following pathways were assessed as potentially having a measurable minor change to surface water quality relative to Base Case.

- **During closure activities, there is the potential for the transport of site runoff to the Winnipeg River.**

The LSA drains to the Winnipeg River. During closure phase activities, specifically those that are demolition-related, there is the potential for the transport of site runoff to the Winnipeg River in the vicinity of the WL site. Site runoff may be compromised by various activities such as the mobile batch plant (increased pH and suspended solids levels), crushing masonry (increased pH and suspended solids levels) and cutting steel (increased metal levels).

All wastewater generated at the LSA is managed in accordance with CNL's *Management and Monitoring of Emissions* (CNL 20b) and is discharged in accordance with CNL's *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids at CNL sites* (CNL 2021b). Wastewater from radiological drains and building sumps in nuclear buildings is collected by the Low Level Liquid Waste (LLLW) treatment systems in the individual buildings, where it is sampled, tested and approved for release to the Winnipeg River via the outfall station. Wastewater from non-radiological drains and process drains is directed to the stormwater system where it flows out to the outfall. Groundwater collected in building sumps of non-nuclear buildings is discharged into the stormwater system to the outfall station. Rainwater collected by the building roofs, paved areas, roads, and stormwater catchments is collected by the stormwater system and is directed to the outfall station. Building sanitary sewer systems drain to the site lagoon that consists of two interconnected cells, allowing water to flow freely between them. Annually, the cells are isolated from each other, so that the effluent in the secondary cell can settle and waste broken down. The secondary cell is then sampled and tested to ensure effluent water is safe to permit discharging into the ditch system that leads to the Winnipeg River. Mixed wastewater at the outfall is sampled and tested regularly.

Currently, wastewater from decommissioning activities is collected and tested and based on the results, is directed either to an onsite waste treatment system, domestic drain, processed drain or ditch systems, or is sent for evaporation and/or solidification and disposal according to CNL's *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids at Canadian Nuclear Laboratories Sites 900-509200-MCP-005* (CNL 2021b). This

process follows the requirements in CNL's *Management and Monitoring of Emissions* (CNL 2022). Wastewater directed to the ground or ditch system only occurs when the wastewater is below levels of concern for all contaminants.

During the closure phase, existing stormwater management systems at the WL site will remain in place to manage site runoff from precipitation. For example, surface water runoff from the site is collected by storm sewers and is discharged to the Winnipeg River. Stormwater is routinely monitored to ensure that stormwater quality is normal.

In addition, containment barriers will be constructed where necessary to provide for the collection, control of and treatment of contaminated water and to reduce surface water runoff during decommissioning and reclamation activities. Surface water quality is also assessed at locations where surface water leaves the WL site's boundary and in water-bodies affected by discharges. Concentrations of radiological and non-radiological contaminants are measured and compared against existing provincial or federal surface water quality guidelines or standards. It is also noted that closure phase activities will occur well away from the river and its riparian zone and therefore no direct changes in surface water quality will result. As per CNL's *Management of Land, Habitat and Wildlife* (CNL 2024a), any work within 30 m of rivers, streams and lakes will have preventative and mitigation measures in place. General provisions adopted for work at CNL sites in or near a watercourse incorporate appropriate sediment retention measures such as silt curtains and straw bales. Consequently, this interaction was determined to have no linkage to effects to surface water quality in the Winnipeg River. Assuming these best management practices are followed and that the current surface water management facilities remain in place during building demolition, this mitigation is expected to be effective. As such, this pathway is determined to result in a negligible residual effect on surface water quality.

- **Non-radiological air emissions and dust emissions (including sulphur dioxide, nitrogen oxides [NOx/NO2] and particulate matter) and subsequent deposition.**

- **Closure activities will result in the atmospheric release of radiological compounds from the WR 1 Building.**

Closure of the Project will generate air and dust emissions such as carbon monoxide (CO), oxides of sulphur (SO_x includes sulphur dioxide [SO_2]), oxides of nitrogen (NO_x includes nitrogen dioxide NO_2), particulate matter ($PM_{2.5}$, PM_{10}) and suspended particulate matter (SPM). Air emissions, such as SO_x and NO_x, can result from the use of fossil fuels in generators, vehicles, and machinery. Vehicle exhaust and fugitive dust from roads is the largest contributor to particulate matter (SPM, PM_{10} and $PM_{2.5}$) during the closure phase (Section 6.2.1.7.2). In addition, radiological emissions will be generated from the demolition of the WR-1 Building.

Examples of mitigation implemented to limit predicted residual effects from Project emissions to air quality (and subsequently surface water quality) include:

- implementation of CNL's *Environmental Protection* (CNL 2021a) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring and air verification monitoring;
- implementation of CNL's Radiation Protection Program and Procedure, which includes Radiation Safety Zones, detailed work planning to limit doses to As Low As Reasonably Achievable (ALARA), dose monitoring and contamination control procedures (e.g., stabilizing and immobilizing agents).

- use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include:
  - wetting techniques during demolition to limit mobility of dust;
  - wind restrictions during demolition to stop work or apply wetting techniques; and
  - hydro seeding during backfilling and landscaping to reduce soil erosion.
- apply road watering and chemical dust suppressant when necessary (dust suppressant is already used annually at the site for select unpaved roads);
- removal of accumulations of particulates (e.g., dirt) on road as soon as possible; and
- use of tarps or 3-sided enclosures for raw material storage.

The residual effects to air quality from non-radionuclide emissions were predicted because of the Project. Fugitive dust from roads is the largest contributor to SPM emissions. Material handling from demolition is the largest contributor to PM_{10} emissions. Non-road equipment exhaust emissions are the largest contributors to $PM_{2.5}$ and NOx (as NO_2) emissions. Finally, the largest contributor to SO_2 and CO emissions is fuel combustion for emergency power generators. Predicted non-radiological concentrations for the Application Case are below applicable air quality guidelines and/or standards (Section 6.2.1.7.2); therefore, no effects on surface water quality in the Winnipeg River from non-radionuclide COPCs are anticipated as a result of airborne effluent from the Project.

Mitigation of fugitive dust emissions is provided in Table 6.2.1-10 (Pathways Analysis for the Air Quality Valued Component). Monitoring of dust emissions and radionuclide emissions includes the use of contamination immobilization agents, containment, ventilation and High-efficiency Particulate Air (HEPA) filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. In addition, use of dust suppression methods during building demolition or soil remediation activities will be implemented to control airborne emissions and nuisance dust during building demolition or soil remediation.

CNL recently demolished a number of other buildings at the WL site. The mitigation listed above was applied and successfully reduced SPM and radiological emissions, which ultimately reduced subsequent deposition. It is expected that this same mitigation will also be effective during the demolition of the WR-1 Building. Therefore, with the implementation of CNL's *Management and Monitoring of Emissions* (CNL 2022) and CNL's Radiation Protection Program and Procedure, radiological and non-radiological air and dust emissions and subsequent deposition are expected to result in local, minor changes relative to Base Case conditions. As such, this pathway is determined to result in a negligible effect on surface water quality.

Atmospheric deposition to the Winnipeg River is considered negligible. This is consistent with the COG DRL guidance (COG 2013) which shows (assuming a modest flow rate for a lake of 0.1 m/s and an assumed water depth of 10 m) that the transfer of radionuclides from the atmosphere to large bodies of water (including lakes and rivers) is considered negligible. Rivers have larger flow rates than lakes; therefore, the conclusion for lakes that the atmospheric deposition pathway is negligible is applicable to rivers as well.

- **Installation of concrete cap and engineered cover may alter drainage rates and flow patterns.**

Installation of concrete cap and engineered cover and alterations of the current precipitation management system may alter drainage rates and flow patterns, and consequently the discharge volume to Winnipeg River. Following

the completion of closure activities, the WL site will be graded to promote drainage from the site to the Winnipeg River. Run-off control for the engineered cover is designed to limit erosion and infiltration of water into the grouted structure. This is achieved by sloping the cover surface to maintain a slope toward the edges and the collection of water by the existing surface water management systems at the WL site (Section 3.0). Although the installation of the concrete cap and engineered cover over the grouted structure is expected to slightly alter the drainage rates and flow patterns and discharge volume to the Winnipeg River; the changes are expected to be within the natural range of variation. As such, changes to the discharge volume from the installation of the cover at closure are predicted to have a negligible effect on surface water quality in the Winnipeg River. Assuming the cover is built to the engineered drawing's specifications, this mitigation measure is expected to be effective. Negligible residual effects are anticipated.

- **Decommissioning and reclamation of the entire WL site, including the Project, may alter drainage rates and flow patterns.**

The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness, and longevity. The contribution to site runoff from the Project is expected to be minor relative to the entire decommissioned WL site. Although closure of the WL site may slightly alter the drainage rates and flow patterns and discharge volume to the Winnipeg River; the changes are expected to be within the natural range of variation. As such, changes to discharge volume to from the closure of the WL site, including the Project, are predicted to have a negligible effect on the surface water quality in Winnipeg River.

- **Release of chemical and radiological contaminants in the long-term during the post-closure phase from the previous activities completed at the WL site.**

The Comprehensive Study Report indicated residual effects on surface water, particularly the Winnipeg River, are related to discharges from the Active Liquid Waste Treatment Centre and the sewage lagoon. No decrease in water quality is expected and effluent emissions to the Winnipeg River are expected to decline to virtually zero following decommissioning. Re-suspension of contaminated sediments is also not expected to lead to a decrease in water quality (see Section 7.0 of AECL 2001b).

The Comprehensive Study Report (AECL 2001b) also examined the potential for effects via groundwater quality from the low-level waste that may be managed in situ in the WMA and their potential to affect the Winnipeg River (see also Section 6.3.2.5.2.4 Groundwater Quality). The assessment considered three general exposure pathways: upward migration (with potential contamination of soils and vegetation), near-surface lateral migration (with potential contamination to local discharge in perimeter and roadside ditches) and downward migration and contamination of the sand and gravel aquifer and subsequently the river). Only the near-surface lateral migration scenario was considered in further detail. With respect to downward migration and release to the river it was determined that the general hydrology of the site limits or eliminates this pathway.

Water concentrations in the ditch were predicted and compared to established guidelines for several of the contaminants in the WMA. Radionuclide modelling in the Comprehensive Study Report (Appendix C of AECL 2001b) indicated that three radionuclides have the potential to exit the WMA through migration over a 200-year period, namely tritium, technetium-99 and carbon-14. Only technetium-99 is potentially present in nonzero concentrations in the ditch adjacent to the WMA in as early as 20 years. The carbon-14 and tritium will be lost to

the atmosphere. When this is modelled, there is no release of these radionuclides to the perimeter ditch. These predictions were considered further for their potential effect on human health (see Section 6.7.1.7 Residual Effects Analysis). With respect to non-radiological contaminants, some exceedances of applicable standards were predicted. Further refinement of the modelling and potential need for selective remediation to remove the hazard was recommended (AECL 2001b).

Both the Project and the WMA are subject to the same regulatory requirements, which require that no member of the public receive a dose greater than 1 mSv/a. *REGDOC 2.11.1, Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018), Section 6.2.1, specifies a 1 mSv/a limit, and also specifies that a lower dose rate target should be set to account for emissions from other sources. Therefore, a value of 0.3 mSv/a dose limit to public has been established for the WL site. The Project specified a 0.25 mSv/a target dose rate limit for the public and results of the assessment for the normal evolution indicates that the Project is well below this target. Consequently, there are negligible effects between the Project and previous activities at the WL site (i.e., effects from the WMA) and changes to surface water quality in the Winnipeg River.

As part of CNL's licence with the CNSC, environmental monitoring around the WL site will continue for the Project. Follow-up monitoring during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects. Consequently, changes to surface water quality from the closure of the WL site, are predicted to be negligible.

6.4.2.6.2.3 Primary Pathways

The Project is expected to have the following primary pathway effects on surface water quality that are carried forward to the residual effects analysis:

- **Release of chemical and radiological contaminants in the long-term during the post-closure phase from the Project.**

6.4.2.7 Residual Effects Analysis

6.4.2.7.1 Methods

Residual effects of the Project are those effects that remain after implementation of all mitigation. During the post-closure phase groundwater will encounter materials from the reactor and migrate to the Winnipeg River. As such, the potential for groundwater seepage to the Winnipeg River is considered a primary pathway and carried forward to the residual effects analysis. It is noted that a relatively large area of the LSA is upgradient of the groundwater seepage flow path. Environmental features or VCs that are upgradient of WR-1 are not considered as there is no complete exposure pathway. As the groundwater flow direction is primarily towards the west, away from the wetlands on the east side of the WL site, there is no reasonably foreseeable groundwater pathway to the wetland; therefore, this pathway was not considered in the assessment, and characterization of the wetland was not required.

The assessment of effects of the Project on surface water quality involves two steps, namely the calculation of groundwater release rates and use of a dispersion model to predict concentrations of surface water parameters. These steps are described below.

6.4.2.7.1.1 Groundwater Release Rates

When groundwater enters the WRDF[1] it will come in contact with radioactive and non-radioactive materials from the reactor. In Section 6.3.2.7.1 Methods (hydrogeology assessment), the groundwater plume from the WRDF was modeled and loadings reaching the Winnipeg River were determined from the start of post-closure, when pumping groundwater away from the WRDF foundation ceases, spanning 500,000 years. The various materials in the reactor building were modeled considering flow of the groundwater through the cover, grout, building foundation and geological pathways. Only radionuclides with half-lives longer than one day were included in the modelling. GoldSim® (Version 12.1) was used to model transportation and is described further in Section 6.3.2.7.1.

The majority of the potentially contaminated groundwater was predicted to reach the Winnipeg River approximately 100 years after groundwater infiltrates the WRDF. Parameters not within the reactor core had an instantaneous mass release. The groundwater plume was estimated to move west-northwest from the WRDF and seep into the river over 95 m of bank.

The groundwater release rates (A_{Bq}) for radionuclides were calculated by using the groundwater loadings in the equation below.

$$A_{Bq} = \frac{m}{m_a} N_A \frac{ln(2)}{t_{1/2}}$$

where,

- m = mass of radionuclide (g)
- m_a = atomic mass (g/mol)
- N_A = Avogadro's number (6.022×10^{23}/mol)
- $t_{1/2}$ = half-life of the radionuclide (s)
- ln(2) = natural log of 2

Atomic masses and the half-lives used in this calculation can be found in Appendix 6.4.2-1.

To calculate the groundwater concentrations, the release rates were divided by the groundwater flow used in the groundwater model (Section 6.3.2.7.1), which ranged from 2.0×10^{-6} to 2.2×10^{-6} m^3/s, depending on the year (Appendix 6.4.2-1). The maximum mass loadings, the year the maximum loading occurs, the release rates to surface water and the concentration of the groundwater are provided in Table 6.4.2-9 for radionuclides and Table 6.4.2-10 for non-radionuclides.

Mass loadings from the groundwater model of argon, helium, radon-222 and xenon were provided but aquatic dispersion of these parameters was excluded as they are expected to volatilize rapidly to air. Samarium-148 also had mass loadings provided from the groundwater model but was determined to have no radiological concern due to its very long half-life and no toxicological concern based on its low groundwater concentration (6.99E-23 µg/L versus an aquatic life benchmark of 0.74 µg/L (Borgmann et al. 2005)). Therefore, samarium-148 was also

[1] The Whiteshell Reactor Disposal Facility (WRDF) is the end-state of the Project, after the WR-1 Building is demolished, grouted and covered with a concrete cap and engineered cover.

excluded from aquatic dispersion modelling. Americium-241, americium-243, curium-244, cobalt-60, caesium-137, europium-152, europium-154, europium-155, iron-55, neodymium-144, nickel-63, neptunium-239, plutonium-238, plutonium-241, strontium-90, uranium-237 and yttrium-90 were also included in the groundwater model but did not reach the river (mass loadings equal zero). Therefore, these parameters are not included in the analysis. For those radionuclides and non-radionuclides that did not achieve maximum loadings before 500,000 years, the groundwater flow and solute transport model was run again without the 500,000 years constraint to determine the peak mass loadings.

The solute transport model assumes background water quality to be clean (i.e., no additional source of carbon-14 is considered external to WR-1). Simulation of carbon-14 migration through the groundwater flow path was completed assuming that all carbon-14 from within WR-1 is converted to dissolved phase carbon-14 in the groundwater. Details are provided in the Groundwater Flow and Solute Transport Modelling Report (Golder 2021).

Table 6.4.2-9: Mass Loadings and Radionuclide Release Rates to the Winnipeg River during Post-Closure

Radionuclide	Maximum Groundwater Mass Loading (g/a)	Time of Maximum (yr)	Maximum Groundwater Release Rate (Bq/s)	Maximum Groundwater Concentration (Bq/L)
Actinium-225	1.70×10^{-17}	87,200	1.16×10^{-09}	5.26×10^{-07}
Actinium-227	1.41×10^{-14}	157,200	1.20×10^{-09}	5.44×10^{-07}
Bismuth-210	2.29×10^{-14}	204,000	3.33×10^{-06}	1.52×10^{-03}
Calcium-41	1.55×10^{-06}	19,500	1.56×10^{-04}	7.08×10^{-02}
Carbon-14	5.55×10^{-04}	1,006	$2.90 \times 10^{+00}$	$1.48 \times 10^{+03}$
Chloride-36	1.15×10^{-08}	162	4.47×10^{-07}	2.27×10^{-04}
Gadolinium-152	1.71×10^{-07}	204	4.37×10^{-15}	2.22×10^{-12}
Iodine-129	1.44×10^{-04}	170	2.99×10^{-05}	1.52×10^{-02}
Lead-210	9.29×10^{-13}	206,200	8.33×10^{-08}	3.79×10^{-05}
Neptunium-237	5.15×10^{-06}	40,700	4.26×10^{-06}	1.94×10^{-03}
Nickel-59	5.48×10^{-05}	486,000	3.86×10^{-03}	$1.76 \times 10^{+00}$
Niobium-94	6.43×10^{-21}	646,000	1.42×10^{-18}	6.44×10^{-16}
Plutonium-239	2.39×10^{-07}	106,400	1.74×10^{-05}	7.91×10^{-03}
Plutonium-240	1.58×10^{-10}	66,200	4.21×10^{-08}	1.91×10^{-05}
Polonium-210	1.64×10^{-10}	199,800	8.68×10^{-04}	3.95×10^{-01}
Protactinium-231	2.16×10^{-11}	159,200	1.20×10^{-09}	5.45×10^{-07}
Protactinium-233	2.33×10^{-16}	40,400	5.68×10^{-09}	2.58×10^{-06}
Radium-223	3.36×10^{-16}	157,700	2.02×10^{-08}	9.18×10^{-06}
Radium-224	6.67×10^{-22}	1,903,000	1.26×10^{-13}	5.71×10^{-11}
Radium-225	2.17×10^{-16}	87,300	9.92×10^{-09}	4.51×10^{-06}
Radium-226	1.65×10^{-11}	203,700	1.91×10^{-08}	8.70×10^{-06}
Radium-228	3.90×10^{-19}	936,000	1.26×10^{-13}	5.73×10^{-11}
Silver-108m	7.96×10^{-13}	3,661	7.07×10^{-09}	3.39×10^{-06}
Technetium-99	1.60×10^{-05}	10,600	3.22×10^{-04}	1.46×10^{-01}
Thorium-227	6.12×10^{-17}	160,000	2.21×10^{-09}	1.01×10^{-06}

Table 6.4.2-9: Mass Loadings and Radionuclide Release Rates to the Winnipeg River during Post-Closure

Radionuclide	Maximum Groundwater Mass Loading (g/a)	Time of Maximum (yr)	Maximum Groundwater Release Rate (Bq/s)	Maximum Groundwater Concentration (Bq/L)
Thorium-228	2.84×10^{-20}	1,090,000	2.73×10^{-14}	1.24×10^{-11}
Thorium-229	8.69×10^{-12}	89,300	2.18×10^{-09}	9.91×10^{-07}
Thorium-230	1.73×10^{-10}	200,400	4.19×10^{-09}	1.90×10^{-06}
Thorium-231	4.63×10^{-18}	117,000	2.89×10^{-09}	1.31×10^{-06}
Thorium-232	2.12×10^{-10}	632,000	2.72×10^{-14}	1.24×10^{-11}
Thorium-234	7.35×10^{-16}	115,400	2.00×10^{-08}	9.08×10^{-06}
Tritium	6.37×10^{-05}	67	$7.20 \times 10^{+02}$	$3.66 \times 10^{+05}$
Uranium-233	2.79×10^{-08}	74,500	3.16×10^{-07}	1.44×10^{-04}
Uranium-234	1.36×10^{-07}	126,500	9.93×10^{-07}	4.52×10^{-04}
Uranium-235	1.60×10^{-04}	118,000	4.05×10^{-07}	1.84×10^{-04}
Uranium-236	7.21×10^{-06}	117,900	5.46×10^{-07}	2.48×10^{-04}
Uranium-238	7.10×10^{-03}	116,600	2.80×10^{-06}	1.27×10^{-03}

Radon-222 and samarium-148 in groundwater were excluded from the surface water assessment as they will not emit radiation to potential receptors.

Multiple radionuclides in WR-1 had mass loadings of 0 (i.e., did not reach the Winnipeg River) and are excluded from the assessment (e.g., caesium-137 and strontium-90).

g/a = grams per year; Bq/s = Becquerel per second; Bq/L = Becquerels per litre.

Table 6.4.2-10: Mass Loadings and Non-radionuclide Release Rates to the Winnipeg River during Post-closure

Non-Radionuclide	Maximum Groundwater Mass Loading (g/a)	Time of Maximum (yr)	Maximum Groundwater Release Rate (µg/s)	Maximum Groundwater Concentration (µg/L)
Barium	1.82×10^{-08}	10,740,000	5.77×10^{-10}	2.62×10^{-07}
Bismuth	1.12×10^{-08}	78,800	3.55×10^{-10}	1.61×10^{-07}
Boron	1.87×10^{-04}	4,235	5.92×10^{-06}	2.84×10^{-03}
Cadmium	3.71×10^{-01}	203,000	1.18×10^{-02}	$5.35 \times 10^{+00}$
Chromium	2.42×10^{-03}	19,998,000	7.68×10^{-05}	3.49×10^{-02}
Cobalt	2.12×10^{-02}	93,800	6.71×10^{-04}	3.05×10^{-01}
Copper	5.47×10^{-04}	876,000	1.73×10^{-05}	7.89×10^{-03}
Gadolinium	6.48×10^{-06}	213	2.05×10^{-07}	1.04×10^{-04}
HB-40[a]	$4.05 \times 10^{+01}$	10,200	$1.28 \times 10^{+00}$	$5.84 \times 10^{+02}$
Lead	$5.05 \times 10^{+00}$	5,596,000	1.60×10^{-01}	$7.27 \times 10^{+01}$
Manganese	8.33×10^{-05}	354,500	2.64×10^{-06}	1.20×10^{-03}
Mercury	4.16×10^{-05}	6,546,000	1.32×10^{-06}	6.00×10^{-04}
Molybdenum	1.17×10^{-02}	17,900	3.72×10^{-04}	1.69×10^{-01}
Nickel	4.81×10^{-05}	840,000	1.53×10^{-06}	6.94×10^{-04}
Nitrogen	5.44×10^{-04}	17,900	1.72×10^{-05}	7.84×10^{-03}
Palladium	1.05×10^{-01}	121,000	3.32×10^{-03}	$1.51 \times 10^{+00}$
Potassium	3.27×10^{-07}	13,000	1.04×10^{-08}	4.72×10^{-06}
Potassium Hydroxide	4.76×10^{-02}	142	1.51×10^{-03}	5.37×10^{-01}
Ruthenium	6.15×10^{-09}	374,100	1.95×10^{-10}	8.87×10^{-08}
Samarium	3.65×10^{-12}	20,000,000	1.16×10^{-13}	5.26×10^{-11}
Sulphur	2.37×10^{-12}	193	7.52×10^{-14}	1.14×10^{-10}
Xylene	$4.32 \times 10^{+00}$	202	1.37×10^{-01}	$6.96 \times 10^{+01}$
Zirconium	1.51×10^{-10}	20,000,000	4.79×10^{-12}	2.18×10^{-09}

g/a = grams per year; > = greater than.

a) HB-40 was used in WR-1 as a cooling agent. It consists mainly of hydrogenated terphenyl (74% to 87%), with smaller fractions of partially hydrogenated terphenyls and terphenyl.

6.4.2.7.1.2 Dispersion Modelling

The Winnipeg River flows approximately 1,014 m^3/s near the WL site, in comparison to a predicted groundwater flow rate at the WL site of 2.0E-06 to 2.2E-06 m^3/s. This results in a dilution factor of 460,000,000:1 to 515,000,000:1 once the groundwater seepage fully mixes with the river. Even if the groundwater seepage mixes with a fraction of the river flow, the attenuation renders it indistinguishable from ambient river water.

Surface water concentrations were estimated using the EcoMetrix Incorporated software IMPACT™ DRL Version 5.5.1 (IMPACT™). IMPACT™ is consistent with the equations outlined in *CSA Standard N288.1-14: Guidelines for Calculating Derived Release Limits for Radioactive Material in Airborne and Liquid Effluents for Normal Operation of Nuclear Facilities* (CSA Group 2014). The equations for surface waters represent the advection, dispersion and radioactive decay and ingrowth of radionuclides from the point of release through the receiving water to the receptor. It also represents the advection and dispersion of trace metals and other parameters. It is applicable to the WL site by representing the groundwater release as an area source within the Winnipeg River. The concentrations of contaminants in water is determined by the release rate and the transfer parameter (P_{02} in seconds per litre (s/L) for non-radiological contaminants and seconds per Becquerel (s/Bq) for radiological contaminants) from the source to the Winnipeg River.

$$P_{02}(x,y) = \frac{1}{2\pi d\sqrt{k_x k_y}} e^{\left(\frac{U_x x}{2k_x} - \lambda_s \frac{x}{U_x}\right)} e^{\left(-\lambda_r \frac{x}{U_x}\right)} K_o\left(\frac{U_x}{2k_x}\sqrt{x^2 \frac{k_x}{k_y}(y-y_o)^2}\right)$$

where,

- d = average water depth between the release point and the receptor (m)
- k_x = longitudinal dispersion coefficient (m^2/s)
- k_y = lateral dispersion coefficient (m^2/s)
- U_x = current velocity (m/s)
- x = downstream distance between the source and the point (x,y) (m)
- λ_s = removal constant for sedimentation (s^{-1})
- λ_r = radioactive decay constant (s^{-1})
- K_o = modified Bessel function of the second kind
- y = offshore distance coordinate for the point (x,y) (m)
- y_o = offshore distance to the plume centreline (m)

The transfer parameter (P_{02}) is multiplied by the release rate ($x_o(w)$) to give the concentration (X_2) at point (x,y). For non-radionuclides, the decay constant was set to zero. This equation above works if there are no riverbanks, as it assumes infinite spread of parameters downstream of the source. To account for the restriction of riverbanks, a mirroring effect was applied as follows:

$$X_2{}' = X_2 + \sum_{n=1}^{\infty} (X_2[x, y_n] + X_2[x, y'_n])$$

where,

- X_2' = concentration modified to account for the effects of the riverbanks (Bq/L)
- X_2 = P_{02} X_0 (w) in accordance with Equation above (Bq/L)
- x = downstream distance between the source and the point (x,y) (m)
- $y = n{\cdot}B - \left(y_0 - \frac{B}{2}\right) + (-1)^n \cdot \left(y - \frac{B}{2}\right)$
- $y'_n = -n{\cdot}B - \left(y_0 - \frac{B}{2}\right) + (-1)^n \cdot \left(y - \frac{B}{2}\right)$

  where,

  - n = number of reflection cycles
  - B = average width of the river between the release point and the receptor (m)
  - y_0 = offshore distance to the plume centreline (m)
  - y = offshore distance coordinator for the point (x,y) (m)

The input parameters for the model are shown in Table 6.4.2-11. The concentration of surface water parameters was determined at 50 m and 3,150 m downstream from the upstream edge of the groundwater seep. These locations correspond to the Nearfield and Farm A receptors (Figure 6.4.2-1), which are used in the Environmental Risk Assessment (EcoMetrix 2024).

Table 6.4.2-11: Input Parameters for Surface Water Modelling

Parameter	Value	Unit	Source
River Depth	0.1 and 7.7	m	Nearfield and Farm in DRL (CNL 2016d)
River Width	470	m	DRL (CNL 2016d)
Longitudinal Dispersion Coefficient	150	m^2/s	DRL (CSA value for Deep River; CNL 2016d)
Lateral Dispersion Coefficient	0.129	m^2/s	Calculated (CSA N288.1-14)
Flow Rate	1,014	m^3/s	WSC (2016)
Current Velocity	0.3	m/s	Calculated
Distance between Upstream Edge of Seep and Nearfield Area	145	m	Calculated
Distance between Downstream Edge of Seep and Nearfield	50	m	Nearfield Assessment
Distance between Upstream Edge of Seep and Farm A Water Intake	3,150	m	Measured on Google Earth
Distance between Downstream Edge of Seep and Farm A Water Intake	3,055	m	Calculated

DRL = derived release limit.

Table 6.4.2-12 presents the predicted dilution at the Nearfield located 50 m downstream and at the Farm A Intake located 3,055 m downstream. The dilution at the Nearfield location exceed 1,000,000:1, which would result in concentrations difficult to detect in situ. Dilution at the Farm A location was 69,000,000:1.

Table 6.4.2-12: Calculated Dilution

Location	Calculated Dilution
Nearfield	1,300,000:1
Farm A Intake	69,000,000:1
Fully mixed condition	460,000,000:1 to 515,000,000:1

Where available, the concentration of the river (Table 6.4.2-5 and Table 6.4.2-6) was added to the concentration derived from the dispersion model to estimate surface water concentrations.

6.4.2.7.2 Application Case Results

The assessment considered maximum surface water concentrations in accordance with *REGDOC-2.9.1, Environmental Principles, Assessments and Protection Measures* (CNSC 2020). Table 6.4.2-9 and Table 6.4.2-10 presented the estimated loadings from the groundwater seep to the Winnipeg River, and Table 6.4.2-13 and Table 6.4.2-14 present the corresponding predicted surface water quality associated with radionuclide and non-radionuclide loadings, respectively. The surface water quality is predicted from the river dispersion model in CSA N288.1-14 (CSA Group 2014) and corresponds to two locations: 1) the Winnipeg River immediately at the point of groundwater release to the river (Nearfield); and 2) the Winnipeg River at the freshwater intake for the nearest downstream farm (Farm A Intake).

Table 6.4.2-13 and Table 6.4.2-14 compares the predicted surface water quality to the available guidelines and to available background concentrations. For radionuclides predicted to reach the Winnipeg River from WR-1 or decay

products of those materials, no water guidelines or background concentrations were available (i.e., Table 6.4.2-13 does not include background or natural generation of any radionuclide, only values predicted from the groundwater model). Surface water concentrations in the Nearfield and Farm A intake are six and eight orders of magnitude lower than the groundwater concentration, respectively. Further, exposure was assessed for the time of maximum loadings to the river for each constituent of potential concern during the post-closure phase, irrespective of when that peak occurs. This simplification is conservative as not all peaks occur at the same time but are effectively assumed to do so for purposes of the assessment.

Table 6.4.2-13: Predicted Radionuclide Concentrations in the Winnipeg River at the Nearfield and Farm A Intake

Radionuclide	Background Surface Water Concentration [(a)] (Bq/L)	Time of Maximum (yr)	Maximum Groundwater Concentration (Bq/L)	Surface Water Concentration Nearfield (Bq/L)	Surface Water Concentration Farm A Intake (Bq/L)
Actinium-225	NV	87,200	5.26×10^{-07}	4.08×10^{-13}	7.61×10^{-15}

Notes:
a. Sample collected from Winnipeg River (Sylvia Lake) on May 6, 2007. Sylvia Lake is a fore bay on the Winnipeg River approximately 19 km upstream of the WL site; sampled from boat ~50m off-shore of Carter Island.
b. Sheppard, S. C., & Sanipelli, B. (2011). Environmental radioactivity in Canada–measurements. Report No. NWMO TR-2011-16, Nuclear Waste Management Organisation, Toronto, Ontario. May.
Bq/L = Becquerels per litre.

Non-radionuclide concentrations estimate in the Nearfield and at Farm A surface water intake were compared to the lowest available guideline, which are presented in Table 6.4.2-5 and Table 6.4.2-6. There was no guideline available for sulphur and guidelines were not applicable for the Noble gasses, such as argon, helium and xenon, because they volatilize out of the surface water immediately. Background concentrations are from Table 6.4.2-5 and Table 6.4.2-6, available from the WL site (CNL 2016b) and Pine Falls (WQMS 2016 and 2020).

For non-radionuclides without background concentrations, the groundwater concentrations were diluted six and eight orders of magnitude lower at the Nearfield and Farm A intake, respectively. The river concentrations for parameters with background concentrations were equal to background. Surface water concentrations of barium, chromium, copper and lead exceed the lowest available guideline. These exceedances are due to background concentrations measured from the Winnipeg River, and not the potential groundwater seep from the WRDF.

Table 6.4.2-14: Predicted Non-Radionuclide Concentrations in the Winnipeg River at the Nearfield and Farm A Intake

Non-Radionuclide	Lowest Guideline (µg/L)	Background (µg/L)	Time of Maximum (yr)	Maximum Groundwater Concentration (µg/L)	Surface Water Concentration Nearfield (µg/L)	Surface Water Concentration Farm A Intake (µg/L)
Barium	4.00×10^{-01}	$1.10 \times 10^{+01}$	10,740,000	2.62×10^{-07}	$1.10 \times 10^{+01}$	$1.10 \times 10^{+01}$
Bismuth	2.50×10^{-01}	$<2.00 \times 10^{-01}$	78,800	1.61×10^{-07}	$<2.00 \times 10^{-01}$	$<2.00 \times 10^{-01}$
Boron	$1.50 \times 10^{+03}$	$1.00 \times 10^{+01}$	4,235	2.84×10^{-03}	$1.00 \times 10^{+01}$	$1.00 \times 10^{+01}$
Cadmium	7.87×10^{-02}	1.00×10^{-02}	203,000	$5.35 \times 10^{+00}$	1.00×10^{-02}	1.00×10^{-02}
Chromium	$1.00 \times 10^{+00}$	$1.70 \times 10^{+00}$	19,998,000	3.49×10^{-02}	$1.70 \times 10^{+00}$	$1.70 \times 10^{+00}$
Cobalt	9.00×10^{-01}	2.00×10^{-01}	93,800	3.05×10^{-01}	2.00×10^{-01}	2.00×10^{-01}
Copper	$2.00 \times 10^{+00}$	$1.40 \times 10^{+01}$	876,000	7.89×10^{-03}	$1.40 \times 10^{+01}$	$1.40 \times 10^{+01}$

Note: Available guidelines and background values are from Table 6.4.2-5 and Table 6.4.2-6.

NV – No value (data source did not include this non-radionuclide).

The CSA N288.1-14 (CSA Group 2014) provides a model for sediment concentrations based on surface water concentrations. The surface water concentration is multiplied by the partition coefficient of the specific parameter (Clause 7.8.1). This approach assumes sediments and water are in equilibrium, and that sediments are fine grain, remain stationary or accumulate. As the Winnipeg River is erosional, with a hard clay bottom strewn with sand, gravel, cobble and boulders (AECL 2001a), it is likely that this model overestimates the contribution of groundwater to concentrations in sediment.

Predicted radionuclide concentrations are presented in Table 6.4.2-15 with NSRDR Unconditional Clearance Levels. The maximum concentrations in sediment were calculated by running the model with the maximum release rates presented in Table 6.4.2-9. Predicted sediment concentrations are lower than their respective Clearance Levels.

Table 6.4.2-15: Predicted Maximum Radionuclide Concentrations in Sediment at the Nearfield and Farm A Intake

Radionuclide	NSRDR Unconditional Clearance Level (Bq/kg)	Maximum Sediment Concentration Nearfield (Bq/kg (dw))	Maximum Sediment Concentration Farm A Intake (Bq/kg (dw))

Thorium-232	1.00×10^{3}	1.82×10^{-12}	3.43×10^{-14}
Thorium-234	1.00×10^{3}	1.34×10^{-06}	2.51×10^{-08}
Uranium-233	1.00×10^{3}	5.57×10^{-09}	1.05×10^{-10}
Uranium-234	1.00×10^{3}	1.75×10^{-08}	3.30×10^{-10}
Uranium-235	1.00×10^{3}	7.14×10^{-09}	1.34×10^{-10}
Uranium-236	1.00×10^{4}	9.63×10^{-09}	1.81×10^{-10}
Uranium-238	1.00×10^{3}	4.94×10^{-08}	9.29×10^{-10}

NSRDR Unconditional Clearance Level = *Nuclear Substances and Radiation Devices Regulations* Unconditional Clearance Level (SOR/2000-207)

Bq/kg – Becquerels per kilogram; dw = dry weight; NV – No value (data source did not include this non-radionuclide).

Table 6.4.2-16 presents the predicted non-radionuclide sediment concentrations with federal sediment quality guidelines. The surface water background and maximum surface water concentrations from Table 6.4.2-10 were used to calculate sediment concentrations.

Where background concentrations of surface water were available, predicted sediment concentrations at the Nearfield and Farm A Intake were the same as sediment concentrations derived from background. Predicted sediment concentrations at Farm A Intake were two orders of magnitude lower than concentrations predicted in the Nearfield, for parameters without background available. Predicted sediment concentrations from background surface water concentrations exceeded available guidelines as background surface water concentrations are high and lead to high predicted background sediment concentrations.

Table 6.4.2-16: Predicted Non-Radionuclide Concentrations in Sediment at the Nearfield and Farm A Intake

Non-Radionuclide	CCME Sediment Quality Guidelines (mg/kg)	Sediment Concentration From Background Surface Water (mg/kg)	Maximum Sediment Concentration Nearfield (mg/kg)	Maximum Sediment Concentration Farm A Intake (mg/kg)
	Probable Effect Level			
Barium	—	$2.20 \times 10^{+07}$	$2.20 \times 10^{+07}$	$2.20 \times 10^{+07}$
Bismuth	—	$1.00 \times 10^{+06}$	$1.00 \times 10^{+06}$	$1.00 \times 10^{+06}$
Boron	—	$5.00 \times 10^{+05}$	$5.00 \times 10^{+05}$	$5.00 \times 10^{+05}$
Cadmium	$3.50 \times 10^{+00}$	$5.00 \times 10^{+03}$	$5.00 \times 10^{+03}$	$5.00 \times 10^{+03}$
Chromium	$9.00 \times 10^{+01}$	$2.21 \times 10^{+08}$	$2.21 \times 10^{+08}$	$2.21 \times 10^{+08}$
Cobalt	—-	$8.60 \times 10^{+06}$	$8.60 \times 10^{+06}$	$8.60 \times 10^{+06}$
Copper	$1.97 \times 10^{+02}$	$7.00 \times 10^{+06}$	$7.00 \times 10^{+06}$	$7.00 \times 10^{+06}$
Gadolinium	—	NV	7.17×10^{-5}	1.35×10^{-6}
HB-40	—	$0.00 \times 10^{+00}$	$5.01 \times 10^{+03}$	$9.43 \times 10^{+01}$
Lead	$9.13 \times 10^{+01}$	$3.38 \times 10^{+06}$	$3.38 \times 10^{+06}$	$3.38 \times 10^{+06}$
Manganese	$1.10 \times 10^{+03}$ ‡	$1.43 \times 10^{+09}$	$1.43 \times 10^{+09}$	$1.43 \times 10^{+09}$
Mercury	$4.86 \times -^{01}$	$1.60 \times 10^{+03}$	$1.60 \times 10^{+03}$	$1.60 \times 10^{+03}$
Molybdenum	—	$2.00 \times 10^{+04}$	$2.00 \times 10^{+04}$	$2.00 \times 10^{+04}$
Nickel	$7.50 \times 10^{+01}$ ‡	$2.49 \times 10^{+06}$	$2.49 \times 10^{+06}$	$2.49 \times 10^{+06}$
Nitrogen	—	NV	$0.00 \times 10^{+00}$	$0.00 \times 10^{+00}$
Palladium	—	NV	$6.33 \times 10^{+00}$	1.19×10^{-01}
Potassium	—	$0.00 \times 10^{+00}$ †	$0.00 \times 10^{+00}$ †	$0.00 \times 10^{+00}$ †
Potassium Hydroxide	—	$0.00 \times 10^{+00}$ †	$0.00 \times 10^{+00}$ †	$0.00 \times 10^{+00}$ †
Ruthenium	—	NV	2.20×10^{-06}	4.14×10^{-08}
Sulphur	—	NV	2.92×10^{-12}	5.48×10^{-14}
Xylene	—	NV	7.49×10^{-01}	1.41×10^{-02}
Zirconium	—	NV	1.69×10^{-09}	3.18×10^{-11}

Note:

CCME Sediment Quality Guidelines = Canadian Council of Ministers of the Environment Sediment Quality Guidelines (CCME 1999b).

† Assumed potassium and potassium hydroxide are extremely soluble and would not be found in sediment.

‡ Values are the severe effect level from the Ontario Sediment Quality Guidelines (MOE 2008).

NV – No value (data source did not include this non-radionuclide); — = no guideline.

Potential groundwater seepage into the Winnipeg River from the WRDF was predicted to produce surface water concentrations of radionuclides six orders of magnitude lower than groundwater concentrations in the Nearfield. Non-radionuclides in the potential groundwater seep were predicted to have no effect on existing elevated surface water concentrations for all parameters with available background concentrations. Similarly, predicted sediment concentrations from radionuclides were below NSRDR Unconditional Clearance Levels and non-radionuclides predicted sediment concentrations were dominated by background surface water contributions. The potential groundwater seep is predicted to have a negligible residual effect on the Winnipeg River surface water quality.

6.4.2.8 Prediction Confidence and Uncertainty

Potential sources of uncertainty in the assessment of surface water quality include:

- the accuracy and representativeness of the groundwater loadings;
- the accuracy and representativeness of the inputs used in the dispersion model; and
- the accuracy of formulations within the river dispersion model.

Uncertainty related to the groundwater loadings is discussed in Section 6.3.2.8 Prediction Confidence and Uncertainty (hydrogeology assessment). In summary, the bedrock was considered to be a single hydrostatic unit and no discrete features (fractures) present in any material. The cover, grout and foundation were assumed to degrade at rates comparable to other projects (i.e., Savannah River), which increased groundwater flow through time, resulting in total failure (degradation) of grout by year 10,000. Parameters outside the reactor were assumed to be instantly released. Partition coefficients to bedrock were applied to parameters, where available, and solubility was only applied to HB-40 and lead. From these inputs, groundwater loadings are likely overestimated since all parameters outside of the reactor were instantly soluble when in contact with groundwater. The exceptions, HB-40 and lead, had a solubility applied from recent toxicity testing (EcoMetrix 2017), that was only achieved through extreme agitation (emulsified), and solubility testing on groundwater from a WL groundwater well (CNL 2017c), respectively. The degradation of the cover, grout and building foundation may occur at different rates than those used in the model, which may mean the peak loadings would occur sooner than predicted. The model was run for 500,000 years to ensure most parameters achieved groundwater loading peaks (past maximum load).

Uncertainty in both the groundwater flow and solute transport modelling is recognized and was evaluated through the completion of a sensitivity analysis. The sensitivity analysis included the evaluation of the effect of 13 various model assumptions on model results as discussed in detail in Golder (2021). One of the key assumptions of the solute transport modelling that was evaluated through the sensitivity analysis was that the source mass was distributed evenly throughout the grout block and that solute transport occurred through the foundation, which was conceptualized as a 1 m thick concrete material, or equivalent barrier. This assumption is conservative, as the grout itself is anticipated to provide some additional separation between the source mass (most of which is confined within the metal components of the reactor) and the downstream environment. Results of the sensitivity analysis indicate that inclusion of the grout as a barrier to solute migration resulted in considerably (5x for conservative species) lower peak mass loadings and significant increases (5x for conservative species) to the arrival time for peak mass loadings relative to the base case. For solutes with relatively short half-lives (e.g., tritium), the mass loadings were reduced by more than one order of magnitude. These changes reflect the additional time required for solute mass to migrate through the grout prior to reaching the foundation.

Dispersion models employ assumptions that simplify the random processes associated with water flow and turbulence. Values for the parameters input into the model were selected to represent the Winnipeg River in the vicinity of the WL site. Historical data collected in the WL site area was used for modelling. To determine if a significant difference of model inputs would change the surface water concentration, the model using the maximum predicted groundwater concentrations was run multiple times varying flow and river depth in a sensitivity analysis. The minimum and maximum of the average daily flows (458 m^3/s and 1,538 m^3/s, respectively) from the 1987 to 2014 from the Water Survey of Canada at the McArthur Generating Station were used (WSC 2016).

Elevations above sea level of the river taken at the WL site varied approximately 1 m. From another source the Winnipeg River in the vicinity of the WL site was reported as 7.7 m deep. The relationship between the river elevation and the reported depth is unknown. Therefore, the water level at the farm was varied 1 m above and below 7.7 m, with water levels of 6.7 and 8.7 m to test sensitivity. This is a conservative approach, as water levels do not vary more than one metre currently. For the Nearfield, water levels were varied 0.05 m, with 0.15 m and 0.05 m used to test sensitivity. Model runs included: 1) low flow and low water level; 2) high flow and low water level; 3) high flow and low water level; and 4) high flow and high-water level.

The groundwater seepage enters the river over a broad area extending into the river. If the groundwater intercepts the full depth of the river, the spatial extent of the influx could extend over 200 m width across the river by 95 m length along the river. This conceptual model differs from the model assumed in CSA N288.1-14 (CSA Group 2014), which assumes an influx over a 95 m length along the riverbank. Assuming an area source, the estimated dilution could be in the order of 283,000:1 if the plume rises 1 cm from the bottom and 1,400,000:1 if the plume rises 5 cm from the bottom. In either case, the available dilution is sufficient to render the plume indistinguishable from ambient river water.

6.4.2.9 Monitoring and Follow-up

As part of CNL's licence (NRTEDL-W5-8.00/2024) with the CNSC, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects predicted and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical.

The existing Environmental Assessment Follow-up and Monitoring Program for the WL site includes collecting water samples at one location 17 km upstream near Pinawa (US on Figure 6.4.2-3), 2 km downstream at the site boundary (DS on Figure 6.4.2-3), 10 km downstream at the town of Lac du Bonnet water intake (LB on Figure 6.4.2-3) and 28 km downstream at the Great Falls generating station (CNL 2016c; Figure 6.4.2-2). Surficial sediment is also collected at two locations upstream, at the outfall and nine locations downstream (CNL 2016a; Figure 6.4.2-3). In addition, CNL has committed to collecting cores in depositional areas in 2026, 2046 and 2066 at Sylvia Lake and upstream and downstream of the waterbody at Lac du Bonnet, which are part of the Winnipeg River system. It is proposed that these same monitoring locations be used to support the Environmental Assessment Follow-up and Monitoring Program for the Project, coordinating with the existing program, where practical. In addition, CNL will add a surface water quality sampling location in the vicinity of the groundwater seepage flow path in the Winnipeg River prior to post-closure. Follow-up monitoring during the post-closure phase is summarized in Table 6.4.2-17.

It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Within this framework, modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS or Decommissioning Safety Assessment Report, including the findings from the Ecological Risk Assessment, the frequency of sampling may be increased and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals for modifications to the monitoring program and the rationale for the modifications will be communicated to the

CNSC prior to implementation. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs.

CNL will continue to proactively seek, engage, and support meaningful discussion on issues and opportunities related to the Project, including the monitoring and follow-up program, with First Nations and the Manitoba Métis Federation and communities of interest. CNL has also had discussions with First Nations and the Manitoba Métis Federation on how future monitoring on the WL site could incorporate Indigenous interests, such as monitoring of country harvested foods. CNL will continually evaluate both the process and the outcome of the ongoing engagement and communication activities, to address and manage issues as they arise.

Table 6.4.2-17: Monitoring and Follow-up Programs for Surface Water Quality

Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Surface Water Quality	**Potential Source(s) of Effects:** ■ Changes to surface water quality from the release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time during the post-closure phases. **Proposed Monitoring:** ■ Monitor the quality of water in the Winnipeg River to evaluate whether the quality of the water is affected by the ISD reactor facility ■ Monitor the quality of water in the vicinity of the groundwater seepage flow path in the Winnipeg River prior to post-closure ■ Monitor the quality of water in on-site ditches to verify the hydrogeological model **Trigger for further action:** ■ Investigation (e.g., sediment analyses) if parameters above predictions, applicable guidelines, or indication of poor maintenance.	■ Verify effects predictions related to surface water quality. ■ Demonstrate compliance with regulatory requirements.	■ Surface water and ditch system water will be sampled on a semi-annual basis at one upstream and two downstream locations. Frequency of recurrence will be assessed based on performance data. ■ Water quality monitoring will continue through closure phase and post-closure phase (i.e., during institutional control).	■ Surface water monitoring in the receiving environment is integrated into the CNL Environmental Monitoring Program and will be compliant with *CSA Standard N288.4-19: Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2019).No new surface water quality monitoring is proposed for the Project.

