- **Regional Study Area:** is defined as the area within which the potential effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. The RSA was adapted from the air quality study area and is defined as a 12 km by 12 km rectangle surrounding the LSA.

6.7.2.4.2 Temporal Boundaries

The temporal boundaries of the assessment are the timeframe during which Project activities are actively occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effect is predicted to last so far into the future that the duration cannot be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of ISD, which includes preparation for ISD, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2030.
- **Post-closure Phase:** The post-closure phase has two discrete periods: institutional control and post institutional control. Institutional control is estimated to be at least 100 years during which long-term monitoring and maintenance activities will continue to demonstrate WRDF performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.7.2.4.3 Assessment Cases

The assessment cases considered for ecological health include the Base Case, Application Case and the Reasonably Foreseeable Development (RFD) Case:

- **Base Case:** represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, hydro-electric dams, transportation, agricultural, mining and residential and recreational development. Current effects from the existing WL facilities and operations, for example, are considered part of the Base Case. In addition, effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case. The base case is represented in the assessment by baseline air quality (Section 6.2.1.5 Description of the Environment) and surface water quality (Section 6.4.2.5 Description of the Environment); for guidelines that limit total exposures, the Project contribution and background are included.
- **Application Case**: represents the effects of the Base Case combined with predicted effects from the Project. The Application Case includes post-closure activities, and therefore, the associated effects during the post-closure phase of the Project represent the bounding case.

RFD Case: represents the predictions of the cumulative effects of the Application Case, plus projects that are currently under application review or that have officially entered a regulatory application process and which overlap with the ecological health RSA. There are no RFDs expected in the RSA other than the continued decommissioning of the remaining WL facilities, as the CSR (AECL 2001). The CSR indicated that no decrease in water quality is expected and effluent emissions to the Winnipeg River are expected to decline following decommissioning. Results of the assessment concluded that no effect on aquatic species is expected as doses were below the limit at which no effects on aquatic populations is expected. Current effects from the existing WL facilities and operations are considered part of the Base Case (i.e., existing conditions). Consequently, cumulative effects of the Base Case and the potential effects from the Project are evaluated in the Application Case. As such, an RFD Case is not applicable to the EcoRA and is not further discussed (Table 6.7.2-4).

Table 6.7.2-4: Reasonably Foreseeable Developments considered in the Ecological Health Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes ISD of the low-level waste trenches).	2016 to 2034	Yes – however, effects are evaluated as part of the Application Case
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – however, effects are evaluated as part of the Application Case

6.7.2.5 Description of the Environment

Monitoring of at the WL site and surrounding area will proceed as described in CNL's ongoing Environmental Assessment Follow-up and Monitoring Program at the WL site. This includes sampling and analysis of ambient air, surface water and groundwater, including the Winnipeg River, sediment, vegetation, garden produce, game animals and fish. A summary of concentrations of radionuclides and non-radionuclide concentrations within the various environmental media are discussed in the "Description of the Existing Environment" section of the relevant discipline section in the EIS. The descriptions incorporate the associated Traditional Knowledge provided by Indigenous Nations.

6.7.2.6 Project Interactions and Mitigation

6.7.2.6.1 Methods

This section describes the process by which interactions between Project components and activities and ecological health were identified and evaluated. Potential effect pathways are identified and mitigation options to eliminate and/or reduce effects are presented. A pathways analysis is then used to focus on key interactions between the Project and the environment. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in Section 6.7.2.7 Residual Effects Analysis. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all phases of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce adverse effects to ecological health. Environmental design features included Project design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the Project's engineering and environmental teams, combined with input from Project specific or regional engagement with other interested parties. The design features and/or mitigation activities were selected considering their effectiveness for implementation and maintenance and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation:

- **No linkage pathway –** pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change relative to Base Case values and therefore would have no residual effects to ecological health.
- **Secondary pathway –** the pathway could result in a measurable minor environmental change, but would have a negligible residual effect on ecological health relative to Base Case and/or guideline values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.

- **Primary pathway –** the pathway is likely to result in an environmental change relative to the Base Case and/or guideline values that could contribute to residual effects to ecological health.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to ecological health through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the Project.

6.7.2.6.2 Results

Pathways through which the Project may interact with the ecological health VCs are summarized in Table 6.7.2-5. Accidents and malfunctions related to Project activities are also possible and are assessed separately in Section 7.0 Accidents and Malfunctions.

Table 6.7.2-5: Pathways Analysis for the Ecological Health Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
General Project activities during the closure phase	Closure activities will alter concentrations of non-radiological indicator compounds (e.g., particulate matter and carbon dioxide), which could affect human health, including: ■ use vehicles and equipment that combust fuel and emit indicator compounds; ■ material handling, for grouting and demolition; ■ vehicles travelling on paved roads; ■ operation of batch mixing plant for grout production.	■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Effluents and Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Implementation of CNL's Occupational Safety and Health Program, including work permit system and personal protection equipment and clothing. ■ Implementation of dust management techniques. ■ On-site vehicles and equipment engines will meet Tier 3 emission standards, where possible, and be maintained in good working order. ■ Limit idling of vehicles on-site and speed on roads. ■ Use of tarps or 3 sided enclosures for raw material storage.	Secondary

Table 6.7.2-5: Pathways Analysis for the Ecological Health Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
General Project activities during the closure phase	Closure activities will result in the atmospheric release of radiological and non-radiological compounds from the WR-1 Building	■ Implementation of CNL's Radiation Protection Program and Procedure, which includes Radiation Safety Zones, detailed work planning to limit doses to as low as reasonably achievable (ALARA), dose monitoring and contamination control procedures (e.g., stabilizing and immobilizing agents). ■ Implementation of CNL's Occupational Safety and Health Program, including work permit system and training requirements. ■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Effluents and Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring.	Primary
Long-term performance during the post-closure phase	Release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time may cause changes in groundwater quality which could migrate towards the Winnipeg River	■ Encapsulation of the reactor by a multi-component WRDF (i.e., geosphere, concrete foundation, grout and facility systems and components) to mitigate groundwater flow into the ISD waste. ■ Installation of a concrete cap and engineered cover system to mitigate moisture infiltration into the WRDF and hence limit release of solutes into the groundwater. ■ Environmental monitoring will be completed throughout the post-closure phase for the Project to confirm that the cover and grout is functioning as intended, and to confirm modelling predictions.	Primary
	Release of chemical and radiological contaminants in the long-term during the post-closure phase from the previous activities completed at the WL site.	■ As part of CNL's Licence No. NRTEDL-W5-8.00/2024 with the CNSC, environmental monitoring around the WL site will continue for the Project. ■ Follow-up monitoring during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Secondary

6.7.2.6.2.1 No Linkage Pathway

There are no pathways identified as having no linkages to effects to the ecological health VCs.

6.7.2.6.2.2 Secondary Pathways

In some cases, a Project source of effect and an interaction with an assessment endpoint exists but mitigation is expected to cause minor changes to ecological health relative to the existing Base Case and/or guidelines. The following pathway is expected to result in negligible effects on the ecological health VCs and will not be evaluated further in the EIS.

- **Closure activities will alter concentrations of non-radiological indicator compounds (e.g., particulate matter and carbon dioxide), which could affect ecological health.**

Closure activities will result in the release of CACs and fugitive dust emissions. Sources of dust deposition and air emissions include stack emissions, fuel use, aggregate material handling, on-site batch mixing plant and road dust. Environmental design features and mitigation have been incorporated into the Project to reduce potential adverse effects from dust deposition and air emissions. CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Effluents and Emissions* (CNL 2022) includes operational control monitoring, air verification monitoring and implementation of dust management techniques developed for the Project.

The release of CACs (particulate matter, nitrogen oxides, sulphur dioxide and carbon monoxide) and fugitive dust were assessed as part of the air quality VC in Section 6.21.7 Residual Effects Analysis. Predicted concentrations for the Application Case (Section 6.2.1.7.2 Application Case Results) are below applicable air quality guidelines and/or standards. Therefore, the release of CACs and fugitive dust is not expected to result in effects to ecological health.

- **Release of chemical and radiological contaminants in the long-term during the post-closure phase from the previous activities completed at the WL site.**

The CSR considered potential effects on the Winnipeg River and management of releases to ensure no residual effect. No decrease in water quality is expected and effluent emissions to the Winnipeg River are expected to decline to virtually zero following decommissioning. Re-suspension of contaminated sediments is also not expected to lead to a decrease in water quality (see Section 7.0 of AECL 2001).

The CSR (AECL 2001) also considered the potential for effects via groundwater quality from the low-level waste that may be managed in situ in the WMA, and their potential to affect the Winnipeg River and human health (see also Section 6.4.2.6.2.2 Project Interactions and Mitigation [surface water quality assessment]). The assessment considered three general exposure pathways: upward migration (with potential contamination of soils and vegetation), near-surface later migration (with potential contamination to local discharge in perimeter and roadside ditches) and downward migration and contamination of the sand and gravel aquifer and subsequently the river). Only the near-surface lateral migration scenario was considered in further detail. With respect to downward migration and release to the river it was determined that the general hydrology of the site limits or eliminates this pathway.

Water concentrations in the ditch were predicted and compared to established guidelines for several of the contaminants in the WMA. Radionuclide modelling in the CSR (Appendix C of AECL 2001) indicated that three radionuclides have the potential to exit the WMA through migration over a 200-year period, namely tritium, technetium-99 and carbon-14. Of these three radionuclides only technetium-99 is potentially present in nonzero concentrations in the ditch adjacent to the WMA in as early as 20 years. The carbon-14 and tritium will be lost to the atmosphere, and when this is modelled there is no release of these radionuclides to the perimeter ditch. The preliminary exposure assessment for radiological contamination of the ditch resulted in a dose of 0.16 mSv/a at the predicted peak concentration of technetium-99 (Appendix C of AECL 2001).

With respect to non-radiological contaminants, some exceedances of applicable standards were predicted. Further refinement of the modelling and potential need for selective remediation to remove the hazard was recommended (AECL 2001). Organic contaminants were also considered; it was concluded that the remaining concentrations of the solvents and DDT are very small and unlikely to present a residual hazard.

Consequently, there is no overlap of effects between the Project and previous activities at the WL site (i.e., effects from the WMA) and changes to surface water quality in the Winnipeg River.

As part of CNL's Licence No. NRTEDL-W5-8.00/2024 with the CNSC, environmental monitoring around the WL site will continue for the Project. Follow-up monitoring during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects. Consequently, changes to surface water quality from the closure of the WL site, are predicted to be negligible.

6.7.2.6.2.3 Primary Pathways

The following primary pathways were identified between the Project and ecological health and therefore, are carried forward to the residual effects analysis:

- **Closure activities will result in the atmospheric release of radiological and non-radiological compounds from the WR-1 Building.**
- **Release of radiological and non-radiological solutes into the groundwater as the grout and reactor components gradually deteriorate over time may cause changes in groundwater quality; which could affect Winnipeg River water quality as groundwater migrates towards the Winnipeg River.**

6.7.2.7 Residual Effects Analysis

An ERA (EcoMetrix 2024) was completed for the Project to assess potential adverse effects of the Project on ecological health during the closure and post-closure phases of the Project. A summary of the methods and results of this assessment during the closure and post-closure phases of the Project is provided in Sections 6.7.2.7.1 Application Case – Closure Phase and 6.7.2.7.2 Application Case – Post-closure Phase, respectively.

6.7.2.7.1 Application Case – Closure Phase

6.7.2.7.1.1 Methods

This section summarizes the specific methods used to assess the residual effects on ecological health during the closure phase for the Project activities and pathways identified as primary in Table 6.7.2-5. Policies, guidelines and standards considered in the analysis, as well as the model used to predict residual effects are described.

Receptor Selection and Characterization

As described in Section 6.7.2.3, the focus for the closure phase is on terrestrial VCs because releases are only expected via atmospheric pathways. The following VCs are evaluated for the closure phase, rationale for their selection is provided in Table 6.7.2-2:

- earthworm;
- American robin;
- loggerhead shrike;
- grass and shrubs;
- berries;
- meadow vole;
- common shrew;
- snowshoe hare;
- white-tailed deer;
- red fox; and
- little brown myotis.

Contaminants of Potential Concern

For the closure phase, the relevant COPCs may be released via atmospheric releases from the WR-1 Building. It has been assumed that the WR-1 Building stack is removed during the closure phase; therefore, any atmospheric releases are assumed to occur at ground level. Atmospheric deposition to the Winnipeg River is considered to be negligible, consistent with COG DRL guidance (COG 2013), therefore, aquatic pathways and VCs are not considered during closure.

Selection of Radiological COPCs

The radionuclides that are considered in the ERA for the closure phase are those radionuclides that have been found in WL's airborne effluent or are reasonably expected to be found in the airborne effluent (CNL 2020b). Radionuclides are considered of public and regulatory interest and therefore all radionuclides identified were carried forward quantitatively in the ERA.

During closure, operational controls and procedures in place to prevent or limit the release of airborne radionuclides will be in effect (e.g., during demolition the above-grade building will be in place, the waste collection system and proven emergency response plans and personnel will all be operational and adequate ventilation and infiltration will be established). As well, decontamination, and the use of stabilizing and immobilizing agents prior to dismantling the WR-1 Building will be used to control the release of airborne radionuclides. Release of radionuclides to the atmosphere during closure are not anticipated to be above those observed during the operation phase of the facility. During demolition of above-grade structures, radionuclides may be released from the PHT system, and some existing surface radionuclides may become airborne. During grouting, remaining radionuclides may be released from the reactor core and biological shield (Table 6.7.2-6. Tritium may also be released, for example, when disruptive activities on the helium and heavy water system are executed during closure. In accordance with *REGDOC-2.9.1, Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2020), average and maximum emission rates have been provided for the Application Case (refer to Section 6.2.1, Tables 6.2.1-11 and 6.2.1-12).

Table 6.7.2-6: Potential Radionuclide Release during the Closure Phase

Reactor Core	Biological Shield	Primary Heat Transport System
■ Carbon-14 ■ Iron-55 ■ Cobalt-60 ■ Nickel-59 ■ Nickel-63 ■ Niobium-94 ■ Silver-108m ■ Tritium	■ Chlorine-36 ■ Calcium41 ■ Nickel-63 ■ Carbon-14 ■ Cobalt-60 ■ Europium-152	■ Strontium-90 ■ Caesium-137 ■ Europium-154 ■ Europium-155 ■ Technetium-99 ■ Iodine-129 ■ Uranium-235 ■ Uranium-238 ■ Neptunium-237 ■ Neptunium-239 ■ Plutonium-238 ■ Plutonium-239 ■ Plutonium-240 ■ Plutonium-241 ■ Americium-241 ■ Americium-243 ■ Curium-244 ■ Silver-108m ■ Cobalt-60

Selection of Non-Radiological COPCs

A select number of non-radiological airborne COPCs have been identified as potentially being released during the closure phase from the WL site. These include:

- asbestos (friable [contains more than 1% asbestos by weight or area and can be crumbled by the human hand] and non-friable [material that contains more than 1% asbestos and cannot be crumbled under hand pressure] asbestos containing materials);
- organic coolant (HB-40 used as reactor coolant, also known as OS-84, primarily hydrogenated terphenyl) in the PHT system;
- lead based paint and lead shielding;
- polychlorinated biphenyls (PCBs) in fluorescent light fixture ballasts;
- small quantities of mercury in thermostats and switches; and
- mould.

With the exception of HB-40, the identified hazardous substances are routinely addressed in construction projects. HB-40 consists mainly of hydrogenated terphenyl (74% to 87%), with smaller fractions of partially hydrogenated terphenyls and terphenyl. Since HB-40 is an oil, or a tar if irradiated, its release to air with dust should be limited.

Non-radiological COPCs are identified through an official screening process and these COPCs are carried forward into the EcoRA. The screening consists of comparing the maximum predicted air concentration during closure to selected benchmarks. If concentration exceeds benchmark it indicates additional risk assessment work is required to demonstrate protection of the public and environment. For closure it was identified that no non-radiological COPCs were required to be carried forward into the EcoRA.

Exposure Pathways

During the closure phase, releases to surface water are not expected, because any release from the grouted reactor would occur after closure, and contaminant transport via groundwater to surface water would take additional time. Accordingly, the focus for the closure phase is on terrestrial VCs because releases are only expected via atmospheric pathways. Relevant exposure for ecological receptors is presented in Table 6.7.2-7 and illustrated on Figure 6.7.2-1. Exposure pathways include the routes of contaminant dispersion from the source to the receptor location and the routes of contaminant transport through the food chain or other media to the receptor organism.

Airborne COPCs partition to soil and plants, and ingestion pathways dominate over inhalation and air immersion for most COPCs. The latter pathways are omitted for ecological receptors in this assessment, except for COPCs such as noble gases, if released, since inhalation and air immersion pathways for these are expected to be important.

The software used for the exposure pathways analysis and for the calculation of radiological doses was IMPACT Version 5.5.1, which is consistent with the equations outlined in CSA N288.1-14 (CSA Group 2014) and the methods outlined in CSA N288.6-12 (CSA Group 2012). The Tool Qualification Report for IMPACT describes the verification and validation activities performed on IMPACT (EcoMetrix 2024).

Table 6.7.2-7: Exposure Pathways for Selected Valued Components during the Closure Phase

Receptor Category	Receptor	Exposure Pathways	Environmental Media

Model Software

An environmental transport and pathways model was used to evaluate the effects of contaminants on the local environment including human and ecological receptors. The software used for the exposure pathways analysis and for the calculation of radiological doses was IMPACT Version 5.5.1, which is consistent with the equations outlined in CSA N288.1-14 (CSA Group 2014) and the methods outlined in CSA N288.6-12 (CSA Group 2012). The Tool Qualification Report for IMPACT describes the verification and validation activities performed on IMPACT. A more detailed description of the model is provided in the ERA (EcoMetrix 2024).

6.7.2.7.1.2 Results

A radiation dose benchmark of 0.1 mGy/hr (2.4 mGy/day) (UNSCEAR 2008) was selected for the WL assessment of effects on terrestrial biota (Table 6.7.2-8) as recommended in CSA N288.6-12 (CSA Group 2012). This is a total dose benchmark, therefore the dose to biota due to each radionuclide of concern is summed to compare against this benchmark.

Table 6.7.2-8: Summary of Total Dose during Closure Phase for Selected Valued Components

Ecological Receptor / Exposure Scenario	Dose (mGy/day)	Percent of Dose Benchmark
Demolition		
American Robin		
Demolition - Maximum	5.27×10^{-5}	<0.01%
Demolition - Average	1.39×10^{-5}	<0.01%

Grouting - Maximum	2.54×10^{-5}	<0.01%
Grouting – Average	1.34×10^{-5}	<0.01%
Fruits		
Grouting - Maximum	5.74×10^{-6}	<0.01%
Grouting – Average	3.57×10^{-6}	<0.01%
Earthworm		
Grouting - Maximum	9.29×10^{-6}	<0.01%
Grouting – Average	5.44×10^{-6}	<0.01%

There are no exceedances of the 2.4 mGy/day radiation benchmark for terrestrial VCs on or near the WL site. All predicted doses are well below this level. Therefore, it is unlikely that there would be significant adverse effects on terrestrial populations or communities as a result of radionuclide releases from closure activities. For the closure phase, all predicted air concentration for non-radiological COPCs were below their relevant ambient air quality criteria (see Section 6.2.1.7.2 Application Case Results); therefore, no non-radiological COPCs were identified for the closure phase and no health effects are anticipated as a result of airborne effluent from the Project.

6.7.2.7.2 Application Case – Post-closure Phase

6.7.2.7.2.1 Methods

This section describes the specific methods used to assess the residual effects on ecological health, during the post-closure phase, for the Project activities and pathways identified in Table 6.7.1-5 Policies, guidelines and standards considered in the analysis, as well as the model used to predict residual effects are described.

Scenarios

Similar to the Human Health assessment, the ecological health assessment considered multiple scenarios including the Normal Evolution Scenario and Disruptive Events. These scenarios are described in Section 6.7.1.7.2.1. Only the WRDF Barrier Failure Disruptive Event was anticipated to interact with ecological health VCs. The Human Intrusion Disruptive Event would result in localized exposure to a person, and is unlikely to result in exposure to ecological health VCs. The Well in Plume Disruptive Events would result in human exposure to groundwater through drinking water. Ecological health VCs would not be exposed to well water.

Receptor Selection and Characterization

As described in Section 6.7.2.3, the focus for the post-closure phase is on aquatic and riparian VCs because releases are only expected via groundwater to surface water pathways. The following VCs are evaluated for the post-closure phase for the Normal Evolution Scenario and WRDF Barrier Failure Disruptive Event and rationale for their selection is provided in Table 6.7.2-2:

- barn swallow;
- little brown myotis;
- Carmine Shiner;
- Lake Sturgeon;
- Walleye;
- aquatic plants;
- benthic invertebrates;
- horned grebe;
- trumpeter swan;
- mallard
- moose; and
- mink.

Contaminants of Potential Concern

For the post-closure phase, no atmospheric releases are expected as the grouting will be completed and the above-grade building and components will have been removed. A concrete cap and engineered cover will have been installed on top of the buried material. During the first 100 years of the post-closure phase the site will be under institutional control. The main potential release mechanism during post-closure is via leakage through the WRDF to groundwater and subsequent migration of groundwater to surface water at the Winnipeg River.

Selection of Radiological COPCs

The radionuclides that are considered in the ERA for the post-closure phase included those that have been historically been found in WL's liquid effluent, are reasonably expected to be found in the WRDF and have the potential to migrate from groundwater to surface water during the post-closure phase (EcoMetrix 2024), or have been measured in river sediment. All radionuclides identified were carried forward quantitatively in the ERA. The radionuclides included for the post-closure scenario were:

- Actinium-225
- Actinium-227
- Americium-241;
- Americium-243;
- Silver-108m;
- Bismuth-210
- Carbon-14;
- Calcium-41;
- Chlorine-36;
- Curium-244;
- Cobalt-60;
- Caesium-137;
- Europium-152;
- Europium-154;
- Europium-155;
- Iron-55;
- Gadolinium-55
- Iodine-129;
- Niobium-94;
- Nickel-59;
- Nickel-63;
- Neptunium-237;
- Neptunium-237;
- Protactinium-231;
- Protactinium-233;
- Lead-210;
- Polonium-210;
- Plutonium-238;
- Plutonium-239;
- Plutonium-240;
- Plutonium-241;
- Radium-223:
- Radium-224;
- Radium-225;
- Radium-226;
- Radium-228;
- Strontium-90;
- Technetium-99;
- Thorium-227;
- Thorium-228;
- Thorium-229;
- Thorium-230;
- Thorium-231;
- Thorium-232;
- Thorium-234;
- Uranium-233;
- Uranium-234;
- Uranium-235;
- Uranium-236;
- Uranium-237;
- Uranium-238;
- Yttrium-90.

Selection of Non-Radiological COPCs

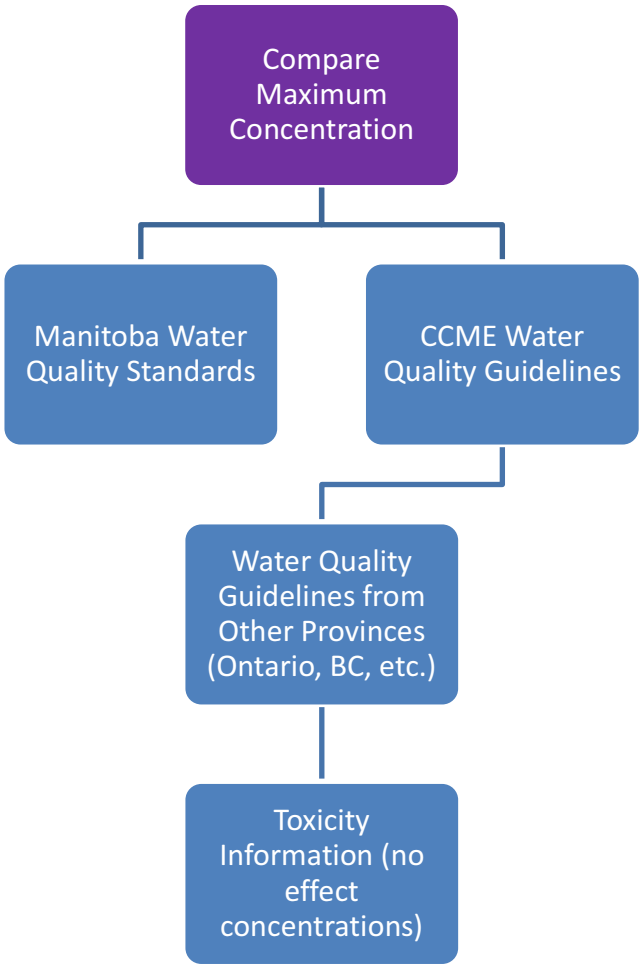
CNL has determined that a select number of non-radiological waterborne COPCs may potentially be released from the WL site during the post-closure phase (CNL 2017). These include:

- Boron;
- Cadmium;
- Chromium;
- HB-40;
- Mercury;
- Palladium;
- Potassium hydroxide; and
- Xylene.

The groundwater model predicted mass loadings for non-radiological contaminants from the WRDF to groundwater for the duration of the modelling assessment timeframe (500,000 years). Maximum mass loadings for each non--radiological parameter were converted to groundwater concentrations using the anticipated flowrate through the WRDF for the time period of maximum mass loadings. The maximum predicted groundwater concentrations were compared to available federal and provincial guidelines and objectives to determine potential COPCs relevant to ecological health. If there was no such guideline or objective, screening criteria were obtained from toxicity benchmarks (e.g., no effect levels) in the literature.

Non-radiological contaminants with maximum concentrations exceeding the selected benchmarks shown on Figure 6.7.2-2, were carried forward in this assessment. Based on the screening process, cadmium, lead, HB-40 and xylene were carried forward for further quantitative assessment in the ERA for the post-closure phase.

Figure 6.7.2-2: Selection Process for Ecological Health Screening of Non-Radiological Contaminants of Potential Concern



Exposure Pathways

Exposure pathways include the routes of contaminant dispersion from the source to the receptor location and the routes of contaminant transport through the food chain or other media to the receptor organism. The post-closure phase is not expected to result in airborne effluent, as the grouting will have been completed, the above-grade building will have been completely decommissioned and a concrete cap and engineered cover will have been installed over the WRDF. The relevant chemical and radiological contaminants may be released via leakage through the grouting to groundwater and subsequent migration via groundwater to surface water at the Winnipeg River. Accordingly, the focus for the post-closure phase is on aquatic and riparian VCs because releases are only expected via groundwater to surface water pathways.

Exposure pathways for aquatic and riparian biota are described in Table 6.7.2-9 and illustrated on Figure 6.7.2-3. Exposure pathways include the routes of contaminant dispersion from the source to the receptor location and the routes of contaminant transport through the food chain or other media to the receptor organism. Airborne COPCs are not relevant during the post-closure phase. For fish and aquatic plants, contact with water and contaminant uptake from water via bioaccumulation represents the main exposure pathway. The dominant exposure pathways for birds and mammals are through the uptake of contaminants via the ingestion of water, incidental ingestion of soil or sediment and ingestion of food. The exposure pathways are the same for the Normal Evolution Scenario and the WRDF Barrier Failure Disruptive Event.

Table 6.7.2-9: Exposure Pathways for Selected Valued Components during the Post-closure Phase

Receptor Category	Receptor	Exposure Pathways	Environmental Media
Bottom Feeding Fish	Lake Sturgeon	Direct Contact	■ In Water[(a)] ■ On Sediment
	Carmine Shiner	Direct Contact	■ In Water[(a)] ■ On Sediment
Pelagic Fish	Walleye	Direct Contact	■ In Water[(a)]
Aquatic Plants	Aquatic Plant	Direct Contact	■ In Water[(a)]
Aquatic Invertebrates	Benthic Invertebrate	Direct Contact	■ In Water[(a)] ■ In Sediment
Riparian Birds	Horned Grebe	Direct Contact	■ On Sediment
		Ingestion	■ Water ■ Sediment ■ Fish (forage) ■ Benthic Invertebrates
	Trumpeter Swan	Direct Contact	■ On Sediment
		Ingestion	■ Water ■ Sediment ■ Aquatic Plants
	Mallard	Direct Contact	■ On Sediment
		Ingestion	■ Water ■ Sediment ■ Benthic Invertebrates ■ Aquatic Plants

Table 6.7.2-9: Exposure Pathways for Selected Valued Components during the Post-closure Phase

Receptor Category	Receptor	Exposure Pathways	Environmental Media
Riparian Mammals	Mink	Direct Contact	■ On Sediment
		Ingestion	■ Water ■ Sediment ■ Benthic Invertebrates ■ Fish (forage)
Terrestrial Birds	Barn Swallow	Direct Contact	■ On Sediment
		Ingestion	■ Water ■ Sediment ■ Benthic Invertebrates
Terrestrial Mammals	Little Brown Myotis	Direct Contact	■ None
		Ingestion	■ Water ■ Benthic Invertebrates
	Moose	Direct Contact	■ On Sediment
		Ingestion	■ Water ■ Sediment ■ Aquatic Plants ■ Grasses

Note: Soil is considered to be clay as defined in the Hydrogeology Study Report (Dillon 2018)

a) The uptake calculated from a water concentration, using a bioaccumulation factor (BAF), implicitly represents uptake from all aquatic media, since water partitions to all media and all uptake pathways operate when a BAF is measured.

Model Software

An environmental transport and pathways model was used to evaluate the effects of contaminants on the local environment including human and ecological receptors. The software used for the exposure pathways analysis and for the calculation of radiological doses was IMPACT Version 5.5.1, which is consistent with the equations outlined in CSA N288.1-14 (CSA Group 2014) and the methods outlined in CSA N288.6-12 (CSA Group 2012). The Tool Qualification Report for IMPACT describes the verification and validation activities performed on IMPACT. A more detailed description of the model is provided in the ERA (EcoMetrix 2024).

6.7.2.7.2.2 Results

Normal Evolution Scenario

The total doses are compared to dose benchmarks of 9.6 mGy/day for aquatic biota and 2.4 mGy/day for terrestrial and riparian biota (Table 6.7.2-10), respectively, as recommended in CSA N288.6-12 (CSA Group 2012). This is a total dose benchmark, therefore the dose to biota due to each radionuclide of concern is summed to compare against this benchmark.

Table 6.7.2-10: Summary of Total Dose during the Post-closure Phase for Select Valued Components

Ecological Receptor / Exposure Scenario	Dose (mGy/day)	Percent of Dose Benchmark
Barn Swallow	8.13×10^{-6}	<0.01%
Little Brown Bat	6.58×10^{-6}	<0.01%
Carmine Shiner	1.14×10^{-4}	<0.01%
Lake Sturgeon	1.14×10^{-4}	<0.01%
Walleye	4.10×10^{-6}	<0.01%
Freshwater plant	4.26×10^{-6}	<0.01%
Benthic Invertebrate	5.77×10^{-4}	<0.01%
Benthic Invertebrate (Groundwater)	5.71×10^{0}	55.52%
Horned Grebe	1.55×10^{-4}	<0.01%
Trumpeter Swan	1.53×10^{-4}	<0.01%
Wild Waterfowl	1.52×10^{-4}	<0.01%
Mink	1.54 x 10-4	<0.01%
Moose	1.01×10^{-5}	<0.01%

mGy/day = milligrays per day.

There are no exceedances of the 9.6 mGy/day radiation benchmark for the aquatic biota in the Winnipeg River. Similarly, there are no exceedances of the 2.4 mGy/day radiation benchmark for terrestrial and riparian biota on or near the WL site. All predicted doses are well below these levels. Therefore, it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of radionuclide releases from post-closure activities.

The HQs for non-radiological COPCs for aquatic receptors are presented in Table 6.7.2-11 and the HQs for mammals and birds are presented in Table 6.7.2-12.

Table 6.7.2-11: Non-Radiological Hazard Quotients for Aquatic Valued Components

Parameter	Benthic Invertebrates (unitless)	Benthic Invertebrates in Groundwater (unitless)	Fish (unitless)	Aquatic Plants (unitless)
Cadmium	6.69×10^{-2}	**3.57×10^{1}**	5.90×10^{-3}	5.02×10^{-3}
HB-40	1.96×10^{-4}	**2.92×10^{1}**	4.56×10^{-6}	8.35×10^{-6}
Lead	2.12×10^{-1}	**5.93×10^{0}**	1.38×10^{-1}	5.20×10^{-3}
Xylene	4.18×10^{-6}	6.96×10^{-1}	1.56×10^{-7}	1.07×10^{-7}

Note:

Bold and shaded values indicate a HQ greater than 1.

Table 6.7.2-12: Non-Radiological Hazard Quotients for Birds and Mammal Valued Components

Parameter	Barn Swallow (unitless)	Horned Grebe (unitless)	Trumpeter Swan (unitless)	Wild Waterfowl (unitless)	Little Brown Myotis (unitless)	Mink (unitless)	Moose (unitless)
Cadmium	5.36×10^{-5}	1.85×10^{-5}	9.87×10^{-4}	1.22×10^{-3}	4.97×10^{-5}	1.92×10^{-5}	1.82×10^{-3}
HB-40	NV	NV	NV	NV	2.04×10^{-3}	1.04×10^{-3}	1.00×10^{-4}
Lead	6.87×10^{-3}	2.15×10^{-3}	4.54×10^{-2}	5.65×10^{-2}	3.58×10^{-4}	1.42×10^{-4}	5.90×10^{-5}
Xylene	3.46×10^{-6}	1.21×10^{-6}	2.06×10^{-7}	5.37×10^{-7}	2.57×10^{-7}	9.96×10^{-8}	2.98×10^{-8}

Note:

NV = no value available to calculate HQ.

There are no exceedances of the HQs identified for exposure of the ecological receptors to cadmium, lead, HB-40 (with the exception of benthic invertebrates in groundwater) and xylene. Therefore, no significant adverse effects on either aquatic or terrestrial populations or communities as a result of these chemical releases are predicted.

The HQs for cadmium, lead and HB-40 exceeded 1 for the scenario where benthic invertebrates are exposed directly to groundwater. However, this does not necessarily imply a significant adverse effect. The assumption of direct exposure to undiluted groundwater is conservative because a diffusion gradient will exist across the sediment-water interface, resulting in some degree of dilution into the top layer of sediment where most benthic organisms reside. Moreover, the seepage area represents a small part of the benthic community habitat, and the maximum groundwater concentration assumed represents the worst-case time period. As such, benthic invertebrates may not be at risk due to cadmium, lead and HB-40 exposure, and any adverse effects will be spatially and temporally limited, such that the community as a whole is not expected to be significantly affected. Overall, no significant adverse effects on terrestrial populations or communities as a result of these chemical releases are predicted. Additional recommendations on monitoring are discussed in Section 6.7.2.10.

There were no data to determine HB-40 benchmarks for birds. As such there is uncertainty around the potential health risks to birds due to HB-40 exposure. Nevertheless, considering that the major constituent of HB-40 (e.g., hydrogenated terphenyl) is closely related to the aromatic hydrocarbon group and that petroleum hydrocarbons are metabolized by vertebrates (CCME 2008), it can be suggested that exposure of birds to HB-40 is likely to be limited because HB-40 will be readily metabolized by birds and therefore is not anticipated to accumulate. In addition, assuming that birds are similar to mammals in terms of HB-40 toxicity, if the HB-40 TRV for mammals is used for birds, all bird doses are far below the TRV. This assumption is considered reasonable, as the thresholds for Birds and Mammals are similar for the other COPCs (same order of magnitude), and the

HQs calculated for mammals are all well below the HQ limit of 1. This provides confidence that there will not likely be any impacts to birds, based on the low exposure levels predicted in the assessment.

Disruptive Events – WRDF Barrier Failure

As indicated in Section 6.7.2.7.2.1, the only Disruptive Event expected to interact with ecological health VCs is the WRDF Barrier Failure. Radiation dose benchmarks of 2.4 mGy/day (UNSCEAR 2008) for terrestrial and riparian biota and 9.6 mGy/day for aquatic biota were used to evaluate effects to ecological receptors. These are total dose benchmarks, therefore the dose to biota due to each radionuclide of concern is summed to compare against this benchmark. All predicted doses are well below these levels indicating that no adverse residual effects are expected. Therefore, it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of radionuclide releases under a barrier failure scenario (Table 6.7.2-13).

Table 6.7.2-13: Summary of Post-closure Total Dose for Ecological Receptors under Barrier Failure Conditions

Ecological Receptor	Dose (mGy/day)	Percent of Dose Benchmark
Barn Swallow	8.28×10^{-6}	<0.01%
Little Brown Bat	6.70×10^{-6}	<0.01%
Carmine Shiner	1.14×10^{-4}	<0.01%
Lake Sturgeon	1.14×10^{-4}	<0.01%
Walleye	4.17×10^{-6}	<0.01%
Freshwater plant	4.34×10^{-6}	<0.01%
Benthic Invertebrate	5.77×10^{-4}	<0.01%
Horned Grebe	1.55×10^{-4}	<0.01%
Trumpeter Swan	1.53×10^{-4}	<0.01%
Wild Waterfowl	1.52×10^{-4}	<0.01%
Mink	1.54×10^{-4}	<0.01%
Moose	1.02×10^{-5}	<0.01%

The risk to ecological receptors that could be exposed to the non-radiological contaminants identified as potentially occurring at elevated concentrations (i.e., cadmium and lead) during post-closure in a WRDF barrier failure scenario were calculated based on total concentration (background plus Project contribution). Hazard quotients are summarized in Table 6.7.2-14. For the ecological health assessment, the HQ benchmark is 1, all calculated HQs were below 1% of protective HQ benchmark (i.e., all below 0.01). All predicted exposures are well below protective benchmark values, therefore, no adverse effects to human or ecological receptors are anticipated from a barrier failure.

Table 6.7.2-14: Summary of Hazard Quotients for Ecological Receptors under Barrier Failure Conditions

Receptor	Cadmium	HB-40	Lead	Xylene
Benthic Invertebrates	6.69×10^{-2}	2.00×10^{-4}	2.12×10^{-1}	4.44×10^{-6}
Fish	5.90×10^{-3}	4.65×10^{-6}	1.38×10^{-1}	1.66×10^{-7}
Aquatic Plants	5.02×10^{-3}	8.50×10^{-6}	5.20×10^{-3}	1.14×10^{-7}
Barn Swallow	5.36×10^{-5}	NV	6.87×10^{-3}	3.68×10^{-6}
Horned Grebe	1.85×10^{-5}	NV	2.15×10^{-3}	1.29×10^{-6}
Trumpeter Swan	9.87×10^{-4}	NV	4.54×10^{-2}	2.19×10^{-7}
Wild Waterfowl	1.22×10^{-3}	NV	5.65×10^{-2}	5.71×10^{-7}
Little Brown Myotis	4.97×10^{-5}	2.07×10^{-3}	3.58×10^{-4}	2.73×10^{-7}
Mink	1.92×10^{-5}	1.23×10^{-4}	1.42×10^{-4}	1.22×10^{-8}
Moose	1.82×10^{-3}	1.02×10^{-4}	5.90×10^{-3}	3.16×10^{-8}

Note:
NV = no value available to calculate HQ.

6.7.2.7.2.3 Sensitivity Scenario – Fractured Geo-Pathway

There are no predicted exceedances of the 9.6 mGy/d radiation dose benchmark for aquatic biota or of the 2.4 mGy/d radiation dose benchmark for terrestrial and riparian biota during Project post-closure. Therefore, it is unlikely that there would be potential adverse effects on terrestrial or aquatic populations or communities as a result of radionuclide releases from the Project for the sensitivity analysis. All HQs are below 1 indicating no adverse ecological effect is anticipated.

6.7.2.8 Prediction Confidence and Uncertainty

The ERA assumptions are conservative to accommodate inherent uncertainties in the modelling and meet the objective of protecting ecological health during the closure and post-closure phases. The conceptual model for ecological health is considered to be complete for the majority of ecological exposures in the vicinity of the WL site. The comprehensive selection of COPCs and receptors is expected to represent all important exposures to contaminants in the vicinity of the WL site.

There is uncertainty in the estimated inventory of radioactive and non-radioactive material that could be present within the WR-1 Building. The estimated inventory of WR-1 and its associated systems were derived by two general methods; physical samples, and computer models. Computer models formed the basis of the inventory estimate and were supplemented by physical sample characterization data to fill gaps and validate model estimates. In all cases, the most conservative results of either the physical samples or computer models were used to derive the final inventory estimate. Each estimation method also included aspects of conservatism in their individual approaches, contributing further to the conservatism built into the final inventory estimate. This compounded conservatism is based on physical data specific to WR-1 and provides an appropriate level of realism to the estimate.