6.4.2.10 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). Acknowledging that changes to surface water quality is an important aspect of the natural and human environment, and may potentially result in effects to other VCs, surface water quality is referred to as an intermediate VC. Indigenous engagement confirmed the importance of surface water quality. Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations were concerned as the Project may indirectly discharge water into the Winnipeg River. Surface water quality measurement indicators include estimated concentrations of surface water parameters in the Winnipeg River. Indigenous peoples did not identify any additional valued components as it relates to the surface water quality assessment.

Residual effects during the Post-closure phase have been identified as the primary linkage to potentially affect surface water quality (Table 6.4.2-18). Groundwater may encounter the WRDF and then flow to the Winnipeg River, resulting in changes to surface water and sediment quality. The predicted maximum radionuclide concentrations in surface water at both the Nearfield and the Farm A Intake on the Winnipeg River are orders of magnitude lower than background groundwater concentrations. Predicted sediment concentrations of radionuclides are lower than their respective clearance levels. The potential groundwater seep is predicted to have a negligible residual effect on the Winnipeg River surface water quality.

Predicted maximum non-radionuclide concentrations in surface water and sediment are driven by current river concentrations and some parameters exceed available surface water or sediment guidelines. For example, the background concentration for lead exceeds the lowest available guidelines for surface water and sediment, but the maximum sediment concentrations at both the Nearfield and the Farm A intake in both surface water and sediment show no change from the background level as a result of the Project.

Overall, the assessment of potential effects determined there are no residual adverse effects on surface water and sediment quality from changes in groundwater quality. This conclusion applies to the surface water quality interests and concerns raised by the engaged Indigenous Nations that were encompassed by the assessment (Table 6.4.2-1).

First Nations and the Red River Métis have interest in the current and future monitoring proposed for the Project. CNL will implement an Environmental Assessment Follow-up and Monitoring Program for WR-1 to verify the accuracy of environmental effects predictions and determine the effectiveness of mitigation that has or is to be implemented. CNL's current environmental monitoring program includes collecting water samples at one location upstream and three locations at varying distances downstream of the WL site. Surficial sediment is also collected at two locations upstream, at the outfall and nine locations downstream. In addition, CNL has committed to collecting cores in depositional areas in 2026, 2046 and 2066 at Sylvia Lake and upstream and downstream of the waterbody Lac du Bonnet. Follow-up monitoring during the post-closure phase is necessary to confirm predicted concentrations in surface water and sediment in the Winnipeg River and to provide information for use in adaptive management to address potential unforeseen effects.

CNL will continue to proactively seek, engage, and support meaningful discussion on issues and opportunities related to the Project, including the monitoring and follow-up program, with First Nations and the Manitoba Métis Federation and communities of interest. CNL has also had discussions with First Nations and the Manitoba Métis Federation on how future monitoring on the WL site could incorporate Indigenous interests, such as monitoring of country harvested foods. CNL will continually evaluate both the process and the outcome of the ongoing engagement and communication activities, to address and manage issues as they arise.

Table 6.4.2-18: Summary of Predicted Residual Adverse Effects for Surface Water Quality

Valued Component	Assessment Endpoint	Residual Effect	Phase Project Effect Occurs in	Contributing Project Activity	Proposed Mitigation	Significance

Surface Water Quality	Intermediate VC (i.e., it does not have an assessment endpoint)	Release of chemical and radiological contaminants in the long-term during the post-closure phase from the Project, which can alter surface water and sediment quality.	Post-Closure	Post-Closure Performance – Grout and reactor components gradually deteriorate over time	■ The planned decommissioning of the WR 1 Complex presently involves:
					  ▪ removal the service area and infilling in these areas with compact soil;
					  ▪ sealing of open conduits in the building foundation; and
					  ▪ grouting the interior portion of the building (containing the remaining components of WR 1) to ground surface elevation.
					■ As part of CNL's licence with the Canadian Nuclear Safety Commission (CNSC), environmental monitoring around the WL site is required and will continue for the Project during institutional control.
					■ Follow up monitoring will be completed during institutional control to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.
						Significance is not determined as VC does not have an assessment endpoint; rather the results provided to other disciplines for inclusion in their assessment.

6.5 Aquatic Environment

This section of the Environmental Impact Statement (EIS) examines the potential residual effects of the Project on the physical aspects of the aquatic environment.

6.5.1 Scope of the Assessment

The scope of the assessment focuses on the evaluation of potential changes in the aquatic environment (the Winnipeg River) that may result from activities associated with the Project. Hydrology, surface water quality and sediment quality are discussed in detail in Section 6.4 Surface Water Environment, and risks to ecological health as the result of chemical and radiological exposures are discussed in Section 6.7 Human and Ecological Health. Results of these assessments are used to support the assessment of effects on the aquatic environment.

The aquatic environment assessment follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment is completed in the following steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Section 6.5.3 Valued Components and Section 6.5.4 Assessment Boundaries) for the aquatic environment assessment. The VCs, assessment endpoints and measurement indicators used to assess Project related changes to the aquatic environment, the spatial and temporal boundaries at which the assessment occurred, and the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.5.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.5.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect the aquatic environment (biota) are identified and mitigation options are presented to limit or avoid these effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded to further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the aquatic assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the aquatic assessment.
- **Step 6 – Classify and determine the significance of the predicted residual effects.** This step was not required as no residual effects to aquatic VCs were identified.
- **Step 7 – Identify monitoring and follow-up** (refer to Section 6.5.7 Monitoring and Follow-up) required to confirm effect predictions and address uncertainty.

- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.5.8 Conclusions) of residual effects on the aquatic environment.

6.5.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement that are related to the aquatic environment assessment are summarized in Table 6.5.2-1. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4 Indigenous Engagement.

Table 6.5.2-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Aquatic Environment Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
Effects on Fish ■ Deterioration of fish quality ■ Protection of fish in the Winnipeg River ■ Contamination of fish through water, aquatic plants and sediment.	Already included in the environmental assessment	■ Effects on fish health are summarized in Section 6.5.6 Project Interactions and Mitigation. ■ The detailed assessment of effects to fish health (including through water, aquatic plants and sediment) is provided in Section 6.7.2.7.2 Application Case – Post Closure.
Effects on Harvesters ■ Importance of the Winnipeg River for the harvesting of fish. ■ Effects of ingestion of fish, waterfowl, and plants on the human health	Already included in the environmental assessment	■ Effects on fish and fish habitat are assessed in Section 6.5.6 Project Interactions and Mitigation. ■ The socio-economic effects on harvesting of fish are assessed in Section 6.8.1.6 Project Interactions and Mitigation. ■ Human health effects resulting from harvesting fish, waterfowl and aquatic plants are assessed in Section 6.7.1.7 Application Case
Monitoring of Fish ■ How fish are tested ■ If contaminants can accumulate in fish over time ■ Interest in being more involved in fish monitoring on site.	Already included in the environmental assessment	■ Information on annual monitoring of radioactivity in fish is provided in Section 6.5.5.2.3 Radioactivity in Fish. ■ Information on monitoring related to fish is provided in Section 6.5.7 Monitoring and Follow-up.

6.5.3 Valued Components

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). For the aquatic environment, fish and fish habitat was selected as a VC as there is a potential for the Project activities to affect aquatic biota in the Winnipeg River (Table 6.5.3-1). Indigenous VCs aligned with fish and fish habitat for the aquatic environment. The Traditional Knowledge and Land Use Studies (Firelight Research and SFN 2018; BRFN, BON, and HWFN 2019; and SVS 2019) identified specific fish species of concern, as well as habitats supporting life history requirements including spawning, nursery, rearing and foraging. Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations identified sturgeon and sturgeon

spawning grounds, pickerel, pike, catfish, sunfish, sucker, goldeye, whitefish, perch, carp, and bass as species for inclusion in the assessment. The fish and fish habitat VC includes the fish species identified by Indigenous Nations that are occurring in the Winnipeg River Regional Study Area, as well as habitats supporting life history requirements including spawning, nursery, rearing and foraging (Sections 6.5.5.2.2 Fish Community and 6.5.5.2.5 Fish Habitat). Traditional Knowledge and Land Use Studies also identified food (such as wild rice) and medicines (such as Weekay) as VCs. Food and medicines are not considered within the aquatic environment assessment, but rather as part of Human and Ecological Health (Section 6.7).

Table 6.5.3-1: Valued Components for Aquatic Environment Assessment

Valued Component	Rationale for Selection
Fish and Fish Habitat	The Winnipeg River supports a diverse fish community, including species at risk and species that support recreational fisheries. This VC captures the fish species identified by Indigenous Nations. The migration of radionuclides to the Winnipeg River via groundwater may potentially affect fish and fish habitat.

Traditional Knowledge and Land Use Studies (Firelight Research and SFN 2018, BRFN, BON, and HWFN 2019, and SVS 2019) and Indigenous engagement with Sagkeeng First Nation, the Manitoba Métis Federation, Brokenhead Ojibway Nation, Black River First Nation, Hollow Water First Nation, and Wabaseemoong Independent Nations identified additional VCs for consideration in the aquatic effects assessment, including sunfish, catfish, and seagull eggs. A coarse-filtered approach was used to determine effects on the aquatic environment. At the broadest level, fish and fish habitat was selected to assess effects on both fish species and fish habitat. Assessing effects using this coarse-filtered approach means that many biodiversity elements were addressed under this umbrella (i.e., measurement indicators). As such, multiple species and habitat types are captured by this type of assessment, including those identified by Indigenous Nations (i.e., sunfish, catfish, and seagull eggs).

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. The assessment endpoint for the aquatic environment is the maintenance of self-sustaining and ecologically effective fish populations. Self-sustaining populations are healthy and viable and, by definition, robust and capable of withstanding environmental change and accommodating stochastic processes (Reed et al. 2003). Maintaining viable fish populations is a conservation target frequently applied by conservation biologists and resource managers (Fahrig 2001; Nicholson et al. 2006; Ruggiero et al. 1994; With and Crist 1995).

Measurement indicators represent the specific properties of the aquatic environment assessment endpoints and VCs that, when changed, could represent an effect on a VC. Measurement indicators also provide the primary factors for discussing the uncertainty of effects on VCs and, subsequently, are the key measures for study in follow-up and monitoring programs. The measurement indicators for the aquatic environment include measurable attributes that broadly represent various facets of the aquatic environment. These include fish habitat (quality and quantity), benthic invertebrate community structure and fish community structure (Table 6.5.3-2).

Table 6.5.3-2: Assessment Endpoints and Measurement Indicators for the Aquatic Environment Assessment

Valued Component	Assessment Endpoint	Measurement Indicators
Fish and Fish Habitat	Maintenance of self-sustaining and ecologically effective fish populations	■ Changes to quality and/or quantity of fish habitat ■ Changes in benthic macroinvertebrate community structure (diversity, abundance) ■ Changes in fish community structure (diversity, abundance) ■ Changes in fish flesh radiochemistry

6.5.4 Assessment Boundaries

6.5.4.1 Spatial Boundaries

The spatial boundaries selected for the aquatic environmental assessment are consistent with hydrology and surface water quality and are presented on Figure 6.5.4-1 and are described below:

- **Site Study Area (SSA):** is the Whiteshell Reactor 1 (WR-1) Building and represents the Project footprint (i.e., where project activities will be undertaken; 0.07 ha).
- **Local Study Area (LSA):** was selected in consideration of the SSA and the spatial extent of potential direct effects of the Project on hydrology, surface water quality and the aquatic environment. The LSA was selected to represent an area that is likely to be directly affected by the Project, helping to identify Project-specific (rather than cumulative effects of the Project in combination with other projects in the region). The LSA is represented by the fenced area of the WL main campus and includes the SSA. The LSA was based on the area of the WL main campus that is currently drained by roadside ditches and storm sewers. The approximate size of the LSA is 29 ha. The LSA does not include the Winnipeg River as direct effects to the aquatic environment from the Project on the Winnipeg River are anticipated to be negligible (i.e., the drainage area of the LSA is several orders of magnitude smaller than that of the Winnipeg River). Conversely, indirect residual effects to the surface water quality of the Winnipeg River may occur as a result of changes to groundwater quality resulting from the Project. As such, the Winnipeg River is considered as part of the Regional Study Area (RSA).
- **Regional Study Area:** is defined as the area within which maximum geographical extent of potential indirect effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. For example, indirect effects on surface water quality from the Project include potential seepage of groundwater into the Winnipeg River. The plume from the discharged effluent during operation was previously assessed to hug the east bank of the river (AECL 1973) and it is assumed that a groundwater seep entering the river in generally the same area will behave similarly. Therefore, the south boundary of the RSA extends from the west shore of the Winnipeg River to the east fence on the property line about 400 m north of Provincial Highway 211. The eastern boundary of the RSA follows the fence on the property line to the north property line. The north boundary follows the north fence on the property line about 1.6 km and then turns north for about 400 m before turning west and extending to the west side of the Winnipeg River. This is to include the first farm downstream on the east bank because this is the most conservative potential water user. The west boundary follows the west bank of the Winnipeg River. The RSA has an approximate size of 3,710 ha.

6.5.4.2 Temporal Boundaries

Temporal boundaries (i.e., project phases) represent the time period during which project activities are actively occurring and considers the duration of predicted residual effects and establishes the timeframe during which Project effects are assessed. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the length of time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of in situ disposal (ISD), which includes preparation for IDS, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2030.
- **Post-closure Phase:** The post closure phase has two discrete periods: institutional control and post-institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue to demonstrate Whiteshell Reactor Disposal Facility (WRDF) performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.
- Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.5.4.3 Assessment Cases

The assessment cases considered in the aquatic environment assessment include the Base Case, Application Case and the Reasonably Foreseeable Development (RFD) Case:

- **Base Case:** represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, hydroelectric and residential and recreational development. Current effects to surface water and sediment quality from the existing facilities at the Whiteshell Laboratories (WL) site and operations are considered part of the Base Case (i.e., existing conditions). In addition, existing conditions of areas not affected by the WL site are also considered as part of the Base Case. Effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case.

- **Application Case:** represents the effects of the Base Case combined with the predicted effects from the Project. The Application Case includes closure and post-closure activities, and therefore, the associated effects during these phases of the Project represents the bounding case.

- **RFD Case:** represents the predictions of the cumulative effects of the Application Case, plus projects that are currently under application review or that have officially entered a regulatory application process and which overlap with the aquatic environment RSA. Foreseeable developments in the aquatic RSA that are expected to overlap with residual effects on the aquatic environment from the Project includes the decommissioning of the remaining infrastructure and support facilities and remediation of affected lands at the WL site as per the existing decommissioning licence (Table 6.5.4-1). A Comprehensive Study Report (AECL 2001a) under the Canadian Environmental Assessment Act (1992) was completed for the decommissioning of the WL site. The Environmental Assessment decision to approve the Project was announced by the Minister of the Environment in March 2002 and a decommissioning licence was issued to Atomic Energy of Canada Limited (AECL) and subsequently to CNL.

Table 6.5.4-1: Reasonably Foreseeable Developments considered in the Aquatic Environment Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes ISD of the low-level waste trenches).	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project

6.5.5 Description of the Environment

6.5.5.1 Methods

Baseline aquatic environment data were compiled from existing information. Sources included the *Whiteshell Laboratories Decommissioning Project Comprehensive Study Report* (AECL 2001a,b), as well as annual environmental monitoring reports (AECL 2012, 2013, 2014; CNL 2015, 2016, 2018, 2020a). Internet searches were also performed to locate additional or more recent relevant information. Where applicable, radionuclide concentrations and radiological dose rates were compared to international, federal or provincial standards, objectives, or guidelines.

6.5.5.2 Results

6.5.5.2.1 General Overview

The principal aquatic habitat occurring within the RSA is the Winnipeg River. The Winnipeg River passes through the WL site, approximately 500 m the west of the WR-1 Building. In addition, there are several small, isolated ponds on the WL site that are fed by local runoff, and intermittent streams that flow primarily during the spring (AECL 2001a). The streams are associated with gullies that dissect the clay plains along the banks of the Winnipeg River. Beaver ponds are a common feature on the WL site; however, ponds rarely persist for more

than a few years, affording limited quality aquatic habitat. There is also a sewage lagoon, situated north of the main plant site that harbours a number of aquatic plants and animals, as well as man-made ditches that convey water during spring runoff, but are generally dry in summer.

Treated liquid effluent from the Active Liquid Waste Treatment Center, as well as stormwater is discharged to the Winnipeg River at an outfall located about 8 m offshore in approximately 5 m of water (AECL 2001a). The concentration of the dominant radionuclide associated with the discharge, caesium-137, in downstream river water was 0.005 Becquerels per litre (Bq/L) in 2015 (CNL 2016), and 0.014 Bq/L in 2019 (CNL 2020b), which for example is considerably lower than the current maximum acceptable concentration guideline for Canadian Drinking Water Quality of 10 Bq/L (Health Canada 2014) (see Section 6.7 Human and Ecological Health). In 2000, elevated radionuclide concentrations were measured in sediments in the immediate vicinity of the outfall (in an area approximately 20 m wide by 80 m downstream); however, the total radionuclide inventory was very low, approximately 1.3 Gigabecquerel (GBq). This level of activity was substantially less than the annual releases of caesium-137 prior to 1985 when the reactor was operating (AECL 2001a). Measured concentrations of caesium-137 were as high as 1,345 Bq/kg in sediments collected near the outfall in 2008 (AECL 2012). Subsequently, concentrations measured during annual environmental monitoring completed between 2009 and 2019 have ranged from 14 to 732 Bq/kg. Sediment concentrations 150 m downstream of the outfall were measured at 118 Bq/kg in 2009 and subsequently ranged from 5.3 to 53 Bq/kg between 2010 to 2019 (AECL 2013, 2014; CNL 2015, 2016, 2020a). Variation of activity is not unexpected for all samples due to the highly localized and spotty nature of the contamination in the river sediments at the outfall. Sample collection is difficult as the sediment layers are not consistent and areas of the river bottom are not uniformly covered with sediment, hence some sample locations will recover little to no sample.

The Winnipeg River supports a diverse fish community and affords spawning, rearing and foraging habitats. A total of 61 native species are reported for the river (Stewart and Watkinson 2004) and two species at risk are known to be present within the vicinity of the WL site: Lake Sturgeon, Saskatchewan – Nelson River populations (*Acipenser fulvescens*) and Carmine Shiner (*Notropis percobromus*) (COSEWIC 2019). Fish occurring within the study reach include species that are primarily resident (present year-round), as well as migratory (passing through). Fish habitat is generally similar throughout the RSA.

6.5.5.2.2 Fish Community

Of the 177 native freshwater fish species present in Canada, 94 species occur in the Hudson Bay drainage, which includes the Winnipeg River (Scott and Crossman 1973). A total of 79 native species are reported for Manitoba including 61 species for the Winnipeg River (Stewart and Watkinson 2004).

Many of the fish species occurring in the Winnipeg River within the vicinity of the WL site are forage fish including minnows (Cyprinidae), suckers (Catostomidae), sculpins (Cottidae) and darters (Percidae). Predatory fish species reported in the area include Walleye (*Sander vitreus*), Northern Pike (*Esox lucius*) and Smallmouth Bass (*Micropterus dolomieu*) (AECL 2001a). Walleye, Northern Pike, Lake Whitefish (*Coregonus clupeaformis*), Yellow Perch (*Perca flavescens*), Lake Sturgeon, Mooneye (*Hiodon tergisus*), Rock Bass (*Ambloplites rupestris*). White Sucker (*Catostomus commersonii*), and Shorthead Redhorse (*Moxostoma macrolepidotum*), are routinely captured upstream and downstream of the WL site, during annual environmental monitoring (CNL 2016). Other species occasionally encountered during annual monitoring between 2007 and 2017, include Smallmouth Bass, Burbot (*Lota lota*), Sauger (*Sander canadensis*), Black Crappie (*Pomoxis nigromaculatus*) and catfish (Ictaluridae) (CNL 2018).

Thirty-six species of fish were reported from the Winnipeg River near Pointe du Bois Generating Station (situated approximately 55 km upstream of the WL site, see Figure 6.5.5-1) during fish community studies conducted between 2006 and 2010 (Manitoba Hydro 2011). The principal large-bodied species captured included Walleye, Sauger, Northern Pike, Yellow Perch, Burbot, Lake Whitefish, Cisco (*Coregonus artedi*), Longnose Sucker (*Catostomus catostomus*), White Sucker and Lake Sturgeon. Small-bodied species included Spottail Shiner (*Notropis hudsonius*), Emerald Shiner (*Notropis atherinoides*), Trout-perch (*Percopsis omiscomaycus*) and Logperch (*Percina caprodes*). The larvae of three families, Salmonidae (Cisco, Lake Whitefish), Percidae (Yellow Perch, Logperch, Walleye, Sauger) and Cottidae (sculpin) were captured in drift nets throughout the study area. Lake Sturgeon and Northern Pike larvae were collected in low abundance.

Two species at risk occur within the Winnipeg River in the vicinity of the WL site: Lake Sturgeon and Carmine Shiner. Lake Sturgeon (Saskatchewan – Nelson River populations) is designated as Endangered by COSEWIC (COSEWIC 2019) and not included on Schedule 1 of the *Species at Risk Act* . Historically, populations supported a commercial fishery and prior to construction of the Seven Sisters Generating Station (situated approximately 7.5 km upstream of the WL site; see Figure 6.5.5-1) there was an important Lake Sturgeon spawning and nursery area located below the Seven Sisters Generating Station site (COSEWIC 2006). This commercial fishery was important to the Red River Métis into the early 20th century (Shared Value Solutions 2019). Currently, Lake Sturgeon remain relatively common within several kilometres downstream of the Seven Sisters Generating Station.

Spawning occurs below the station and recruitment is occurring (Cleator et al. 2010). The current status of Lake Sturgeon in this reach of the Winnipeg River is thought to be cautious, although a population trend is unknown (DFO 2010). The Carmine Shiner is designated as Endangered by COSEWIC (2019) and is listed on Schedule 1 of the *Species at Risk Act*. The known distribution of the Carmine Shiner is limited to the Winnipeg River, at the base of Whitemouth Falls (located approximately 7 km upstream of the WL site; see Figure 6.5.5-1) and its tributaries (Whitemouth, Birch, Bird and Lee rivers; DFO 2013).

6.5.5.2.3 Radioactivity in Fish

Fish consumption is the dominant exposure pathway of caesium-137 for people in the local area. CNL undertakes annual monitoring of radioactivity in fish flesh (muscle and tissue) collected from the Winnipeg River upstream and downstream of the WL site (CNL 2016, 2020a). Walleye, Northern Pike, Shorthead Redhorse, White Sucker and Lake Whitefish are usually captured and analyzed. It is important to note the Seven Sisters Generating Station, located approximately 7.5 km upstream from WL, acts as an effective barrier, separating fish populations downstream of WL from the upstream (control) populations.

Table 6.5.5-1 provides a summary of the caesium-137, potassium-40 and gross beta activity found in fish flesh at three locations on the Winnipeg River, from 1992 to 2019. Average concentrations of all three radionuclides were slightly greater for Walleye at downstream locations compared to upstream (CNL 2018). However, for the White Sucker, on average radionuclide levels were slightly lower downstream of the WL site compared to upstream. Overall, no significant differences or trends in radionuclide concentrations were apparent among areas over the last five years. Based on an average Cs-137 level in Walleye from 1992 to 2019 at the 2 km downstream location of 1.5 mg/kg fw, the expected dose would be approximately $6x10^{-6}$ mG/d. This is a small fraction of the aquatic dose benchmark of 9.6 mGy/d (UNSCEAR 2011). In 2019, downstream fish were not collected due to unsafe conditions resulting from high river flows (CNL 2020a).

6.5.5.2.4 Benthic Macroinvertebrates and Zooplankton

The benthic macroinvertebrate community within a riverine system is often comprised of both infauna and epifauna. Typically, infauna are burrowing taxa that live in the sediment, whereas epifauna live on the sediment surface. Both types of macroinvertebrates can be important food sources for fish. Benthic fauna include protozoa, ostracods, nematodes, oligochaetes, leeches, mysids (opossum shrimp), crayfish, amphipods, mollusks (snails), bivalve clams (e.g., mussels) and immature stages of aquatic insects. The latter include dipteran larvae such as chironomids and *Chaoborus*, dragonflies nymphs, mayflies nymphs, caddisflies nymphs, true bugs and aquatic beetles (AECL 2001a).

Benthic invertebrate studies were undertaken on the Winnipeg River in the vicinity of the WL site by AECL (1973). The abundance and total beta activity of benthic organisms were determined during 1966 and 1967 upstream and downstream of the liquid effluent outfall. Tubificid worms, chironomid larvae and mayfly (*Hexagenia* spp.) nymphs were the most abundant species among a total of 20 benthic taxa collected. The radioactivity concentration ratios (total beta activity of organism/total beta activity of water) of these species was approximately 2. The range of individual diversity indices (d) obtained during the study was 2.45 to 2.94, indicative of mesotrophic conditions.

Wong et al. (1996) undertook studies downstream of the WL site near Pine Falls. Benthic invertebrates were collected in sediment dredge samples from the Winnipeg River, upstream and downstream of the Pine Falls pulp mill, and examined in order to assess the effects of mill effluent. Considerable organic enrichment was evident in sediments below the mill outfall based on ratios of organic carbon to total nitrogen. The zone below the outfall exhibited the highest density of invertebrates and the community was dominated by species noted to be tolerant to pollution. The benthic community below the outfall for the WL site was comprised of 67% oligochaetes, 20% chironomids and 3% mayflies and caddisflies combined. In contrast, at upstream reference sites, oligochaetes comprised 18%, chironomids 23% and mayflies and caddisflies 44%. Visible deformities were evident in the mentum and mandibles of chironomids (*Chironomus)* collected below the outfall and the preponderance of deformities tended to decrease with increasing distance downstream of the mill. It was concluded that there was serious organic pollution along the south shore of the Winnipeg River for at least 2.5 km below the outfall for the WL site.

The distribution of aquatic snails and their association with aquatic plants in nearby Whiteshell Provincial Park was documented by McKillop (1996).

Most recently, Manitoba Hydro (2011) undertook multi-year studies associated with the Pointe du Bois Generating Station that is situated approximately 55 km upstream of the WL site (see Figure 6.5.5-1). At Pointe du Bois, 42 sediment-dwelling macroinvertebrate taxa were collected. The majority of these were found in shallow habitats where sediments predominantly consisted of clay. Sediments in deeper habitats generally consisted of sand. For the most part, non-biting midges (Chironomidae) numerically dominated total benthic invertebrate abundance. Worms (Olichochaeta), amphipods (Amphipoda), mayflies (Ephemeroptera) and pea clams (Sphaeriidae) also were also common in sediments (Manitoba Hydro 2011). Macroinvertebrates collected in drift traps consisted of 64 discrete taxa, 44 of which were from the Class Insecta. During all years and within all study reaches, amphipods (Hyalellidae) and mites (Hydrachnidae) numerically dominated the non-insect group of the macroinvertebrates; whereas mayflies (Ephemeridae), stoneflies (e), caddisflies (Hydropsychidae) and non-biting midges (*Chironomidae*) were the numerically dominant insect groups.

A 2000 study found caesium-137 levels in clam shells and soft tissues collected downstream of the WL outfall to be slightly elevated compared to upstream (AECL 2001b). There was considerable variation in levels with slight trends to higher tissue concentrations nearer to the outfall and higher concentrations in larger (older) clams.

The effect of exposure from radionuclides in sediments on aquatic biota was estimated in 2000 using clams (AECL 2001b). The doses for the 99th and 99.9th percentile scenarios were 0.0106 milligray per day (mGy/day) and 0.0465 mGy/day (AECL 2001a), a small fraction of the United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR 2011) benchmark of 9.6 mGy/day and the limit at which no effect on aquatic populations would be expected.

Among the many species of zooplankton in Winnipeg River, rotifers, cladocera and copepod are usually dominant (AECL 2001a). Near Pointe du Bois Generating Station, total mean density (individuals/m^3) of zooplankton was relatively similar among years and Cyclopoida and Cladocera were the most abundant taxa, with Calanoida accounting for only 10% to 12% of the mean total collected (Manitoba Hydro 2011).

6.5.5.2.5 Fish Habitat

General physical habitat attributes of the river in the vicinity of the WL site include a width of approximately 0.3 km, a depth of 7 m and a flow velocity of approximately 0.3 m/s (AECL 2001a). Additional data on currents and velocities in the vicinity of the WL outfall are presented in AECL (1973). Typical baseflow at Seven Sisters Generating Station ranges seasonally between 600 and 1,200 m^3/s, but discharge rates in the order of 2,400 m^3/s and 220 m^3/s have been measured during flood and drought conditions, respectively (LWCB 2017). Downstream, channel width within the RSA reaches about 0.6 km. The shoreline consists of a steep clay till bank with frequent cobbles and some large boulders. The substrates are similar to the exposed stream banks and typical of an erosional habitat, largely comprised of gravel, cobbles and boulders, overlying dense clay (AECL 2001a). Gullies and ravines are found along the Winnipeg River. These gullies and ravines provide ideal habitat for beavers (*Castor canadensis*) and result in beaver dams and ponds on-site. These dams, however, are only removed when they begin to disrupt safe site operations (ex. Road drainage ditch blockages), and only under permit from the Province of Manitoba. The site also contains two sewage lagoons that support aquatic plants and animals. Man-made ditches that carry water during spring run-off are also present on the WL site but are not likely to provide an ideal aquatic habitat for plants and animals because they are dry in the summer (AECL 2001a).

Spawning habitat for several species, including Lake Sturgeon, Carmine Shiner, Walleye, Smallmouth Bass and suckers occurs 7 to 8 km upstream of the WL site, associated with the rapids downstream of the Seven Sisters Generating Station and Whitemouth falls (see Figure 6.5.5-1). Northern Pike spawning habitat would be more likely to occur downstream in Lac du Bonnet, although suitable spawning habitats may be present within the RSA, associated with the confluence of smaller tributaries. Optimal spawning habitat for Northern Pike is flooded vegetation in shallow, sheltered areas (Casselman and Lewis 1996), which is more often associated with lacustrine environments. Habitat use by fishes with the RSA would also include nursery, foraging and migration for species that spawn upstream.

Emergent macrophytes such as bulrushes (*Scirpus* spp.), cattails (*Typha* spp.) and wild rice (*Zizania palustris*) are found to a depth of about 1 m along the shores of the Winnipeg River. There are no major aquatic macrophyte beds on the WL site (AECL 2001a); however, in riverine environments, a relatively large amount of vascular plant and algal biomass is transported downstream by flowing water. A recent study undertaken upstream of the RSA, in the vicinity of Pointe du Bois Generating Station (see Figure 6.5.5-1), recorded at least 18 aquatic macrophyte taxa, collected from drift traps deployed in the main stem of the Winnipeg River (Manitoba Hydro 2011). Algae, mainly filamentous, were the most abundant type of vegetation collected in drift traps. Dominant macrophytes collected include pondweeds (*Potamogeton* spp.), grasses (Poaceae), sedges (Cyperaceae), rushes (Juncaceae), water milfoil (*Myriophyllum* spp.), wild celery (*Vallisneria americana)*, bladderworts (*Utricularia* spp.), spikerush (*Eleocharis acicularis*) and duckweed (*Lemna trisulca*). These aquatic plants would also be expected to occur within the RSA.

Phytoplankton (algae) of the Winnipeg River is comprised of a diverse assemblage of nearly all major algal taxonomic groups (AECL 2001a). Studies in upstream reaches have indicated the phytoplankton abundance and composition varies between years and among sites (Manitoba Hydro 2011). The overall mean phytoplankton biomass was 84,410 mg/m^3 and phytoplankton biomass peaked in August. Phytoplankton community composition dominance varied seasonally among chlorophytes, cyanophytes and diatoms.

6.5.5.2.6 Indigenous Traditional Knowledge

This section summarizes observations and concerns shared by Indigenous Nations in their Traditional Land Use and Occupancy Studies. The following are quotes relevant to the aquatic environment.

From the Sagkeeng First Nation:

> "*There's a lot of pickerel in there [Winnipeg River], so that was kind of a delicacy besides the sturgeon, eh? Most of the time … if you got sturgeon, they wouldn't cook it or do anything with it there. They'd always take it home and freeze it and whatever, keep for the winter kind of thing. Or send it to Winnipeg with the other family members, the ones that are going back to Winnipeg."* (Firelight Group Inc and Sagkeeng Anicinabe 2018)
>
> *"In that whole area, in that whole area of the Lac du Bonnet, Bird River…we would catch fish… [our father] used to catch sturgeon, and that's what we lived on… But I know that my dad used to come up into the Silver Falls area, up that way. There's an area just above the—between the two dams, I guess. And there used to be a lot of sturgeon there."* (Firelight Group Inc and Sagkeeng Anicinabe 2018)
>
> *"Yeah, he [husband] caught – I believe it was four pickerel or something but I don't believe he got any sturgeon. And because of what my dad had said [about contamination], we threw them back...we didn't keep them because we were still at that stage being told by my dad, although we were living in Winnipeg, we were told that the fish is not going to be good, like you were taking a chance eating that fish... We had already heard stories of deformed fish and things like that."* (Firelight Group Inc and Sagkeeng Anicinabe 2018)
>
> *"A lot of this fish [in the Winnipeg River] is spoiling…not that much at the spawns anymore because of oil and stuff getting into the – in the water, on the beds of these, where they spawn. It's just water and oil coming from the creeks and stuff like that. Where people, you know, farmers dump their oils and stuff like that instead of properly disposing them in, you know, where old oil should go and stuff like that. They just throw them in their creeks and stuff like that."* (Firelight Group Inc and Sagkeeng Anicinabe 2018)

From Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation:

> *My brother-in-law and sister-in-law are catching fish with deformities. They look at it and won't eat. That's pollution coming down the river. I'm concerned about the fish. That's how they make their living in Hollow Water."* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019)
>
> *"It's not just about our drinking water. It's also got to do with our fisherman that fish in the lake. The fish have growths on them. Where does that come from? I can't rule out this Pinawa site as part of the problem."* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019)

From the Manitoba Métis Federation:

> *"Interviewee: "I'll mention that it's all very good sturgeon habitat too. We don't harvest it. But the population was depleted, but the population is coming back up and hopefully someday we can start harvesting again."*
>
> *Interviewer 2: "In that same area?"*
>
> *Interviewee: "Oh yeah, in that same area right from CNL upstream, downstream, anywhere there.""* (SVS 2019)

For further information on how CNL incorporated traditional knowledge into the EIS refer to Section 4.3 Influence of Traditional Knowledge on the Environmental Assessment and to Section 5.0 of the Indigenous Engagement Report (CNL 2024b) Traditional Land and Resources Use.

6.5.6 Project Interactions and Mitigation

6.5.6.1 Methods

This section describes the process by which interactions between Project components/activities and the aquatic environment were evaluated. Potential effect pathways were identified and mitigation developed, where possible, to eliminate and/or reduce effects. A pathways analysis was then used to focus the assessment on key interactions between the Project and the environment by evaluating the different effect pathways to assess if, after incorporating mitigation, there remained a potential to cause residual effects. Where effects were adequately mitigated and were not forwarded for further analysis (i.e., secondary pathways, or where mitigation removed the pathway altogether), the rationale for concluding the assessment at this stage were articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce effects to the aquatic environment. Environmental design features included design elements, environmental best practices and management policies and procedures.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage pathway** – pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change relative to the Base Case, and therefore would have no residual effects on the aquatic environment.
- **Secondary pathway** – the pathway could result in a measurable minor change to features of the aquatic environment, but these changes would represent a negligible residual effect relative to the Base Case and are not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.

- **Primary pathway** – the pathway is likely to result in an environmental change relative to the Base Case that could contribute to residual effects to the aquatic environment.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects to the aquatic environment were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect on the aquatic environment through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways are carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the Project on the aquatic environment.

6.5.6.2 Results

Pathways through which the Project may interact with the aquatic environment and result in changes to the fish and fish habitat VC are summarized in Table 6.5.6-1. Project activities are described in more detail in Section 3.5 Project Components.

Table 6.5.6-1: Pathways Analysis for Aquatic Environment Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
General Project activities during the closure phase	During closure activities, there is the potential for the transport of site runoff to the Winnipeg River.	■ Wastewater from decommissioning activities is collected and tested, and based on the results, is directed either to our waste treatment center, domestic drain, processed drain, ditch systems or is sent for evaporation and/or solidification and disposal. ■ Existing surface water management systems at the WL site will remain in place to manage site runoff.	Secondary
General Project activities during the closure phase	Non-radiological air emissions and dust emissions (including sulphur dioxide, nitrogen oxides [NOx/NO2] and particulate matter) and subsequent deposition.	■ Implementation of CNL's *Environmental Protection Program* (CNL 2023) and *Management and Monitoring of Effluents and Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Implementation of dust management techniques to control dust generated by the Project, consistent with the current Environmental Assessment Follow-up and Monitoring Program. ■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. ■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include: ▪ wetting techniques during demolition to limit mobility of dust; ▪ wind restrictions during demolition to stop work or apply wetting techniques; and ▪ hydro seeding during backfilling and landscaping to reduce soil erosion. ■ Road watering and chemical dust suppressant when necessary. Dust suppressant is already used annually at the site for select unpaved roads. ■ Removal of accumulations of particulates (e.g., dirt) on road as soon as possible. ■ On-site vehicles and equipment engines will meet Tier 3 emission standards, where possible, and be maintained in good working order. ■ Limit idling of vehicles on-site and speed on roads. ■ Use of tarps or 3-sided enclosures for raw material storage.	Secondary

Table 6.5.6-1: Pathways Analysis for Aquatic Environment Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
General Project activities during the closure phase	Closure activities will result in the atmospheric release of radiological compounds from the WR-1 Building	■ Implementation of CNL's Radiation Protection Program and Procedure, which includes Radiation Safety Zones, detailed work planning to limit doses to As Low As Reasonably Achievable (ALARA), dose monitoring and contamination control procedures (e.g., stabilizing and immobilizing agents). ■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring.. ■ Implementation of CNL's Environmental Monitoring Program (CNL 2020a).	Secondary
Installation of concrete cap and engineered cover over grouted WR-1 Building during closure and final restoration	Installation of concrete cap and engineered cover at the WR-1 Building may alter drainage rates and flow patterns.	■ The Project site and engineered cover will be graded to promote drainage to the Winnipeg River.	Secondary
Closure of the entire WL site	Decommissioning and reclamation of the entire WL site, including the Project, may alter drainage rates and flow patterns.	■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ The drainage system for the reclaimed WL site will have physical characteristics similar to the natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity.	Secondary

Post-closure Performance	Release of chemical and radiological contaminants in the long-term during the post-closure phase from the Project.	■ The planned decommissioning of the WR-1 Building presently involves:
		  ▪ removal the service area and infilling in these areas with compact soil;
		  ▪ sealing of open conduits in the building foundation; and
		  ▪ grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation.
		■ As part of CNL's licence with the Canadian Nuclear Safety Commission, environmental monitoring around the WL site is required and will continue for the Project during the post-closure phase.
		■ Follow-up monitoring during the post-closure phase will be completed to verify effects predictions and to provide information for use in adaptive management to address potential unforeseen effects.
			Secondary

	Release of chemical and radiological contaminants in the long-term from the closure of the entire WL site, in combination with the Project.		Secondary

6.5.6.2.1 No Linkage Pathway

No pathways were identified between the Project and the aquatic environment as being no linkage to residual effects on VCs for the aquatic environment.

6.5.6.2.2 Secondary Pathways

The following pathways were assessed as potentially having a measurable minor environmental change, but negligible residual effect on the aquatic environment relative to Base Case.

- **During closure activities, there is the potential for the transport of site runoff to the Winnipeg River.**

Drainage from the LSA is to the Winnipeg River. During closure phase activities, specifically those that are demolition-related, there is the potential for the transport of site runoff to the aquatic environment in the Winnipeg River in the vicinity of the WL site. Unabated, this runoff could negatively affect the aquatic environment through indirect habitat degradation (e.g., increase in suspended solids levels in water, increase in metal concentrations in water, swamping of the benthic environment through the settling of solids) that could result in reductions in diversity and abundance of aquatic biota in the nearshore area.

All wastewater generated at the LSA is managed in accordance with CNL's *Management and Monitoring of Emissions* (CNL 20b) and is discharged in accordance with CNL's *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids at CNL sites* (CNL 2021). Wastewater from radiological drains and building sumps in nuclear buildings is collected by the Low Level Liquid Waste (LLLW) treatment systems in the individual buildings, where it is sampled, tested and approved for release to the Winnipeg River via the outfall station. Wastewater from non-radiological drains and process drains is directed to the stormwater system where it flows out to the outfall. Groundwater collected in building sumps of non-nuclear buildings is discharged into the stormwater system to the outfall station. Rainwater collected by the building roofs, paved areas, roads, and stormwater catchments is collected by the stormwater system and is directed to the outfall station. Building sanitary sewer systems drain to the site lagoon that consists of two interconnected cells, allowing water to flow freely between them. Annually, the cells are isolated from each other, so that the effluent in the secondary cell can settle and waste broken down. The secondary cell is then sampled and tested to ensure effluent water is safe to permit discharging into the ditch system that leads to the Winnipeg River. Mixed wastewater at the outfall is sampled and tested regularly.

Currently, wastewater from decommissioning activities is collected and tested and based on the results, is directed either to an onsite waste treatment system, domestic drain, processed drain or ditch systems, or is sent for storage, evaporation and/or solidification and disposal according to CNL's *Acceptability Criteria for Routine and Non-Routine Discharge of Liquids at Canadian Nuclear Laboratories Sites 900-509200-MCP-005* (CNL 2021). This process follows the requirements in CNL's *Management and Monitoring of Emissions* (CNL 2024a). Wastewater directed to the ground or ditch system only occurs when the wastewater is below levels of concern for all contaminants.

In addition, containment barriers will be constructed where necessary to provide for the collection, control of and treatment of contaminated water and to reduce surface water runoff during decommissioning and reclamation activities. Surface water quality is also assessed at locations where surface water leaves the WL site's boundary and in waterbodies affected by discharges. Concentrations of radiological and non-radiological contaminants are measured and compared against existing provincial or federal surface water quality guidelines or standards. It is also noted that closure phase activities will occur well away from the river and its riparian zone and therefore

no direct changes in surface water quality will result. As per *Management of Land, Habitat and Wildlife* (CNL 2024), any work within 30 m of rivers, streams and lakes must have preventative measures and mitigation in place. Best management practices already exist and will be fully implemented. General provisions adopted for work at CNL sites in or near a watercourse incorporate appropriate sediment retention measures such as silt curtains and straw bales.

It is also noted that closure phase activities will occur well away from the river and its riparian zone and therefore no direct habitat loss, either in terms of quality or quantity, will result. Consequently, this interaction was determined to have a negligible residual effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

- **Installation of concrete cap and engineered cover at the WR-1 Building may alter drainage rates and flow patterns.**

Installation of concrete cap and engineered cover at the WR-1 Building may alter drainage rates and flow patterns, and consequently the discharge volume to Winnipeg River. This could in turn affect the quality and quantity of fish habitat in the Winnipeg River. Following the completion of closure activities, the Project site and engineered cover will be graded to promote drainage to the Winnipeg River. Run-off control for the cover is designed to limit erosion and infiltration of water into the grouted structure. This is achieved by sloping the cover surface to maintain slope toward the edges and the collection of water by the existing surface water management systems at the WL site. As part of the closure of the WL site, a storm water management plan will be developed using best management practices and taking into consideration the effect of the site's drainage following the demolition of the infrastructure (e.g., buildings, roads, catch basins, storm drainage system). Alternate drainage works (e.g., swales, ditches, culverts) along with aligning landscaping to the lines and grades so that proper drainage is achieved would be an output of this plan. Typically, the storm water will be directed to the Winnipeg River using existing topography's drainage paths (creeks) to the greatest extent possible.

Although the installation of the concrete cap and engineered cover at the WR-1 Building is expected to slightly alter the drainage rates and flow patterns and discharge volume to the Winnipeg River; the changes are expected to be within the natural range of variation (Section 6.4.1.5.2.3). As such, changes to the hydrology from the installation of the cover at closure is predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

- **Decommissioning and reclamation of the entire WL site, including the Project, may alter drainage rates and flow patterns.**

The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. The drainage system for the reclaimed WL site will have physical characteristics similar to the natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. The contribution to site runoff from the Project is expected to be minor relative to the entire decommissioned WL site. Similar to the decommissioning plan for the Project, the WL site will be graded to promote drainage to the Winnipeg River; therefore, limiting changes to fish and fish habitat in the Winnipeg River. Although closure of the WL site may slightly alter the drainage rates and flow patterns and discharge volume to the Winnipeg River; the changes are expected to be within the natural range of variation. As such, changes to hydrology from the closure of the WL site, including the Project, are predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

- **Release of chemical and radiological contaminants in the long-term during the post-closure phase from the previous activities completed at the WL site.**

The Comprehensive Study Report (AECL 2001a) indicated residual effects on surface water, particularly the Winnipeg River, are related to discharges from the Active Liquid Waste Treatment Centre and the sewage lagoon. No decrease in water quality is expected and effluent emissions to the Winnipeg River are expected to decline to virtually zero following decommissioning. Re-suspension of contaminated sediments is also not expected to lead to a decrease in water quality. As part of CNL's licence with the Canadian Nuclear Safety Commission (CNSC), environmental monitoring around the WL site will continue for the Project. Follow-up monitoring during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects. Consequently, changes to surface water quality from the closure of the WL site, are predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

- **Non-radiological air emissions and dust emissions (including sulphur dioxide, nitrogen oxides [NOx/NO_2] and particulate matter) and subsequent deposition.**

- **Closure activities will result in the atmospheric release of radiological compounds from the WR 1 Building.**

Closure of the Project will generate air and dust emissions such as carbon monoxide (CO), oxides of sulphur (SO_x includes sulphur dioxide [SO_2]), oxides of nitrogen (NO_x includes nitrogen dioxide NO_2), particulate matter ($PM_{2.5}$, PM_{10}) and suspended particulate matter (SPM). Air emissions, such as SO_x and NO_x, can result from the use of fossil fuels in generators, vehicles and machinery. Vehicle exhaust and fugitive dust from roads is the largest contributor to particulate matter (SPM, PM_{10} and $PM_{2.5}$) during the closure phase (Section 6.2.1.7.2) In addition, radiological emissions will be generated from the demolition of the WR-1 Building, which can result in deposition to the aquatic environment.

Examples of mitigation implemented to limit predicted residual effects from Project emissions to air quality (and subsequently surface water quality) include:

- implementation of CNL's Environmental Protection Program (CNL 2023) and *Management and Monitoring of Effluent and Emissions* (CNL 2022), which includes operational control monitoring and air verification monitoring;
- implementation of CNL's Radiation Protection Program and Procedure, which includes Radiation Safety Zones, detailed work planning to limit doses to As Low As Reasonably Achievable (ALARA), dose monitoring and contamination control procedures (e.g., stabilizing and immobilizing agents).
- use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include:
  - wetting techniques during demolition to limit mobility of dust;
  - wind restrictions during demolition to stop work or apply wetting techniques; and
  - hydro seeding during backfilling and landscaping to reduce soil erosion.

- apply road watering and chemical dust suppressant when necessary (dust suppressant is already used annually at the site for select unpaved roads);
- removal of accumulations of particulates (e.g., dirt) on road as soon as possible; and
- use of tarps or 3-sided enclosures for raw material storage.

The predicted residual effects air quality from non-radionuclide emissions were estimated to increase because of the Project. Fugitive dust from roads is the largest contributor to SPM emissions. Material handling from demolition is the largest contributor to PM_{10} emissions. Non-road equipment exhaust emissions are the largest contributors to $PM_{2.5}$ and NOx (as NO_2) emissions. Finally, the largest contributor to SO_2 and CO emissions is fuel combustion for emergency power generators. Predicted non-radiological concentrations for the Application Case are below applicable air quality guidelines and/or standards (Section 6.2.1.7.2).

Mitigation of fugitive dust emissions is provided in Table 6.2.1-10 (Pathways Analysis for the Air Quality Valued Component). Monitoring of dust emissions and radionuclide emissions includes the use of contamination immobilization agents, containment, ventilation and High-efficiency Particulate Air (HEPA) filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. In addition, use of dust suppression methods during building demolition or soil remediation activities will be implemented to control airborne emissions and nuisance dust during building demolition or soil remediation. Consequently, air emissions are predicted to be below applicable air quality guidelines and/or standards as discussed in Section 6.2.1.7.2 (Application Case Results), and will not impact the surrounding aquatic environment.

CNL recently demolished a number of other buildings at the WL site. The mitigation listed above was applied and successfully reduced SPM and radiological emissions which ultimately reduce subsequent deposition. It is expected that this same mitigation will also be effective during the demolition of the WR-1 building. Therefore, with the implementation of CNL's *Management and Monitoring of Emissions* and CNL's Radiation Protection Program and Procedure (CNL 2022), radiological and non-radiological air and dust emissions and subsequent deposition are expected to result in local, minor changes to soil quality relative to Base Case conditions. As such, this pathway is determined to result in a negligible effect on the maintenance of self-sustaining and ecologically effective aquatic populations, including species at risk.

Atmospheric deposition to the Winnipeg River is considered negligible. This is consistent with the COG DRL guidance (COG 2013) which shows (assuming a modest flow rate for a lake of 0.1 m/s and an assumed water depth of 10 m) that the transfer of radionuclides from the atmosphere to large bodies of water (including lakes and rivers) is considered negligible. Rivers have larger flow rates than lakes; therefore, the conclusion for lakes that the atmospheric deposition pathway is negligible is applicable to rivers as well. Consequently, changes to fish and fish habitat from the closure of the WL site, are predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

- **Release of chemical and radiological contaminants in the long-term during the post-closure phase from the Project.**

Successful closure of the WR-1 Building will require that the dose limit is not exceeded for the protection of aquatic health. The planned decommissioning of the WR-1 Building presently involves removal the service area and infilling in these areas with compact soil, sealing of open conduits in the building foundation and grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation.

An Ecological Risk Assessment (EcoMetrix 2024) was completed to evaluate the potential for adverse effects on aquatic health associated with exposure to chemical and radiological contaminants from the Project (Section 6.7.2) in the long-term. For the post-closure phase, the relevant chemical and radiological contaminants may be released over time by a combination of diffusion and advection through the grout and concrete barriers to groundwater and subsequent migration of groundwater to surface water at the Winnipeg River. The risk assessment utilized groundwater release rates (see Section 6.4.2.7.1.1 Groundwater Release Rates) and dispersion modelling to estimate radionuclide concentrations in surface water (see Section 6.4.2.7.1.2 Dispersion Modelling), to calculate dose rates to aquatic biota. These dose rates were compared to international standards (UNSCEAR 2011) and used as a surrogate to assess effects to resident fish and benthos.

The incremental change in radionuclide levels in the Winnipeg River as the result of the transport of radionuclides from the WR-1 Building to the Winnipeg River via groundwater in the post-closure phase is predicted to be not practically distinguishable from background levels (see Section 6.4.2.7.2 Application Case Results) and, therefore, no negative effects on the quality or quantity of available fish habitat in the RSA are anticipated as the result of decommissioning.

During the closure and post-closure phases, there are no exceedances of the 9.6 mGy/day radiation benchmark for the aquatic biota in the Winnipeg River. All predicted doses are well below these levels. Therefore, based on the assessment completed in Section 6.7.2.7 Residual Effects Analysis, it is unlikely there would be significant adverse effects on aquatic populations or communities as a result of radionuclide releases from closure activities or in the long-term during the post-closure phase.

There are no exceedances of the HQs identified for exposure of the aquatic receptors to cadmium, lead, HB-40 (with the exception of benthic invertebrates in groundwater) and xylene. The HQs for cadmium, lead and HB-40 exceeded 1 for the scenario where benthic invertebrates are exposed directly to groundwater. However, this does not necessarily imply a significant adverse effect. Sessile organisms, such as benthic invertebrates may be more directly exposed to groundwater, if inhabiting the point of discharge. The assessment conservatively assumes the organisms spend their entire lives in the peak discharge zone, and that no dilution of the groundwater occurs in the shallow sediment layers where most benthic organisms reside. Moreover, the seepage area represents a small part of the benthic community habitat, and the maximum groundwater concentration assumed represents the worst case time period. As such, a realistic benthic invertebrate population is not likely to be at risk due to cadmium, lead and HB-40 exposure, and any adverse effects will be spatially and temporally limited. Overall, the changes in water quality and sediment quality are expected to result in a negligible residual effect to the benthic invertebrate population relative to existing conditions.

Table 6.5.6-2: Post-closure Maximum Total Radiological Dose to Aquatic Biota in the Winnipeg River

Aquatic Biota	Maximum Total Dose (mGy/day)
Carmine Shiner	1.14×10^{-04}
Lake Sturgeon	1.14×10^{-04}
Walleye	4.10×10^{-06}
Aquatic Macrophytes	4.26×10^{-06}
Benthic Invertebrates (River Water)	5.77×10^{-04}
Benthic Invertebrates (Groundwater)	5.71
Benchmark (UNSCEAR 2011)	**9.6**

mGy = milligray.

The dominant contributor to the total dose is caesium-137 due to external exposure to sediment; however, the caesium-137 sediment concentrations are based on existing conditions and do not result from the source-term in the post-closure period. Based on the source-term concentrations expected to be released to groundwater during post-closure, the largest contributor to dose during post-closure is carbon-14. Baseline data for carbon-14 in fish flesh were not available. It is expected that the predicted incremental change in carbon-14 in fish flesh (5.8 Bq/kg fresh weight) is not a measurable change from baseline, because carbon-14 global background levels are high, supported by natural production due to cosmic irradiation in the upper atmosphere. Carbon-14 is readily exchanged between atmospheric radioactive carbon dioxide and stable carbon in surface water and fish flesh. A typical background level measured in Great Lakes fish is 240 Bq/kg-carbon (OPG 2013; Bruce Power 2013), which is equivalent to approximately 29,000 Bq/kg fresh weight, much higher than the predicted change. Plutonium-239 and tritium (tritiated water and organically bound tritium) are minor contributors to dose (1% or less). Tritium is also unlikely to be detectable against the natural background in fish flesh.

In consideration of these results, decommissioning of the WR-1 Building is not expected to adversely affect radionuclide levels in aquatic biota flesh during the post-closure phase. As part of CNL's licence with the CNSC, environmental monitoring around the WL site is required. The current program includes collecting fish flesh at one location upstream and two locations downstream of the WL site (CNL 2016). Follow-up monitoring might include both carbon-14 and tritium in the radiochemical analyses of fish, to confirm that there is no measurable upstream-downstream difference, as expected. Monitoring of both surface water quality and fish flesh will continue into the post-closure period. Overall, changes to surface water quality from the Project, are predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

- **Release of chemical and radiological contaminants in the long-term from the closure of the entire WL site, in combination with the Project.**

Historically, liquid effluent from the Active Liquid Waste Treatment Center was discharged to the Winnipeg River and elevated radionuclide concentrations were measured in sediments in the local outfall area (AECL 2001a). Exposure pathways to aquatic biota include radiation from nuclides in the water and sediment. An immeasurable increase in radionuclide concentrations in water and sediments are anticipated once groundwater from the WL site reaches the river (during the post-closure period). The effect of exposure from radionuclides in sediments on aquatic biota was estimated in 2000 using clams (AECL 2001b). The study found caesium-137 concentration in shells and tissues collected downstream of the WL outfall to be slightly elevated (AECL 2001b). Given the erosional nature of the Winnipeg River in the vicinity of WL site, it would be highly unlikely that residual sediment contamination would persist for a century. Regardless, cumulative (residual plus incremental groundwater concentrations from the Project during the post-closure period) doses to aquatic biota would remain a small fraction of the UNSCEAR (2011) benchmark of 9.6 mGy/day and the limit at which no effect on aquatic populations would be expected. Follow-up monitoring during the post-closure phase will be completed to confirm radionuclide concentrations in both surface water quality and fish flesh will verify the anticipated low effects (or lack thereof) and provide information for use in adaptive management to address potential unforeseen effects. Overall, changes to surface water quality from the closure of the WL site, including the Project, are predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

6.5.6.2.3 Primary Pathways

No primary pathways were identified between the Project and the aquatic environment. As discussed in Section 6.5.6.2.2, the dose and risk to fish from predicted loadings to the Winnipeg River were well below the dose benchmark from UNSCEAR (2008) and the HQ target value from *CSA N288.6-12: Environmental Risk*

Assessment at Class 1 Nuclear Facilities and Uranium Mines and Mills (CSA Group 2012). As such, a residual effects analysis and determination of significance has not been completed for the aquatic environment assessment.

6.5.7 Monitoring and Follow-up

Monitoring and follow-up programs for the aquatic environment are not identified specific to the Project as there are no predicted residual effects to fish and fish habitat. However, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as identified for other environmental components (e.g., groundwater quality and surface water quality) to verify the accuracy of environmental effects predicated and determine the effectiveness of mitigation that has or is to be implemented. For example, environmental monitoring will be completed throughout the institutional control period to confirm that the WRDF barriers are functioning as intended. This monitoring will be integrated into the overall CNL WL Groundwater Monitoring Program to verify that changes to surface water quality, and subsequently fish and fish habitat, as a result of groundwater are negligible. In addition, CNL's *Management and Monitoring of Emissions* will include monitoring objectives air quality to verify that air emissions during closure have a negligible effect on surface water quality, and subsequently fish and fish habitat. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical.

As part of CNL's licence (NRTEDL-W5-8.00/2024), CNL's existing Environmental Monitoring Program includes water monitoring and collecting fish flesh at one location upstream and two locations downstream of the WL site (CNL 2016). Although not specific to the Project, this monitoring will also verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. CNL will continue to carry out the existing Environmental Assessment Follow-up and Monitoring Program for the WL site as it is a requirement of CNL's current licence (NRTEDL-W5-8.00/2024) with the CNSC.

It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Within this framework, modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS or the Decommissioning Safety Assessment Report (Golder 2021), including the findings from the Ecological Risk Assessment (EcoMetrix 2024), the frequency of sampling may be increased and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized, or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals for modifications to the monitoring program and the rationale for the modifications will be communicated to the CNSC prior to implementation. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs:

- CNL continues to adapt their environmental monitoring approach in support of fish monitoring and protection of the Winnipeg River. CNL presented on their environmental monitoring program during a fish monitoring workshop with Sagkeeng First Nation representatives, including topics on how fish are sampled, explanation of the results, and trends and what they mean. CNL environmental protection staff also engaged with the Manitoba Métis Federation, Brokenhead Ojibway Nation, Black River First Nation, Hollow Water First Nation, and Wabaseemoong Independent Nations and explained the annual monitoring campaign that has occurred since the inception of the site, such as fish sampling. The CNSC conducted an independent monitoring campaign with assistance from Sagkeeng First Nation. The independent program included collecting and

analyzing fish caught near Sagkeeng First Nation. The results of the independent monitoring campaign concluded that fish in the vicinity of the WL site are protected.

- CNL will continue to proactively seek, engage, and support meaningful discussion on issues and opportunities related to the Project, including the monitoring and follow-up program, with First Nations and the Manitoba Métis Federation and communities of interest. CNL has also had discussions with First Nations and the Manitoba Métis Federation on how future monitoring on the WL site could incorporate Indigenous interests, such as monitoring of country harvested foods. CNL will continually evaluate both the process and the outcome of the ongoing engagement and communication activities, to address and manage issues as they arise.

6.5.8 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). For the aquatic environment, fish and fish habitat was selected as a VC, as there is a potential for the Project activities to affect aquatic biota in the Winnipeg River. The fish and fish habitat VC includes the fish species identified by Indigenous Nations that are occurring in the Winnipeg River, as well as habitats supporting life history requirements including spawning, nursery, rearing and foraging The assessment endpoint for the aquatic environment is the maintenance of self-sustaining and ecologically effective fish populations. Fish habitat, benthic macroinvertebrate community structure, fish community structure and fish flesh radiochemistry were selected as the measurement indicators for the aquatic environment VCs.

During closure, potential effects to fish and fish habitat during closure include the transport of site runoff to the aquatic environment in the Winnipeg River in the vicinity of the WL site, changes in drainage rates and flow patterns due to the installation of the concrete cap and engineered cover at the WR1 Building, and air emissions from demolition activities. As part of the closure of the WL site, a storm water management plan will be developed using best management practices and taking into consideration the effect of the site's drainage following the demolition of the infrastructure (e.g., buildings, roads, catch basins, storm drainage system). Alternate drainage works (e.g., swales, ditches, culverts) along with aligning landscaping to the lines and grades so that proper drainage is achieved would be an output of this plan. With implementation of CNL's *Management and Monitoring of Effluent and Emissions* (CNL 2022), air and dust emissions and subsequent deposition are not predicted to impact the surrounding aquatic environment. As such, closure activities are predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

For the post-closure phase an Ecological Risk Assessment (EcoMetrix 2024) was completed to evaluate the potential for adverse effects on aquatic health associated with exposure to chemical and radiological contaminants from the Project in the long-term. In the post-closure phase, there are no exceedances of the 9.6 mGy/day radiation benchmark for the aquatic biota in the Winnipeg River and all predicted doses are well below this level. Therefore, based on the assessment completed in Section 6.7.2, it is unlikely there would be significant adverse effects on aquatic populations or communities as a result of radionuclide releases from closure activities or in the long-term during the post-closure phase.

There are no exceedances of the HQs identified for exposure of the aquatic receptors to cadmium, lead, HB-40 (with the exception of benthic invertebrates in groundwater) and xylene. The HQs for cadmium, lead and HB-40 exceeded 1 for the scenario where benthic invertebrates are exposed directly to groundwater. However, this does not necessarily imply a significant adverse effect. Sessile organisms, such as benthic invertebrates may be more directly exposed to groundwater, if inhabiting the point of discharge. The assessment conservatively

assumes the organisms spend their entire lives in the peak discharge zone, and that no dilution of the groundwater occurs in the shallow sediment layers where most benthic organisms reside. Moreover, the seepage area represents a small part of the benthic community habitat, and the maximum groundwater concentration assumed represents the worst-case period. As such, a realistic benthic invertebrate population is not likely to be at risk due to cadmium, lead and HB-40 exposure, and any adverse effects will be spatially and temporally limited. Overall, the changes in water quality and sediment quality are expected to result in a negligible residual effect to the benthic invertebrate population relative to existing conditions.

First Nations and the Manitoba Métis Federation have interest in the current and future monitoring proposed for the Project. CNL continues to adapt their environmental monitoring approach in support of fish monitoring and protection of the Winnipeg River. CNL will continue to proactively seek, engage, and support meaningful discussion on issues and opportunities related to the Project, including the monitoring and follow-up program, with First Nations and the Red River Métis and communities of interest.

6.6 Terrestrial Environment

This section of the Environmental Impact Statement (EIS) characterizes potential residual effects of the Project on the terrestrial environment, including potential effects on the ecological and biological processes that connect species with each other and their physical environment.

6.6.1 Scope of the Assessment

The scope of the assessment focuses on the evaluation of potential changes in the terrestrial environment that may result from activities associated with the Project. Risks to ecological health as the result of chemical and radiological exposures are discussed in detail in Section 6.7 Human and Ecological Health. Results of these assessments are used to support the assessment of effects on the terrestrial environment.

The terrestrial environment assessment follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment is completed in the following steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Sections 6.6.3 Valued Components and Section 6.6.4 Assessment Boundaries) for the terrestrial environment assessment. The VCs, assessment endpoints and measurement indicators used to assess project-related changes to the terrestrial environment, the spatial and temporal boundaries at which the assessment occurred, and the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.6.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.6.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect the terrestrial environment are identified and mitigation options are presented to limit or avoid these effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the terrestrial assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the terrestrial assessment.
- **Step 6 – Classify and determine the significance of the predicted residual effects.** This step was not required as no residual effects to terrestrial VCs were identified.
- **Step 7 – Identify monitoring and follow-up** (refer to Section 6.6.7 Monitoring and Follow-up) required to confirm effects predictions and address uncertainty.

- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.6.8 Conclusions) of residual effects on the terrestrial environment.

6.6.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the terrestrial environment assessment are summarized in Table 6.6.2-1. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4 Indigenous Engagement.

Table 6.6.2-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Terrestrial Environment Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
Migratory Birds	Already included in the environmental assessment	Migratory birds are encompassed by assessment of most sensitive species (golden-winged warbler [*Vermivora chrysoptera*] and barn swallow [*Hirundo rustica*]). See Section 6.6.3 Valued Components.
Effects on Harvesters ■ Consuming deer (*Odocoileus* sp.) and moose (*Alces alces*) ■ Consuming harvested foods and medicinal plants ■ Importance of the Winnipeg River for the harvesting of waterfowl	Already included in the environmental assessment Moose and weekay were added to the Harvester's diet in post-closure Assessment	Effects on harvesters during the closure and post-closure phases from the consumption of deer, moose and plants are assessed in 6.7.1.7 Residual Effects Analysis. The effects on the ability to harvest and hunt foods is assessed in Section 6.8.1.6 Project Interactions and Mitigation.
Effects on the Health of Plants and Wildlife Important to Indigenous People ■ White-tailed Deer (*O. virginianus*) ■ Moose Weekay (*Acorus americanus*) ■ Berries	White-tailed deer and berries were already included in the environmental assessment Weekay was already included in the environmental assessment through the 'Aquatic Plants' VC. Moose was added as a VC to the Ecological Health Assessment	The VCs assessed in the Ecological Health Assessment are listed in Section 6.7.2.3 Valued Components. Effects on wildlife health are summarized in Section 6.7.2.7 Residual Effects Analysis (Tables 6.7.2-8 and 6.7.2-10). Weekay is an aquatic plant and is represented by the Freshwater Plant category in Section 6.7.2.7.2.2. Forage plants, grasses and fruits (berries) are addressed in Section 6.7.2.7.1.2.

6.6.3 Valued Components

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). They are elements of the environment that are considered to have economic, social, biological, conservation, aesthetic and/or ethical value. Identifying VCs helps to focus the assessment on the most important or representative components of the environment that are likely to be affected by the Project. This section describes how VCs were selected for the terrestrial environment assessment and identifies the assessment endpoints and measurement indicators that were used to assess the effects of the Project on each VC. Because this assessment is for a designated project, as described in the *Canadian Environmental Assessment Act, 2012* (CEAA 2012) and is regulated by the Canadian Nuclear Safety Commission (CNSC), VC selection considered guidance from Appendix A of the CNSC's *REGDOC-2.9.1, Environmental Principles, Assessments and Protection Measures* (CNSC 2020). Specifically, VC selection focused on providing a "*full accounting of effects on species with elevated conservation status and their habitat*" (CNSC 2020).

Based on the nature of this project and limited pathways of effects on natural terrestrial ecosystems, the focus of this assessment is at a species-level and primarily focuses on wildlife species identified on Schedule 1 of the federal *Species at Risk Act* (SARA). On a federal level, designations for species at risk occurring in Canada are initially determined by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). If approved by the federal Minister of the Environment, species are added to the federal List of Wildlife Species at Risk under Schedule 1 of SARA. Once included on Schedule 1, it is prohibited to kill, harm, harass, capture, possess, collect, buy, sell, or trade individuals, as well as damage or destroy the residence of a species listed as Extirpated, Endangered or Threatened. Furthermore, species that are included on Schedule 1 as Extirpated, Endangered or Threatened are afforded protection of species-specific critical habitat on federal lands (such as the Whiteshell Laboratories [WL] site), once critical habitat is defined in a recovery strategy.

Baseline wildlife data were compiled for the WL site based on incidental observations by staff collected from 2014 to 2021, targeted surveys for species at risk in 2015 (i.e., bats and barn swallow), song bird automated recording unit acoustic surveys during the late breeding period from June 12 to July 3, 2018 and early breeding period from May 9 to June 10, 2019 (Dillon 2019a,b), and daytime visual searches for roosting bats in the interior of the WR-1 building conducted by CNL staff in 2021 on 4 dates (July 20, 21, 27 and 28) (McKinnon et al. 2022). There has also been a spatial query conducted by Manitoba Conservation Data Centre to determine the potential for 33 species at risk (animals and plants), to occur within the RSA (CNL 2016a). Staff observation records and wildlife surveys have confirmed the presence of nine terrestrial wildlife species at risk listed on Schedule 1 of SARA within the WL site (Appendix 6.6-1).

All SARA listed species identified in Appendix 6.6-1 with confirmed observation records within the WL site (the Regional Study Area: RSA), as well as all species returned from the Manitoba Conservation Data Centre query with the potential to occur within the WL site, were considered as potential VCs at the species level. Each species was evaluated to determine whether or not its presence was likely within the Site Study Area (SSA) or the Local Study Area (LSA) defined for the terrestrial environment assessment (Section 6.6.4.1 Spatial Boundaries). Species with a very low likelihood of occurrence, for which habitat was not present in the LSA, or for which measurable effects from the Project were unlikely or suitably considered by another indicator species, were excluded as VCs. Rationale for inclusion or exclusion species at risk with confirmed or potential presence within the WL site is presented in Appendix 6.6-1.

Species at risk identified as VCs for the terrestrial environment assessment are presented in Table 6.6.3--1. Individual species for which the potential effects of the Project are similar were grouped into a single VC (e.g., bats; Table 6.6.3--1). Both avian VC species (barn swallow and golden-winged warbler) are also protected by additional federal legislation (*Migratory Birds Convention Act, 1994* [MBCA]). Section 5 of the MBCA prohibits the disturbance, destruction or removal of a nest or related shelter, or egg of a migratory bird, or possession of a live migratory bird, or a carcass, nest or egg of a migratory bird. The Project has the potential to affect migratory birds and adherence to the MBCA 1994 is required as part of the Project works. Because the RSA is a federally owned site, the applicable legislation for wildlife species at risk protection is SARA. However, CNL also recognizes the importance of protecting species designated under provincial legislation (i.e., the provincial *Endangered Species and Ecosystems Act, C.C.S.M. c. E111*; ESEA).

Most of the VCs identified for the terrestrial assessment can also be used as indicators for broader groups of species. For example, golden-winged warbler represents migratory bird species that may breed in the edge habitat within adjacent forested areas and could be affected by decommissioning-related noise. Snapping turtle (*Chelydra serpentina*) represents herptile species vulnerable to mortality on roadways. Consequently, understanding the potential effects of the Project on the selected VCs provides inferences about effects on other wildlife species or guilds with similar life history traits and habitat requirements (Appendix 6.61).

Predicted doses of radiation and exposure to non-radionuclides through relevant pathways to deer (closure phase) and waterfowl (post-closure phase) were assessed in the Environmental Risk Assessment (see Section 6.7 Human and Ecological Health). Potential risks to waterfowl were only assessed for the post-closure phase because there was determined to be an absence of a significant aquatic source in the closure phase. Potential risks to deer were assessed for the closure phase, but not post-closure phase since exposure to radionuclides were predicted to be minimal (i.e., only from drinking water from the Winnipeg River). The Environmental Risk Assessment found the predicted doses would be far below any effect level to these wildlife groups. As a result, because there was predicted to be no potential for adverse effects on individuals or habitat, large mammals (such as deer) and waterfowl were not selected as VCs for assessment of effects on the terrestrial environment.

Table 6.6.3-1: Valued Components for Terrestrial Environment Assessment

Valued Component	Rationale for Selection
Barn Swallow	■ Barn swallow (*Hirundo rustica*) has been recently downgraded to Special Concern by COSEWIC, is currently federally listed as Threatened under SARA (as amended February 2022, with potential for downgrading to Special Concern based on COSEWIC re-assessment) and is listed under the MBCA. It currently has legal individual and habitat protection provisions under SARA and individual and nest protection under the MBCA. ■ Because the WL site is federally owned, critical habitat of the species will be afforded protection under SARA, once the features of critical habitat have been defined in a federal recovery strategy and described in an order made by the competent minister (in this case, the Minister of Environment and Climate Change). A federal recovery strategy for barn swallow has not yet been prepared but with the potential down listing may not be published and Critical Habitat not identified. ■ There is the potential for barn swallow to be indirectly and directly affected by the Project through sensory disturbance, habitat loss and mortality. Barn swallows have been observed nesting within the WL main campus.
Golden-winged warbler	■ Golden-winged warbler (*Vermivora chrysoptera*) is federally listed as Threatened under SARA (as amended February 2022) and listed under the MBCA. It has legal individual and habitat protection provisions under SARA and individual and nest protection under MBCA. ■ As the RSA is federally owned, this species is afforded protection of critical habitat because it is listed as Threatened on Schedule 1 of SARA. Critical habitat has been partially defined for this species in the federal recovery strategy [Government of Canada 2016). ■ There is the potential for golden-winged warbler to be indirectly affected by the Project through sensory disturbance (i.e., noise created by decommissioning activities). ■ Avian species with the potential to occur within the WL site (no confirmed observation records to-date), that represents a guild of edge habitat specialists.
Bats ■ Little brown myotis ■ Northern myotis	■ Little brown myotis (*Myotis lucifugus*) and northern myotis (*M. septentrionalis*) have observation records within the WL main campus. Both bat species are federally listed as Endangered (as amended February 2022) and have legal individual protection provisions under the federal SARA. ■ As the WL site is federally owned, these bat species are afforded protection of critical habitat and residences because they are listed as Endangered on Schedule 1 of SARA. ■ Critical habitat has only been “partially identified”, for one life history requirement and habitat type (overwintering habitat), as the largest threat to these species is associated with that habitat type (Government of Canada 2018). No active hibernacula have been identified in the WL site and the geological conditions make the presence of caves or exposed bedrock highly unlikely (See Section 6.3.1.5 Description of the Environment). ■ Other critical habitat types that are identified, but not yet legally defined and protected as “critical habitat”, include: roosting, foraging and swarming habitat. ■ Maternity roost habitat for little brown myotis and northern myotis is potentially present in the treed areas of the WL site surrounding the WL main campus. There is the potential for both species to be indirectly affected by the Project through sensory disturbance and related habitat avoidance (caused by noise associated with decommissioning activities and potential roost abandonment). ■ Maternity roost habitat for little brown myotis is also potentially present in the WR1 Building, and little brown myotis have the potential to be indirectly and directly affected through disturbance, habitat loss and mortality. ■ Represents small mammal species recorded in the WL main campus that may utilize buildings for part of their life history (i.e., maternity roosting, diurnal roosting and evening roosting, and hibernation).

Table 6.6.3-1: Valued Components for Terrestrial Environment Assessment

Valued Component	Rationale for Selection
Snapping Turtle	■ Snapping turtle (*Chelydra serpentina*) have been observed within the WL site. They are federally listed as Special Concern under SARA (as amended February 2022), but they do not have legal individual protection provisions under the Act, nor do they receive protection of critical habitat. ■ There is the potential for snapping turtle to be indirectly and directly affected by the Project through sensory disturbance (noise) and mortality (i.e., vehicle strike on roads). All snapping turtle observations to-date within the WL site have been on roads. ■ Represents herpetile species that are vulnerable to mortality on roadways.

Note: Each Valued Component was assessed using the assessment endpoints and measurement indicators listed in Table 6.6.3-2. COSEWIC = Committee on the Status of Endangered Wildlife in Canada; SARA = *Species at Risk Act*; MBCA = *Migratory Birds Convention Act, 1994*; WL = Whiteshell Laboratories; RSA = Regional Study Area

Traditional Knowledge and Land Use Studies (Firelight Research and SFN 2018, BRFN, BON, and HWFN 2019, and SVS 2019) and Indigenous engagement with Sagkeeng First Nation, the Manitoba Métis Federation, Brokenhead Ojibway Nation, Black River First Nation, Hollow Water First Nation, and Wabaseemoong Independent Nations identified additional VCs for consideration in the terrestrial effects assessment (Table 6.6.3-2). Table 6.6.3-2 provides the rationale for why the identified Indigenous VCs for the terrestrial environment were not included in the assessment.

Table 6.6.3-2: Rationale for Why Specific Indigenous Valued Components Were Not Assessed for the Terrestrial Environment

Valued Component	Rationale for Why the Indigenous Valued Component Was Not Assessed for the Terrestrial Environment
White-tailed Deer, Moose, and Elk	White-tailed deer (*Odocoileus virginianus*) and other ungulates were not selected as VCs for the terrestrial assessment because: ■ Project activities occur within the WL site on previously disturbed areas; therefore, there are no direct effects to habitat availability and distribution for white-tailed deer, moose, and elk (*Cervus elaphus* and *C. elaphus nelsoni*). ■ Indirect effects of the building demolition works (noise, equipment use) was deemed to be of low risk to wildlife in natural areas adjacent to the fenced campus, and they were considered to be unlikely to occur within the fenced campus. ■ Vehicle collision risk on Ara Mooradian Way is addressed by implementation of existing employee and contractor standard safety training and environmental awareness training, enforcement of existing speed limits on access roads, and monitoring of wildlife collisions with vehicles. Although the road mortality mitigation program is directed at snapping turtles, it will serve to benefit all wildlife species potentially affected by vehicle collisions. The monitoring program will provide feedback for adaptive management (and the potential need for more signage, extension of existing fencing, or other fencing to restrict wildlife access to road surfaces). ■ White-tailed deer and moose populations are not at risk in Manitoba. The nelsoni subspecies of elk is ranked S3S4 meaning it is considered potentially vulnerable or special concern or apparently secure in the province, but it is not listed on the Manitoba ESEA. None of these species are considered endangered, threatened or special concern on the *Species at Risk Act* (SARA). ■ Consideration of health risks to white-tailed deer and moose are included in the effects assessment for Ecological Health (Section 6.7.2).

Table 6.6.3-2: Rationale for Why Specific Indigenous Valued Components Were Not Assessed for the Terrestrial Environment

Valued Component	Rationale for Why the Indigenous Valued Component Was Not Assessed for the Terrestrial Environment
Porcupine	North American porcupine (*Erethizon dorsata*) was not selected as a VC for terrestrial assessment because: ■ Project activities occur within the WL site on previously disturbed areas; therefore, there are no direct effects to habitat availability and distribution for porcupine. ■ Indirect effects of the building demolition works (noise, equipment use) was deemed to be of low risk to wildlife in natural areas adjacent to fenced campus, and they were considered to be unlikely to occur within the fenced campus where direct effects would be possible and be affected by the works. ■ The porcupine species population is not at risk in Manitoba, and not considered endangered, threatened or special concern on the *Species at Risk Act* (SARA).
Furbearers, including Fox, Lynx, Marten, Fisher, Weasel, Chipmunks, Rabbit, Squirrel, Beaver, Muskrat, and Otter.	These furbearers were not selected as VCs for terrestrial assessment because: ■ Project activities occur within the WL site on previously disturbed areas; therefore, there are no direct effects to habitat availability and distribution for furbearers. ■ Indirect effects of the building demolition works (noise, equipment use) was deemed to be of low risk to wildlife in natural areas adjacent to fenced campus, and they were considered to be unlikely to occur within the fenced campus where direct effects would be possible and be affected by the works. ■ Most of these species populations are not at risk in Manitoba (of this list, long-tailed weasel and eastern fox squirrel are considered special concern in the province), and none are considered endangered, threatened or special concern on the *Species at Risk Act* (SARA). ■ The red fox (*Vulpes vulpes*) is considered to be the representative species for terrestrial mammals and is included in the effects assessment for Ecological Health (Section 6.7.2). ■ American mink (*Neogale vison*) is considered to be the representative species for riparian mammals and is included in the effects assessment for Ecological Health (Section 6.7.2).
Grouse	Grouse (Phasianidae) was not selected as a VC for terrestrial assessment because: ■ Project activities occur within the WL site on previously disturbed areas; therefore, there are no direct effects to habitat availability and distribution for grouse. ■ Indirect effects of the building demolition works (noise, equipment use) was deemed to be of low risk to wildlife in natural areas adjacent to fenced campus, and they were considered to be unlikely to occur within the fenced campus where direct effects would be possible. ■ Grouse species populations (sharp-tailed grouse [*Tympanuchus phasianellus*], ruffed grouse [*Bonasa umbellus*], and spruce grouse [*Falcipennis canadensis]*) are not at risk in Manitoba, and not considered endangered, threatened or special concern on the *Species at Risk Act* (SARA).
Geese, Ducks, and Waterfowl	Geese and other aquatic bird species were not selected as VCs for terrestrial assessment because: ■ The direct effects of the building demolition works (noise, equipment use) was deemed to be of low risk to birds potentially occurring in the sewage lagoons, Winnipeg River, or in natural areas adjacent to fenced campus, and they were considered to be unlikely to occur in proximity to the building demolition works where indirect effects would be possible. ■ Horned grebe (*Podiceps auritus*); western population) and mallard (*Anas platyrhynchos*) are considered to be the representative species for riparian birds and are included in the effects assessment for Ecological Health (Section 6.7.2).

VC = valued component

Assessment endpoints represent the key properties of each VC that should be protected. The assessment endpoint for the terrestrial environment is the maintenance of self sustaining and ecologically effective wildlife populations (Table 6.6.3-3). Self sustaining populations are healthy and viable and, by definition, robust and capable of withstanding environmental change and accommodating stochastic processes (Reed et al. 2003). Maintaining viable wildlife populations is a conservation target frequently applied by conservation biologists and resource managers (Fahrig 2001; Nicholson et al. 2006; Ruggiero et al. 1994; With and Crist 1995).

Changes in measurement indicators were used to evaluate potential changes in the status of each VC relative to the assessment endpoints. Each measurement indicator was assessed quantitatively where sufficient information existed to support a numerical assessment and qualitatively where necessary. Habitat availability, habitat distribution and survival and reproduction were selected as the measurement indicators for the terrestrial environment species VCs (Table 6.6.3-3). The measurement indicators are defined as follows:

- **habitat availability**: changes to the amount (e.g., hectares) and quality (e.g., probability of use by animals) of different habitats;
- **habitat distribution**: changes to spatial configuration and connectivity of habitats and changes to the spatial distribution and movement of animals; and,
- **survival and reproduction:** changes to abundance caused by altering survival and/or recruitment.

Table 6.6.3-3: Assessment Endpoints and Measurement Indicators for the Terrestrial Environment Assessment

6.6.4 Assessment Boundaries

6.6.4.1 Spatial Boundaries

The spatial boundaries selected for the terrestrial environment assessment were chosen because they permit description of Base Case conditions in sufficient detail to enable potential project-VC interactions and effects to be identified, understood and assessed, including understanding and assessing the contribution of the Project to cumulative effects.

The spatial boundaries selected for the terrestrial environment assessment are presented on Figure 6.6.3-1 and are described below:

- **Site Study Area**: the SSA is the Project footprint, which accounts for the direct physical disturbance and alteration of potential wildlife habitat caused by demolition and reclamation of the WR-1 Building (0.07 ha).
- **Local Study Area**: was selected in consideration of the SSA and the spatial extent of potential direct effects of the Project on the terrestrial environment. The LSA was selected to represent an area that is likely to be directly affected by the Project, helping to identify Project-specific (rather than cumulative effects of the Project in combination with other projects in the region). The LSA includes the fenced area of the WL main campus, which includes the SSA. This spatial area was chosen as it represents an area under the highest anthropogenic activity levels that is distinct from, and also separated from, the surrounding area by a physical barrier (i.e., a six-foot high chain-link fence). Ground-based VC species (i.e., snapping turtle) have restricted access to, or from, the LSA, although movement of aerial VC species (i.e., birds, bats) is less constrained by the presence of the fence. The spatial extent of project-related physical disturbances to wildlife VCs (through noise) is also highest within this defined area. The approximate size of the LSA is 29 ha.
- **Regional Study Area**: is defined as the area within which the maximum geographical extent of potential indirect effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. The RSA is the 3,710 ha portion of the WL site on the east side of the Winnipeg River (Figure 6.6.3-1). This federally-owned property is not fenced around the perimeter, which means there is no physical barrier restricting access to or from the area by ground-based wildlife from the north, east, or south. The Winnipeg River itself represents a partial barrier to (primarily ground-based) wildlife access from the west. The RSA is relevant to the evaluation of effects on wildlife VCs because it is under distinct management and ownership relative to the surrounding landscape. The entire area is under ownership by CNL, and because there are nuclear facilities within the area, it is managed differently from the surrounding landscape (i.e., with respect to active fire suppression and prevention). The RSA also represents a suitable scale to assess potential cumulative effects on wildlife VCs. Cumulative effects of beyond regional disturbance factors (e.g., forestry and climate change) are considered if they are likely to affect populations of wildlife VCs with ranges that are much larger than, but overlap the RSA.

6.6.4.2 Temporal Boundaries

The temporal boundaries of the assessment are the timeframe during which Project activities are actively occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effect is predicted to last so far into the future that the duration cannot be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of in situ disposal (ISD), which includes preparation for ISD, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031..
- **Post-closure Phase:** The post closure phase has two discrete periods: institutional control and post institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue to demonstrate Whiteshell Reactor Disposal Facility (WRDF) performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.6.4.3 Assessment Cases

The assessment cases considered in the terrestrial environment assessment include the Base Case, Application Case and the Reasonably Foreseeable Development (RFD) Case:

- **Base Case:** represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining and residential and recreational development. Current effects from the existing facilities and operations at the WL site, for example, are considered part of the Base Case. In addition, existing conditions of areas not affected by the WL site are also considered as part of the Base Case. Effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case.
- **Application Case**: represents predictions of the effects that may result from the Project combined with the existing effects of the Base Case.

- **RFD Case**: represents the effects of the Base Case combined with the predicted incremental effects from the Project, as well as effects from other RFDs within the RSA that are currently under application review or that have officially entered a regulatory application process. There are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the Comprehensive Study Report (AECL 2001). The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. The Comprehensive Study Report indicated that no effects were identified for terrestrial biota, as natural vegetation will re-establish following completion of decommissioning and reclamation activities. Airborne emissions from decommissioning activities are likely to be less than in the past and no effect from this exposure pathway is expected (see Section 6.3.5 of AECL 2001). Overall, decommissioning of these structures is anticipated to positively affect the terrestrial environment. Species such as barn swallow may be negatively affected through the loss of anthropogenic habitat on the WL site through the decommissioning of structures; however, implementation of habitat offsetting (e.g., installation of nesting structures for barn swallow in 2018) in advance of additional decommissioning is designed to proactively address this potential.

  Effects of RFDs in the RSA are expected to be primarily positive, because activities will focus on decommissioning existing infrastructure. Once existing infrastructure is removed and the RSA is reclaimed the level of anthropogenic disturbance within RSA will be reduced, benefiting the terrestrial environment of the RSA. Because RFD identified in the RSA is expected to have a generally positively effect on the terrestrial environment, an RFD Case is not presented as part of this assessment (Table 6.6.4-1).

Table 6.6.4-1: Reasonably Foreseeable Developments Considered in the Terrestrial Environment Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes in situ disposal of the low-level waste trenches).	2016 to 2034	Yes – however, potential future effects to species that use anthropogenic habitat have been addressed through implementation of habitat offsetting (e.g., installation of nesting structures for barn swallow) in advance of additional decommissioning in the LSA and, remaining effects may be positive (which are therefore not assessed)
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – however, effects are considered to be positive and therefore, are not assessed

6.6.5 Description of the Environment

6.6.5.1 General Overview

The RSA is located within the larger Boreal Shield Ecozone, Lake of the Woods Ecoregion and Stead Ecodistrict (Smith et al. 2001). In general, this ecoregion has a large number of forest types characterized by tall, closed stands of jack pine (*Pinus banksiana*), trembling aspen (*Populus tremuloides*), paper birch (*Betula papyrifera*), white spruce (*Picea glauca*), eastern white cedar (*Thuja occidentalis*), black ash (*Fraxinus nigra*) and American elm (*Ulmus americana*) (Smith et al. 2001). The English, Winnipeg and Rainy rivers are the dominant waterways, with small to large bedrock-shore lakes in the northern portion of the ecoregion. Wildlife are diverse and abundant and characteristic regional species include: gray wolf (*Canis lupus*), American black bear (*Ursus americanus*), moose, snowshoe hare (*Lepus americanus*), hooded merganser (*Lophodytes cuculata*), turkey vulture (*Cathartes aura*) and ruffed grouse (Smith et al. 2001). This description of the characteristic habitat types and wildlife species of the Lake of the Woods Ecoregion has been provided as context for the RSA, which is described below.

The RSA is located on the east bank of the Winnipeg River (Figure 6.6.5-1), at an elevation of approximately 267 metres above sea level. It lies within a broader zone at the convergence of prairie grassland to the southwest and boreal forest to the northeast and is also on the edge of the Precambrian Shield (AECL 2001). The surrounding area consists of cleared lands with areas of peat bog. Whiteshell Provincial Park, the largest provincial park in Manitoba, is located on the east side of the RSA; Pinawa and Whitemouth Falls Provincial Parks are both immediately south of the RSA.

There is a relatively high degree of diversity in terrestrial habitat within the RSA (Figure 6.6.5-1). The RSA is primarily under treed cover (83% of total area), consisting of a mixture of wetlands and forests of broadleaf, mixed and coniferous stand types. A large area (1,946 ha, or 52% of the total area) contains a complex of bog, fen and swamp wetlands spanning the center and east portions of the RSA, from north to south. Black spruce dominates large portions of this wetland habitat and it is reported that stands may be over 100 years old (AECL 2001). Black spruce-dominated bog wetlands have understories of tamarack (*Larix* sp.), willow sp. (*Salix* sp.), blueberry (*Vaccinium* sp.), common Labrador tea (*Rhododendron groenlandicum*), horsetail sp. (*Equisetum* sp.) and mosses. The herbaceous wetland types contain mannagrass sp. (*Glyceria* sp.), cattail sp. (*Typha* sp.), sedge sp. (*Carex* sp.) and bulrush sp. (*Schoenoplectus sp.*). A ridge of well-drained sandy soil within the wetland area contains jack pine dominated forest stands. To the west of the wetland area, forests dominated by black ash and poplar sp., are present on poorly drained clay plains (AECL 2001). There are also areas of unutilized farm fields and areas where vegetation height is controlled, that contain a mixture of regenerating grasses and shrub species such as bluegrass (*Poa* sp.), sedge sp., strawberry (*Fragaria* sp.), clover sp. (*Trifolium* sp.) and aster sp. (*Aster* sp.). The area near the Field Irradiator Gamma site contains upland mixed forests with jack pine and trembling aspen dominant stands, as well as spruce sp., fir sp. (*Abies* sp.), birch and an understory of common Labrador tea, hazelnut (*Corylus* sp.), wild plum (*Prunus americana*) and blueberry. There is a broadleaf forest dominated by trembling aspen with an understory of willow sp., rose (*Rosa* sp.), alder sp. (*Alnus* sp.), currant (*Ribes* sp.) and dogwood (*Cornus* sp.) on the west half of the RSA, with gullies and ravines adjacent to the Winnipeg River.

There have been few formal wildlife inventories within the RSA. The focus of this terrestrial environment assessment is therefore based on known ranges of wildlife species, habitat suitability incidental observations by WL staff from 2014 to 2021, with incorporation of data from acoustic and visual surveys conducted for bats in 2015 and 2021 and for birds in 2018 and 2019. White-tailed deer are reportedly common, with established wintering areas on site, and beaver (*Castor canadensis*) activity is common within the gullies adjacent to the Winnipeg River (AECL 2001). Permits have been obtained by WL staff for dam removal on numerous occasions. Other commonly observed mammal species within the RSA include black bear, red fox and groundhog (a.k.a., woodchuck; *Marmota monax*). The two bat VC species (little brown myotis and northern myotis) were confirmed to occur within the LSA based on acoustic surveys conducted in 2015 (Murrant 2016) with two additional incidental observation records of unconfirmed bat species made by staff in July 2018 (on a pallet near B412) and in August 2021 (observed on the north brick wall exterior of B100 building that houses the WR-1 reactor). No bats have been confirmed within the WR-1 building based on targeted surveys to-date. Detailed surveys to confirm bat roosting habitat presence have not yet been completed.

Commonly observed amphibian and reptile species include northern leopard frog (*Lithobates pipiens*) and gartersnake (*Thamnophis* sp.), and there have also been observations of snapping turtle and western painted turtle (*Chrysemys picta bellii*). According to the Comprehensive Study Report (AECL 2001), there are important bird migration staging areas on, or near the RSA, centering on the Winnipeg River. The Winnipeg River is an important migratory corridor for many species including common loon (*Gavia immer*), red-necked grebe (*Podiceps grisegena*), horned grebe (*P. auritus*), double-crested cormorant (*Phalacrocorax auritus*), American white pelican (*Pelecanus erythrorhynchos*), Bonaparte's gull (*Chroicocephalus philadelphia*), common tern (*Sterna hirundo*), Caspian tern (*Hydroprogne caspia*), lesser scaup (*Aythya affinis*), greater scaup (*A. marila*) and bald eagle (*Haliaeetus leucocephalus*) (AECL 2001). Bird species recorded within the RSA by WL staff since 2014 have included many federally secure (i.e., not at risk) species. There have been observations of passerines such as cliff swallow (*Petrochelidon pyrrhonota*) and American robin (*Turdus migratorius*), woodpeckers such as pileated woodpecker (*Dryocopus pileatus*) and northern flicker (*Colaptes auratus*), owls including great gray owl (*Strix nebulosa*) and great horned owl (*Bubo virginianus*), as well as sandhill crane (*Grus canadensis*) and bald eagle. Observations of species at risk have included trumpeter swan (provincially listed) (*Cygnus buccinator*), barn swallow, loggerhead shrike (*Lanius ludovicianus*), Peregrine falcon (provincially listed) (*Falco peregrinus*) and red-headed woodpecker (*Melanerpes erythrocephalus*) and are described in Appendix 6.6-1.

Automated recording unit acoustic surveys for birds were conducted in 2018 and 2019 (see map of monitoring stations in Figure 6.6.5-2 and description in Appendix 6.6--1). These acoustic surveys confirmed the presence of Canada warbler (*Cardellina canadensis*) and auditory breeding evidence based on calls recorded at a monitoring location on the east side of the LSA in 2018 (station 3) and at two monitoring locations at the northeast and southeast corners of the LSA in 2019 (stations 5 and 1). The acoustic surveys from 2019 also confirmed the presence of olive-sided flycatcher (*Contopus cooperi*) and auditory breeding evidence based on calls recorded at monitoring locations at the northwest and northeast corners of the LSA (stations 6 and 5). Field surveys to confirm the precise locations of where the calls originated from were not conducted (i.e., the actual breeding habitat in use was not precisely located or confirmed with visual observation).

The Base Case for each wildlife VC represents the outcome of past and present effects of natural disturbances and anthropogenic activities on the environment. Wildfire was likely the primary disturbance factor in the RSA before the 1890s and remains the primary disturbance and stand determining agent in forested areas of the Boreal Shield Ecozone (Smith et al. 2001). Human development in the area around Lac du Bonnet began in 1898 when a large number of mining claims were staked in the area (Lac du Bonnet Pioneer Club 1980). The road from Molson to Lac du Bonnet was finished in the fall of 1899 as far as Milner Ridge, and wood and lumber operations were started soon after (Lac du Bonnet Pioneer Club 1980). The construction of the Pinawa power plant began in 1903 and was completed in 1906 (Manitoba Historical Society 2017). Most roads in the Lac du Bonnet area were built after 1917, when the rural municipality of Lac du Bonnet was formed (Lac du Bonnet Pioneer Club 1980). The WL site was established by AECL in the early 1960s as a nuclear research facility. Since the 1960s, land uses within the RSA have been limited to operations and activities undertaken at the WL site (AECL 2001).

As part of the Comprehensive Study Report (AECL 2001), the WL site was divided into “affected” and “unaffected” land. Affected land was defined as areas where nuclear development, operations or supporting activities are conducted and includes land potentially affected by such activities (AECL 2001). This area includes the LSA derived for the terrestrial environment assessment, plus some surrounding areas with supporting infrastructure. Outside of this area, the majority of the WL site consists of unaffected land. These broad categories are also applicable to the likely extent of noise-related effects on wildlife; with the areas beyond the affected land having low likelihood of being subject to noise levels that would have effects on wildlife.

Anthropogenic disturbance of the RSA and current activity (e.g., the WL main campus area, access roads and waste management areas) is largely concentrated in the northwest quarter of the RSA. Disturbance in the form of roads is primarily within the far western portion of the RSA, with the main access road for employees (Ara Mooradian Way) aligned north-south, with a few secondary roads branching off the main Plant Road to various locations (i.e., landfill, sewage lagoons and waste management area). There is one cleared and maintained hydroelectric corridor for a 115 kV transmission line through the WL site. The transmission line corridor spans the north-south length of the WL site and is in the western portion of the RSA.

The LSA (main campus area) comprises a small proportion of the RSA (less than 1% of the RSA) and is located on the west side of the RSA, on the east bank of the Winnipeg River (Figure 6.6.5-2). As of 2016, it contained 10 major buildings and support facilities (a total of 61 structures) within a chain link fenced perimeter. Since 2016 there has been on-going decommissioning with buildings, storage sheds, and covered access / sampling points in various stages from occupied or in use, to active demolition. Infrastructure and paved areas comprise 25% of the total area and the remaining 74% is primarily landscaped and maintained turf grass lawn (Figure 6.6.5-2). A small proportion of the area contains broadleaf forest (less than 1%).

Overall, the operation of WL and federal ownership of the RSA have likely allowed for conditions of the terrestrial environment to improve over time, as the majority of the lands owned have not been disturbed from WL related development and activity for the last 50+ years. Consequently, much of the RSA, with the exception of the LSA itself, sustains a high value terrestrial environment in the Base Case, including habitat for the VCs identified for this assessment.

6.6.5.2 Methods

The following information sources were used to describe Base Case conditions for terrestrial environment VCs:

- species at risk file data file, assumed to be compiled through a spatial query by the Manitoba Conservation Data Centre (CNL 2016a);
- incidental wildlife species observations recorded by WL staff (CNL 2024b);
- results of bat acoustic monitoring surveys conducted from June to August 2015 (22 acoustic monitoring sites) (Murrant 2016) and visual surveys and acoustic monitoring surveys conducted in the WR-1 building in July 2021 (McKinnon et al. 2022);
- results of avian automated recording unit acoustic surveys conducted during the late breeding period from June 12 to July 3, 2018 and early breeding period from May 9 to June 10, 2019 (6 monitoring station locations used for both years) (Dillon 2019a,b);
- studies published in scientific journals and reports providing information on VC habitat preferences, current stressors and threats to populations and documented effects caused by anthropogenic disturbances;
- previous environmental assessments conducted for the WL site (primarily the Comprehensive Study Report, AECL 2001);
- federal Recovery Strategies or Management Plan documents for VCs available in Environment and Climate Change Canada's (ECCC) Species at Risk database (Government of Canada 2019);
- Manitoba Breeding Bird Atlas 2010-2014 (MBBA 2016);
- eBird web-based bird observation database hosted by the Cornell Lab of Ornithology and National Audubon Society (eBird 2016, 2017);
- Manitoba Herps Atlas (Manitoba Herps Atlas 2016);
- landcover and buildings spatial data (CNL 2016b); and
- wetlands spatial data (MLI 2013).