There is also uncertainty in how long each closure activity will take (e.g., how long it will take to grout the heavy water moderator system). As such, there is uncertainty in the COPC release rates to the atmosphere and geosphere. To address this uncertainty, appropriate assumptions are integrated into the model to provide an appropriate level of conservatism. For example, although the duration of demolition prior to grouting may be carried out in 1 to 2 months, it has been conservatively assumed that it will occur for 6 months. Prior to the execution of closure activities, system characterizations and radiological surveys will be completed to inform detailed work

planning. This work will provide greater accuracy; however, it is expected that any variation would be well encompassed by the conservatism build into the model.

The IMPACT model was used to predict dose to identified ecological receptors during the closure phase. The IMPACT model used was a steady state model; however, it included time dependent equations to account for buildup in soil from irrigation, for all radionuclides released. Uncertainties in predictions of media concentrations arise from inherent uncertainty in the air model in IMPACT. The model reports an average concentration, and typically over-predicts this concentration by a factor of 1.5. Considering the conservatism in the estimation of releases, and in the air model, it is reasonable to conclude that doses arising from closure activities have not been underestimated.

There are uncertainties associated with the components contributing to the overall risk assessment. This includes receptor exposure factors, such as transfer factors, intake rates and bioaccumulation factors and dose coefficients, as well as benchmark values used to determine risk of potential effects. Overall, considering uncertainties in the exposure assessment and in the benchmark values, the risk characterization has been undertaken in a manner that has not underestimated risk; the results are either overestimates or realistic estimates of risk, both of which are considered acceptable.

Exposure factors were based on best-available information from literature with preference for exposure factors identified in CSA N288.1-14. For parameters that did not have exposure factors in CSA N288.1-14, surrogate parameters were identified based on proximity in the periodic table, which is considered appropriate. Since the exposure assessment is predictive, BAFs were used to calculate uptake into tissues. The BAFs used for the exposure assessment were taken from reputable sources (e.g., CSA N288.1-14) and are considered to be representative of the conditions found at the site. Wildlife exposure factors, such as intake rates and diets, are a potential source of uncertainty. Reputable sources are used for these factors and they are considered to be representative for the organisms assessed.

Dose coefficients were obtained from reputable sources for reference organisms (ICRP 2008; ERICA Tool 2016) but have not been derived specifically for all the organisms assessed. Dose coefficients for surrogate organisms were often used. They were selected with attention to similar body size and exposure habits, and are believed to adequately represent the organism assessed. Dose coefficients for each receptor were not adjusted for body size and dimensions.

Uncertainties in the exposure assessment include the representativeness of the predicted concentrations used in the assessment at each location. Maximum predicted concentrations of COPCs were used for each location and environmental medium as an upper bound on exposure. These values are, by definition, not representative for mobile organisms that can move around the site, effectively averaging their exposure concentrations. Maximum values are representative for exposures of any sessile organisms that reside at the location of the maximum value. Therefore, maximum concentrations are considered to overestimate exposure for all mobile receptors.

The uncertainties from the exposure assessment include model uncertainty and uncertainty in the exposure factors selected. The uncertainties from the toxicity assessment include conservatisms built into the radiation dose constraint. Taken together, the approaches to exposure and toxicity assessment have ensured that the characterization of dose and risk has been undertaken in a manner that has not underestimated dose or risk.

6.7.2.9 Residual Effects Classification and Determination of Significance

The residual effects analysis methods for the EcoRA are different from those used by other VCs. Specifically, the assessment of potential effects to ecological health VCs results in the generation of risk factors that inherently consider the geographic extent, duration, frequency and other characteristics of the predicted changes to the environment that may result from Project activities. As such, these inherent attributes cannot be used to determine environmental significance, as they can with other components. Instead, significance for ecological health is evaluated based on: (i) the potential magnitude of the response, as indicated by the comparison to benchmarks and (ii) the degree of conservatism and uncertainty in the analysis.

There are no exceedances of the 2.4 mGy/day radiation benchmark for terrestrial VCs on or near the WL site for the closure phase. All predicted doses are well below this level. Therefore, it is unlikely that there would be significant adverse effects on terrestrial populations or communities as a result of radionuclide releases from closure activities. For the closure phase, all predicted air concentration for non-radiological COPCs were below their relevant ambient air quality criteria; therefore, no non-radiological COPCs were identified for the closure phase and no health effects are anticipated as a result of airborne effluent from the Project during the closure phase.

There are no exceedances of the 9.6 mGy/day radiation benchmark for the aquatic biota in the Winnipeg River during the post-closure phase. Similarly, there are no exceedances of the 2.4 mGy/day radiation benchmark for terrestrial and riparian biota on or near the WL site. All predicted doses are well below these levels for the post-closure phase. Therefore, it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of radionuclide releases from post-closure activities.

There are no exceedances of the HQs identified for exposure of the ecological receptors to cadmium, lead, HB-40 (with the exception of benthic invertebrates in groundwater) and xylene. Therefore, no significant adverse effects on either aquatic or terrestrial populations or communities as a result of these chemical releases are predicted.

The HQs for cadmium, lead and HB-40 exceeded 1 for the scenario where benthic invertebrates are exposed directly to groundwater. However, this does not necessarily imply a significant adverse effect. The assumption of direct exposure to undiluted groundwater is conservative because a diffusion gradient will exist across the sediment-water interface, resulting in some degree of dilution into the top layer of sediment where most benthic organisms reside. Moreover, the seepage area represents a small part of the benthic community habitat, and the maximum groundwater concentration assumed represents the worst-case time period. As such, benthic invertebrates may not be at risk due to cadmium, lead and HB-40 exposure, and any adverse effects will be spatially and temporally limited, such that the community as a whole is not expected to be significantly affected.

For the WRDF Barrier Failure Disruptive Event, all predicted radiological and non-radiological doses are well below their respective protective benchmark values indicating that no adverse residual effects are expected. Therefore, it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of radionuclide and non-radionuclide releases under a barrier failure scenario.

6.7.2.10 Monitoring and Follow-up

As part of the CNL's licence (NRTEDL-W5-8.00/2024), environmental monitoring of the WL site is required. It is anticipated that for closure, the monitoring at the WL site and surrounding area will continue in accordance with CNL's existing Environmental Monitoring Program. This includes sampling and analysis of ambient air, surface water and groundwater, including the Winnipeg River, sediment, vegetation, garden produce, game animals and fish. CNL's Environmental Monitoring Program includes assessment of dose to members of the public, based on emissions monitoring and measurements in environmental media. Additionally, the dose to workers at WL is monitored and reported to the CNSC annually. As decommissioning of the site proceeds the environmental monitoring for the site is anticipated to evolve to reflect the creation, removal or limitation of hazards during the institutional control period.

CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented, identify any unanticipated effects and provide for the implementation of adaptive management to limit these effects, if required. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program at the WL site, where practical. The Environmental Assessment and Follow-up Program for the Project will be undertaken during the closure and post-closure phases. Once the WL site has been decommissioned, monitoring to support institutional control will continue, as well as any other requirements identified in the Environmental Assessment and Follow-up Program for the Project.

CNL has committed to working collaboratively with the First Nations and the Manitoba Métis Federation to support the Indigenous Nations to participate in environmental monitoring at the WL site. Some of the key elements of the initiative may include expansion and evolution of the monitoring program at WL, through incorporation of feedback, recommendations, Traditional Knowledge, capacity development, including training in environmental monitoring, and opportunities for monitors from each First Nation and the Red River Métis to collect samples on site and in the surrounding area. For example, CNL has had discussions with First Nations and the Manitoba Métis Federation on how future monitoring on the WL site could incorporate Indigenous interests, such as fish species of interest, and traditional knowledge. The goal of the initiative is to help address concerns regarding protection of the environment, health of people, confidence in the health of country foods and stigma associated with the Project.

It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS or Decommissioning Safety Assessment Report, including the findings from the Environmental Risk Assessment, the frequency of sampling may be increased and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized, or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals for modifications to the monitoring program, and the rationale for the modifications will be communicated to the CNSC prior to implementation.

The Environmental Assessment Follow-up and Monitoring Program for the Project will expand on the regulatory requirements of *CSA N288.5-22: Effluent Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2022) for the management of emissions from the Project. For a comprehensive summary of the monitoring and follow-up recommendations made based on the results of the environmental assessment refer to Section 11.0.0 Summary of Monitoring and Follow-up Programs. Table 6.7.2-15 outlines the monitoring and follow up programs for ecological health.

This page intentionally left blank

Table 6.7.2-15: Monitoring and Follow up Programs for Ecological Health

Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Ecological Health	**Potential Source(s) of Effects:** ■ Closure activities will result in the release of airborne effluent from the WR 1 Building which could affect ecological health. ■ Release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time during the post-closure phase may cause changes in groundwater quality which could migrate towards the Winnipeg River and affect receptors along the Winnipeg River. **Proposed Monitoring:** ■ Monitoring for air quality as noted above (i.e., for dust). ■ Verification monitoring for tritium in air (post venting through the WR-1 stack). ■ Passive tritium in air network monitoring (semi-annual change out) will be included as part of the Environmental Assessment Follow-up and Monitoring Program for the Project. Monitoring locations (approximately 4 of them) will be selected to be within the main upriver and downriver windrose sectors, at the site boundary and on-site mainly to monitor airborne tritium plumes potentially originating from the WRDF. ■ Estimate combustible gases (e.g., based on project-related traffic and equipment), as per atmospheric environment above; ■ Monitor contaminants of concern (e.g., lead, asbestos, tritium) in air displaced from grouting the below-grade structure, as per the atmospheric environment above. ■ Groundwater monitoring surrounding the Whiteshell Reactor Disposal Facility, as noted above. ■ Surface water quality monitoring in the Winnipeg River, as noted above. **Trigger for Further Action:** ■ Investigation if parameters are above applicable guidelines identified.	■ Verify effects predictions related to air quality, groundwater quality and surface water quality to confirm no health effects are anticipated as a result of exposure to COPCs from the Project. ■ Verify mitigation is effective.	■ Dust monitoring would be initiated during the closure phase. ■ WL currently conducts industrial hygiene assessments of lead, asbestos and mould within facilities as part of the decommissioning planning process. ■ Monitoring of tritium in air will be initiated when the stack monitoring system is discontinued. This monitoring would be on-going during post-closure. The need for and duration of monitoring will be assessed based on annual review of monitoring data. ■ Groundwater and surface water quality monitoring would be on-going during closure and post-closure. The need for and duration of monitoring will be assessed based annual review of monitoring data.	■ Air quality monitoring for the Project will be captured through the implementation of CNL's WL Effluent Verification and WL Environmental Monitoring Programs. ■ Groundwater monitoring for the Project will be integrated into the overall CNL WL Groundwater Monitoring Program. ■ Surface water monitoring in the receiving environment is already completed through CNL's WL Environmental Monitoring Program. No new surface water quality monitoring is proposed for the Project.

6.7.2.11 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous peoples, or the public (The Agency 2018). It is generally an impractical task to assess the effect of radiological and non--radiological emissions on all the species of biota within a natural ecosystem, and specifically within the ecosystem around the WL site. Therefore, representative organisms are chosen for dose and risk analysis. These organisms are selected because they are known to exist on the site and are representative of major taxonomic groups or exposure pathways, or have a special importance or value. For example, based on feedback from Indigenous peoples during engagement activities, moose was added as a VC to the ecological health assessment given the species importance to Indigenous people.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future human generations (i.e., incorporates sustainability). The assessment endpoint is the protection of ecological health. Measurement endpoints represent properties of the environment, that when changed, could result in or contribute to an effect on an assessment endpoint. Measurement endpoints for the EcoRA include changes in air quality, groundwater quality, surface water quality, sediment quality, soil quality and vegetation.

An environmental transport and pathways model was used to evaluate the effects of contaminants on the local environment including ecological receptors. During closure, the focus is on terrestrial VCs because releases are only expected via atmospheric pathways. During post-closure phase, the focus is on aquatic and riparian VCs, because releases are only expected via groundwater to surface water pathways.

Results of the radiological dose assessment for the closure and post--closure phases indicate that doses to ecological health VCs are below their respective benchmark values. In addition, there are no exceedances of the HQs identified for exposure of the ecological receptors to cadmium, lead, HB-40 (with the exception of benthic invertebrates in groundwater) and xylene. Therefore, no significant adverse effects on either aquatic or terrestrial populations or communities as a result of these chemical releases are predicted.

The HQs for cadmium, lead and HB-40 exceeded 1 for the scenario where benthic invertebrates are exposed directly to groundwater; however, this does not necessarily imply a significant adverse effect. The assumption of direct exposure to undiluted groundwater is conservative and the seepage area represents a small part of the benthic community habitat, and the maximum groundwater concentration assumed represents the worst-case time period. As such, benthic invertebrates may not be at risk due to cadmium, lead and HB-40 exposure, and any adverse effects will be spatially and temporally limited, such that the community as a whole is not expected to be significantly affected.

For the WRDF Barrier Failure Disruptive Event, all predicted radiological and non-radiological doses are well below their respective protective benchmark values indicating that no adverse residual effects are expected. Therefore, it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of radionuclide and non-radionuclide releases under a barrier failure scenario.

The uncertainties from the exposure assessment include model uncertainty and uncertainty in the exposure factors selected. The uncertainties from the toxicity assessment include conservatisms built into the radiation dose constraint. Taken together, the approaches to exposure and toxicity assessment have ensured that the characterization of dose and risk has been undertaken in a manner that has not underestimated dose or risk.

A key concern of Indigenous peoples was long-term effects of the Project on fish, plants and wildlife important to Indigenous peoples. Overall, residual effects from radiological and non-radiological COPCs are considered to be not significant for all ecological VCs during the closure and post-closure phases.

Indigenous peoples have interest in the current and future monitoring proposed for the Project. CNL will implement an Environmental Assessment Follow-up and Monitoring Program for WR-1 to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as identified for other environmental components to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical.

As part of CNL's licence (NRTEDL-W5-8.00/2024), environmental monitoring of the WL site is required. It is anticipated that for closure, the monitoring at the WL site and surrounding area will continue to proceed in accordance with CNL's existing Environmental Monitoring Program. This includes sampling and analysis of ambient air, surface water and groundwater, including the Winnipeg River, sediment, vegetation, garden produce, game animals and fish. These activities will verify effects predictions for ecological health.

6.8 Land and Resource Use

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project) seeks to understand and characterize the potential residual effects of the Project and past, present, and reasonably foreseeable developments on traditional land and resource use (Section 6.8.1) and other land and resource use (Section 6.8.2).

6.8.1 Traditional Land and Resource Use

The assessment of traditional land and resource use considers traditional land and resource use activities in proximity to the Project, including hunting, trapping, and gathering by Indigenous Nations, archaeological and cultural sites, and the overall importance of the Winnipeg River.

6.8.1.1 Scope of the Assessment

The assessment on traditional land and resource use follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment is completed in the following steps.

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Sections 6.8.1.3 Valued Components and Section 6.8.1.4 Assessment Boundaries) for the assessment of traditional land and resource use. The VCs, the assessment endpoints and measurement indicators used to assess the Project related changes to traditional land and resource use; the spatial and temporal boundaries at which the assessment occurred; and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 6.8.1.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing conditions present historical (to the extent information is available) and current traditional land and resource use and the associated conditions that affected current traditional land and resource use practices (e.g., industrial development, legislation).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.8.1.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect traditional land and resource use are identified and mitigation options are presented to limit or avoid effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described. Primary pathways that may lead to residual effects to traditional land and resource use after incorporating mitigation are carried forward to Step 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the traditional land and resource use assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the traditional land and resource use assessment.

- **Step 6 – Classify and determine the significance of the predicted residual effects**. This step was not required as no primary pathways were identified in the traditional land and resource use assessment.
- **Step 7 – Identifying monitoring and follow-up** (refer to Section 6.8.1.7 Monitoring and Follow-up) required to confirm effects predictions and address uncertainty.
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.8.1.8 Conclusions) on traditional land and resource use.

6.8.1.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the traditional land and resource use assessment are summarized in Table 6.8.1.2-1. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4.0 Indigenous Engagement.

Table 6.8.1.2-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Traditional Land and Resource Use Assessment

Interest and Concern	Inclusion Status	Additional Information and Rationale
Effects to the Winnipeg River as an important location for traditional land and resource use.	Included in the environmental assessment.	The Winnipeg River was included as a valued component, and potential effects on it are considered in sections 6.4.1 Surface Water Quality and 6.5 Aquatic Environment.
Cumulative effects on surface water quality, fish and fish habitat, wild rice, berries, medicinal and food plants, and animals as it supports traditional way of life, traditional land and resource use, and harvesting rights.	Included in the environmental assessment. Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations has been updated to include a description of how traditional land and resource use activities have changed in response to past historical events and external pressures, which has been summarized from the Traditional Knowledge and Land Use Studies.	CNL has helped to fund four Traditional Knowledge and Land Use Studies with six Indigenous Nations. The results of these studies and continued dialogue with Indigenous Nations is described in Sections 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations and 6.8.1.6 Project Interactions and Mitigation. Section 6.4.2 Surface Water Quality, Section 6.5 Aquatic Environment, and Section 6.8.1.6 Project Interactions and Mitigation describes existing conditions for and Project effects to surface water quality, fish and fish habitat, and wild rice, medicinal plants and animals, respectively. Participation in monitoring going forward is described in Section 6.8.1.7 Monitoring and Follow-up.

Table 6.8.1.2-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Traditional Land and Resource Use Assessment

Interest and Concern	Inclusion Status	Additional Information and Rationale
Future Land Use, including how much of the current site will be available for use and return of traditional lands to Indigenous Nations, to be considered collaboratively with Indigenous Nations (i.e., change the proportion of the site that will have restrictions on use)	Included in the environmental assessment. The commitment by CNL to determine the future use of the WL site, including collaboration with Indigenous Nations has been added to Section 6.8.1.6.2 Results.	Changes to access restrictions associated with the WL site end state as a result of the Project are described in Section 6.8.1.6.2 Results.
Impacts on Future Land Use caused by fear, stigma and associated alienation, due to the creation of a permanent radioactive waste disposal facility through ISD, and associated psycho-social impacts on Indigenous Nations.	Suitability of the site for future uses is assessed in Section 6.8.1.6.2.2 Secondary Pathways.	Psychosocial impacts are assessed directly only if they are the result of a biophysical impact of the Project. As the Project is not predicted to have any biophysical impacts, psychosocial impacts are not complete pathways. However, due to the significant importance of this concern, and in the spirit of understanding and cooperation, the EIS discusses the psychosocial impacts of perceptions of the Project in Section 4.0 Indigenous Engagement, as well as mitigations CNL has and will put in place to address concerns related to fear and stigma associated with the site.
Effects on Indigenous cultural, archeological, and sacred sites, spiritual places, practices and ceremonies as a result of Project activities.	Included in the environmental assessment. CNL has made a commitment to support reconnection to the land on the WL site through ceremony or other cultural activities. This commitment has been added to Section 6.8.1.7 Monitoring and Follow-up.	There are no documented cultural, archaeological, or sacred sites within the WL site boundary; however, mitigation has been incorporated if an unexpected discovery of a heritage resource is made during Project activities. Mitigation is described in Section 6.8.1.6.2 Results.
All site clean-up and release criteria and deviation of desired end-state(s) for the Whiteshell Reactor Disposal Facility should be developed collaboratively with affected Indigenous Nations.	The commitment by CNL to determine the future use of the WL site, including collaboration with Indigenous Nations has been added to Section 6.8.1.6.2.2 Secondary Pathways.	As discussed in Section 6.8.1.6.2 Results, CNL will develop appropriate criteria for site remediation and clean-up activities of the WL site, aligned with meeting Canadian Council of Ministers of the Environment land use criteria, and based on feedback received from Indigenous Nations and other stakeholders.

Table 6.8.1.2-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Traditional Land and Resource Use Assessment

Interest and Concern	Inclusion Status	Additional Information and Rationale
Concerns about the spatial boundaries used in the assessment not being reflective of those employed in traditional land use studies.	Adjusted in assessment boundaries in Section 6.8.1.4.1 Spatial Boundaries	CNL has separated Indigenous traditional land and resource use from other non-Indigenous land and resource use in order to reflect spatial boundaries that more closely reflect the boundaries as identified in traditional land use studies, combined with consideration of where effects are likely to be measurable.
Concerns that the assessment approach relies on a “damaged base case” resulting in conclusions that cannot result in a significant adverse effect.	Factors contributing to existing conditions are described in Section 6.8.1.5 Description of the Existing Environment.	The methodology used in the assessment regarding use of the current conditions as the baseline are in line with guidance on assessments under CEAA 2012
Safe Transportation of Waste and effects on the public roads	Included in the environmental assessment.	Transportation of waste is considered in connection with public safety in Section 6.9 Socio-economic Environment and in Section 7.0 Accidents and Malfunctions.
Uncertainty about Conclusions in the Assessment	Included in the environmental assessment. Section 6.8.1.6.2.2 Secondary Pathways has been updated to include a summary of Indigenous Nation’s conclusions about the potential effects of the Project, which has been summarized from the Traditional Knowledge and Land Use Studies.	To address the differing conclusions and uncertainty, CNL’s commitment to involving Indigenous Nations in monitoring and to engaging with them over the long-term to address ongoing concerns is described in Section 6.8.1.7 Monitoring and Follow-up.
Concerns about future monitoring and distrust of monitoring results.	Included in the environmental assessment. CNL’s commitment to involving Indigenous Nations in monitoring and engaging with them over the long-term to address ongoing concerns has been added to Section 6.8.1.7 Monitoring and Follow-up.	CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as described in Section 6.8.1.7 Monitoring and Follow-up.

Table 6.8.1.2-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Traditional Land and Resource Use Assessment

Interest and Concern	Inclusion Status	Additional Information and Rationale
Concerns about the extent of Indigenous participation in the assessment of effects to traditional land and resource use (from the identification of pathways to the verification of results)	Sagkeeng First Nation and the Manitoba Métis Federation have had the opportunity to review Section 6.8.1 Traditional Land and Resource Use in advance of the submission of the EIS Rev 3D2. As a result of the feedback received the spatial boundaries (Section 6.8.1.4.1 Spatial Boundaries) for the assessment of traditional land and resource use were modified. Section 6.8.1.6.2.2 Secondary Pathways has been updated to include a summary of Indigenous Nation's conclusions about the potential effects of the Project, which has been summarized from the Traditional Knowledge and Land Use Studies.	CNL has separated Indigenous traditional land and resource use from other non-Indigenous land and resource use in order to reflect spatial boundaries that more closely reflect the boundaries as identified in traditional land use studies, combined with consideration of where effects are likely to be measurable. To address the differing conclusions and uncertainty, CNL's commitment to involving Indigenous Nations in monitoring and to engaging with them over the long-term to address ongoing concerns is described in Section 6.8.1.7 Monitoring and Follow-up.

6.8.1.3 Valued Components

Valued components refer to socio economic and environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous Nations, or the public (The Agency 2018). The traditional land and resource use VCs chosen for the Project to reflect identified concerns, professional judgement and/or standard practice in environmental assessment are Cultural and Archaeological Sites, Traditional Land and Resource Use by Indigenous Nations and the Winnipeg River. The rationale for selecting these VCs is discussed in Table 6.8.1.3-1.

Table 6.8.1.3-1: Valued Components for the Traditional Land and Resource Use Assessment

Valued Component	Rationale for Selection
Cultural and Archaeological Sites	Cultural and archaeological sites are those sites protected under legislation and administered by the Manitoba Heritage Resource Branch. Cultural and archaeological sites are important for revealing past and present land use, cultural identity and relationships with other cultures and the social and biophysical environments. Potential alteration or loss of cultural and archaeological sites can have an effect on Indigenous people. Consideration of physical and cultural heritage is a requirement under Section 5 of the *Canadian Environmental Assessment Act, 2012*. The cultural and archaeological sites VC is of known importance to Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations as identified through Traditional Knowledge and Land Use Studies, engagement with CNL, and verification discussions. Consideration of physical and cultural heritage is a requirement under Section 5 of the *Canadian Environmental Assessment Act, 2012*.

Table 6.8.1.3-1: Valued Components for the Traditional Land and Resource Use Assessment

Valued Component	Rationale for Selection
Traditional Land and Resource Use by Indigenous People	Traditional Land and Resource Use is defined as the land and resource by Indigenous Nations for traditional purposes, including hunting, fishing, trapping and gathering. Traditional land and resource use by Indigenous people is important for maintaining meaningful connections with cultural identity and community history, for food security, economic self-sufficiency, and the maintenance of individual and population health. Traditional land and resource use can also promote intergenerational connections within communities as knowledge is passed down from elders to community members, including youth. Potential changes to traditional land and resource use by Indigenous people can have an adverse effect on Indigenous people by preventing them from fully expressing their cultural identity and Treaty rights. The traditional land and resource use by Indigenous people VC is representative of the values identified by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations, as identified through Traditional Knowledge and Land Use Studies, engagement with CNL, and verification discussions. Consideration of current land and resources use for traditional purposes is a requirement under Section 5 of *Canadian Environmental Assessment Act, 2012*. Section 6.9 Community Well-being included consideration of the presence of long-lived radioactively material having the potential to affect community well-being through the changes of the suitability of the site for future uses, the continued inability to exercise stewardship and governances over land and resource use management decisions (Section 6.9.6.2.2).
Winnipeg River	The public and Indigenous Nations identified the importance of the Winnipeg River. A number of communities depend on the river for drinking water, recreation, cultural vitality, inter-generational knowledge transfer and food security. The river flows into the Lake Winnipeg, one of the largest lakes in the world. The eastern shore of the lake is included in a United Nations World Heritage Site proposal (Manitoba Wildlands 2008). This watershed is valued for many reasons by many people and groups. Indigenous Nations identified the Winnipeg River as a critical resource for traditional and rights-based activities, including harvesting of fish, waterfowl, plants and other animals. The river was identified as a source of drinking water and as a transportation corridor. Further, Indigenous Nations recognize the sacredness of water, the interconnectedness of all life and the importance of protecting water. The Winnipeg River VC is of known importance to Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations as identified through Traditional Knowledge and Land Use Studies, engagement with CNL, and verification discussions.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. The assessments of each VC has incorporated the community and/or traditional knowledge provided. Measurement indicators represent properties of the environment and VCs that, when changed in comparison to existing conditions, could result in or contribute to an effect on a VC. Changes in measurement indicators were used to evaluate potential changes in the status of each VC relative to the assessment endpoints. The assessment endpoints and measurement indicators associated with the land and resource assessment are outlined in Table 6.8.1.3-2.

Table 6.8.1.3-2: Assessment Endpoints and Measurement Indicators for the Traditional Land and Resource Use Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Cultural and Archaeological Sites	Protection and preservation of cultural and archaeological sites.	■ Value, quantity, and quality of cultural and archaeological sites.
Traditional Land and Resource Use by Indigenous Nations	Continued opportunity for, and desire to engage in, traditional activities such as hunting, fishing, swimming, trapping and plant, berry, wild rice and medicine gathering.	■ Relative abundance and distribution of fish species. ■ Relative abundance and distribution of plant species. ■ Relative abundance and distribution of wildlife species. ■ Changes to vegetation, fish and wildlife habitat. ■ Relative abundance and distribution of vegetation and fish and wildlife habitat. ■ Changes to opportunities for traditional land use ■ Perceived and observed changes to the area's suitability for land use and/or quality of harvested resources.
Winnipeg River	Maintenance of self-sustaining and ecologically effective fish populations that are available for traditional use.	■ Changes to ambient levels of surface water parameters ■ Relative abundance and distribution of fish species. ■ Relative abundance and distribution of aquatic plant species (wild rice). ■ Changes to aquatic vegetation and fish habitat. ■ Relative abundance and distribution of aquatic plant and fish habitat. ■ Expanded opportunities for traditional use. ■ Perceived and observed qualities of water, aquatic plant species, fish, and aquatic habitat by traditional users.

6.8.1.4 Assessment Boundaries

6.8.1.4.1 Spatial Boundaries

The spatial boundaries selected for the traditional land and resource use assessment were chosen because they permit description of Base Case conditions in sufficient detail to enable potential project-VC interactions and effects to be identified, understood, and assessed, including understanding and assessing the contribution of the Project to cumulative effects. These boundaries were developed in consideration of known land and resource use around the WL site, including resource harvesting and traditional land and resource use by Indigenous Nations and the study areas of other disciplines (e.g., Terrestrial Environment; Human Health) that may have an effect on land and resource use. The spatial boundaries selected for the traditional land and resource use assessment are presented on Figure 6.8.1-1 and are described below.

- **Site Study Area (SSA)** is the WR-1 Building and represents the Project footprint (i.e., where Project activities will be undertaken; 0.07 ha).
- **Local Study Area (LSA)** is defined as the area within which there is potential for measurable changes resulting from the proposed Project activities. The LSA is intended to capture traditional land and resource use within proximity of the WL site and extends approximately 5 km beyond the WL site boundaries (approximately 11,917 ha).
- **Regional Study Area (RSA)** represents the area where potential effects on traditional land and resource use are expected to be experienced at a broader scale and where indirect effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. The RSA includes the RSAs for aquatic environment and the terrestrial environment as these are used for the assessments of Project effects on resources that support traditional land and resource use and also extends downstream on the Winnipeg River. Therefore, the south boundary of the RSA extends from the west shore of the Winnipeg River to the east fence on the property line about 400 m north of Provincial Highway 211. The eastern boundary of the RSA follows the fence on the property line to the north property line. The north boundary follows the north fence on the property line about 1.6 km and then turns north for about 400 m before turning west and extending to the west side of the Winnipeg River. To incorporate input from Indigenous Nations, the RSA was revised to include the Winnipeg River from the WL site downstream to Lake Winnipeg with a 100 m buffer on either side of the river to capture traditional land and resource use activities on either shore of the river (approximately 14,182 ha).

6.8.1.4.2 Temporal Boundaries

The temporal boundary of the assessment includes effects observed under existing conditions, the timeframe during which Project activities are actively occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of in situ disposal (ISD), which includes preparation for ISD, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031.
- **Post-closure Phase:** The post-closure phase has two discrete periods: institutional control and post-institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue, to demonstrate WRDF performance is in compliance with the safety case assumptions and performance modelling. The 100-year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the Canadian Nuclear Safety Commission (CNSC), or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.8.1.4.3 Assessment Cases

The assessment on traditional land and resource use has three assessment cases:

- **Base Case**: This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining and residential and recreational development. Current effects from the existing WL facilities and operations, for example, are considered part of the Base Case. In addition, effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case.
- **Application Case**: The Application Case represents predictions of the effects that may results from the Project combined with the existing effects of the Base Case.

- **Reasonably Foreseeable Developments (RFD) Case**: This scenario represents the effects of the Base Case combined with the predicted incremental effects from the Project, as well as effects from other RFDs within the RSA that are currently under application review or that have officially entered a regulatory application process. There are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the Comprehensive Study Report (AECL 2001). Cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site (see Table 6.8.1.4-1) are presented as part of this assessment.

Table 6.8.1.4-1: Reasonably Foreseeable Developments considered in the Traditional Land and Resource Use Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes ISD of some low-level waste trenches).	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project

6.8.1.5 Description of the Environment

This section describes the setting and characterization for traditional land and resource use as relevant for the assessment of the Project. It describes the existing conditions against which potential changes from the Project are compared and evaluated.

6.8.1.5.1 Methods

The characterization of the existing environment for traditional land and resource use reflects review of both primary and secondary data sources. Data collection began with a review of existing literature and databases from a variety of public sources. Where sufficient detail was not available from secondary data sources to describe the existing environment, primary data collection was undertaken in the form of key person interviews.

6.8.1.5.1.1 Literature Review

The review of literature and databases included the following sources:

- federal, provincial and municipal government reports and data;
- documents produced for other environmental assessment processes (e.g., environmental impact statements, regulatory submissions);
- academic literature (dissertations, cultural chronologies);
- archival research;
- the Whiteshell Laboratories Decommissioning Project: Comprehensive Study Report (AECL 2001);

- Project-specific Indigenous traditional knowledge studies:
  - For Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation: api migizik pii pa giiot – When Eagles Call Traditional Knowledge and Land Use Study for the WR-1 Nuclear Reactor In Situ Decommissioning Project (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019);
  - For Sagkeeng First Nation: Sagkeeng Anicinabe Land Use and Occupancy Study Specific to Canadian Nuclear Laboratories' Proposed In Situ Decommissioning of the WR-1 Reactor at Whiteshell Laboratories (Firelight and Sagkeeng 2018);
  - For the Manitoba Métis Federation: Whiteshell Reactor #1 Decommissioning: Manitoba Métis Traditional Knowledge, Land Use and Occupancy Study (SVS 2019).
  - For Wabaseemong Independent Nations: Traditional Knowledge and Environmental Impact Assessment (WIN 2018).
- Other community-led studies:
  - Sagkeeng Anicinabe Psychosocial Impact Assessment (Narratives 2020).
- the Environmental Assessment and Follow-up Program for Whiteshell Laboratories (AECL 2002); and
- online sources (e.g., community websites, online business profiles).

6.8.1.5.1.2 Primary data collection

Primary data collection, in the form of interviews or other techniques, was undertaken at the discretion of First Nations and the Métis in undertaking community-directed traditional land use or other studies. As such, the analysis is bound by the availability of data presented and any confidentiality associated with the data as determined by the various studies authors.

6.8.1.5.1.3 Indigenous Engagement

Information shared by the public and from Indigenous Nations was also used to inform both the base case and application case. Where applicable within this section, interests and information gained through the engagement program relevant to traditional land and resource use has been highlighted for each community (Table 6.8.1.2-1). For example, historical and present-day traditional land and resource use by First Nations and the Red River Métis is described in Section 6.8.1.5.2.2, which was considered in the identification of Project interactions in Section 6.8.1.6.2. Further detail on the outcomes of engagement processes can be found in Section 4.0 Indigenous Engagement.

6.8.1.5.2 Results

6.8.1.5.2.1 Archaeological and Cultural Sites

A review of the documented archaeological site data from the Government of Manitoba's Historic Resources Branch, Sport, Culture and Heritage provided the following cultural overview. As no site can be examined in isolation, archaeological sites recorded within 5,000 m (5 km) of the Winnipeg River, from the Manitoba/Ontario border to the mouth were reviewed to consider the wider landscape and establish the wider context of contemporary sites in the broader region.

Human occupation of the Winnipeg River system most likely began after the meltwater of glacial Lake Agassiz drained from the area *ca*. 8,500 years ago, prior to that the area was covered by the Late Wisconsinan ice sheet (MAS 1998; Teller and Clayton 1983; Steinbring 1980; Bowe 1999). A cultural chronology or timeline has been created, which is based on technological innovations and historical happenings. The chronology comprises two major time periods: Pre-European Contact and Post-European Contact. These are further divided into Early (Paleo-Indian [Northern Plano]), Middle (Archaic [Shield, Plains]) and Late (Woodland [Initial, Terminal]) sub-periods.

Human movement in the Winnipeg River system possibly began during the Paleo Indian Period (*ca*. 11,000 to 7,000 years ago) after the continental glacier and associated glacial Lake Agassiz retreated from the area approximately *ca*. 8,500 years ago (MAS 1998; Teller and Clayton 1983). During the period of deglaciation and meltwater drainage, the plant succession progressed northwards, followed by a wide range of animal species and by people. These semi-nomadic people were big game hunters, whom archaeologists refer to as the Plano (Pettipas 1984). Archaeological sites from this period are represented by solely lithic assemblages, which include slender leaf-shaped points, knives, scrapers and other tools. Over 30 registered archaeological sites within 5,000 m of the Winnipeg River system have been identified as being occupied during the Paleo-Indian Period.

Several important cultural adaptations are found within the Middle Archaic Period, including the appearance of notched or stemmed projectile points, end scrapers, adzes and other cutting implements (OAS 2011). The appearance of new style projectile points and the introduction of the atlatl (a spear extender, which provided leverage to the spear thus increasing the velocity and accuracy of the projectile) suggest adaptive technological changes for procuring food resources. Raw materials used by the Archaic period people became much more diverse, including the appearance and use of native copper which was used for making tools and adornments. The range of dates suggests cultural interaction and movement across a vast landscape (Wright 1972). Culturally, this was a society of hunters, fishers and gatherers whose members subsisted on a seasonally diverse diet of large game, fish and local plants (Wright 1972; Kennett and Winderhalder 2006). The lithic tool kit included plains grasslands projectile point/dart forms such as Logan Creek (*ca*. 500 to 6,500 years ago), Oxbow (*ca*. 3,500 to 5,300 years ago), McKean (*ca*. 2,800 to 3,200 years ago) and Pelican Lake (*ca*. 1,600 to 3,200 years ago), along with stone knives and scrapers. However, most Shield Archaic projectile points were “home-grown” stemmed and side-notched variants. An Archaic occupation is represented at over 80 sites along the Winnipeg River. Ancient copper mines located at Isle Royale on Lake Superior have been identified as the source material for projectile points within the southern part of Manitoba (Wright 1972; Steinbring 1980; Bouge 2007), to which at least seven sites have been documented along the Winnipeg River.

The introduction of native clay pottery marks the differentiation between the Woodland (*ca*. 3,000 to 360 years ago) (Wright 1972) and Archaic periods. The Eastern Woodland Tradition has shown to have first developed in eastern North America and moved westwards. In Manitoba, the Woodland Period is further divided into two temporal periods, Middle and Late, which is based on vessel construction and stylistic attributes.

The Middle Woodland people using pottery in Manitoba are represented by the Laurel Culture (*ca*. 2,700 to 1,000 years ago) and the type of ceramic ware produced during this time period. Pottery was conical in shape, manufactured using a coiling method and was decorated with various stamping techniques and incised design. The Laurel lithic toolkit consisted of a variety of lithic tools including triangular projectile points and copper awls and beads (Stoltman 1973). The Middle Woodland Culture is also characterized by people representing a shift from a reliance on grassland to forest and aquatic resources, including fish and wild rice harvesting (MAS 1998).

The Late Woodland Tradition contains several important pottery types that represent local variations that made them distinctive. Although pottery construction is believed to use similar techniques, there are signature differences within this tradition. For the Winnipeg River study area, Blackduck, Minontoba and Selkirk pottery styles are the three main derivatives (Hyslop 2012, 2014). The Indigenous Nations associated with these types of pottery constructed globular shaped vessels made from masses of wet clay, using a lamination technique. Archaeologists believe that these pots were pre-formed in a woven bag that left a distinct fabric impression on the exterior. Vessel rims, necks and lips were embellished with combinations of design attributes such as decorative punctuates, small cord-wrapped-stick impressions, or incising (OAS 2011).

Lithic tools associated with the Late Woodland Tradition include small triangular and side-notched projectile points, stone drills and smoking pipes (Wright 1972). Over 200 sites along the Winnipeg River contain the cultural materials of a Woodland occupation.

The largest concentration of petroform sites in Manitoba is found within the Winnipeg River's drainage system (Steinbring 1980). These rock mosaics were created by placing stones and/or boulders on bedrock surfaces to achieve the desired outline, usually human or animal effigies. There has been no success in assigning these cultural features to a particular time period. However, there is a direct link between the people of the Late Pre-Contact Period and the Anishinaabe who continued to use and occupy this area, and who continue to use some of the major petroforms in their ceremonies (Manitoba Sustainable Development n.d.d). There are over 20 documented sites comprised of boulder foundations within 5,000 m of the Winnipeg River.

With guidance from the local Indigenous Nations who had well-established trade routes for thousands of years, French explorers and early traders first gained entry into the interior by way of the Winnipeg River (Steinbring 1980). With the help of Auchagah, a Cree guide, La Vérendrye identified the Winnipeg River as a trade route and established fur trade forts near native camps throughout the area, including Fort Maurepas (1735) (Burpee 1927). Gradually European trade goods filtered into the local Indigenous settlements and traditional products, such as clay pottery and stone tools were generally replaced by copper and brass pots, metal knives and guns.

The Winnipeg River became an important travel route in accessing lands west of the Great Lakes (Rich 1967) With the granting of a charter in 1670 to the London, England based Hudson's Bay Company the commercial fur trade began and a long term relationship with local Indigenous Nations was established. Indigenous individuals and groups acted as traders and middlemen and undoubtedly benefited from the increased competition between the Hudson's Bay Company and the Montreal-based independents, which were generally referred to as "les Canadians." In 1779, the Montreal traders formed an organization to reduce expenses and ease the rivalry between traders, which became the North West Company. Later on, the intense rivalry between the Hudson's Bay Company and the Northwest Company for control the fur trade sparked the establishment of numerous trade houses in close proximity to one another; this had the effect of increasing the trading opportunities for Indigenous trappers. Fort Bas de la Rivière was established by the Northwest Company in 1792 at the mouth of the Winnipeg River. The Hudson's Bay Company built Fort Alexander in 1795 to counter the Northwest Company post.

Extreme demands in Europe for fur coats and beaver hats and the intense competition between the two companies led to a severe depletion of the fur resources. In 1821, the social and financial stress of both the Hudson's Bay Company and North West Company resulted in the companies amalgamating under the banner of the Hudson Bay Company, a fur trading monopoly resulted that covered one-quarter of North America. Reorganization caused closure of numerous unprofitable posts and outpost, affecting local employment opportunities.

According to the Manitoba Heritage Resource Branch archaeological site database, cultural materials of the historic period have been documented at over 50 sites along the Winnipeg River. This is most likely an inaccurate representation as material culture from Pre-European Contact Periods would take precedence in recording value.

During the early twentieth century, physical changes to the Winnipeg River began with the construction of the hydroelectric dams. Hydro development began on the Winnipeg River in 1903 with the construction of the Pinawa Dam, completed in 1906. Subsequently six more dams were constructed, Pointe du Bois (1926), Great Falls (1928), Slave Falls (1948) Seven Sisters (1952), Pine Falls (1952) and McArthur (1955) (Manitoba Hydro 2018). The Pinawa Dam ceased operation in 1951 and has since been designated a Provincial Heritage Site (Manitoba Sustainable Development n.d.e).

6.8.1.5.2.1.1 Archaeological Sites

The tangible history of the Winnipeg River is documented by physical artifacts and features that are distributed over the landscape. Much of this rich history was recorded by archaeologist Anthony Buchner, who conducted a two-year archaeological investigation of the waterway between Great Falls to McArthur Falls and Seven Sisters to Sturgeon Falls. The cultural materials collected during the Winnipeg River Archaeological Project (1980 to 1982) documented a human occupation dating back to the Late Paleo Indian Period (*ca*. 8,500 to 6,000 years ago) (Buchner 1982a).

A review of the registered archaeological site data provided by the Historic Resource Branch reveals the presence of 434 registered sites within 5,000 m of the Winnipeg River spanning from the Manitoba/Ontario border to the mouth at Lake Winnipeg. While there are no documented archaeological sites within the WL site boundary, it should not be assumed that sites are not present as the Sieg Serpent Site (formally called Sweet Creek Petroform) is located approximately 1,700 m south of the property (AECL 2001). In addition, three important sites can be found approximately 3,500 m south at the confluence of the Whitemouth and Winnipeg Rivers. Excavated in the 1960s and 1970s by Dr. Jack Steinbring, sites EaLa-01, 02, 03 (Whitemouth Falls Site, Porth Site, Bjorkland Site) comprised of multi-component campsites and burial mounds indicate that the area was frequented as much as 5,000 years ago. (Pettipas 2015; Buchner 1982b).

6.8.1.5.2.1.2 Historic Sites

One provincially recognized historic site, the Pinawa Dam Provincial Heritage Park, is located with the 5,000 m of the Winnipeg River. This park is under the management of Manitoba Conservation and Climate. During the construction of the amphitheatre Historic Resources Branch staff conducted some archaeological investigations, and a cultural component related to the dam construction was identified. The site was assigned an archaeological site designation (AECL 2001).

6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations

The Project is located on Treaty 3 land, while the overall WL site which extends west of the Winnipeg River falls on Treaty 1 land. Communities that form part of these Treaties and Treaty 5 also have historical and current land use ties with the area. Anishinaabe and Ojibway communities with historic traditional territories that have expressed some level of interest in the Project include the Sagkeeng First Nation and Brokenhead Ojibway Nation in Treaty 1; Black River and Hollow Water First Nations in Treaty 5; and Wabaseemoong Independent Nations in Treaty 3 (TRCM n.d.; Ontario Ministry of Aboriginal Affairs 2014).

First Nation community locations in vicinity to the WL site are described below and presented on Figure 6.8.1-2:

- **Sagkeeng First Nation**, an Anishinaabe community, is the closest Indigenous Nation to the WL site. Sagkeeng reserve land is located 52 km directly downriver from the WL site and includes land parcels on either side of the Winnipeg River.
- **Brokenhead Ojibway Nation** is located near the southern basin of Lake Winnipeg, occupies three reserves: 44 km northwest, 55 km northwest and 73 km southwest of the WL site. Brokenhead is primarily surrounded by the RM of St. Clements.
- **Black River First Nation** is an Ojibway community located along the eastern shoreline of Lake Winnipeg at the confluence of the Black and O'Hanly Rivers. The Black River reserve land is 75 km north of the WL site.
- **Hollow Water First Nation**, an Anishinaabe community, is located along the eastern shore of Lake Winnipeg approximately, 113 km north of the WL site.
- **Wabaseemoong Independent Nations** is comprised of four communities, Whitedog First Nation, serving as the main reserve parcel; One Man Lake; Swan Lake and Agency 30 (shared with 12 other First Nations). Occupy four reserves: 80 km east, 85 km east, 95 km east and 140 km southeast of the WL site.

The Project is also located in the homeland of the Red River Métis, as represented by the Manitoba Métis Federation. Figure 6.8.1-3 shows mapped recognized areas for Métis natural resource harvesting in Manitoba and Figure 6.8.1-4 shows the expanded areas bordering the recognized Métis harvesting area.

While Statistics Canada enumerated self-identified Métis residents in many communities in proximity to the Project, Métis communities that historically emerged in the region include:

- **Bas de la Rivière –**Situated on both shores of the Winnipeg River and established in 1732, the community served as a wintering post and trading depot. Fishing and agriculture were particularly important in the area. Originally a North West Company outpost, the post lost its importance as a provisioning and transportation hub following amalgamation with the Hudson's Bay Company in 1821. It became known as Fort Alexander and then eventually Pine Falls.
- **Berens River –** an initial trading post was built at the mouth of the river in 1814 and was a thriving Métis community until fishing was banned on Lake Winnipeg in 1970 as a result of mercury contamination.
- **Fort Alexander –** built by the Hudson's Bay Company on the Winnipeg River to counter the North West Company's Fort Bas de la Rivière, this post also had ties to the Métis in the area (Barkwell 2016).

6.8.1.5.2.2.1 Historical and Present Day Traditional Land Use

This section of the EIS describes historical and present-day traditional land and resource use by First Nations and the Red River Métis. The First Nations within the area have resided at or near their respective reserve parcels since time immemorial (Sagkeeng Anicinabe n.d.). In the nineteenth century, First Nations living near Fort Alexander, present day Sagkeeng First Nation, were nomadic and would make frequent trips north to the Hudson's Bay post to trade and obtain food supplies (Sagkeeng First Nation 2000). The Winnipeg River has historically provided a network of travel routes for local communities (Petch 2005). Present day traditional land and resource use activities, including trapping and wild rice harvesting, continue to supplement the diet and income of local First Nation and Métis communities in the RSA. Wild rice harvesting was originally for domestic purposes but eventually became a commercial economy (Manitoba Hydro and Golder Associates Ltd. 2012).

To fully understand present-day traditional land use activities by Indigenous Nations, it is key to understand the historical and external factors that have affected traditional land and resource use activities including the *Indian Act*, the creation of the reserve system, and residential schools. These factors, among other policies and programs, have continued to alienate Indigenous Nations from their traditional territories and hinder the full expression of their cultures.

Sagkeeng First Nation

Sagkeeng First Nation's reserve is located where the Winnipeg River empties into Lake Winnipeg and their traditional territory encompasses land within Treaty 1 along with land north and west of the Winnipeg River, falling within four Treaty areas (Sagkeeng First Nation 2015). Sagkeeng First Nation is currently in Treaty Land Entitlement specific claims discussions with the Government of Canada (Sagkeeng Anicinabe n.d.), including lands outside the Treaty 1 boundary (Firelight Research Inc. and Sagkeeng Anicinabe 2018). According to the completed Land Use and Occupancy Study, Treaty 1 was signed by Sagkeeng's Anicinabe ancestors on August 3, 1871, at Lower Fort Garry. This resulted in the establishment of the reserve and the Fort Alexander Band, which later was renamed as Sagkeeng Anicinabe (Firelight Research Inc. and Sagkeeng Anicinabe 2018).

The land and waterways have historically been an important part of the economic well-being and transportation system for the Sagkeeng First Nation. "A strongly held conviction among members is that the lands and waterways are the sustaining factors for all life. To members, the land and waters are indivisible and anything that is done to either will have far reaching effects for all life" (Sagkeeng First Nation 2015). In early spring and late fall, fishing was preferred near Catfish Creek and at Point au Mitasse on Lake Winnipeg (Sagkeeng First Nation 2000); however, the Sagkeeng First Nation makes full use of the territory for subsistence fishing.

> *"In that whole area, in that whole area of the Lac du Bonnet, Bird River … we would catch fish … [our father] used to catch sturgeon, and that's what we lived on … But I know that my dad used to come up into the Silver Falls area, up that way. There's an area just above the—between the two dams, I guess. And there used to be a lot of sturgeon there. (S07 2018)" (p.34).*
>
> *And:*
>
> *"Well, we used to go fishing down the bank [at Pine Falls] for the pickerel and the jackfish … The pickerel, but they call it walleye ... Yeah, that was our staple. (S07 2018)".*

Travel in the fall was typically to the Lac du Bonnet area, where the Pinawa Channel meets the Winnipeg River, to harvest wild rice (Sagkeeng First Nation 2000). Family units had preferred hunting areas which included areas close to Fort Alexander and spanned north to Black River First Nation and over 200 km southeast to Dalles and Big Island First Nations in Ontario (Sagkeeng First Nation 2000). Previous studies have confirmed that Sagkeeng First Nation participates in traditional activities of harvesting wild rice, sturgeon fishing, gathering plants and medicines and berry picking in the vicinity of the WL (AECL 2001). Members of Sagkeeng First Nation continue to have a fundamental attachment to the physical, biological, and spiritual environment, lands and waterways, as a way of life (Sagkeeng First Nation 2015). Sagkeeng First Nation currently uses the Winnipeg River as its source for water supply to the community (J.R. Cousin Consultants Ltd. n.d.).

A traditional knowledge and land use study titled, *Sagkeeng Anicinabe Land Use and Occupancy Study Specific to Canadian Nuclear Laboratories' Proposed In Situ Decommissioning of the WR-1 Reactor at Whiteshell Laboratories* (Sagkeeng Land Use and Occupancy Study; Firelight Research Inc. and Sagkeeng Anicinabe 2018) was prepared specifically for the proposed Project. The land use study involved interviews with 33 Sagkeeng members and identification of 519 site-specific use values within 25 km of the WL site (Table 6.8.1.5-1). Site-specific data were mapped according to five categories of values. These included: Habitation values (including temporary, occasional, seasonal and permanent camps and cabins); Cultural and Spiritual values (including burial sites, ceremonial areas and community gathering areas); Subsistence values (including harvest and kill sites, plant collection areas and trapping areas); Environmental Feature values (including specific, highly-valued habitat for moose, elk and deer); and Transportation values (including trails, water routes and navigation sites).

Values were generally labelled according to four categories: Water; Medicine, Berries and Other Food Plants; Hunting and Trapping; and, Anicinabe Pimatiziwin. The Water category focused primarily on catch sites for numerous fish species such as: sturgeon, suckers, goldeye, sunfish, carp, whitefish, pickerel (walleye), pike and catfish spawning areas. Water sites can also include wild rice harvest sites and drinking water sites. It should also be noted that Water is important as it was historically the key travel corridor and is still a major way in which harvesters access areas. The Medicine, Berries and Other Food Plants category included areas for harvesting medicinal plants and food products such as blueberries, plums, raspberries, strawberries, gooseberries, chokecherries, pin cherries, saskatoon berries, low bush cranberries. The Hunting and Trapping category included known harvest and processing sites for animal species such as moose, white-tailed deer, beaver, muskrat, otter, rabbit, prairie chickens, squirrel, weasel, fox and also important wildlife sites such as mineral licks.

The study (Firelight Research Inc. and Sagkeeng Anicinabe, 2018) also organizes some values according to the category, "Anicinabe Pimatiziwin". Anicinabe Pimatiziwin values are those that have a broader social, historical and spiritual significance and include: sacred places and gathering sites used by Sagkeeng members and their ancestors for ceremonial purposes and the transmission of traditional knowledge; camping sites, including those used as a base for fishing and hunting activities; trails and water routes, some of which have been used for multiple generations; and findings of archaeological materials.

Table 6.8.1.5-1: Site-Specific Values Identified by Sagkeeng First Nation

Sagkeeng-identified Valued Components	Within 250 m of the Project		Within 5 km of the Project[a, b]		Within 25 km of the Project[a, b]	
	Reported values (#)	Reported values (%)	Reported values (#)	Reported values (%)	Reported values (#)	Reported values (%)
Water Resources	4	12%	5	9%	172	33%
Medicines, Berries and Other Food Plants	7	21%	13	23%	101	19%
Hunting and Trapping	5	15%	14	25%	61	12%
Anicinabe Pimatiziwin	18	53%	24	43%	185	36%
TOTAL[c]	**34**	**100%**	**56**	**100%**	**519**	**100%**

Source: Firelight Research Inc. and Sagkeeng Anicinabe 2018
a) Values are cumulative; values within 250 m of the Project footprint are included in the values 25 km from the Project.
b) The study area used in the assessment and used by Sagkeeng First Nation in the traditional land use study are different.
c) Totals may not add up to 100 due to rounding.

The types of sites documented within the LSA include (Firelight Research Inc. and Sagkeeng Anicinabe 2018):

- Water Resources: catch sites for species including sturgeon, suckers, and catfish; a sturgeon spawning area;
- Medicines, Berries, and Other Food Plants: areas used for picking blueberries and plums; harvesting areas for medicinal plants;
- Hunting and Trapping: kills sites for white-tailed deer and moose, game processing sites; and
- Anicinabe Pimatiziwin: sacred places and gathering sites for ceremonial purposes and the transmission of traditional knowledge; camping sites including base camps for fishing, hunting, and harvesting; trails and water routes; sites where archaeological materials were found; a burial site; a site where a Sagkeeng member used to lived.

Additional sites documented within 25 km of the WL site include (Firelight Research Inc. and Sagkeeng Anicinabe 2018):

- Water Resources: catch sites for species including sturgeon, suckers, pickerel, goldeye, sunfish, whitefish, perch, carp, pike, bass and catfish; sturgeon spawning areas; fish processing sites; high-value wild rice harvesting areas; and water collection/drinking sites;
- Medicines, Berries, and Other Food Plants: areas used for picking blueberries, raspberries, strawberries, pin cherries, saskatoon berries, low-bush cranberries, gooseberries, chokecherries, and plums and harvesting areas for medicinal plants;
- Hunting and Trapping: trapping areas for beaver, muskrat, otter, rabbit, squirrel, and weasel; kill sites for moose, white-tailed deer, and fox; a mineral lick; and game processing sites; and

- Anicinabe Pimatiziwin values including: sacred places and gathering sites for ceremonial purposes and the transmission of traditional knowledge; a burial site dating back several thousand years; a place where a Sagkeeng First Nation member once lived; an old Sagkeeng village site; camping sites including base camps for fishing, hunting, and harvesting; teaching areas where Sagkeeng First Nation members learned to harvest plants and wildlife; trails and water routes, some of which have been used for multiple generations; sites where archaeological materials were found.

The study noted that:

> *"The site-specific data show that the Project is situated in an area that is highly-valued for fishing, harvesting wild rice, medicines, berries and other food plants, hunting wild game, trapping fur-bearing animals, as well as for participating in important cultural activities such as ceremonies, as well as sharing knowledge with younger Sagkeeng generations. Qualitative interview data clearly reveal the study areas as central to Sagkeeng livelihood, cultural identity and connection to the land, waterways and resources, as it is an area that has been used and relied on by Sagkeeng for generations" (p. 3).*

The study notes, and CNL recognizes, that while 33 individuals participated in the Sagkeeng First Nation TKLUOS, there were potentially more with knowledge of the area that did not participate. It should be noted that a couple of participants in the study reported use at the WL site prior to the development of the WL site; the nearly 60 years of fencing off of the site for nuclear research purposes has reduced the number of Sagkeeng First Nation members who have memories of actively using the WL site.

The sites documented in the *Sagkeeng Anicinabe Land Use and Occupancy Study Specific to Canadian Nuclear Laboratories' Proposed In Situ Decommissioning of the WR-1 Reactor at Whiteshell Laboratories* (Firelight Research Inc. and Sagkeeng Anicinabe 2018) include sites that have been used between 1940 and 2017. Use has changed in response to historical events and external pressures. The Sagkeeng First Nation use the term "impacted baseline" throughout the study to describe their current understanding of baseline conditions for the values included in their study. Sagkeeng First Nation members in the impacted baseline sections describe not only fishing, hunting, gathering, and ceremonial activities but also the external factors that prevent them from fully expressing their rights and culture. These external factors include the continuing effects of residential schools, game wardens and conservation officers, non-Indigenous recreational fishers, private property, and industrial activity like hydroelectric dams, mines and forestry. Residential schools replaced the traditional ways of teaching and learning and contributed to a general loss of language and culture. Several members of Sagkeeng First Nation feel a loss of ability to connect with their identity and traditional way of life as a result of these multiple overlapping barriers imposed on them by forces beyond their control:

> *And that [connection to the land] was taken away during the residential school time, they [children] were taken away from their families. (p. 75).*

The discrimination against ceremonies and Indigenous cultures was transmitted through legislation and had negative effects on Sagkeeng First Nation members' ability to perform ceremonies. By being prevented from participating in ceremonies, some members feel that the very practice of ceremonies in the community was diminished.

> *I don't know if there's anybody that knows how to do those [ceremonies] anymore. Because like I said, you know, the Christianity had a lot of impact on a lot of our stuff that we used to do, eh? You know, it was almost like it was—what would you call it? Outlawed? (p. 76).*

Sagkeeng First Nation members are increasingly experiencing difficulties in exercising their Treaty right to fish in the region and at times feel harassed by officials and non-Indigenous recreational fishers:

> *Well, of course, it has an effect on everybody. You know, the craziest thing about that is you go and exercise a Treaty right and the province of Manitoba turns you into a criminal. (p. 40)*
>
> *…and the fish, like I said, they don't know – we always put our nets out there [Lee River] and we don't go out there now. You know, the recreational fishermen do, but we'd set nets and then they'd come along, you know, drag them up without even letting us know, we'd just go out there and look, "hey, where's our net!?" you know, they say, "you're not supposed to be here." (p. 41).*

Broader industry presence was also identified as having impacts on the SFN's ability to exercise its rights, with two main developments, the Winnipeg River dams and the Pine Falls Paper Company contributing to environmental degradation, water quality, and associated changes to the resources that sustain the community (Narratives 2020) "The impacts have had lasting repercussions on trust and credibility of proponents for existing and future projects" (p. 37).

Sagkeeng First Nation members commented in the Sagkeeng Anicinabe Land Use and Occupancy Study Specific to Canadian Nuclear Laboratories' Proposed In Situ Decommissioning of the WR-1 Reactor at Whiteshell Laboratories that industrial development has also changed traditional land use activities by reducing the availability of wildlife for harvesting and access to the land:

So, when it [development] affects the growth of the plant life, then you're not going to have any animals around. It's going to have an effect on them as well. Then they're not so abundant in that area anymore. And I've noticed a lot of that, even today, like—even with the moose ... And where they used to cut [trees], and we used to go into that area, and see where they cut — the animals weren't there. The beaver aren't there, the weasels, the skunks — all those little animals, and even the deer and the moose aren't in those areas, because the trees are not there. And what they used to rub against, to get the ticks off, or you know, to—their fur, whatever, their winter fur, like you know — so that's affecting all of that. It's not only — like I said, it's not only hydro, it's the industries as well, like take the mining industries, you know, that affect all of that. It affects the environment. You know, they don't — they don't realize the impacts that it has on our areas. And not only that but on the livelihood. Like, I was talking to a couple of relatives of mine that are still fishermen, and they're saying that there's no pickerel (p. 60).

During the engagement process for the Project and from the Sagkeeng First Nation TKLUOS, Sagkeeng First Nation identified several interests and concerns regarding Traditional Land and Resource Use (further details are provided in Section 4.4 Summary of Issues Raised During Engagement). These issues are not always specifically linked directly to the Project, but rather the overall operation and closure of the WL site; however, due to their overall importance to the community they are noted herein:

- Concerns about the long-term effects of the WL site and the Project on water quality and fish:
  - there is a perceived deterioration of fish quality in the Winnipeg River, which may in part be attributed to the paper mill that previously operated in Pinefalls-Powerview but is also directly linked to concerns raised by prior spills from the WL site into the Winnipeg River and the continued presence of radioactive waste in close proximity to the Winnipeg River;
- An interest in fish monitoring at locations in proximity to the community.

- Concern about the availability of wild rice and medicinal plants (calamus root, Labrador tea, wild ginger and waterlily roots) that are safe for future use by Sagkeeng First Nation members.
- Concerns about the transport of nuclear materials, particularly in the event of an accident and associated contamination within their traditional territory.
- Concerns about not currently being meaningfully engaged in the determination of appropriate end land use goals and designations for the WL, and about the increasing temporal scope (longer into the future) of effects on land use at and around the site as a result of transforming it from a temporary radioactive waste storage facility to a permanent radioactive waste disposal facility.
- In the Sagkeeng First Nation TKLUOS, Sagkeeng First Nation members identified a set of VCs relating to Sagkeeng knowledge and use that may be impacted by the Project. These values included: water resources; medicines, berries and other food plants; hunting and trapping; and Anicinabe Pimatiziwin. CNL confirmed through discussions that these are values of very high importance to Sagkeeng First Nation.

A summary of the specific issues raised by the Sagkeeng First Nation and specific responses by CNL can be found in Appendix 4.0-1 of Section 4.0.

Brokenhead Ojibway Nation

Information about Brokenhead Ojibway Nation traditional land and resource use has come from community websites, consultations and most recently the traditional knowledge and land use study titled *api migizik pii pa gilot – When Eagles Call Traditional Knowledge and Land Use Study for the WR-1 Nuclear Reactor In Situ Decommissioning Project* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019), completed in November 2019. This study was undertaken for all three of Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation communities and covers a number of topics including the Worldview of the three communities and perspectives on cultural understandings, spirituality and water. Traditional land use including: the ancestral territory; travelling along the River; fishing; harvesting wild rice, berries and other plants; harvesting medicines; hunting, trapping and other harvesting; sacred sites and cultural gathering areas are described. Concerns are reported about how the Traditional Way of Life is Being Lost; the Project; and on recommendations moving forward.

A total of 56 unique individuals from these communities attended one or more events, interviews and/or visits associated with the study including 19 from Brokenhead Ojibway Nation. The mapping of traditional uses also records information from previous traditional knowledge studies that occurred. The three First Nations documented traditional land use over a large area of southeastern Manitoba, east and southeast of the southern basin of Lake Winnipeg. Generally, this is an area that would be bounded by Selkirk in the southwest, Hecla/Grindstone Provincial Park in the northwest and the Manitoba-Ontario border in the east. Traditional use is documented along river systems, recognizing the importance of rivers as travel corridors. The study (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019) also documents the importance of sacred sites, ceremonies and cultural practices and how the 1876 *Indian Act* banned Indigenous gatherings and ceremonies, which continued for many decades. The study (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019) describes how the communities are trying to re-establish cultural traditions. Important cultural sites such as the Bannock Point Petroforms east of the community of Pinawa are also mentioned.

Within the LSA, one site of interest was documented where a member of the Brokenhead Ojibway Nation participated in land clearing for a building, although they did not share additional details (e.g., who or what the building was for). Within the RSA, Brokenhead Ojibway Nation members identified a historic settlement from the eighteenth century along the south shore of Lac du Bonnet between the Winnipeg River and the Lee River and an area used for medicine picking along the Winnipeg River downstream from the McArther Generating Station. Burial and sacred sites were identified near Pine Falls. (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019).

Brokenhead resource harvesters currently use traditional areas north of the Manigotagan River and as far south as the RM of Brokenhead (Brokenhead Ojibway Nation 2015). This traditional use area spans Treaties 1, 3 and 5 (TRCM n.d.). Brokenhead Ojibway Nation resource harvesting activities occur within wildlife management areas, parks and within reserve boundaries. Resource harvesting sites within this area include locations along the Winnipeg and Brokenhead Rivers (Brokenhead Ojibway Nation 2015). Current resource harvesting activities include, but are not limited to, moose hunting and trapping for muskrat and beaver (Brokenhead Ojibway Nation 2015). Brokenhead continues to address outstanding Treaty Land Entitlement specific claims discussions with the Province of Manitoba and Government of Canada. Included in these discussions is the selection of land within the Whiteshell Provincial Park Petroform area located east and south of Pinawa (Brokenhead Ojibway Nation 2015).

In the traditional knowledge and land use study (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019), Brokenhead Ojibway Nation members also mapped traditional land use outside of the RSA, including along the southeastern short of Lake Winnipeg, as well as some use along the Winnipeg River. Brokenhead Ojibway Nation community members described traditional uses in these areas including: plant harvesting, fishing, hunting and trapping. The Winnipeg River itself was identified as an important area of plant harvesting, particularly medicinal plants with wild rice and berries formerly harvested in the Whiteshell Provincial Park area. Some other harvest of pulp/cord wood (commercial harvest) was recorded further east.

The collective study (Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation 2019) discussed cumulative effects in terms of external factors that have influenced traditional land and resource use activities. Factors mentioned include the highway going through the Brokenhead Ojibway Nation reserve, increased pollution, hydroelectric dams, the Pine Falls Paper Mill, hog farms, and the CNL WL site. One Brokenhead Ojibway Nation Elder noted that

> *"hydro development impacts hunting, trapping, and harvesting. The mouth of the river was liveable area before hydro dams" (p. 56) and*
>
> *"the paper mill in Pine Falls – that's a hotspot for cancer. All those people down the river, those people drank that water (p. 56).*

Brokenhead Ojibway Nation identified the following interests and concerns during the engagement process (further details are provided in Appendix 4.0-1 of Section 4.0). These issues are not always specifically linked directly to the Project, but rather the overall operation and closure of the WL site; however due to their overall importance to the community are noted herein:

- Traditional and cultural perspectives are important in relation to the Project.
- Interests regarding future land use in relation to the overall site closure.

- Concerns regarding water quality, particularly as waters flow from the east, from the west, into the Winnipeg River system, and into Lake Winnipeg. The watershed extends to Hudson Bay.
- Concerns about contamination in the Winnipeg River and a distrust in monitoring results and the ability to predict future effects were expressed.
- Concerns about potential effects to wildlife and to human health.

Further to this, in the traditional knowledge and land use study, Brokenhead Ojibway Nation identified the importance of water and concerns about moving nuclear material to the traditional territories of other communities (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019). A summary of the issues raised by the Brokenhead Ojibway Nation and specific responses by CNL can be found in Appendix 4.0-1 of Section 4.0.

Black River First Nation

Information about Black River First Nation traditional land and resource use has come from community websites, consultations and most recently the traditional knowledge and land use study titled *api migizik pii pa gilot – When Eagles Call Traditional Knowledge and Land Use Study for the WR-1 Nuclear Reactor In Situ Decommissioning Project* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019), completed in November 2019.

A total of 56 unique individuals from these communities attended one or more events, interviews and/or visits associated with the study including 21 from Black River First Nation. The mapping of traditional uses also records information from previous traditional knowledge studies that occurred. The three First Nations documented traditional land use over a large area of southeastern Manitoba, east and southeast of the southern basin of Lake Winnipeg. Generally, this is an area that would be bounded by Selkirk in the southwest, Hecla/Grindstone Provincial Park in the northwest and the Manitoba-Ontario border in the east. Traditional use is documented along river systems, recognizing the importance of rivers as travel corridors.

Within the LSA, Black River First Nation did not document site-specific values. Within the RSA, Black River First Nation noted fishing areas in the Winnipeg River downstream of McArthur Falls and from Powerview-Pine Falls to the mouth of the Winnipeg River. It was noted by a Black River elder that sturgeon fishing would occur on the Winnipeg River by McArthur Falls. Previous traditional knowledge and land use studies also documented other fishing locations upstream from Powerview-Pine Galls and habitation sites near the shores of the Winnipeg River (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019).

The Black River First Nation's traditional lands are primarily located south of the Manigotagan River, west of the Manitoba-Ontario border, and north of the Winnipeg River in Treaties 3 and 5 (Handkamer 2016; TRCM n.d.). Prior to the 1940s, Black River First Nation members participated in cattle ranching along with horses and hay fields, established in proximity to the community, which were important activities for the community (Black River First Nation 2015). In the following years members of Black River maintained an economy based on commercial fishing, logging and cutting cord wood (Black River First Nation 2015). Traditional resource use has historically been and continues to be important to members of Black River First Nation. Resource use activities include hunting, fish, trapping, wild rice harvesting and plant collection both a far a field and near the community (Black River First Nation 2015). Members of Black River have historically used the Black and Winnipeg Rivers most frequently for travel (Handkamer 2016). The Black River served as an access route for resource harvesting in the east, specifically wild rice harvesting and hunting near Nopiming Provincial Park (Handkamer 2016). Black River First Nation is currently pursuing a claim with the federal government regarding the Treaty 5 Disparity Claim

concerning per capita reserve land allotment and the lack of free and informed consent to this disparity at the time of the later adhesion to Treaty 5 document (Maurice 2016).

In the traditional knowledge and land use study (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019), Black River First Nation members also mapped land use outside of the RSA, including along and near the Little Black River and throughout the area east of the southern basin of Lake Winnipeg. Black River First Nation community members described traditional uses in this broader area including: fishing, hunting, plant harvesting, trapping, travel routes and wild rice harvesting. Some plant harvesting and fishing was also reported approximately 25 km away from the WL site in and near Whiteshell Provincial Park.

Harvesting medicines are also important to the Black River First Nation traditions, and were also discussed in the traditional knowledge and land use study (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019):

> *"Long ago, there were no roads. We travelled by boat to get to the hospital to see the doctor. So our people from long ago used traditional medicine to cure the sickness. Now, you can't find anything very much to use for that. Nowadays you run to the hospital and you don't really know what they give you. But with traditional [medicine], they knew what they were giving us. They had all different kinds. If I had an earache, they had something for that; toothache, something for that. All the different sicknesses. But then in those days too there was no cancer. Because people lived off the land." (p.32).*

The collective study (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019) discusses cumulative effects in terms of external factors that have influenced traditional land and resource use activities. Factors mentioned include government restrictions on harvesting, increased pollution, hydroelectric dams, the Pine Falls Paper Mill, hog farms, and the WL site. Elders from the Black River First Nation note that traditional fishing practices of First Nations have been steadily restricted despite Treaty promises that they would be allowed to continue harvesting as before. For example, there are constraints placed on sturgeon fishing as it is listed as a species at risk, which historically had both cultural and subsistence importance to First Nations Nations:

> *"One time we got caught catching sturgeon at Sturgeon Point. We weren't allowed to catch that; I don't know why. Yet the First Nation people have a right to fish for their own use. But we got stopped catching sturgeon. Even when we go as far as the Whiteshell. We're not allowed to catch sturgeon there also. You get a big fine. This was just recently. It's still in effect." (p.50).*

Additional historical factors and current issues that members noted prevent the expression of First Nation members' culture include non-Indigenous resource users and regulations.

> *"Many of our traditional areas have been converted to other land uses over time. We've seen people coming up from the south to come and harvest moose and other game. Increasing regulations, such as the need for a firearm possession and acquisition license, and the need to carry a treaty card also create barriers that discourage land use and sharing with youth." (p.53).*

During the engagement process for the Project, Black River First Nation identified several interests and concerns regarding traditional land and resources use (further details are provided in Appendix 4.0-1 of Section 4.0). These issues are not always specifically linked directly to the Project, but rather the overall operation and closure of the WL site; however due to their overall importance to the community are noted herein:

- The petroforms given to the Black River First Nation by Nanabush are present in the general Whiteshell area, approximately 20 km away from the WL site.
- Black River First Nation holds ceremonies in the Whiteshell area during the period of the Harvest Moon.
- Wild rice was identified as a dietary staple.
- Concerns were expressed about water quality and contamination of the Winnipeg River.

Further to this, in the traditional knowledge and land use study the Black River First Nation shared the importance of water, and concerns about moving nuclear material to the traditional territories of other communities (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019). A summary of the issues raised by the Black River First Nation and specific responses by CNL can be found in Appendix 4.0-1 of Section 4.0.

Hollow Water First Nation

Information about Hollow Water First Nation traditional land and resource use has come from community websites, consultations and the traditional knowledge and land use study titled *api migizik pii pa gilot – When Eagles Call Traditional Knowledge and Land Use Study for the WR-1 Nuclear Reactor In Situ Decommissioning Project* (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019), completed in November 2019.

A total of 56 unique individuals from these communities attended one or more events, interviews and/or visits associated with the study including 16 from Hollow Water First Nation. The mapping of traditional uses also records information from previous traditional knowledge studies that occurred. The three First Nations documented traditional land use over a large area of southeastern Manitoba, east and southeast of the southern basin of Lake Winnipeg. Generally, this is an area that would be bounded by Selkirk in the southwest, Hecla/Grindstone Provincial Park in the northwest and the Manitoba-Ontario border in the east. Traditional use is documented along river systems, recognizing the importance of rivers as travel corridors. No sites were documented by Hollow Water First Nation members in the LSA or RSA (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019).

Hollow Water First Nation's traditional lands encompass an area south of the Bloodvein River, west of the Manitoba-Ontario border, and north of the Manigotagan River in Treaties 3 and 5 (TRCM n.d.). Historically Hollow Water First Nation's primary food source and economy was based on wild rice harvesting on the Wanipigow and Rice Rivers along with Clangula Lake and bays on Lake Winnipeg (Thompson and Bushie 2015). The woodlands were used for hunting and trapping in the winter, fishing along the shores of Lake Winnipeg was popular in the spring, and wild rice was harvested on the shallow rivers and lakes in the fall (Reder 2013). Hollow Water First Nation community members currently maintain the historical tradition of gathering on Black Island to harvest blueberries. Economic activities for the community currently include fishing, hunting, trapping and wild rice harvesting. Fishing is considered the most important of these activities as a majority of community residents are directly employed in the Lake Winnipeg fishery (Manitoba Eco-Network 2010). Hollow Water First Nation does not have any outstanding Treaty Land Entitlement claims (SERDC 2016).

Harvesting medicines are also important to the Hollow Water First Nation traditions, and were also discussed in the traditional knowledge and land use study (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019):

> *"The medicines would help the people in the community when they needed the medicine for the purpose of healing from sickness."(p.33).*
>
> *"Remember those willows we used to eat when we were hungry? You would split them in half and there was something green in there and it would keep you going. We wouldn't want to go home for supper or lunch when we were on the island [Black Island] – busy playing in the bush. So we would have a little axe and we would chop it and eat it and then we weren't hungry anymore." (p.33).*
>
> *"Poplar trees could also be used as medicine. We'd put the white phloem of poplar trees on cuts; that would take the sting away. We put potato peelings on a forehead to bring down a fever. We used labrador tea by putting it in the oven, crushing it, making a powder, and making a wrap for healing; this is still done. We made a salve from rose hips, which could also be found in the winter. We would take frozen rose hips, heat them up, crush them, and mix them with lard." (p.33)*

The collective study (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019) discusses cumulative effects in terms of external factors that have influence traditional land and resource use activities. Factors mentioned include government restrictions on harvesting, increased pollution, hydroelectric dams, the Pine Falls Paper Mill, hog farms, and the WL site. Additional historical factors and current issues that prevent the expression of First Nation members' culture include regulations and industries' impact on the land. One Hollow Water First Nation Elder commented that

> *I was a trapper for 54 years. [The government is now] taking away hunting rights and [industries are] destroying hunting grounds . . . You need to go 300 metres off the road to hunt now. (p.53).*

Changes to hunting and trapping are more ways in which the cumulative effects of development have slowly altered the traditional way of life:

> *We used to have lots of moose a long time ago. Deer. Rabbits. Now we just have a lot of bannock! (p.54).*

In the traditional knowledge and land use study (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019), Hollow Water First Nation members mapped traditional land use east of the south basin of Lake Winnipeg and generally north of Manigotagan River Provincial Park. Uses documented included: trapping (muskrat, beaver, otter fisher, lynx, fox), plant harvesting (berries, wild rice, plums, cranberries, crab apples, wild rice, Labrador tea, sand berries, blackberries, gooseberries, rose hips), hunting (moose, ducks, geese, fowl), fishing (pickerel (walleye), whitefish, sunfish, perch) campsites, travel routes along the Manigotagan River and commercial uses such as commercial timber harvesting. Hollow Water First Nation members did not identify uses along the Winnipeg River System. Hollow Water First Nation identified the following interests and concerns during the engagement process (further details are provided in Appendix 4.0-1 of Section 4.0). These issues are not always specifically linked directly to the Project, but rather the overall operation and closure of the WL site; however due to their overall importance to the community are noted herein:

- Concerns about contamination of the soil and of the river were expressed.
- Concerns about fish.

Further to this, in the traditional knowledge and land use study Hollow Water First Nation identified the importance of water, and concerns about moving nuclear material to the traditional territories of other communities (Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019). A summary of the issues raised by the Hollow Water First Nation and specific responses by CNL can be found in Appendix 4.0-1 of Section 4.0.

Wabaseemoong Independent Nations

Wabaseemoong Independent Nations traditional land use area is located in Treaty 3 and is about 60 km wide and 120 km long spanning approximately 6,720 km^2 adjacent to the Manitoba – Ontario border, north of the Town of Kenora (WIN n.d.). The southwest boundary of the traditional land use area is established by the White Dog Parkway, approximately 50 km, which extends along Provincial Road 525 from the intersection of Highway 596. The Parkway continues north through White Dog reserve to the terminus at Caribou Falls located at the confluence of the English River system and the Winnipeg River system (WIN n.d.). This Parkway provides access to approximately one third of the Wabaseemoong Independent Nations traditional land use area and allows the only road access to the north (WIN n.d.). Wabaseemoong Independent Nations has historically used and currently utilizes the English and Winnipeg River systems for traditional land and resource use activities (Energy East Project 2016). Water routes from these two systems have provided resource use access to hundreds of kilometres in all directions (WIN n.d.). Previous discussions with Wabaseemoong Independent Nations, have confirmed interest in the area where traditional land and resource use activities regularly occur (AECL 2001).

In 2018, Wabaseemoong Independent Nations submitted a *Traditional Knowledge and Environmental Impact Assessment Report* (WIN 2018) that considered historical land use data and noted that seven modified map biography interviews had been collected at the time the report was submitted in early 2018 with more interviews to be completed in 2019. The spatial scope for the interviews was focused on the Winnipeg River system. The study (WIN 2018) concludes that members use the Winnipeg River system for a range of purposes.

Before interviews were completed for the study (WIN 2018), some Wabaseemoong Independent Nations members commented on their reluctance to participate because of the historical distrust of government and industry:

> *Many of the community members approached to participate in the study were reluctant to share their knowledge due to personal feelings of mistrust directed towards government and industry initiatives in general; a legacy of the flooding of the One Man Lake reserve and the mercury contamination of the local river systems.* (p. 5)

Wabaseemoong Independent Nations identified the following interests and concerns during the engagement process (further details are provided in Appendix 4.0-1 of Section 4.0). These issues are not always specifically linked directly to the Project, but rather the overall operation and closure of the WL site; however due to their overall importance to the community are noted herein:

- Whitedog is approximately 50 km from the site. Many of their members rely on the land. Although they reside upstream, they are located downwind of the Project.
- Concern was expressed about air emissions, and in particular about the earlier operation of the WL site.
- Concern was expressed that animals do not obey the same sorts of boundaries as humans and could come into contact with hazardous materials.
- Concerns were expressed about fish, and how contaminants can accumulate in fish over time.

- Concerns were expressed about water quality – specifically about the release of hazardous and radioactive materials to the Winnipeg River.

A summary of the specific issues raised by the Wabaseemoong First Nation and specific responses by CNL can be found in Appendix 4.0-1 of Section 4.0.

Manitoba Métis Federation

Three Indigenous Nations are constitutionally recognized by the government in Canada, as per s.35 (2) of the *Constitution Act, 1982*. First Nations, Inuit and Métis. The term “Métis” is defined by the Métis National Council (MNC) as: “a person who self-identifies as Métis, is distinct from other Aboriginal peoples, is of historic Métis Nation Ancestry and who is accepted by the Métis Nation.” (MNC 2022). The MNC is a federally recognized national administrative and representative body for the Métis Nation both nationally and internationally since 1983. Five democratically elected provincial organizations exist within Canada and are comprised of regional councils, community councils and Métis locals. The Manitoba Métis Federation is one of these provincial organizations, alongside the Métis Nation of Ontario, Métis Nation Saskatchewan, Métis Nation of Alberta and Métis Nation of British Columbia. The Manitoba Métis Federation is the democratically elected self-government representative of the Manitoba Métis also known as the Red River Métis, an “Aboriginal peoples’ under Section 35 of the *Constitution Act*, 1982 and currently includes the Manitoba Métis Federation Inc., a non-share corporation incorporated pursuant to the laws of Manitoba. Founded in 1967, the Federation has over 650 staff across the province (MMF 2018a).