A description of the Base Case conditions is provided for each terrestrial environment VC in the following sections. Base Case conditions are described according to the measurement indicators selected for each VC (Table 6.6.3-1).

For each wildlife VC, landcover and wetlands spatial data were used to provide descriptions of habitat availability and distribution under existing conditions, representing an estimate of suitable habitat available as a result of past and present development and activities. A review of habitat requirements and species ecology was completed for each wildlife VC to identify habitat that is most likely to be limiting for the species in the RSA and the loss of which would be most likely to result in change to its abundance in the RSA. The limiting habitat was selected as the focus of the assessment.

6.6.5.3 Barn Swallow

6.6.5.3.1 Habitat Availability

The breeding range of barn swallow overlaps the RSA. Breeding habitat for barn swallow typically includes three components: a vertical or horizontal substrate (often enclosed) for the nest site itself, open habitat (e.g., fields, meadows) for foraging and a body of water that provides mud for nest building (Brown and Brown 2019). Barn swallow nests are typically found inside or outside of buildings, under bridges and in road culverts. As of 2016, there were a total of 128 buildings and permanent structures of various sizes within the RSA and 61 buildings and permanent structures within the LSA. Decommissioning and demolition have been on-going since that time. Common foraging habitat includes open riparian areas, road rights-of-way, urban and residential areas and clearings in wooded areas (Brown and Brown 2019; Heagy et al. 2014).

This species is listed as Threatened under SARA, but has also been recently proposed to be downlisted by COSEWIC to Special Concern. Barn swallow does not have legally defined critical habitat described in a recovery strategy but does have a residence description. A pair of nesting barn swallows was observed with eggs in a nest within the LSA, in a temporary storage facility housed in a marine container (approximate location of marine container on Figure 6.6.5-2). Although a nest survey completed in the summer of 2015 found no nesting activity observed on the outside of the WR-1 Building (CNL 2016c), the 2015 survey did confirm 13 barn swallow nests on other WL main campus buildings in the LSA.

For the purposes of this assessment, a conservative approach has been taken and all mapped buildings in the RSA and LSA were considered suitable nesting habitat for barn swallow. As of 2016, there were a total of 128 buildings of various sizes in the RSA and 61 buildings in the LSA. A total of 4 hectare (ha) (0.1%) and 3 ha (11%) of suitable nesting habitat for barn swallow is estimated to be present in the RSA and LSA, respectively, in the Base Case (Table 6.6.5-1). There is also likely additional nesting habitat located in the culverts at any watercourse crossings, particularly at the three watercourse crossings at Ara Mooradian Way, south of the LSA (two of which are visible on Figure 6.6.5-2). Although not quantified, the other two required habitat components are most likely met within the RSA: the sewage lagoons and Winnipeg River represent likely locations of potential mud sources and there is open foraging habitat within the LSA and non-treed portions of the RSA.

Table 6.6.5-1: Nesting Habitat Availability for Barn Swallow in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	4	0.1	3	11.0
Unsuitable	3,706	99.9	26	89.0
Total	**3,710**	**100.0**	**29**	**100.0**

Disturbances can have both positive and negative effects on barn swallow breeding habitat availability. Past and present anthropogenic development has most likely increased the amount of nesting habitat in the LSA for barn swallow by providing suitable substrate for nest building (e.g., buildings and culverts). Vegetation clearing can also improve breeding habitat by creating open areas for foraging (Brown and Brown 2019; Heagy et al. 2014). Utility and road corridors and the open turf grass lawn areas of the campus likely provide suitable foraging habitat for barn swallow in the Base Case. Fire suppression activities have likely had negative effects

on barn swallow foraging habitat availability relative to what was historically available for this species in the RSA, as barn swallow require open areas for foraging.

6.6.5.3.2 Habitat Distribution

The range of barn swallow in Manitoba is largely unknown; this species is considered widespread in southern Manitoba but is considered to be a very local breeder in northern Manitoba (Brown and Brown 2019). At Base Case, suitable barn swallow nesting habitat (i.e., buildings) is patchily distributed throughout the RSA Figure 6.6.5-1) and LSA (Figure 6.6.5-2). Habitat may be a limiting factor for barn swallow in the Base Case because this species relies heavily on buildings for nest sites; however, this species is highly mobile and can establish territories in new areas.

Narrow linear disturbances, such as road corridors in the LSA and RSA, generally do not represent barriers to bird movement (Desrochers and Hannon 1997). Existing disturbances in the RSA do not likely function as dispersal barriers for this species in the Base Case. Habitat fragmentation is not thought to be a limiting factor for barn swallow (Gaines et al. 2003), likely because of their high mobility and use of open areas for foraging.

6.6.5.3.3 Survival and Reproduction

Canada is thought to support approximately 22% of the North American population of barn swallow (10.9 million individuals) and 6% of the global population (COSEWIC 2011). As of 1999, Manitoba supported approximately 1.5 million individuals of the species (COSEWIC 2011). Long-term Breeding Bird Survey (BBS) data show a decline of barn swallow abundance in Manitoba of 2.78% per year from 1970 to 2012 (overall 69% decline; Environment Canada 2014).

Because the barn swallow population in Canada has declined by 69% from 1970 to 2012, it is considered a priority species under the Bird Conservation Strategy for the region, which has the objective of doubling current abundance (Environment Canada 2014). The barn swallow was designated as Threatened by COSEWIC in 2011 and is listed under SARA.

Barn swallow is recorded as a confirmed breeder in the Manitoba Breeding Bird Atlas squares that overlap the RSA (squares 14QA06 and 14QA16). Breeding activity was confirmed within the LSA in June 2016 in a marine container located west of Building 411 (see approximate location of the marine container with documented nesting activity on Figure 6.6.5-2).

The main threats to barn swallow populations in Canada are not well understood. Habitat loss and degradation of breeding grounds, large scale changes in insect prey abundance, climate change, interspecific competition for nest sites from invasive species, nest parasitism and human-caused nest destruction and removal are all threats that may be affecting barn swallow populations (COSEWIC 2011).

Barn swallow primarily feed on flying insects. Insect populations are declining worldwide, and this may be contributing to barn swallow declines (COSEWIC 2011). Many aerial foraging insectivorous birds, such as barn swallow, have experienced large declines since the 1980s (Blancher et al. 2009; NABCIC 2019). The declines suggest a single cause related to insect abundance as both forest and non-forest aerial foraging birds are declining (Blancher et al. 2009; Nebel et al. 2010; Nocera et al. 2012; Paquette et al. 2014). Potential causes of reduced availability of insects include habitat loss, changes to timing of peak food abundance from climate change and pesticide use (Nebel et al. 2010; Nocera et al. 2012; Paquette et al. 2014). Insect and bird populations in the RSA have likely been affected by all of these factors at Base Case.

6.6.5.4 Golden-winged Warbler

6.6.5.4.1 Habitat Availability

The breeding range for golden-winged warbler overlaps the RSA. Golden-winged warbler is a habitat specialist that relies on early successional habitat (10 to 30 years after disturbance) (COSEWIC 2006). Forest type appears to be less important for this species than habitat structure (Confer et al. 2011), with most individuals found in shrubby, deciduous habitats (Beaudry et al. 2010). Golden-winged warblers prefer habitats with low to moderate tree canopy cover and moderate shrub and herb cover (Confer et al. 2011). Critical habitat has been partially identified in the federal recovery strategy for this species to be a combination of habitat suitability and habitat occupancy, where suitable breeding and foraging habitat has been identified as the interface (shared edge) between young forest and open habitat within an appropriately sized and specific type of forest landscape (ECCC 2016a). Forest cover must be at least 50% to 75% within a 5 km by 5 km area with primarily deciduous or mixed tree composition (greater than 50%), and no more than 30% coniferous forest composition (ECCC 2016a). The edges of wetland habitat including bogs and fens with greater than 15% sapling and shrub cover is also considered breeding and foraging habitat for this species (ECCC 2016a). Nests are often located within 200 m on either side of a forest edge (ECCC 2016a). Edges can also be located along cutblocks, transmission line rights-of-way and other anthropogenic disturbances if there is sufficient cover of tall grass (i.e., not mown turf grass lawn), herb and shrub species (ECCC 2016a).

The available land cover and wetlands spatial data were used to map suitable breeding and foraging habitat for golden-winged warbler in the LSA and RSA as follows:

- confirmation of suitable forest cover on the local landscape (minimum 50% to 75% forest cover with some openings of shrub / herbaceous habitat, no more than 30% coniferous forest type) that spans a minimum of 5 km by 5 km area overlapping the RSA;
- if the above criterion is met, broadleaf dense forest stands within 200 m of the forest polygon edge where it abuts open habitat (wetland – all [i.e., bog, fen, marsh, swamp], waterbody, herbaceous);
- if the above criterion is met, mixedwood dense forest stands within 200 m of the forest polygon edge where it abuts open habitat (wetland – all, waterbody, herbaceous); and
- 200 m buffer into the following polygon types where they abut broadleaf dense or mixedwood dense forest stands:
  - Wetland – all; and
  - Herbaceous.

Suitable breeding and foraging habitat for golden--winged warbler consists of early successional habitat at the interface of forest and open habitat (i.e., edge habitat). Availability of breeding and foraging habitat for golden--winged warbler was predicted at Base Case using the available land cover and wetlands spatial data.

The dimensions of the RSA are approximately 5 km by 6.5 km, with a total of 83% tree cover (meeting the minimum size criterion and exceeding the minimum total forest cover criterion of 50%). There is 23% coniferous forest cover, which meets the criterion of less than 30% coniferous forest cover. Within the edge habitats between mixedwood and broadleaf forest and open / shrubby habitat, there is no suitable habitat for golden-winged warbler in the LSA in the Base Case, but 986 ha (27%) of suitable habitat estimated in the RSA (Table 6.6.5-2). The federal recovery strategy identifies focal areas across the species' range that contain core populations that sustain the current breeding distribution and are important for expanding the population into adjacent areas (ECCC 2016a). The RSA falls within focal area GL3 and within a grid square identified to contain critical habitat for this species (ECCC 2016a). The BBS data for Manitoba found no breeding evidence of golden-winged warbler within Manitoba Breeding Bird Atlas squares 14QA06 or 14QA16 that overlap the RSA; however, there is possible breeding evidence for this species in the areas surrounding these two squares. No eBird sightings of golden--winged warbler have been reported in the LSA or RSA; however, there has been a recent sighting of a male individual approximately 11 km to the southeast of the RSA in August 2016, near Pinawa (eBird 2017).

Table 6.6.5-2: Breeding Habitat Availability for Golden-winged Warbler in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	986	26.6	0	0.0
Unsuitable	2,723	73.4	29	100.0
Total	**3,710**	**100.0**	**29**	**100.0**

Note: Some of the numbers are rounded for presentation purposes. Therefore, it may appear that the totals do not equal the sum of the individual values.

Disturbances can have both positive and negative effects on golden--winged warbler habitat availability. Fire suppression activities within the RSA since the 1960s have likely had negative effects on golden--winged warbler habitat relative to what was historically available for this species in the RSA, because golden-winged warblers are reliant on early successional habitat. Maturation of young forests is considered a threat to golden--winged warbler populations in Canada (ECCC 2016a). Stand ages for the RSA were not provided with the land cover dataset; therefore, the age of forests in the RSA is not known precisely. It can be assumed they are at least 60 years old, as there has not been active tree harvesting activity throughout the majority of the WL site since opening in the 1960s.

Vegetation clearing can improve habitat around the disturbance perimeter by creating early succession habitats that are positively associated with species abundance (Askins 1994; Beaudry et al. 2010; Confer et al. 2011). However, vegetation clearing can also result in a net loss of habitat. Disturbances with higher edge-to-interior ratios (e.g., long and narrow disturbance area as opposed to circular) are more likely to have positive effects on golden-winged warbler habitat availability.

6.6.5.4.2 Habitat Distribution

At Base Case, suitable breeding and foraging habitat for golden-winged warbler is distributed throughout the RSA, primarily along the edges of the wetland complex that spans north-south through the centre of the WL site (Figure 6.6.5-1), and is absent within the LSA (Figure 6.6.5-2). There are many areas where broadleaf and mixedwood forest stands are adjacent to open / shrub habitat in the RSA. Avian automated recording unit acoustic surveys conducted during the late breeding period from June 12 to July 3, 2018 and early breeding period from May 9 to June 10, 2019 (6 monitoring station locations used for both years) (Dillon 2019a,b) found no evidence of golden-winged warbler presence within the WL site. Golden-winged warblers are edge habitat specialists, and edge habitat suitable for this species is increased with some types of linear development (i.e., transmission line rights-of-way that maintain some level of natural ground cover in the form of grasses, herbaceous and shrub species). Therefore, past anthropogenic activities within the RSA have likely positively affected the distribution of habitat for golden-winged warbler, due to the increased level of habitat fragmentation from linear disturbances present in the RSA. There is a maximum amount of potential benefit that linear development can have for golden--winged warbler, as extensive habitat fragmentation resulting in small forest patches may negatively affect this species. One study found golden-winged warblers do not use forest patches smaller than 10 ha (Confer and Knapp 1981). Although some forms of linear disturbance can create suitable habitat for golden-winged warbler, gaps in forest cover can also create barriers to the movement of songbirds, if they become too large. Narrow linear disturbances generally do not represent barriers to bird movement (Desrochers and Hannon 1997) and are less likely to be perceived as movement barriers by edge species such as golden-winged warblers, compared to other species of songbirds that are interior forest- specialists. There is potentially a maximum width for linear disturbances beyond which they become a barrier to bird movement; it has been shown that songbirds often avoid crossing gaps in forest cover greater than 45 m wide (Tremblay and St. Clair 2009).

Within the RSA, the availability of breeding and foraging habitat does not appear to be a limiting factor for golden-winged warbler. Linear disturbances in the RSA are generally less than 30 m wide and the RSA is composed mostly of forested habitat in patches larger than 10 ha. The linear disturbances in the RSA do not likely function as dispersal or movement barriers for this species. However, the LSA itself, which contains the WL campus, is a larger gap in forest cover that is approximately 800 m wide at the widest point. It contains a dense cluster of buildings, parking lot areas and mown / maintained turf grass lawn. The landfill is also approximately 500 m wide at the widest point. Both areas likely serve as local barriers to golden-winged warbler movement, as they contain ground cover that is unsuitable for their nesting and foraging needs.

6.6.5.4.3 Survival and Reproduction

Canada is estimated to support 17% of the global population of golden-winged warbler, with most individuals occurring in Ontario (ECCC 2016a). Historical analysis of golden-winged warblers noted a dramatic population decline of 79% between 1993 and 2002; however, more recent analysis of BBS data suggests that golden-winged warbler populations have been stable between 1970 and 2012 (ECCC 2016a).

Golden-winged warbler is considered a priority species under the Bird Conservation Strategy with the objective of doubling current abundance (Environment Canada 2014). Golden-winged warbler was designated as Threatened by COSEWIC in 2006 and was listed under Schedule 1 of SARA as Threatened in 2007. The population objective for golden--winged warbler, as identified in the federal recovery strategy, is to maintain self-sustaining populations in the focal areas in Manitoba, Ontario and Quebec, while maintaining-, at a minimum, the current abundance of approximately 35,000 pairs in Canada (ECCC 2016a).

Population data for this species are not available for the RSA; however, the RSA is located within one of the three focal areas in Manitoba (GL3) identified in the federal recovery strategy (ECCC 2016a). These focal areas are known to contain core populations that sustain the current breeding distribution and are important for expanding the population into adjacent areas (ECCC 2016a). Golden-winged warblers were not recorded in the RSA during acoustic monitoring surveys in 2018 and 2019 (Dillon 2019a,b; monitoring locations shown on Figure 6.6.5-2); however, there is possible breeding evidence for this species in the areas surrounding the two Manitoba Breeding Bird Atlas squares that overlap the RSA. No eBird sightings of golden-winged warbler have been reported in the RSA; however, there has been a recent sighting of a male approximately 11 km to the southeast, in August 2016 near Pinawa (eBird 2017).

The primary threat to golden-winged warbler populations is considered to be hybridization with blue-winged warblers (*V. cyanoptera*; ECCC 2016a); however, the current range of blue-winged warbler does not approach the vicinity of the RSA (Gill et al. 2001). Further, a recent study found that only six genomic regions differ between golden-winged and blue-winged warblers (Toews et al. 2016). This suggests golden-winged and blue-winged warblers are the same species, and therefore hybridization may not be a threat to the sustainability of golden-winged warbler populations.

6.6.5.5 Bats

6.6.5.5.1 Habitat Availability

All bat species in Canada have four primary habitat requirements: overwintering sites (hibernacula), swarming sites, roosts and foraging areas. Maternity roost sites and, especially, hibernacula are considered to be the main limiting habitat features for little brown myotis and northern myotis within their ranges (COSEWIC 2013). Critical habitat for these SARA listed bat species has only been "partially identified" for a portion of their over-all critical habitat requirements (i.e., hibernacula). It is acknowledged that protection of hibernacula alone is insufficient to meet the population and distribution objectives for the three endangered bat species (ECCC 2018). Critical habitat requirements for maternity roosts and summering habitat for roosting and foraging have not yet been formally identified and are the focus of future research effort (ECCC 2018). Maternity roosts are considered residences which are protected from damage or destruction under SARA.

Within the RSA, the potential for hibernacula in exposed bedrock that typically forms caves (i.e., karst topography with limestone, dolomite and gypsum-containing minerals) was coarsely assessed at an overview-level. Based on Figure 6.3.1-1, which describes regional geology in the RSA, the potential for bat hibernacula is low across the RSA, because these mineral types are not present. There have been no surveys to -date that would confirm the presence or absence of hibernacula or potential hibernacula features within the RSA; however, the potential for hibernacula to be present within the RSA is considered to be very low based on geological conditions. Although little brown myotis occasionally hibernate in anthropogenic structures (like houses), it is unlikely that this is occurring within the WR-1 building, as there are likely few gaps between the outer walls and below-grade floors that would permit entry, as there was significant shielding and barrier installation of the below-grade floors to limit the release of radioactivity during the time when the reactor was functional. The report on the results of acoustic monitoring conducted in 2015 also reported there have been no hibernacula identified within any buildings in the RSA to-date (Murrant 2016). As a final confirmation to ensure their absence, pre-demolition visual surveys will be conducted in all below-grade floors of the WR-1 building (Section 6.6.7). Foraging habitat requirements are varied between the two species representing this VC and not likely limiting in the local environment. As a result, the focus of this assessment is on potential maternity roost habitat.

Based on research conducted to date on maternity roosting behaviour in natural habitats, older forests are generally preferred by bats, including the two species represented by this VC, likely because of higher snag availability (COSEWIC 2013). Snags contain cavities and loose bark required for sheltering roosting females and pups (ECCC 2018). Little brown myotis and northern myotis show a preference for large diameter (i.e., older) trees and little brown myotis females show evidence of philopatry in roost selection (the tendency to return to the same home area following hibernation; COSEWIC 2013; ECCC 2018).

There is considerable variation in preferred roost tree species. Lacki et al. (2007) determined that little brown myotis most often roost in large trembling aspen, but also in white spruce and red spruce (*P. rubens*). Olson and Barclay (2013) found the majority of roosts located in trembling aspen or balsam poplar. In Alberta's boreal forest, females are known to locate maternity roosts in tall trees of the genus *Populus* (i.e., balsam poplar, trembling aspen and cottonwood) with early stages of decay, located in old forest stands with moderate canopy cover (Crampton and Barclay 1998). Poplar-leading deciduous and mixed forest stands are common within the RSA. However, preferred roost tree species may vary by region and availability in the forest community.

The available landcover and wetlands spatial data were used to determine a conservative, coarse-scale estimation of the availability of forests or swamp wetland types representing maternity roost habitat preferences for little brown myotis and northern myotis as follows:

- forest stands (all types); and
- treed wetlands (swamps).

A total of 3,091 ha and 0.2 ha of suitable natural maternity roost habitat for little brown myotis and northern myotis is estimated to occur in the RSA and LSA, respectively, in the Base Case, comprising 83% of total land cover in the RSA and 0.6% of total land cover in the LSA (Table 6.6.5-3).

Anthropogenic structures such as buildings, bridges and bat boxes are used for maternity roosts by little brown myotis and less commonly by northern myotis (Whitaker et al. 2006). For the purposes of this assessment, as part of a conservative approach, all mapped buildings in the RSA and LSA were considered potential suitable maternity roost habitat for little brown myotis. As of 2016, there were 128 buildings of various sizes in the RSA and 61 buildings in the LSA. A total of 4 ha and 3 ha of suitable anthropogenic maternity roost habitat for bats (primarily little brown myotis) is estimated to occur in the RSA and LSA, respectively, in the Base Case, comprising 0.1% of total land cover in the RSA and 11% of total land cover in the LSA (Table 6.6.5-3).

Table 6.6.5-3: Maternity Roosting Habitat Availability for Bats in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable – Natural (both species)	3,091	83.3	<1	0.6
Suitable – Buildings (primarily little brown myotis)	4	0.1	3	11.0
Unsuitable	615	16.6	26	88.4
Total	**3,710**	**100.0**	**29**	**100.0**

In 2015, a single season of acoustic monitoring surveys were completed to determine the composition of the bat community at specific areas within the RSA and LSA (monitoring locations shown on Figure 6.6.5-2). The surveys focused on the area of the main campus, (i.e., LSA). The presence of both SARA listed species, little brown myotis and northern myotis, was confirmed within the LSA. A summary memo from the 2015 acoustic monitoring bat surveys reported that the recordings of bats occurred at intervals spaced throughout the night, without an activity burst at sunset (Murrant 2016). The conclusion was made that this indicates bats are likely travelling to the campus area (i.e., built-up area) from farther away and not roosting within the LSA, because an initial burst of bat activity, typically observed when bats emerge *en masse* from their communal roosts at sunset, was not recorded. There is uncertainty in this conclusion, as it is possible that some locations within the LSA that have roosting bats were not within the detection range of the acoustic monitoring devices and the potential emergence of bats from some buildings or structures within the campus area was not captured. Daytime visual searches for roosting bats in the interior of the WR-1 building were conducted by CNL staff in 2021 on 4 dates (July 20, 21, 27 and 28) (McKinnon et al. 2022). A total of 18 person-hours of search effort was conducted on numerous below-ground floors of the building, including removal of suspended ceiling tiles to search above the tiles. An acoustic monitoring device (Wildlife Acoustic SM4BAT) was also installed within a crawl space and set to record from 19:48 to 04:45 between July 21 and 26. No visual confirmation of bat presence within the building (individuals or signs) was made, nor were any bats recorded by the acoustic monitoring device. There has been no physical evidence of roosting activity recorded to-date within the WR1 Building or any buildings within the LSA (i.e., piles of bat feces/guano, or observations of bats in buildings) (Murrant 2016). Within the LSA, any building with suitable access for bat entry could potentially provide suitable maternity roosting habitat, and for the purposes of this assessment, all mapped buildings are considered potential anthropogenic roosting habitat (for little brown myotis) as part of the conservative approach.

The acoustic monitoring conducted to-date supports a conservative assumption that little brown myotis and northern myotis could be roosting within treed areas of the RSA. The nature of acoustic monitoring (which only detects individual bats moving past the detector while in flight) cannot identify the location of individual roosts in buildings or trees. Only visual roost emergence surveys can definitively confirm where bats are roosting, by observing bat emergence from the roost. Although it does not confirm individual roost locations, the use of passive acoustic detectors in habitats that contain candidate roosts can provide evidence of roosting activity within an area, as the peak in bat activity immediately following sunset indicates that bats are roosting in an area and are emerging to forage. Because the forest types present in the RSA are consistent with roosting habitat preferences and because SARA-listed bats have been recorded flying within the LSA, this assessment applies the precautionary assumption that the small, treed area within the LSA and treed areas within the outer RSA could provide suitable natural habitat and likely contains maternity roosts for both bat species.

The RSA contains abundant areas of potential maternity roosting habitat for bats. The majority of the RSA has been undisturbed for the last 50+ years as a result of WL activities focused primarily within the main campus area. Fire suppression within the RSA has likely had a generally positive effect on the availability of maternity roost tree habitat for little brown myotis and northern myotis, because both of these species are more commonly found roosting in large diameter trees that are present in mature forest stands. In addition, suitable foraging habitat in the form of wetlands and riparian areas around the Winnipeg River is also abundant in close proximity to potential roosting habitats.

The clearing, building construction and maintenance of large turf grass covered lawns within the LSA, and the presence of roads and associated infrastructure have likely reduced natural maternity roosting habitat availability within the LSA. However, as described above, these changes do not represent a complete reduction of potential roosting habitat availability for one of the two bat species. Little brown myotis are well adapted to human disturbance and use buildings, bat houses and bridges for maternity roosts. Considering the natural and anthropogenic roosting habitat within the RSA, the availability of maternity roosting habitat is not likely a limiting factor for bats in the Base Case.

6.6.5.5.2 Habitat Distribution

In the Base Case, potential maternity roost habitat for little brown myotis and northern myotis is common and well distributed across the RSA in the form of tree covered habitat (Figure 6.6.5-1). Required foraging habitat features (wetlands, open water features such as the sewage lagoons and east bank of the Winnipeg River) are also well distributed and commonly intersperse the potential maternity roosting habitat of the RSA. Throughout the RSA, linear features in the form of roads, the hydroelectric corridor and other gaps in forest cover create gaps and potential commuting corridors, if they are not too wide. Both species generally avoid large clearcuts in forested areas, as well as open areas (COSEWIC 2013; ECCC 2018). Studies in Alberta found the center of clearcuts greater than 30 m from the forest edge were completely avoided by northern myotis and that little brown myotis traveled 2 to 2.5 times less in the center than through the forest edges or along retained stands of trees within the clearcut block (COSEWIC 2013).

The effects of edges and corridors around mature forest stands on little brown myotis and northern myotis are not well known and there are inter-specific differences among them. A number of studies suggest that some degree of forest fragmentation may be beneficial for little brown myotis (Broders and Forbes 2004; Broders et al. 2006; Ethier and Fahrig 2011; Jantzen and Fenton 2013; Segers and Broders 2014). Other studies have found that little brown myotis prefer closed and cluttered canopy areas and avoid edges (Kalcounis and Brigham 1995; Jung et al. 1999; Morris et al. 2010). The forest structure preferred by northern myotis is not well characterized; however, edge habitat around the outer limits of mature forest stands, riparian and cleared corridors (from roads and hydroelectric lines) represent potential foraging and commuting corridors (COSEWIC 2013). Consequently, not only are maternity roost and foraging habitats common in the RSA in the Base Case, they are also well connected.

Within the LSA, although potential maternity roosting habitat for little brown myotis in the form of buildings is dispersed throughout the area, with the much larger area of undisturbed forest surrounding the main campus, it does not appear to represent an area with a high likelihood of containing significant maternity roost numbers (Figure 6.6.5-2).

6.6.5.5.3 Survival and Reproduction

Little brown myotis and northern myotis occur in every province and territory in Canada (except Nunavut) and approximately 50% and 40%, respectively, of their global range is within Canada. These two bat species were listed as Endangered on Schedule 1 of SARA through an emergency listing order in 2014. The urgency of this listing was due to dramatic population declines caused by white-nose syndrome (WNS), which is a fungal disease caused by *Pseudogymnoascus destructans* that affects bats while hibernating.

Whitenose syndrome causes physical damage (erosion of the skin, as well as damage to sweat glands, muscles, hair follicles and other tissue) and results in whitegrey blotches on the surface of wings and ears and fuzzy white growth on the muzzle (i.e., the source of the name; ECCC 2018). The physical damage causes bats to arouse from their state of torpor and expend energy that is typically reserved until spring emergence. The change in activity levels and physical damage combined are what eventually causes death (ECCC 2018). Canada is currently divided into WNS affected and non WNS affected areas. The provinces of Ontario, Quebec, New Brunswick, Nova Scotia and PEI are considered WNS affected and all other provinces and territories (including Manitoba) are currently non WNS affected areas.

In general, the total population sizes of bats in Canada are not clearly known based on limitations in survey effort. However, prior to the introduction of WNS, little brown myotis was likely the most common bat species in Canada, with northern myotis also common. Populations of both species might have exceeded one million individuals (COSEWIC 2013). Since detection of WNS in 2010, the recorded population of myotis bats (which includes little brown and northern myotis) has been reduced by 94% in Nova Scotia, New Brunswick, Ontario and Quebec.

White-nose syndrome has been estimated to travel at an average rate of 200 to 250 km per year in Canada (COSEWIC 2013). It is anticipated that the entire Canadian population of little brown myotis will be affected by WNS within 11 to 22 years, or possibly sooner based on the recent confirmation of WNS in Washington State (USGS 2016). Based on modelling at the time, little brown myotis was predicted to be functionally extirpated (i.e., less than 1% of existing population) in Canada and the United States by 2026 (COSEWIC 2013); however, this modeling did not consider higher rates of WNS survival in the north portion of the species' range than originally expected. The northern myotis population is expected to have similar declines based on the similarity of their life history characteristics (ECCC 2018). Little brown myotis and northern myotis populations that overlap the RSA are currently within the non WNS-affected area of Canada. Consequently, these populations are not likely as susceptible to any additional pressures as those in WNS-affected areas to the east.

Beyond the devastating effects of WNS, other threats to little brown myotis and northern myotis have been recognized as habitat loss and degradation (at hibernacula, maternity roosts and foraging areas), disturbance or harm (through collision with or barotrauma from wind turbines, intentional harm from extermination, or unintentional harm from recreational or scientific disturbances and industrial disturbance), pollution and climate change (ECCC 2018). Little brown myotis in particular are vulnerable to persecution and extermination efforts because of their tendency to roost in anthropogenic structures such as attics (ECCC 2018). Extermination of large colonies can affect local populations, particularly in WNS-affected areas, but also potentially in non-affected areas, depending on local densities.

Regarding reproduction and life span, both bat species are relatively long-lived and have low reproductive rates, making their populations sensitive to increases in adult mortality and slow to recover when the population size is already small. Individuals of little brown myotis have been recorded to live to over 30 years of age (Fenton and Barclay 1980), although the average life span is thought to be shorter (COSEWIC 2013). The life span of northern myotis is at least 15 years (COSEWIC 2013).

Survivorship of both species is not well understood and there is uncertainty based on deficiencies in study design and analysis used in studies that have reported survival rates (COSEWIC 2013). Survival rates are lowest in the first year of life because juveniles often lack sufficient fat reserves needed for hibernation (COSEWIC 2013). Females of both species start breeding after their first year and continue breeding annually. Females give birth to one pup per year after 44 to 60 days of gestation. For little brown myotis, which are more widely studied, reproductive rates seem to decline with increasing latitude; a reproductive rate of greater than 96% was recorded in the eastern United States, with lower rates of 33% to 74% in the Yukon (COSEWIC 2013). In summary, because the RSA is within a non WNS affected area, survival and reproduction of bat populations overlapping the RSA are not likely impaired at the Base Case, assuming WNS has not yet passed from Ontario into Manitoba.

6.6.5.6 Snapping Turtle

6.6.5.6.1 Habitat Availability

Snapping turtle are considered one of the most aquatic freshwater turtle species in Canada (i.e., they are primarily located in wetted habitats) and their preferred aquatic habitat consists of shallow, slow-flowing, permanent streams, lakes and ponds with soft mud substrate and dense aquatic vegetation (Canadian Herpetological Society 2020; COSEWIC 2008; ECCC 2020). Based on records from established snapping turtle populations in Canada, natural habitat types typically include wetland habitats such as marshes, swamps, peat bogs; lentic habitats including ponds and lake edges and shallow bays, as well as lotic habitat, including river edges and slow-moving streams (ECCC 2020). Overwintering habitat is also aquatic, as snapping turtle also typically hibernate in lentic or lotic habitat, beneath a thick layer of mud (ECCC 2020).

Upland (terrestrial) habitat is also required by snapping turtle, for nesting and overland migration to/from nesting and aquatic habitats. Nesting habitat consists of exposed sand or gravel substrate adjacent to water and can be located on road shoulders (which are present within the RSA and LSA). Movement corridors to and from bodies of water are also required habitat components and this type of terrestrial habitat is particularly important if local aquatic habitat conditions become unfavourable and overland migration to areas with better conditions is undertaken (ECCC 2020). Although terrestrial habitat is important, the focus of this spatial habitat assessment is on aquatic habitat, with particular focus on aquatic habitat near roadways. Road crossings of streams represent one of the largest threats to the species (road mortality during overland migration), and also a primary pathway of effects for this project. The chain link fencing surrounding the LSA greatly limits the potential for adult snapping turtle access and habitat use within the LSA.

The land cover and wetlands spatial data were used to determine a conservative, coarse-scale estimation of the availability of aquatic habitat for snapping turtle as follows:

- waterbodies; and
- marsh wetlands.

The highest quality potentially suitable aquatic habitats for snapping turtle in the RSA are wetlands and watercourses that are located 500 m and 2 km and 2.5 km southeast of the LSA, near Ara Mooradian Way and connected to the Winnipeg River. There is no suitable aquatic habitat within the LSA (Table 6.6.5-4).

Table 6.6.5-4: Aquatic Habitat Availability for Snapping Turtle in the Base Case

Habitat Suitability	Regional Study Area		Local Study Area	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)
Suitable	43	1.1	0	0.0
Unsuitable	3,667	98.9	29	100.0
Total	**3,710**	**100.0**	**29**	**100.0**

6.6.5.6.2 Habitat Distribution

Approximately 10% of the snapping turtle range is contained within Canada. Snapping turtle have been recorded in the Winnipeg River near the Project location (Canadian Herpetological Society 2020) and within the RSA, by the Manitoba Herps Atlas (Manitoba Herps Atlas 2016) and CNL staff (CNL 2022a). The highest likelihood areas of suitable habitat for snapping turtle in the RSA is limited to wetlands and streams that are connected to the Winnipeg River and the sewage lagoons north of the LSA (Figure 6.6.5-1). Potential natural aquatic habitat is located from 500 m to 2.5 km southeast of the LSA, but there is no suitable habitat within the LSA itself (Figure 6.6.5-1). The Winnipeg River shoreline is expected to provide higher quality habitat than wetlands in the RSA. Although there have been no habitat assessments or turtle nesting surveys completed in the RSA, there is potential for snapping turtle to use roads such as Ara Mooradian Way as travel corridors and possibly the gravel shoulders of the roads as nesting areas. Snapping turtle have been incidentally observed and recorded by staff on the WL site on site roads (CNL 2022a).

6.6.5.6.3 Survival and Reproduction

Snapping turtle populations are primarily limited by this species' late age of maturity, long lifespan, high adult survival and slow recruitment (COSEWIC 2008). Females in southern populations reach sexual maturity at 12 years of age, while individuals in more northern populations (e.g., in Manitoba) reach sexual maturity between 15 and 20 years of age (COSEWIC 2008). Lifespan in the wild is largely unknown but is has been suggested that individuals can live over 100 years (COSEWIC 2008). Females lay approximately 40 eggs in late May to June (COSEWIC 2008).

Snapping turtle populations are particularly vulnerable to increases in adult mortality and do not recover quickly from declines. It has been suggested that a 0.1% increase in annual adult mortality rate will cause a population to be halved in under 20 years (COSEWIC 2008). A primary cause of adult mortality is from traffic, especially on roads located through or adjacent to wetlands (COSEWIC 2008). Female turtles are most vulnerable to mortality from vehicle collisions during the reproductive season because females frequently cross roads in search of nesting sites and soft gravel road shoulders are attractive nesting sites (Aresco 2005; COSEWIC 2008). In populations with high mortality of females from road mortality, the sex ratio of the population can become highly skewed towards males. In an area of New York State with high road density, a population of snapping turtles was found to be made up of 95% males (Steen and Gibbs 2004). Other causes of adult mortality include fishing (swallowing hooks or being hooked by anglers), human persecution and legal and illegal hunting.

Eggs and juveniles are susceptible to nest predation (particularly in road rights-of-way and areas with high road densities; Browne 2003), contaminants (Bishop et al. 1998) and short, cool summers in the northern portion of this species range, which affect hatching success as embryo development is temperature dependent (COSEWIC 2008).

6.6.5.7 Traditional Knowledge

This section summarizes observations and concerns shared by Indigenous Nations in their Traditional Land Use and Occupancy Studies. The following are quotes relevant to the terrestrial environment.

From the Sagkeeng First Nation:

> *And the berries, of course, those are very important. And as far as I can remember, the wild berries were so important. And now they're so, so tiny. And so scarce and so tiny. I remember them being so huge and luscious. And I remember how important those were. That was part of our diet. And now, when you go out you can walk for miles and miles and miles and when you do find them, they're so puny and so – and they used to be so huge."* (Firelight Group Inc and Sagkeeng Anicinabe 2018)
>
> *I looked at the trees [in the Project Footprint] and I noticed how skinny they were. I says why are your trees so skinny, you know? ... But the trees, I found them really, really skinny. So maybe it's from the soil, you know?"* (Firelight Group Inc and Sagkeeng Anicinabe 2018)
>
> *You know, there was a lot of deer or whatever back there [Project Footprint]. There was lots back then. You could see them all the time. Here now you got to wait for them. You got to wait and wait. Back then these people just seen them all the time. It wasn't hard for them to go get a moose or a deer or something like that eat. Not like today. Everything is scared off and they're hiding somewhere."* (Firelight Group Inc and Sagkeeng Anicinabe 2018)
>
> *Well, even them [rabbits] are hard to come by now. There's not too many of them. Not like, I guess, you know in the 70s, there used to be lots of them and, now there's hardly any. Hardly see them now...Well, you know, they were supposed to die out every seven years, but, that's more than seven years now that, you know, it's hardly any now. It's, I guess, maybe the weather affecting them...The food that they eat. Hardly any. I know, in the 70s there, yeah, in the 70s, me and, my wife used to go out in the moonlight there and, shoot them. Yeah. But, you know, after that, you know, she couldn't kill any more. So, we stopped. We used to go out and, shoot 20, 25, like, you know in not even an hour, because, they'd be sitting in the moonlight, on the trails. But, now there's none."* (Firelight Group Inc and Sagkeeng Anicinabe 2018)

From Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation:

> *"Wild rice is dying out because of contamination. It used to be a good crop. I used to go to the Whiteshell every fall to pick wild rice."* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019)
>
> *"Wild rice was good years ago, now there isn't much wild rice."* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019)
>
> *"Rabbits are found with pus under their fur, foxes without fur on their tail, and deer are acting crazy because of contamination and disease."* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019)

> *"There are clear signs of sickness in animals throughout our Traditional Territory. Moose have brain worms and rot in their meat, so they cannot be eaten. Disease is spread from deer and also because they are eating polluted roots from the river."* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019)
>
> *"There used to be muskrats, beaver, ducks - all types on wildlife in the river. Now you don't see it because the river is contaminated."* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019)

From the Manitoba Métis Federation:

> *Interviewer 1: "Is there anywhere of that you know of that is good mammal habitat near the site?"*
>
> *Interviewee: "For deer? Oh yeah, all along the river pretty well, there's a lot of, there's some brush, good places for them to hide. And I know, you see them with their young a lot, in those places. Actually, right around the ACL here too, I know, I don't hunt there but I know there's- you aren't really supposed to, there is a lot of deer in that area.""* (SVS 2019)

For further information on how CNL incorporated traditional knowledge into the EIS refer to Section 4.3 Influence of Traditional Knowledge in the Environmental Assessment and to Section 5.0 Traditional Land and Resources Use of the Indigenous Engagement Report (CNL 2024b).

6.6.6 Project Interactions and Mitigation

6.6.6.1 Methods

This section describes the process by which interactions between Project components and activities and the terrestrial environment were identified and evaluated. Potential effect pathways are identified, and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the Project and the terrestrial environment by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in the assessment. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation that could be incorporated into the Project to eliminate and/or reduce adverse effects on the terrestrial environment. Environmental design features included Project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project's engineering and environmental teams, combined with input from Project-specific or regional engagement with other interested parties. The environmental design features and/or mitigation were selected considering their effectiveness for implementation and maintenance and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage pathway –** pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects on the terrestrial environment.
- **Secondary pathway –** the pathway could result in a measurable minor environmental change but would have a negligible residual effect on the terrestrial environment relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway –** the pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects on terrestrial environment.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect on terrestrial environment through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways are carried forward for more detailed quantitative and/or qualitative effects analysis to characterize the residual effects of the Project.

6.6.6.2 Results

Potential interactions between the Project and terrestrial environment VCs are presented in Table 6.6.6-1. Mitigations identified to address and, if possible, remove potential interactions between the Project and terrestrial environment are also integrated into the pathway analysis presented in Table 6.6.6-1.

This page left intentionally blank

Table 6.6.6-1: Pathways Analysis for Terrestrial Environment Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Construction of temporary supporting infrastructure during decommissioning (e.g., batch mixing plant or other similar equipment for preparation of grout)	Potential loss or alteration of wildlife habitat from demolition of the WR-1 Building and construction of temporary supporting infrastructure.	■ The Project is located in an already disturbed area. ■ Temporary supporting infrastructure will be located within the LSA (i.e., previously disturbed and developed area). ■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the RSA will be used during decommissioning activities around disturbed areas, where appropriate. This will reduce the potential for effects on adjacent natural areas that provide suitable wildlife habitat.	No Linkage

Activities associated with in situ disposal (ISD) of WR-1 and demolition of above-ground structures of the WR-1 Building	■ Potential mortality or injury to wildlife (particularly snapping turtle) from movement of decommissioning-related heavy equipment and other vehicles on roads.
	■ Sensory disturbance from increased noise levels created by ISD of the WR-1 and demolition of above-ground structures of the WR-1 Building.
	■ Potential loss of nest/roost substrate for barn swallow and little brown myotis within WR-1 Building.
		■ Wildlife have the right of way.
		■ Employees and contractors are provided with standard safety training and environmental awareness training.
		■ Enforcement of existing CNL property speed limits on access roads (90 km/hr or 60 km/hr for vehicles transporting dangerous goods).
		■ CNL will:
		  ▪ Post turtle crossing warning signage at the existing watercourse crossings on Ara Mooradian Way approximately 300 m south of the LSA fenceline and at 2 km and 2.5 km south of the LSA fenceline, where snapping turtle are likely to cross.
		  ▪ Install reptile and amphibian fencing at these three potential crossing locations, or alternate locations to be determined by CNL biologists based on a combination of turtle observation data and assessment of suitable habitat adjacent to Ara Mooradian Way.
		  ▪ Implement routine annual wildlife road surveys using protocols for road surveys available from other Canadian jurisdictions for similar species (e.g., Survey Protocol for Blanding's Turtle in Ontario [MNRF 2015]), to be conducted when snapping turtles are likely to cross (i.e., terrestrial life history period from May 1 to October 15.
		  ▪ Based on results of routine wildlife road surveys, evaluate implementation of traffic calming measures during the season when snapping turtles are expected to cross the road (i.e., terrestrial life history period from May 1 to October 15). These may include options such as further reduction of posted speed limit, installation of speed bumps, or other measures.
		■ As per CNL's *Management of Land, Habitat and Wildlife* (CNL 2024a), dead or wounded animals on roads must be reported to the Environmental Protection department.
		■ Wildlife collisions with vehicles will be monitored, which provides feedback for adaptive management (and the potential need for more signage, extension of existing fencing, or other fencing to restrict wildlife access to road surfaces).
		■ Decommissioning activity will be primarily limited to daytime hours and noise will be short-term and sporadic. Decommissioning of the WR-1 Building will be completed in a controlled manner and no blasting will be required. The loudest decommissioning activity will be jack hammering to remove deeply embedded contaminants in concrete – this activity will be limited to the interior of the building envelope, which will serve to reduce the level of noise outside the building and in the surrounding RSA where there may be wildlife present.
		■ Pre-disturbance surveys by suitably trained and experienced biologists or environmental specialists will be conducted to confirm presence/absence of little brown myotis roosts and active barn swallow nests inside the WR-1 Building prior to removal of suitable nesting areas (assumed to be limited to above-grade building structures). Surveys to be conducted the year prior to initiation of decommissioning, during the appropriate season, over multiple visits, if necessary.
			Secondary

Table 6.6.6-1: Pathways Analysis for Terrestrial Environment Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Activities associated with in situ disposal (ISD) of WR-1 and demolition of above-ground structures of the WR-1 Building	■ Potential mortality or injury to wildlife (particularly snapping turtle) from movement of decommissioning-related heavy equipment and other vehicles on roads. ■ Sensory disturbance from increased noise levels created by ISD of WR-1 and demolition of above-ground structures of the WR-1 Building ■ Potential loss of nest/roost substrate for barn swallow and little brown myotis within WR-1 Building	■ As a precaution, pre-disturbance searches for hibernating little brown myotis will also be conducted during the winter prior to the initiation of decommissioning to confirm the absence of hibernating individuals inside the below-grade floors of the WR-1 Building, taking As Low As Reasonably Achievable (ALARA) into consideration. ■ If active bat maternity roosts or barn swallow nests are identified in any structure to be affected by decommissioning, initiate erection of species-appropriate barriers once individuals have left the structure and roosts/nests are no longer active.	Secondary
	Release of chemical and radiological contaminants during the closure phase.	■ As part of CNL's licence with the CNSC, environmental monitoring around the WL site is required and will continue for the Project. ■ Follow-up monitoring during the closure phase will be completed to verify effects predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Secondary
	Air and dust emissions (including sulphur dioxide, nitrogen oxides and particulate matter) and subsequent deposition.	■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022b), which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Implementation of dust management techniques to control dust generated by the Project, consistent with the current Environmental Assessment Follow-up and Monitoring Program. ■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. ■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include: ▪ wetting techniques during demolition to limit mobility of dust; ▪ wind restrictions during demolition to stop work or apply wetting techniques; and ▪ hydro seeding during backfilling and landscaping to reduce soil erosion. ■ Road watering and chemical dust suppressant when necessary. Dust suppressant is already used annually at the site for select unpaved roads. ■ Removal of accumulations of particulates (e.g., dirt) on road as soon as possible. ■ On-site vehicles and equipment engines will meet Tier 3 emission standards, where possible, and be maintained in good working order. ■ Limit idling of vehicles on-site and speed on roads. ■ Use of tarps or 3-sided enclosures for raw material storage.	Secondary
Installation of concrete cap and engineered cover over the grouted WR-1 Building and final restoration	Potential introduction and spread of noxious weed species during decommissioning and reclamation.	Locally appropriate grass seed mixtures that are certified weed free will be applied to any cleared and reclaimed areas as soon as practical following decommissioning. ■ Upon completion of the installation of the concrete cap and engineered cover, a grass seed mixture native to the area will be used to establish vegetative cover. Maintenance of the concrete cap and engineered cover includes restricting weed growth and preventing surface erosion and abrasion. The surrounding grounds that were disturbed during demolition and decommissioning activities will be graded and restored with a grass seed mixture compatible with the surrounding area. ■ The former WR-1 Building location will be fenced around the perimeter with six foot-high chain link fence. This will serve to reduce access to ground-based wildlife species. The concrete cap and engineered cover will be maintained during the institutional control period to deter wildlife and avoid the disruption of roots to the Whiteshell Reactor Disposal Facility.	No Linkage
Post-closure Performance	Release of chemical and radiological contaminants in the long-term during the post-closure phase.	■ As part of CNL's licence with the CNSC, environmental monitoring around the WL site is required and will continue for the Project. ■ Follow-up monitoring during the post-closure phase will be completed to verify effects predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Secondary

6.6.6.2.1 No Linkage Pathways

The following pathways were assessed as having no measurable environmental change and hence, no linkage to residual effects on VCs for the terrestrial environment.

- **Potential loss or alteration of wildlife habitat from demolition of the WR-1 Building and construction of temporary supporting infrastructure.**

The footprint of the WR-1 Building is approximately 0.07 ha; and it is located in an area that has been previously disturbed, where wildlife habitat value is considered to be negligible to low. In addition, temporary supporting infrastructure will be located within the LSA on previously disturbed and developed areas. Therefore, the Project is not expected to result in an incremental loss of wildlife habitat from current conditions at the WL site. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the RSA will be used during decommissioning activities around disturbed areas, where appropriate. This will reduce the potential for effects on adjacent natural areas that provide suitable wildlife habitat. Consequently, this interaction was determined to have no residual effect on the maintenance of self sustaining and ecologically effective wildlife populations in the RSA.