The Manitoba Métis Federation represents and advance the interests of the Métis people of Manitoba and uses an electoral process where all formal positions are elected by Federation members in each designated Region or Local. Governance includes: a President, Board of Directors, regional associations or “Regions” and community-level "Locals". The President functions as the Federation leader and spokesperson and Chief Executive Officer. This position oversees day-to-day Federation operations and is elected through a province-wide election every four years. A Board of Directors, comprised of 23 democratically elected members, provides guidance, leadership and management toward Federation (and its subsidiaries) policies, objectives and strategic direction. Seven Regions across Manitoba are administered by a vice-president and two executive officers, who are also of the Federation’s Board of Directors, and who administer programs and services independently to their specific geographic area. Each Region comprises various Locals. These are administered by a chairperson, a vice-chairperson and a secretary-treasurer, and have a minimum of nine members which meet at least four times a year. Each Federation member belongs to a Local. Specific Locals determine the timing of election of their respective Local representatives, while regional officers are elected every four years (MMF 2018a).

The governance structure of the Manitoba Métis Federation is provided on Figure 6.8.1-5.

The Red River Métis have been known by many names throughout history, such as Bois Brûlés, Flower Beadwork People, Otipemisiwak (The People Who Own Themselves), Riel’s People, Les Michif, and Manitoba Métis – from the beginning, they have all referred to the same people – the Red River Métis. The Red River Settlement, which is present day Winnipeg, Manitoba, was the birthplace of the Red River Métis and continues to be the heart of the Red River Métis Homeland. This independent Red River Métis population constituted a historic rights-bearing community in present day Manitoba and beyond within the Northwest. Since the early 1800s, the Red River Métis has asserted themselves as a distinct Indigenous collectivity with rights and interests in its Homeland. The Red River Métis share a language, national symbols, and culture, including music, dance, and dress.

In early times, the Red River Métis were mostly nomadic. Later, they established permanent settlements centered on hunting, trading and agriculture (Marcus 2011). The Red River Métis were employed by both of the fur trade's major players, the Hudson's Bay Company and the Northwest Company. At the same time, however, the Red River Métis became extensively involved in the buffalo hunt.

The fur trade was vital to the ethnogenesis of the Red River Métis and was active in Manitoba from at least the late 1770s, and numerous posts and outposts were established along cart trails and waterways throughout the North-West. These trails and waterways were crucial transportation networks for the fur trade (Jones 2014) and were the foundation of the Red River Métis' extensive use of the lands and waters throughout the province. In the early 20th century, the Red River Métis continued to participate in the commercial fisheries and in trapping activities, which is well documented in Provincial government records.

The Crown, as represented by the Manitoba Government, has recognized some aspects of the Red River Métis' harvesting rights through a negotiated agreement: The Manitoba Métis Federation - Manitoba Points of Agreement on Métis Harvesting (the Manitoba Métis Federation - Manitoba Harvesting Agreement). This Agreement recognizes that collectively held Métis Harvesting Rights, within the meaning of Section 35 of the Constitution Act, 1982, exist within the Recognized Métis Harvesting Zone, and that these rights may be exercised by Red River Métis Rights Holders consistent with Métis customs, practices and traditions (Manitoba Métis Federation - Manitoba Harvesting Agreement).

As affirmed by the Supreme Court of Canada, such rights are "recognize[d] as part of the special aboriginal relationship to the land" (R. v. Powley. 2003) and are grounded on a "communal Aboriginal interest in the land that is integral to the nature of the Métis distinctive community and their relationship to the land" (Manitoba Métis Federation v. Canada 2013). In particular, the Manitoba Métis Federation - Manitoba Harvesting Agreement recognizes that Métis rights include hunting, trapping, fishing and gathering for food and domestic use, including for social and ceremonial purposes and for greater certainty, Métis harvesting includes the harvest of timber for domestic purposes throughout an area spanning approximately 169,584 km² (the Métis Recognized Harvesting Area; Manitoba Métis Federation - Manitoba Harvesting Agreement). Importantly, courts have also recognized that Métis harvesting rights may not be limited to Unoccupied Crown Lands (R. v. Kelley 2007).

Unlike First Nations in Manitoba, whose commercial rights were converted and modified by treaties and the Natural Resources Transfer Agreement (NRTA) (R. v. Horseman 1990), the Métis' pre-existing customs, practices, and traditions, including as they relate to commerce and trade, were not affected by the NRTA (R. v. Blais 2003) and continue to exist and be protected as Aboriginal rights. First Nations' treaty rights in Manitoba are, for example, inherently limited by the Crown's power to take up lands (Mikisew Cree First Nation v Canada 2005). Métis rights, in contrast, are not tempered by the "taking up" clauses found in historic treaties with First Nations. Métis rights must be respected as they are, distinct from First Nations' rights and unmodified by legislation or agreements.

According to the Métis Law of the Harvest, Métis harvesters may harvest throughout Recognized Métis Harvesting Area on all unoccupied provincial Crown Lands in Manitoba and occupied provincial Crown lands, including provincial parks, wherever First Nation Members are allowed to harvest; and on any privately owned lands in Manitoba on which that Métis Harvester has been given permission by the owner or occupant, or reserve lands with permission of Band Council (Manitoba Métis Federation v Canada 2013).

Recognized Métis Natural Resource Harvesting Areas 36, 34 34B and 25A and Game Hunting Area 26 are situated in the vicinity of the WL site (Manitoba Sustainable Development n.d.f). It should be noted that the WL site on the east side of the Winnipeg River appears to be not in the Recognized Métis Harvesting Area but is in an area labelled as the "Recognized Métis Harvesting Area – Expansion Area" (Figure 6.8.1-4), or provincial Game

Hunting Area 26 also known as Manigotagan. Although the WL site is located in an area that the Province of Manitoba has not recognized as a Métis harvesting area (MMF 2018b), CNL acknowledges that the Métis have existing, asserted, and/or harvesting rights in the vicinity of the Project.

According to the Métis Law of the Harvest (MMF 2013), harvest includes hunting, trapping, fishing and gathering for food and domestic use, including sharing, social and ceremonial purposes, of fish, big-game, small game, furbearers, game-bird (upland and migratory), berries, mushrooms, medicinal and other plants including wild rice and firewood or timber. Plant harvesting has been undertaken for food, crafts and medicines and has included birch, cedar, dandelion, milkweed, berries, wood products, roots, nuts and mushrooms. These activities were typically undertaken in the summer months and are known to occur in areas southwest of the Project.

During the public and Indigenous engagement process, the Manitoba Métis Federation noted that their citizens' place of residence did not always correlate with their resource use areas, as the population is mobile, and land use tends to be associated with where an individual learned to harvest. As such, their citizens often travel to other locations across the province when undertaking harvesting activities, which reflects the location in which they learned (e.g., where their grandfather taught them).

A traditional knowledge and land use study, titled *Whiteshell Reactor #1 Decommissioning Manitoba Métis Traditional Knowledge, Land Use and Occupancy Study*"(TKLUOS) was prepared by Shared Values Solutions (SVS 2019) for the Manitoba Métis Federation specifically for the proposed Project. The TKLUOS (SVS 2019) provides an overview of the types of traditional knowledge, land use and occupancy values that were collected in the interviews with Métis knowledge holders. A total of ten Métis harvesters were surveyed for the study resulting in the identification of 424 locations of Land Use and Occupancy Values (LUOs). Two study areas were used, the first is a study area that includes 100 m on either side of the Winnipeg River from Seven Sisters Generating Station to the mouth of the Winnipeg River, Lac du Bonnet and the Lee River. The second is a 25 km radial study area around the WR-1. A total of 192 LUOs were mapped within 25 km of the WL site and 75 were within 100 m of the WL site.

The Red River Métis citizens interviewed noted sites of cultural significance. One Red River Métis citizen noted that the WL site is excellent deer habitat and that they have seen deer on the riverbank at the site and have gathered firewood, and harvested blueberries, cranberries, pin cherries, and saskatoon berries. They also noted a boat launch. No hunting or trapping sites were documented in the LSA. In the RSA, Métis citizens documented numerous fishing spots along the Winnipeg River downstream of the Project. Species fished include sauger, pickerel/walleye, jackfish/northern pike, sturgeon, and perch. Historically, populations supported a commercial fishery and prior to construction of the Seven Sisters Generating Station (situated approximately 7.5 km upstream of the WL site; see Figure 6.5.5-1) there was an important Lake Sturgeon spawning and nursery area located below the Seven Sisters Generating Station site (COSEWIC 2006). This commercial fishery was important to the Red River Métis into the early 20th century (SVS 2019). Métis citizens also noted areas where they had hunted duck, grouse, and partridge in the RSA. In the RSA, cultural sites documented by Métis citizens include multiple boat launches, an important landscape feature, and a recreational area for tubing (SVS 2019).

The TKLUOS (SVS 2019) noted that:

> "*it can be said with confidence that members of the Manitoba Métis Community rely on and use the lands and waters around the WR-1 site for various cultural and traditional purposes, including actively exercising their s. 35 harvesting and other Aboriginal rights*." (p.2)

The TKLUOS (SVS 2019) goes on to comment that:

> "*Despite the noted limitations set out in this report, SVS is of the position that the study provides a reasonable representation of the Manitoba Métis Community patterns of LUO within the study areas."* (p.24)

A summary of the specific issues raised by the Manitoba Métis Federation and specific responses by CNL can be found in Appendix 4.0-1 of Section 4.0.

6.8.1.5.2.2.2 Winnipeg River

As described in Section 6.4.2 Surface Water Quality, the Winnipeg River is considered to be a medium-sized lowland river (AECL 2001). Its drainage area is approximately 150,000 km^2, originating in Ontario at Lake of the Woods. The Winnipeg River tributaries include the Rainy River (flows into the Lake of the Woods), Black Sturgeon River, English River, Bird River, Lee River, Whiteshell River, Whitemouth River and the Macfarlane River. There are six hydroelectric dams on the river, the closest approximately 7.5 km upstream of the WL site. These dams have extensively modified flow patterns in the river (AECL 2001). Adjacent to the WL site, the river is approximately 0.3 km wide and 7 m deep, and flows northerly between 436 m^3/s and 1,842 m^3/s to Lake Winnipeg (2010 to 2015 average at Seven Sisters Generating Station; Manitoba Hydro 2016).

Historically, liquid effluent from the Active Liquid Waste Treatment Center was discharged to the Winnipeg River via the process sewer at the sewer outfall located about 8 m offshore in approximately 5 m of water (AECL 2001). The Winnipeg River Task Force (WRTF 1995) looked at potential sources of Winnipeg River water quality degradation near the community of Sagkeeng First Nation. The Task Force found that WL has not had an adverse effect on water quality in the Winnipeg River for downstream communities (AECL 2001). The task force included members from the Sagkeeng First Nation, Environment Canada, Indian and Northern Affairs Canada and Health Canada.

The monthly average of water chemistry for 2011 to 2015 for the intake water at the WL site had concentrations of copper, iron and lead exceeding the Manitoba Water Quality Standards, Objectives, and Guidelines (WQSOG; see Section 6.4.2.5.2.2 Surface Water and Sediment Quality). Phosphorous concentrations in the river also exceed the WQSOG and increased between 2011 and 2015. Recently, the Winnipeg River has been classified as meso-eutrophic (Environment Canada 2015). This indicates that nutrient levels are moderate, which may lead to plant growth and reduced water clarity. Samples collected upstream of the WL site (Pinawa) has consistently had cesium-137 and strontium-90 concentrations below the federal drinking water standard (see Section 6.4.2.5.2.2 Surface Water and Sediment Quality).

During the 2000 sediment investigation, the sediment downstream of the outfall was determined to be erosional, with a clay bottom covered in parts with sand, gravel, cobble and boulders (AECL 2001). The highest measured caesium-137 level in a sediment sample during the 2000 study was 2,610 Becquerels per kilogram (Bq/kg) (AECL 2001). This exceeds the *Nuclear Substance and Radiation Devices Regulation* (SOR/200-207; NSRDR) Clearance Level of 100 Bq/kg for caesium-137. Although the activity level in the sediment at the K03 location is above NSRDR unconditional clearance level, it is well below a human external exposure level of concern 2.8×10^6 Bq/kg. It is also well below the Tier 2 estimated no-effect value (ENEV) for benthic invertebrates' value of 1.5×10^5 Bq/kg. The caesium-137 levels detected in the samples collected during routine monitoring at locations OFL, K03, K05, K14 and K23 from 2010 to 2015 were one to two orders of magnitude lower than the highest 2000 sample (CNL 2020). Caesium-137 levels at all locations except OFL and KO5 were below the NSRDR Clearance Level of 100 Bq/kg. The activity at OFL has historically varied from less than 5 Bq/kg to 75,500 Bq/kg (CNL 2020).

Variation of activity is not unexpected for all samples due to the highly localized and spotty nature of the contamination in the river sediments. This variability is the likely reason for the unusually high caesium-137 activity noted in the K05 sample in 2015 (CNL 2020).

As part of the routine monitoring at the WL site, river bottom sediments were collected from twelve locations along the Winnipeg River, ranging from 0.8 km upstream to 13.1 km downstream of the Outfall. In 2015, the gross alpha activity detected in the samples ranged from 214 to 410 Bq/kg (CNL 2020). In five years prior, average minimums and maximums activities ranged from 268±14 to 520±35 Bq/kg. The alpha activity in these samples is due to naturally occurring isotopes such as uranium-238 or thorium-232 and their progeny, as both upstream and downstream samples contain similar levels. All samples are below the NSRDR Clearance Level for naturally occurring uranium-238 and thorium-232 of 1,000 Bq/kg (CNL 2020).

The gross beta activity in sediment ranged from 488 to 781 Bq/kg in 2015 at the twelve sampling locations apart of the routine monitoring (CNL 2020). The previous five years average minimums and maximums ranged from 390±94 to 2,128±1233 Bq/kg. The variability of the average maximum five year range is large due to extremely high concentrations measured in 2012 at K23 of 7,058 Bq/kg. Beta activity includes contributions from naturally occurring potassium-40 and from caesium-137. The majority of the beta activity for all locations continues to be from naturally occurring potassium-40 (CNL 2020). The NSRDR Clearance Level for potassium-40 is 10,000 Bq/kg.

The Winnipeg River supports a diverse fish community and affords spawning, rearing and foraging habitats. A total of 61 native species are reported for the river (Stewart and Watkinson 2004) and two species at risk are known to be present within the vicinity of the WL site: Lake Sturgeon (*Acipenser fulvescens*) and Carmine Shiner (*Notropis percobromus* [COSEWIC 2019]). Fish occurring within the study reach include species that are primarily resident (present year-round), as well as migratory (passing through). Fish habitat is generally similar throughout the assessment area (Section 6.5.5.2.2 Fish Community).

The Town of Lac du Bonnet and Pinawa draw water from the Winnipeg River System and treat it at their water treatment plants (Province of Manitoba 2004; LGD of Pinawa 2015). Sagkeeng First Nation is the only First Nation in the socio-economic RSA known to draw water from the Winnipeg River for residential purposes (J.R. Cousin Consultants Ltd. n.d.).

6.8.1.6 Project Interactions and Mitigation

6.8.1.6.1 Methods

This section describes the process by which interactions between Project components and activities and traditional land and resource use VCs were identified and evaluated. Potential effect pathways are identified and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the Project and the environment by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such, the Project Interactions and Mitigation section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce effects to traditional land and resource use VCs. Environmental design features included design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the engineering and environmental teams, combined with input from project-specific or regional engagement with other interested parties. The design features and/or mitigation activities were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation.

- **No pathway** – pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change to measurement indicators identified for traditional land and resource use VCs relative to Base Case values, and therefore would have no residual effects to land and resource use VCs.
- **Secondary pathway** – the pathway could result in a measurable minor change to measurement indicators identified for traditional land and resource use VCs but would have a negligible residual effect on traditional land and resource use VCs relative to Base Case values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway** – the pathway is likely to result in an environmental change to measurement indicators identified for traditional land and resource use VCs relative to the Base Case that could contribute to residual effects to traditional land and resource use VCs.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects to traditional land and resource use VCs were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to traditional land and resource use VCs through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment.

6.8.1.6.2 Results

Pathways through which all stages of the Project may interact with and result in changes to measurement indicators for traditional land and resource use VCs is provided in Table 6.8.1.6-1.

Table 6.8.1.6-1: Pathways Analysis for Traditional Land and Resource Use Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

Overall activities associated with WL site preparation, ISD of WR-1 and decommissioning of above-ground facilities	■ Changes to traditional land use resulting from changes to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River.	■ The Project is located in an already disturbed area.
		■ Temporary supporting infrastructure will be located within the Local Study Area (i.e., previously disturbed and developed area).
		■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the Regional Study Area will be used during decommissioning activities around disturbed areas, where appropriate.
		■ Project activity will typically be limited to daytime hours, where possible, and noise will be short-term and sporadic.
		■ Decommissioning of the WR-1 Building will be completed in a controlled manner, and no blasting will be required.
		■ The planned decommissioning of the WR-1 Building presently involves:
		  ▪ removing the service wings and infilling in these areas with compacted fill;
		  ▪ sealing of open conduits in the building foundation;
		  ▪ grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation and removing the superstructure; and
		  ▪ Installation of reinforced concrete cap.
		■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring.
		■ As part of CNL's licence with the Canadian Nuclear Safety Commission, environmental monitoring around the WL site is required and will continue for the Project.
		■ Follow-up monitoring during the post-closure phase will be completed to verify effects predictions and to provide information for use in adaptive management to address potential unforeseen effects.
		■ CNL is committed to involving Indigenous Nations in the follow-up monitoring, including initiatives that considers Indigenous values. This would involve Indigenous Nations during the monitoring stage of the Project to assess potential effects on fish and wildlife resources and changes to vegetation and water quality upon which traditional uses are dependent. It would also involve discussions in post decommissioning monitoring.
			Secondary

Table 6.8.1.6-1: Pathways Analysis for Traditional Land and Resource Use Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Overall activities associated with WL site preparation, ISD of WR-1 and decommissioning of above-ground facilities	■ Nuisance factors such as dust and noise may affect the desirability of engaging in traditional land and resources use.	■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring. ■ Implementation of dust management techniques to control dust generated by the Project, consistent with the current Environmental Assessment Follow-up and Monitoring Program. ■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures. ■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and dust during building demolition or soil remediation. Methods may include: ▪ wetting techniques during demolition to limit mobility of dust; ▪ wind restrictions during demolition to stop work or apply wetting techniques; and ▪ hydro seeding during backfilling and landscaping to reduce soil erosion. ■ Removal of accumulations of particulates (e.g., dirt) on road as soon as possible. ■ On-site vehicles and equipment engines will meet Tier 3 emission standards, where possible, and be maintained in good working order. ■ Limit idling of vehicles on-site and speed on roads. ■ Use of tarps or 3-sided enclosures for raw material storage. ■ Road watering and chemical dust suppressant when necessary. ■ Decommissioning activity will be limited to daytime hours and noise will be short-term and sporadic. Decommissioning of the WR-1 Building will be completed in a controlled manner, and no blasting will be required. ■ CNL is committed to involving Indigenous Nations during the monitoring stage of the Project.	No linkage

Table 6.8.1.6-1: Pathways Analysis for Traditional Land and Resource Use Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Overall activities associated with WL site preparation, ISD of WR-1 and decommissioning of above-ground facilities (continued)	■ Project activities could affect unidentified or unknown heritage resources.	■ Implementation of the Environmental Assessment Follow-up and Monitoring Program for the Project, which describes the commitment to protection and preservation of cultural and archaeological sites. ■ Per the *Heritage Resources Act C.C.S.M. c. H39.1*, if unanticipated heritage resources are encountered during Project activities, the following will apply: ▪ all Project activity in the immediate vicinity will cease; ▪ the Heritage Resources Branch will be contacted; and ▪ based on the information provided, a mitigation plan will be formulated and implemented in consultation with the Heritage Resources Branch. ■ Project activity at the site can resume only after the Heritage Resources Branch has granted permission. ■ Indigenous organizations will be contacted for input with respect to any actions related to heritage resources.	No Linkage
Preparation for and implementation of institutional control	■ The use of ISD as the decommissioning method for WR-1 will change the proportion of the site that can be released for unrestricted use. ■ The Project may change the suitability of the LSA for traditional land and resource uses.	■ Continued activities through the Community Regeneration Partnership to help the region develop economically. ■ Communication of environmental monitoring results to confirm the safety of the WL site and lands around it. ■ Final ISD designed so that projections of doses to members of the public are well below the established limits for dose to any member of the public. ■ Final ISD design will be done to maximize hazard reduction. ■ Continued collaboration with Indigenous Nations on environmental monitoring activities and communication of results. ■ Implementation of an engagement plan supported by a community advisory committee with Sagkeeng First Nation to help address recommendations from their psychosocial impacts study.	Secondary

Table 6.8.1.6-1: Pathways Analysis for Traditional Land and Resource Use Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Preparation for and implementation of institutional control Closure of the entire WL site	■ Decommissioning and reclamation of the entire WL site, including the Project, may change the future land tenure and uses of the WL site.	■ CNL is committed to involving Indigenous Nations in the follow-up monitoring, including initiatives that considers Indigenous values. ■ CNL will work with Indigenous Nations to ensure that relationships endure, grow and adapt to future activities. As such, CNL will work to establish contribution/relationship agreements with each engaged Indigenous Nation, which include liaison positions, and create mechanisms to develop and implement initiatives that will help address each Nation's unique interests and concerns related to the Project and the Whiteshell Laboratories Restoration Project. ■ Follow-up monitoring during the post-closure phase will be completed to verify effects predictions and to provide information for use in adaptive management to address potential unforeseen effects. Results will be shared with Indigenous Nations. ■ Continued activities through the Community Regeneration Partnership to help the region develop economically. ■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe, and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ Affected areas will be remediated to meet the WL preliminary soil cleanup and the non-radiological and radiological clearance and release criteria in accordance with the target end state of the associated land-use category. ■ Engagement with Indigenous Nations on future uses of the WL lands surrounding the WL site. ■ Continued collaboration with the Sagkeeng First Nation on initiatives that support the community's cultural expression and reconnection to the land on site.	Secondary

6.8.1.6.2.1 No Linkage Pathway

The following pathway was assessed as having no measurable environmental change and hence, no linkage to residual effects on traditional land and resource use VCs.

■ **Project activities could affect unidentified or unknown heritage resources.**

Although there are currently no archaeological sites located on the WL site, there is a site located approximately 1,700 m south of the WL site (AECL 2001) and the Winnipeg River has been an important travel route throughout history, potentially beginning in the Paleo Indian Period (*ca.* 11,000 to 7,000 years ago). Project activities that could affect cultural and archaeological sites include those activities that could cause ground disturbance of any previously undisturbed area, especially if the undisturbed area is located between the western edge of the WL site's built infrastructure and the Winnipeg River.

The Environmental Assessment Follow-up and Monitoring Program for the WL site describes CNL's commitment to the protection and preservation of cultural and archaeological sites. Decommissioning activities are not expected to include any undisturbed land or areas on the WL site. If an unexpected discovery of a heritage resource is made during Project activities, CNL will, in accordance with the *Heritage Resources Act*, cease activities until the Heritage Resources Branch can be consulted on the need to conduct a Heritage Resource Impact Assessment before resuming decommissioning activities. CNL will also engage interested Indigenous organizations with respect to the identification and management of such heritage resources. With this mitigation in place, this pathway is considered to have no linkage to effects on traditional land and resource use.

- **Nuisance factors such as dust and noise may affect the desirability of engaging in traditional land and resource use.**

During construction, traditional land and resource use will be restricted on the WL site, but will continue to persist in locations adjacent to the WL site. Project activities, including site preparation, WR-1 Building demolition and operation of the batch mixing plant, are expected to increase the level of nuisance factors (dust and noise) in the LSA; however they are not expected to have an effect on an individual's land and resource use experience or on harvested species because of mitigation and management practices put in place for the Project.

Nuisance factors could make traditional land and resource use activity experience on the Winnipeg River to the west of the WL site less enjoyable, but changes are expected to be temporary and people will still be able to access the river upstream and downstream of the WL site to engage in activities. No emissions from Project activities are anticipated to exceed the appropriate standards and guidelines (Table 6.2.1-14). Project activity will typically be limited to daytime hours, where possible, and noise will be short-term and sporadic. Decommissioning of the WR-1 Building will be completed in a controlled manner, and no blasting will be required. The loudest decommissioning activity will likely be noise from a percussion hammer on an excavator, which will be used to break up reinforced concrete walls and floors during demolition. This activity will be limited to the interior of the building envelope, which will serve to reduce the level of noise outside the building, and in the surrounding area. The WL site has also retained heavy tree coverage, which provides a natural noise barrier (AECL 2001).

Due to the restriction on use and access to the WL site, the nature of Project-related noise, the absence of threshold exceedances for emissions and mitigation for minimizing dust, which includes implementation of dust management techniques to control dust generated by the Project, nuisance factors as a result of Project activities are not expected to have an effect on traditional land and resource use in the LSA. This pathway is therefore considered to have no linkage to effects on traditional land and resource use. That being said, CNL is aware that Indigenous organizations have indicated their concerns about potential effects on traditional land and resource use that occurs in close proximity to the WL site. CNL is committed to working closely with each nation to develop and maintain monitoring programs that will allow each nation the ability to gather the data they need to inform their communities in a meaningful way, and to help guide the project into the future.

6.8.1.6.2.2 Secondary Pathways

In some cases, a potential interaction with an assessment endpoint exists but mitigation is expected to cause minor changes to the environment and a negligible effect on traditional land and resource use relative to the existing Base Case. The following are expected to result in negligible effects on traditional land and resource use and will not be examined further in the EIS.

- **Changes to traditional land use resulting from changes to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River.**

The Project could affect traditional land use through changes to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River. Changes to these VCs could result from a change in the abundance and distribution of resources, the quality of the resource, and the ability to access the resource including fish, wildlife and vegetation. Any of these changes could subsequently affect the ability and the desire to engage in activities in the LSA.

The footprint of the WR-1 Building is approximately 0.07 ha and is located in an area that has been previously disturbed, where wildlife habitat value is considered to be negligible to low. In addition, temporary supporting infrastructure will be located within the LSA on previously disturbed and developed areas. Therefore, the Project is not expected to result in an incremental loss of wildlife habitat from current conditions at the WL site. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the RSA will be used during decommissioning activities around disturbed areas, where appropriate. This will reduce the potential for effects on adjacent natural areas that provide suitable wildlife habitat. Once decommissioning of the WR-1 Building and ISD of WR-1 are completed and the engineered cover installed, the area will be graded and restored with native vegetation. Once institutional control begins in 2031, there will be monitoring activities, but the Project site will remain otherwise undisturbed.

Disturbance Factors

Project activities, including site preparation, demolition of the WR-1 Building and the development of temporary infrastructure, will increase noise levels and the amount of dust produced in the LSA, which could affect the distribution of wildlife species harvested by resource users. Changes to the distribution of wildlife species could in turn affect traditional land and resource use, as they constitute some of the resources on which these activities are dependent. Due to the nature of the noise produced by Project activities (sporadic, short-term, no blasting), wildlife species that live near the WL site are not expected to experience habitat loss (AECL 2001). Increases in dust are expected to be short-term, reversible, and not exceed the appropriate guidelines and standards. Noise and dust are not expected to result in changes of wildlife distribution that could affect traditional land and resource use. CNL has made a strong commitment to ongoing Indigenous engagement. In this context, CNL will be working closely with Indigenous Nations to share information regarding future decommissioning activities, and ensuring we have strong communication on matters that may have consequences in relation to the practice of Indigenous rights. We are confident that our approach will allow us to address any potential concern.

Airborne Dispersion of Contaminants

The Project may result in airborne contaminants that could deposit to soil and surface water, where they could affect vegetation, wildlife/wildlife habitat, fish/fish habitat and surface water quality. Changes to vegetation, wildlife/wildlife habitat and fish/fish habitat could in turn affect traditional land and resource use, as they constitute some of the resources on which these activities are dependent. The Environmental Risk Assessment (ERA) predicated that there will be no exceedances of the 2.4 mGy/day radiation benchmark for terrestrial and riparian biota on or near the WL site resulting from atmospheric releases (Section 6.7.2.7.1 Application Case – Closure Phase). All predicted doses are well below this level. Therefore, it is unlikely that there would be significant adverse effects on terrestrial populations or communities (including terrestrial plants [e.g., berries] and terrestrial wildlife [e.g., snowshoe hare, white-tailed deer and red fox]) as a result of radionuclide releases from closure activities. In addition, the ERA predicts that the total radiation dose to all human receptors (including harvesters) during closure activities is well below the public dose limit of 1 mSv/a (Section 6.7.1.7.1 Application Case – Closure Phase). Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure of potential critical groups to radioactive releases from the WL site during closure.

Waterborne Dispersion of Contaminants

The Project may result in waterborne dispersion of contaminants that could affect vegetation, wildlife/wildlife habitat, fish/fish habitat and surface water quality. Waterborne dispersion may occur after the start of institutional control through leakage via the grouting to groundwater. Groundwater may then migrate to surface water at the Winnipeg River, where contaminants could travel downstream and affect vegetation, wildlife/wildlife habitat and fish/fish habitat. Changes to water quality or fish/fish habitat could in turn affect traditional land and resources use, as they constitute some of the resources on which these activities are dependent. The ERA predicts that there will be no exceedances of the 9.6 mGy/day radiation benchmark for the aquatic biota in the Winnipeg River (Section 6.7.2.7.2 Application Case – Post-closure Phase). Similarly, there are no predicted exceedances of the 2.4 mGy/day radiation benchmark for terrestrial and riparian biota on or near the WL site (Section 6.7.2.7.2 Application Case – Post-closure Phase). All predicted doses are well below these levels. For non-radiological contaminants of potential concern, the ERA predicts no exceedances of cadmium, lead, HB-40 and xylene exposure to ecological receptors. Therefore, it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of radionuclide releases or the release of non-radiological contaminants from post-closure activities.

There are no anticipated exceedances for the radiation benchmarks for human receptors, including an on-site harvester, a farm north of the WL site on the Winnipeg River, and an on-site farm, a human receptor located on the Whiteshell Reactor Disposal Facility (WRDF; i.e., the end-state of the Project). The on-site farm receptor was assessed because the temporal boundary of the post-closure phase extends past a number of human generations. The total radiation dose for all receptors are below the public dosage limit of 1 mSv/a and the dose constraint for the Project of 0.25 mSv/a for all age groups (Section 6.7.1.7.2 Application Case – Post-closure Phase). Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure of these receptors to radioactive releases from the WL site during the post-closure phase.

The doses to human receptors that could be exposed to the non-radiological contaminants of potential concern in surface water during post-closure were calculated based on total concentration (background plus Project contribution). Incremental hazard quotients were compared to a benchmark hazard quotient of 0.2, which is consistent with Health Canada. The hazard quotients derived for constituents of potential concern were below the protective benchmark for all receptors, with the exception of a toddler harvester, which slightly exceeded the benchmark. If only the project contribution is considered, the HQs are reduced even further, and hazard quotients are well below for all receptors (the Project contribution to the total is 0.0021% for cadmium and 0.00002% for lead). Therefore, no discernable health effects are anticipated due to exposure of potential critical groups from the Project during post-closure.

Summary

Through these pathways, the Project is expected to have a negligible effect on traditional land and resource use according to western scientific analysis. There are not anticipated to be any threshold exceedances in harvested receptors through atmospheric releases and waterborne dispersion of contaminants. In addition, the mitigation proposed to minimize Project effects on surface water quality, the aquatic environment, and the terrestrial environment, are anticipated to eliminate or mitigate any potential adverse effects to the resources on which traditional land and resource use are dependent. These pathways are therefore characterized as secondary.

Based on their worldview and experience, the Indigenous Nations studies reached different conclusions than the western scientific analysis completed for the EIS. As the Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation (2019) note:

> *"As Anishinaabe Traditional Knowledge holders, we have concerns about the decommissioning of this nuclear reactor that cannot be addressed through science. We want to acknowledge that CNL has given careful scientific consideration to our questions and that CNSC is providing a second scientific opinion on the project." (p. 59)*

In their TKLU Study (Firelight Group Inc and Sagkeeng Anicinabe 2018), SFN members shared that they believed that the Project would affect the resources they harvest. For example:

> *I think [decommissioning the site] will affect the animals and the plant life in there (p. 81); and*
>
> *…because of the radioactive stuff I wouldn't feel comfortable taking stuff in that area. I don't even feel comfortable because knowing that it could actually seep into the river, yeah. And we're downstream from where that site is, a lot of our animal life like I said is not safe (p. 83).*

Métis citizens also believe that the Project could affect the health of fish, birds, and deer over time and in turn affect their health (SVS 2019):

> *If that stuff's going to get in the deer, it's not [just] going to impact the deer, it's going to impact the people eating the deer, right? So by the time we figure that out it's going to be too late (p. 52).*

According to the Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation (2019), the Project could ultimately affect the Winnipeg River:

> *Water is strong. When it rains, it leaves a lot of water on the ground. Lots of it sinks. It is still going to get into the ground no matter what they put on top. Eventually it will go into the river (p. 65).*

The Wabaseemoong Independent Nations in their review of the EIS expressed their believe that the Project will change resources and their availability. In particular they are concerned about the destruction and alteration of habitat, changes in water quality, and modified ecosystem function, and bioaccumulation, which would affect their ability to engage in traditional land use activities (WIN 2018).

Indigenous Nations have indicated their concerns and perceptions about potential effects on wildlife, fish and plants and the resulting effects on traditional land and resource use that occurs close to the WL site. To address the difference between the conclusions of the effects assessment and the TKLU studies, CNL has engaged with Indigenous Nations to understand their perspectives on Project effects and develop opportunities and mechanisms for their ongoing involvement and participation, which are described in more detail in Section 6.8.1.7. The measures proposed in Section 6.8.1.7 to involve Indigenous Nations in a country food monitoring program and risk communication program, environmental monitoring and communication efforts to help demonstrate ongoing protection of the environment. CNL is committed to involving Indigenous Nations during the monitoring stage of the Project to help better understand and alleviate such concerns.

- **The use of ISD as the decommissioning method for WR-1 will change the proportion of the WL site that can be released for unrestricted use.**

- **Decommissioning and reclamation of the entire WL site, including the Project, may change the future land tenure and uses of the WL site.**

The WL site has been operational since the 1960s, with restrictions on public access for safety and security reasons. Exceptions to this include parcels of the WL site on the west side of the Winnipeg River that have been continuously used for agricultural purposes under agreements with AECL. The area to the east of the WL main campus has been left undeveloped and is meant to act as a buffer to the industrial site (LGD of Pinawa 2004). No traditional land and resource uses are permitted on the WL site. Traditional land and resource use activities have persisted adjacent to the site, including uses of the Winnipeg River. It is expected that activities and land use adjacent to the site will be able to continue in the future as the Project will have no effect on land tenure or usage beyond the WL site boundaries.

Future use of the WL site will depend on the ability to release parts of the site with no restriction on use upon completion of the Project. Future uses/zoning have not been determined, but the end-state plan for the WL site is to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-state. The criteria developed will prioritize the environment and safety while incorporating Traditional knowledge if provided. Indigenous Nations priorities will also be included provided they align with environmental and safety priorities. Some lands will have restrictions on the future use so that there are no adverse effects to people and the environment as assessed in the safety assessment and modelling associated with the ISD of infrastructure and facilities, such as WR-1 and the Waste Management Area. These areas will require ongoing controls including institutional control, access restrictions and environmental monitoring. However, the amount of land associated with these areas is negligible relative to the size of the WL site that will have no restrictions on land use. CNL will be engaging Indigenous Nations in a discussion on future uses for the WL site, with site closure planned for early 2031.

The following are the key roles and responsibilities to determine the future use of the WL site:

- AECL owns the site and has responsibility for all assets and liabilities.
- CNL is the contractor responsible to perform the decommissioning and site remediation of the WL site.
- CNL is preparing a WL Remediation Plan (formerly Land Use and End State Plan) defining the end state criteria in collaboration with stakeholders, Indigenous Nations and the public, and will submit it to the CNSC for acceptance.
- CNL informs and engages the public, Indigenous, and other key stakeholders such as the Province of Manitoba.

While the Project will change the proportion of the site with restricted access and future uses, decommissioning is designed with the environment and safety as a priority. Future use will incorporate Traditional knowledge and CNL will work collaboratively with Indigenous Nations so their concerns can be considered and aspirations around the site incorporated. Since the Project will make the WL site safer when compared to baseline conditions and it will increase the amount of land available for future use in the LSA, these pathways are categorized as secondary.

The Project in combination with the decommissioning and reclamation of the WL site is also anticipated by CNL to contribute to positive effects on the environment, which will positively affect traditional land and resource use within the RSA (e.g., less industrial activity that could affect hunting, fishing, trapping and plant and berry gathering). Consequently, cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site are anticipated to be negligible.

- **The Project may change the suitability of the LSA for traditional land and resource uses.**

The WL site was established in the 1960s with WR-1 becoming operational in 1965. Since that time, there have been nuclear research and more recently, decommissioning activities at the site. The area around the WL site in the LSA is currently used for agricultural activities, wildlife harvesting activities, fishing and private residences. Decommissioning activities at the WL Site do not appear to have altered traditional land and resource use in proximity to the WL site with activities, as such deer hunting and fishing still popular. For example, Métis citizens have used the LSA for traditional land and resource use activities within the past 10 years (SVS 2019). Other land and resource use activities are described in Section 6.8.2. The presence of the encased WR-1 is not expected to cause changes in these existing activities, although a small number of users may consider areas in proximity to the site as less optimal than if the reactor had been removed in its entirety.

The Project will be engineered to demonstrate long-term safety through a combination of site characteristics and engineered design features and to isolate and contain contamination inside the reactor vault and limit releases of hazardous substances, including radiological substances. According to the ERA, thresholds for airborne and waterborne contaminants will not be exceeded as a result of the Project (EcoMetrix 2024). Therefore, there is no need to change land use category of the land released for unrestricted use or of the land in the LSA around the WL site; however, the presence of an encapsulated reactor and associated perceptions may make engaging in activities in the LSA less desirable for some users.

While the western scientific analysis concludes that for most environmental disciplines, there are no residual effects predicted, and where there are residual effects (i.e., Section 6.7 Human and Ecological Health), they are not predicted to be significant, Indigenous Nations have reached other conclusions in their Project-specific studies. The Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation (2019) acknowledge the differing lenses for analysis.

> *We want to acknowledge that CNL has given careful scientific consideration to our questions and that CNSC is providing a second opinion on the project. However, experience shows that even good science has been wrong in the past…We are people of the land, not nuclear scientists, and it is important that we share the concerns we see through our worldview.* (p. 59)

In the studies, the Indigenous Nations express their uncertainty regarding the Project's durability and longevity (Firelight Group Inc. and Sagkeeng Anicinabe 2018; SVS 2018; Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation 2019; WIN 2018). Some members note that the uncertainty could result in a change in their resource use patterns. As one Sagkeeng First Nation member commented (Firelight Group Inc. and Sagkeeng Anicinabe 2018)

> *I don't think I would feel comfortable to be fishing near the area itself (p. 83).*

An Red River Métis citizen shared their uncertainty (SVS 2019):

> *I think there's a lot of unknowns. For me, there's a lot of unknowns, and most of it is, I'm worried about water quality and for the fish, and for migrating birds, drinking water too. And whether or not, I'm not sure if the decommissioning will put more pollution into the water, or if it's kind there already and we're stuck with it no matter what happens. (p. 51)*

Sagkeeng First Nation has expressed concerns regarding gaps in the assessment of effects to traditional land and resource use and the processes followed to arrive at conclusions. This included questions around how Indigenous people were engaged in the assessment process, from the identification of pathways, the assessment of effects on traditional land and resource use, and verification of CNL's conclusions. Sagkeeng First Nation would prefer to see changes to traditional land use behaviours arising from fear and stigma assessed as a primary pathway. Fundamental to the concerns is the use of a "damaged baseline" in which Indigenous Nations have been alienated from the site and its surroundings for the past 60 years, meaning that the assessment will inevitably arrive at a conclusion of no significant adverse effect.

To support continued understanding and dialogue around the suitability for use of the WL site and the lands around it for traditional land and resource use purposes, and to address the difference between the conclusions of the effects assessment and the TKLU studies, CNL will support robust communication of environmental monitoring results to confirm the safety of the WL to and help address concerns about future uses. To date, CNL has engaged with Indigenous Nations to understand their perspectives on Project effects and develop opportunities and mechanisms for their ongoing involvement and participation, which are described in more detail in Section 6.8.1.7. For example, beginning in 2019, the Manitoba Métis Federation had an Environmental Monitor observing CNL's environmental monitoring program, and other Indigenous Nations have been extended an invitation to do the same. The measures proposed in Section 6.8.1.7 to involve Indigenous Nations in a country food monitoring program and risk communication program, environmental monitoring and communication efforts to help demonstrate ongoing protection of the environment. CNL is committed to involving Indigenous Nations during the monitoring stage of the Project to help better understand and alleviate such concerns.