- **Potential introduction and spread of noxious weed species during reclamation can affect vegetation community species composition.**

Reclamation of temporarily disturbed areas and the former WR-1 Building site has potential to introduce noxious weed species listed under the *Noxious Weeds Act* of Manitoba. There is also potential to introduce invasive plant species into new areas, which can disrupt adjacent natural vegetation communities and decrease habitat quality (Mack et al. 2000; Carlson and Shepherd 2007; Truscott et al. 2008). Weed species introduced into natural areas have the potential to affect plant community structure and species diversity directly through competition and indirectly through alterations to soil microorganisms, nutrients and soil moisture (Mack et al. 2000; Truscott et al. 2008).

The majority of weed species introductions arise from human transport (Mack et al. 2000; Reichard and White 2001) and roads also act as dispersal route and habitat for weed establishment (Parendes and Jones 2000). Ara Mooradian Way is the primary access route to the site and provides a means of ingress for noxious weed species through direct dispersion of plant propagules (seeds and/or vegetative parts) from vehicles and machinery, and indirectly through the formation of suitable sites for weeds, in the form of disturbed road edges. Many weed species are able to spread more easily in landscapes that have been fragmented, often become established along edge habitats, such as disturbed road edges associated with transportation corridors (Lafortezza et al. 2010).

Preventing weed species from entering an area is often more efficient and cost effective than dealing with their removal once established (Clark 2003; Polster 2003; Carlson and Shephard 2007). Locally appropriate grass seed mixtures that are certified weed free will be applied to any cleared and reclaimed areas as soon as practical following decommissioning. This will reduce the potential for the establishment and spread of invasive plant and weed species. Upon completion of the installation of the concrete cap and engineered cover, a grass seed mixture native to the area will be used to establish vegetative cover. Maintenance of the concrete cap and engineered cover includes restricting weed growth and preventing surface erosion and abrasion. The surrounding grounds that were disturbed during demolition and decommissioning activities will be graded and restored with a grass seed mixture compatible with the surrounding area.

The implementation of mitigation will reduce the potential for introduction of weed species during decommissioning activities. Some localized introduction of weed and invasive species may occur, but mitigation to address these identified in Table 6.6.5-1 would result in no measurable changes to the abundance and distribution of natural wildlife habitat relative to Base Case conditions. Therefore, this interaction was determined to have no residual effect on the maintenance of self-sustaining and ecologically effective wildlife populations in the RSA.

6.6.6.2.2 Secondary Pathways

The following pathways were assessed as potentially having a measurable minor environmental change, but negligible residual effect on the terrestrial environment relative to Base Case.

- **Sensory disturbance from increased noise levels created by ISD of WR-1 and demolition of above-ground structures of the WR-1 Building.**

Short-term sensory effects of noise from ISD of WR-1 and demolition of above-ground structures of the WR-1 Building has the potential to affect golden-winged warbler. Noise levels greater than 50 dB can negatively affect local birds, including golden-winged warbler, and may lead to temporary displacement if birds avoid otherwise suitable habitat in areas of the RSA adjacent to the LSA where decommissioning activities create noise levels greater than 50 dB. It should be noted that this displacement would only occur if noise at that level is propagated to the required distance to suitable habitat. If experienced at sufficient levels, noise can also potentially reduce reproductive success and survival by raising stress levels and interfering with communications (e.g., reducing ability to hear approaching predators or intraspecific vocalizations; Ortega 2012).

Short-term sensory effects of noise from decommissioning activities also have the potential to affect bat survival by altering their ability to effectively carry out echolocation (Mackay and Barclay 1989; Schaub et al. 2008; Siemers and Schaub 2011). Available research has not resulted in definition of measurable thresholds that may negatively affect bat activity (e.g., dB levels). The pathway of this potential effect is limited by the primary work period (during daylight hours, when bats are inactive), and because bats are highly mobile, they are also able to avoid areas with elevated noise. Noise could also result in adverse changes to the availability of potential bat maternity roosting habitat in the RSA area outside of the LSA, if the level of disturbance causes avoidance and abandonment of occupied maternity roosts. Detailed information on how bats respond to anthropogenic noise is limited and varies among species; however, it is known that female bats may abandon their maternity roosts and young if noise is at a sufficient level. Bats have been found to abandon roosts when they are directly disturbed by human activity, especially those causing loud and sudden noises (California Department of Transportation 2016).

The creation of noise likely represents more of a potential effect on habitat availability for both golden-winged warbler and bats and any wildlife species in proximity to the LSA, if the noise causes individuals to avoid previously occupied breeding or maternity roost habitat that is in or around areas with high noise levels. However, this potential effect is reduced by a number of factors. The closest potential natural bat maternity roosting habitat (forested land) is approximately 250 m away from the SSA and there is already anthropogenic activity ongoing within the LSA that bats would have become habituated to since the inception of WL in the 1960s. Similarly, for golden-winged warbler, there is mapped suitable habitat present in the area surrounding the LSA; however, the ongoing anthropogenic activity has likely habituated songbirds to ongoing noise levels and disturbance. In addition, the predicted level and nature of noise associated with decommissioning activities (with the loudest activity occurring inside the building), and the attenuation of noise that occurs with distance and tree cover is expected to result in a negligible increase in noise levels at habitat features that are a direct result of WR-1 demolition works. As a result, noise is expected to have a negligible effect on golden-winged warbler and bat survival and reproduction or habitat availability.

- **Potential mortality or injury to wildlife (particularly snapping turtle) from movement of decommissioning-related heavy equipment and other vehicles on roads.**

The ISD of WR1 will have project-associated vehicular traffic, primarily along Ara Mooradian Way. This could result in increased injury and mortality to wildlife VCs, particularly snapping turtle. The risk of vehicle wildlife collisions is not uniform with regards to species, as species with small size and slow speed (e.g., amphibians and turtles) have a higher mortality risk from crossing roads than larger and/or more mobile species (e.g., birds; Hels and Buchwald 2001; Fahrig and Rytwinksi 2009).

Traffic speed and volume are the primary factors that contribute to road related wildlife mortality. Speed limits (90 km/hr or 60 km/hr for vehicles transporting dangerous goods) are clearly posted on the main access road (Ara Mooradian Way) and enforced to mitigate against potential wildlife mortalities during decommissioning, as well as all other WL site activity. In addition, CNL staff have standard safety training and are provided with environmental and wildlife awareness training. It is expected that this will serve to reduce the risk for vehicular collision with avian and bat VC species, as well as other large mammals that frequent the RSA such as deer.

CNL will also enact the following mitigation measures related to vehicle-wildlife interactions, particularly considering snapping turtle, in advance of the Project:

- Post turtle crossing warning signage at the existing watercourse crossings on Ara Mooradian Way (approximately 300 m south of the LSA fenceline and at 2 km and 2.5 km south of the LSA fenceline), which represent the three highest potential snapping turtle crossing locations (the closest two locations are shown on Figure 6.6.5-2).
- Install reptile and amphibian fencing at these three potential crossing locations, or alternate locations to be determined by CNL biologists based on a combination of turtle observation data and assessment of suitable habitat adjacent to Ara Mooradian Way. Fencing should be checked annually, in early May of each year, to confirm it is still functional for directing reptiles and amphibians through culverts versus the road surface. If required, maintenance or replacement should occur to maintain effectiveness.
- Implement routine annual wildlife road surveys using protocols for road surveys available from other Canadian jurisdictions for similar species (e.g., Survey Protocol for Blanding's Turtle in Ontario [MNRF 2015]), to be conducted when snapping turtles are likely to cross (i.e., terrestrial life history period from May 1 to October 15).
- Based on results of routine wildlife road surveys, evaluate implementation of traffic calming measures during the season when snapping turtles are expected to cross the road (i.e., terrestrial life history period from May 1 to October 15). These may include options such as further reduction of posted speed limit, installation of speed bumps, or other measures.

Suitable design and materials for fencing will reflect Best Management Practices available from other Canadian jurisdictions with similar species (e.g., Best Management Practices for Mitigating the Effects of Roads on Amphibian and Reptile Species at Risk in Ontario; MNRF 2016). The length of fencing required at each culvert crossing location will depend on the area of suitable habitat on both sides of the roadway and require on-site assessment by a biologist to determine what length is required to funnel turtles toward the culvert and keep them off the road. Fencing will require monitoring and maintenance to ensure it remains effective over the duration it is in place.

Considering the mitigation to be implemented in advance of the Project (i.e., speed limits and staff awareness training for wildlife, signage to alert drivers at turtle crossing locations, installation of fencing as access barriers and funnels at high potential crossing locations and enactment of wildlife patrolling) increases in vehicle traffic during decommissioning activities is expected to result in a minor increase in mortality risk to wildlife populations as compared to Base Case conditions. It should be noted that there have been no reported road mortalities of snapping turtles at the WL site to date, but there has been reported road mortality of painted turtles near the sewage lagoons (CNL 2022a). Overall, collisions with vehicles are expected to have negligible residual effect on wildlife populations (and snapping turtle in particular) and are not predicted to affect the maintenance of self-sustaining and ecologically effective wildlife populations that overlap the RSA. A follow-up monitoring program to address the uncertainty regarding the effectiveness of this mitigation for protecting snapping turtle populations is described in Section 6.6.7 Monitoring and Follow-up.

- **Potential loss of nest/roost substrate for barn swallow and little brown myotis within WR-1 Building.**

The MBCA and Migratory Birds Regulation, 2022 prohibit the destruction of migratory bird nests during the breeding season and the SARA protects critical habitat and residences of Endangered or Threatened species listed on Schedule 1, once it has been defined in a recovery strategy for example. Residences (e.g., nests) of SARA-listed species are immediately protected from damage or destruction, once the species is listed on Schedule 1. In the RSA (Zone C4), the migratory bird breeding season for all habitat types (forested, open and wetlands) extends from April 14 to August 27 (ECCC 2016b). The only VC bird species likely to nest in an area to be directly affected by decommissioning of the WR-1 Building is barn swallow. A nest survey was completed in the summer of 2015 and no barn swallow nesting activity was found on the outside of the WR-1 Building (CNL 2016c); however, CNL staff have reported barn swallow do nest in many other buildings within the LSA (CNL 2017). Barn swallows commonly reuse nests from previous years (Brown and Brown 2019). Because there has been no nesting activity on the WR-1 Building observed, it is less likely that new nests will be established on, or in, the WR-1 Building before demolition. However, the potential remains for new nests to be created on the building exterior.

A detailed pre-disturbance survey for nesting barn swallow will be conducted in the summer preceding the initiation of decommissioning activities in the WR1 Building. A suitably trained biologist or environmental specialist will conduct a minimum of two visual surveys during the appropriate nesting season and weather conditions to confirm the presence/absence of barn swallow nesting activity on all external structures of the WR1 Building. If there are no barn swallow nests observed, no further exclusion methods will be required, if the building will be demolished before the start of the breeding season in the following year. If demolition activities are not initiated prior to the start of the breeding season, deterrents will be installed at any potential barn swallow nesting areas (e.g., overhanging rooflines). In keeping with guidance from ECCC, deterrents may only be installed outside of the barn swallow occupation period, which in Manitoba, is between May 1 and August 31 (Government of Canada 2019). This will serve to reduce the likelihood that new barn swallow nests will be created on the building exterior.

If barn swallow nesting activity (or nesting activity of any other species – including Peregrine falcon) is observed on the WR1 Building, the locations of any nests will be recorded and nest activity monitored until the young have fledged. For barn swallow this can occur as late as September, as there can be two broods per season in Manitoba (COSEWIC 2011). If they are found nesting on the WR-1 Building, appropriate mitigation would then be put into place following consultation with and approval by ECCC, in accordance with nest (residence) protection provisions and timing windows.. In order to avoid new nests from being built on the WR1 Building the next year (when demolition is to commence), species-specific and appropriate deterrents may be installed the year before demolition activities commence but again, only outside of the barn swallow occupation period. In locations where

there are active nests, this period is between May 1 or the date when adults are first observed building or occupying a nest (whichever is earlier) and August 31 or the date when an adult is last observed on the nest (whichever is later) (Government of Canada 2019). This could include installation of netting to block the area used as nest substrate and any other similar areas where nests may be built (e.g., overhanging roofs) or to adjust the timing of activities.

Little brown myotis and northern myotis are SARA listed species. There are prohibitions against killing or harming individuals or destroying a residence, including actively used maternity roosting habitat. This risk is highest for little brown myotis, which are commonly known to roost in buildings, and much less so for northern myotis, as they are less frequently documented to roost in anthropogenic structures and typically only resort to them if natural tree roosting habitat is fragmented and less available (ECCC 2018). Little brown myotis show a high degree of philopatry (tendency to return to the same home area each year) and site fidelity (individuals will tend to roost in the same sites and buildings once established; ECCC 2018). They also are highly loyal to roost locations in anthropogenic structures (like buildings), with some sites used continually for 50 years or more (ECCC 2018). This site fidelity behaviour would mean that because there has been no roost activity identified within the WR1 Building to-date (surveys conducted in 2015 and 2021), there is lower likelihood that a new roost would be established in the building, prior to the initiation of decommissioning activity. Pre-disturbance surveys to confirm the absence of roosting bats will be conducted in the following phased approach.

Female bats form maternity roost colonies to give birth and raise their young; most young are born in late June or early- -July and are weaned at 26 days of age (COSEWIC 2013). Roosts are also used during the pre--maternity roosting period and swarming period. Therefore, the bat roosting period is assumed to be from April 1 to September 30 A survey for roosting bats will be conducted in the summer preceding the initiation of decommissioning activities in the WR-1 Building. Visual surveys for evidence of roosting bats and roost emergence surveys will be conducted, using hand-held acoustic bat monitoring detectors (to determine species identification), on all four sides of the building exterior. The objective of these surveys is to visualise and confirm bats exiting from any potential roosting locations within the building. This monitoring will be conducted in the summer – from June to July – during the expected period of highest bat activity in the RSA. Monitoring will be conducted for a minimum of two nights, during suitable conditions (i.e., not on nights with rainfall events or high winds). If there are no bats detected leaving the WR-1 Building, it can be concluded that bats are not likely roosting in the building and no further survey or exclusion effort is required.

If the visual roost emergence survey of the WR1 Building determines there is active bat maternity roosting occurring in the building, any potential access point to the roost location will be blocked from the outside, once the maternity roosting period is completed (i.e., mid-August), if authorized by ECCC under a SARA permit. Exclusion tubes (following Bat Conservation International designs; BCI 2014) will be installed at all observed and potential bat access points on the building envelope. These tubes will allow any remaining bats to exit the building, but will not permit re-entry. At the end of October, permanent exclusion materials can be installed on these above-ground, exterior portions of the building, as per the Bat Conservation International guidelines (BCI 2014), if necessary.

Pre-disturbance searches for hibernating little brown myotis will be conducted during the winter prior to the initiation of decommissioning to confirm the absence of hibernating individuals inside the below-grade floors of the WR-1 Building. Starting in November of the calendar year prior to decommissioning activities, searches will be conducted for hibernating bats. An appropriate survey method will be used, which may include the use of a laser thermometer or thermal imaging camera. The laser thermometer survey method is described as follows: a surveyor will use a laser thermometer to measure the ambient temperature of the walls and ceilings on each sub-surface floor of the WR-1 Building, along perimeter walls. If the temperature on the ceiling and/or walls on a particular floor

is outside the suitable temperature range identified for hibernacula in the recovery strategy; between 2°C to 10°C, no further surveys will be performed. On any floor where there are ambient ceiling and/or wall temperatures between 2°C to 10°C, all available lights will be turned on and a suitably trained biologist or environmental specialist will use a high-powered spotlight to search all surfaces of the walls and ceiling for individual hibernating little brown myotis. Searches for guano (to be distinguished from mouse feces) will also be conducted. If there are no bats detected within the below-grade floors of the WR-1 Building, it can be concluded that bats are not hibernating in the building and no further survey or exclusion effort is required.

The guidance document for the emergency listing order for little brown myotis, northern myotis and tricolored bat (Environment Canada 2018) suggests if active bat roosts are found in a building on a federal site, managers should consider installation of alternate roosting habitat in the form of bat boxes. Offsetting the removal of unoccupied bat maternity roost substrate (buildings) is not required under SARA. Bat boxes can be highly effective at providing habitat for roosting little brown myotis and possibly northern myotis, both of which are currently listed as endangered across Canada due to the effects of WNS.

As a proactive approach and in consideration of all future decommissioning and building demolition activities that will occur on the WL site, barn swallow nesting structures with nest cup design examples (BSC 2017), were installed by CNL in 2018 to compensate for potential future loss of anthropogenic barn swallow nesting habitat. If bats are found to be roosting in the WR-1 building, or any other anthropogenic structures on the WL site, additional installation of bat boxes as compensatory habitat would be initiated. CNL has made a corporate commitment to sustainable development and responsible environmental stewardship at all of their sites, and installation of these compensatory habitat structures will demonstrate visible and measurable commitments to improving habitat availability for these species at risk that occur on the WL site (i.e., RSA). Installation of the habitat structures should occur the year preceding demolition of the building. This is in keeping with guidance that recommends replacement of roost/nest habitat to be lost prior to the removal of habitat, to allow for individuals to recognize and potentially colonize the new structures before old ones are removed (BSC 2017).

Overall, potential loss of nest/roost substrate for barn swallow and little brown myotis within the WR-1 Building are expected to have negligible residual effect on the maintenance of self--sustaining and ecologically effective wildlife populations that overlap the RSA. The follow-up monitoring program regarding the effectiveness of the bat boxes and barn swallow nesting structure, if required, is further described in Section 6.6.7 Monitoring and Follow--up.

- **Non-radiological air emissions and dust emissions (including sulphur dioxide, nitrogen oxides [NOx/NO_2] and particulate matter) and subsequent deposition.**

The Project will generate air and dust emissions such as carbon monoxide (CO), oxides of sulphur (SO_x includes sulphur dioxide [SO_2]), oxides of nitrogen (NO_x includes nitrogen dioxide NO_2), particulate matter ($PM_{2.5}$, PM_{10}) and suspended particulate matter (SPM). Air emissions, such as SO_x and NO_x, can result from the use of fossil fuels in generators, vehicles and machinery. The LSA is characterized as an anthropogenically altered landscape, with limited habitat quality in the form of native tree and shrub species. As described above, infrastructure and paved areas comprise 25% of the total area and the remaining 74% is primarily landscaped and maintained turf grass (Figure 6.6.5-2). A small proportion of the area contains broadleaf forest (less than 1%).

Examples of mitigation implemented to limit predicted residual effects from Project emissions to air quality and subsequently the terrestrial environment include:

- implementation of CNL's Environmental Protection Program (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022b), which includes operational control monitoring, air verification monitoring and environmental monitoring;
- use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include:
  - wetting techniques during demolition to limit mobility of dust;
  - wind restrictions during demolition to stop work or apply wetting techniques; and
  - hydro seeding during backfilling and landscaping to reduce soil erosion.
- apply road watering and chemical dust suppressant when necessary (dust suppressant is already used annually at the site for select unpaved roads);
- removal of accumulations of particulates (e.g., dirt) on road as soon as possible; and
- use of tarps or 3-sided enclosures for raw material storage.

The predicted residual effects on air quality were estimated to increase because of the Project. Fugitive dust from roads is the largest contributor to suspended particulate matter emissions. Material handling from demolition is the largest contributor to PM_{10} emissions. Non-road equipment exhaust emissions are the largest contributors to $PM_{2.5}$ and NOx (as NO_2) emissions. Finally, the largest contributor to SO_2 and CO emissions is fuel combustion for emergency power generators. Predicted concentrations for the Application Case are below applicable air quality guidelines and/or standards (Section 6.2.1.77.2 Application Case Results).

Mitigation of fugitive dust emissions is provided in Table 6.2.1-10 (Pathways Analysis for the Air Quality Valued Component) and includes the use of contamination immobilization agents, containment, ventilation and High-efficiency Particulate Air (HEPA) filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. In addition, use of dust suppression methods during building demolition or soil remediation activities will be implemented to control airborne emissions and nuisance dust during building demolition or soil remediation. Consequently, air emissions are predicted to be below applicable air quality guidelines and/or standards as discussed in Section 6.2.1.77.2 Application Case Results, and will not impact the surrounding terrestrial or aquatic environment.

CNL recently demolished a number of other buildings at the WL site. The mitigation listed above was applied and successfully reduced SPM emissions which ultimately reduce subsequent deposition. It is expected that this same mitigation will also be effective during the demolition of the WR-1 building. Therefore, with the implementation of CNL's *Management and Monitoring of Emissions* (CNL 2022b), and through the implementation of the dust management techniques for the Project, air and dust emissions and subsequent deposition are expected to result in minor changes to soil quality relative to Base Case conditions. As such, this pathway is determined to result in a negligible residual effect on the maintenance of self-sustaining and ecologically effective wildlife populations in the RSA.

- **Release of chemical and radiological contaminants during the closure phase.**
- **Release of chemical and radiological contaminants in the long-term during the post-closure phase.**

An Environmental Risk Assessment was completed to evaluate the potential for adverse effects on terrestrial biota health associated with exposure to chemical and radiological contaminants from the Project (Section 6.7.2.7 Residual Effects Analysis) during the closure and post--closure phases.

For the closure phase, sources of the relevant chemical and radiological contaminants include release via atmospheric releases from the WR-1 Building during grouting and demolition (Section 6.7.2.7.1 Application Case - Closure Phase). Exposure pathways include the routes of contaminant dispersion from the source to the receptor location and the routes of contaminant transport through the food chain or other media to the receptor organism.

During the closure phase, there are predicted to be no exceedances of the 2.4 milligray per day (mGy/day) radiation benchmark for terrestrial biota on or near the WL site (Section 6.7.2.7.1). All predicted doses are well below this level. For the closure phase, all predicted air concentration for non-radiological COPCs were below their relevant ambient air quality criteria (see Section 6.2.1.7.2 Application Case Results); therefore, no non-radiological COPCs were identified for the closure phase and no health effects are anticipated as a result of airborne effluent from the Project Therefore, it is unlikely that there would be significant adverse effects on terrestrial wildlife populations or communities as a result of chemical and radionuclide releases from closure activities (Section 6.7.2.7.1).

Following the completion of closure activities, the Project site and engineered cover will be graded to promote drainage from the site to the Winnipeg River. Run-off control for the concrete cap and engineered cover is designed to limit erosion and infiltration of water into the grouted structure. This is achieved by sloping the concrete cap and engineered cover surface to maintain a slope toward the edges and the collection of water by the existing surface water management systems at the WL site.

A grass seed mixture native to the area will be used to establish vegetative cover, restricting weed establishment and preventing erosion and abrasion. A six-foot-high chain link perimeter fence will be installed and maintained for perpetuity. The concrete cap and engineered cover will be actively maintained during the institutional control period to deter wildlife and avoid the disruption of roots to the WRDF. Consequently, the post-reclamation state of the SSA will be highly modified and unlikely to support a diverse community of terrestrial wildlife VCs. The expansive remaining portions of RSA will provide much higher wildlife habitat value. Aerial species (i.e., birds and bats) that could potentially access the SSA will have much larger areas of natural habitat in which to forage and the addition of the relatively small turf grass covered mound on the landscape is unlikely to cause an increase in level of attraction.

For the post-closure phase, the relevant chemical and radiological contaminants may be released via leakage through the grouting to groundwater and subsequent migration of groundwater to surface water at the Winnipeg River. The assessment of ecological health (Section 6.7.2.7.2 Application Case – Post-closure Phase) used groundwater release rates and dispersion modelling to estimate radionuclide concentrations in surface water, to calculate dose rates to terrestrial biota.

During post-closure, the incremental change in radionuclide levels in the Winnipeg River resulting from the transport of radionuclides from the WRDF to the Winnipeg River via groundwater is predicted to be not practically distinguishable from background levels (see Section 6.4.2.7.2 Application Case Results). Similar to the closure phase, there are predicted to be no exceedances of the 2.4 mGy/day radiation benchmark for terrestrial biota on or near the WL site (Section 6.7.2.7.2) during the post-closure phase. All predicted doses are well below this level.

There are also no exceedances of the HQs identified for exposure of the terrestrial receptors to cadmium, lead, HB-40 and xylene. Therefore, no significant adverse effects on terrestrial populations or communities as a result of these chemical releases are predicted.

6.6.6.2.3 Primary Pathways

No primary pathways were identified between the Project and the terrestrial environment. As such, a residual effects analysis and determination of significance has not been completed for the terrestrial environment assessment.

6.6.7 Monitoring and Follow-up

The conceptual outline for monitoring and follow-up programs recommended to confirm the predictions made in the terrestrial environment assessment during the closure phase are presented in Table 6.6.7-1. Although no residual effects to terrestrial VCs are predicted, these conceptual monitoring and follow-up programs are provided as proactive mitigation by CNL and includes consideration of all future decommissioning and building demolition activities that will occur on the WL site.

CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as identified for other environmental components to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical.

As part of CNL's licence (NRTEDL-W5-8.00/2024), environmental monitoring of the WL site is required. It is anticipated that for closure, the monitoring at the WL site and surrounding area will continue to proceed in accordance with CNL's existing Environmental Monitoring Program. This includes sampling and analysis of ambient air, surface water and groundwater, including the Winnipeg River, sediment, vegetation, garden produce, game animals and fish. This current follow-up monitoring program includes collection of vegetation within the vicinity of the WL site and garden crop samples upstream and downstream of the WL site.

Connected to the assessment of effects to the terrestrial environment, monitoring is also identified in the assessment of ecological health described in Section 6.7.2.10 Monitoring and Follow-up. Follow-up monitoring during the post-closure phase to confirm surface water quality as the primary pathway will serve to verify the accuracy of predicted environmental effects on the potential ecological receptors in the terrestrial environment undertaken in this assessment. It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs.

CNL will continue to proactively seek, engage, and support meaningful discussion on issues and opportunities related to the Project, including the monitoring and follow-up program, with Indigenous peoples and communities of interest. CNL has also had discussions with Indigenous Groups on how future monitoring on the WL site could incorporate Indigenous interests, such as locations where the community fishes or harvests in proximity to the WL site, as well as discussion on participation and/or oversight by Indigenous peoples. CNL is also providing the opportunity and funding for an MMF environmental monitor to observe CNL's environmental monitoring program in action, including collection of water, soil and plant samples for analysis. CNL will continually evaluate both the process and the outcome of the ongoing engagement and communication activities, to address and manage issues as they arise.

This page intentionally left blank

Table 6.6.7-1: Monitoring and Follow-up Programs for the Terrestrial Environment

Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Barn swallow	**Potential Source(s) of Effects:** ■ Closure and Post-Closure: If barn swallow are confirmed to be using the WR-1 Building as habitat through pre-disturbance surveys, there will be incremental contribution of the Project and all future decommissioning activities to the loss of potential nesting habitat in the RSA. There is predicted to be negligible effects on barn swallow, if determined to be nesting in the WR-1 Building, through the implementation of habitat compensation. **Proposed Monitoring:** ■ Barn swallow nest structures were installed in 2018 at the WL site proactively in consideration of potential loss of barn swallow nesting habitat from future decommissioning activities. ■ Effectiveness monitoring of compensatory barn swallow nest structures will be conducted to determine if the compensatory nest habitat is being used. This compensation model and follow-up monitoring would be consistent with what has been designed by the Ontario Ministry of Natural Resources and Forestry. Barn swallows are designated as "Threatened" on the Ontario *Endangered Species Act*'s Species at Risk in Ontario list. An equivalent protocol has not been developed for Manitoba (barn swallow are not currently designated on the provincial ESEA). Barn swallow is designated as "Threatened" under the federal *Species at Risk Act and is proposed to be down-listed as a Special Concern species by COSEWIC*. **Trigger for Further Action:** ■ If effectiveness monitoring shows that the barn swallow nest structure is not being used, it would be relocated to other suitable habitat on the site.	■ Offset the incremental contribution of the Project and all future decommissioning activity to the loss of potential nesting habitat in the RSA using compensatory nesting habitat. ■ Determine number of individuals using compensatory nesting habitat on an annual basis.	Annually (in June, July or August) for three years following installation.	■ Integrated into CNL's Environmental Protection Program. ■ A Biodiversity Plan will be developed and included in the Environmental Assessment Follow-up and Monitoring Program for the WL site.
Bats	**Potential Source(s) of Effects:** ■ Closure and Post-Closure: If bats are confirmed to be using the WR-1 Building as habitat through pre-disturbance surveys, incremental contribution of the Project and all future decommissioning activity to the loss of potential anthropogenic maternity roosting habitat in the RSA. There is predicted to be negligible effects on bats, if determined to be roosting in the WR-1 Building, through the implementation of habitat compensation. **Proposed Monitoring:** In consultation with CNL biologists on other CNL sites to be decommissioned in the future, and in consideration of future losses of anthropogenic structures that may provide roosting habitat at the WL site, offsetting in the form of bat boxes may be required if bats are confirmed to be using the WR-1 Building as maternity roost habitat. ■ Criteria for appropriate siting, if required, may include: accessibility of box locations for installation and future monitoring of utilization/effectiveness, avoidance of areas with radiological contamination in surface water features and appropriate distance to anthropogenic disturbances to avoid sensory effects (i.e., noise). Immature forested areas adjacent to larger waterbodies (i.e., Winnipeg River) and wetlands are high priority locations, because these forest types do not currently provide high quality tree roosting habitat and would be most benefited by installation of bat roost boxes to expand the spatial coverage of potential roosting habitat within the RSA. Final site selection would be at the discretion of CNL biologists. ■ Effectiveness monitoring may be conducted to determine if boxes are being used for three years post-installation. **Trigger for Further Action:** ■ If effectiveness monitoring shows that the bat boxes are not being used by the target species, they would be relocated to other suitable habitat on the site.	■ Offset the incremental contribution of the Project and all future decommissioning activity to the loss of potential anthropogenic maternity roosting habitat across the RSA. ■ Install bat boxes and determine number of individuals and species using bat boxes on an annual basis.	Bat boxes should remain in place throughout the Closure Phase at minimum. Monitoring should take place annually for three years post-installation.	■ Integrated into CNL's Environmental Protection Program. ■ A Biodiversity Plan will be developed and included in the Environmental Assessment Follow-up and Monitoring Program for the WL site.

Table 6.6.7-1: Monitoring and Follow-up Programs for the Terrestrial Environment

Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Snapping turtle	**Potential Source(s) of Effects:** ■ Closure: Minor increase in mortality risk on snapping turtle as a result of vehicle collisions, and negligible residual effect, if mitigation is implemented. ■ CNL will implement a follow-up monitoring program to address the uncertainty regarding the effectiveness of proposed mitigation for protecting snapping turtle populations. **Proposed Monitoring:** Implementation of routine annual wildlife road surveys using protocols for road surveys available from other Canadian jurisdictions for similar species (e.g., Survey Protocol for Blanding's Turtle in Ontario [MNRF 2015]), to be conducted when snapping turtles are likely to cross (i.e., terrestrial life history period from May 1 to October 15). ■ Any road mortality or injury of snapping turtle (or other reptile species) will be reported and data will be compiled in a database that can be used to inform adaptive management for the site. **Trigger for Further Action:** If, after mitigation and operational measures are shown to be ineffective and any mortality or injury of snapping turtle occurs, further mitigation will be considered in an adaptive management framework. This mitigation may take the form of: surveys of high -risk road crossing locations to determine if they are being used by turtles for crossing, potential upgrade of existing crossing culverts to enhance snapping turtle passage, consideration of the potential need to re-design or lengthen the existing amphibian and reptile fencing at the three most likely turtle crossings on Ara Mooradian Way, or consideration of the need to add fencing on any other roads where injuries or mortality of snapping turtle is recorded. Based on results of routine wildlife road surveys, evaluate implementation of traffic calming measures during the season when snapping turtles are expected to cross the road (i.e., terrestrial life history period from May 1 to October 15). These may include options such as further reduction of posted speed limit, installation of speed bumps, or other measures.	Track turtle observations during routine wildlife road surveys and use information for adaptive management.	Ongoing reporting and monitoring should take place annually over the active decommissioning period (until the start of institutional control).	■ Integrated into CNL's Environmental Protection Program. ■ A Biodiversity Plan will be developed and included in the Environmental Assessment Follow-up and Monitoring Program for the WL site. ■ Continuation of WL staff reporting of incidental wildlife observations.

6.6.8 Conclusions

Valued components refer to environmental features that may be affected by a project. The VCs have been identified to be of concern by the proponent, scientists, government agencies, Indigenous people, or the public (The Agency 2018). Indigenous Traditional Knowledge and Land Use Studies (Firelight Research and SFN 2018, BRFN, BON, and HWFN 2019, and SVS 2019) and Indigenous engagement with Sagkeeng First Nation, the Manitoba Métis Federation, Brokenhead Ojibway Nation, Black River First Nation, Hollow Water First Nation, and Wabaseemoong Independent Nations identified additional VCs for consideration in the terrestrial effects assessment. CNL explained that SARA listed wildlife species with the potential to occur within the WL site (or with confirmed occurrence records) and had a reasonable pathway of terrestrial environment effects were considered as potential VCs at the species level. Species that were well represented by the broader groups of species were not explicitly included, as the selected VCs provides inferences about effects on other groups of species with similar life history traits and habitat requirements. Species with a very low likelihood of occurrence in the LSA, for which habitat was not present in the RSA, or for which effects of the Project were unlikely, were excluded as VCs. Other species identified by the Indigenous Nations (e.g., deer, moose, and furbearers) were included in the assessment of ecological health effects in Section 6.7.2.

The VCs assessed for the terrestrial environment included barn swallow, golden-winged warbler, bats and snapping turtle. The assessment endpoint for the terrestrial environment is the maintenance of self-sustaining and ecologically effective populations. Habitat availability, habitat distribution and survival and reproduction were selected as the measurement indicators for the terrestrial environment VCs.

During closure, the Project will generate air and dust emissions from demolition activities. With implementation of CNL's *Management and Monitoring of Emissions (reference)*, there is predicted to be negligible effects on the terrestrial environment from the Project as a result of air and dust emissions. Sensory disturbance, road mortality, and loss of nest/roost substrate also have the potential to affect terrestrial valued components during closure. Surveys to confirm whether nesting and/or roosting activity is occurring in the WR-1 Building will be conducted during the appropriate season the year prior to the initiation of decommissioning activities. If evidence of nesting or roosting activity is found, appropriate mitigation in the form of deterrents will be implemented under consultation with ECCC and in accordance with habitat protection provisions and the required permitting process under Species at Risk Act and potentially the Migratory Bird Conservation Act. The objective of the selected mitigation will be to prevent birds and bats from accessing the building during the period when it will be demolished. The potential for road mortality of snapping turtle will be addressed through adaptive management and ongoing monitoring and documentation of road mortalities. If road mortality of snapping turtle occurs, additional mitigation will be enacted, as required. Following implementation of mitigation and monitoring in an adaptive management framework, there is predicted to be negligible effects on the terrestrial environment during the closure phase as a result of the Project. As such, closure activities are predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective wildlife populations, including species at risk.

Surveys during the appropriate season, to be undertaken the year prior to initiation of decommissioning activities, will confirm whether nesting and/or roosting activity is occurring in the WR-1 Building. If evidence of nesting or roosting activity is found, appropriate mitigation in the form of deterrents will be implemented, under consultation with ECCC and in accordance with habitat protection provisions and the required permitting process under SARA and potentially MBCA. The potential for road mortality of snapping turtle will be addressed through adaptive management and ongoing monitoring and documentation of road mortalities. If road mortality of snapping turtle occurs, additional mitigation will be enacted, as required.

The objective of the selected mitigation will be to prevent birds and bats from accessing the building during the period when it will be demolished. Compensatory habitat features (i.e., bat boxes) may be installed or adjusted depending on the outcome of the above surveys and to demonstrate CNL's commitment to environmental stewardship. Barn swallow nesting structures have already been installed in consideration of potential future losses of anthropogenic nesting habitat associated with site-wide decommissioning. The potential for road mortality of snapping turtles will be addressed through adaptive management and ongoing monitoring and documentation of road mortalities. If road mortality of snapping turtle occurs, additional mitigation will be enacted, as required. Following implementation of mitigation and monitoring in an adaptive management framework, there is predicted to be negligible effects on the terrestrial environment as a result of the Project.

During the post-closure phase, there are predicted to be no exceedances of the 2.4 mGy/d radiation benchmark for terrestrial biota on or near the WL site. All predicted doses are well below these levels. Therefore, based on the assessment completed in Section 6.7.2.7.2, it is unlikely there would be significant adverse effects on terrestrial populations or communities as a result of radionuclide releases from closure activities or in the long-term during the post-closure phase. There are also no exceedances of the HQs identified for exposure of the terrestrial receptors to cadmium, lead, HB-40 and xylene. Therefore, no significant adverse effects on terrestrial populations or communities as a result of these chemical releases are predicted. Because the Environmental Risk Assessment found the predicted doses would be far below any effect level, no significant effects are predicted for the VCs identified by Indigenous peoples.

Overall, the assessment of potential pathways of effects determined there are no primary pathways that would lead to residual effects on terrestrial VCs. Although no residual effects on terrestrial VCs are predicted, monitoring programs are described as possible proactive mitigation by CNL and includes consideration of all future decommissioning and building demolition activities that will occur on the WL site. In addition, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for WR-1 as outlined for other environmental components to verify the accuracy of indirect environmental effects and determine the effectiveness of mitigation that has been, or is to be, implemented.

CNL will continue to proactively seek, engage, and support meaningful discussion on issues and opportunities related to the Project, including the monitoring and follow-up program, with Indigenous peoples and communities of interest. CNL has also had discussions with Indigenous peoples on how future monitoring on the WL site could incorporate Indigenous interests, such as locations where the community fishes or harvests in proximity to the WL site, as well as discussion on participation and/or oversight by Indigenous peoples. CNL will provide Indigenous Nations and the public with the opportunity to participate in the implementation and review of mitigation measures.

6.7 Human and Ecological Health

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project) summarizes the results of the Environmental Risk Assessment (ERA) completed for the Project (EcoMetrix 2024). The purpose of the ERA is to evaluate effects to physical human health (Section 6.7.1 Human Health) and ecological health (Section 6.7.2 Ecological Health) from changes in ambient levels of radioactivity and non-radiological substances. The assessment considers potential effects on human and ecological health during the closure phase and the post-closure phase, which includes a Normal Evolution Scenario. The Normal Evolution Scenario represents a reasonable extrapolation of present-day site features and receptor lifestyles, and it includes the expected evolution of Whiteshell Reactor 1 (WR-1) after closure and degradation of engineered controls. Disruptive Events are identified in the Decommissioning Safety Assessment Report (DSAR) (Golder 2021) for the Project and represent the occurrence of very unlikely events that could lead to higher risk conditions. Disruptive Events are summarized in this section as they apply to physical human and ecological health. CNL acknowledges that human health is more than just physical health. Assessments of other aspects contributing to overall human well-being, while similar to physical health, are not assessed here, but are assessed in Sections 6.8 Land and Resource Use and 6.9 Socio-economic Environment.

6.7.1 Human Health

6.7.1.1 Scope of the Assessment

The scope of the assessment focuses on summarizing the potential health effects to humans from Project activities. The general approach to in situ disposal (ISD) involves permanently encasing with grout the below-grade WR-1 systems. ISD is a permanent, passive decommissioning end state. The decommissioning activities proposed as part of the Project include:

- preparation for ISD;
- grouting of below-grade structures and systems;
- removal of above-grade WR-1 Building;
- installation of a concrete cap and engineered cover over the WRDF;
- final site restoration;
- preparation of institutional control; and
- institutional control.

The above-grade structures will be demolished and removed. Some above-grade structures (e.g., part of the Primary Heat Transport [PHT] system that is above-ground) will be dismantled and placed within the WR-1 Building prior to ISD. A concrete cap and engineered cover will then be constructed over the below-grade structure (refer to Section 3.5 for more detail) and the Project site will be regraded and reclaimed. The end state of the Project (i.e., after the WR-1 Building is demolished, grouted and covered with a concrete cap and engineered cover) is referred to as the Whiteshell Reactor Disposal Facility (WRDF). Environmental monitoring will be completed to confirm that the WRDF is functioning as intended in the long-term (see Section 11 Monitoring and Follow-up for details).

The human health environment assessment follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment is completed in the following steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Section 6.7.1.3 Valued Components and Section 6.7.1.4 Assessment Boundaries) for the human health assessment. The VCs, assessment endpoints and measurement indicators used to assess Project related changes to human health, the spatial and temporal boundaries at which the assessment occurred, and the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.7.1.5 Description of the Existing Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.7.1.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect human health are identified and mitigation options to limit or avoid effects are presented. A pathways analysis is then used to assess key interactions between the Project and human health. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded to further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects to human health after incorporating mitigation are carried forward to Step 4; residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 6.7.1.7 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to human health from primary effect pathways. The analysis results are presented, including the characterization of: (i) residual incremental effects of the Project and the effects of the Project in combination with past and present developments on human health (Application Case); and (ii) residual effects of the Project in combination with past and present developments, as well as other reasonably foreseeable developments (Reasonably Foreseeable Development Case). A key outcome of this section is the predicted effects to human health that are passed on to other VCs for inclusion in their assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 6.7.1.8 Prediction Confidence and Uncertainty). Evaluate the available literature, data and models used for the assessment and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.

- **Step 6 – Classify and determine the significance of the predicted residual effects** (refer to Section 6.7.1.9 Residual Effects Classification and Determination of Significance). Residual effects predicted from primary pathways are classified using a common set of criteria: direction, magnitude, geographic extent, duration, reversibility, frequency and likelihood. A determination of the significance of the predicted residual effects of the Project on human health is made. Relative to other sections, the human health assessment uses a slightly different approach to the classification of residual effects and evaluation of significance, because several of the criteria (e.g., geographical extent, duration, frequency, and reversibility) are already incorporated into the risk estimates and, therefore, are not independent variables.
- **Step 7 – Identify monitoring and follow-up** (refer to Section 6.7.1.10 Monitoring and Follow-up) required to confirm effect predictions and address uncertainty.
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.7.1.11 Conclusions) of residual effects on human health.

6.7.1.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the human health risk assessment are summarized in Table 6.7.1-1. These concerns were gathered through direct engagement and through the analysis of the array of studies provided to CNL. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4 Indigenous Engagement. Specific interests and concerns from each Indigenous Nation are consolidated in Section 4 Appendices.

Table 6.7.1-1: Summary of Issues Raised During Engagement Activities Related to the Human Health Risk Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
Effects on Harvesters ■ Consuming fish and wildlife ■ Consuming plants ■ Reduced (or continuation of existing low) faith in country foods impacting on country food harvesting rates and consumption rates	Included in the environmental assessment Weekay and Moose were added to the diet of a Harvester in the Human Health Assessment	Effects on harvesters from the consumption of fish, plants, and wildlife are assessed in Section 6.7.1.7 Residual Effects Analysis. Other effects on overall well-being are assessed in Section 6.8 Land and Resource Use and Section 6.9 Socio-economic Environment
Health of the Environment ■ Long-term effects of the Project on the quality of air and water quality groundwater	Included in the environmental assessment	Effects on the Project on air and water quality and subsequent human health effects are assessed in Section 6.7.1.7 Residual Effects Analysis.

Table 6.7.1-1: Summary of Issues Raised During Engagement Activities Related to the Human Health Risk Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
Monitoring ■ Current monitoring practices ■ Future monitoring practices including the need for Indigenous-led community environmental monitoring program(s), including country foods monitoring and country foods risk communication	Included in the environmental assessment	Information on the current monitoring program at the WL site is described in Section 6.7.1.5 Description of the Environment. Information on the monitoring program for the Project is available in Section 6.7.1.10 Monitoring and Follow-up. Indigenous participation on the development of the Environmental assessment Follow Up Program is described in Section 11.4.
Accidents and Malfunctions ■ Failure of the grout and ISD barriers	Included in the environmental assessment	The effects of a failure of the ISD system are examined as a disruptive event in Section 6.7.1.7.2.1 (WRDF Barrier Failure)

6.7.1.3 Valued Components

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018) through studies, submissions and direct engagement. The HHRA focused on public health and the health of on-site workers not involved in performing closure activities. Consistent with CSA N288.6-12, Nuclear Energy Workers were not assessed because their potential doses are controlled through CNL's Radiation Protection Program. The assessment for public health considered locations where people are known to be present. During post-closure, there is no exposure pathway for workers (i.e., surveillance and monitoring personnel during period of institutional control) as airborne emissions will be limited by the Project and workers will not be exposed to liquid emissions. Valued components and rationale for their selection for the HHRA are provided in Table 6.7.1-2.

Table 6.7.1-2: Valued Components for the Human Health Risk Assessment

Valued Component	Rationale for Selection
Public Health	Potential exposure to airborne and waterborne radiological and non-radiological emissions ■ Farms A and F includes year-round occupants, with livestock, located near the east bank of the Winnipeg River. Farm F being north-northeast of the WL site and Farm A being north of the WL site. ■ Harvesters represent Indigenous or traditional users of the area who may be exposed through harvesting of country foods. ■ In the long-term, during post-institutional control, there is the potential that a farm may inhibit the site.
Worker Health	On-site workers not involved in performing closure activities may be potentially exposed to both radiological and non-radiological hazards (e.g., asbestos).

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future human generations (i.e., incorporates sustainability). The assessment endpoint is the protection of human health. Measurement endpoints represent properties of the environment, that when changed, could result in or contribute to an effect on an assessment endpoint. The measurement endpoints for the HHRA are outlined in Table 6.7.1-3. The human health section draws on many other assessments within the EIS (e.g., air quality).

Table 6.7.1-3: Assessment Endpoints and Measurement Indicators for the Human Health Risk Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Public Health	Protection of human health	■ Changes to air quality. ■ Changes to surface water quality. ■ Changes to groundwater quality.
Worker Health		

Contaminants of potential concern for measurement indicators are further defined in Section 6.7.1.7.1 and 6.7.1.7.2.

a) Health of on-site workers not involved in performing closure activities.

6.7.1.4 Assessment Boundaries

6.7.1.4.1 Spatial Boundaries

In order to assess the potential effects of the Project on human health, an appropriate spatial boundary was defined, with consideration given to locations where people could be affected by Project activities directly or where they could be indirectly affected by interacting with aquatic and terrestrial resources affected by Project activities (Figure 6.7.1-1):

- **Site Study Area (SSA):** is the WR-1 Building and represents the Project footprint (i.e., where project activities will be undertaken; 0.07 ha).
- **Local Study Area (LSA):** is defined as the area within which there is potential for measurable changes to measurement indicators resulting from the proposed Project activities. The LSA was adapted from the surface water Regional Study Area (RSA) and is designed to include receptors from both the HHRA and Ecological Risk Assessment (EcoRA). Therefore, the southern boundary of the LSA extends from the west shore of the Winnipeg River to the east fence on the property line about 400 m north of Provincial Highway 211. The eastern boundary of the LSA follows the fence on the property line to the north property line. The northern boundary follows the north fence on the property line about 1.6 km and then turns north for about 400 m before turning west and extending to the west side of the Winnipeg River. This is to include the closest existing farm (Farm A) downstream on the east bank because this is the most conservative potential water user. The western boundary follows the west bank of the Winnipeg River for about 1.5 km and then turns west for 370 m, north for 1.4 km and then turns east for 630 m to the west side of the Winnipeg River. This is to include the closest farm (Farm F) and harvester that could be affected by air emissions from the Project. The LSA has an approximate size of 4,174 ha.
- **Regional Study Area:** is defined as the area within which the potential effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. The RSA is the same as the air quality study area and is defined as a 12 km by 12 km rectangle surrounding the LSA (approximately 14,400 ha).

6.7.1.4.2 Temporal Boundaries

The temporal boundaries of the assessment are the timeframe during which Project activities are actively occurring, and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effect is predicted to last so far into the future that the duration cannot be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of in situ disposal, which includes preparation for in situ disposal, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2030.
- **Post-closure Phase:** The post-closure phase has two discrete periods: institutional control and post-institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue to demonstrate WRDF performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is at least 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects (i.e., doses) are anticipated.

6.7.1.4.3 Assessment Cases

The assessment cases considered for human health include the Base Case, the Application Case and the Reasonably Foreseeable Development (RFD) Case:

- **Base Case:** represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, hydro-electric dams, transportation, agricultural, mining and residential and recreational development. Current effects from the existing WL facilities and operations, for example, are considered part of the Base Case. In addition, effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case. The base case is represented in the assessment by baseline air quality (Section 6.2.1.5 Description of the Environment) and surface water quality (Section 6.4.2.5 Description of the Environment) and used in the assessment as required by the relevant human health guideline for each contaminant of potential concern (COPC).
- **Application Case**: represents the effects of the Base Case combined with predicted effects from the Project. The Application Case includes post-closure activities, and therefore, the associated effects during the post-closure phase of the Project represent the bounding case.

- **RFD Case**: represents the predictions of the cumulative effects of the Application Case, plus projects that are currently under application review or that have officially entered a regulatory application process and which overlap with the human health RSA. Effects from the future decommissioning and reclamation activities to be completed at the WL site, as described in the Comprehensive Study Report (AECL 2001), are considered as part of the RFD Case. There are no other foreseeable developments in the human health environment RSA that are expected to overlap with residual effects on human health (Table 6.7.1-4). The Comprehensive Study Report (AECL 2001) indicated that no public health threats were predicted from the decommissioning and reclamation activities for the WL site. Releases are well within regulatory limits for the protection of human health and regular monitoring provides that any aberrations are detected immediately (AECL 2001). Current effects from the existing WL facilities and operations are considered part of the Base Case (i.e., existing conditions). Consequently, cumulative effects of the Base Case and the potential effects from the Project are evaluated in the Application Case, and an RFD Case is not applicable to the human health assessment and is not further discussed.