CNL will continue to use a public website and other media mechanisms to share information and receive feedback from local communities and Indigenous Nations through the duration of the Project. Future communication mechanisms to keep local communities and Indigenous Nations informed will be determined as necessary, and in consultation with them. Collaboration and information sharing with Indigenous Nations will be important to ensuring mitigation is effective. Overall, with mitigation and engagement in place, Project effects on traditional land and resource use are expected to be negligible. These pathways are, therefore, characterized as secondary.

6.8.1.6.2.3 Primary Pathways

There are no interactions with primary linkages to effects to the traditional land and resource use VC. While Indigenous Nations in their TKLU studies reached different conclusions related to the Project's effects to traditional land and resource use, CNL's ongoing commitments to collaborating with Indigenous Nations on mitigation and monitoring, are expected to keep all pathways secondary, which means there may be a minor detectable change to measurement indicators but they are expected to be negligible relative to the Base Case.

6.8.1.7 Monitoring and Follow-up

As there are no primary pathways for traditional land and resource use VCs, monitoring is not anticipated for traditional land and resource use. However, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project that will be integrated with the existing Environmental Assessment Follow-up Program for the WL site. The Environmental Assessment Follow-up and Monitoring Program for the Project will include sufficient information on the type, quantity and quality of information required to reliably verify effects predicted by the environmental assessment and confirm the effectiveness of mitigations. Wherever possible, existing programs will be adapted to meet the objectives of the Environmental Assessment Follow-Up and Monitoring Program for the Project.

Monitoring for environmental pathways (i.e., for air quality, water quality, and groundwater quality) will be implemented to verify effects predictions for traditional land and resource use. It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Within this framework, modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS or Decommissioning Safety Assessment Report, the frequency of sampling may be increased and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals for modifications to the monitoring program and the rationale for the modifications will be communicated to the Canadian Nuclear Safety Commission prior to implementation. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs.

During Project engagement activities, the First Nations and the Manitoba Métis Federation expressed concerns about the potential long-term effects of the Project on the environment, including different conclusions about Project effects. They indicated that the health of the environment, species relied on for fishing and harvesting, and the risk to people in the area of the WL site are of great concern. They also expressed an interest in being actively involved in the development and implementation of an ongoing monitoring program.

To address the differing conclusions and uncertainty, CNL is committed to involving the First Nations and the Red River Métis in monitoring and to engaging with them over the long-term to address ongoing concerns. This section outlines commitments and suggestions made by CNL to the Black River First Nation and Hollow Water First Nation, the Manitoba Métis Federation, and Sagkeeng First Nation on the topic of environmental monitoring, including next steps. CNL intends to continue to work with the First Nations and the Manitoba Métis Federation to increase mutual knowledge and awareness of environmental monitoring activities at the WL site, including the use of Indigenous Environmental Monitors in monitoring activities.

For Black River First Nation and Hollow Water First Nation, CNL has proposed hosting a community workshop to discuss CNL's environmental protection program and look for ways to include species of interest to Indigenous Nations into CNL's environmental protection program. CNL will work with the community to develop a plain language summary report for CNL's annual environmental monitoring reports, explaining the results and main conclusions, and share this document with all the Indigenous Nations. In addition, CNL has committed to supporting the Indigenous Nations participation in environmental monitoring. While not specific to environmental monitoring, CNL has committed to funding Black River First Nation and Hollow Water First Nation's engagement proposal, which may include participation in environmental monitoring activities. CNL has also committed to engage with Black River First Nation and Hollow Water First Nation to discuss future land use for the WL site.

CNL is committed to working with the Manitoba Métis Federation on their long-term interests such as environmental monitoring by sharing monitoring results, seeking input on our current environmental protection program, implementing improvement based on feedback received from Manitoba Métis Federation, and discussing potential remediation as necessary. CNL has also committed to augment the overall EAFP (CNL 2022) based on how the First Nations and the Manitoba Métis Federation wish to be involved. One of the anticipated benefits of the program is to provide near-term confidence in the harvested goods for the Red River Métis citizens through reporting. Further to this, CNL commits to continue its testing of wildlife in the vicinity of the WL site and has invited Red River Métis harvesters to participate in the donation of locally harvested meat for testing. CNL hosted a technical workshop with Manitoba Métis Federation and their consultants, Shared Value Solutions Ltd, to further explore and address the issue of ground water monitoring. As a result of these discussions, CNL has agreed to the Manitoba Métis Federation request to have an additional groundwater monitoring well installed at a location closer to the WRDF. CNL will provide a plain language summary report to support CNL's annual environmental monitoring reports. CNL has also committed to engage with Manitoba Métis Federation to discuss future land use for the WL site.

The Sagkeeng First Nation is located downstream from the WL site and therefore has a different relationship to the Project, which is reflected in CNL's commitments. CNL has committed to augment the overall monitoring based on the interests and feedback received from Sagkeeng First Nation. CNL and AECL have entered into a contribution agreement with Sagkeeng First Nation that outlines commitments to Indigenous independent monitoring, and a scope of work for a Community Environmental Monitoring Program (CEMP) led by Sagkeeng First Nation has been agreed upon. This work will be undertaken by Niigan Aki, a program established by Sagkeeng First Nation through the contribution agreement to undertake the CEMP.

CNL regularly invites Indigenous Nations to observe and participate in CNL's ongoing environmental monitoring activities. CNL will provide a plain language summary report that summarizes CNL's annual environmental monitoring reports. Further to this, CNL is committed to the following:

- CNL has committed funding to support SFN's Indigenous Liaison for two years;
- CNL has committed to provide monthly engagement summaries to Sagkeeng First Nation to enhance community understanding;
- CNL has committed to hosting workshops and webinars, as suggested by Sagkeeng First Nation's Liaison, to share information about the safety of in-situ disposal as it relates to people and the environment;
- CNL has committed to engage with Sagkeeng First Nation to discuss future land use for the WL site; and
- CNL has expressed interest in exploring initiatives that will support SFN's reconnection to the land on the WL site through ceremony or other cultural activities, as well as through the International Centre of Indigenous Knowledge and Wellness at Turtle Lodge.

6.8.1.8 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous Nations, or the public (The Agency 2018). The traditional land and resource use VCs chosen for the Project to reflect identified concerns, professional judgement and/or standard practice in environmental assessment are Cultural and Archaeological Sites, Traditional Land and Resource Use by Indigenous Nations, and the Winnipeg River.

The Project could affect traditional land use through effects to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River. Changes to these VCs could result from a change in the abundance and distribution of resources, the quality of the resource, and the ability to access resources including fish, wildlife and vegetation. Any of these changes could subsequently affect the ability and the desire to engage in activities in the LSA. There are not anticipated to be any threshold exceedances in harvested receptors through atmospheric releases and waterborne dispersion of contaminants. In addition, the mitigation proposed to minimize Project effects on surface water quality, the aquatic environment, the terrestrial environment, human health and ecological health are anticipated to eliminate or mitigate any potential adverse effects to the resources on which traditional land and resource use are dependent. While CNL is confident in these results, it will continue engaging with Indigenous Nations on mitigation and monitoring.

The WL site has been operational since the 1960s, with restrictions on public access for safety and security reasons. Exceptions to this include parcels of the WL site on the west side of the Winnipeg River that have been continuously used for agricultural purposes under agreements with AECL. No traditional land and resources uses are permitted on the WL site. Traditional land and resource use activities have persisted adjacent to the site, including uses of the Winnipeg River. It is expected that all activities and land uses adjacent to the site will be able to continue in the future as the Project will have no effect on land tenure or usage beyond the WL site boundaries.

In collaboration with Indigenous Nations and the public, CNL is committed to meaningful and ongoing engagement on the WL site remediation and clean-up activities. Although a small proportion of the WL site will have restrictions on use because of the Project, it is still anticipated that the majority of the site will be safe and appropriate for unrestricted use. Overall, decommissioning of the WL site will result in an increase in the amount available for future use in the LSA. This may include transfer of the land to other parties following engagement with stakeholders, Indigenous Nations and the public. Future uses/zoning have not been determined, but the end-state plan for the WL site is to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-state. Consequently, the Project is expected to have a negligible effect on traditional land and resource use VCs.

CNL will implement a WR-1 Environmental Assessment Follow-up and Monitoring Program to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. In addition, to mitigate perceptions related to the suitability for use of the WL site and the lands around it, CNL will support robust communication of environmental monitoring results to confirm the safety of the WL site and help address concerns about future uses. CNL will continue to engage with local communities, municipalities and Indigenous Nations.

6.8.2 Other Land and Resource Use

The assessment of other land and resource use includes consideration of non-Indigenous commercial, municipal, and federal land and resource use activities in proximity to the Project. These activities include agriculture, forestry, mineral claims and leases, water use, and outdoor recreation and tourism, sport fishing, outfitting, hunting, trapping, and other winter activities.

6.8.2.1 Scope of the Assessment

The assessment on other land and resource use follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment is completed in the following steps.

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Sections 6.8.2.3 Valued Components and Section 6.8.2.4 Assessment Boundaries) for the assessment of other land and resource use. The VCs, the assessment endpoints and measurement indicators used to assess the Project related changes to other land and resource use; the spatial and temporal boundaries at which the assessment occurred; and the assessment cases considered.
- **Step 2 – Describe the existing conditions** (refer to Section 6.8.2.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents historical and current land and resource use.
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.8.2.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect other land and resource use are identified and mitigation options are presented to limit or avoid effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described. Primary pathways that may lead to residual effects to other land and resource use after incorporating mitigation are carried forward to Step 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis**. This step was not required as no primary pathways were identified in the other land and resource use assessment.
- **Step 5 – Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the other land and resource use assessment.
- **Step 6 – Classify and determine the significance of the predicted residual effects**. This step was not required as no primary pathways were identified in the other land and resource use assessment.
- **Step 7 – Identifying monitoring and follow-up** (refer to Section 6.8.2.7 Monitoring and Follow-up) required to confirm effects predictions and address uncertainty.
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.8.2.8 Conclusions) on other land and resource use.

6.8.2.2 Public Engagement Feedback – Key Interests and Concerns

Key interests and concerns raised by stakeholders/general public related to other land and resource use and the steps CNL took to incorporate it into ongoing engagement on the EIS are summarized in Table 6.8.2.2-1. Other general public interests and concerns are documented in Section 5 Public Engagement.

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the Indigenous land and resource use assessment are summarized in Section 6.8.1, Table 6.8.1.2-1.

Table 6.8.2.2-1: Summary of Key Interests and Concerns Raised by the Public During Engagement Activities Related to the Other Land and Resource Use Assessment

Interest and Concern	Inclusion Status	Additional Information and Rationale
Future Land Use - Requested more information on the plans for the WR-1 site after ISD is completed.	Already included in the environmental assessment. A commitment by CNL to determine the future use of the WL site, including collaboration with local stakeholders has been added to Section 6.8.6.2.2 Secondary Pathways.	CNL is working in collaboration with AECL and will be engaging local communities to discuss and consider options for the future use of the WL site. Changes to land use restrictions associated with the WL site end state as a result of the Project are described in Section 6.8.2.6.2.2 Secondary Pathways.
Impact on the Winnipeg River	Already included in the environmental assessment.	The continued protection of the Winnipeg River is a key focus of the EIS. Although the assessments indicated that there will be no negative effects on the Winnipeg River or its sediment and aquatic organisms as confirmed in EIS Sections 6.4.1 Hydrology, 6.4.2 Surface Water Quality and 6.5 Aquatic Environment, CNL is planning to include the WRDF in the existing environmental monitoring program. The list of monitoring activities proposed to verify the effects predictions from the Project is provided in Section 11 Summary of Monitoring and Follow-up Programs.
Environmental Monitoring - Information was sought on how the in situ design incorporates ongoing environmental monitoring.	Already included in the environmental assessment.	CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project that will be integrated with the existing Environmental Assessment Follow-up and Monitoring Program for the WL site (see Section 6.8.2.7 Monitoring and Follow-up and Section 11 Summary of Monitoring and Follow-up Programs).

6.8.2.3 Valued Components

Valued components refer to socio economic and environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous Nations, or the public (The Agency 2018). The other land and resource use VCs chosen for the Project to reflect identified concerns, professional judgement and/or standard practice in environmental assessment are Land Tenure, Outdoor Recreation and Tourism, and the Winnipeg River. The rationale for selecting these VCs is discussed in Table 6.8.2.3-1.

Table 6.8.2.3-1: Valued Components for the Other Land and Resource Use Assessment

Valued Component	Rationale for Selection
Land Tenure	Land tenure considers the uses, allocations and ownership of lands in proximity to the Project, including the Whiteshell Laboratories (WL) site itself. The change in decommissioning for the Whiteshell Reactor 1 (WR-1) Building will decrease the proportion of the WL site available for future land tenure by private or public entities. The use of in situ disposal may also change the perceived suitability of land use surrounding the WL site. The land tenure VC is of known importance to Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations as identified through Traditional Knowledge and Land Use Studies, engagement with CNL, and verification discussions.
Outdoor Recreation and Tourism	The WL site is located in an area with several provincial parks, including the Whiteshell Provincial Park, that offer a variety of outdoor recreation opportunities while also being located near towns and Rural Municipalities (RMs) that rely on cottagers and tourism to contribute to their local economies.
Winnipeg River	The public identified the importance of the Winnipeg River. A number of communities depend on the river for drinking water, recreation and food. The river flows into the Lake Winnipeg, one of the largest lakes in the world. The eastern shore of the lake is included in a United Nations World Heritage Site proposal (Manitoba Wildlands 2008). This watershed is valued for many reasons by many people and groups.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. The assessments of each VC will incorporate community knowledge where available. Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on a VC. Measurement indicators can be used to monitor the success of mitigation and management programs. The assessment endpoints and measurement indicators associated with the other land and resource assessment are outlined in Table 6.8.2.3-2.

Table 6.8.2.3-2: Assessment Endpoints and Measurement Indicators for the Other Land and Resource Use Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Land Tenure	Capacity for continued land use	■ Availability of portions of WL site for alternative future uses. ■ Ability to maintain current land uses/tenures in proximity to the Project.
Outdoor Recreation and Tourism	Continued opportunity for outdoor recreation and tourism activities such as hunting, fishing and trapping.	■ Relative abundance and distribution of fish species. ■ Relative abundance and distribution of wildlife species. ■ Changes to fish and wildlife habitat. ■ Relative abundance and distribution of vegetation and fish and wildlife habitat. ■ Continued opportunity for recreational land use. ■ Perceived suitability of area for outdoor recreation and tourism activities.
Winnipeg River	Maintenance of self-sustaining and ecologically effective fish populations that are available for fishing.	■ Changes to ambient levels of surface water parameters ■ Relative abundance and distribution of fish species. ■ Changes to fish habitat. ■ Relative abundance and distribution of fish habitat.

6.8.2.4 Assessment Boundaries

6.8.2.4.1 Spatial Boundaries

The spatial boundaries selected for the other land and resource use assessment were chosen because they permit description of Base Case conditions in sufficient detail to enable potential project-VC interactions and effects to be identified, understood, and assessed, including understanding and assessing the contribution of the Project to cumulative effects. These boundaries were developed in consideration of known land and resource use around the WL site and the study areas of other disciplines (e.g., Terrestrial Environment; Human Health) that may have an effect on other land and resource use. The spatial boundaries selected for the other land and resource use assessment are presented on Figure 6.8.1-1.

6.8.2.4.2 Temporal Boundaries

The temporal boundary of the assessment includes effects observed under existing conditions, the timeframe during which Project activities are actively occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the Project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of in situ disposal (ISD), which includes preparation for ISD, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031.
- **Post-closure Phase:** The post closure phase has two discrete periods: institutional control and post institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue to demonstrate WRDF performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.8.2.4.3 Assessment Cases

The assessment on other land and resource use has three assessment cases.

- **Base Case**: This scenario represents existing conditions and characterizes combined effects from previous and existing developments and activities. The Base Case reflects the effects of existing disturbances, such as forestry, transportation, agricultural, mining and residential and recreational development. Current effects from the existing WL facilities and operations, for example, are considered part of the Base Case. In addition, effects from the decommissioning and reclamation activities already completed at the WL site are also considered as part of the Base Case.
- **Application Case**: The Application Case represents predictions of the effects that may results from the Project combined with the existing effects of the Base Case.

- **Reasonably Foreseeable Developments (RFD) Case**: This scenario represents the effects of the Base Case combined with the predicted incremental effects from the Project, as well as effects from other RFDs within the RSA that are currently under application review or that have officially entered a regulatory application process. There are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the Comprehensive Study Report (AECL 2001). Cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site (see Table 6.8.2.4-1) are presented as part of this assessment.

Table 6.8.2.4-1: Reasonably Foreseeable Developments considered in the Other Land and Resource Use Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes ISD of some low-level waste trenches).	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	Yes – there is both spatial and temporal overlap of effects with the Project

6.8.2.5 Description of the Environment

This section describes the setting and characterization for other land and resource use as relevant for the assessment of the Project. It describes the existing conditions against which potential changes from the Project are compared and evaluated.

6.8.2.5.1 Methods

The characterization of the existing environment for other land and resource use reflects review of both primary and secondary data sources. Data collection began with a review of existing literature and databases from a variety of public sources. Where sufficient detail was not available from secondary data sources to describe the existing environment, primary data collection was undertaken in the form of key person interviews.

6.8.2.5.1.1 Literature Review

The review of literature and databases included the following sources:

- federal, provincial and municipal government reports and data;
- documents produced for other environmental assessment processes (e.g., environmental impact statements, regulatory submissions);
- academic literature (dissertations, cultural chronologies);
- archival research;
- the Whiteshell Laboratories Decommissioning Project: Comprehensive Study Report (AECL 2001);
- the Environmental Assessment and Follow-up Program for Whiteshell Laboratories (AECL 2002); and
- online sources (e.g., community websites, online business profiles).

6.8.2.5.1.2 Key Person Interview Program

A limited Key Person interview (KPI) Program was undertaken to address gaps that could not be readily filled by secondary sources and to gain an understanding of other land and resource use surrounding the WL site. Interviews were conducted with four individuals primarily from Manitoba Sustainable Development (now Manitoba Environment, Climate and Parks). Interview guides for the KPIs were developed to address the subject areas discussed in this section of the environmental assessment.

6.8.2.5.1.3 Public Engagement

Information shared by the public was also used to inform both the base case and application case. Where applicable within this section, interests and information gained through the engagement program relevant to other land and resource use has been highlighted. Further detail on the outcomes of engagement processes can be found in Section 5 Public Engagement.

6.8.2.5.2 Results

This section describes land tenure and use in proximity of the WL site, including parcels on both sides of the Winnipeg River. Land interests in the area include wildlife management and protected areas, trapping and outfitting concessions, mineral and quarry reserves, agricultural lands and forestry.

6.8.2.5.2.1 Whiteshell Laboratories Site

The Project is located within the WL site, which is situated in the northwest corner of the LGD of Pinawa and borders the RM of Lac du Bonnet to the north, east and west. The LGD of Pinawa was established in 1962 as the WL site (LGD of Pinawa 2004). The WL site was established in the early 1960s to facilitate research and development of higher temperature versions of the Canada Deuterium Uranium (CANDU) reactor. The WL site included WR-1, an organic cooled reactor, which became operational in 1965 (AECL 2001). In the early 1970s, the organic cooled reactor program was eliminated, and full focus was concentrated on the heavy water-cooled CANDU reactor system. In 1985, WR-1 was permanently shut down (CNL 2016).

The site occupies 4,375 ha of land that was either privately owned or Crown land before the establishment of the WL site. Currently, Atomic Energy of Canada Limited (AECL), a federal government crown corporation, holds the title to the WL site lands. Access to these areas generally has restriction on use for security and safety. The WL site occupies the following different land use designations in the LGD of Pinawa (2004).

- **AG – General Agriculture:** AECL land on the western side of the Winnipeg River is used for agriculture, which is considered a minor land use in the LGD of Pinawa. The purpose of the designation is to protect existing agricultural developments and to protect environmentally sensitive areas from the potential effects of agricultural practices.
- **MH – Heavy Industrial:** AECL land including the WL main campus, waste management area and landfill are used for industrial use. The purpose of this designation is to encourage industrial development while limiting potential land use conflicts and potential adverse environmental effects.
- **RC – Recreational/Commercial:** The southeast corner of the WL site is zoned as recreational/commercial. In the future, this classification may allow access for residents of Pinawa to spaces for passive recreational uses.

- **NA - Natural Area:** The majority of the WL site located on the east side of the Winnipeg River, is designated as natural areas, the purpose of which is to protects areas from development. In the future, this classification may allow access for residents of Pinawa to spaces for passive recreational uses.

6.8.2.5.2.1.1 Wildlife Management and Protected Areas

The WL site is located near the following management and protected areas (Figure 6.8.1-1).

- **Pinawa Dam Provincial Park:** Located on Provincial Route 520 approximately 10 km northeast of the WL site. The park commemorates Manitoba's first year-round hydroelectric generating station. The park is 193 ha in size. The park is a day-use recreation area. It contains picnic areas, a picnic shelter, trails and interpretive facilities. In the winter, a snowmobile trail runs through the park (MCWS 2012a).
- **Whitemouth Falls Provincial Park:** Located approximately 6 km southeast of the WL site and is 483 ha in size. The park is at the confluence of the Whitemouth and Winnipeg rivers. The portion of the park south of the Winnipeg River is a day-use recreation area, while the area north of the Winnipeg River is to protect great gray owl habitat (MCWS 2012b).
- **Whiteshell Provincial Park** is directly east of the WL site and is 276,400 ha in size. Pinawa is located within the park boundaries. The park is intended to be a key recreational area in the Canadian Shield, provide cottaging opportunities, provide an accessible wilderness zone, accommodate resource harvesting and maintain a diverse sport fishery. The park offers swimming, boating, biking, golf, hiking, cross country skiing and snowmobiling. There are a range of accommodations located in the park, including several campgrounds (Department of Natural Resources 1983).
- **Pinawa Provincial Park** is located south of Provincial Route 211 on the east short of the Winnipeg River. It is less than 1 ha in size. The park is intended to provide a point of access to the Winnipeg River for boating and fishing and day-use opportunities (MCWS 2012c).
- **Lewis Bog Ecological Reserve** is located in Agassiz Provincial Forest southwest of the WL site. It was recently expanded from 570 ha to 5,240 ha. The reserve supports several types of bogs and forests. Rare orchid species and rare wildlife species have been seen in the reserve. The expansion is expected to help reduce the risk to the area and the rare species it supports from the effects of nearby commercial peat harvesting and agricultural activities. (Manitoba Sustainable Development n.d.a).
- **Lee River Wildlife Management Area** is located east of the Town of Lac du Bonnet off Provincial Route 520 and north of the WL site, and is 1,187 ha in size. It features a variety of grouse, white-tailed deer and moose. Coyotes, wolves and foxes use the area for denning and it is within a breeding and migration corridor for northern forest owls (Manitoba Sustainable Development n.d.b.).

6.8.2.5.2.1.2 Agricultural Lands

Land to the north and west of the WL site have been zoned by the RM of Lac du Bonnet for agricultural purposes. This agricultural zoning designation is intended to provide a buffer around the Town of Lac du Bonnet. The zoning designations allow a full range of agricultural activities; however, only existing livestock operations can be expanded (RM of Lac du Bonnet 2019). Other areas west of the Winnipeg River have been designated for mixed use, including residential and rural uses. Rural residential zones are low-density residential developments that use on-site waste management facilities, while residential areas allow for single-family and multi-family dwellings. There is conditional allowance of commercial resorts in these zones (RM of Lac du Bonnet 2019).

On the west side of the Winnipeg River, AECL permits agricultural use within the WL site lands. This land is in the LGD of Pinawa and comprises the majority of agricultural property in the LGD (LGD of Pinawa 2004).

6.8.2.5.2.1.3 Forestry

To the south and west of the WL site, in the RM of Lac du Bonnet is the Agassiz Provincial Forest. Provincial forests were established as a source of sustainable timber supply (Manitoba Conservation n.d.). The Agassiz Provincial Forest is approximately 795 km^2 in size. It is also used for peat moss extraction and snowmobile trails.

Forestry has historically been important to the region, but there has traditionally been little forestry activity near the WL site (AECL 2001). Since the Comprehensive Study Report (AECL 2001) was filed, the forestry industry has decreased. Tembec, which owned and operated the Pine Falls Mill in Powerview-Pine Falls, stopped production there in 2009 and permanently closed the facility in 2010; Tembec later sold the site (Pulp-Paper World 2011). Overall, the forestry industry in Manitoba has shrunk due to a variety of factors, including the collapse of the US housing market in 2006 and the closure of multiple mills in the province (MCWS 2012c).

6.8.2.5.2.1.4 Mineral Claims and Leases

There are quarry permits to the northeast and southwest of the WL site and several quarry withdrawals in the area, including near the northeast boundary of the WL site. There are no other mineral claims or leases in proximity of the WL site (Manitoba Growth, Enterprise and Trade n.d.).

6.8.2.5.2.1.5 Water Use

There are multiple municipal water rights licences and an irrigation water rights licence for the Winnipeg River in the RSA. The municipal water rights licences are held by the Town of Lac du Bonnet and Pinawa, along with various water co-ops and a residential development (Manitoba Sustainable Development 2017). The WL site also draws water from the Winnipeg River. Water from the Winnipeg River is likely also used for domestic purposes as there are residences along the shore, but water withdrawals of less the 25,000 L/d do not generally require licensing.

6.8.2.5.2.2 Outdoor Recreation and Tourism

The WL site is in eastern Manitoba west of the Whiteshell Provincial Park on the Winnipeg River. The region is popular for cottagers and campers as it is the gateway for access to a number of Provincial Parks, including Old Pinawa Dam Provincial Park, Nopiming Provincial Park and the Whiteshell Provincial Park. The area around the WL site, including Pinawa, along with the Town and RM of Lac du Bonnet are important areas for outdoor recreation and related cottaging and tourism in southern Manitoba. Section 6.9.5.2.3 Employment and Income discusses the economic effect of cottaging and tourism for Pinawa and the Town and RM of Lac du Bonnet, which is an important economic driver for all three municipalities.

Pinawa is located adjacent to the boundary of the Whiteshell Provincial Park and offers many outdoor activities to year-round and seasonal cottage residents including sailing, canoeing, fishing, hiking, swimming, golfing, snowmobiling and cross-country skiing (LGD of Pinawa 2019a). Whiteshell Provincial Park is a four-season park that boasts rushing rivers, clear deep lakes and sandy beaches. There are numerous self-guided hiking trails, canoe routes, campgrounds, picnic areas, among other amenities (Manitoba Sustainable Development n.d.c). Pinawa also has a number of tourist attractions that draw visitors to the area including the Pinawa Heritage Sundial, the Pinawa Suspension Bridge, and Pinawa's section of the Great Trail (also known as the Trans Canada Trail), which includes the Pinawa Channel Heritage Walk, the Ironwood Trail and the Alice Chambers Trail which is internationally recognized as Manitoba's Pine to Prairie Birding Trail (LGD of Pinawa 2019b). The Pinawa Dam

Provincial Park, showcasing concrete ruins, highlights the first hydroelectric power dam in Manitoba including interpretive signage, self-guiding interpretive brochures, an amphitheatre, the Heritage Walk Picnic Shelter, picnic facilities, Centennial Spillway Trail and bridge access to an interpretive nature trail (Pinawa Community Development Corporation 2019).

Pinawa has a local beach, two launching ramps for powerboats and watercraft, a boat marina and canoe rentals. The Pinawa Channel, between the diversion dam and the suspension bridge, is popular for tubing and provides exceptional canoeing and kayaking through to the Pinawa Dam Provincial Park. The Pinawa Rowing and Sailing Club are located near the marina and offer lessons, equipment for members and accommodation for non-motorized watercraft (Pinawa Community Development Corporation 2019).

The Winnipeg River, including the stretch from the WL site downstream to the Town of Lac du Bonnet is lined with residential developments, which include year-round and seasonal residences. The other waterways in the RM of Lac du Bonnet, including Lac du Bonnet and the Lee River also attract seasonal residents who want to remain relatively close to a population centre and still enjoy a rural lifestyle. During the KPI Program, it was noted that many people who decide to eventually move to either the Town or RM of Lac du Bonnet originally spent their summers in the area (KPI Program 2016).

There are three marinas on the Winnipeg River in the RM of Lac du Bonnet. The LaVerendrye Boat Launch at the north end of the Town of Lac du Bonnet on Provincial Road 502, one on the east side of Provincial Route 313 and the Winnipeg River Bridge and the board launch at Roadside Park, which is off Highway 11 north, 15 km away from the Town of Lac du Bonnet.

6.8.2.5.2.2.1 Sport Fishing

Sport fishing is popular in the region due to the number of waterways, which include the Winnipeg River and the Lee River. Major species include walleye, northern pike, sturgeon, smallmouth bass, mooneye, sauger and channel catfish. These species are common in the region and are known to have stable populations (KPI Program 2016). The WL site is located in the Southern Division, which includes all of southern Manitoba. The fishing season is generally closed from the beginning of April through to mid-May annually and typically opens on Saturday before the long weekend. Catch limits vary by species and for some species also vary by fish size. Lake sturgeon also occur in the Winnipeg River near the WL site and favour the outfall of the WL site, because lake sturgeon is a protected species, it must be released if caught (AECL 2001).

Fishing locations on the Winnipeg River vary by the species desired by an angler. Popular locations include the Town Pier in Lac du Bonnet, the Winnipeg River Bridge and the dike along Highway 11, “Pickerel Point” (located upstream of the town of Lac du Bonnet where there is a constriction in the river) and near the McArthur Falls generating station (KPI Program 2016). It is also possible to ice fish around Lac du Bonnet (Town and RM of Lac du Bonnet 2019a).

Individuals interested in fishing on the Winnipeg River near the Town of Lac du Bonnet are able to do so in their own boats or there are outfitters who offer guiding services on the Winnipeg River. Fishing guides in the area are popular with American and Manitoban tourists, and the species pursued are dependent on the interests of the fishers.

Fishing for sustenance or traditional purposes is considered in Section 6.8.1.5.2.2.1 Historical and Present Day Traditional Land Use.

6.8.2.5.2.2.2 Outfitting

Outfitters are located in and around Pinawa, the Town of Lac du Bonnet, Point Du Bois and Eriksdale. These outfitters provide black bear, whitetail deer, wolf and waterfowl hunts, while others offer local trophy fishing trips and fly-in fishing expeditions to Atikaki, Nopiming and Whiteshell Provincial Parks (Hoards Hunting Camps 1999-2019; Jackson's Lodge and Outposts 2019; Trail End Camp and Outfitters 2019; Agassiz Outfitters 2019; Eagle Nest Lodge 2019; Big Track Outfitters 2019). Outfitting activities tend to be geared towards a client's interests and will vary accordingly (KPI Program 2016).

6.8.2.5.2.2.3 Hunting

The WL site is located in Game Hunting Area (GHA) 26 (Figure 6.8.2-1). White-tailed deer hunting in the area around the WL site, especially northwest of the Project, is popular (KPI Program 2016). General rifle hunting season for white-tailed deer in GHA 26 is open November 14 through to December 18 with the bag limit of one buck (antlered) deer per licence per year. Deer muzzleloader and deer general rifle seasons have been extended in GHA 26 and 36, an area directly south of GHA 26 along the Manitoba-Ontario border (Manitoba Sustainable Development 2018). This season extension has been implemented to reduce white-tailed deer numbers; additionally GHA 26 is one of the few areas to offer a second and third purchase of deer licences for Manitoba residents who are Canadian citizens. The effort to reduce white-tailed deer numbers is driven by the brain worm and liver fluke parasites carried by white-tailed deer that negatively affect the struggling moose population (Manitoba Sustainable Development 2018).

Upland game birds and migratory waterfowl are also hunted, with a population of rough grouse and sharp-tailed grouse noted in proximity to the site. Grouse season is open between early September through to mid-December, with a daily bag limit of six, and possession limit of 12. Migratory bird seasons vary by species, but are typically open between September 1 and November 30, with daily limits for eight ducks, coots and dark geese and possession limits of 24. Snow geese have a daily limit of 50, and no possession limited. (Manitoba Sustainable Development 2018).

Moose populations in the southeast region of the province are known to be rapidly declining due to disease and overhunting. In an effort to allow moose population levels to recover, cancellation of all licensed moose hunting seasons are in effect for 13 of the GHAs across the province, including GHA 26. A partial area closure for all licensed hunters and rights-based hunters, including Indigenous Nations, has been implemented north of the Black River to the northern boundary of GHA 26. In addition to prohibiting hunting, Manitoba Sustainable Development (now Manitoba Environment, Climate and Parks) is researching and implementing other programs to aid in moose population recovery. One of two wildlife biologists hired by the Province to implement moose recovery programs is located in the Town of Lac du Bonnet. Other programs established to aid in moose population recovery include extension of the white-tailed deer hunting season and wolf trapping season, increasing staff dedicated to enforcement, establishing moose management committees, and engagement with Indigenous Nations (Manitoba Sustainable Development 2018).

Black bear hunting in GHA 26 is limited to Manitoba residents who are Canadian citizens and opens April 25 to June 19 with a bag limit of one adult black bear. Females with cubs may not be taken and Manitoba Sustainable Development (now Manitoba Environment, Climate and Parks) puts forth detailed description on how to identify female black bears in their annual Hunting Guide (Manitoba Sustainable Development 2018).

A gravel pit located just northeast of the LSA is a popular staging point for resource use activities (Manitoba Sustainable Development 2018). Hunting within the WL site is prohibited due to safety concerns.

6.8.2.5.2.2.4 Trapping

There are no registered traplines (RTL) in the WL site. Registered trapline 23 runs along the southern border of the site (Figure 6.8.2-1). The holder of RTL 23 is active and traps a variety of species, including marten, red fox, otter, fisher weasel, muskrat and mink. There are no other RTLs that share a boundary with the WL site. The majority of RTLs are east of the WL site in the Whiteshell Provincial Park.

6.8.2.5.2.2.4.1 Winter Activities

Outdoor winter activities in Pinawa include skating, snowmobiling, ice fishing, bird watching, snowshoeing, skiing and hiking. Whiteshell Cross Country Ski Club maintains over 40 km of ski trails and 24 km of the Great Trail throughout the winter. SnoMan (Snowmobilers of Manitoba) actively maintains trails all through Pinawa and the Town and RM of Lac Du Bonnet (Town and RM of Lac du Bonnet 2019b).

6.8.2.5.2.3 Winnipeg River

As described in Section 6.4.2 Surface Water Quality, the Winnipeg River is considered to be a medium-sized lowland river (AECL 2001). Its drainage area is approximately 150,000 km^2, originating in Ontario at Lake of the Woods. The Winnipeg River tributaries include the Rainy River (flows into the Lake of the Woods), Black Sturgeon River, English River, Bird River, Lee River, Whiteshell River, Whitemouth River, and the Macfarlane River. There are six hydroelectric dams on the river, the closest approximately 7.5 km upstream of the WL site. These dams have extensively modified flow patterns in the river (AECL 2001). Adjacent to the WL site, the river is approximately 0.3 km wide and 7 m deep and flows northerly between 436 m^3/s and 1,842 m^3/s to Lake Winnipeg (2010 to 2015 average at Seven Sisters Generating Station; Manitoba Hydro 2016).

Historically, liquid effluent from the Active Liquid Waste Treatment Centre was discharged to the Winnipeg River via the process sewer at the sewer outfall located about 8 m offshore in approximately 5 m of water (AECL 2001). The Winnipeg River Task Force (WRTF 1995) looked at potential sources of Winnipeg River water quality degradation near the community of Sagkeeng. The Task Force found that WL has not had an adverse effect on water quality in the Winnipeg River for downstream communities (AECL 2001). The task force included members from the Sagkeeng First Nation, Environment Canada, Indian and Northern Affairs Canada and Health Canada.

The monthly average of water chemistry for 2011 to 2019 for the intake water at the WL site had concentrations of copper, iron and lead exceeding the Manitoba Water Quality Standards, Objectives, and Guidelines (WQSOG; see Section 6.4.2.5.2.2 Surface Water and Sediment Quality). Copper and lead also exceeded the Canadian Council of Ministers of the Environment Water Quality Guidelines (CCME WQG; Table 6.4.2-5 and Figure 6.4.2-3), although concentrations have decreased starting in 2016, and lead concentrations have been under the WQSOG and CCME WQG since 2017. Concentrations of mercury exceeded the WQSOG in 2016 but not in any other years. Phosphorous concentrations in the river also exceeded the WQSOG between 2014 and 2017 but have since decreased to below guideline levels. The intake water quality is considered to be uninfluenced by the WL site because it is located upstream of discharges from the WL site. Recently, the Winnipeg River has been classified as meso-eutrophic (at Pointe du Bois; ECCC 2015). This indicates that nutrient levels are moderate, which may lead to plant growth and reduced water clarity.

During the 2000 sediment investigation, the sediment downstream of the outfall was determined to be erosional, with a clay bottom covered in parts with sand, gravel, cobble and boulders (AECL 2001). The highest measured caesium-137 level in a sediment sample during the 2000 study was 2,610 Becquerels per kilogram (Bq/kg) (AECL 2001). This exceeds the *Nuclear Substance and Radiation Devices Regulation* (SOR/200-207; NSRDR) Clearance Level of 100 Bq/kg for caesium-137. Although the activity level in the sediment at the K03 location is above NSRDR unconditional clearance level, it is well below a human external exposure level of concern 2.8×10^6 Bq/kg. It is also well below the Tier 2 estimated no-effect value (ENEV) for benthic invertebrates' value of 1.5×10^5 Bq/kg. The caesium-137 levels detected in the samples collected during routine monitoring at locations OFL, K03, K05, K14 and K23 from 2010 to 2015 were one to two orders of magnitude lower than the highest 2000 sample (CNL 2020). Caesium-137 levels at all locations except OFL and KO5 were below the NSRDR Clearance Level of 100 Bq/kg. The activity at OFL has historically varied from less than 5 Bq/kg to 75,500 Bq/kg (CNL 2020). Variation of activity is not unexpected for all samples due to the highly localized and spotty nature of the contamination in the river sediments. This variability is the likely reason for the unusually high caesium-137 activity noted in the K05 sample in 2015 (CNL 2020).

As part of the routine monitoring at the WL site, river bottom sediments were collected from twelve locations along the Winnipeg River, ranging from 0.8 km upstream to 13.1 km downstream of the Outfall. In 2019, the gross alpha activity detected in the samples ranged from 167 to 633 Bq/kg (CNL 2020). In five years prior, average minimums and maximums activities ranged from 214±173 to 534±255 Bq/kg. The alpha activity in these samples is due to naturally occurring isotopes such as uranium-238 or thorium-232 and their progeny, as both upstream and downstream samples contain similar levels. All samples are below the NSRDR Clearance Level for naturally occurring uranium-238 and thorium-232 of 1,000 Bq/kg (CNL 2020).

The gross beta activity in sediment ranged from 333 to 1,133 Bq/kg in 2019 at the twelve sampling locations (CNL 2020). The previous five years average minimums and maximums ranged from 283±119 to 1,504±206 Bq/kg. The gross beta activities measured in 2019 for most sediment samples are higher than averages for the previous five years, with no trends observed. Beta activity includes contributions from naturally occurring potassium-40 and from caesium-137. Aliquots of samples collected in 2019 were submitted for strontium-90 analysis, and results indicated that strontium-90 makes an insignificant contribution to radioactivity in sediments. The majority of the beta activity for all locations continues to be from naturally occurring potassium-40 (CNL 2020). The NSRDR Clearance Level for potassium-40 is 10,000 Bq/kg.

The Winnipeg River supports a diverse fish community and affords spawning, rearing and foraging habitats. A total of 61 native species are reported for the river (Stewart and Watkinson 2004) and two species at risk are known to be present within the vicinity of the WL site: Lake Sturgeon (*Acipenser fulvescens*) and Carmine Shiner (*Notropis percobromus* [COSEWIC 2019]). Fish occurring within the study reach include species that are primarily resident (present year-round), as well as migratory (passing through). Fish habitat is generally similar throughout the assessment area.

The Town of Lac du Bonnet and Pinawa draw water from the Winnipeg River System and treat it at their water treatment plants (Province of Manitoba 2004; LGD of Pinawa 2015). Sagkeeng First Nation is the only First Nation in the socio-economic RSA known to draw water from the Winnipeg River for residential purposes (J.R. Cousin Consultants Ltd. n.d.).

6.8.2.6 Project Interactions and Mitigation

6.8.2.6.1 Methods

This section describes the process by which interactions between Project components and activities and other land and resource use VCs were identified and evaluated. Potential effect pathways are identified and mitigation developed to eliminate and/or reduce effects is presented. A pathways analysis is then used to focus the assessment on key interactions between the Project and the environment by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment. As such, the Project Interactions and Mitigation section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce effects to other land and resource use VCs. Environmental design features included design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the engineering and environmental teams, combined with input from project-specific or regional engagement with other interested parties. The design features and/or mitigation activities were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation.

- **No pathway** – pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change to measurement indicators identified for other land and resource use VCs relative to Base Case values, and therefore would have no residual effects to land and resource use VCs.
- **Secondary pathway** – the pathway could result in a measurable minor change to measurement indicators identified for other land and resource use VCs but would have a negligible residual effect on other land and resource use VCs relative to Base Case values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect.
- **Primary pathway** – the pathway is likely to result in an environmental change to measurement indicators identified for other land and resource use VCs relative to the Base Case that could contribute to residual effects to other land and resource use VCs.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects to other land and resource use VCs were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to other land and resource use VCs through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment.

6.8.2.6.2 Results

Pathways through which all stages of the Project may interact with and result in changes to measurement indicators for other land and resource use VCs is provided in Table 6.8.2.6-1.

Table 6.8.2.6-1: Pathways Analysis for Other Land and Resource Use Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

Overall activities associated with WL site preparation, ISD of WR-1 and decommissioning of above-ground facilities	■ Changes to outdoor recreational activities and tourism resulting from changes to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River.	■ The Project is located in an already disturbed area.
		■ Temporary supporting infrastructure will be located within the Local Study Area (i.e., previously disturbed and developed area).
		■ Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the Regional Study Area will be used during decommissioning activities around disturbed areas, where appropriate.
		■ Project activity will typically be limited to daytime hours, where possible, and noise will be short-term and sporadic.
		■ Decommissioning of the WR-1 Building will be completed in a controlled manner, and no blasting will be required.
		■ The planned decommissioning of the WR-1 Building presently involves:
		  ■ removing the service wings and infilling in these areas with compacted fill;
		  ■ sealing of open conduits in the building foundation;
		  ■ grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation and removing the superstructure; and
		  ■ Installation of reinforced concrete cap.
		■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring.
		■ As part of CNL's licence with the Canadian Nuclear Safety Commission, environmental monitoring around the WL site is required and will continue for the Project.
		■ Follow-up monitoring during the post-closure phase will be completed to verify effects predictions and to provide information for use in adaptive management to address potential unforeseen effects.
			Secondary

Table 6.8.2.6-1: Pathways Analysis for Other Land and Resource Use Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

Overall activities associated with WL site preparation, ISD of WR-1 and decommissioning of above-ground facilities	■ Nuisance factors such as dust and noise may affect the desirability of engaging in outdoor recreational or tourism activities.	■ Access to the WL site will have restrictions on resources use.
		■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring.
		■ Implementation of dust management techniques to control dust generated by the Project, consistent with the current Environmental Assessment Follow-up and Monitoring Program.
		■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures.
		■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include:
		  ■ wetting techniques during demolition to limit mobility of dust;
		  ■ wind restrictions during demolition to stop work or apply wetting techniques; and
		  ■ hydro seeding during backfilling and landscaping to reduce soil erosion.
		■ Removal of accumulations of particulates (e.g., dirt) on road as soon as possible.
		■ On-site vehicles and equipment engines will meet Tier 3 emission standards, where possible, and be maintained in good working order.
		■ Limit idling of vehicles on-site and speed on roads.
		■ Use of tarps or 3-sided enclosures for raw material storage.
		■ Road watering and chemical dust suppressant when necessary.
		■ Decommissioning activity will be limited to daytime hours and noise will be short-term and sporadic. Decommissioning of the WR-1 Building will be completed in a controlled manner, and no blasting will be required.
			No linkage

Table 6.8.2.6-1: Pathways Analysis for Other Land and Resource Use Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Preparation for and implementation of institutional control	■ The use of ISD as the decommissioning method for WR-1 will change the proportion of the site that can be released for unrestricted use by a small percentage. ■ The Project may change the suitability of the Project footprint for outdoor recreation and tourism.	■ Continued activities through the Community Regeneration Partnership to help the region develop economically. ■ Communication of environmental monitoring results to confirm the safety of the WL site and lands around it. ■ Final ISD designed so that projections of doses to members of the public are well below the established limits for dose to any member of the public. ■ Final ISD design will be done to maximize hazard reduction.	Secondary
Preparation for and implementation of institutional control	■ Changes to access restrictions associated with the WL site end-state as a result of the Project may result in changes to future land tenure and uses of the site itself.	■ Communication of environmental monitoring results to confirm the safety of the WL site and lands around it. ■ Continued activities through the Community Regeneration Partnership to help the region develop economically.	Secondary
Closure of the entire WL site	■ Decommissioning and reclamation of the entire WL site, including the Project, may change the future land tenure and uses of the WL site.	■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe, and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ Affected areas will be remediated to meet the WL preliminary soil cleanup and the non-radiological and radiological clearance and release criteria in accordance with the target end state of the associated land-use category.	Secondary

6.8.2.6.2.1 No Linkage Pathway

The following pathway was assessed as having no measurable environmental change and hence, no linkage to residual effects on other land and resource use VCs.

- **Nuisance factors such as dust and noise may affect outdoor recreational or tourism experiences.**

During construction of the WRDF, there will be restrictions on the use of the WL site, although land and resource use will continue to persist in locations adjacent to the WL site. Project activities, including site preparation, WR-1 Building demolition and operation of the batch mixing plant, are expected to increase the level of nuisance factors (dust and noise) in the LSA; however, they are not expected to have a substantial effect on an individual's land and resource use experience or on harvested species because of mitigation and management practices put in place for the Project.

Nuisance factors could make other land and resource use activity experience on the Winnipeg River to the west of the WL site less enjoyable but changes are expected to be temporary and people will still be able to access the river upstream and downstream of the WL site to engage in activities. No emissions from Project activities are anticipated to exceed the appropriate standards and guidelines (Table 6.2.1-14). Project activity will typically be limited to daytime hours, where possible, and noise will be short-term and sporadic. Decommissioning of the WR-1 Building will be completed in a controlled manner, and no blasting will be required. The loudest decommissioning activity will likely be noise from a percussion hammer on an excavator, which will be used to break up reinforced concrete walls and floors during demolition. This activity will be limited to the interior of the building envelope, which will serve to reduce the level of noise outside the building, and in the surrounding area. The WL site has also retained heavy tree coverage, which provides a natural noise barrier (AECL 2001).

Due to the restriction on use and access to the WL site, the nature of Project-related noise, the absence of threshold exceedances for emissions and mitigation for minimizing dust, which includes implementation of dust management techniques to control dust generated by the Project, nuisance factors as a result of Project activities are not expected to have an effect on recreation and tourism activities in the LSA. This pathway is therefore considered to have no linkage to effects on other land and resource use.

6.8.2.6.2.2 Secondary Pathways

In some cases, a potential interaction with an assessment endpoint exists but mitigation is expected to cause minor changes to the environment and a negligible effect on other land and resource use relative to the existing Base Case. The following are expected to result in negligible effects on other land and resource use and will not be examined further in the EIS.

- **Changes to outdoor recreational activities and tourism resulting from changes to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River.**

The Project could affect outdoor recreation and tourism activities, and traditional land use through changes to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River. Changes to these VCs could result from a change in the abundance and distribution of resources, the quality of the resource, and the ability to access the resource including fish, wildlife and vegetation. Any of these changes could subsequently affect the ability and the desire to engage in activities in the LSA.

The footprint of the WR-1 Building is approximately 0.07 ha and is located in an area that has been previously disturbed, where wildlife habitat value is considered to be negligible to low. In addition, temporary supporting infrastructure will be located within the LSA on previously disturbed and developed areas. Therefore, the Project is not expected to result in an incremental loss of wildlife habitat from current conditions at the WL site. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the RSA will be used during decommissioning activities around disturbed areas, where appropriate. This will reduce the potential for effects on adjacent natural areas that provide suitable wildlife habitat. Once decommissioning of the WR-1 Building and ISD of WR-1 are completed and the engineered cover installed, the area will be graded and restored with native vegetation. Once institutional control begins in 2031, there will be monitoring activities, but the Project site will remain otherwise undisturbed.

Nuisance Factors

Project activities, including site preparation, demolition of the WR-1 Building and the development of temporary infrastructure, will increase noise levels and the amount of dust produced in the LSA, which could affect the distribution of wildlife species harvested by resource users. Changes to the distribution of wildlife species could in turn affect outdoor recreation and tourism activities, as they constitute some of the resources on which these activities are dependent. Due to the nature of the noise produced by Project activities (sporadic, short-term, no blasting), wildlife species that live near the WL site are not expected to experience habitat loss (AECL 2001). Increases in dust are expected to be short-term, reversible, and not exceed the appropriate guidelines and standards. Noise and dust are not expected to result in changes of wildlife distribution that could affect other land and resource use.

Airborne Dispersion of Contaminants

The Project may result in airborne contaminants that could deposit to soil and surface water, where they could affect vegetation, wildlife/wildlife habitat, fish/fish habitat and surface water quality. Changes to vegetation, wildlife/wildlife habitat and fish/fish habitat could in turn affect outdoor recreation and tourism activities, as they constitute some of the resources on which these activities are dependent. The Environmental Risk Assessment (ERA) predicated that there will be no exceedances of the 2.4 mGy/day radiation benchmark for terrestrial and riparian biota on or near the WL site resulting from atmospheric releases (Section 6.7.2.7.1 Application Case – Closure Phase). All predicted doses are well below this level. Therefore, it is unlikely that there would be significant adverse effects on terrestrial populations or communities (i.e., vegetation and wildlife) as a result of radionuclide releases from closure activities. In addition, the ERA predicts that the total radiation dose to all human receptors during closure activities is well below the public dose limit of 1 mSv/a (Section 6.7.1.7.1 Application Case – Closure Phase). Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure of potential critical groups to radioactive releases from the WL site during closure.

Waterborne Dispersion of Contaminants

The Project may result in waterborne dispersion of contaminants that could affect vegetation, wildlife/ wildlife habitat, fish/fish habitat and surface water quality. Waterborne dispersion may occur after the start of institutional control through leakage via the grouting to groundwater. Groundwater may then migrate to surface water at the Winnipeg River, where contaminants could travel downstream and affect vegetation, wildlife/wildlife habitat and fish/fish habitat. Changes to water quality or fish/fish habitat could in turn affect outdoor recreation and tourism activities and traditional land and resources use, as they constitute some of the resources on which these activities are dependent. The ERA predicts that there will be no exceedances of the 9.6 mGy/day radiation benchmark for the aquatic biota in the Winnipeg River (Section 6.7.2.7.2 Application Case – Post-closure Phase). Similarly, there are no predicted exceedances of the 2.4 mGy/day radiation benchmark for terrestrial and riparian biota on or near the WL site (Section 6.7.2.7.2 Application Case – Post-closure Phase). All predicted doses are well below these levels. For non-radiological contaminants of potential concern, the ERA predicts no exceedances of cadmium, lead, HB-40 and xylene exposure to ecological receptors. Therefore, it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of radionuclide releases or the release of non-radiological contaminants from post-closure activities.

There are no anticipated exceedances for the radiation benchmarks for human receptors, including an on-site harvester, a farm north of the WL site on the Winnipeg River, and an on-site farm, a human receptor located on the Whiteshell Reactor Disposal Facility (WRDF; i.e., the end-state of the Project). The on-site farm receptor was assessed because the temporal boundary of the post-closure phase extends past a number of human generations. The total radiation dose for all receptors are below the public dosage limit of 1 mSv/a and the dose constraint for the Project of 0.25 mSv/a for all age groups (Section 6.7.1.7.2 Application Case – Post-closure Phase). Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure of these receptors to radioactive releases from the WL site during the post-closure phase.

The doses to human receptors that could be exposed to the non-radiological contaminants of potential concern in surface water during post-closure were calculated based on total concentration (background plus Project contribution). Incremental hazard quotients were compared to a benchmark hazard quotient of 0.2, which is consistent with Health Canada. The hazard quotients derived for constituents of potential concern were below the protective benchmark for all receptors, with the exception of a toddler harvester, which slightly exceeded the benchmark. If only the project contribution is considered, the HQs are reduced even further, and hazard quotients are well below for all receptors (the Project contribution to the total is 0.0021% for cadmium and 0.00002% for lead). Therefore, no discernable health effects are anticipated due to exposure of potential critical groups from the Project during post-closure.

Through these pathways, the Project is expected to have a negligible effect on recreation and tourism activities. There are not anticipated to be any threshold exceedances in harvested receptors through atmospheric releases and waterborne dispersion of contaminants. In addition, the mitigation proposed to minimize Project effects on surface water quality, the aquatic environment, the terrestrial environment, human health and ecological health are anticipated to eliminate or mitigate any potential adverse effects to the resources on which recreation and tourism activities are dependent. These pathways are therefore characterized as secondary.

- **The use of ISD as the decommissioning method for WR-1 will change the proportion of the site that will have restrictions on use.**
- **Changes to access restrictions associated with the WL site end state as a result of the Project may result in changes to future land tenure and uses of portions of the site itself.**
- **Decommissioning and reclamation of the entire WL site, including the Project, may change the future land tenure and uses of the WL site.**

The WL site has been operational since the 1960s, with restrictions on public access for safety and security reasons. Exceptions to this include parcels of the WL site on the west side of the Winnipeg River that have been continuously used for agricultural purposes under agreements with AECL. The area to the east of the WL main campus has been left undeveloped and is meant to act as a buffer to the industrial site (LGD of Pinawa 2004). No outdoor recreation and tourism activities are permitted on the WL site. Other land and resource use activities have persisted adjacent to the site, including uses of the Winnipeg River. It is expected that all activities and land use adjacent to the site will be able to continue in the future as the Project will have no effect on land tenure or usage beyond the WL site boundaries.

Future use of the WL site will depend on the ability to release parts of the site with no restriction on use upon completion of the Project. Future uses/zoning have not been determined, but the end-state plan for the WL site is to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-state. The criteria developed will prioritize the environment and safety. Some lands will have restrictions on the future use so that there are no adverse effects to people and the environment as assessed in the safety assessment and modelling associated with the ISD of infrastructure and facilities, such as WR-1 and the Waste Management Area. These areas will require ongoing controls including institutional control, access restrictions and environmental monitoring. However, the amount of land associated with all of these areas is negligible relative to the size of the WL site that will have no restrictions on land use. CNL will be engaging the public, Indigenous Nations, and other key stakeholders in a discussion on future uses for the WL site, with site closure planned for early 2031.

The following are the key roles and responsibilities to determine the future use of the WL site:

- AECL owns the site and has responsibility for all assets and liabilities.
- CNL is the contractor responsible to perform the decommissioning and site remediation of the WL site.
- CNL is preparing a Land-Use and End-State Plan defining the end state criteria in collaboration with stakeholders, Indigenous Nations and the public, and will submit it to the CNSC for acceptance.
- CNL informs and engages the public, Indigenous, and other key stakeholders such as the Province of Manitoba.

Changes in the future uses of the site may affect the Local Government District of Pinawa's desire to develop economic activity at the WL site to offset lost jobs due to closure of the site, including nuclear and non-nuclear developments. As noted in Section 6.9.6 Project Interactions and Mitigation, the previous decommissioning plan for WL, described in the Comprehensive Study Report (AECL 2001), assumed that radioactive wastes would eventually be removed and placed in permanent disposal facilities with the assumption that a national disposal facility for low level radioactive waste would be available by 2025 and a national disposal facility for intermediate-level waste operational by 2050 (CNSC 2002). Under the previous decommissioning plan for WL, described in the Comprehensive Study Report (AECL 2001), a smaller percentage of the site (the Waste Management Area) would have had restrictions on use than with the Project; however, the area with anticipated restrictions on use under the Project is still small when compared with the remainder of the WL site.

While the Project will change the proportion of the site with restricted access and future uses, decommissioning is designed with the environment and safety as a priority. Since the Project will make the WL site safer when compared to baseline conditions and it will increase the amount of land available for future use in the LSA, these pathways are categorized as secondary.

The Project in combination with the decommissioning and reclamation of the WL site is also anticipated to contribute to positive effects on the environment, which will positively affect other land and resource use within the RSA (e.g., less industrial activity that could affect outdoor recreation, hunting, fishing, and trapping). Consequently, cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site are anticipated to be negligible.

- **The Project may change the suitability of the LSA for outdoor recreation and tourism.**

The WL site was established in the 1960s with WR-1 becoming operational in 1965. Since that time, there have been nuclear research and more recently, decommissioning activities at the site. The area around the WL site in the LSA is currently used for agricultural activities, wildlife harvesting activities, fishing and private residences. This has not altered land and resources use in proximity to the WL site with activities, as such deer hunting, agricultural activities, fishing and other uses of the Winnipeg River still popular. The presence of the encased WR-1 is not expected to cause changes in these existing activities, although a small number of users may consider areas in proximity to the site as less optimal than if the reactor had been removed in its entirety.

The Project will be engineered to demonstrate long-term safety through a combination of site characteristics and engineered design features and to isolate and contain contamination inside the reactor vault and limit releases of hazardous substances, including radiological substances. According to the ERA, thresholds for airborne and waterborne contaminants will not be exceeded as a result of the Project (EcoMetrix 2024). Therefore, there is no need to change land use in land released for unrestricted use or on the land in the LSA around the WL site; however, the presence of an encapsulated reactor and associated perceptions may make engaging in activities in the LSA less desirable for some users.

To support continued understanding and dialogue around the suitability for use of the WL site and the lands around it for other land and resource use purposes, CNL will support robust communication of environmental monitoring results to confirm the safety of the WL to and help address concerns about future uses. Members of the Public Liaison Committee, which focuses on building relationships and creating dialogue between CNL, stakeholder groups, and communities and RMs around the WL site (Section 6.9.7 Monitoring and Follow-up) are currently expected to share outcomes with residents of their respective home communities, and it is anticipated that they will have a substantial role with sharing monitoring results with community members once decommissioning is complete.

CNL will continue to use a public website and other media mechanisms to share information and receive feedback from local communities and Indigenous Nations through the duration of the Project. Future communication mechanisms to keep local communities and Indigenous Nations informed will be determined as necessary, and in consultation with them. Collaboration and information sharing with Indigenous Nations will be important to ensuring mitigation is effective. Overall, with mitigation and engagement in place, Project effects on other land and resource use are expected to be negligible. These pathways are therefore characterized as secondary.

6.8.2.6.2.3 Primary Pathways

There are no interactions with primary linkages to effects to the other land and resource use VCs. Mitigation and monitoring efforts are expected to keep all pathways secondary, which means there may be a measurable change to measurement indicators but they are expected to be minor relative to the Base Case.

6.8.2.7 Monitoring and Follow-up

As there are no primary pathways for other land and resource use VCs, monitoring is not anticipated for other land and resource use. However, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project that will be integrated with the existing Environmental Assessment Follow-up and Monitoring Program for the WL site. The Environmental Assessment Follow-up and Monitoring Program for the Project will include sufficient information on the type, quantity and quality of information required to reliably verify effects predicted by the environmental assessment and confirm the effectiveness of mitigations. Wherever possible, existing programs will be adapted to meet the objectives of the Environmental Assessment Follow-Up and Monitoring Program for the Project.

Monitoring for environmental pathways (i.e., for air quality, water quality and groundwater quality) will be implemented to verify effects predictions for other land and resource use. It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Within this framework, modifications to the program may be appropriate to confirm data continue to fulfill program objectives. For example, should a contaminant of potential concern reach concentrations outside the range predicted in the EIS or Decommissioning Safety Assessment Report, the frequency of sampling may be increased and additional locations may be sampled to investigate the source of the increased concentrations. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals for modifications to the monitoring program and the rationale for the modifications will be communicated to the Canadian Nuclear Safety Commission prior to implementation. Additional information on the Environmental Assessment Follow-up and Monitoring Program for the Project can be found in Section 11.0 Summary of Monitoring and Follow-up Programs.

CNL will continue to engage with local communities, municipalities and Indigenous Nations on findings of the environmental assessment and status of the Project.

6.8.2.8 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous Nations, or the public (The Agency 2018). The other land and resource use VCs chosen for the Project to reflect identified concerns, professional judgement and/or standard practice in environmental assessment are Land Tenure, Outdoor Recreation, and the Winnipeg River.

The Project could affect outdoor recreation and tourism activities through effects to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River. Changes to these VCs could result from a change in the abundance and distribution of resources, the quality of the resource, and the ability to access resources including fish, wildlife and vegetation. Any of these changes could subsequently affect the ability and the desire to engage in activities in the LSA. There are not anticipated to be any threshold exceedances in harvested receptors through atmospheric releases and waterborne dispersion of contaminants. In addition, the mitigation proposed to minimize Project effects on surface water quality, the aquatic environment, the terrestrial environment, human health and ecological health are anticipated to eliminate or mitigate any potential adverse effects to the resources on which recreation and tourism activities are dependent.

The WL site has been operational since the 1960s, with restrictions on public access for safety and security reasons. Exceptions to this include parcels of the WL site on the west side of the Winnipeg River that have been continuously used for agricultural purposes under agreements with AECL. No outdoor recreation and tourism activities are permitted on the WL site. Other land and resource use activities have persisted adjacent to the site, including uses of the Winnipeg River. It is expected that all activities and land uses adjacent to the site will be able to continue in the future as the Project will have no effect on land tenure or usage beyond the WL site boundaries.

In collaboration with Indigenous Nations and the public, CNL is committed to meaningful and ongoing engagement on the WL site remediation and clean-up activities. Although a small proportion of the WL site will have restrictions on use because of the Project, it is still anticipated that the majority of the site will be safe and appropriate for unrestricted use. Overall, decommissioning of the WL site will result in an increase in the amount available for future use in the LSA. This may include transfer of the land to other parties following engagement with stakeholders, Indigenous Nations and the public. Future uses/zoning have not been determined, but the end-state plan for the WL site is to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-state. Consequently, the Project is expected to have a negligible effect on other land and resource use VCs.

CNL will implement a WR-1 Environmental Assessment Follow-up and Monitoring Program to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. In addition, to mitigate perceptions related to the suitability for use of the WL site and the lands around it, CNL will support robust communication of environmental monitoring results to confirm the safety of the WL site and help address concerns about future uses. CNL will continue to engage with local communities, municipalities and Indigenous Nations.

This page intentionally left blank

6.9 Socio-economic Environment

This section of the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project) seeks to understand and characterize the potential residual effects of the Project and past, present, and reasonably foreseeable developments on the socio-economic environment. Socio-economics refers to the way social and economic factors influence one another in local communities and households. The socio-economic environment assessment considers potential effects of the Project on the people and communities who are part of the existing socio-economic environment in the immediate vicinity of the Project. Potential residual effects of the Project on land and resource use, including sites of cultural or archaeological significance and traditional land and resource use, are assessed in Section 6.8 Land and Resource Use. Indigenous engagement and input were an important element in the assessment. and details of CNL's engagement with potentially affected Indigenous Nations is provided in Section 4.0. Information is incorporated throughout this assessment.

6.9.1 Scope of the Assessment

The socio-economic assessment follows the overall environmental assessment approach and methods described in Section 6.1 Environmental Assessment Approach. The assessment is completed in the following eight primary steps.

- **Step 1 – Identify Valued Components (VCs) and define the spatial boundaries, temporal boundaries and assessment cases** (refer to Sections 6.9.3 Valued Components and Section 6.9.4 Assessment Boundaries) for the socio-economic assessment. The VCs, assessment endpoints and measurement indicators used to assess Project related changes to socio-economics, are also described.
- **Step 2 – Describe the existing conditions** (refer to Section 6.9.5 Description of the Environment). Existing conditions in the local and regional areas are described, including the combined effects of previous and existing developments (Base Case). The existing environment represents the historical and current socio-community characteristics, including non-tangible features and the "built" environment (e.g., community infrastructure).
- **Step 3 – Evaluate Project interactions and mitigation** (refer to Section 6.9.6 Project Interactions and Mitigation). Project components and/or activities with the potential to affect socio-economics are identified and mitigation options are presented to limit or avoid these effects. A pathways analysis is then used to focus on key interactions between the Project and the environment and determine if mitigation can limit or eliminate the predicted residual effects. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. Where effects are adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are described. Primary pathways that may lead to residual effects to socio-economics after incorporating mitigation are carried forward to Steps 4 for further analysis and residual effects characterization.
- **Step 4 – Present the methods and results of the residual effects analysis.** This step was not required as no primary pathways were identified in the socio-economic assessment.

- **Step 5 – Describe the level of certainty and management of uncertainty.** This step was not required as no primary pathways were identified in the socio-economic assessment.
- **Step 6 – Classify and determine the significance of the predicted residual effects.** This step was not required as no primary pathways were identified in the socio-economic assessment.
- **Step 7 – Identifying monitoring and follow-up** (refer to Section 6.9.7 Monitoring and Follow-up) required to confirm effects predictions and address uncertainty.
- **Step 8 – Present a consolidated summary of conclusions and outcomes of the assessment** (refer to Section 6.9.8 Conclusions) of residual effects on socio-economics.

6.9.2 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the socio-economic assessment are summarized in Table 6.9.2-1. Other general concerns and questions raised during Indigenous engagement activities are documented in Section 4.0 Indigenous Engagement.

Table 6.9.2-1: Summary of Issues Raised During Engagement Activities Related to the Socio-economic Environment

Interest and Concern	Inclusion Status	Additional information and Rationale
Employment and Business Opportunities: ■ Interest in procurement policies and potential economic participation opportunities with the Project ■ Interest in First Nation and Red River Métis businesses to be involved in the overall closure work ■ Interest in training to enhance skills of community members ■ Interest in seasonal employment and the proportion of the workforce that is Indigenous ■ Compensation for permanent storage of nuclear materials in traditional territories ■ Concern about competitiveness with larger business in the tender process	Included in the environmental assessment. Commitments by CNL have been restated in Section 6.9.6.2 Results and Section 6.9.7 Monitoring and Follow-up.	■ Employment and business opportunities from the Project are assessed in Section 6.9.6.2 Results
Waste Transportation and Management: ■ Interest in storage and transportation of radioactive waste off-site	Already included in the environmental assessment	■ Methods for transporting waste off-site are described in Section 3.4.8.4 Transporting Waste Off-Site ■ Transportation of waste off-site are assessed in Section 6.9.6.2 Results

Table 6.9.2-1: Summary of Issues Raised During Engagement Activities Related to the Socio-economic Environment

Interest and Concern	Inclusion Status	Additional information and Rationale
Future Land Use Concern that the Project may limit each Nation's participation in land and resource use activities, which would affect their well-being through the ability to express their culture.	The italicized text in the following pathway has been added to Section 6.9.6.2.2 Secondary Pathways: The presence of long-lived radioactive material as part of ISD may affect community well-being for Indigenous Nations through the changes to the suitability of the site for future uses*, the continued inability to exercise stewardship and governance over land and resource management decisions* Psychosocial aspects are important to SFN, and as such CNL has included them in Section 6.9.6.2.2 Secondary Pathways.	■ CNL has committed to engaging each Nation on the future land use and final clean up criteria of the site and to provide the necessary capacity support to enable each First Nation and the Manitoba Métis Federation to meaningfully participate in this engagement. This commitment has been added to Section 6.9.6.2.2 Secondary Pathways and Section 6.9.7 Monitoring and Follow-up. ■ This pathway has been elevated from a no linkage to a secondary pathway due to the importance to Indigenous Nations
Establishment of the WL site Concern about the collective effects of historical changes to each Nation's cultural practices, land and resource use, and Aboriginal and Treaty rights as a result of the establishment of WL site.	Section 6.9.5.2.1.1 Indigenous Community Perspectives on the Whiteshell Laboratories Site has been added to the assessment. A subsection on Indigenous Community Perspectives on Health and Wellness was added to Section 6.9.5.2.6.4 Indigenous Health.	■ CNL confirmed that historical grievances are outside of the scope of this Project; however, these sections have been added to recognize the First Nations' and Manitoba Métis Federation's' perspectives on the establishment of the WL site and perspectives on health and wellness. ■ CNL is working closely with AECL to address the interests and concerns of each Nation related to the Project and the overall WL site.
Concern about the health of the environment, species relied on for fishing and harvesting, and the risk to people in the area of the WL site	Included in the environmental assessment. CNL's commitment to involving Indigenous Nations in monitoring and engaging with them over the long-term to address ongoing concerns has been added to Section 6.9.7 Monitoring and Follow-up.	■ CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as described in Section 6.9.7 Monitoring and Follow-up.

Table 6.9.2-1: Summary of Issues Raised During Engagement Activities Related to the Socio-economic Environment

Interest and Concern	Inclusion Status	Additional information and Rationale
Concerns about the spatial boundaries used in the assessment not being reflective of those used in traditional land use studies.	Indigenous Nations that were previously included as part of the RSA were revised to be part of the LSA, reflective of the role of traditional land and resources use and its contribution to well-being (Section 6.9.4.1 Spatial Boundaries).	■ CNL expanded the spatial boundaries relative to traditional land and resources use VCs (Section 6.8.1 Traditional Land and Resource Use) to be more reflective of the traditional territories identified through traditional land use studies. As such, updates were also warranted in Section 6.9.4.1 Spatial Boundaries as the relationship between traditional land and resources use has linkages to well-being.
The absence of Indigenous indicators of well-being.	A subsection on Indigenous Community Perspectives on Health and Wellness was added to Section 6.9.5.2.6.4 Indigenous Health of the assessment.	■ Indigenous health and well-being are included in a dedicated section 6.9.5.2.6.4 Indigenous Health that is discussed in addition to the standardized elements that are used for non-Indigenous Nations. This allows direct comparison of the communities for several factors, and then additional analysis and discussion of those factors that are specific to indigenous people.

6.9.3 Valued Components

Valued components refer to socio-economic and environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous Nations, or the public (The Agency 2018). The socio-economic VCs chosen for the Project to reflect identified concerns, professional judgement and/or standard practice in environmental assessment are Employment and Income, Business Opportunities, Government Finances, Community Infrastructure and Services, Community Well-being and Public Safety. The rationale for selecting these VCs is discussed in Table 6.9.3-1.

Table 6.9.3-1: Valued Components for Socio-economic Assessment

Valued Component	Rationale for Selection
Employment and Income	Local communities recognize that the decommissioning of the WL site will result in changes to local employment and income opportunities. There are concerns that the change in approach to decommissioning the WR-1 Building may result in challenges to attracting new businesses to the WL site and creating future employment opportunities. The Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations also identified employment as important through engagement and verification discussions.
Business Opportunities	The proposed changes in decommissioning activities for the WR-1 Building create a different set of opportunities for contractors than the previous decommissioning plan. The Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations also identified business opportunities as important through engagement and verification discussions.
Government Finances	The LGD of Pinawa relies on a grant-in-lieu of taxes from AECL associated with the presence and operation of the WL site. The proposed changes in decommissioning activities may accelerate changes to the grant-in-lieu of taxes, which would change Pinawa's municipal revenue streams.
Community Infrastructure and Services	A wide range of essential human needs are fulfilled by infrastructure and services in communities. Projects can place additional demands on them and their ability to meet community needs. The Project may also affect how community infrastructure and services are funded in Pinawa as AECL pays the LGD a grant-in-lieu of taxes, which is used to fund infrastructure and services, including the School District of Whiteshell.
Community Well-being	Community well-being is affected by a variety of factors, including consideration of economic well-being, physical well-being, social well-being and the environment. The change in approach to decommissioning the WR-1 Building may restrict access to more of the WL site than previously anticipated and limit its subsequent use for other activities. Indigenous Nations have expressed concern that the Project may limit their participation in land and resource use activities, which would affect their well-being through the ability to express their culture or exercise Aboriginal and Treaty rights. Communities have also expressed concern that attracting a new business/industry to the WL site is important for their continued viability, both in terms of employment/income and in terms of their long-term sustainability.

Table 6.9.3-1: Valued Components for Socio-economic Assessment

Valued Component	Rationale for Selection
Public Safety	Public Safety has been a concern for the overall decommissioning of the WL site, which included medium-term storage of radioactive waste and eventual transport of radiological waste to permanent disposal facilities. The Project will reduce the amount of radiological waste being transported to disposal facilities, which will reduce one public safety hazard; however, the shift to in situ disposal will create a new public concern that was also identified by Indigenous Nations as some waste will be stored on the WL site permanently. Public safety related to the transportation of radiological waste off-site is considered in this assessment; while concern related to public exposure from in situ disposal is evaluated in Section 6.7 Human and Ecological Health. Psychosocial impacts are not considered a VC; however, due to the significant importance of this concern, and in the spirit of understanding and cooperation, the EIS discusses the psychosocial impacts of perceptions of the Project in Section 4.0 Indigenous Engagement, as well as mitigations CNL has and will put in place to address concerns related to fear and stigma associated with the site,

LGD = Local Government District; AECL = Atomic Energy Canada Limited.

Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs and represent the key properties of the VC that should be protected for future generations. The assessments of each VC have incorporated community and/or traditional knowledge where available. Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on a VC. Measurement indicators can be used to monitor the success of mitigation and management programs. The assessment endpoints and measurement indicators associated with the socio-economic assessment are outlined in Table 6.9.3-2.

Table 6.9.3-2: Assessment Endpoints and Measurement Indicators for the Socio-economic Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Employment and Income	Employment opportunities and associated income for residents of communities in the LSA at the WL site during decommissioning, including opportunities for Indigenous Nations.	The measurement indicators consider changes to local employment and income opportunities based on the change in decommissioning strategy for the Project and the ability to create future employment opportunities by attracting new businesses to the WL site.
Business Opportunities	Contracting opportunities for decommissioning work at the WL site provided to local and regional businesses, including Indigenous businesses.	The measurement indicators consider incremental expenditures for procurement requirements created by the Project and implications to the existing industry and business profile in the local and regional study areas.
Government Finances	■ The grant-in-lieu paid by AECL to the LGD of Pinawa. ■ Changes in the fiscal relationship among AECL, Provincial Government and the LGD of Pinawa.	The measurement indicators consider the continued financial viability of the communities and rural municipalities in proximity to the Project. Particular attention is paid to the LGD of Pinawa and its relationships with the federal government, which pays the grant-in-lieu of taxes, and the provincial government, which provides a reduced level of funding to the school district because of the grant-in-lieu of taxes.

Table 6.9.3-2: Assessment Endpoints and Measurement Indicators for the Socio-economic Assessment

Valued Component	Assessment Endpoints	Measurement Indicators
Community Infrastructure and Services	■ Capacity of local and regional transportation infrastructure to accommodate Project-related traffic. ■ Capacity of Pinawa to continue providing the same level of infrastructure and services to residents as a result in potential changes to municipal funding.	■ Traffic volumes and road infrastructure will be considered in relation to employee traffic and waste hauling. ■ The Project is not expected to place stress on other infrastructure and services, but a potential change in the municipal revenue stream because of changes in the grant-in-lieu could alter the level of services offered in the LGD of Pinawa.
Community Well-being	■ Nature of post-decommissioning uses of the WL site, which may change as a result of changes in the original decommissioning plan. ■ Capacity of the Community Regeneration Partnership to create a feasible socio-economic plan for the region to promote continued economic and community development. ■ Economic development opportunities available to the communities and RMs in the LSA. ■ Continued use of the area by First Nation member or Red River Métis citizens for traditional land and resource use activities.	The measurement indicators consider the continued socio-economic sustainability and overall well-being of communities in proximity to the Project, with a particular focus on the LGD of Pinawa due to the community's historical ties with the WL site.
Public Safety	■ Safety related to transportation infrastructure. ■ Safety related to access to the WL site, including the consideration of radiation exposure and non-radiological exposure).	The measurement indicators considered for public safety for the Project are related to potential hazards associated with decommissioning activities including waste hauling and public access to the site during institutional control.

LSA = Local Study Area; LGD = Local Government District; RM = Rural Municipality.

6.9.4 Assessment Boundaries

6.9.4.1 Spatial Boundaries

- **Local Study Area (LSA)** for the socio-economic VCs encompasses the municipalities and rural municipalities most likely to be affected by the Project. The LSA contains the municipalities of the Local Government District (LGD) of Pinawa, the Town of Lac du Bonnet and the Town of Beausejour (Beausejour), as well as the Rural Municipality (RM) of Whitemouth, the RM of Lac du Bonnet and the RM of Brokenhead. The workforce at the WL site since it began operations in the 1960s has traditionally resided in these municipalities and RMs; the largest proportion of the current workforce also resides here. These communities have a historical relationship with the operators of the WL site and currently have a relationship with the operators through the Public Liaison Committee and the Whiteshell Laboratories Community Regeneration Partnership (the Partnership), which is intended to help the communities affected by decommissioning develop a socio-economic plan to promote the viability of the regional economy.

  There are also three First Nations communities included in the LSA located in relative proximity to the Project that have an interest from a socio-economic perspective (i.e., employment and business opportunities as well as negative socio-economic effects from permanent ISD affecting future site suitability). These include:

  - Sagkeeng First Nation (Fort Alexander Indian reserve 3 is approximately 66 km northwest of the WL site).
  - Black River First Nation (Black River Indian reserve 9 is approximately 92 km northwest of the WL site).
  - Brokenhead Ojibway Nation (Brokenhead Indian reserve 4 is approximately 73 km northwest of the WL site). Brokenhead Ojibway Nation has two additional reserves, Birch Landing and Na-Sha-Ke-Penais.

  The Manitoba Métis Federation has Locals throughout their southeast region, including one in Lac du Bonnet which is part of the LSA. Additional Indigenous Nations are identified with respect to land and resource use, which is discussed in Section 6.8 Indigenous Land and Resource Use. As other Indigenous people's express interest in the Project from a socio-economic viewpoint, their inclusion in the effects assessment will be considered.

- **Regional Study Area (RSA)** is where potential effects are expected to be experienced at a broader scale, including potential economic activities and the use of transportation infrastructure. Economic effects could be a result of participation in Project employment or through contracting opportunities created by the Project. Effects on infrastructure and services would result from the use of transportation infrastructure to the WL site and between the WL site and the Chalk River Laboratories site. To capture the maximum extent of potential effects expected to be experienced, the RSA encompasses the Southeast Region of Manitoba and the City of Winnipeg, which includes population centres with well-developed business communities, residents with labour skills that could be relevant to the Project and transportation infrastructure to be used by the Project. The Southeast Region is Census Divisions 1, 2 and 12, which follow RM boundaries. Approximate geographic landmarks for RSA boundaries are the Manitoba-Ontario border in the east, the Manitoba-US border in the south, the Red River/PTH 75 in the west and the Winnipeg River in the north. The major population centres outside of the municipalities in the LSA are the Towns of Niverville, Powerview-Pine Falls and Ste-Anne; the City of Steinbach and the Village of St-Pierre-Jolys. The Manitoba Métis Federation has Locals throughout the RSA, which falls within their southeast region. The LSA and RSA are shown on Figure 6.9.4-1.

6.9.4.2 Temporal Boundaries

The temporal boundary of the assessment includes the timeframe during which Project activities are actively occurring and the duration of predicted residual effects. The duration of an effect is defined as the amount of time between the start and end of a Project activity or stressor (which is related to the project phases) plus the time required for the residual effect to be reversed. In some cases, a residual effect may be irreversible within the temporal boundaries of the Project if the effects were predicted to last so far into the future that they could not be predicted with any level of certainty (e.g., residual effect lasts for thousands of years). The following phases were identified for the Project:

- **Closure Phase:** Preparation and implementation of in situ disposal (ISD), which includes preparation for ISD, grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031.
- **Post-closure Phase:** The post-closure phase has two discrete periods: institutional control and post-institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue, to demonstrate WRDF performance is in compliance with the safety case assumptions and performance modelling. The 100-year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

6.9.4.3 Assessment Cases

The socio-economic assessment considers the following three assessment cases:

- **Base Case:** represents existing conditions and includes effects from previous and existing developments and activities. For the socio-economic assessment, the effects of current and future decommissioning activities for the WL site are included in the Base Case. As described in the Comprehensive Study Report (AECL 2001), the original decommissioning approach for the WL site proposed three phases that would ultimately lead to final decommissioning activities being completed over a 60-year period (i.e., 2061). Since the environmental assessment decision in 2002, the overall approach to decommissioning, in keeping with international best practices, has shifted to an accelerated process with reduced deferment periods with a targeted timeframe for closure of the WL site by 2031.
- First Nations and the Manitoba Métis Federation identified concern about the collective effects of historical changes to each Nation's cultural practices, land and resource use, and Aboriginal and Treaty rights as a result of the establishment of WL site. CNL is working closely with AECL to discuss historical grievances with each Nation.