Table 6.7.1-4: Reasonably Foreseeable Developments Considered in the Human Health Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes ISD of the low-level waste trenches).	2016 to 2034	Yes – however, effects are evaluated as part of the Application Case
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – however, effects are evaluated as part of the Application Case

6.7.1.5 Description of the Environment

Background radiation dose from natural and anthropogenic sources and historical radiation dose from WL operations are used to establish a baseline characterization of radiation dose for the HHRA prior to the Project. Section 6.9.5.2.6 Community Well-being outlines the factors that contribute to the communities' overall sense of well-being, including their relationship to the WL site.

6.7.1.5.1 Background Sources of Radiation and Radioactivity

This section describes the background radiation (i.e., ambient radioactivity) that is present in the environment due to natural and anthropogenic sources independent of WL operations, including air, soil, food, water, aquatic sediments and plant or animal tissue. The background radiation dose varies greatly, both spatially and temporally. The main natural sources of radiation are cosmic rays; naturally occurring radionuclides in air, water and food; and naturally occurring radionuclides in the soil, rocks and building materials used in homes (CNSC 2013).

Cosmic radiation penetrates the Earth's atmosphere and gives an external radiation dose at the earth's surface. Naturally occurring radionuclides such as uranium, potassium and thorium are present in soils, rocks and building materials. These naturally occurring radionuclides also contribute to the background gamma radiation dose.

Naturally occurring radionuclides are also in plants, animals and water from surrounding soils and rocks. Humans ingest these foodstuffs and receive an internal radiation dose. Radon gas, a product of the decay of uranium in soil, is inhaled and also contributes to the internal radiation dose. The average annual background radiation doses in Canada are shown on Figure 6.7.1-2; the total average annual dose is about 1.8 millisieverts (mSv), worldwide the average is 2.4 mSv (CNSC 2013). The average dose reported for Winnipeg is 4.1 mSv/a (CNSC 2013).

6.7.1.5.2 Radiation Dose from Whiteshell Operations

Canadian Nuclear Laboratories reports the results of the Environmental Monitoring Program for the WL site each year to the Canadian Nuclear Safety Commission (CNSC). The Environmental Monitoring Program data are collected to verify that radiation doses to members of the public as a result of the operations of the WL site remain As Low As Reasonably Achievable (ALARA). The calculated radiation dose to members of the public from WL operations is shown in Table 6.7.1-5, and represents the baseline radiation dose from WL prior to the Project.

The 2019, dose assessment showed the radiation dose to the public from WL operations was 2.3×10^{-6} mSv/a for airborne effluent and 8.7×10^{-5} mSv/a for liquid effluent (CNL 2020a). The 2019 total adult dose of 8.9×10^{-5} mSv/a represents 0.009% of the effective dose limit of 1 mSv/a for members of the public. The 5-year average adult dose from 2015 to 2019 was 2.8×10^{-6} mSv/a for airborne effluent and 5.8×10^{-5} mSv/a for liquid effluent. The 5-year average total adult dose of 6.0×10^{-5} mSv/a represents 0.006% of the effective dose limit. The dose to members of the public is predominantly from liquid effluents.

Table 6.7.1-5: Total Dose to Critical Groups outside the Whiteshell Laboratories Boundary Based on Environmental Monitoring Results – 2015 to 2019

Year	Airborne Effluent Pathway – Adult Dose (mSv/a)	Liquid Effluent Pathway – Adult Dose (mSv/a)
2019	2.3×10^{-6}	8.7×10^{-5}
2018	1.6×10^{-6}	3.6×10^{-5}
2017	2.0×10^{-6}	4.8×10^{-5}
2016	2.0×10^{-6}	7.5×10^{-5}
2015	6.0×10^{-6}	1.1×10^{-4}
5-year Average (2015 – 2019)	**2.8×10^{-6}**	**5.8×10^{-5}**

Source: CNL 2020a, Table 1.
mSv/a = millisieverts per year.

In 2019, the estimated adult dose due to fish ingestion was 6.9×10^{-6} mSv/a for adults (CNL 2020a). This was equivalent to about 0.0007% of the annual regulatory limit of 1 mSv/a for members of the public. Table 6.7.1-6 shows the dose estimates for 2014 to 2019 along with the five-year average (2014 to 2018). The 2019 dose was lower than the previous five years and lower than the five-year average.

Table 6.7.1-6: Estimated Adult Dose from WL Effluents due to Fish Ingestion – 2014 to 2019

Dose (mSv/a)						
2014	**2015**	**2016**	**2017**	**2018**	**Five-Year Average**	**2019**
4.8×10^{-5}	4.2×10^{-5}	6.7×10^{-5}	4.8×10^{-5}	1.4×10^{-5}	4.4×10^{-5}	6.9×10^{-6}

6.7.1.6 Project Interactions and Mitigation

6.7.1.6.1 Methods

This section describes the process by which interactions between Project components and activities and human health were identified and evaluated. Potential effect pathways are identified and mitigation options to eliminate and/or reduce effects are presented. A pathways analysis is then used to focus on key interactions between the Project and the environment. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the assessment is concluded at this stage and the reasons are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in Section 6.7.1.7 Residual Effects Analysis. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce adverse effects to human health. Environmental design features included Project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project's engineering and environmental teams, combined with input from Project specific or regional engagement with other interested parties. The design features and/or mitigation activities were selected considering their effectiveness for implementation and maintenance and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage pathway –** pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects to human health.
- **Secondary pathway –** the pathway could result in a measurable minor environmental change, but would have a negligible residual effect on human health relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway –** the pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects to human health.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to human health through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and/or qualitative effects analysis to characterize the residual effects of the Project.

6.7.1.6.2 Results

Pathways through which the Project may interact with the human health environment are summarized in Table 6.7.1-7.

Table 6.7.1-7: Pathways Analysis for the Human Health Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
General Project activities during the closure phase	Closure activities will alter concentrations of non--radiological indicator compounds (e.g., particulate matter and carbon dioxide), which could affect human health, including: ■ use vehicles and equipment that combust fuel and emit indicator compounds; ■ material handling, for grouting and demolition; ■ vehicles travelling on paved roads; ■ operation of batch mixing plant for grout production.	■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Effluents and Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Implementation of CNL's Occupational Safety and Health Program, including work permit system and Personnel Protection Equipment and Clothing. ■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. ■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include: ▪ wetting techniques during demolition to limit mobility of dust; ▪ wind restrictions during demolition to stop work or apply wetting techniques; and ▪ hydro seeding during backfilling and landscaping to reduce soil erosion. ■ Road watering and chemical dust suppressant when necessary. Dust suppressant is already used annually at the site for select unpaved roads. ■ All vehicles will pass through a vehicle monitoring station. ■ Removal of accumulations of particulates (e.g., dirt) on road as soon as possible. ■ On-site vehicles and equipment engines will meet Tier 3 emission standards, where possible, and be maintained in good working order. ■ Limit idling of vehicles on-site and speed on roads. ■ Use of enclosure for batch mixing plant and raw material handling.	Secondary

Table 6.7.1-7: Pathways Analysis for the Human Health Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
	Closure activities will result in the atmospheric release of radiological and non-radiological compounds from the WR-1 Building	■ Implementation of CNL's Radiation Protection Program and Procedure, which includes Radiation Safety Zones, detailed work planning to limit doses to As Low As Reasonably Achievable (ALARA), dose monitoring and contamination control procedures (e.g., stabilizing and immobilizing agents). ■ Implementation of CNL's Occupational Safety and Health Program, including work permit system and training requirements. ■ Implementation of CNL's *Environmental Protection* (CNL 20223) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring.	Primary
General Project activities during the closure phase	During closure activities, there is the potential for the transport of site runoff to the Winnipeg River	■ Wastewater from decommissioning activities is collected and tested, and based on the results, is directed either to the waste treatment center, domestic drain, processed drain or ditch systems, or is sent for evaporation and/or solidification and disposal. ■ Existing surface water management systems at the WL site will remain in place to manage site runoff. ■ As per CNL's *Management of Land, Habitat and Wildlife* (CNL 2024), any work within 30 metres of rivers, streams and lakes will have preventative and mitigation measures in place.	Secondary
Long-term performance during the post--closure phase	Release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time may cause changes in groundwater quality which could migrate towards the Winnipeg River	■ Encapsulation of the reactor by a multi-component Whiteshell Reactor Disposal Facility (WRDF) (i.e., geosphere, concrete foundation, grout and facility systems and components) to mitigate groundwater flow into the ISD waste. ■ Installation of a concrete cap and engineered cover system to mitigate moisture infiltration into the WRDF and hence limit release of solutes into the groundwater. ■ Environmental monitoring will be completed throughout the post-closure phase for the Project to confirm that the cover and grout is functioning as intended, and to confirm modelling predictions.	Primary
Long-term performance during the post--closure phase	Release of chemical and radiological contaminants in the long-term during the post-closure phase from the previous activities completed at the WL site.	■ As part of CNL's Licence No. NRTEDL-W5-8.00/2024 with the Canadian Nuclear Safety Commission, environmental monitoring around the WL site will continue for the Project. ■ Follow-up monitoring during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Secondary

6.7.1.6.2.1 No Linkage Pathway

There are no pathways identified as having no linkages to effects to the human health VCs.

6.7.1.6.2.2 Secondary Pathways

In some cases, a Project source of effect and an interaction with an assessment endpoint exists but mitigation is expected to cause minor changes to human health relative to the existing Base Case and/or guidelines. The following pathway is expected to result in negligible effects on the human health VCs and will not be evaluated further in the EIS.

- **Closure activities will alter concentrations of non-radiological indicator compounds (e.g., particulate matter and carbon dioxide), which could affect human health.**

Closure activities will result in the release of Criteria Air Contaminants (CACs) and fugitive dust emissions. Sources of dust deposition and air emissions include stack emissions, fuel use, aggregate material handling, on-site batch mixing plant and road dust. Environmental design features and mitigation have been incorporated into the Project to reduce potential adverse effects from dust deposition and air emissions. CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Effluents and Emissions* (CNL 2022) include operational control monitoring, air verification monitoring and implementation of dust management techniques.

The release of CACs (particulate matter, nitrogen oxides, sulphur dioxide and carbon monoxide) and fugitive dust were assessed as part of the air quality VC in Section 6.2 Air Quality. Predicted concentrations for the Application Case (Section 6.2.1.7 Residual Effects Analysis) are below applicable air quality guidelines and/or standards. Therefore, the release of CACs and fugitive dust are expected to result in negligible effects to human health.

- **During closure activities, there is the potential for the transport of site runoff to the Winnipeg River.**

The LSA drains to the Winnipeg River. During closure phase activities, specifically those that are demolition-related, there is the potential for the transport of site runoff to the Winnipeg River in the vicinity of the WL site. Site runoff may be compromised by various activities such as the mobile batch plant (increased pH and suspended solids levels), crushing masonry (increased pH and suspended solids levels) and cutting steel (increased metal levels).

Currently, wastewater from decommissioning activities is collected and tested and based on the results, is directed either to the waste treatment center, domestic drain, processed drain or ditch systems, or is sent for evaporation and/or solidification and disposal. This process follows the requirements in CNL's *Management and Monitoring of Effluents and Emissions* (CNL 2023). Wastewater directed to the ground or ditch system only occurs when the wastewater is below levels of concern for all contaminants.

During the closure phase, existing stormwater management systems at the WL site will remain in place to manage site runoff from precipitation. For example, surface water runoff from the site is collected by storm sewers and is discharged to the Winnipeg River. Stormwater is routinely monitored to confirm that stormwater quality is normal.

In addition, containment barriers will be constructed where necessary to provide for the collection, control of and treatment of contaminated water and to reduce surface water runoff during decommissioning and reclamation activities. Surface water quality is also assessed at locations where surface water leaves the WL site's boundary and in water-bodies affected by discharges. Concentrations of radiological and non-radiological contaminants are measured and compared against existing provincial or federal surface water quality guidelines or standards. It is also noted that closure phase activities will occur well away from the river and its riparian zone and therefore no direct changes in surface water quality will result. As per CNL's *Management of Land, Habitat and Wildlife* (CNL 2024), any work within 30 m of rivers, streams and lakes will have preventative and mitigation measures in place. General provisions adopted for work at CNL sites in or near a watercourse incorporate appropriate sediment retention measures such as silt curtains and straw bales. Consequently, this interaction was determined to have no linkage to effects to surface water quality in the Winnipeg River. Assuming these best management practices are followed and that the current surface water management facilities remain in place during building demolition, this mitigation is expected to be effective. As such, changes to surface water quality in the Winnipeg River a are expected to result in negligible effects to human health.

- **Release of chemical and radiological contaminants in the long-term during the post-closure phase from the previous activities completed at the WL site.**

The Comprehensive Study Report (CSR) indicated no residual effects on public health are expected as a result of the closure of the WL site. The assessment considered potential effects on the Winnipeg River and management of releases to ensure no residual effect. No decrease in water quality is expected and effluent emissions to the Winnipeg River are expected to decline to virtually zero following decommissioning. Re-suspension of contaminated sediments is also not expected to lead to a decrease in water quality (see Section 7.0 of AECL 2001).

The CSR (AECL 2001) also examined the potential for effects via groundwater quality from the low-level waste that may be managed in situ in the Waste Management Area (WMA), and their potential to affect the Winnipeg River and human health (see also Section 6.4.2.6.2.2 Project Interactions and Mitigation [surface water quality assessment]). The assessment considered three general exposure pathways: upward migration (with potential contamination of soils and vegetation), near-surface later migration (with potential contamination to local discharge in perimeter and roadside ditches) and downward migration and contamination of the sand and gravel aquifer and subsequently the river). Only the near-surface lateral migration scenario was considered in further detail. With respect to downward migration and release to the river it was determined that the general hydrology of the site limits or eliminates this pathway.

Water concentrations in the ditch were predicted and compared to established guidelines for several of the contaminants in the WMA. Radionuclide modelling in the CSR (Appendix C of AECL 2001) indicated that three radionuclides have the potential to exit the WMA through migration over a 200-year period, namely tritium, technetium-99 and carbon-14. Only technetium-99 is potentially present in nonzero concentrations in the ditch adjacent to the WMA in as early as 20 years. The carbon-14 and tritium will be released to the atmosphere, and when this is modelled there is no release of these radionuclides to the perimeter ditch. The preliminary exposure assessment for radiological contamination of the ditch, when these losses were conservatively ignored, resulted in a dose of 0.16 mSv/a at the predicted peak concentration of technetium-99 (Appendix C of AECL 2001).

With respect to non-radiological contaminants, some exceedances of applicable standards were predicted. Further refinement of the modelling and potential need for selective remediation to remove the hazard was recommended (AECL 2001). Organic contaminants were also considered; it was concluded that the remaining concentrations of the solvents and dichlorodiphenyltrichloroethane (DDT) are very small and unlikely to present a residual hazard.

The work at the WMA is subject to approval pending a final safety analysis be performed to confirm these conclusions. That analysis has not been finalized at this time, however both the Project and the WMA are subject to the same regulatory requirements, which require that no member of the public receive a dose greater than 1 mSv/a. *REGDOC 2.11.1, Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2021), Section 6.2.1, specifies a 1 mSv/a limit, and also specifies that a lower dose rate target should be set to account for emissions from other sources. Therefore, a value of 0.3 mSv/a dose limit to public has been established for the WL site. The Project specified a 0.25 mSv/a target dose rate limit for the public and results of the assessment for the normal evolution indicates that the Project is well below this target.

Consequently, there are negligible effects between the Project and previous activities at the WL site (i.e., effects from the WMA) and changes to surface water quality in the Winnipeg River.

As part of CNL's Licence No. NRTEDL-W5-8.00/2024 with the CNSC, environmental monitoring around the WL site will continue for the Project. Follow-up monitoring during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects. Consequently, changes to surface water quality, and therefore human health, from the closure of the WL site, are predicted to be negligible.

6.7.1.6.2.3 Primary Pathways

The following primary pathways were identified between the Project and human health and therefore, were carried forward to the residual effects analysis for their potential to affect human health:

- **Closure activities will result in the atmospheric release of radiological and non-radiological compounds from the WR-1 Building.**
- **Release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time may cause changes in groundwater quality; which could migrate towards the Winnipeg River.**

6.7.1.7 Residual Effects Analysis

An ERA (EcoMetrix 2024) was completed for the Project to assess potential adverse effects on human health during the closure and post-closure phases of the Project. A summary of the methods and results of this assessment during the closure and post-closure phases of the Project is provided in Section 6.7.1.7.1 Application Case – Closure Phase and Section 6.7.1.7.2 Application Case – Post--closure Phase, respectively.

6.7.1.7.1 Application Case - Closure Phase

6.7.1.7.1.1 Methods

This section summarizes the methods used to assess the residual effects on human health, during the closure phase, for the Project activities and pathways identified as primary in Table 6.7.1-7. Policies, guidelines and standards considered in the analysis, as well as the model used to predict residual effects are described.

Receptor Selection and Characterization

The receptors for the HHRA were selected to be appropriate for assessment of both radiological and non--radiological stressors on human health. Off-site members of the public will potentially be exposed to low levels of airborne contaminants from decommissioning of the WR-1 Building. The most-affected off-site members of the public are defined as the “critical group” which include:

- Farm A and F (year-round occupants, with livestock); and
- Harvesters (separate receptor, represented by single receptor in the derivation of derived release limits [DRL] for the WL site [CNL 2018]).

Radiological dose to workers at WR-1 may result from external exposure to radiation emitted from WR-1 during closure.

On-site workers performing ISD activities will be Nuclear Energy Workers. Doses to these workers will be monitored and managed as part of CNL’s Radiation Protection Program and Occupational Safety and Health Program in place under the WL Decommissioning Licence (NRTEDL-W5-8.00/2024). The application of the Radiation Protection Program provides that exposures will be kept ALARA and below the effective dose limit of 100 mSv over 5 years, and below 50 mSv in any single year, with human factors taken into account. An assessment of the radiological hazards and risks to workers performing closures activities, exposure mitigating measures and monitoring of worker doses is addressed in Section 7.1 of the DSAR (Golder 2021) and is based on the dose estimates provided in CNL 2019b. Therefore, this worker group has not been considered as a receptor for the HHRA in the EIS, consistent with Section 1.6 of *CSA N288.6-12: Environmental Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2012).

Other on-site workers (also classified as Nuclear Energy Workers the same as above, and subject to the same protections) not involved in performing closure activities were identified as a receptor for potential radiological exposures from environmental emissions during in situ decommissioning activities. Doses for other workers on-site, not directly involved in decommissioning activities, are assessed in Section 4.0 in the ERA (EcoMetrix 2024). Decommissioning work will be conducted in accordance with requirements of the CNL Occupational Safety and Health Program Manual and CNL Work Permit System. The foundation of the safeguards against industrial hazards is qualified staffing and the implementation of proven and approved procedures through a system that requires continual improvement.

Farms A and F are the highest likely exposure group (i.e., critical groups) and are shown on Figure 6.7.1-1. Farms A and F are both livestock farms with the same characteristics as each other except for the location. Farm F being north-northeast of the WL site and Farm A being north of the WL site. Doses presented for Farm F are considered bounding for Farm A, as modelling during closure indicated that doses to residents at Farm F would be higher than at Farm A (EcoMetrix 2024); therefore, radiological doses are presented only for Farm F. For radiological parameters and consistent with *CSA N288.1-14: Guidelines for Calculating Derived Release Limits for Radioactive Material in Airborne and Liquid Effluents for Normal Operation of Nuclear Facilities* (CSA Group 2014) and CANDU Owners Group (COG) DRL Guidance Document (COG 2013) an adult, 10-year-old child, 1-year-old infant and 3-month-old infant were the age groups assessed for Farm F. The 1-year-old infant was evaluated to represent an infant that drinks cows’ milk and an infant that drinks formula. The 3-month-old infant

was evaluated to represent an infant that drinks breast milk (nursing) and an infant that drinks formula. Members of Farms A and F are considered to:

- reside at the farm 100% of the time;
- obtain the majority of their fruit and vegetables from their on-site garden;
- supply all of their own milk, poultry and eggs from their farm;
- supply some of their beef and pork from their farm;
- acquire honey from another local farm;
- obtain game (deer) (i.e., meat requirement) from hunting on their own property; and
- use a backyard swimming pool filled with well water 3 months out of the year.

Harvesters represent Indigenous or traditional users of the area who may be exposed through harvesting of country foods. The age groups evaluated for the Harvester included adult, 10-year-old child, and 1-year old infant, since Harvesters would likely bring back harvested food to feed their families. Harvesters are considered to:

- spend part of their time on-site, part near Farm F and part at an unexposed location;
- obtain deer and hare from hunting and trapping; and
- harvest plants including berries, weekay, and cedar.

CNL conducted an Indigenous food intake survey to understand the types and quantities of local food consumed. This survey was completed by members of the Sagkeeng First Nation. CNL also partnered with the Manitoba Métis Federation to conduct Harvester food intake surveys with Manitoba Métis Citizens that harvest in the area of the WL site. Additional Traditional knowledge on harvested foods was shared by Sagkeeng First Nation in a Traditional Knowledge Study, by the Manitoba Métis Federation in a Traditional Knowledge, Land Use and Occupancy Study, by Broken Head Ojibway, Black River and Hollow Water First Nations through their Traditional Use Study and by Wabaseemoong First Nation through their Traditional Use Study. The information collected through the surveys and the studies was used to validate the assumptions made for wild game, fish and plant (including medicinal plants) ingestion rates for the subsistent Harvester receptors. The survey results have also been incorporated into the Harvester's diet. The intake rates from the Manitoba Métis Federation survey were lower than the intake rates identified by the Sagkeeng First Nation. Therefore, the Harvester receptor in the model uses the intake rates from the Sagkeeng First Nation Indigenous food intake survey, and is considered to be a conservative reflection of potential health effects to a Harvester.

Recreational users such as swimmers, anglers and boaters that occasionally carry out recreational activities along the Winnipeg River at locations close to the WL site, as compared to the most critical group locations (Farm A and Farm F), are not directly considered for the assessment because exposures to these individuals are anticipated to be well encompassed by those to the critical group.

Contaminants of Potential Concern

As part of normal operation, nuclear facilities release, in a controlled manner, small quantities of radioactive substances into the atmosphere and geosphere. These releases are regulated by the CNSC. Doses received by members of the public from routine releases at nuclear facilities are too low to be measured directly; therefore, a quantity known as a DRL is established for the site. Operating DRLs for the WL site were established in accordance with CSA N288.1-14 (CSA Group 2014). The DRLs have been calculated for 30 radionuclides that have been found or may reasonably expected to be present in airborne and liquid effluent streams at the WL site (CNL 2023). As noted in the ERA (EcoMetrix 2024), the radionuclides that are considered for the closure period are primarily those that have been identified in the DRL Report (CNL 2023) and the source term characterization report (CNL 2020b). These radionuclides have been found in WL's airborne effluent or are reasonably expected to be found in the airborne effluent during closure activities.

For the closure phase, the relevant COPCs are expected to be released via airborne effluents from the WR-1 Building as reactor systems are dismantled, transported off-site or encapsulated within the WRDF. No Project releases to the surface water environment are anticipated during the closure period. It has been assumed that the WR-1 Building stack will be dismantled during the closure phase, after grouting has been completed; therefore, airborne effluents are assumed to occur at ground level. Airborne emission estimates have been provided for demolition activities prior to grouting (referred to as demolition) and during grouting activities (refer to Section 6.2.1, Tables 6.2.1-11 and 6.2.1-12) as emissions are anticipated to be elevated during grouting (6 months). For both stages (demolition and grouting) airborne emission estimates have been provided for the average scenario or anticipated activities and activity level, as well as for the potential maximum scenario or accelerated activities and/or activity level.

Soil around the WR-1 building will be remediated if radioactivity is encountered that exceeds soil clean-up criteria established for the site end-state and land use (CNL 2019a). As indicated in Section 6.3.1.6.2 Results [geology assessment], soil surrounding the foundation is not expected to exceed clean-up criteria; however, if soil contamination is encountered, it would be removed and segregated using standard excavation equipment and practices. As indicated in Table 6.2.1-10, dust suppression methods (e.g., water misting, use of applicable immobilization agent onto the soil surface) would be applied during excavation as required to suppress dust levels to meet environmental dust limit. Therefore, the release of radiological and non-radiological contaminants related to soil remediation was not anticipated to result in a residual effect.

Selection of Radiological COPCs

The radionuclides that are considered in the HHRA for the closure phase have been found in WL's airborne effluent or are reasonably expected to be found in the airborne effluent. All radionuclides identified through the source-term characterization process were carried forward quantitatively in the HHRA and did not undergo a formal screening assessment.

During closure, operational controls and procedures to prevent or limit the release of airborne effluents will be in effect (e.g., during demolition the above-grade building will be in place, the waste collection system and proven emergency response plans and personnel will all be operational and adequate ventilation and infiltration will be established). As well, decontamination and the use of stabilizing and immobilizing agents prior to dismantling the WR-1 Building, will be used to control the release of airborne radionuclides. Release of radionuclides to the atmosphere during closure are not anticipated to be above the levels observed during the operation phase of the facility. During demolition of above-grade structures, radionuclides may be released from the Primary Heat Transport (PHT) system, and some existing surface contamination may become airborne (Table 6.7.1-8).

During grouting, radionuclides may be released from the reactor core and biological shield (Table 6.7.1-9). During grouting it was conservatively assumed that the entire inventory of radionuclides is made available for release with dust particulate. In reality, much of the inventory will be fixed on surfaces of WR-1 structures. Tritium may also be released, for example, when disruptive activities are executed on the helium and heavy water system.

Table 6.7.1-8: Potential Radionuclide Release during the Closure Phase

Reactor Core	Biological Shield	Primary Heat Transport System
■ Carbon-14 ■ Iron-55 ■ Cobalt-60 ■ Nickel-59 ■ Nickel-63 ■ Niobium-94 ■ Silver-108m ■ Tritium	■ Chlorine-36 ■ Calcium-41 ■ Nickel-63 ■ Carbon-14 ■ Cobalt-60 ■ Europium-152	■ Strontium-90 ■ Caesium-137 ■ Europium-154 ■ Europium-155 ■ Technetium-99 ■ Iodine-129 ■ Uranium-235 ■ Uranium-238 ■ Neptunium-237 ■ Neptunium-239 ■ Plutonium-238 ■ Plutonium-239 ■ Plutonium-240 ■ Plutonium-241 ■ Americium-241 ■ Americium-243 ■ Curium-244 ■ Silver-108m ■ Cobalt-60

Note: The list of radionuclides potentially released during the closure phase was generally consistent with those identified in CNL's Derived Release Limits (2021), with the exception of calcium-41, chlorine-36, europium-155, nickel-59, and neptunium-239 which were identified in the WR-1 Reactor Radiological Characterization Summary and Radionuclide Inventory Estimates Report (CNL 2020b)

Selection of Non-Radiological COPCs

Non-radiological airborne COPCs have been identified as potentially being released during the closure phase from the WL site. These include:

- asbestos (friable [contains more than 1% asbestos by weight or area and can be crumbled by the human hand] and non-friable [material that contains more than 1% asbestos and cannot be crumbled under hand pressure] asbestos containing materials);
- organic coolant (HB-40 used as reactor coolant, also known as OS-84, primarily hydrogenated terphenyl) in the PHT system;
- lead based paint and lead shielding;
- polychlorinated biphenyls (PCBs) in fluorescent light fixture ballasts;
- small quantities of mercury in thermostats and switches; and
- mould.

With the exception of HB-40, the identified hazardous substances are routinely addressed in construction projects. HB-40 consists mainly of hydrogenated terphenyl (74% to 87%), with smaller fractions of partially hydrogenated terphenyls and terphenyl. Since HB-40 is an oil, or a tar if irradiated, its release to air with dust should be limited.

The non-radiological COPCs listed above were compared against applicable air quality criteria as part of the ERA (EcoMetrix 2024). The predicted air concentrations for all non-radiological COPCs evaluated are below their relevant ambient air quality criteria. Therefore, exposure concentrations and dose for non-radiological COPCs were not completed as part of the ERA (EcoMetrix 2024).

Exposure Pathways

During the closure phase, releases to surface water are not expected, because any release from the grouted WRDF would occur after closure, and contaminant transport via groundwater to surface water would take additional time. Pathways relevant to exposure to airborne effluents are presented for the human receptors in Table 6.7.1-9 illustrated on Figure 6.7.1-3 and Figure 6.7.1-4. During the closure phase, human receptors on Farm A and F could potentially be exposed via air (inhalation, immersion), soil (incidental ingestion, groundshine), well water (ingestion, bathing), and ingestion of home-grown vegetables, fruits and livestock, and ingestion from locally hunted deer. Exposure pathways for on-site workers include inhalation of air on-site as well as immersion, and soil external contact and incidental ingestion pathways for outdoor workers. Non-radiological pathways are not applicable as no non-radionuclides were identified as COPCs for the closure phase.

CNL conducted an Indigenous food intake survey completed by members of the Sagkeeng First Nation to understand the types and quantities of local food consumed (CNL 2018). The results indicate that survey participants consume animals such as wild game (e.g., moose, deer, rabbit and hare), waterfowl (e.g., duck and geese), fish, fruits and berries and medicinal plants (e.g., weekay and cedar). During the closure period, the focus is on terrestrial pathways, since only atmospheric releases are expected. Based on these considerations terrestrial animals including hare and deer, terrestrial plants including berries and medicinal plants including cedar and weekay are included in the assessment for the harvester. Other considerations for the harvester are considered in the post closure period where aquatic pathways are more applicable. It was noted from engagement with Indigenous peoples that Sagkeeng First Nation members in the Whiteshell area harvest wild rice and medicinal plants; however, wild rice does not grow in close proximity to WR-1.

CNL also partnered with the Manitoba Métis Federation to conduct Harvester food intake surveys with Red River Métis Citizens that harvest in the area of the WL site (SVS 2019). The information provided supported the VCs selected for the EIS and was used to validate the assumptions made for wild game, fish and plant ingestion rates for subsistent receptors. The intake rates from the Manitoba Métis Federation survey were lower than the intake rates identified by the Sagkeeng First Nation. Therefore, the Harvester receptor in the model uses the intake rates from the Sagkeeng First Nation Indigenous food intake survey. In addition, some diet components were not included in the model, such as moose. Diet components that exist in the Whiteshell area were considered for the ERA (EcoMetrix 2024), and it has been reported that moose populations are extremely low in the study area considered in the ERA (EcoMetrix 2024). Therefore, moose was excluded from the model in the closure phase but was added to the post closure phase model. This was done because moose is a very important VC to Indigenous people and in the future, moose may become more abundant in the area.

Traditional Knowledge and Land Use Studies (BRFN, BON, and HWFN 2019) and Indigenous engagement with Brokenhead Ojibway Nation, Black River First Nation and Hollow Water First Nation identified additional species for consideration (in addition to weekay) in the human health assessment. This included muskeg tea, willow, Seneca root, rose hips, cedar, and poplar. These species were not included in the Closure assessment as

bioaccumulation factors used in modelling radionuclide uptake into plants are defined for broad types of plants, such as aquatic plants, or forage plants. Therefore, modelling for a specific medicinal plant species is generally not possible. As such, the terrestrial plants selected for inclusion in the ERA modelling (Table 6.7.1-9) are considered to be representative of a Harvester's diet component.

Atmospheric deposition to the Winnipeg River is considered negligible. This is consistent with the COG DRL guidance (COG 2013) which shows (assuming a modest flow rate for a lake of 0.1 m/s and an assumed water depth of 10 m) that the transfer of radionuclides from the atmosphere to large bodies of water (including lakes and rivers) is considered negligible. Rivers have larger flow rates than lakes; therefore, the conclusion for lakes that the atmospheric deposition pathway is negligible is applicable to rivers as well.

In CSA N288.1-14 (CSA Group 2014) the release of radionuclides from surface soil to the atmosphere is considered negligible because transfer is predominately from the atmosphere to soil. This pathway was not included during closure for this reason.

Table 6.7.1-9: Exposure Pathways for Receptors for Exposure to COPCs during Closure

Receptor	Exposure Pathway	Environmental Media
Farm F	Inhalation	■ Air
	Ingestion	■ Water (well water) ■ Soil (incidental) ■ Terrestrial plants (homegrown) ■ Terrestrial animals (beef, pork, poultry, eggs, milk, game, honey)
	External	■ Air ■ Water (well water) ■ Soil
Harvester	Inhalation	■ Air
	Ingestion	■ Terrestrial animals (hare, deer) ■ Terrestrial plants (berries, weekay, cedar) ■ Soil (incidental)
	External	■ Air ■ Soil
On-Site WL Worker	Inhalation	■ Air
	Ingestion	■ Soil (incidental)
	External	■ Air ■ Soil

Note: Soil is considered to be clay as defined in the Hydrogeology Study Report (Dillon 2018).

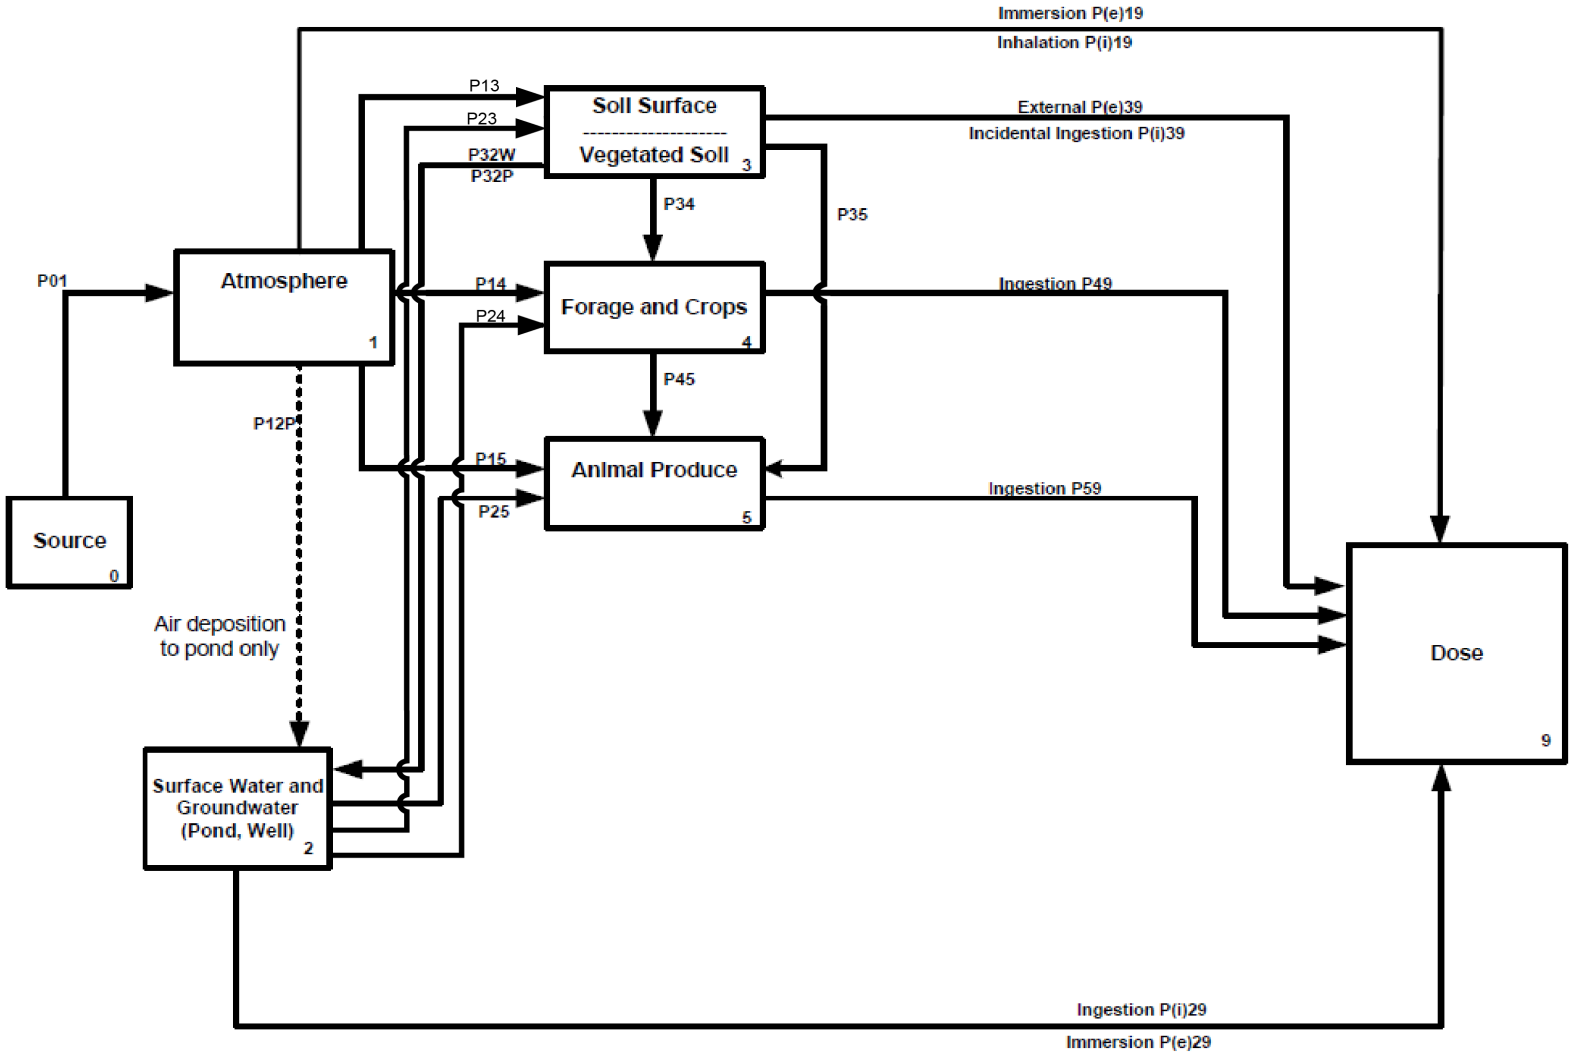

Figure 6.7.1-4: Conceptual Model for Human Receptors during the Closure Phase harvester

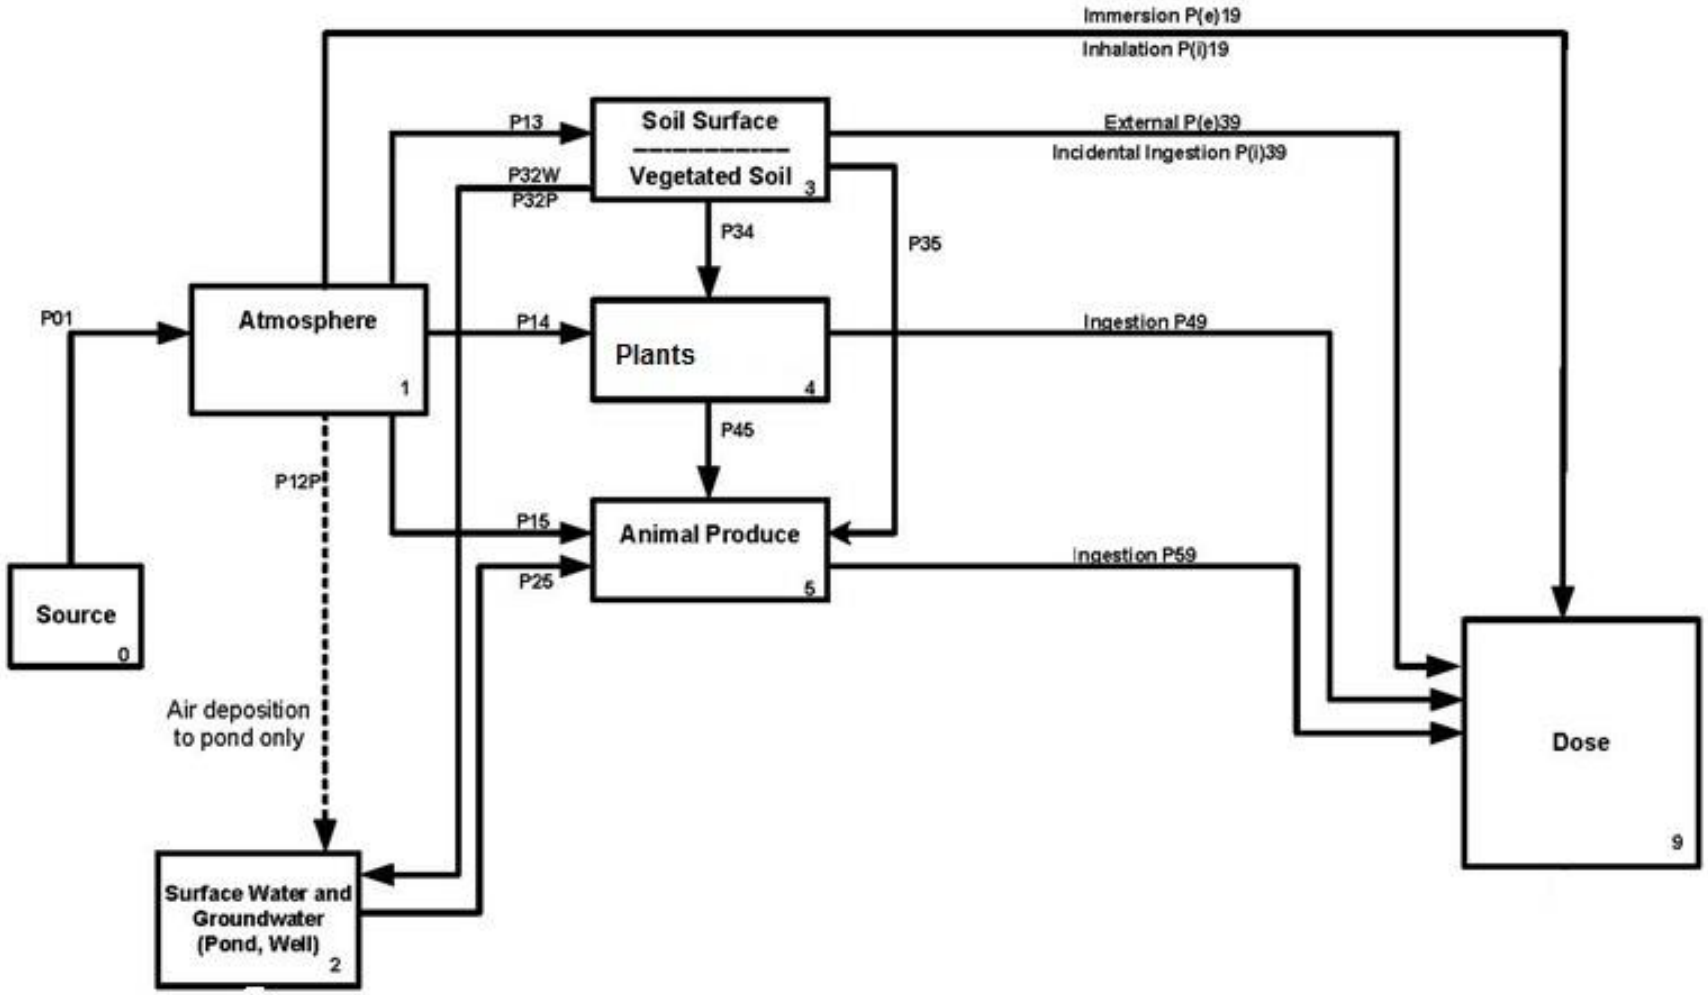

Model Software

An environmental transport and pathways model was used to evaluate the effects of contaminants on the local environment including human and ecological receptors. The software used for the exposure pathways analysis and for the calculation of radiological doses was IMPACT™ Version 5.5.1, which is consistent with the equations outlined in CSA N288.1-14 (CSA Group 2014) and the methods outlined in CSA N288.6-12 (CSA Group 2012). The Tool Qualification Report for IMPACT describes the verification and validation activities performed on IMPACT. A more detailed description of the model is provided in the ERA (EcoMetrix 2024).

6.7.1.7.1.2 Results

The public dose limit for radiation protection is 1 mSv/a, as described in the *Radiation Protection Regulations* (SOR/2000-203) under the *Nuclear Safety and Control Act*. This limit is defined as an incremental dose, and is set at a fraction of natural background dose. For the Project, an established dose constraint to the public from all nuclides and all pathways for the long-term expected evolution of 0.25 mSv/a is applied for the Project (CNL 2016).

For radionuclides, the total doses were compared to the public dose limit of 1 mSv/a and the dose constraint for the Project of 0.25 mSv/a. A summary of the total dose for each receptor and age group is provided in Table 6.7.1-10 along with a comparison to the public dose limit and dose constraint. The calculated radiological doses are all below these limits, for all human receptors in the candidate critical groups. Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure to radioactive releases from Project activities. Individual dose results for each radionuclide is provided in the ERA completed for the Project, in Tables 4-9 through 4-24 (EcoMetrix 2024).

Table 6.7.1-10: Summary of Total Dose during the Closure Phase Human Health Valued Components

Age Group / Exposure Scenario	Dose (mSv/a)	Percent of Dose Constraint	Percent of Public Dose Limit
Demolition			
Adult Harvester			
Demolition - Maximum	3.50×10^{-3}	1.40%	0.35%
Demolition - Average	9.19×10^{-4}	0.37%	0.09%
Child Harvester			
Demolition - Maximum	1.52×10^{-3}	0.61%	0.15%
Demolition - Average	4.00×10^{-4}	0.16%	0.04%
Infant Harvester			
Demolition - Maximum	6.66×10^{-4}	0.27%	0.07%
Demolition - Average	1.75×10^{-4}	0.07%	0.02%
Adult Farm F Resident			
Demolition - Maximum	3.46×10^{-3}	1.39%	0.35%
Demolition - Average	9.11×10^{-4}	0.36%	0.09%
Demolition			
Child (10-years old) Farm F Resident			
Demolition - Maximum	3.38×10^{-3}	1.35%	0.34%
Demolition - Average	8.89×10^{-4}	0.36%	0.09%

Table 6.7.1-10: Summary of Total Dose during the Closure Phase Human Health Valued Components

Age Group / Exposure Scenario	Dose (mSv/a)	Percent of Dose Constraint	Percent of Public Dose Limit
Infant (1-year old) Farm F Resident Cow's Milk			
Demolition - Maximum	2.61×10^{-3}	1.04%	0.26%

Infant (1-year old) Farm F Resident Formula Fed			
Demolition - Maximum	1.17×10^{-3}	0.47%	0.12%
Demolition - Average	3.07×10^{-4}	0.12%	0.03%
3-month Old Farm F Resident Nursing			
Demolition - Maximum	1.23×10^{-3}	0.49%	0.12%
Demolition - Average	3.23×10^{-4}	0.13%	0.03%
3-month Old Farm F Resident Formula Fed			
Demolition - Maximum	3.96×10^{-4}	0.16%	0.04%
Demolition - Average	1.04×10^{-4}	0.04%	0.01%
Demolition			
On-Site Worker			
Demolition - Maximum	6.04×10^{-3}	2.42%	0.60%
Demolition - Average	1.59×10^{-3}	0.64%	0.16%
Grouting			
Adult Harvester			
Grouting - Maximum	1.58×10^{-5}	<0.01%	<0.01%
Grouting – Average	8.82×10^{-6}	<0.01%	<0.01%
Child Harvester			
Grouting - Maximum	1.69×10^{-5}	<0.01%	<0.01%
Grouting – Average	9.40×10^{-6}	<0.01%	<0.01%
Infant Harvester			
Grouting - Maximum	1.85×10^{-5}	<0.01%	<0.01%
Grouting – Average	1.04×10^{-6}	<0.01%	<0.01%
Adult Farm F Resident			
Grouting - Maximum	1.01×10^{-4}	0.04%	0.01%
Grouting – Average	5.69×10^{-5}	0.02%	<0.01%
Child (10-years old) Farm F Resident			
Grouting - Maximum	1.21×10^{-4}	0.05%	0.01%
Grouting – Average	6.79×10^{-5}	0.03%	<0.01%
Infant (1-year old) Farm F Resident Cow's Milk			
Grouting - Maximum	1.59×10^{-4}	0.06%	0.02%
Grouting – Average	8.88×10^{-5}	0.04%	<0.01%

Table 6.7.1-10: Summary of Total Dose during the Closure Phase Human Health Valued Components

Age Group / Exposure Scenario	Dose (mSv/a)	Percent of Dose Constraint	Percent of Public Dose Limit
Infant (1-year old) Farm F Resident Formula Fed			
Grouting - Maximum	1.23×10^{-4}	0.05%	0.01%
Grouting – Average	6.72×10^{-5}	0.03%	<0.01%
Grouting			
3-month Old Farm F Resident Nursing			
Grouting - Maximum	1.09×10^{-4}	0.04%	0.01%
Grouting – Average	6.30×10^{-5}	0.03%	<0.01%
3-month Old Farm F Resident Formula Fed			
Grouting - Maximum	8.91×10^{-5}	0.04%	<0.01%
Grouting – Average	4.89×10^{-5}	0.02%	<0.01%
Grouting			
On-Site Worker			
Grouting - Maximum	1.80×10^{-4}	0.07%	0.02%
Grouting – Average	9.76×10^{-5}	0.04%	0.01%

Note:

A dose of 0.0025 millisieverts per year (mSv/a) is equivalent to 1% of the dose constraint and a dose of 0.01 mSv/a is equivalent to 1% of the public dose limit.

Non-radiological COPCs are identified through the completion of a formal screening process. For the closure phase, all predicted air concentrations for non-radiological COPCs were below their relevant ambient air quality criteria (Section 4.1.2.2 of the ERA [EcoMetrix 2024] therefore, no non-radiological COPCs were identified for the closure phase and no health effects are anticipated as a result of airborne effluent from the Project.

6.7.1.7.2 Application Case – Post-closure Phase

This section describes the specific methods used to assess the residual effects on human health, during the post-closure phase (see Table 6.7.1-5). Policies, guidelines and standards considered in the analysis, as well as the model used to predict residual effects, are described.

6.7.1.7.2.1 Methods

Scenarios

The Normal Evolution Scenario is a description of the most likely, expected, evolution of the WRDF and its surrounding environment. The Normal Evolution Scenario accounts for the expected degradation of the engineered barriers over the post-closure phase. It starts immediately following the closure phase, to capture the entire post-closure phase (i.e., institutional control and post--institutional control periods). It is assumed that the WRDF will degrade over time due to mechanical stresses and chemical reactions.

Disruptive event scenarios are variants on the Normal Evolution Scenario, designed to address uncertainties that have arisen during the definition of scenarios and conceptual models. Each is described with scenario specific assumptions. Bounding scenarios are then identified to represent “worst case” with consequences greater than the other events considered. The following disruptive event scenarios were assessed in the safety assessment:

- **Unsealed Borehole:** This scenario considers the consequence of an enhanced permeability pathway for contaminated groundwater to affect downgradient receptors (i.e., the Winnipeg River).
- **Well in Plume:** To confirm the long-term safety of future generation, the assumptions was made that after institutional control a human receptor (On-site Farm) would obtain drinking water from a well, established half-way between the WRDF and the Winnipeg River.
- **Localized Failure of the WRDF:** This scenario represents a localized failure that results in an enhanced hydraulic connection through the WRDF containment barrier and an associated elevated exposure of human and non-human receptors near the WL site to contaminated groundwater.
- **WRDF Barrier Failure:** This scenario considers that failure of the WRDF concrete foundation resulting in an open fracture. It considers that the grouting fabrication and/or installation is inappropriate, or that the long-term performance deteriorates rapidly due to unforeseen or underestimated physical, chemical and/or biological processes.
- **Human Intrusion:** The specific human activity considered for the Human Intrusion Scenario is exploratory drilling. Exposure to (1) drill crew at the wellhead, (2) residents near to the site, (3) core transportation personnel and (4) laboratory technicians were all considered possible. Sources of exposure include gas released from the borehole, the drill core itself and contaminated groundwater.
- **Glaciation:** Considers an eventual glacial advance causing a full excision and surface distribution of the WRDF radionuclide inventory and exposure of humans resettling in the area following glacial retreat, approximately 140,000 years from closure.
- **Seismicity:** Considers the potential effects from a seismic event during the 10,000 year assessment timeframe. This disruptive event is encompassed by the WRDF Barrier Failure event as a potential outcome of a larger than design basis earthquake.
- **Liquefaction:** Considers the potential for liquefaction of soils surrounding the WRDF.

Three of the Disruptive Events described above were considered Bounding Scenarios and were identified as “worst case” with consequences greater than the other events considered. These were:

- Human Intrusion: an exploration borehole drilled into the WRDF and exposure of wastes;
- WRDF Barrier Failure: a substantial failure of the WRDF foundation; and
- Well in Plume: an on-site resident drinking groundwater from a well capturing the plume from the WRDF.

In addition to Normal Evolution Scenario and disruptive event scenarios, the safety assessment also considers other types of scenarios, including Defence in Depth Cases and Sensitivity Analysis Cases.

- Defence in Depth Cases are aimed at building confidence in the performance of the WRDF after closure. These cases examine the extent to which the Project depends on key engineered barriers and what would happen if those barriers were not present. This group of scenarios therefore involves hypothetical combinations to analyze the barriers in the system. Each scenario involves a change in one or more parameters related to a particular barrier; by comparing the results to those of the Normal Evolution Scenario, the influence of the barrier is tested. The Defence in Depth Cases developed for the Project are described in the DSAR (Golder 2021).
- Sensitivity Analysis Cases are used to directly examine the effect of important uncertainties in the models and data used to represent the system. As many modelling aspects can in practice be expressed through parameter values, sensitivity cases focus on using alternative parameter value choices. The alternative parameter values that are assigned need not represent specific bounds on uncertainty (as in some cases these cannot easily be established); in other words, the alternative parameters need not necessarily be the “highest” or “lowest” possible values. Rather, they are used to test the effect of uncertainty; for example, if parameter x is increased by a factor of 10, by what factor does the dose increase? The Sensitivity Analysis Cases developed for the Project are described in the DSAR (Golder 2021).

These cases serve to illustrate the importance of facility design features, address uncertainty in model parameters and provide perspective on the limits of safety performance. These scenarios are not relevant for the EIS effects assessment and are therefore not discussed further in this report. In general, the EIS only restates necessary information from the ERA. Further information on scenarios, receptors, calculations and results in general, is available in the DSAR (Golder 2021).

Receptor Selection and Characterization

Normal Evolution Scenario

The receptors for the HHRA were selected to be appropriate for both radiological and non--radiological stressors on human health. Consistent with the closure scenario and CSA N288.6-12 (CSA Group 2012), Nuclear Energy Workers are not addressed for the radiological assessment because their radiation exposure is monitored, and their doses are controlled through CNL’s Radiation Protection Program. On-site workers are not assessed during post-closure for non-radiological exposures since there is no aquatic pathway to on-site workers.

An On-site Farm was considered reasonable for the normal evolution scenario after the end of institutional control. The WRDF will be under institutional control for at least 100 years of post-closure, which will physically restrict residential use of the site, including any farming activities. To account for the possibility of a farm closer to the WRDF, an On-site Farm receptor drinking river water has been included after institutional control.

For evaluation of disruptive event scenarios, the On-site Farm receptor drinks groundwater. Other disruptive event scenarios include a WRDF barrier failure and a human intrusion via an exploration borehole. In the exploration borehole scenario receptors include a driller that handles the core and nearby residents that spend time near the borehole (EcoMetrix 2024). These on-site receptors are considered bounding for any other potential land users (e.g., industrial personnel) or farms established closer to the site than the existing farms.

Human receptors evaluated for both the radiological and non-radiological assessment for the post-closure scenario include:

- Farm A (year-round occupants, with livestock) (located near the east bank of the Winnipeg River);
- On-site Farm (located on the WRDF site after institutional control); and
- Harvesters.

Farm A is the most exposed critical group for releases to the Winnipeg River because liquid releases from the site travel downstream along the east bank according to the DRL report (CNL 2023). Therefore, radiological doses presented for Farm A are considered bounding for Farm F. For radiological parameters and consistent with N288.1-14 (CSA Group 2014) and COG DRL Guidance Document (COG 2013) an adult, 10-year-old child, 1-year-old infant and 3-month-old infant were the age groups assessed for Farm A. The 1-year-old infant was evaluated to represent an infant that drinks cows' milk and an infant that drinks formula. The 3-month-old infant was evaluated to represent an infant that drinks breast milk (nursing) and an infant that drinks formula. For non--radiological dose calculations an adult and toddler were assessed, consistent with Health Canada Preliminary Quantitative Risk Assessment guidance (Health Canada 2010), as recommended by Clause 6.3.5 of CSA N288.6-12 (CSA Group 2012). Members of Farm A and the new On-site Farm are considered to:

- reside at the farm 100% of the time;
- obtain the majority of their fruit and vegetables from their on-site garden;
- supply all of their own milk, poultry and eggs from their farm;
- supply some of their beef and pork from their farm;
- obtain game (i.e., meat requirement) from hunting on their own property
- obtain fish from the Winnipeg River; and
- swim and drink water from the Winnipeg River.

The new On-site Farm receptor has the same characteristics as Farm A; however, residents obtain water for drinking, irrigation and bathing from the Winnipeg River directly downstream of the WRDF groundwater seep into the river. The farm does not have a well in normal evolution because the well capacity would not meet all the water needs of the residential family, which would therefore be more likely to use the adjacent Winnipeg River. One disruptive event scenario includes the On-site Farm using well water as drinking water *only,* since the well capacity could not meet other water needs.

Harvesters represent Indigenous and traditional users of the area who may be exposed through harvesting of country foods. The age groups evaluated for the Harvester included adult, 10-year-old child, and 1-year old infant, since Harvesters would likely bring back harvested food to feed their families. Harvesters are considered to:

- spend part of their time on-site, part near Farm A and part at an unexposed location.
- obtain moose and waterfowl from hunting;
- obtain fish from the Winnipeg River; and
- harvest plants including weekay.

CNL conducted an Indigenous food intake survey (CNL 2018) completed by members of the Sagkeeng First Nation to understand the types and quantities of local food consumed. CNL also partnered with the Manitoba Métis Federation (SVS 2019) to conduct Harvester food intake surveys with Red River Métis Citizens that harvest in the area of the WL site. The survey results have been incorporated into the Harvester's diet. Additional Traditional knowledge on harvested foods was shared by Sagkeeng First Nation in a Traditional Knowledge Study, by the Manitoba Métis Federation in a Traditional Knowledge, Land Use and Occupancy Study, by Broken Head Ojibway, Black River and Hollow Water First Nations through their Traditional Use Study and by Wabaseemoong First Nation through their Traditional Use Study. Human receptors during the post-closure- phase are shown on Figure 6.7.1-1. For radiological parameters an adult, 10-year-old child and 1-year-old infant were the age groups assessed for the Harvester. For non-radiological dose calculations an adult and toddler were assessed for the Harvester.

For each receptor, the exposure factors (e.g., intake rates, occupancy and shielding factors, etc.) are generally those used in N288.1-14 (CSA 2014) or other federal guidelines. For example, water ingestion rates for receptors are from Guidelines for Canadian Drinking Water Quality (Health Canada 2010), and are given as 0.6, 0.8 and 1.5 L/day for Toddlers, Child and Adults respectively. Detailed information on other receptor behaviours such as food ingestion rates and occupancy factors are documented in the Environmental Risk Assessment Tables 5-7 and 5-8 (EcoMetrix 2024).

Disruptive Scenarios

The receptors used for the Disruptive Scenarios were similar to those used in the Normal Evolution Scenario with a few variations as described below:

- Human Intrusion (Exploration Borehole): In this disruptive event scenario it was assumed that an exploration borehole was drilled through the concrete cap and engineered cover, grout, cement, and WRDF from ground surface to bedrock. The material encountered would be brought to surface, handled by the driller and dumped on the ground. Once the driller had left, nearby residents would spend time at the drill location.
- WRDF Barrier Failure: For this disruptive scenario, an open fracture was modeled in the foundation of WRDF. Everything is the same as in the normal evolution scenario, except that groundwater loadings to surface water are based on an open fracture.
- Well in Plume: This disruptive scenario is the same as the normal evolution scenario, except that the On-site Farm has a well in the groundwater plume from WRDF and uses it for drinking water. Water for other purposes, including bathing and irrigation of garden crops is taken from the Winnipeg River near the site.

Contaminants of Potential Concern

For the post-closure phase, no atmospheric releases are expected as the grouting will be completed, and the above-grade building and components will have been removed. Atmospheric releases that occurred during closure that are dispersed and subsequently deposited on the ground or transported to a groundwater well near the WL site are not considered during the post-closure phase. The soil (internal and external) pathways and drinking water pathway (from a farm well) have small contributions to total dose during the closure phase and would have minimal impact on the total dose for the post-closure phase. Therefore, the phases were assessed separately to understand the effects of each phase of the Project separately.

A concrete cap and engineered cover will have been installed on top of the buried material. The site will also be under institutional control for 100 years. The main potential release mechanism during post-closure is via leakage through the WRDF to groundwater and subsequent migration of groundwater to surface water at the Winnipeg River.

Selection of Radiological COPCs

The radionuclides that were considered in the HHRA for the post-closure phase included those that have been historically found in WL's liquid effluent, are reasonably expected to be found in the WRDF and have the potential to migrate from groundwater to surface water during the post-closure phase (EcoMetrix 2024),or have been measured in the river bottom sediment. Radionuclides are considered of public and regulatory interest and therefore all radionuclides identified were carried forward quantitatively in the HHRA. The radionuclides included for the post-closure scenario were:

- Actinium-225
- Actinium-227
- Americium-241;
- Americium-243;
- Silver-108m;
- Bismuth-210
- Carbon-14;
- Calcium-41;
- Chlorine-36;
- Curium-244;
- Cobalt-60;
- Caesium-137;
- Europium-152;
- Europium-154;
- Europium-155;
- Iron-55;
- Gadolinium-55
- Iodine-129;
- Niobium-94;
- Nickel-59;
- Nickel-63;
- Neptunium-237;
- Neptunium-237;
- Protactinium-231;
- Protactinium-233;
- Lead-210;
- Polonium-210;
- Plutonium-238;
- Plutonium-239;
- Plutonium-240;
- Plutonium-241;
- Radium-223:
- Radium-224;
- Radium-225;
- Radium-226;
- Radium-228;
- Strontium-90;
- Technetium-99;
- Thorium-227;
- Thorium-228;
- Thorium-229;
- Thorium-230;
- Thorium-231;
- Thorium-232;
- Thorium-234;
- Uranium-233;
- Uranium-234;
- Uranium-235;
- Uranium-236;
- Uranium-237;
- Uranium-238;
- Yttrium-90.

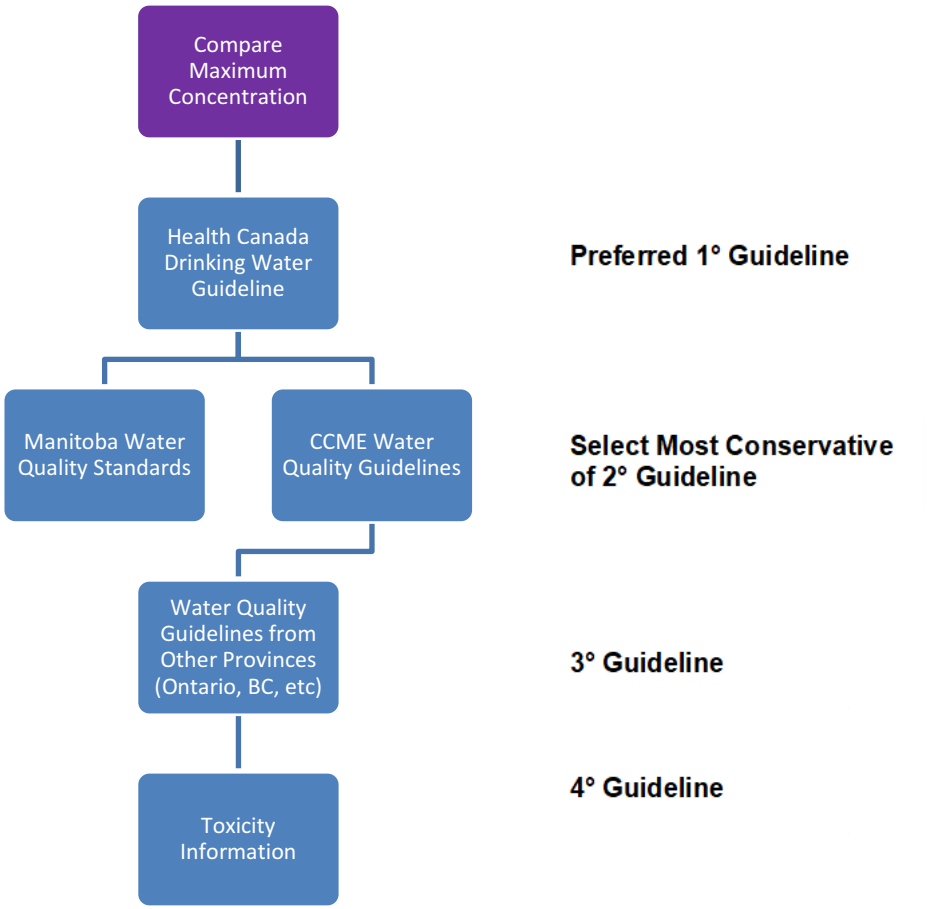
Selection of Non-Radiological COPCs

CNL has determined that a select number of non-radiological waterborne COPCs may potentially be released from the WL site during the post-closure phase (CNL 2017). These include:

- Boron;
- Cadmium;
- Chromium;
- HB-40;
- Mercury;
- Palladium;
- Potassium hydroxide; and
- Xylene.

Non-radiological parameters that may exceed the benchmarks as shown on Figure 6.7.1-5 were carried forward as non-radiological COPCs in this assessment. Based on the screening process, lead was carried forward for further quantitative assessment in the HHRA for the post-closure phase. While based on most recent Health Canada drinking water quality guidelines maximum concentrations do not exceed the guideline, cadmium was retained as COPC for consistency with previous iterations of the ERA (EcoMetrix 2024).

Figure 6.7.1-5: Selection Process for Human Health Screening of Non-Radiological Contaminants of Potential Concern



Exposure Pathways

Normal Evolution Scenario

The post-closure phase is not expected to result in airborne effluent, as the grouting will have been completed, the above-grade building will have been completely decommissioned and a concrete cap and engineered soil cover will have been installed over the WRDF. During the post-closure phase groundwater releases to surface water may occur. Aquatic dispersion will carry contaminants to downstream locations on the Winnipeg River. Waterborne contaminants can partition to sediment. River water and sediment will be the primary exposure media. River water will also be used for irrigation.

Pathways relevant to exposure to releases to surface water are presented for the human receptors in Table 6.7.1-11 and illustrated on Figure 6.7.1-6 and Figure 6.7.1-7. For non-radiological COPCs only the ingestion pathway has been considered, since the dermal pathway is considered negligible for inorganics (i.e., cadmium and lead). During post-closure, human receptors on Farm A and the On-site Farm could potentially be exposed via use of water from the Winnipeg River for drinking, bathing, livestock watering and irrigation (lawns and gardens) and by ingestion of home-grown vegetables, fruit and livestock. Ingestion of terrestrial plants and animals is included for the On-site and Farm A receptors since the Winnipeg River is used for irrigation of these plants and as drinking water for the animals. Residents from these farms are also assumed to fish in the Winnipeg River.

As described in Section 6.7.1.7.1.1, CNL conducted an Indigenous food intake survey completed by members of the Sagkeeng First Nation to understand the types and quantities of local food consumed (CNL 2018). The results indicate that survey participants consume animals such as wild game (e.g., moose, deer, rabbit and hare), waterfowl (e.g., duck and geese), fish, fruits and berries and medicinal plants (e.g., weekay and cedar). During the post-closure phase, the focus is on aquatic pathways, since groundwater releases to surface water will occur. Since the focus is on aquatic pathways, moose has been included instead of deer (which was assessed during the closure phase), since a portion of the moose's diet is from ingestion of aquatic plants. Weekay is a wetland plant and could grow along the shore of the Winnipeg River or in shallow areas. It is unlikely that weekay would be exposed to direct groundwater, but could potentially be exposed to river water. Based on these considerations, exposure via consumption of food harvested from the site (e.g., plants, fish, waterfowl, and moose) would be the important pathways for exposure of the harvester to contaminants released from WRDF to the river.

CNL also partnered with the Manitoba Métis Federation to conduct Harvester food intake surveys with Red River Métis Citizens that harvest in the area of the WL site (SVS 2019). The information provided supported the VCs selected for the EIS and was used to validate the assumptions made for wild game, fish and plant ingestion rates for subsistent receptors. The intake rates from the Manitoba Métis Federation survey were lower than the intake rates identified by the Sagkeeng First Nation. Therefore, the Harvester receptor in the model uses the intake rates from the Sagkeeng First Nation Indigenous food intake survey.

Traditional Knowledge and Land Use Studies (BRFN, BON, and HWFN 2019) and Indigenous engagement with Brokenhead Ojibway Nation, Black River First Nation and Hollow Water First Nation identified additional species for consideration (in addition to weekay) in the human health assessment. This included muskeg tea, willow, Seneca root, rose hips, cedar, and poplar. These species were not included in the Post-closure assessment as bioaccumulation factors used in modelling radionuclide uptake into plants are defined for broad types of plants, such as aquatic plants, or forage plants. Therefore, modelling for a specific medicinal plant species is generally not possible.

There is no direct release to air; however, for volatile radionuclides (tritium oxide, carbon-14, iodine-129), receptors will be exposed via the air pathway (inhalation and immersion) through volatilization from irrigated soil. During post-closure, aquatic release (groundwater flow to the Winnipeg River) is the relevant pathway; therefore, terrestrial pathways, including the country foods muskeg tea, willow, Seneca root, rose hips, cedar, and poplar are not evaluated for the harvester in post-closure. Harvesters will ingest aquatic-related country foods such as weekay, fish and waterfowl, as well as moose that drink from the Winnipeg River.

Table 6.7.1-11: Exposure Pathways for Receptors for Potential Exposure to Radiological and Non-Radiological COPCs during Post--closure (Normal Evolution Scenario)

Receptor	Exposure Pathway	Environmental Media
Farm A and On-site Farm	Inhalation	■ Air
	Ingestion	■ Water (Winnipeg River) ■ Soil/Sediment (incidental) ■ Terrestrial plants (homegrown) ■ Aquatic animals (fish) ■ Terrestrial animals (beef, pork, poultry, eggs, milk, game, honey)
	External	■ Air ■ Water (Winnipeg River) ■ Soil/Sediment
Harvester	Inhalation	■ Air
	Ingestion	■ Riparian plants (weekay) ■ Aquatic animals (fish) ■ Terrestrial animals (waterfowl, moose) ■ Sediment (incidental)
	External	■ Air ■ Soil/Sediment

Note: Soil is considered to be clay as defined in the Hydrogeology Study Report (Dillon 2018).

Figure 6.7.1-6: Conceptual Model for Human Receptors during the Post-closure Phase for Farm A and On-site Farm

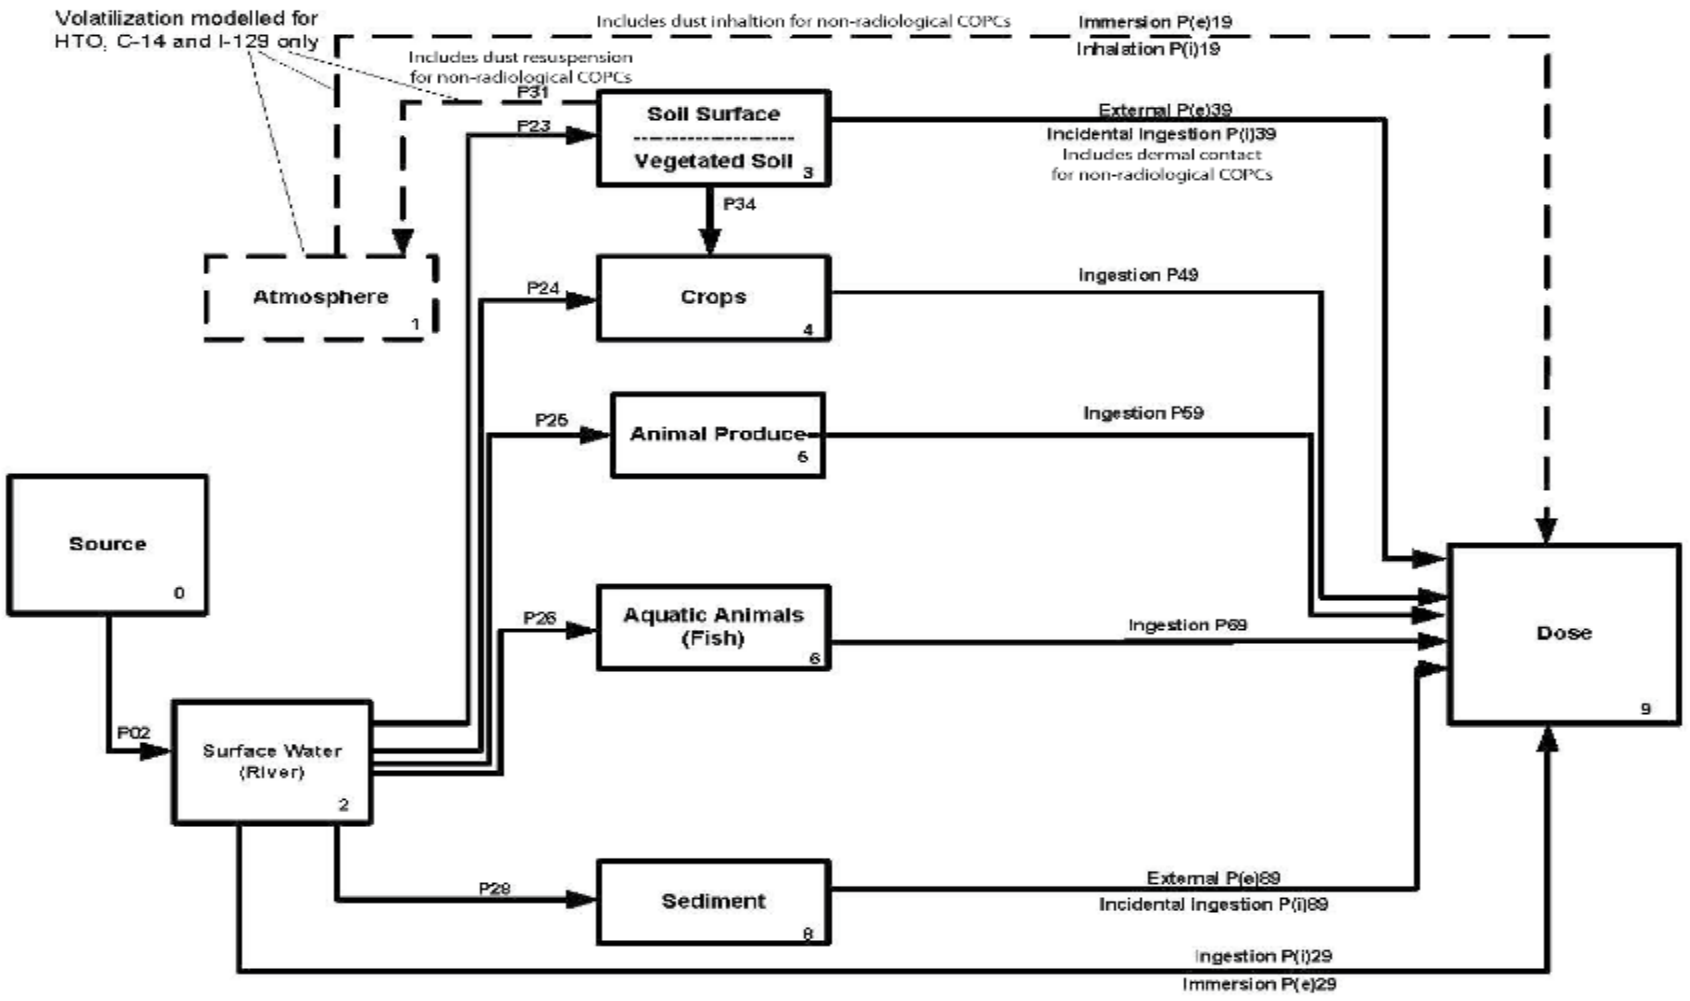


Figure 6.7.1-7: Conceptual Model for Human Receptors during the Post-closure Phase for Harvester

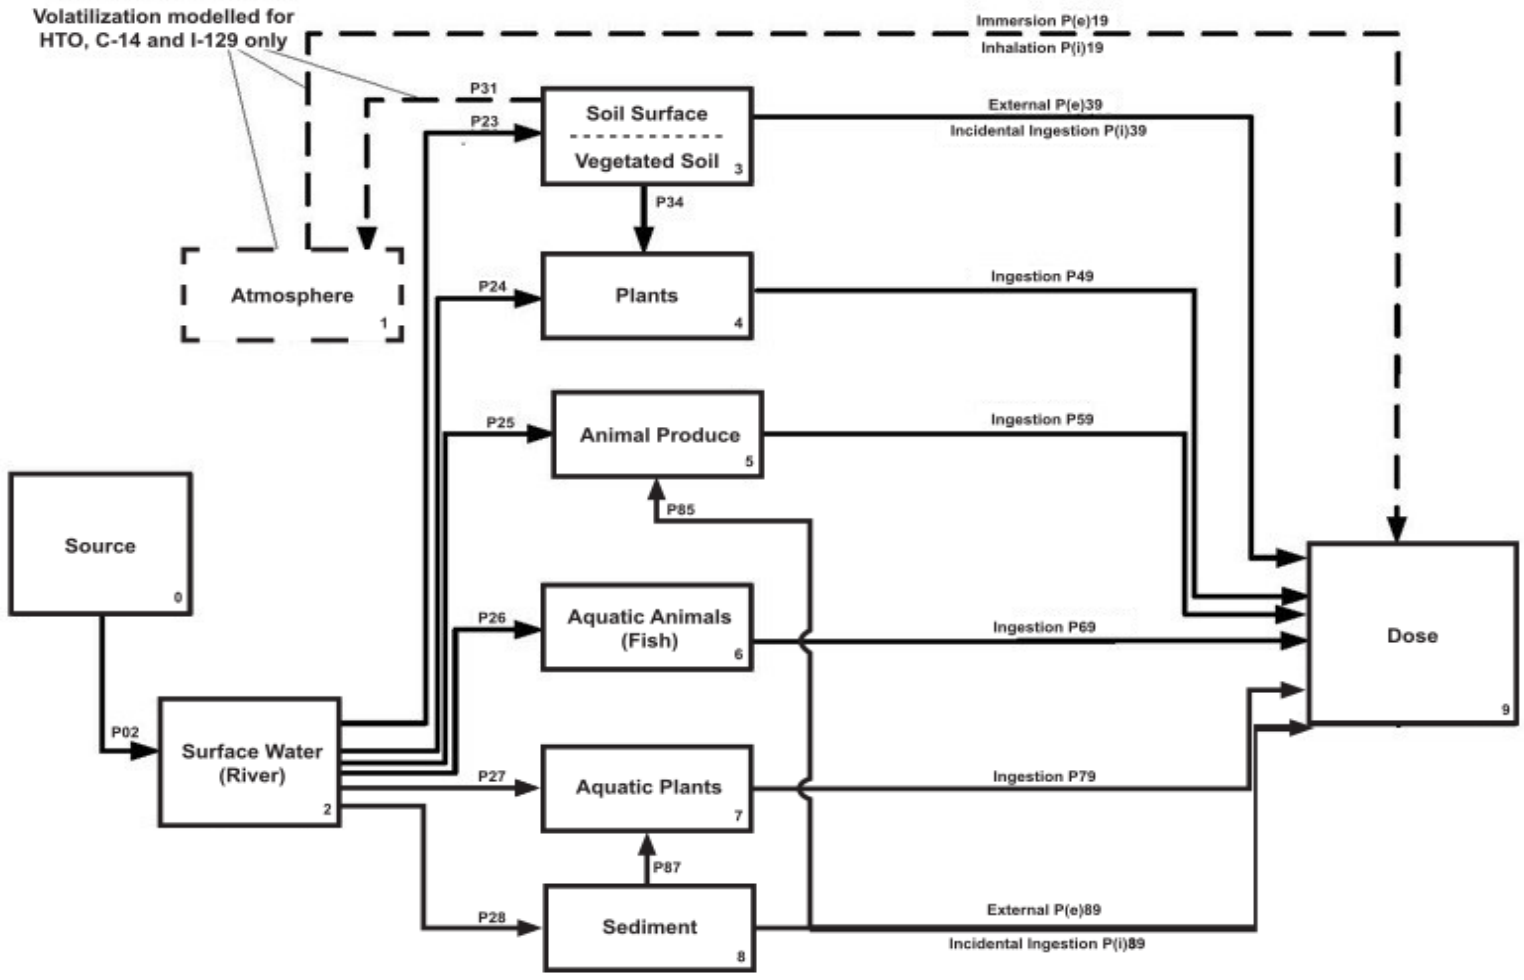

Note: Animal produce exposure to sediments is for waterfowl only.

Disruptive Scenarios

As described above for the Normal Evolution Scenario, the post-closure phase is not expected to result in airborne effluent, but groundwater releases to surface water may occur. Aquatic dispersion will carry contaminants to downstream locations on the Winnipeg River. Waterborne contaminants can partition to sediment. River water and sediment will be the primary exposure media. River water will also be used for irrigation. Pathways relevant to exposure to groundwater releases to surface water for the Disruptive Scenarios are presented for the human receptors in Table 6.7.1-12.

Table 6.7.1-12: Exposure Pathways for Receptors for Potential Exposure to Radiological and Non-Radiological COPCs during Post-closure- (Disruptive Scenarios)

	Receptor	Exposure Pathway	Environmental Media
Inadvertent Human Intrusion (Exploration Borehole)	On-site Worker (Driller) - 1 hr	Inhalation	■ Air

Model Software

An environmental transport and pathways model was used to evaluate the effects of contaminants on the local environment including human and ecological receptors. The software used for the exposure pathways analysis and for the calculation of radiological doses was IMPACT Version 5.5.1, which is consistent with the equations outlined in CSA N288.1-14 (CSA Group 2014) and the methods outlined in CSA N288.6-12 (CSA Group 2012). The Tool Qualification Report for IMPACT describes the verification and validation activities performed on IMPACT. A more detailed description of the model is provided in the ERA (EcoMetrix 2024).

6.7.1.7.2.2 Results

Normal Evolution Scenario

The public dose limit for radiation protection is 1 mSv/a, as described in the *Radiation Protection Regulations* (SOR/2000-203) under the *Nuclear Safety and Control Act*. This limit is defined as an incremental dose, and is set at a fraction of natural background dose. A dose constraint of 0.25 mSv/a was established for the public from all nuclides and all pathways for the Project (CNL 2016). The total radiation dose to human receptors during the post-closure phase are below the CNSC public dose limit of 1 mSv/a, as well as the dose constraint of 0.25 mSv/a. Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure of potential critical groups to radioactive releases from the WL site during post--closure.

The maximum dose was conservatively assessed at a single point in time, corresponding to the peak loading rate from groundwater to the Winnipeg River for each radionuclide. The total dose is presented in Table 6.7.1-13. However, to assess the total radiation dose for each identified human receptor over the groundwater modelling timeframe, a more realistic representation of predicted dose rate to human receptors over the post-closure phase from the Normal Evolution scenario is presented in Figure 6.7.1-8. The dose increases steadily with time, generally peaking around 1,000 years (due to contribution from carbon-14) after closure and is greatly reduced as time progresses. The exception is the 3-month old formula-fed infant where the dose peaks at the beginning of modelling and then again after 100,000 years. This is because the dose from tritium peaks towards the beginning of the modelling timeframe, and the dose from polonium-210 peaks after 100,000 years.

Table 6.7.1-13: Summary of Total Dose during the Post-closure Phase Human Health Valued Components

Age Group	Dose (mSv/a)								
	On-site Farm			Farm A			Harvester		
	Dose	Percent of Dose Constraint	Percent of Public Dose Limit	Dose	Percent of Dose Constraint	Percent of Public Dose Limit	Dose	Percent of Dose Constraint	Percent of Public Dose Limit
Adult	3.24×10^{-3}	1.30%	0.32%	3.35×10^{-4}	0.13%	0.03%	4.75×10^{-5}	0.02%	<0.01%
Child	3.25×10^{-3}	1.30%	0.33%	3.36×10^{-4}	0.13%	0.03%	3.05×10^{-5}	<0.01%	<0.01%
Infant (cow's milk)	4.23×10^{-3}	1.69%	0.42%	4.37×10^{-4}	0.17%	0.04%	2.00×10^{-5}	<0.01%	<0.01%
Infant (formula)	4.18×10^{-3}	1.67%	0.42%	4.36×10^{-4}	0.17%	0.04%	N/A	N/A	N/A
3 month old (nursing)	5.48×10^{-4}	0.22%	0.05%	1.04×10^{-5}	<0.01%	<0.01%	N/A	N/A	N/A
3 month old (formula)	3.65×10^{-6}	<0.01%	<0.01%	6.85×10^{-8}	<0.01%	<0.01%	N/A	N/A	N/A

Note:
A dose of 0.0025 mSv/a is equivalent to 1% of the dose constraint.
mSv/a = millisieverts per year; N/A = not available; <= less than.

As presented in Figure 6.7.1-9, the main contributors to total dose for the 3 month old nursing infant include tritium, carbon-14, neptunium-237, and polonium-210. The dose contribution from tritium is greatest at the beginning of modelling, then is dominated by carbon-14, until later in the modelling period where the main contributors to total dose are from neptunium-237 and polonium-210.

Figure 6.7.1-8: Dose Rate to Human Receptors from Normal Evolution Scenarios

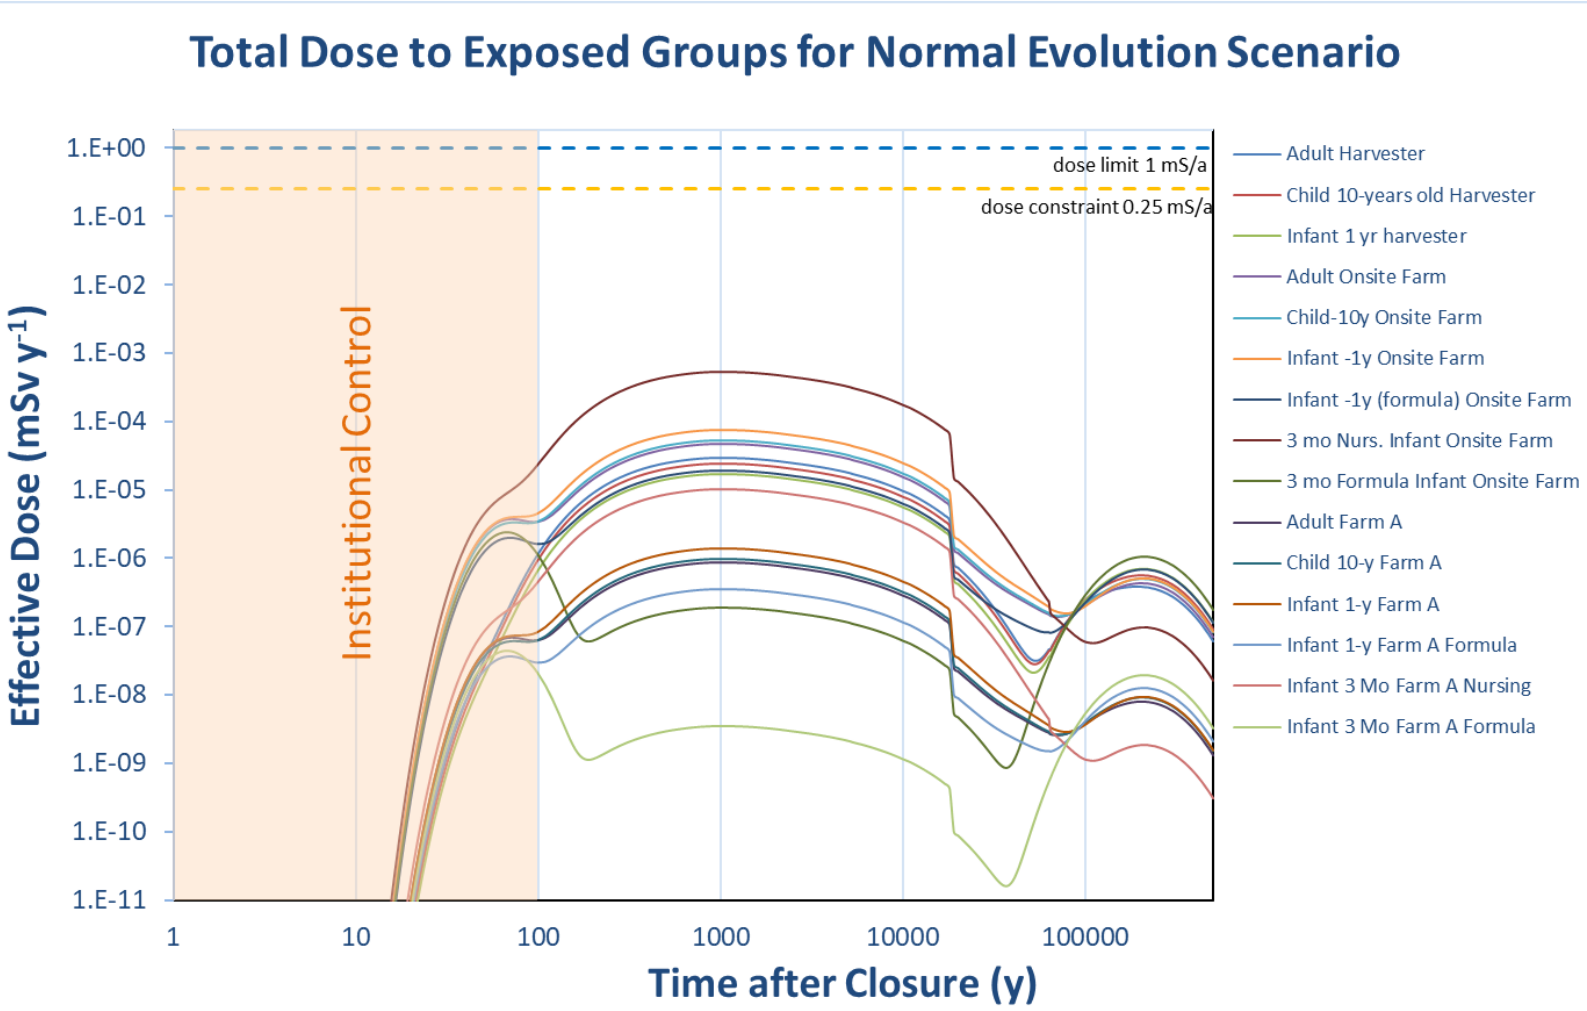

Figure 6.7.1-9: Estimated Contribution of Radionuclides to Total Dose of 3 Month Old Nursing Infant over the Post-Closure Phase Dose

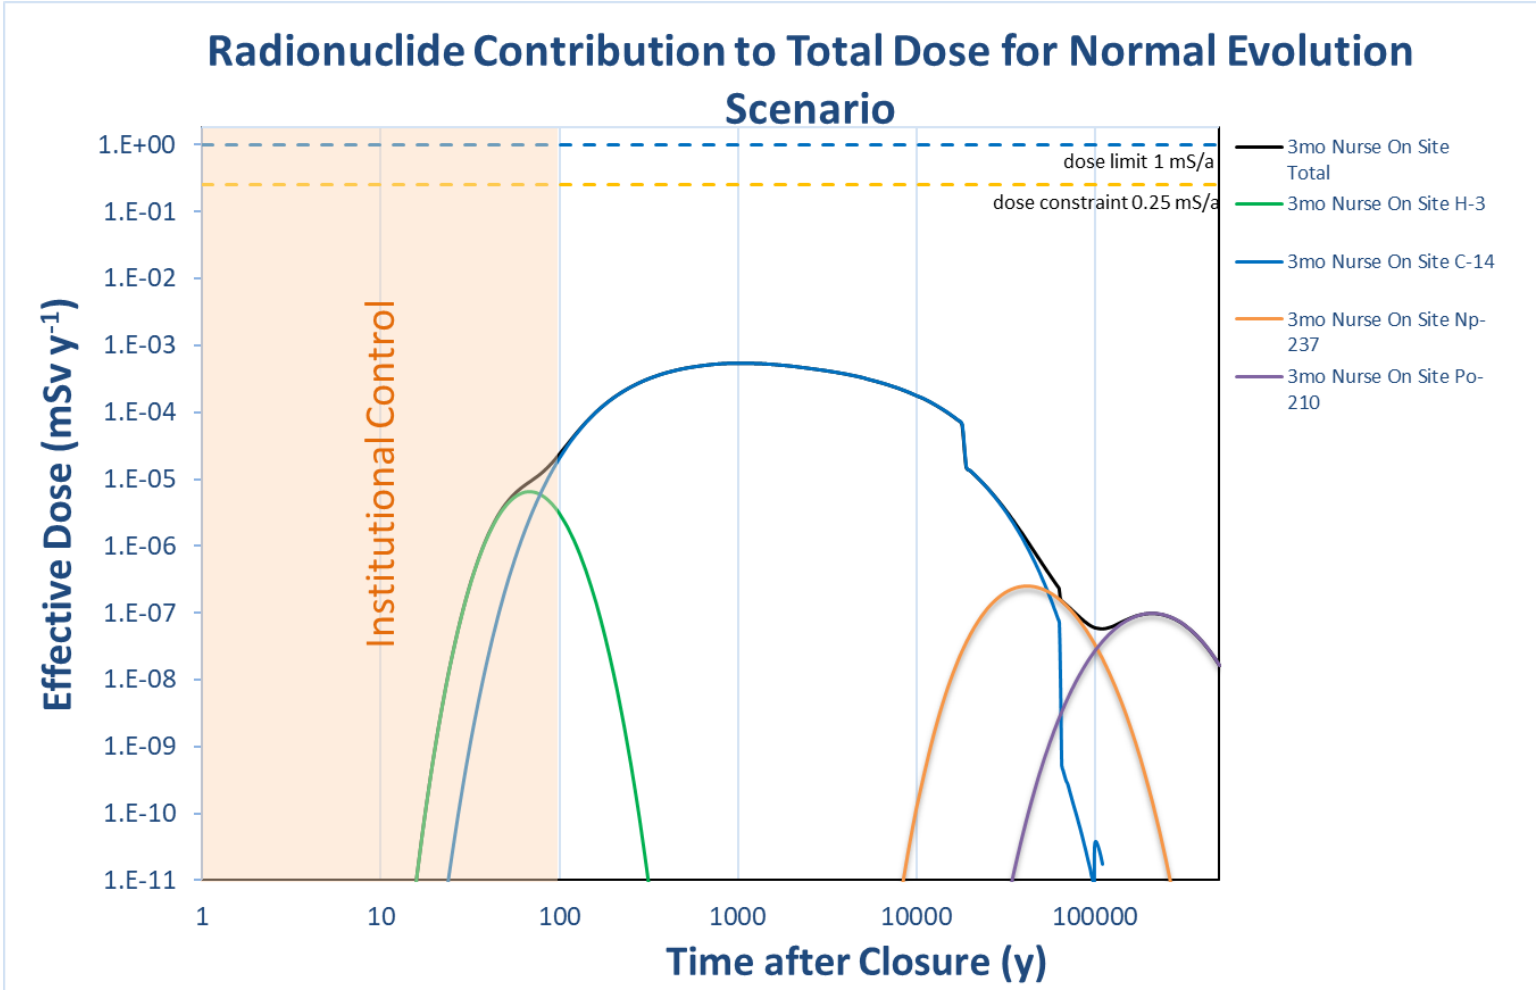

The dominant pathway for both the On Site Farm as well as for Farm A is from Cs-137 through external exposure to sediment for the adult and 10-year old child, from the existing background concentration of Cs-137 in sediment, and is not associated with the source term from the WRDF. Based on the source-term concentrations expected to be released to groundwater during post-closure of the WRDF, the dominant contributor to the total dose for most of the human receptors is carbon-14 through ingestion of terrestrial animals. The exception is for the 3-month-old drinking formula, which has tritium as the dominant contributor to dose. The total dose is based on maximum mass loadings for each radionuclide. For carbon-14, the time of maximum mass loadings to the Winnipeg River occurs at year 1,006.

The doses and HQs to human receptors that could be exposed to the non-radiological COPCs (i.e., cadmium and lead) in surface water during post-closure were calculated based on total concentration (existing background plus Project contribution) as well as Project contribution only (Table 6.7.1-14, Table 6.7.1-15, and Table 6.7.1-16).

Risk was quantified for the human receptor based on the calculation of a hazard quotient (HQ) by dividing the estimated exposure by a toxicity reference value (TRV) that is known to be protective. To account for uncertainty in pathways beyond Project activities it was determined that to be protective a benchmark HQ value of 0.2 per medium (e.g., water, soil, food, air) would be used for the assessment. This is consistent with the approach taken by Health Canada (2010) in their guidance on human health quantitative risk assessment.

The HQs for the Harvester are below the acceptable risk level of 0.2 for cadmium and lead for all pathways and age groups. The HQs for the On-Site Farm and Farm A are below the acceptable risk level of 0.2 for cadmium and lead for all pathways, except for lead from drinking water from the Winnipeg River – based on existing background concentrations of lead in the Winnipeg River. When only Project exposures are considered, the HQs for all receptors and all pathways are below the acceptable risk level of 0.2 for cadmium and lead. The Project contribution to the lead HQ for drinking water is 0.002%. This indicates that the Project contribution to the total HQ is negligible and any exceedance is from existing background concentrations of lead in the Winnipeg River.