- **Application Case:** represents predictions of the effects that may result from the Project. As described above, the Base Case already includes effects from the eventual decommissioning of the entire WL site. Consequently, the Application Case for the Project only considers effects from the accelerated process with reduced deferment periods (i.e., accelerated from 2016 to 2034).
- **Reasonably Foreseeable Developments (RFD) Case:** represents the effects of the Base Case combined with the predicted incremental effects from the Project (the Application Case), as well as effects from other RFDs within the RSA that are currently under application review or that have officially entered a regulatory application process. There are no RFDs expected in the RSA (Table 6.9.4-1).

Table 6.9.4-1: Reasonably Foreseeable Developments considered in the Socio-economic Environment Assessment

Type of Project	Location	Description	Timeframe	Overlap with Valued Components
Infrastructure Decommissioning	WL	Decommissioning of remaining infrastructure on the WL site (includes ISD of the low-level waste trenches).	2016 to 2034	No – there is no overlap of effects with the Project (i.e., no new workforce is required for these activities)
Environmental Remediation	WL	Remediation of affected lands, with the exception of the low-level waste trenches.	2016 to 2034	No – there is no overlap of effects with the Project (i.e., no new workforce is required for these activities)

6.9.5 Description of the Environment

This section describes the setting and characterization for socio-economics as relevant for the assessment of the Project. It describes the existing conditions against which potential changes from the Project are compared and evaluated.

6.9.5.1 Methods

The characterization of the existing socio-economic environment reflects review of both primary and secondary data sources. Data collection began with a review of existing literature and databases from a variety of public sources. Where sufficient detail was not available from secondary data sources to describe the existing environment, primary data collection was undertaken in the form of Key Person Interviews.

6.9.5.1.1 Literature Review

The review of literature and databases included the following sources:

- Project-specific Indigenous-community led studies for Sagkeeng First Nation (recognizing these reports contain information relevant to socio-economic assessment, but are not assessments of Sagkeeng First Nation socio-economic impacts);
  - For Sagkeeng First Nation: *Sagkeeng Anicinabe Land Use and Occupancy Study Specific to Canadian Nuclear Laboratories' Proposed In Situ Decommissioning of the WR-1 Reactor at Whiteshell Laboratories* (Firelight Research Inc. and Sagkeeng Anicinabe 2018) and *Sagkeeng Anicinabe Psychosocial Impact Assessment* (Narratives Inc 2020).
- statistical data sources (e.g., Statistics Canada, Indigenous and Northern Affairs Canada);
- federal, provincial and municipal government reports and data;

- health reports and data;
- regional-level documents (i.e., Community Futures Winnipeg River);
- the previous Whiteshell Laboratories Decommissioning Project: Comprehensive Study Report (AECL 2001); and,
- online sources (e.g., community websites, online business profiles).

Data from these sources was used to characterize the existing environment, based upon the most recently available data.

6.9.5.1.1.1 Limitations of Statistics Canada Data

Statistics Canada data should be interpreted with caution because of issues of comparability across years, confidentiality, and data quality. The characterization of the existing socio-economic environment relies on the 2016 and 2006 Census of Population data along with data from the 2011 National Household Survey (NHS). It is noted that in 2011 there was a shift in how the census was administered, with the NHS replacing the long-form census. One of the key differences was a shift from a mandatory to an optional response requirement for citizens. Statistics Canada also suppresses data for confidentiality or data quality.

Statistics Canada collects and reports data based on geographic locations, which means data are tied to the location of the respondent. While this provides insight into geographic communities, when a population, such as the Métis citizens or First Nation members living off-reserve, is disperse, the usefulness of Statistics Canada data is limited in describing the specific populations. Statistics Canada data presented herein focus on the communities (Indigenous and municipal) in the LSA. Further, for Indigenous populations living in municipalities, Statistics Canada reports self-identified Indigenous populations, which means that individuals identifying as Indigenous may not be registered members of a First Nation or a Métis citizen. It is recognized that as the national government of the Red River Métis, the Manitoba Métis Federation represents more than 125,000 citizens and harvesters within the provincial boundaries of Manitoba and thousands more across their National Homeland and around the world.

6.9.5.1.2 Key Person Interview Program

A limited Key Person Interview Program (KPI Program 2016) was undertaken to address gaps that could not be readily filled by secondary sources to provide perspectives on community interests and concerns in Pinawa, the Town and RM of Lac du Bonnet, Beausejour, the RM of Brokenhead and the RM of Whitemouth. Interview guides for the Key Person Interviews were developed to address the subject areas discussed in this section. One limitation of the KPI Program is the focus on municipalities and RMs in the LSA and RSA. The perspectives of Indigenous Nations were not captured as part of the KPI program but gathered through various community-led studies (primarily traditional land and occupancy studies) and Project engagement activities.

6.9.5.2 Results

6.9.5.2.1 Historical Background

The WL site was established in the early 1960s by Atomic Energy of Canada Limited (AECL) to facilitate research and development of higher temperature versions of the Canada Deuterium Uranium (CANDU) reactor. Also, at that time, AECL designed and established the local government district of Pinawa. The WL site included WR-1, an organic cooled reactor which became operational in 1965 (AECL 2001). In the early 1970s, the organic cooled reactor program was eliminated, and full focus was concentrated on the heavy water-cooled CANDU reactor system. In 1985, WR-1 was permanently shut down. Over the years many nuclear research, management and safety programs were developed at the WL site which led to its reputation as a diverse centre for research (CNL 2016a; AECL 2001).

As a result of a federal review process that led to the reduction in funding to nuclear research, the Federal Government decided in 1997 to discontinue research programs at the WL site (AECL 2001). The initial efforts to secure a private owner to run the facility were unsuccessful and in 1998 AECL determined the WL site would be closed and decommissioned to meet regulatory requirements. A Comprehensive Study Report for the decommissioning of the WL site was completed in 2001 and the Environmental Assessment decision to approve the project was announced in March of 2002 (CNL 2016b). In 2003, the decommissioning framework for the WL site received approval. This decommissioning framework included a completed Environmental Assessment and the subsequent site decommissioning licence by the Canadian Nuclear Safety Commission (CNSC) (CNL 2016c).

Phase 1 of the WR-1 decommissioning began in 1989 and was completed in 1995. The initial shutdown and Phase 1 decommissioning of WR-1 included, amongst other decommissioning activities, removal of fuel and radioactive material and preparation of WR-1 for a deferment period for the radioactivity levels to decrease through natural decay prior to subsequent decommissioning activities. In 2001, a monitoring program began for WR-1 (AECL 2001; CNL 2016b).

CNL was established on May 30, 2014 as part of the Government of Canada's restructuring of AECL, and preparation for full implementation of a Government-owned, Contractor-operated (GoCo) model. Once CNL was established, AECL applied to the CNSC to transfer the WL site licence to CNL. This licence transfer was approved by the CNSC on October 22, 2014 (CNSC 2014). CNL became a private-sector entity with the transfer of ownership to Canadian National Energy Alliance. CNL currently operates the WL site on behalf of AECL. It has been mandated by AECL to proceed with decommissioning work (CNL 2016a). Change in number of full-time employees at the WL site between 1962 and 2019 is shown in Figure 6.9.5-1.

6.9.5.2.1.1 Indigenous Nations Perspectives on and Observations of the Whiteshell Laboratories Site

The WL site was established in the 1960s without consideration of and consultation with Indigenous Nations in the region, which Sagkeeng First Nation, Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation noted through engagement. The Sagkeeng First Nation stated concern about the collective effects of historical changes to their cultural practices, land and resource use, and Aboriginal and Treaty rights as a result of the establishment of WL site (Section 4.2.4.1 Sagkeeng First Nation). Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation were concerned that a large parcel of land could have been removed from treaty land without discussion with Indigenous Nations (Section 4.2.4.3 Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation). While consultation with Indigenous Nations was not standard practice in the 1960s and the Duty to Consult was not formally established by the Supreme Court of Canada until 2004 (Gonzalez 2020), the WL site in its entirety is understood by CNL as being a source of concern relative to community well-being and cultural expression for Indigenous Nations in the LSA.

Most of the concerns expressed by Indigenous Nations about well-being are tied to a series of historical activities and developments such as hydroelectric dams, large-scale agriculture, the Pine Falls Mill and the WL site (Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations). These activities and development affected lands used for traditional land and resource use activities through restricted access and other changes to the environment. The Sagkeeng First Nation in the *Sagkeeng Anicinabe's Alternative Means Assessment for the Environmental Assessment of Canadian Nuclear Laboratories' Proposed WR-1 Reactor Decommissioning Project* (Sagkeeng Anicinabe and Firelight Research Inc 2020), *Sagkeeng Anicinabe Psychosocial Impact Assessment*(Narratives Inc 2020), and Traditional Knowledge and Land Use (TKLU) Study (Firelight Research Inc. and Sagkeeng Anicinabe 2018) document the changes brought by the WL site on community well-being and the associated land and resource use activities that support it. The Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation (2019) collectively describe the effects of past industrial development,including the establishment of the WL site on the communities and community well-being.

Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Nations describes some of the historical and external factors that have affected land and resource use activities (e.g., the *Indian Act*, residential schools, industrial development). These factors have also contributed the socio-economic environment for Indigenous Nations, including community well-being. The Sagkeeng First Nation, which is downstream from the WL site and whose members have historically used and occupied the WL site prior to it being fenced off, notes that "mental stress, fear, and stigma associated with Whiteshell has already had a significant effect on Sagkeeng people" (Sagkeeng Anicinabe and Firelight Research Inc 2020, p. 35). The presence of the WL site, along with other industrial developments, has led Sagkeeng First Nation members to consider the existing conditions "dirty" and "polluted." For example, one member shared (Narratives Inc. 2020):

> *That was the reason why we left the reserve as well, because my dad started saying that the land and the things were being damaged. Everybody knew about that; that going down the river and close to Lac du Bonnet, you were going to get bad fish. You were going to get deer that sometimes had big pockets of pus or something on the sides. And they'd talk about this, that it was dangerous to get meat and food from over there... And although I didn't understand when I was little, I understand it now, that it had to do with the nuclear [Whiteshell Laboratory Site]. But it also had to do with the dams. And it probably had to do with that mill, too. (p.43)*

The Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation also document in their TKLU Study (Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation 2019) that the existing conditions are “sick” and “contaminated.” Observations by community members include:

> *It’s not just about our drinking water. It’s also got to do with our fisherman that fish in the lake. The fish have growths on them. Where does that come from? I can’t rule out this Pinawa site as part of the problem” (p.50)*

And

> *There are clear signs of sickness in animals throughout our Traditional Territory. Moose have brain worms and rot in their meat, so they cannot be eaten. Disease is spread from deer and also because they are eating polluted roots from the river. (p. 53)*

While these observations are related to the physical environment, community members for Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation shared that their worldview is based on cultural teachings that “tells us how we are to conduct ourselves in relation to other beings on the earth, and how we are to move forward in a positive way” (p. 14). This traditional understanding of the world is “inherently holistic, intergenerational, and spiritual in nature” (p. 14). As a Back River First Nation member shared:

> *Basically, it’s how we live, how we were raised by our parents and grandparents. They respected everything that we had: water, trees, land and the animals too. Everything that they killed, wildlife, nothing was wasted. Everything was shared and used. (p. 14)*

Changes in the environment, including the establishment of the WL site, have affected the health and well-being of community members. One member noted

> *We survived back then with nothing like this [nuclear power]. We were healthier then. Then they had to come along (p. 55)*

6.9.5.2.2 Population

Over the last 15 years the communities within the LSA have generally displayed a population increase, with the exception of the RM of Whitemouth, which has experienced an overall decline. These population increases may be a reflection of people moving out of urban centres, choosing to commute to work while maintaining a rural lifestyle and/or an increase of retirees moving out of city centres or away from family farming in appreciation of rural lifestyle, access to municipal services and easy access to outdoor recreation. Table 6.9.5-1 presents the total population for municipalities and rural municipalities in the RSA from 2001, 2006, 2011 and 2016.

According to Statistics Canada (2001, 2006, 2011, 2016), the population of Pinawa decreased from 2001 to 2011, while increasing between 2011 and 2016. This initial decline has been linked to the departure of individuals and families associated with layoffs at the WL site, which began in 1998. Meanwhile, retirees have been attracted to the LGD, reportedly because it is considered to be a safe community and health care is readily accessible; however, this has not offset the overall population decline (KPI Program 2016).

The Town of Lac du Bonnet has experienced very little change in population since 2001, however, the Town of Beausejour has experienced a population increase since 2001. In Beausejour, an aging population in the town is partially attributed to the shift from small family farms to industrial farming. As farmers retire, they have tended to sell their farms and move to the town (KPI Program 2016).

Two of the RMs closest to the Project, the RM of Lac du Bonnet and the RM of Brokenhead, have also experienced population growth between 2001 and 2016, while the population in the RM of Whitemouth has decreased since 2001. The RM of Brokenhead has younger demographics than the other municipalities in the LSA. There has been an influx of young families into the villages of Garson and Tyndall. These communities are on Highway 44 between Winnipeg and Beausejour. Many residents of the villages commute to Winnipeg for employment (KPI Program 2016).

Table 6.9.5-1: Total Population for Municipal Communities in the Local Study Area, 2001, 2006, 2011, 2016[a]

Community	2001	2006	2011[b]	2016	Population Change 2001 to 2016[c] (%)
Municipalities					
Local Government District of Pinawa	1,500	1,450	1,444	1,504	0.27%
Town of Lac du Bonnet[d]	1,089	1,009	1,069	1,089	0.00%
Town of Beausejour	2,772	2,823	3,126	3,219	16.13%
Rural Municipalities					
Lac du Bonnet[c]	2,405	2,812	2,930	3,121	29.77%
Brokenhead	3,527	3,940	4,635	5,122	45.22%
Whitemouth	1,617	1,480	1,548	1,557	-3.71%

Source: Statistics Canada (2001, 2006, 2011, 2012, 2016).

a) Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Columns may not add up due to rounding.

b) Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

c) Population Change 2001-2016 was calculated based on Statistics Canada data.

d) In a review of the 2011 Census, Statistics Canada originally misallocated population and dwellings belonging in the Rural Municipality of Lac du Bonnet to the Town. This is the revised population counts (Statistics Canada 2012).

Indigenous Population

Indigenous populations in the municipalities of the LSA and RSA based on self-identification rates of Census respondents are presented in Table 6.9.5-2. It is noted that Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Some data may also be suppressed for data quality or confidentiality reasons by Statistics Canada. Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

Table 6.9.5-2 shows that reported Indigenous population in Pinawa has increased since 1996; however, the reported 2006 Indigenous population was more than double the reported 2016 population. Beausejour's reported Indigenous population has shown the largest change between 1996 and 2016 with an increase of 385 people. Although this Indigenous population increase was notable for Beausejour, the Town of Lac du Bonnet had a proportionately larger percentage of the total population identified as Indigenous (22.0%) as compared to Beausejour (13.2%) in 2016. The rural municipalities have shown a general increase in Indigenous population since 1996, although Whitemouth's reported Indigenous population remained unchanged from 2011 to 2016.

Table 6.9.5-2: Indigenous Population of Municipal Communities in the Local Study Area, 1996, 2001, 2006, 2011 and 2016

b) Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

c) Total Indigenous identity population is composed of those persons who reported identifying with at least one Indigenous group, that is, North American Indian, Métis or Inuit and/or those who reported being a Treaty Indian or a Registered Indian, as defined by the *Indian Act* of Canada and/or those who reported they were members of an Indian band or First Nation.

d) Percentage of Total Indigenous Identity has been calculated based on Total Population of the community.

e) Not available (N/A) indicates data for this area has been suppressed for data quality or confidentiality reasons.

f) Percentage of North American Indian has been calculated based on Total Indigenous Identity for the community.

g) Percentage of Métis has been calculated based on Total Indigenous Identity for the community.

h) Percentage of Inuit has been calculated based on Total Indigenous Identity for the community.

i) In a review of the 2011 Census, Statistics Canada originally misallocated population and dwellings belonging in the Rural Municipality of Lac du Bonnet to the Town. This is the revised population counts (Statistics Canada 2012).

The Indigenous population of First Nation communities in the LSA as reported through the Census are presented in Table 6.9.5-3. Between 1996 and 2016 the total reported Indigenous population of all three communities grew. The Sagkeeng First Nation grew by approximately 220 people which was an increase of 13% of the total population reported. The Brokenhead Ojibway Nation grew by approximately 180 people an increase of 56%, and the population of Black River First Nation grew by 355 people between 1996 and 2016 representing a reported population increase of over 200%. All three First Nation communities include people that identify as Métis; however, no people identifying as Inuit were recorded in these communities.

Table 6.9.5-3: Indigenous Population of First Nation Communities in the Local Study Area, 1996, 2001, 2006, 2011 and 2016

Community	Population	1996	2001	2006	2011	2016

Source: Statistics Canada (1996, 2001, 2006, 2011, 2012, 2016).

a) Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Columns may not add up due to rounding. Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

b) Statistics Canada refers to Sagkeeng First Nation as Fort Alexander 3.

c) Total Indigenous identity population' is composed of those persons who reported identifying with at least one Indigenous group, that is, North American Indian, Métis or Inuit and/or those who reported being a Treaty Indian or a Registered Indian, as defined by the *Indian Act* of Canada and/or those who reported they were members of an Indian band or First Nation.

d) Percentage of Total Indigenous Identity has been calculated based on Total Population of the community.

e) Not available (N/A) indicates data for this area has been suppressed for data quality or confidentiality reasons.

f) Percentage of North American Indian has been calculated based on Total Indigenous Identity for the community.

g) Percentage of Métis has been calculated based on Total Indigenous Identity for the community.

h) Percentage of Inuit has been calculated based on Total Indigenous Identity for the community.

i) Statistics Canada refers to Brokenhead Ojibway Nation as Brokenhead 4.

j) Statistics Canada refers to Black River First Nation as Black River 9.

Population data for Sagkeeng First Nation, Brokenhead Ojibway Nation and Black River First Nation are also available from Indigenous and Northern Affairs Canada (INAC) and Indigenous Services Canada (ISC).[1] Several sources have been cited throughout this section as data collection methods vary by source. Variations in data collection methods can lead to differences among sources with respect to reported population. Actual population levels are expected to be somewhere within the ranges reported. Table 6.9.5-4 presents on- and off-reserve population data according to INAC/ISC. Based on registered population, the membership for the First Nations in the LSA have increased between 1996 and February 2022 on-reserve and off-reserve. The proportion of members living off-reserve has consistently increased for Sagkeeng First Nation over this time frame, while the proportion of Brokenhead Ojibway Nation and Black River First Nation members living off-reserve varied over this time frame but increased slightly overall. Statistics Canada (2021) notes the increase in First Nation members living off-reserve occurring across Canada and is expected to continue. The reasons for this trend include legislative changes that would enable more people, living mainly off-reserve, to apply for Registered Indian status, and negative net migration of reserves.

Table 6.9.5-4: On- and Off-reserve Population for First Nations in the Local Study Area, 1996 to 2022 (as of February)

First Nation	Population	1996	2001	2006	2011	2016	2022 (February)
Sagkeeng First Nation[a]	Total Number of Members	5,249	6,022	6,640	7,196	7,834	8,295
	Members On reserve	2,971	2,902	3,191	3,280	3,504	3,691
	Members Off reserve[b]	2,277	3,120	3,449	3,916	4,330	4,604
Brokenhead Ojibway Nation	Total Number of Members	1,231	1,426	1,592	1,805	2,037	2,165
	Members On reserve	423	343	549	499	791	675
	Members Off reserve[b]	808	1,083	1,043	1,306	1,246	1,490
Black River First Nation[c]	Total Number of Members	655	799	937	1,162	1,331	1,504
	Members On reserve	472	495	676	867	950	1,023
	Members Off reserve[b]	183	304	261	295	381	481

Source: Indigenous and Northern Affairs Canada (INAC) 1997, 2002, 2007, and 2012. Indigenous Services Canada (ISC) 2018 and 2022.
a) Indigenous and Northern Affairs Canada and Indigenous Services Canada refers to Sagkeeng First Nation as Fort Alexander First Nation.
b) Off-reserve members include registered members who live on Crown land and on other reserves.
c) Indigenous and Northern Affairs Canada referred to Black River First Nation as Little Black River for years 1996, 2001, 2006, and 2011.

[1] In 2017, INAC was dissolved and replaced by two new departments: Crown-Indigenous Relations and Northern Affairs Canada (CIRNAC) and Indigenous Services Canada (ISC).

6.9.5.2.3 Employment and Income

6.9.5.2.3.1 CNL Whiteshell Laboratories Employment

Overall employment in the region have been affected by activities at the WL site. The WL site received a decommissioning licence in 2002; however, it has been scaling back employment since the overall peak employment of 1,168 workers in fall 1984. A series of major layoffs occurred in 1998, when the total employment went from 802 employees to 349 (AECL 2001). This number has remained fairly consistent over the past two decades. As of July 31, 2021, there were 321 employees employed on-site, with almost all of them working directly on or supporting decommissioning projects. Positions included engineering, scientific and technical staff; licensed skilled trades; unskilled trades; managers; and administrative and business professionals. Of these employees, approximately 6 full-time equivalents work directly on WR-1 and approximately 14 full-time equivalents support the ongoing storage with surveillance of the WR-1.

CNL employed 41 people at WL who self-identify as Indigenous. This represents approximately 13% of the workforce at WL in 2021. Since 2017 this has remained relatively consistent, ranging from 12.94% to 15.33% of the WL workforce.

The decommissioning workforce has been maintained since July 2021 and is expected to increase to approximately 430 staff. The employment is expected to decline to less than 10 employees by 2031. Employment opportunities related to future site monitoring due to the Project have not yet been determined but they are not anticipated to be substantial.

Employment areas for the Project include skilled trades, heavy equipment operators, radiation surveyors and utility workers. When opportunities arise to fill vacant positions or hire local contractors, CNL will attempt to fill positions or hire contractors with local and Indigenous individuals or contractors; however, certain positions may require expertise from beyond the local communities. Canadian Nuclear Laboratories has a goal of developing skilled local talent, including participating in local skill development fairs and expos. More specific to the WL site, CNL maintains a communication protocol with Sagkeeng First Nation and provides job postings to the band office (CNL 2020). CNL is working collaboratively with Sagkeeng First Nation to find meaningful ways to provide economic opportunities.

The majority of CNL employees currently reside in Pinawa (90 employees), Lac du Bonnet (54 employees), and Beausejour (67 employees). There are currently programs in place at the WL site to help employees transition to other employment. Programs include access to a certified career coach, training tuition reimbursement and resume preparation.

6.9.5.2.3.2 Employment by Sector

Municipalities and Rural Municipalities

Major employers in the LSA for residents of the municipalities and rural municipalities include the CNL WL site; Manitoba Hydro, which has a district office in the Town of Lac du Bonnet, SunGro Horticulture, the Government of Manitoba, which has offices in Beausejour and Lac du Bonnet (Manitoba Conservation) and the Interlake-Eastern Regional Health Authority (RHA; KPI Program 2016). Employment specifics for the CNL WL site are provided in greater detail in Section 6.9.5.2.3.2 Employment by Sector.

Participants in the KPI Program also noted the presence and importance of local businesses. In multiple communities, it was noted that local governments are trying to foster an entrepreneurial sensibility in order that residents establish businesses in their home communities. The communities in the LSA have a variety of programs in place to encourage and support the establishment and development of local businesses (KPI Program 2016).

Table 6.9.5-5 outlines employment by key industries for residents of municipalities and the rural municipalities in the LSA for which 2006 and 2016 Census of Population data and 2011[2] National Household Survey data are available, as well as for residents of Manitoba for comparison purposes. Data indicate that for 2006, 2011, and 2016 the key occupational categories for communities in the LSA typically include sales and service occupations; trades, transport, and equipment operators; and education, law and social, and community and government services. Comparatively, the key occupational categories in Manitoba over this time frame were sales and service occupations; trades, transport, and equipment operators; and business, finance, and administration occupations. Pinawa also saw key occupational categories of natural and applied sciences and related occupations for 2006, 2011, and 2016 which increased over this time frame and was higher than the provincial average.

All municipalities and rural municipalities in the LSA saw an increase to its occupations in education, law and social, and community and government services and a decrease to sales and service occupations from 2006 to 2016, including for the province of Manitoba. Occupations in trades, transport, and equipment operators and related occupations varied depending on the municipality and rural municipality, however the majority saw an increase from 2006 to 2016 including for the Town of Lac du Bonnet, Beausejour, the RM of Lac du Bonnet, the RM of Whitemouth, and the province of Manitoba.

CNL has traditionally been an important employer for residents of municipalities in the LSA. CNL employees reside primarily in Pinawa, Beausejour and the Town of Lac du Bonnet. CNL employment has typically been seen as providing high-quality opportunities in terms of both the pay scale and the education requirements associated with many of the jobs (KPI Program 2016).

[2] Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

a) Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Columns may not add up due to rounding. Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

b) Data from the National Household Survey (2011) is suppressed for data quality or confidentiality reasons.

c) Statistics Canada uses the National Occupational Classification (NOC) for Statistics. Occupations are based on the type of job the person holds and the description of his or her duties; it considers the kind of work done by persons aged 15 and over.

First Nation Communities

Table 6.9.5-6 outlines employment by key industries for First Nations in the LSA for which 2006 and 2016 Census of Population data and 2011[3] National Household Survey data are available. Data indicate that for 2006, 2011, and 2016 the key occupational categories for Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nation on-reserve members include sales and services occupations; occupations in education, law and social, community and government services; and trades, transport, and equipment operators and related occupations. Comparatively, the key occupational categories in Manitoba include occupations in sales and service occupations; trades, transport, and equipment operators; and business, finance, and administration.

Sales and service occupations decreased from 2006 to 2016 for on-reserve members of Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nation, which is the same trend in the province of Manitoba. Where Black River First Nation and Brokenhead Ojibway Nation saw an increase to trades, transport, and equipment operators and related occupations from 2006 to 2016, Sagkeeng First Nation saw a decrease. The province of Manitoba saw an increase to trades, transport, and equipment operators and related occupations from 2006 to 2016. Sagkeeng First Nation and Brokenhead Ojibway Nation on-reserve members saw an increase to occupations in education, law and social, and community and government services from 2006 to 2016 where Black River First Nation had minimal change to this key occupational category. Another notable trend includes a large proportional decrease for natural resources, agriculture, and related production occupations for on-reserve members of each of Sagkeeng First Nation and Black River First Nation from between 2006 and 2011, which was similar for the province as a whole. Brokenhead Ojibway Nation also experienced a substantial proportional decrease for natural resources, agriculture, and related production occupations but since data were suppressed for 2011, it is not known during which census period the decrease occurred.

The First Nations in the LSA have local businesses. Sagkeeng First Nation operates the Sagkeeng Superstore (not affiliated with Loblaws Corporation) and a Tim Hortons. Sagkeeng First Nation has also suggested that it may have members and businesses that could aid with decommissioning activities (e.g., trucking, excavation) (reference needed). Brokenhead Ojibway Nation owns Wavers, a gas station and confectionary, and Chief Jim Bear currently sits on the Board of Directors for the South Beach Casino, which benefits all First Nations communities in Manitoba (Brokenhead Ojibway Nation 2014). Black River First Nation has a window plant, water treatment facility, truss plant, health centre, Head Start Program and a general store/gas bar (Black River First Nation 2009).

[3] Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

Mining

The Tanco Mine, located 60 km east of the Town of Lac du Bonnet, produces cesium, tantalum and spodumene. A decrease in Tanco Mine operation in 2016 was primarily the result of reduced demand for spodumene (KPI Program 2016). The True North Gold Mine (formerly the Rice Lake Gold Mine), owned and operated by Klondex Mines Ltd., is located approximately 250 km northeast of Winnipeg near the Town of Bissett and approximately 100 km northeast of Pinawa. Klondex Mines Ltd. filed a technical report and pre-feasibility study for the True North Gold Mine and has generally been pleased with the amount of ore extracted from reprocessing tailings (Klondex Mines Ltd 2016a,b). The site held employment sessions around the Town of Lac du Bonnet in 2016 (KPI Program 2016). The mine has since changed ownership to 1911 Gold. There are also quarry licences in the area and quarries were noted as providing employment to residents of the LSA (KPI Program 2016).

Tourism

Although tourism is not the primary economic driver in the region, seasonal recreational uses and cottaging remain important sources of revenues for all the municipalities and RMs in the LSA. The Whiteshell Provincial Park runs along the eastern boundary of the municipalities in the LSA and provides a steady draw of outdoor enthusiasts to the area. More specifically, the economies of the Town and RM of Lac du Bonnet rely on revenue from tourism as the RM is a prime area for summer cottaging and the population increases substantially in the summer. Retail and services in the Town of Lac du Bonnet benefit from this annual influx. There are plans to improve the town as a tourist destination. The bridge on Provincial Route 313 needs repairs and the community has successfully lobbied the Province of Manitoba to raise the height of the bridge so that a wider variety of boats can pass through the river underneath. The major rehabilitation work on the bridge was completed in November of 2019 (Government of Manitoba 2019). This upgrade will help the town to develop a new harbour, which is expected to attract an increased quantity and diversity of marine user groups, including seasonal boaters (KPI Program 2016).

The economies of Pinawa and Beausejour do not rely as heavily on tourism. Pinawa does not have sufficient accommodations to support a tourist industry. Its location also hampers its ability to take advantage of tourism dollars as it is located at the end of the highway, with no through traffic. Beausejour has other economic drivers that reduce the importance of tourism and cottaging relative to other communities in the LSA (KPI Program 2016).

The communities are part of the Eastman Tourism Region, which includes Birds Hill Provincial Park, Cooks Creek Heritage Museum, Grand Beach Provincial Park, Mennonite Heritage Village, South Beach Casino and Resort and the Whiteshell Provincial Park. In 2014, 20% of Manitoba's visitors (about 2,223,000 people) traveled to and through the region and spent $138.4 million in the region. Tourism resulted in an estimated $29 million in direct tax revenues (Tourism Manitoba 2016).

Agriculture

Agriculture in the LSA has been evolving. Smaller-scale family-owned farms had previously been characteristic of agricultural operations, especially in the RM of Brokenhead. These smaller operations have given way to larger agricultural firms with a more corporate organization (Community Futures Winnipeg River 2016). In the RMs of Whitemouth and Brokenhead, Sun Gro Horticulture is one of the main employers. The RM of Brokenhead is home to rich agricultural lands, with the production of wheat, canola, alfalfa, barley and oats comprising the majority of crops. Agriculture creates important seasonal employment (KPI Program 2016).

6.9.5.2.3.3 Labour Force

Municipalities and Rural Municipalities

Table 6.9.5-7 presents the 2006, 2011, and 2016 labour force characteristics for residents of municipalities and RMs in the LSA for which there are data available. Labour force characteristics include participation, employment, and unemployment rates. The participation rate is the percentage of the population eligible to participate in the labour force (i.e., individuals aged 15 years and over). Less than half of the eligible population in Pinawa participated in the labour force for 2006, 2011, and 2016 representing the lowest rate of all municipalities compared. The Town of Lac du Bonnet had a similar participation rate to Pinawa in 2016. The participation rates in Beausejour and the RM of Lac du Bonnet were higher than Pinawa yet lower than the Manitoba provincial rate over this time frame. The RM of Brokenhead and the RM of Whitemouth had participation rates similar to or greater than the provincial rate for 2006, 2011, and 2016.

For 2006, 2011, and 2016 Pinawa, the Town of Lac du Bonnet, Beausejour, and the RM of Lac du Bonnet had employment rates lower than the provincial average. The RM of Whitemouth and the RM of Brokenhead had employment rates greater than the provincial average for 2006, 2011, and 2016.

Pinawa (8.5%) and the Town of Lac du Bonnet (14.1%) had unemployment rates greater than the provincial average (6.7%) in 2016, while Beausejour's unemployment rate matched the provincial rate (6.7%). The RM of Lac du Bonnet (6.4%), the RM of Brokenhead (5.4%), and the RM of Whitemouth (1.9%) had unemployment rates lower than the provincial average (6.7%) in 2016.

Table 6.9.5-7: Labour Force Characteristics for Municipal Communities in the Local Study Area, 2006, 2011, and 2016

Community	Labour Force Characteristics[a]	2006	2011	2016

a) Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Columns may not add up due to rounding. Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

b) Data for the National Household Survey (2011) has been suppressed for data quality or confidentiality reasons.

First Nation Communities

Table 6.9.5-8 presents the 2006, 2011, and 2016 labour force characteristics for First Nations in the LSA for which data are available. Over this time frame, less than half the eligible on-reserve population for Sagkeeng First Nation (46.7% in 2011 and 29.6% in 2016) and Black River First Nation (47.2% in 2006, 41.4% in 2011, and 47.6% in 2016) participated in the labour force with the participation rate remaining fairly steady on-reserve for Black River First Nation and decreasing substantially for on-reserve members of Sagkeeng First Nation. Brokenhead Ojibway Nation had participation rates greater than Sagkeeng First Nation and Black River First Nation, but not greater than the provincial average. Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nation had employment rates that declined for 2006, 2011, and 2016 and were lower than the provincial average. The province of Manitoba's employment rate was unchanged over this time frame.

The unemployment rate on-reserve for Sagkeeng First Nation (22.2% in 2006, 25.8% in 2011 and 23.4% in 2016), Black River First Nation (24.0% in 2006, 20.8% in 2011, and 40.0% in 2016), and Brokenhead Ojibway Nation (16.2% in 2006 and 20.9% in 2016) is higher than for Manitoba as a whole (5.5% in 2006, 6.2% in 2011, and 6.7% in 2016).

6.9.5.2.3.4 Income

Municipalities and Rural Municipalities

Table 6.9.5-9 presents personal income for the residents of municipalities and RMs in the LSA for 2005, 2010, and 2015 for which data are available. Residents of Pinawa and the RM of Lac du Bonnet had the highest average personal income after taxes in 2005, 2010, and 2015 compared to the LSA, and was similar to or slightly higher than the Manitoba provincial average over this time frame. Pinawa had average personal income after tax of $25,528 in 2005, $35,194 in 2010, and $37,220 in 2015 (this represents a growth of 45.8% from 2005 to 2015). The RM of Lac du Bonnet had average personal income after tax of $25,250 in 2005, $29,725 in 2010, and $37,303 in 2015 (this represents a growth of 47.7% from 2005 to 2015). The RM of Whitemouth had the lowest average personal income after taxes in the LSA in 2005 ($22,030), 2010 ($25,354), and 2015 ($31,504). The provincial average personal income after tax was $25,978 in 2005, $30,702 in 2010, and $35,957 in 2015 (this represents a growth of 38.4% from 2005 to 2015).

The majority of residents in all municipalities had personal incomes (total individuals 15 years and older with income) between $10,000 and $50,000 for 2005, 2010, and 2015. This is also true for the province where the majority of individuals 15 years of age and older with income also had personal incomes between $10,000 and $50,000 for 2005, 2010, and 2015.

Table 6.9.5-9: Personal Income for Municipal Communities in the Local Study Area, 2005, 2010, and 2015[a]

Community	Income Group	2005	2010	2015

Columns may not add up due to rounding. Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

b) The Statistics Canada 2006 Census of Population reported an income range of $50,000 and over.

c) Data for the National Household Survey (2011) has been suppressed for data quality or confidentiality reasons.

Table 6.9.5-10 presents household income for residents of municipalities and RMs in the LSA for 2005, 2010, and 2015. Pinawa had the largest proportion of private households with an income of $60,000 and over (41.3% in 2005, 67.6% in 2010, and 70.4% in 2015) compared to the LSA. The Town of Lac du Bonnet had the largest proportion of private households with an income of under $60,000 (77.1% in 2005 and 57.1% in 2015) compared to the LSA. Comparatively Manitoba had 61.1% in 2005, 52.2% in 2010, and 43.6% in 2015 of private households with an income under $60,000, and approximately 38.9% in 2005, 47.8% in 2010, and 56.3% in 2015 of private households with an income of $60,000 and over.

a) Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Columns may not add up due to rounding. Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

b) Data for the National Household Survey (2011) has been suppressed for data quality or confidentiality reasons.

Table 6.9.5-11 presents sources of total income for 2005, 2010, and 2015 for residents of the municipalities in the LSA. For 2005, 2010, and 2015, income from employment (wages, salaries, and self-employment income) was the most prevalent source of income for residents in the municipalities in the LSA. Of the municipalities compared, residents of Pinawa had the lowest proportion of income from employment income at approximately half the population (46.6% in 2005, 53.3% in 2010, and 52.6% in 2015) yet also had the highest proportion of income from other sources (35.8% in 2005, 31.3% in 2010, and 32.1% in 2015) including dividends, interest and other investment income, retirement pensions, superannuation and annuities and other money income. This is likely reflective of the large population of retirees in Pinawa. The Town of Lac du Bonnet had just over 60% of income from employment income for 2005 and 2015 and, when compared to other municipalities in the LSA, had the highest source of income from government transfer payments (22.5% in 2005 and 19.7% in 2015). The residents of the RM of Lac du Bonnet had a relatively low percentage of income from employment income (63.1% in 2005, 54.4% in 2010, and 61.7% in 2015) along with a comparatively high percentage of income from other sources (20.1% in 2005, 28.7% in 2010, and 24.1% in 2016). Similar to residents of Pinawa, this may reflect the growing retiree demographic of the RM of Lac du Bonnet. All the municipalities in the LSA had employment income levels below the Manitoba provincial level (75.2% In 2005, 75.4% in 2010, and 73.6% in 2015).

a) The composition of the total income of a population group or a geographic area refers to the relative share of each income source or group of sources, expressed as a percentage of the aggregate total income of that group or area. Total of income is considered from all sources, including employment income, income from government programs, pension income, investment income and any other money income.

b) Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Columns may not add up due to rounding. Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

c) Employment income includes income from wages and salaries and self-employment income.

d) Government transfer payments include Old Age Security pension and Guaranteed Income Supplement, Canada and Quebec Pension Plan benefits, Employment Insurance benefits, Child Benefits and other income from government sources (Statistics Canada 2013).

e) Other income includes dividends, interest and other investment income; retirement pensions, superannuation and annuities; and other money income (Statistics Canada 2013).

f) Data for the National Household Survey (2011) has been suppressed for data quality or confidentiality reasons.

First Nation Communities

Table 6.9.5-12 presents personal income for the First Nations in the LSA for 2005, 2010, and 2015. For Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nation, the average personal income after tax was lower than the provincial average for each of 2005, 2010, and 2015. Brokenhead Ojibway Nation had the highest average personal income after tax in 2015 ($18,734) when compared to Sagekeeng First Nation and Brokenhead Ojibway Nation, however Black River First Nation had the largest proportional increase to its average personal income after tax from 2005 to 2015 (from $11,788 in 2005 to $15,255 in 2015 or 29.4%). The provincial average personal income after tax grew at an even larger rate (from $25,978 in 2005 to $35,957 in 2015, or 38.4%) when compared to the First Nations.

For Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nation, the majority of individuals 15 years of age and older with income on-reserve, had personal incomes of under $20,000. These proportions of individuals 15 years of age and older with income under $20,000 are in contrast to the Province of Manitoba as a whole where less than half the proportion of the population had incomes under $20,000 (45.9% in 2005, 38.4% in 2010, and 31.8% in 2015).

Table 6.9.5-12: Personal Income for First Nations in the Local Study Area, 2005, 2010, and 2015[a]

Columns may not add up due to rounding. . Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

b) Statistics Canada refers to Sagkeeng First Nation as Fort Alexander 3.

c) Statistics Canada refers to Black River First Nation as Black River 9.

d) Statistics Canada refers to Brokenhead Ojibway Nation as Brokenhead 4.

e) Data for the National Household Survey (2011) has been suppressed for data quality or confidentiality reasons.

f) The Statistics Canada 2006 Census of Population reported an income range of $50,000 and over.

Table 6.9.5-13 presents household income for the First Nations in the LSA for 2005, 2010, and 2015. For 2005, 2010, and 2015, the majority of on-reserve households for Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nation had incomes of less than $30,000, which is in contrast to the province of Manitoba where, as of 2016, the majority of households had an income of $60,000 and over.

For Sagkeeng First Nation the majority of on-reserve households with income had incomes of less than $60,000 (85.2% in 2005, 82.9% in 2010, and 81.0% in 2015), with the majority of households having incomes of less than $30,000 (53.7% in 2005, 57.1% in 2010, and 49.5% in 2015). Sagkeeng First Nation had a small proportion of private households on-reserve with an income of $60,000 and over (13.0% in 2005, 16.2% in 2010, and 19.0% in 2015). For Black River First Nation the majority of on-reserve households with income had incomes of less than $60,000 (92.0% in 2005 and 85.7% in 2015), with the majority of households having incomes of less than $30,000 (60.0% in 2005 and 62.9% in 2015). The Black River First Nation had approximately 22.9% of households with an income of $60,000 and over in 2015 and no households with an income of $60,000 and over in 2005. Within Brokenhead Ojibway Nation, the majority of households had an income of less than $60,000 (86.7% in 2005 and 77.4% in 2015) with approximately half of the households having an income of less than $30,000 (56.7% in 2005 and 48.4% in 2015). In contrast, a small proportion of households had incomes of less than $30,000 provincially (29.0% in 2005, 23.7% in 2010 and 17.9% in 2015). As of 2016, the majority (56.3%) of households in the province of Manitoba had an income of $60,000 and over.

e) Statistics Canada refers to Brokenhead Ojibway Nation as Brokenhead 4.