Human Intrusion (Exploration Borehole)

For the occurrence of a human intrusion, the worst-case scenario was evaluated, which encompassed following the 100-year institutional control period, an unsealed borehole into the reactor and improperly disposed of material being left on top of the WRDF. The total dose to a drill crew member (adult exposed during drilling the borehole) was below both the lower 1 mSv/a IAEA reference level for Disruptive Events and the upper 20 mSv/a IAEA reference level for Disruptive Events. It was also considered that nearby residents could interact with the site following a human intrusion (Adult, child, infant and 3-month old assumed to be spending 1 hour a day on-site). The dose predictions for these human receptors were below both the upper (20 mSv/a) and lower (1 mSv/a) IAEA reference level for Disruptive Events (Table 6.7.1-17. The dominant contributor to the total dose is niobium-94 through groundshine (i.e., from the drilled material improperly disposed of on-site). Doses to the core transportation personnel and laboratory technicians were bounded by the dose calculations for the first two receptors as they would have a reduced exposure time.

Table 6.7.1-17: Summary of Total Radiological Dose for Nearby-Resident under Human Intrusion Conditions

Age Group	Dose (mSv/a)	Percent of Public Dose Limit (for Normal Evolution scenarios)	Percent of IAEA Reference Level for Disruptive Events
Adult	1.98×10^{-1}	20%	1%
Child	2.01×10^{-1}	20%	1%
Infant	3.19×10^{-1}	32%	2%
3-Month Old	2.86×10^{-1}	29%	1%
Driller	6.35×10^{-3}	1%	0%

mSv/a = millisieverts per year

The doses to human receptors that could be exposed to the non-radionuclides nuclides identified as potentially occurring at elevated concentrations (i.e., HB-40, lead) as a result of a human intrusion event occurring during post-closure were calculated based on total concentration (background plus Project contribution). The HQ for HB-40 exceeded the target values for both the adult and the toddler for soil ingestion and soil dermal contact (i.e., exposure as a result of material being improperly disposed of on-site). The HQ for lead exceeded the target values for the adult and the toddler through soil ingestion, soil dermal contact and dust inhalation (i.e., exposure as a result of material being improperly disposed of on-site) and was exceeded for the driller through soil ingestion and soil dermal contact. Hazard quotients are summarized in Table 6.7.1-18. HQs greater than 0.2 (per pathway) are not statistical probabilities of harm occurring. Instead, they are a simple statement of whether (and by how much) an exposure dose exceeds the reference dose.

The TRVs for HB-40 and lead incorporate safety factors to account for uncertainty, making the results conservative. The HB-40 TRV incorporates a safety factor of 1,000 and the lead TRV incorporates a safety factor of 2 (EcoMetrix 2024). The TRV for lead is from Health Canada (2021) and is considered provisional. The TRV recommended by Health Canada is 0.0005 mg/kg bw/day and is a risk-specific dose from the European Food Safety Authority. In this scenario, it was assumed that an exploration borehole was drilled through the engineered cover, grout, reinforced concrete, and WRDF from ground surface to bedrock. The waste emplacement strategy and design of the engineered cover is more robust than a typical hazardous waste landfill; therefore, the likelihood of installing an exploration borehole directly into the WRDF, as well as extruding the highest concentrations is low.

Table 6.7.1-18: Summary of Hazard Quotients for Human Intrusion Conditions

Age Group	Parameter	HQ by Pathway (unitless)			Total
		Soil Ingestion	Soil Dermal Contact	Dust Inhalation	
Adult	HB-40	**3.52**	**4.57×10^{-1}**	1.16×10^{-1}	**4.09**
	Lead	**8.18E+02**	**5.31E+01**	**2.69E+01**	**8.98E+02**
Toddler	HB-40	**2.05×10^{-1}**	**2.34×10^{1}**	5.40×10^{-2}	**4.93×10^{1}**
	Lead	**4.78E+01**	**2.72E+01**	**1.26E+01**	**8.75E+01**
Driller	HB-40	6.62×10^{-3}	7.55×10^{-2}	NA	8.21×10^{-2}
	Lead	**1.54E+00**	**8.78E+00**	**NA**	**1.03E+01**

Note:
Bold and shaded values indicate HQ greater than 0.2.

The assessment demonstrates that human intrusion into the WRDF, could result in exposures to human receptors to HB-40 and lead in waste material brought to the surface at levels where risk cannot be ruled out. As such, while this is a very unlikely worst-case scenario, reasonable effort is warranted to reduce the probability of these unplanned events from occurring. During the post-institutional control period, passive controls will still be in place including the limited footprint, the WRDF composition being relatively impervious and made of material of no economic value, and the land use restriction acting to reduce the likelihood of a human intrusion event.

WRDF Barrier Failure

The WRDF Barrier Failure Disruptive Event considers the potential for an uncontrolled release of contaminants from the WRDF into the geosphere. Specifically, the scenario considers a significant failure of the concrete foundation, or that the long-term performance of the foundation deteriorates rapidly due to unforeseen or underestimated physical, chemical, and/or biological processes. The source of exposure is due to a zone of increased permeability in a 2-m wide section (i.e., a fracture) spanning the full width of the containment barrier, and an elevated exposure to human and non-human receptors near the WL site to contaminated groundwater.

The WRDF Barrier Failure Disruptive Event was considered because the foundation was not originally designed as the primary containment barrier for an ISD facility. It is considered a containment barrier within the WRDF in the groundwater flow model based on its properties determined through the original design drawings and the building condition assessment carried out (Golder 2021). For this disruptive event to occur, a significant failure of large components or multiple smaller components of work planning, and execution must fail (e.g., failure to adhere to Quality Assurance programs when reviewing the condition of the existing foundation wall). This disruptive event could also be caused by a significant external event, such as a beyond design basis; earthquake that creates significant damage to the WRDF foundation.

This scenario was evaluated in the DSAR (Golder to demonstrate the importance of particular sources of uncertainty and provide meaningful illustration of future conditions to inform the Project design (Golder 2021). For modelling the scenario, a fracture was assumed in the foundation of the WR-1 Building (2 m wide, with hydraulic conductivity greater than the below bedrock) that will remain in place as a component of the WRDF. Exposure pathway characterization is the same as was modelled in the Normal Evolution Scenario, except that groundwater loadings to the surface water are based on an open fracture. As emissions from the WRDF are changed under a failure scenario, both the human and ecological receptors in the vicinity of the WL site could be affected. Predicted exposures for human and non-human biota were compared to relevant dose guidelines for both radiological and non-radiological contaminants of potential concern.

As a conservative assumption, the maximum dose after a hypothetical WRDF barrier failure was assessed at a single point in time; however, a more realistic representation of predicted dose rate to human receptors shows that the peak doses from each radionuclide occur at different times (Figure 6.7.1-8), and thus would not overlap in a cumulative dose (Golder 2021).

For the residents of an on-site farm (located on the WRDF site, Farm A (located near the east bank of the Winnipeg River) and Harvester receptors, the total radiation dose during the post-closure period during barrier failure scenario are well below the lower 1 mSv/a IAEA reference level and the upper 20 mSv/a IAEA reference level for Disruptive Events (Table 6.7.1-19). The farm residents are year-round, full-time residents, and the Harvester represents a Traditional user exposed through harvesting country foods spending part of their time on-site, near Farm A, and at an unexposed location.

Table 6.7.1-19: Summary of Post-closure Total Dose for Human Receptors under Barrier Failure Conditions

Age Group	On-Site Farm			Farm A			Harvester		
	Dose (mSv/a)	Percent of Public Dose Limit (for Normal Evolution scenarios)	Percent of IAEA Reference Level for Disruptive Events	Dose (mSv/a)	Percent of Public Dose Limit (for Normal Evolution scenarios)	Percent of IAEA Reference Level for Disruptive Events	Dose (mSv/a)	Percent of Public Dose Limit (for Normal Evolution scenarios)	Percent of IAEA Reference Level for Disruptive Events
Adult	3.24×10^{-3}	0.32%	0.02%	3.35×10^{-4}	0.03%	<0.01%	4.81×10^{-5}	<0.01%	<0.01%

Note:

1 millisievert per year (mSv/a) IAEA Lower Reference Level; 20 mSv/a IAEA Reference Level for Disruptive Events.

The risk to human receptors that could be exposed to the non-radiological contaminants potentially occurring at elevated concentrations (i.e., cadmium and lead) in surface water during post-closure were calculated based on total concentration (background plus Project contribution). Risk was quantified for the human receptor based on the calculation of a HQ by dividing the estimated exposure by a TRV that is known to be protective. To account for uncertainty in pathways beyond Project activities, a protective benchmark HQ value of 0.2 per medium was used for the assessment. This is consistent with the approach taken by Health Canada (2010) for human health quantitative risk assessment.

The HQs for the harvester are below the acceptable risk level of 0.2 for cadmium and lead for all ingestion pathways for the toddler and adult (Table 6.7.1-20). The HQs for the Farm A and the On-Site Farm are below the acceptable risk level of 0.2 for cadmium and lead for all pathways, except for lead from drinking water from the Winnipeg River (Table 6.7.1-21 and Table 6.7.1-22, respectively). The HQs for all receptors are based on background plus project exposure. If only the project contribution is considered, the HQs for the toddler and adult for the On-Site Farm and Farm A are well below the acceptable risk level of 0.2. Therefore, adverse effects to human receptors are not anticipated from WRDF Barrier Failure.

Table 6.7.1-20: Summary of Post-closure Hazard Quotients for Harvester Receptors under Barrier Failure Conditions

Human Type	Non-radionuclide	Total River Contribution					WRDF Barrier Failure Contribution				
		Ingestion of Fish	Ingestion of Wild Waterfowl	Ingestion of Moose	Ingestion of WeeKay	Total	Ingestion of Fish	Ingestion of Wild Waterfowl	Ingestion of Moose	Ingestion of WeeKay	Total

Well in Plume

Human habitation was considered not feasible until after the 100-year institutional control period ends. During institutional control, long-term monitoring and maintenance activities will occur to demonstrate compliance with the safety case assumptions; therefore, unplanned human habitation is unlikely during institutional control. Groundwater concentrations used to calculate radiological and non-radiological dose are based on mass loadings post 100 years of institutional control. Following cessation of the Institutional Controls, it was assumed that an on-site farm will be established at the WRDF site as part of the Normal Evolution Scenario. As part of the Well In Plume disruptive scenario, the farm has a water well drilled through the WRDF groundwater plume. This was considered an unlikely disruptive scenario due to the low-permeability soils surrounding the WRDF not being suitable for water extraction (Golder 2021).

For the residents of an on-site farm who drink groundwater, the total radiation dose during this disruptive event is below the IAEA reference level of 20 mSv/a for Disruptive Events for all receptors, but is above the IAEA lower reference level of 1 mSv/a for most receptors other than the infant who drinks cow's milk (Table 6.7.1-23). The dominant contributor to the total dose is from tritium through ingestion of water (i.e., drinking the groundwater). For carbon-14, the time of maximum mass loading to the Winnipeg River occurs in approximately 1,000 years.

Table 6.7.1-23: Summary of Total Dose for an On-site Farm from Well in Plume Post-Institutional Control (with Groundwater Consumption)

Age Group	Dose (mSv/a)	Percent of IAEA Lower Reference Level for Disruptive Events	Percent of IAEA Upper Reference Level for Disruptive Events
Adult	**2.54×10^{0}**	**254.00%**	12.70%
Child	**1.34×10^{0}**	**134.00%**	6.70%
Infant (cow's milk)	4.23×10^{-3}	0.42%	0.02%
Infant (formula)	**1.96×10^{0}**	**196.00%**	9.80%
3-month Old (nursing)	**3.29×10^{0}**	**329.00%**	16.45%
3-month Old (formula)	**4.02×10^{0}**	**402.00%**	20.10%

Note:
Bolded cells indicate exceedance of the lower IAEA reference level for Disruptive Events of 1 mSv/a .

The doses to human receptors that could be exposed to the non-radiological contaminants identified as potentially occurring at elevated concentrations (i.e., cadmium and lead) during post-closure were calculated based on total concentration (background plus Project contribution). Risk was quantified for the human receptor based on the calculation of a HQ using the same approach as described above for the Normal Evolution Scenario. The HQs derived for both cadmium and lead were well below the protective benchmark for all pathways other than groundwater ingestion (Table 6.7.1-24). A calculated HQ of 0.01 represents 5% of the HQ target value of 0.2. For non-radiological contaminants the HQ for cadmium and lead exceeded the target value for both the adult and toddler. HQs greater than 0.2 (per medium) are not statistical probabilities of harm occurring. Instead, they are a simple statement of whether (and by how much) an exposure dose exceeds the reference dose.

Table 6.7.1-24: Summary of Post-closure Hazard Quotients for Well in Plume Post-Institutional Control (with Groundwater Consumption)

Note:

Bold and shaded values indicate HQ greater than 0.2.

The assessment demonstrates that human habitation with groundwater use for drinking water could result in exposures to cadmium and lead at levels where risk cannot be ruled out. The TRV for lead incorporates a safety factor of 2 to account for uncertainty, making the results conservative (EcoMetrix 2024). While the TRV for cadmium does not incorporate a safety factor, the assessment is considered conservative as it assumes that the maximum concentrations of COPCs occur at the same time, where in reality maximum concentrations occur at different timeframes during post-closure.

During institutional control, long-term monitoring and maintenance activities will occur to demonstrate compliance with the safety case assumptions; therefore, a well in the groundwater plume is unlikely. Additionally, for a well situated in this area, the well capacity is too low and therefore, cannot be used for purposes other than drinking. This is supported by observations during routine groundwater sampling campaigns at boreholes on the WL site (i.e., inability to obtain sufficient groundwater for sampling in 2018 and 2019).

Overall, the failure of passive controls to prevent human intrusion into the WRDF and/or human habitation of the WRDF during the post-institutional control period (after 100 years) is conceivable; however, is unlikely. The assessment was conservatively conducted to predict exposures to human receptors under these unlikely future conditions.

6.7.1.8 Prediction Confidence and Uncertainty

6.7.1.8.1.1 Normal Evolution Scenario

The HHRA assumptions are conservative to accommodate inherent uncertainties in the modelling and meet the objective of protecting human health during the closure and post-closure phases. The conceptual model for human health is considered to be complete for the majority of general public exposures in the vicinity of the WL site. The selected receptors are expected to lead to conservative estimates of health risks. The selected exposure pathways are consistent with available guidance (e.g., CSA N288.1-14), and are expected to account for primary exposure pathways for human receptors in the area.

There is uncertainty in the estimated inventory of radioactive and non-radioactive material that could be present within the WR-1 Building. The estimated inventory of WR-1 and its associated systems were derived by two general methods; physical samples, and computer models. Computer models formed the basis of the inventory estimate and were supplemented by physical sample characterization data to fill gaps and validate model estimates. In all cases, the most conservative results of either the physical samples or computer models were used to derive the final inventory estimate. Each estimation method also included aspects of conservatism in their individual approaches, contributing further to the conservatism built into the final inventory estimate. This compounded conservatism is based on physical data specific to WR-1 and provides an appropriate level of realism to the estimate.

There is also uncertainty in how long each closure activity will take (e.g., how long it will take to grout the heavy water moderator system). As such, there is uncertainty in the COPC release rates to the atmosphere and geosphere. To address this uncertainty, appropriate assumptions are integrated into the model to provide an appropriate level of conservatism. For example, although the duration of demolition prior to grouting may be carried out in 1 to 2 months, it has been conservatively assumed that it will occur for 6 months. Prior to the execution of closure activities, system characterizations and radiological surveys will be completed to inform detailed work planning. This work will provide greater accuracy; however, it is expected that any variation would be well encompassed by the conservatism build into the model.

The IMPACT model was used to predict dose to identified human receptors during the closure and post-closure phases. The IMPACT model used is a steady state model; however, it includes time dependent equations to account for buildup in soil from irrigation, for all radionuclides released. It includes progeny buildup through use of progeny inclusive dose coefficients. Forty years of ingrowth was used to develop the progeny inclusive dose coefficients for each radionuclide, which is the timeframe is used in CSA N288.1-14 for development of progeny-inclusive dose coefficients for sediment and soil exposure. Exposure factors were based on best-available information from literature with preference for exposure factors identified in CSA N288.1-14. For parameters that did not have exposure factors in CSA N288.1-14, surrogate parameters were identified based on proximity in the periodic table, which is considered appropriate.

During the closure phase, there are uncertainties in the predicted radiological and non-radiological release rates to the atmosphere; however, the estimates are expected to be appropriate as they are based on best available information on existing inventory of radiological and non-radiological contaminants in WR-1. Conservative assumptions were made about duration of release (constant release at peak) and particulate release rates (highest release rates). Considering the conservatism in the estimation of releases, and in the air model, it is reasonable to conclude that doses arising from closure activities have not been underestimated.

A constant release at the peak time for each radionuclide over the modelling period during the post-closure phase was assumed, which is a conservative assumption. Within each time window, over the timeframe of the groundwater model, the doses from all radionuclides were summed, ensuring that all dose contributions were captured in the total dose. For each radionuclide, the highest release rate within the time window was assumed, which is also a conservative assumption. Considering the conservatism in the estimation of releases it is reasonable to conclude that doses arising from post-closure activities have not been underestimated.

The uncertainties from the exposure assessment include model uncertainty and uncertainty in the exposure factors selected. The uncertainties from the toxicity assessment include conservatisms built into the radiation dose constraint. Taken together, the approaches to exposure and toxicity assessment have ensured that the characterization of dose and risk has been undertaken in a manner that has not underestimated dose or risk.

6.7.1.8.1.2 Disruptive Events

The conservative assumptions used for the Normal Evolution Scenario also apply to the Disruptive Events (i.e., Human Intrusion, Well in Plume, and WRDF Barrier Failure). For the Human Intrusion Disruptive Event, the TRVs for HB-40 and lead incorporate safety factors to account for uncertainty, making the results conservative. Additionally, the human intrusion scenario is a very unlikely scenario based on worst-case assumptions, since it is unlikely someone would drill down to bedrock in the WRDF without realizing they were drilling through a facility.

For the Well in Plume Disruptive Event, the assessment is based on the assumption that the groundwater well is situated in the plume at the time of maximum loadings, which is a conservative assumption. In addition, the results are based on the conservative assumption that the on-site residents are exposed to the maximum groundwater concentrations for all COPCs in the plume at the same time. For the WRDF Failure Disruptive Event, the results are based on the conservative assumption that maximum loadings to the Winnipeg River occur at the same time for all COPCs. Considering the conservatism in the estimation of releases for each Disruptive Event, it is reasonable to conclude that doses arising from post-closure activities have not been underestimated.

6.7.1.8.1.3 Sensitivity Scenario – Fractured Geo-Pathway

The groundwater solute transport model for the Project was updated to expand the sensitivity analysis in consideration of the geo-pathway as a fractured bedrock pathway for the purposes of solute transport (i.e., advection and dispersion along the fractures, with diffusion into the rock matrix [WSP 2024]). The intent of the sensitivity analysis in the groundwater solute transport model was to explore model sensitivity to various input parameters, and the analysis does not necessarily reflect a plausible scenario. The total radiation dose to all human receptors during post-closure for the geo-pathway sensitivity scenario is predicted to be well below the regulatory public dose limit of 1 mSv/yr and the dose constraint of 0.25 mSv/yr (EcoMetrix 2024). Including background Cs-137, the maximum percent of public dose limit is 0.55% and the maximum percent of dose constraint is 2.2%. Overall, since the radiation dose estimates would be below the public dose limit and the dose constraint, no discernable health effects are anticipated due to exposure of these receptors to radioactive releases from the Project for the geo-pathway sensitivity analysis scenario (EcoMetrix 2024).

The HQs for the harvester, on-site farm, and Farm A are below the acceptable risk level of 0.2 for cadmium, chromium, and xylene for all pathways for the toddler and adult. The HQs for the harvester, on-site farm and Farm A are above the acceptable risk level of 0.2 for lead for ingestion of weekay for the harvester (toddler), and from drinking water from the Winnipeg River for the on-site farm (toddler and adult) and Farm A (toddler and adult) (EcoMetrix 2024). The HQs for all receptors are based on background plus Project exposure. If only the Project contribution is considered, all HQs for all receptors are well below the acceptable risk level of 0.2.

The dose is conservative as it is based on the maximum mass loadings for each COPC provided in the groundwater solute transport model. The maximum dose for each radionuclide was assessed at a single point in time, corresponding to the peak loading rate from groundwater to the Winnipeg River.

6.7.1.8.1.4 Sensitivity Scenario – Modified Well in Plume Disruptive Event

The on-site farm receptors were also evaluated based on a modification to the Well in Plume scenario from the DSAR to consider placement of a drinking water well at a distance closer than previously assumed downgradient of the WRDF. Consistent with the Well in Plume scenario in the DSAR, the focus is on human health because it is assumed that the on-site Farmer would obtain drinking water from a groundwater well in the groundwater plume from the WRDF. The maximum mass loadings from a well location at 100 m (Scenario 19) and 10 m (Scenario 20) were converted to groundwater concentrations using the anticipated flowrate through the bedrock pathway for the time period of maximum mass loadings (EcoMetrix 2024). To bound the assessment, the worst case loadings between the 100 m and 10 m distance were considered.

The maximum estimated total dose for on-site farm residents who drink groundwater from a well in the WRDF is estimated to be 2.44E+01 mSv/a for the new on-site farm (3-month-old who drinks formula) (EcoMetrix 2024). The main contribution to total dose is from Pu-240 and Pu-239 from drinking groundwater (the internal water pathway). Consistent with the DSAR, for disruptive events, a reference level ranging from 1 mSv/a to 20 mSv/a has been defined (IAEA 2011). The total radiological dose to the on-site farmer receptors that drink groundwater from a well in the plume from WRDF exceeds the lower IAEA reference level of 1 mSv/a for all receptors, except the nursing infant who drinks cow's milk (EcoMetrix 2024). All doses are below the upper IAEA reference level of 20 mSv/a for all receptors, except for the 3-month-old (formula) where the dose is 24.4 mSv/a.

The results are based on the conservative assumption that the on-site residents are exposed to the maximum groundwater concentrations for all COPCs in the plume at the same time. Realistically, predicted dose rates from individual radionuclides peak at different times over the post-closure phase. Therefore, considering only the contributions of radionuclides that peak at similar timeframes, the maximum dose to the 3-month old would be approximately 20 mSv/a (considering only Pu-239 and Pu-240) (EcoMetrix 2024).

For non-radionuclides, the hazard quotients for cadmium and lead exceed the target value for the adult and toddler, based on the drinking water pathway. Risk could not be ruled out for the on-site farm residents drinking groundwater in the plume of WRDF. The hazard quotients for cadmium and lead for all other pathways are below the target value (0.2 per medium) for both adult and toddler.

6.7.1.9 Residual Effects Classification and Determination of Significance

The residual effects analysis methods for the HHRA are different in some notable ways from those used by other VCs. Specifically, the assessment of potential effects to human health VCs results in the generation of risk factors that inherently consider the geographic extent, duration, frequency and other characteristics of the predicted changes to the environment that may result from Project activities. As such, these inherent attributes cannot be used to determine environmental significance, as they can with other components. Instead, significance for human health is evaluated based on: (i) the potential magnitude of the response, as indicated by the comparison to benchmarks and (ii) the degree of conservatism and uncertainty in the analysis.

Results of the radiological dose assessment for the closure and post-closure phases indicates that doses to human health VCs are below the CNSC public dose limit of 1 mSv/a, as well as the dose constraint for the Project of 0.25 mSv/a. The hazard quotients derived for constituents of potential concern were below the protective benchmark for all receptors and pathways, other than the river water drinking water pathway. If only the Project contribution is considered, the HQs are well below the protective benchmark for all receptors (the Project contribution to the total is 0.002% for lead). This indicates that the Project contribution to the total HQ is minimal and the exceedance is from existing background concentrations of lead in the Winnipeg River. Although uncertainties in the assessment exist, conservatism, such as using the highest release rates, has been included in the modelling so that residual effects are not greater than predicted. As such, residual effects are considered to be not significant for all human health VCs during the closure and post-closure phases.

For all Disruptive Events the total radiation dose to human receptors during the post-closure phase are below the IAEA Reference Level for Disruptive Events of 20 mSv/a. For exposure to non-radiological COPCs (i.e., cadmium and lead) the HQ exceeded the target values for some scenarios. However, the assessment was conservatively conducted to predict exposures to human receptors under these future unlikely conditions. Further, controls can be put in place to reduce the probability of the Disruptive Events (e.g., land use restrictions during post-institutional control period to reduce the likelihood of a human intrusion event).

6.7.1.10 Monitoring and Follow-up

As part of the CNL's licence (NRTEDL-W5-8.00/2024), environmental monitoring of the WL site is required. It is anticipated that for closure, the monitoring at the WL site and surrounding area will continue in accordance with CNL's existing Environmental Monitoring Program. This includes sampling and analysis of ambient air, surface water and groundwater, including the Winnipeg River, sediment, vegetation, garden produce, game animals and fish. CNL's Environmental Monitoring Program includes assessment of dose to members of the public, based on emissions monitoring and measurements in environmental media. Additionally, the dose to workers at WL site is monitored and reported to the CNSC annually. As decommissioning of the site proceeds, the environmental monitoring for the site is anticipated to evolve to reflect the creation, removal or limitation of hazards during the period of institutional control.

CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented, identify any unanticipated effects and provide for the implementation of adaptive management to limit these effects, if required. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program at the WL site, where practical.

The Environmental Assessment Follow-up and Monitoring Program for the Project will be undertaken during the closure and post-closure phases. Once the WL site has been decommissioned, monitoring to support institutional control will continue, as well as any other requirements identified in the Environmental Assessment Follow-up and Monitoring Program for the Project.

CNL has committed to working collaboratively with the First Nations and the Manitoba Métis Federation to support each Indigenous Nation to participate in environmental monitoring at the WL site. Some of the key elements of the initiative may include expansion and evolution of the monitoring program at WL, through incorporation of feedback, recommendations, Traditional Knowledge, capacity development, including training in environmental monitoring, and opportunities for monitors from each First Nation and the Red River Métis to collect samples on site and in the surrounding area. For example, CNL has had discussions with First Nations and the Manitoba Métis Federation on how future monitoring on the WL site could incorporate Indigenous interests, such as fish species of interest, and traditional knowledge. The goal of the initiative is to help address concerns regarding protection of the environment, health of people, confidence in the health of country foods and stigma associated with the Project.

It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS or Decommissioning Safety Assessment Report, including the findings from the Environmental Risk Assessment, the frequency of sampling may be increased and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized, or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals for modifications to the monitoring program, and the rationale for the modifications will be communicated to the CNSC prior to implementation.

The Environmental Assessment Follow-up and Monitoring Program for the Project will expand on the regulatory requirements of *CSA N288.5-22: Effluent Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2022) for the management of emissions from the Project. The Environmental Assessment Follow-up and Monitoring Program for the Project will be required to demonstrate compliance with the effective dose limit of 1 mSv/a for members of the public established by the *Nuclear Safety and Control Act* as well as the WL site public dose limit of 0.25 mSv/a. For a comprehensive summary of the monitoring and follow-up recommendations made based on the results of the environmental assessment refer to Section 11.0 Summary of Monitoring and Follow-up Programs. The monitoring a follow-up programs for human health are outlined in Table 6.7.1-25.

Table 6.7.1-25: Monitoring and Follow up Programs for Human Health

Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Human Health	**Potential Source(s) of Effects:** ■ Closure activities will result in the release of airborne effluent from the WR-1 Building which could affect human health. ■ Release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time during the post-closure phase may cause changes in groundwater quality which could migrate towards the Winnipeg River and affect receptors along the Winnipeg River. **Proposed Monitoring:** ■ Monitoring for air quality as noted above (i.e., for dust, gross alpha, beta and gamma radiation monitoring of the filters). ■ Verification monitoring for tritium in air (post venting through the WR-1 stack). ■ Passive tritium in air network monitoring (semi-annual change out) will be included as part of the Environmental Assessment Follow-up and Monitoring Program for the Project. Monitoring locations (approximately 4 of them) will be selected to be within the main upriver and downriver windrose sectors, at the site boundary and on-site mainly to monitor airborne tritium plumes potentially originating from the WRDF. ■ Estimate combustible gases (e.g., based on project-related traffic and equipment), as per atmospheric environment above; ■ Monitor contaminants of concern (e.g., lead, asbestos, tritium) in air displaced from grouting the below-grade structure, as per the atmospheric environment above. ■ Groundwater monitoring surrounding the WRDF, as noted above. ■ Surface water quality monitoring in the Winnipeg River, as noted above. **Trigger for Further Action:** ■ Investigation if parameters are above applicable guidelines identified.	■ Verify effects predictions related to air quality, groundwater quality and surface water quality to confirm no health effects are anticipated as a result of exposure to COPCs from the Project. ■ Verify mitigation is effective.	■ Dust monitoring would be carried out during the closure phase. ■ WL currently conducts industrial hygiene assessments of lead, asbestos and mould within facilities as part of the decommissioning planning process. ■ Monitoring of tritium in air will be initiated when the stack monitoring system is discontinued. This monitoring would be on-going during post-closure. The need for and duration of monitoring will be assessed based on annual review of monitoring data. ■ Groundwater and surface water quality monitoring would be on-going during closure and post-closure. The need for and duration of monitoring will be assessed based on an annual review of monitoring data.	■ Air quality monitoring for the Project will be captured through the implementation of CNL's WL Effluent Verification and WL Environmental Monitoring Programs. ■ Groundwater monitoring for the Project will be integrated into the overall CNL WL Groundwater Monitoring Program. ■ Surface water monitoring in the receiving environment is already completed through CNL's WL Environmental Monitoring Program. No new surface water quality monitoring is proposed for the Project.

This page intentionally left blank

6.7.1.11 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). The HHRA focused on public health and the health of on-site workers not involved in performing closure activities. Assessment endpoints are qualitative expressions used to assess the significance of residual effects on human health VCs and represent the key properties of the VCs that should be protected for future human generations (i.e., incorporates sustainability). The assessment endpoint is the protection of human health. Measurement endpoints represent properties of the environment, that when changed, could result in or contribute to an effect on an assessment endpoint. Measurement endpoints for the human health assessment include changes in air quality, groundwater quality and surface water quality.

The receptors for the HHRA were selected to be appropriate for assessment of both radiological and non-radiological stressors on human health. Off-site members of the public will potentially be exposed to low levels of airborne contaminants from decommissioning of the WR-1 Building. The most-affected off-site members of the public are defined as the “critical group” which include:

- Farm A and Farm F (year-round occupants, with livestock) for closure and post-closure;
- On-site Farm (post-closure); and
- Harvesters for closure and post-closure.

For the closure phase, the relevant COPCs are expected to be released via atmospheric releases from the WR-1 Building as reactor systems are dismantled, transported off-site or entombed within the WRDF. It has been assumed that the WR-1 Building stack is removed during the closure phase; therefore, atmospheric releases are assumed to occur at ground level. Doses to workers will be monitored and managed as part of CNL’s Radiation Protection Program. The application of the Radiation Protection Program provides that exposures will be kept ALARA and below the effective dose limit of 100 mSv over 5 years, and below 50 mSv in any single year.

An environmental transport and pathways model was used to evaluate the effects of contaminants on the local environment including human receptors. The calculated radiological doses for all human receptors in the candidate critical groups are all below the CNSC public dose limit of 1 mSv/a, as well as the dose constraint for the Project of 0.25 mSv/a limit for the Project. Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure to radioactive releases from Project activities. For the closure phase, all predicted air concentration for non-radiological COPCs were below their relevant ambient air quality criteria; therefore, no non-radiological COPCs were identified for the closure phase and no health effects are anticipated as a result of airborne effluents from the Project.

The closure activities are well encompassed by existing engineering and administrative controls currently in place at the WL site. Although there are some uncertainties to be defined (e.g., exact quantities of hazardous substances), the existing programs and procedures can be applied to manage these potential hazards. Proven operational programs will be in effect ensuring worker doses are below regulatory criteria and are ALARA.

The total radiation dose to human receptors during the post-closure phase are below the CNSC public dose limit of 1 mSv/a, as well as the dose constraint for the Project of 0.25 mSv/a. Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure of potential critical groups to radioactive releases from the WL site during post-closure.

The doses to human receptors that could be exposed to the non-radiological COPCs (i.e., cadmium and lead) in surface water during post-closure were calculated based on total concentration (background plus Project contribution). Risk was quantified for the human receptor based on the calculation of a HQ by dividing the estimated exposure by a toxicity reference value TRV that is known to be protective. The HQs were compared to a benchmark HQ of 0.2, which is consistent with approach taken by Health Canada (2010) in their guidance on human health quantitative risk assessment. The HQs derived for COPCs were below the protective benchmark for all receptors and pathways, other than the river drinking water pathway, and ingestion of weekay for the Harvester. If only the Project contribution is considered, the HQs are well below the protective benchmark, indicating the Project contribution to the risk is minimal. Although uncertainties in the assessment exist, conservatism, such as using the highest release rates, has been included in the modelling so that residual effects are not greater than predicted.

A key concern of Indigenous peoples was effects to the health of harvesters from consuming fish, plants, and wildlife in the vicinity of the WL site. Overall, residual effects from radiological and non-radiological COPCs are considered to be not significant for all human health VCs, including harvesters, during the closure and post-closure phases.

Three Disruptive Events were also assessed to address uncertainties that arose during the definition of scenarios and conceptual models. These were:

- Inadvertent Human Intrusion: an exploration borehole drilled into the WRDF and exposure of wastes;
- Substantial Failure of In Situ Decommissioning Structure (WRDF Barrier Failure); and
- Well in Plume: an on-site resident drinking groundwater from a well capturing the plume from the WRDF.

For all Disruptive Events the total radiation dose to human receptors during the post-closure phase are below the IAEA Upper Reference Level for Disruptive Events of 20 mSv/a. For exposure to non-radiological COPCs (i.e., cadmium and lead) the HQ exceeded the target values for some scenarios. However, the assessment was conservatively conducted to predict exposures to human receptors under these future unlikely conditions. Further, controls can be put in place to reduce the probability of the Disruptive Events (e.g., land use restrictions during post-institutional control period to reduce the likelihood of a human intrusion event).

The total radiation dose to all human receptors during post-closure for the fractured geo-pathway sensitivity scenario is predicted to be well below the regulatory public dose limit of 1 mSv/yr and the dose constraint of 0.25 mSv/yr. The HQs for all receptors are based on background plus Project exposure. If only the Project contribution is considered, all HQs for all receptors are well below the acceptable risk level of 0.2. Overall, since the radiation dose estimates would be below the public dose limit and the dose constraint, no discernable health effects are anticipated due to exposure of these receptors to radioactive releases from the Project for the fractured geo-pathway sensitivity analysis scenario.

The total radiological dose to the on-site farmer receptors that drink groundwater from the modified well in the plume scenario exceeds the lower IAEA reference level of 1 mSv/a for all receptors, except for the 3-month-old. For non-radionuclides, the hazard quotients for cadmium and lead exceed the target value for the adult and toddler, based on the drinking water pathway; therefore, risk could not be ruled out for the on-site farm residents drinking groundwater in the plume of WRDF. However, the assessment was conservatively conducted to predict exposures to the on-site farmer under these unlikely conditions.

Indigenous peoples have interest in the current and future monitoring proposed for the Project. CNL will implement an Environmental Assessment Follow-up and Monitoring Program for WR-1 to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as identified for other environmental components to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical.

As part of CNL's licence (NRTEDL-W5-8.00/2024), environmental monitoring of the WL site is required. It is anticipated that for closure, the monitoring at the WL site and surrounding area will continue to proceed in accordance with CNL's existing Environmental Monitoring Program. This includes sampling and analysis of ambient air, surface water and groundwater, including the Winnipeg River, sediment, vegetation, garden produce, game animals and fish. These activities will verify effects predictions for human health.

6.7.2 Ecological Health

6.7.2.1 Scope of the Assessment

The scope of the assessment focuses on summarizing the potential health effects to non-human biota (plants and animals) from Project activities. The general approach to ISD involves permanently encasing with grout the below-grade WR-1 systems. In situ disposal is a permanent, passive decommissioning end state. The decommissioning activities proposed as part of the Project include:

- preparation for ISD;
- grouting of below-grade structures and systems;
- removal of above-grade WR-1 Building;
- installation of a concrete cap and engineered cover over the WRDF;
- final site restoration;
- preparation of institutional control; and
- institutional control.

The above-grade structures will be demolished and removed using traditional demolition methods. During decommissioning, equipment from the PHT system that is currently located on the ground-level reactor floor will be placed below-grade for ISD. The above-grade structures will be demolished and removed using traditional demolition methods. A concrete cap and engineered cover will then be constructed over the below-grade structure (refer to Section 3.5 for more detail) and the Project site will be regraded and reclaimed. The end state of the Project (i.e., after the WR-1 Building is demolished, grouted and covered with a concrete cap and engineered cover) is referred to as the WRDF. Environmental monitoring will be completed to confirm that the WRDF is functioning as intended in the long-term (see Section 11.0 Summary of Monitoring and Follow-up Programs).

The ecological health risk assessment (EcoRA) follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment is completed in the following steps:

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Section 6.7.2.3 Valued Components and Section 6.7.2.4. Assessment Boundaries) for the EcoRA. The VCs, assessment endpoints and measurement indicators used to assess Project related changes to ecological health, the spatial and temporal boundaries at which the assessment occurred and the assessment cases considered are described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.7.2.5 Description of the Existing Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current environmental pressures that have shaped the observed patterns in the environment (i.e., natural variation).

- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.7.2.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect ecological health are identified and mitigation options to limit or avoid effects are presented. A pathways analysis is then used to focus on key interactions between the Project and ecological health by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded to further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects to ecological health after incorporating mitigation are carried forward to Step 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis** (refer to Section 6.7.2.7 Residual Effects Analysis). This section outlines the methods used to predict and characterize residual effects to ecological health from primary effect pathways. The analysis results are also presented including the characterization of: (i) residual incremental effects of the Project and the effects of the Project in combination with past and present developments on ecological health (Application Case); and (ii) residual effects of the Project in combination with past and present developments, as well as other reasonably foreseeable developments (Reasonably Foreseeable Development [RFD] Case). A key outcome of this section is the predicted effects to ecological health that are passed on to other VCs for inclusion in their assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty** (refer to Section 6.7.2.8 Prediction Confidence and Uncertainty). Evaluate the available literature, data and models used for the assessment and describe the level of certainty that can be placed on predicted residual effects. This section will also identify how the uncertainty has been managed so that the effects are not underestimated.
- **Step 6 – Classify and determine the significance of the predicted residual effects** (refer to Section 6.7.2.9 Residual Effects Classification and Determination of Significance). Residual effects predicted from primary pathways are classified using a common set of criteria: direction, magnitude, geographic extent, duration, reversibility, frequency and likelihood. A determination of the significance of the predicted residual effects of the Project on ecological health is made. Relative to other sections, the EcoRA uses a slightly different approach to the classification of residual effects and evaluation of significance, because several of the criteria (e.g., geographical extent, duration, frequency and reversibility) are already incorporated into the risk estimates and, therefore, are not independent variables.
- **Step 7 – Identify monitoring and follow-up** (refer to Section 6.7.2.10 Monitoring and Follow-up) required to confirm effect predictions and address uncertainty.
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.7.2.11 Conclusions) of residual effects on ecological health.

6.7.2.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the human health risk assessment are summarized in Table 6.7.2-1. These concerns were gathered through direct engagement and through the analysis of the array of studies provided to CNL. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4 Indigenous Engagement. Specific interests and concerns from each community are consolidated in Section 4 Appendices.

Table 6.7.2-1: Summary of Issues Raised During Engagement Activities Related to the Ecological Health Risk Assessment

Interest and Concern	Inclusion Status	Additional information and Rationale
Health of the Environment ■ Long-term effects of the Project on water quality ■ Accumulation of contaminants in fish over time ■ Long-term health effects of the Project on plants and wildlife important to Indigenous people ■ Concern that communities have seen changes to the health of the animals they harvest ■ Animals may cross the barriers and come into contact with hazardous materials	Encompassed by the initial environmental assessment Moose was added as a VC to the Ecological Health Assessment	Potential changes in ecological health considered a broad suite of ecological valued components, including a number of fish, plant and wildlife species (see Section 6.7.2.3). Effects on fish, plants, and wildlife health are assessed in Section 6.7.2.7 Residual Effects Analysis. A summary of concerns and observations of Indigenous Nations on the changes to the health of animals is provided in Section 6.6.5.7 Traditional Knowledge. During closure, sensory disturbance (noise, equipment use, presence of humans) is anticipated to deter wildlife from the active work area (see Section 6.6.6 Project Interactions and Mitigation)
Monitoring ■ Current monitoring practices ■ Future monitoring practices	Encompassed by the initial environmental assessment	Information on the current monitoring program at the WL site is described in Section 6.7.1.5 Description of the Environment. Information on the monitoring program for the Project is available in Section 6.7.2.10 Monitoring and Follow-up.

6.7.2.3 Valued Components

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). It is generally an impractical task to assess the effect of radiological and non-radiological emissions on all the species of biota within a natural ecosystem, and specifically within the ecosystem around the WL site. Therefore, representative organisms are chosen for dose and risk analysis. These organisms are selected because they are known to exist on the site, and are representative of major taxonomic groups or exposure pathways, or have a special importance or value. CNL verified the list of important species identified by each Indigenous community to confirm that each was adequately represented by the selected representative organisms. Based on feedback from Indigenous peoples during engagement activities, moose was added as a VC to the ecological health assessment given the species importance to Indigenous people.

During closure, the focus is on terrestrial VCs because releases are only expected via atmospheric pathways. During post-closure phase, the focus is on aquatic and riparian VCs, because releases are only expected via groundwater to surface water pathways. Valued components and rationale for their selection for the EcoRA are provided in Table 6.7.2-2.

Table 6.7.2-2: Valued Components for the Ecological Health Risk Assessment

Category	Valued Component	Rationale
Closure Phase		
Terrestrial Invertebrates	Earthworm	Detritivore. Exposure to atmospheric release through soil.
Terrestrial Birds	American Robin	Observed on-site. Exposure to atmospheric release through the ingestion of soil invertebrates. A surrogate for insect eating birds including various Species at Risk under COSEWIC, ESEA or SARA.
	(Prairie) Loggerhead Shrike	Historically observed on-site. Exposure to atmospheric release through the ingestion of soil invertebrates, small mammals and birds. Identified as a Species at Risk under COSEWIC, ESEA or SARA. A surrogate for other predatory birds identified as Species at Risk under COSEWIC, ESEA or SARA.
Terrestrial Plants	Grass and shrubs	Present on-site. Exposure to atmospheric release through soil. Food source for other VCs.
	Berries	Present in the area. Exposure to atmospheric release through soil. Food source for VCs.
Terrestrial Mammals	Meadow Vole	Common in the area. Exposure to atmospheric release through ingestion of terrestrial plants. A food source for VCs.
	Common Shrew	Common in the area. Exposure to atmospheric release through ingestion of soil invertebrates. A food source for VCs.
	Snowshoe Hare	Common in the area. Exposure to atmospheric release through ingestion of terrestrial plants. A game species.
	White-tailed Deer	Common in the area. Over winters on-site. Exposure to atmospheric release through ingestion of terrestrial plants. A game species. An important game species for Traditional Communities.

Table 6.7.2-2: Valued Components for the Ecological Health Risk Assessment

Category	Valued Component	Rationale
Closure Phase		
Terrestrial Mammals	Red Fox	Common in the area. Exposure to atmospheric release through the ingestion of small mammals and birds. A surrogate for the Grey Fox identified as a Species at Risk under COSEWIC, ESEA or SARA.
	Little Brown Myotis	Bats detected during acoustic surveys at WL site. Exposure to atmospheric release through ingestion of soil invertebrates. Exposure to aquatic release through ingestion of aerial stages of benthic invertebrates. Identified as a Species at Risk under COSEWIC and SARA. A surrogate for other bats identified as Species at Risk under COSEWIC, ESEA or SARA.
Post-closure Phase		
Terrestrial Birds	Barn Swallow	Observed on-site. Exposure to aquatic release through ingestion of aerial stages of benthic invertebrates. Identified as a Species at Risk under COSEWIC, ESEA or SARA. A surrogate for aquatic insect eating birds including various Species at Risk under COSEWIC, ESEA or SARA.
Terrestrial Mammals	Little Brown Myotis	Bats observed roosting in forested areas of the WL site. Exposure to atmospheric release through ingestion of soil invertebrates. Exposure to aquatic release through ingestion of aerial stages of benthic invertebrates. Identified as a Species at Risk under COSEWIC, ESEA and SARA. A surrogate for other bats identified as Species at Risk under COSEWIC, ESEA or SARA.
	Moose	Present on-site to a limited extent. Identified as a game animal of interest for some Indigenous Nations. Exposure to aquatic release through ingestion of aquatic plants.
Fish	Carmine Shiner	Present in the Winnipeg River. Exposure to aquatic release through surface water and sediment. Identified as a Species at Risk under COSEWIC, ESEA or SARA. Small-bodied forage fish. A food source for other VCs.
	Lake Sturgeon	Present in the Winnipeg River. Exposure to aquatic release through surface water and sediment. Identified as a Species at Risk under COSEWIC, ESEA or SARA.
	Walleye	Present in the Winnipeg River. Exposure to aquatic release through surface water. A sport fish. A surrogate for other pelagic fish in the Winnipeg River such as Northern Pike and Mooneye.
Aquatic Plants	Aquatic Plants	Present in the Winnipeg River. Exposure to aquatic release through surface water. Food source for other VCs.
Aquatic Invertebrates	Benthic Invertebrate	Present in the Winnipeg River. Exposure to aquatic release through surface water and sediment. Food source for other VCs.
Riparian Birds	Horned Grebe	Present in the area. Exposure to aquatic release through ingestion of water and fish. Identified as a Species at Risk under COSEWIC, ESEA or SARA. Food source for other VCs. Surrogate for other important species such as the common loon and red-necked grebe.
	Trumpeter Swan	Observed on-site. Exposure to aquatic release through ingestion of water and aquatic plants. Identified as a Species at Risk under COSEWIC, ESEA or SARA.
	Mallard	Representative of waterfowl. Exposure to aquatic release through ingestion of water, aquatic plants and benthic invertebrates. Food source for other VCs and human receptors.
Riparian Mammals	Mink	Present in the area. Exposure to aquatic release through ingestion of water, waterfowl and fish.

COSEWIC = Committee on the Status of Endangered Wildlife in Canada; ESEA = Manitoba's *Endangered Species and Ecosystems Act*; SARA = *Species at Risk Act;* VC = valued component.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future human generations (i.e., incorporates sustainability). Measurement endpoints represent properties of the environment, that when changed, could result in or contribute to an effect on an assessment endpoint. The measurement endpoints for the ecological health assessment are outlined in Table 6.7.2-3. The ecological health section draws on many other assessments within the EIS (e.g., air quality).

Table 6.7.2-3: Assessment Endpoints and Measurement Indicators for the Ecological Health Risk Assessment

Valued Components	Assessment Endpoint	Measurement Indicator
Terrestrial Invertebrates (Earthworm)	Viability of Populations	■ Changes to air quality ■ Changes to groundwater quality ■ Changes to surface water quality ■ Changes to soil quality ■ Changes to vegetation quality
Terrestrial Birds (American Robin, Loggerhead Shrike, Barn Swallow)		
Terrestrial Plants (Grasses, shrubs, berries)		
Terrestrial Mammals (Meadow Vole, Common Shrew, Snowshoe Hare, White-Tailed Deer, Red Fox, Moose, Little Brown Myotis)		
Aquatic Plants		■ Changes to air quality ■ Changes to groundwater quality ■ Changes to surface water quality ■ Changes to sediment quality
Aquatic Invertebrates (Benthic Invertebrates)		
Fish (Carmine Shiner, Lake Sturgeon, Walleye)		
Riparian Birds (Horned Grebe, Trumpeter Swan, Mallard)	Viability of Populations	■ Changes to air quality ■ Changes to groundwater quality ■ Changes to surface water quality ■ Changes to sediment quality ■ Changes to soil quality ■ Changes to vegetation quality
Riparian Mammals (Mink)		

Viability of Populations is evaluated in the ERA by estimating VC exposures for the COPC and comparing those to benchmarks that are protective of growth, survival and reproduction. COPCs are further defined in Section 6.7.2.7.1 and 6.7.2.7.2.

6.7.2.4 Assessment Boundaries

6.7.2.4.1 Spatial Boundaries

In order to assess the potential effects of the Project on ecological health, an appropriate spatial boundary was defined, with consideration given to locations where VCs could be affected by Project activities directly or where they could be indirectly affected by interacting with other aquatic and terrestrial VCs affected by Project activities (Figure 6.7.1-1).

- **Site Study Area (SSA):** is the WR-1 Building and represents the Project footprint (i.e., where project activities will be undertaken). The size of the SSA is approximately 0.07 ha.

- **Local Study Area (LSA):** is defined as the area within which there is potential for measurable changes to measurement indicators resulting from the proposed Project activities. The LSA was adapted from the surface water RSA and is designated to include receptors from both the HHRA and EcoRA. Therefore, the south boundary of the LSA extends from the west shore of the Winnipeg River to the east fence on the property line about 400 m north of Provincial Highway 211. The eastern boundary of the LSA follows the fence on the property line to the north property line. The north boundary follows the north fence on the property line about 1.6 km and then turns north for about 400 m before turning west and extending to the west side of the Winnipeg River. The west boundary follows the west bank of the Winnipeg River for about 1.5 km and then turns west for 370 m, north for 1.4 km and then turns east for 630 m to the west side of the Winnipeg River. The LSA has an approximate size of 4,174 ha.