Table 6.9.5-14 presents sources of total income for the First Nations in the LSA for 2005, 2010, and 2015. For Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nation, the majority of on-reserve total income came from employment income; however, the proportion was lower than the provincial average for 2005, 2010, and 2015. The proportion of total income from employment income also decreased between 2005 and 2015 on-reserve for the three First Nations. The lowest source of on-reserve total income for 2005, 2010, and 2015 for Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nation was from other sources. Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nations all had higher percentages of on-reserve total income from government transfer payments as compared to the provincial percentage.

Table 6.9.5-14: Sources of Total Income for First Nations in the Local Study Area, 2005, 2010, and 2015[a,b,c]

First Nation	Source of Income	2005	2010	2015

a) The composition of the total income of a population group or a geographic area refers to the relative share of each income source or group of sources, expressed as a percentage of the aggregate total income of that group or area. Total of income is considered from all sources, including employment income, income from government programs, pension income, investment income and any other money income.

b) Income data for the 2016 Census of Population were derived from 25% data. However, on Indian reserves and in remote communities, Statistics Canada attempts to obtain data from 100% of the population.

c) Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Columns may not add up due to rounding. Response to the 2011 National Household Survey was voluntary, compared with compulsory response in the other reported years, resulting in some variation in response rate and sample area in smaller communities between years.

d) Statistics Canada refers to Sagkeeng First Nation as Fort Alexander 3.

e) Statistics Canada refers to Black River First Nation as Black River 9.

f) Statistics Canada refers to Brokenhead Ojibway Nation as Brokenhead 4.

g) Data for the National Household Survey (2011) has been suppressed for data quality or confidentiality reasons.

h) Employment income includes income from wages and salaries and self-employment income.

i) Government transfer payments include Old Age Security pension and Guaranteed Income Supplement, Canada and Quebec Pension Plan benefits, Employment Insurance benefits, Child Benefits and other income from government sources (Statistics Canada 2013).

j) Other income includes dividends, interest and other investment income; retirement pensions, superannuation and annuities; and other money income (Statistics Canada 2013).

6.9.5.2.4 Government Finances

As a federal Crown corporation, AECL is exempt from property taxes and instead pays a grant-in-lieu of taxes. Under the *Payments in Lieu of Taxes Act,* AECL has obligations to pay amounts similar to what would otherwise be required in taxes, notwithstanding the AECL and Provincial Government Master Agreement. The grant-in-lieu from AECL to Pinawa currently represents about 40% of the LGD's revenue base. The majority of the grant (57%) goes to the School District of Whiteshell, which oversees the two schools in Pinawa (KPI Program 2016). The community has received a stable amount of money for the grant-in-lieu of taxes since 2002 with the amount adjusted for inflation.

6.9.5.2.5 Community Infrastructure and Services

This section reviews existing facilities and services within the LSA.

6.9.5.2.5.1 Roads

The WL site is accessed from Winnipeg via Highway 44 east, Highway 11 north and Highway 211 east. Highway 44 begins at Lockport, runs through Garson to Beausejour (33 km) and is a four-lane divided highway. East of Beausejour, Highway 44 is a two-lane highway and continues southeast from the junction with Highway 11 terminating at the Trans-Canada Highway near West Hawk Lake. Connecting Lake Winnipeg to the north and the Trans-Canada Highway to the south, Highway 11 is a two-lane paved road spanning 9 km from Highway 44 to Highway 211 east. Highway 11 continues past the Highway 211 junction past Lac du Bonnet and northward to Highway 59.

For the majority of the year within the LSA, there are no load restrictions on any of the paved roads in the area; restrictions apply in the spring to portions of Highway 211 and Highway 11 and may also apply in the spring on unpaved roads (Manitoba Infrastructure and University of Manitoba Transportation Information Group 2019; Manitoba Infrastructure 2020). The bridge nearest to the WL site, at Highway 211 over the Winnipeg River, has no load restrictions (Manitoba Infrastructure 2020). At the WL site, the main access roads to the facility are paved, with access roads to facilities beyond the main complex, for example the waste management facility, generally unpaved. Spatial boundaries, including highways, for the socio-economic assessment are displayed on Figure 6.9.3-1.

6.9.5.2.5.2 Water Supply

The Town of Lac du Bonnet and Pinawa draw water from the Winnipeg River System and treat it at their water treatment plants (Province of Manitoba 2004; LGD of Pinawa 2015).

Pinawa has an emergency generator for the water and lift stations to maintain services if hydroelectric power is interrupted (LGD of Pinawa 2016a). The LGD of Pinawa has approximately 660 residential and 20 commercial water system connections. A 50-plus housing complex (Ironwood Housing) and subdivision (Trillium Ridge), along with two campgrounds (Pioneer Bay and Tim Horton's Children's Camp), have been connected to the water system. These additions will serve over 281 tenants (LGD of Pinawa 2015). All in-ground infrastructure requires updating and the Pinawa Public Works Committee has completed development of a 5-year plan for strategic water main renewal.

The Town of Lac du Bonnet water system has approximately 500 customers, the majority of which are residential, along with a few small commercial customers. The Town of Lac du Bonnet's bulk water station is also heavily used by seasonal customers located outside of the town's limits. The Town of Lac du Bonnet served a few customers beyond the town's limits (11 customers), provided water services to the RM of Lac du Bonnet and additionally had an agreement with the RM to directly serve the Glen Howard Inn (Province of Manitoba 2007). The Glenn Howard Inn has since closed and there are currently no water customers of the Town of Lac du Bonnet remaining in the Rural Municipality (Manitoba Public Utilities Board 2018). In general, the town's infrastructure is aging and the water lines need to be replaced. The community has begun replacing the water lines, the north half of the town has been replaced with work on the southern half awaiting grant application approval (KPI Program 2016). Council resolution has indicated that it has upcoming expenses associated to further replacement of cast iron water and wastewater lines (Manitoba Public Utilities Board 2020).

Sagkeeng First Nation is the only First Nation in the LSA known to draw water from the Winnipeg River for residential purposes (J.R. Cousin Consultants Ltd. n.d.).

6.9.5.2.5.3 Community Facilities

Municipalities

A summary of the facilities available in each of the LSA municipal communities is provided in Table 6.9.5-15.

Table 6.9.5-15 Community Facilities for Local Study Area Municipalities

Facility	Pinawa	Beausejour	Town of Lac du Bonnet
School	■ F.W. Gilbert School (Kindergarten to Grade 6) ■ Pinawa Secondary School (Grades 7-12)	■ Beausejour Early Years School (Kindergarten to Grade 5) ■ École Edward Schreyer School (Grades 6-12)	■ Centennial School (Kindergarten to Grade 6) ■ Lac du Bonnet Senior School (Grades 7-12)
Child care	■ Children's Place Co-op Day Care	■ Beausejour Kids Centre	■ Centennial School Daycare
Healthcare	■ Ambulance/Emergency Medical Services ■ Hospital /Community Health Centre (17 bed facility) ■ Community Cancer Program (at hospital) ■ Supportive Housing ■ Community Health Services (Public & Mental Health/Home Care) ■ Services to Seniors (Day Programs/ Meals on Wheels) ■ Medical Clinic ■ Dental clinic ■ Pharmacy	■ Ambulance/Emergency Medical Services ■ Hospital/Community Health Centre (30 bed facility) ■ Personal Care Home ■ Supportive Housing ■ Primary Health Care ■ Services to Seniors (Day Programs/Meals on Wheels/Outreach for Seniors) ■ Handivan Transportation ■ Medical Clinics (Beausejour Clinic and First Street Medical Clinic) ■ Dental Clinic ■ Pharmacy	■ Ambulance/Emergency Medical Services ■ Community Health Centre ■ Personal Care Home ■ Community Health Services (Public & Mental Health/Home Care) ■ Services to Seniors (Day Programs/Senior Resource) ■ Two Rivers Transit ■ Medical Clinic ■ Dental Clinic ■ Pharmacy
Recreational Facilities	■ Community Centre ■ Orville Acres Arena (indoor and outdoor ice rink) ■ Public Pool ■ Tennis courts ■ Library ■ Pinawa Golf and Country Club ■ Marina ■ Cross-country ski trails ■ Vanier Centre	■ Sun Gro Centre (indoor ice rink, curling club, outdoor pool and indoor walking track) ■ Rivers Edge Golf and Country Club	■ Community Centre ■ Curling Club ■ Arena (indoor ice rink) ■ Lac du Bonnet Granite Hills Golf Club

Table 6.9.5-15 Community Facilities for Local Study Area Municipalities

Facility	Pinawa	Beausejour	Town of Lac du Bonnet
Temporary Accommodations	■ Pinawa Motel ■ Deer Ridge Cabins ■ Wilderness Edge Retreat & Conference Centre ■ Pioneer Bay Campground ■ Relax Ridge Seasonal Park	■ Howland Hotel ■ Beausejour Hotel ■ Beausejour Motel ■ Superior Inn & Conference ■ Glass Lake B&B ■ Great Woods Park and Campground ■ Brokenhead River Park and Campground	■ Drifters Inn ■ Glenn Howard Inn ■ Lakeview Inn ■ Casey's Motor Inn ■ Champagne's RV Park ■ White Spruce on the Lake ■ Ember Ranch B&B ■ Wild Rose B & B

Source: Sunrise School Division 2018a,b,c; Beausejour Kids Centre 2012; Province of Manitoba 2012; LGD of Pinawa 2016b-i; Interlake-Eastern RHA. n.d.a,b,c; The Town and RM of Lac du Bonnet 2019a,b; Beausejour Dental Centre 2019; Sun Gro Centre 2019; Granite Hills Golf Centre 2019; Golf Link 2016; Pinawa Golf and Country Club n.d.

Physician recruitment and retention is a challenge in Pinawa and Beausejour; the goal of a family doctor for everyone and 24/7 operation of the Emergency Room remains a current pursuit (LGD of Pinawa 2016d).

First Nation Communities

Sagkeeng First Nation, Black River First Nation, and Brokenhead Ojibway Nation have schools and Head Start Programs. All three First Nations offer health care within the community; see summary in Table 6.9.5-16.

Table 6.9.5-16 Community Facilities On-reserve for Local Study Area First Nations

Facility	Sagkeeng First Nation	Black River First Nation	Brokenhead Ojibway Nation
School	■ Sagkeeng Anicinabe School (Nursery School to Grade 8) ■ Sagkeeng Anicinabe High School (Grades 9-12)	■ Black River School (Nursery School to Grade 9) ■ Alternative Education Program	■ Sergeant Tommy Prince School (Nursery School to Grade 9)
Childcare	■ Sagkeeng Health Centre's Aboriginal Head Start on Reserve	■ Head Start Program	■ Sergeant Tommy Prince School Daycare/Head Start Program
Healthcare	■ Sagkeeng Health Centre ■ Sagkeeng Mino Pimatiziwin Family Treatment Centre (Family Addictions Treatment Centre) ■ George M. Guimond Care Centre – Personal Care Home	■ Health Centre	■ Brokenhead Health Centre
Recreational Facilities	■ Sagkeeng Arena	■ Information not publicly available	■ Brokenhead Ojibway Nation Entertainment Centre ■ Brokenhead Recreational Centre

6.9.5.2.5.4 Housing

Municipalities and Rural Municipalities

A summary of the housing available in each of the LSA municipalities and rural municipalities is provided in Table 6.9.5-17. The average number of rooms per dwelling was 6.65 across all four municipalities (Statistics Canada 2016). Additionally, only the Towns of Pinawa and Beausejour have households with more than one person per room. Compared to other communities in the LSA, the RM of Lac du Bonnet and Whitemouth had the greatest percentage of households requiring major repairs (7.8% and 7.5% respectively).

In addition to private dwellings, Pinawa also maintains a 50-plus facility (The Ironwood), as well as a residential development called Trillium Ridge, which is a locally owned subdivision and the Awanipark residential development (Trillium 2016; KPI Program 2016). It was noted through the KPI Program that while there is ample housing available in the RM of Lac du Bonnet, there is a shortage of affordable housing. The housing market in the RM of Lac du Bonnet has been driven by the cottage market, which has increased the cost of housing throughout the RM.

Table 6.9.5-17: Housing Characteristics for Municipalities and Rural Municipalities in the Local Study Area, 2016

Housing Characteristics	Pinawa	Beausejour	RM of Lac du Bonnet	RM of Whitemouth
Total number of occupied private dwellings	675	1,445	1,285	595
Average number of rooms per dwelling	7.0	6.2	6.5	6.9
Number of households with more than one person per room	10	10	0	0
Percentage of households requiring major repairs	3.0%	5.5%	7.8%	7.5%

Source: Statistics Canada 2016.

a) Housing characteristic data for the 2016 Census of Population were derived from 100% data.

b) Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Columns may not add up due to rounding.

RM = Rural Municipality.

First Nation Communities

A summary of housing characteristics in First Nation communities in the LSA is provided in Table 6.9.5-18. Over half of the on-reserve households required major repair in Sagkeeng First Nations. In addition, 16.2% of on-reserve households had more than one person per room in Sagkeeng First Nation community. In the Black River First Nation community 36.1% of on-reserve households required major repair and almost 14% of on-reserve households had more than one person per room. Brokenhead Ojibway Nation had 25.0% of households on-reserve requiring major repair, and 6.3 % of households had more than one person per room.

Table 6.9.5-18 Housing Characteristics for Local Study Area First Nations, 2016

Housing Characteristics[a,b]	Sagkeeng First Nation[c]	Black River First Nation[d]	Brokenhead Ojibway Nation[e]
Total number of occupied private dwellings	525	180	160
Average number of rooms per dwelling	5.2	5.4	5.8
Number of households with more than one person per room	85	25	10
Percentage of households requiring major repairs	58.1%	36.1%	25.0%

Source: Statistics Canada 2016.
a) Housing characteristic data for the 2016 Census of Population were derived from 100% data.
b) Statistics Canada data have been subjected to a confidentiality procedure known as random rounding whereby values are rounded either up or down to a multiple of 5 and in some cases, 10. Columns may not add up due to rounding.
c) Statistics Canada refers to Sagkeeng First Nation as Fort Alexander 3.
d) Statistics Canada refers to Black River First Nation as Black River 9.
e) Statistics Canada refers to Brokenhead Ojibway Nation as Brokenhead 4.

6.9.5.2.5.5 Services

Municipalities and Rural Municipalities

A summary of the services offered in the municipalities are displayed in Tables 6.9.5-19.

Table 6.9.5-19: Community Services for Local Study Area Municipalities and Rural Municipalities

Services	Pinawa	Beausejour	RM of Lac du Bonnet
RCMP	24 hr/day 7 days a week		
Fire	Volunteer	Volunteer paid on-call	Fire Department
Ambulance	Winnipeg River Ambulance Service		
Telephone/ Television/ Internet	Manitoba Telephone Services (MTS)		
	Shaw satellite service; Bell satellite service; Bell MTS; Xplornet; Pinawa Community Development Corporation	Shaw cable and fibre; Bell MTS phone and high-speed internet; Xplornet	Granite Internet Services, Waterside Wireless, Satellite
Transportation	Two Rivers Transit Services	Handivan	Two Rivers Transit Services

Source: LGD of Pinawa 2016c,d,,i; Government of Canada 2013a;b; KPI Program 2016; Beausejour Brokenhead Fire Department 2019; Interlake-Eastern RHA n.d.a; The Town and Lac du Bonnet 2019b; Beausejour Brokenhead Development Corporation 2019; Xplornet 2020; Bell Canada 2021.
RM = Rural Municipality; RCMP = Royal Canadian Mounted Police.

Two Rivers Transit Services is available in Pinawa and the RM of Lac du Bonnet. This service is available to seniors 55 years or older, or those unable to operate a motor vehicle. Service is provided throughout the Town and RM of Lac du Bonnet, Pinawa and the RM of Alexander by one handivan that can accommodate 18 passengers and two wheelchairs (LGD of Pinawa 2016e; Government of Canada 2013a). Beausejour offers a handivan service which provides door-to-door transportation to seniors and persons with disabilities via three wheelchair accessible vans. This service provides transportation throughout Beausejour, the RM of Brokenhead and travel to Winnipeg via special booking (Government of Canada 2013b).

Pinawa maintains a volunteer fire department which currently has 13 members, a pumper truck, a wildfire response trailer and a rescue vehicle equipped with the Jaws of Life. A new fire hall was built in 2011 to accommodate the newly acquired pumper truck and the goal is to purchase a new tanker truck (KPI Program 2016). The Volunteer Fire Department is a member of the North East Mutual Aid District which draws on 13 other Fire Departments for additional resources (LGD of Pinawa 2016d). The RM of Whitemouth has plans to build a new fire hall in the spring of 2017 (completed December 2018) and maintains four helicopter pads throughout the RM (KPI Program 2016).

In addition to housing the local RM of Lac du Bonnet fire department, the Town of Lac du Bonnet is home to the new Manitoba Environment, Climate and Parks, Fire Operations Centre. This regional fire operations centre improves firefighting capacity and forest protection in eastern and central Manitoba (KPI Program 2016). The Beausejour Brokenhead Fire Department services Beausejour, Garson, Tyndall and the residents of the RM of Brokenhead (Beausejour Brokenhead Fire Department 2019). Pinawa, Lac du Bonnet and Beausejour have ambulance services provided by Interlake Regional Emergency Medical Services 911, the Winnipeg River Ambulance Service (Interlake-Eastern RHA n.d.a, LGD of Pinawa 2016d).

The Pinawa waste disposal service collects household and yard waste and offers curbside recycling services. Recycling is supported by Pinawa Recycling Inc. which offers pick up services for commercial businesses, the post office and hospital (LGD of Pinawa 2016f). LGD of Pinawa recently entered into an agreement with Whitemouth, Reynolds, North Whiteshell Waste Management Facility to receive recycled materials. This effort will reduce materials headed for and extend the life of, the landfill facility (LGD of Pinawa 2016f). The Town of Lac du Bonnet provides garbage and recycling collection services for residents. Grass clippings and electronic waste curb-side pick-up is also available. Battery recycling and yard wastes can be dropped off at designated locations for recycling (The Town and Lac du Bonnet 2019b). Beausejour offers garbage tags which must be attached to bags to be picked up. Curbside recycling is offered via blue box collection and seasonal lawn and garden waste can be dropped off at the Lawn and Garden Compost Site (Beausejour Brokenhead Development Corporation 2019).

First Nation Communities

Sagkeeng First Nation has First Nations Safety Officers, a fire department and medical transportation (Sagkeeng Anicinabe 2020a,b; Sagkeeng Health Centre 2016b). Brokenhead Ojibway Nation has a security team that patrols the community as well as the buildings owned by the First Nation (Brokenhead Ojibway Nation 2020). A summary of the services offered in the First Nation communities is displayed in Table 6.9.5-20.

Table 6.9.5-20: Community Services for Local Study Area First Nations

6.9.5.2.6 Community Well-being

Community well-being can be defined by a variety of factors. The most common elements of community well-being and quality of life include economic well-being (e.g., employment and income to meet the basic needs of food, shelter, clothing), physical well-being (e.g., personal health and safety), social well-being (e.g., family stability and social supports) and the environment. This section outlines a variety of factors that contribute to the communities' overall sense of well-being, including their relationship to the WL site.

6.9.5.2.6.1 Community Goals and Plans

During the KPI Program, participants noted that they wanted to ensure that their respective communities were able to thrive. Further description of community values shared through the KPI Program included the self-identification as nuclear communities by municipal communities, the high value placed on rural living and proximity and accessibility to remote wilderness (KPI Program 2016).

To contribute to the continued development of each community, all had some degree of focus on economic development. Economic development was seen as an important driver in maintaining quality of life and attracting and retaining residents. Most of the municipalities in the LSA have a community or economic development corporation with a dedicated economic development officer. Pinawa has a community development corporation and a dedicated economic development officer. Beausejour and the RM of Brokenhead have a joint economic development corporation (Beausejour-Brokenhead Development Corp.) and an economic development officer. In the Town of Lac du Bonnet, a community development corporation has been incorporated and a committee is currently working on the operational details, such as determining funding sources and by-laws (KPI Program 2016). Those municipalities that did not have a dedicated resource or development corporation at the time of the KPI Program (RM of Whitemouth, RM and Town of Lac du Bonnet) were still actively engaged in economic development. In the RM of Whitemouth, for example, the Chief Administrative Officer and a member of Council were working on economic development. The RM of Lac du Bonnet is currently in the process of expanding their airport in response to the new Manitoba Environment, Climate and Parks – Fire Operations Centre. It is hoped that the expansion will help attract future businesses to the area (KPI Program 2016).

Each municipality fosters economic development with a variety of means. In Pinawa, the LGD provides tax incentives, an incubator program (funded by CNL), the possibility of negotiating flexible business agreements and available commercial, industrial and retail space (LGD of Pinawa 2016h). While the community has commercial and industrial lots available, due to limited demand, they are undeveloped. The Beausejour-Brokenhead Development Corp. provides a variety of supports to attract business (KPI Program 2016).

The municipalities consider their development activities to be successful at the current time. Pinawa is the home of an eastern Manitoba office (North Forge East) of the North Forge Technology Exchange, which is an economic development agency with offices and a fabrication lab in Winnipeg (North Forge Technology Exchange 2016). North Forge East began operations in October 2016. Interest in participating in the incubator program, which helps entrepreneurs develop their ideas into viable businesses, secure funding and build prototypes at a reduced price, has been higher than originally anticipated. The organization is also seeking to expand its outreach efforts so residents of eastern Manitoba have a better understanding of entrepreneurship and will then be interested in taking advantage of the services North Forge East offers. The Beausejour-Brokenhead Development Corp. has attracted national retail and service chains (Tim Hortons, Home Hardware, and Dollar Tree) to open locations in Beausejour (BBDC 2021a). These operations provide local jobs and raise the profile of the municipalities (KPI Program 2016).

While each municipality is focused on developing its own economy, they also acknowledge that regional development activities are critical to their success. A large employer in any of the municipalities is anticipated to provide direct and indirect employment to residents of all the municipalities. One current initiative is the development of a technical school in Beausejour with an estimated completion date for 2023 to 2024 (BBDC 2021b). Multiple municipalities have contributed funding for a feasibility study that is currently underway. The hope is that once a technical school is established in Beausejour, it can help attract and/or retain younger residents (KPI Program 2016).

Whiteshell Laboratories Community Regeneration Partnership

In spite of their efforts to increase the economic development of the region, the communities have remained concerned about the closure of the WL site and the prospect of attracting a new industry or user for the location. The Partnership was formed in 2015 to address this concern and is facilitated and funded by CNL. According to the Terms of Reference from October 21, 2015: “the mandate of the Community Regeneration Partnership is to develop a Socio Economic Plan for the region by the WL site decommissioning activities, to subsequently implement the plan and to review, update and report on the plan annually” (Skinner 2016). Overall, the goal of the Partnership’s activities is to replace the positions lost in the past, along with the jobs that will be lost by the time decommissioning is complete. Partnership members are pleased with the current activities and tangible outcomes of the Partnership; there is a sense of greater commitment to Partnership efforts (KPI Program 2016).

The municipalities and rural municipalities in the LSA strongly identify with the nuclear industry (e.g., atomic energy) and the past activities at the WL site and would like to attract a future industry to the site either during or after decommissioning activities (KPI Program 2016). They feel that the site is an asset to attracting business because of the site’s basic characteristics (e.g., inexpensive land, good power supply, good and abundant water), which discussions with a site selector have confirmed. While the Partnership is open to pursuing both nuclear and non-nuclear options for the site, they acknowledge that ISD of WR-1 may limit its attractiveness for certain opportunities (Whiteshell Laboratories Community Regeneration Partnership 2016). However, CNL continues to participate in ongoing programs to support hosting, for example, a small modular reactor at the WL site, and proposed associated businesses.

Public Liaison Committee

In addition to working with the communities through the Partnership, CNL also engages them through the Public Liaison Committee. This committee meets twice a year and the focus is on building relationships and creating dialogue between CNL, stakeholder groups and communities and RMs around the WL site. Discussions focus on environmental practice and performance of CNL. Members of the committee are expected to share information from the meetings with their home communities and/or organizations.

6.9.5.2.6.2 Community Well-being Index

The Community Well-being Index (CWB) uses data from Statistics Canada about education, labour force, income and housing to provide "a relatively quick and convenient measure of well-being, focusing on the socio-economic dimensions" (Murphy 2010). A community's CWB score is a single number that can range from zero to 100. The lower a community's Community Well-being Index, the poorer that community's well-being is considered to be. The index is intended to provide a systematic summary of socio-economic well-being for communities, illustrate differences across communities, enable tracking over time, and be compatible with other community-level data on well-being (ISC 2019).

The component scores consider the following:

- **Income,** which is based on income per capita;
- **Education,** which factors in the proportion of a community's population, 20 years and older, that has at least a high school certificate and the proportion of a community's population, 25 years and older, that has at least a bachelor's level degree;
- **Housing,** which comprises indicators of housing quantity and quality; and
- **Labour Force Activity,** which quantifies the labour force participation and employment rates in the community (Government of Canada 2019).

The CWB is calculated as follows:

$$CWB = \frac{Income\ [(2/3)\ Literacy + (1/3)\ HSP] + (HQual + HQuant/2) + (LFP + Employment/2)}{4}$$

Where: HSP: High School Plus;
HQual: Housing Quality;
HQuant: Housing Quantity; and
LFP: Labour Force Participation.

The community well-being index presents one aspect of community well-being dictated by available quantitative data. Among the critiques of numerical indices to measure well-being and quality of life is that they rely on quantitative data and, therefore, cannot capture some aspects of well-being and, in Canada, one of the criticisms is that the community well-being index do not incorporate any aspects of Indigenous worldviews (Cooke 2008).

Municipalities and Rural Municipalities

Table 6.9.5-21 presents the Community Well-being Index for municipal communities in the LSA. Pinawa's CWB score increased between 2006 to 2016 from 79 to 82. Except for housing, all the component scores for Pinawa increased between 2006 and 2016. Beausejour's CWB score also increased between 2006 and 2016. During this time frame, the component scores for income and education increased, while the component score for housing remained the same and the component score for labour force activity decreased by one point. The CWB score and component scores of the Town of Lac du Bonnet followed a similar trend as Beausejour. The RMs all experiences an increase in CWB scores between 2006 and 2016.

Table 6.9.5-21: Community Well-being Index for Municipalities and Rural Municipalities in the Local Study Area, 2006, 2011, 2016

		Income	Education	Housing	Labour Force Activity	Community Well-being Index
Pinawa	2006	72	64	99	79	79
	2011	82	70	99	82	83
	2016	82	68	97	81	82
Beausejour	2006	68	44	96	87	74
	2011	74	48	97	90	77
	2016	76	55	96	86	80
Lac du Bonnet	2006	67	47	91	86	73
	2011	74	38	94	84	73
	2016	76	59	97	82	78

	2016	72	43	97	90	75

Source: CIRNAC 2019.

RM = Rural Municipality.

First Nation Communities

Table 6.9.5-22 presents the Community Well-being Index for First Nations in the LSA. The First Nations in the LSA had substantively lower CWB scores compared to the municipalities and rural municipalities in the LSA. The CWB index score for two of the First Nations in the LSA, Black River First Nation and Brokenhead Ojibway Nation increased between 2006 and 2016, while the CWB index score for Sagkeeng First Nation decreased slightly during the same time period. Component scores for Sagkeeng First Nation increased except for the component score for labour force activity, which decreased substantially. The component scores for Black River First Nation followed similar trends to Sagkeeng First Nation, while for Brokenhead Ojibway Nation the component scores for income and education increased between 2006 and 2016 and component scores for housing and labour force activity decreased.

Table 6.9.5-22: Community Well-being Index for First Nations in the Local Study Area, 2016

		Income	Education	Housing	Labour Force Activity	Community Well-being Index
Sagkeeng First Nation[a]	2006	40	34	51	68	48
	2011	38	35	52	65	48
	2016	41	35	55	56	47
Black River First Nation[b]	2006	33	29	52	67	45

6.9.5.2.6.3 Regional Health Overview

Health is influenced by a wide variety of factors, which makes it difficult to describe a community's overall health status. Drinking water, food choices, personal behaviours, such as smoking and physical activity and air quality, among others, all affect health. Socio-economic factors, including housing, income, social status, education, early childhood development and family and community support, are also considerations. Measuring these determinants of health can be challenging due to the breadth of factors and the lack of availability of data, since this type of information is not routinely collected.

This section presents data regarding five indicators of community health, as follows:

- infant and maternal health;
- life expectancy and causes of death;
- chronic diseases;
- service delivery; and
- non-medical determinants of health.

These data are often not available at the community-level for confidentiality reasons; therefore, community health data are presented at the regional health authority level. The municipalities and RMs of the LSA are located in the Interlake-Eastern RHA. The RHA extends east to the Ontario border, north to the 53rd parallel, west to the eastern shores of Lake Manitoba and south to Winnipeg's north perimeter dipping down just past Winnipeg to slightly below the Trans-Canada (Interlake-Eastern RHA 2015).

Infant and Maternal Health

This section outlines infant and maternal health, including statistics regarding birth rates, birth weight and infant mortality data. Birth rates and infant health, such as high- and low-birth weights, provide useful indications of the health of a community.

The Interlake-Eastern RHA reports number of live births per 1000 female residents. In 2016/17 there were 54.7 live births per 1000 which is slightly lower than the rate for Manitoba as a whole (55.5 live births per 1000 female residents). Overall, live birth rates have decreased over time. Female residents in Northern Remote Zone have a birth rate three times higher than female residents in Selkirk. Over time the disparity in live birth rates has slightly increased between districts. Low birth weight (under 10th percentile at birth) has remained consistent at 6% of live births which is slightly lower than the provincial average (8%). Teen pregnancies have been in decline over a five-year period; there were 30.8 births per 1000 females aged 15-19 (2012/13-16). At the district level, there has been a narrowing of disparity over time (Interlake Eastern RHA 2019).

Life Expectancy and Cause of Death

Life expectancy is an indicator that can measure the overall effectiveness of a health care system in maintaining the health of the population. While it measures the quantity of life (i.e., the number of years), it does not measure the quality of life. In the Interlake-Eastern RHA, the life expectancy for females have remained stable between 2007-2011 and 2012-2016 and did not differ substantially from the provincial average, see Table 6.9.5-23 (Interlake-Eastern RHA 2019. However, life expectancy for males has increased from 76.8 to 78.2 years at both the regional and provincial level (Interlake-Eastern RHA 2019).

Table 6.9.5-23: Male and Female Life Expectancy in the Interlake-Eastern RHA and Manitoba, 2007 to 2016

	2007 to 2011	2012 to 2016
Female	82.2	82.5
Manitoba Female Average	82.2	82.8
Male	76.8	78.2
Manitoba Male Average	77.5	78.5

Source: Interlake-Eastern RHA 2019.

Between 2007-2011 and 2012-2016 there were no considerable changes in the order of most frequent causes of death for Interlake Eastern residents during the two time periods, with exception to mental illness where the proportions of deaths increased over time from 2.6% to 4.7%. Similar to the provincial key findings, both cancer and circulatory diseases account for the majority of all deaths within Interlake-Eastern (Interlake-Eastern RHA 2019).

Chronic Diseases

Chronic disease includes cancer, heart disease, diabetes, chronic lung disease, kidney disease and arthritis. Chronic disease is an important measure of a community's overall health because not only does it reflect a community's demographics, but also has negative effects on the quality of life of affected individuals, causes premature deaths and creates adverse economic effects on families, communities and societies (WHO 2005). In the Interlake-Eastern RHA, the rates for new diagnosis of diabetes are higher than the provincial average (0.97 instances per 100 person years compared to 0.80 at the provincial level). The number of residents in Interlake-Eastern RHA with diabetes has increased to 10.3% in 2014/15-2016/17 from 9.1% in 2009/10-2011/12. The prevalence rate for hypertension (23.8%) and congestive heart failure (1.93%) in the RHA are also higher than provincial rates (20.7% and 1.59% respectively). The 2014-16 regional cancer incidence rate was 511.8 per 100,000 residents which is higher than the provincial average of 478.4. The proportion of residents with arthritis has decreased, decreasing from 22% in 2010/11-2011/12 to 21% in 2015/16-2016/17 which was similar to the provincial average of 20.4%. Chronic lung diseases include asthma, chronic obstructive pulmonary disease, lung cancer, cystic fibrosis, sleep apnea and occupational lung disease. Total respiratory morbidity declined from 9.8%

in 2011/12 to 9.4% in 2016/17. This rate was lower than the provincial average of 10.3%. Overall instances of respiratory illness increased in Manitoba from 9.6% to 10.3%. There is, however some variance by region with in the Interlake-Eastern RHA (Interlake-Eastern RHA 2019).

Service Delivery

According to Interlake-Eastern RHA (2014), there were 97 physicians practicing full- or part-time in the RHA and 83 of those had hospital admitting privileges in 2014. Nearly 85% of residents in the RHA have a medical doctor and 88% of those who visited their doctor were satisfied with the experience. The LSA municipalities, however, note that there has been a physician shortage in their communities and are working together on a regional level to recruit physicians to the area (KPI Program 2016).

According to Interlake-Eastern RHA (2019), 78.9% of residents visited a physician or nurse practitioner in 2016/17 which is a slight decrease compared to 2011/12. In 2015-2016, nearly 85% of residents in Interlake-Eastern reported they have access to a regular health care provider.

In 2016/17, a total of 8,232 Interlake-Eastern residents were hospitalized which represents 6.2% of the population. This is slightly higher than the provincial average of 5.8% and a decrease compared to 2011/12 (6.9%). There was a statistically significant decrease in Interlake-Eastern inpatient hospitalization from 98.9 to 87.5 per 1,000 population. (Interlake-Eastern RHA 2019).

Non-medical Determinants of Health

Non-medical determinants of health include factors such as education, income and employment. These three factors are linked, since education presents pathways to employment and higher income potential. Improved job security and education provide people with a feeling of control over their life (Health Council of Canada 2005), which influences overall health. People who are unemployed are more likely to experience “psychological distress, anxiety, health problems, hospitalization, etc. than the employed” (Health Canada 1999). There is a growing body of evidence to indicate that income and social status are the most important social determinants of health, since “health status improved at each step up the income and social hierarchy” (Health Council of Canada 2005). Higher income is also associated with improved living conditions and the ability to access resources. These predominantly economic factors contributing to health in the LSA are described in greater detail in Section 6.9.5.2.3 Employment and Income.

Living conditions are also among the factors of the physical environment that contribute to health. Housing, for example, can contribute to quality of life, since the average number of persons per room, indoor air quality and need for repairs are indicators related to housing that influence overall health status. Accessibility of services, such as proximity to a hospital, also contributes to health (Natural Resources Canada 2019). These factors that contribute to health in the LSA are described in greater detail in Section 6.9.5.2.5 Community Infrastructure and Services.

6.9.5.2.6.4 Indigenous Health

Health Overview

Data on Indigenous Health are also presented at the RHA level, which is described above. In the Interlake-Eastern RHA, 27% of residents self-identify as Indigenous (Interlake-Eastern RHA 2019). The region's Indigenous population is generally young and growing with a high birth rate, although the on-reserve birth rates for Indigenous Nations within the RHA have declined gradually between 1993 and 2012, especially among the 15-19 and 20-24 age categories (Interlake-Eastern RHA 2014).

Indigenous people living on-reserve in the Interlake-Eastern RHA were hospitalized primarily for injury, poisoning and respiratory conditions, while non-First Nations residents were hospitalized most frequently for digestive and circulatory conditions (Interlake-Eastern RHA 2014).

The overall cancer incidence rate among the Indigenous population of the Interlake-Eastern RHA was 629.6 cases per 100,000 people, substantively higher than the Manitoba average of 471.2. First Nations incidence for lung, rectal, prostate and breast cancer were all above the regional and provincial averages, but these differences were not statistically significant (Interlake-Eastern RHA 2014). The age- and sex-adjusted cancer incidence rates for 2005-2015 were higher for registered First Nations members living off-reserve than on-reserve (Manitoba Centre for Health Policy 2019).

According to the Manitoba Centre for Health Policy (2019) The top three causes of death (2012-2016) for registered First Nations members living off-reserve in the Interlake-Eastern RHA are external causes (e.g., self-harm or poisoning), circulatory, and cancer, which are also the same three leading causes of death for registered First Nations members living on-reserve. The 2012-2016 rates for premature mortality for are higher for registered First Nations members living on-reserve in the Interlake-Eastern RHA than for registered First Nation members living off-reserve. The premature mortality rates are substantially higher for both populations than for all other Manitobans in the Interlake-Eastern RHA. The top three causes of premature morality for registered First Nations members living on- and off-reserve in the Interlake-Eastern RHA were external causes, circulatory, and cancer.

Non-medical Determinants of Health

Raphael (2004), in his analysis of Canadian health determinants, identifies Indigenous status as one of the key determinants of health in Canada. Indigenous people are more likely than other Canadians to experience inequalities and disadvantages that act as barriers to overall health. Examples of these inequalities include the following:

- **Education:** Indigenous people have lower education levels than their non-Indigenous counterparts. Indigenous youth are less likely to complete high school. Insufficient education diminishes the level of skills people have to enter the labour market.
- **Employment:** Unemployment rates are higher for Indigenous people than the general Canadian population. See Sections 6.9.5.2.3.2 Employment by Sector and 6.9.5.2.3.3 :Labour Force for additional detail on Indigenous employment.
- **Income and Social Status:** Indigenous people are typically overrepresented in the low-income bracket. Annual earnings are lower than other Canadians, irrespective of whether they are working full-time or part-time. See Section 6.9.5.2.3.4 Income for additional detail on Indigenous income.

- **Social Support Networks:** Colonialism resulted in losses of land, language and socio-cultural resources. The residential school system furthered these losses by removing young children from their communities, which has been linked to Indigenous people being unable to establish effective family relationships.
- **Physical Environments:** Indigenous Nations often face housing shortages and people are more likely to live in crowded conditions or in homes in need of major repairs. This can result in stressors, such as children having little room to study or play, or adults lacking private space to relax. Housing is discussed in Section 6.9.5.2.5.4.
- **Access to Services:** Indigenous Nations are less likely to have community facilities and infrastructure to promote healthy lifestyle choices/behaviours, such as recreation centres, playgrounds, swimming pools (Loppie and Wien 2009; Health Council of Canada 2005). Community facilities are described in Section 6.9.5.2.5.3 Community Facilities.

Indigenous Community Perspectives and Observations on Health and Wellness

Indigenous perspectives and observations on-health are rooted in four balanced aspects of wellness: emotional, mental, physical, and spiritual, which is often represented by the medicine wheel (National Collaborating Centre for Aboriginal Health 2013). Emotional needs include the need for relationships and belonging, while mental needs include the need for identity and self-actualization. Physical needs include the need for shelter, food, water, safety, and security. Lastly, spiritual needs may be met through spirituality and feeling that one has a life purpose (First Nations Information Governance Centre 2020). Indigenous ways of knowing and being frame these four aspects of health and wellness through their interaction across the environment, people and community, and history (First Nations Information Governance Centre 2020).

In Manitoba, the First Nations Health and Social Secretariat uses a holistic health framework to describe First Nations health, which also includes aspects of emotional, mental, physical, and spiritual wellness. Their holistic health framework has five components (First Nations Health and Social Secretariat of Manitoba 2018):

- community wellness, which is considered the core of health and wellness and includes strengths, progress, challenges, and relationships, as well as the language and culture of a community;
- holistic well-being, which considers the balance of emotional, mental, physical, and spiritual health and well-being;
- physical well-being, which considers the health conditions and access to health care (both western and traditional);
- healthy behaviours and lifestyle, which considers health habits such as diet, food security, sexual health, recreational activity, and health challenges like smoking and substance use; and
- mobility: movement, which considers the movement to and from communities, as well as non-medical determinants of health such as education, employment, and income.

The Red River Métis' perspective on health and wellness, as described by the Manitoba Métis Federation as holistic, consider both Indigenous and Western "ways of knowing." This holistic approach is also founded on four pillars of health and wellness: data, experience, information, and narrative. Data encompasses research and what is physical; experience encompasses the emotional aspects; information describes the intellectual fusion of the data, experience, and narrative; and narrative encompasses one's story and spirituality. The Manitoba Métis Federation considers eight wellness areas that define the health and wellness of the Red River Métis: nature, identity, development, relationships, networks, supports, environment, and governance (Sanguins et. al. 2013).

While these frameworks are an important starting point for understanding health and wellness for Indigenous Nations, each Indigenous community has their own perspectives on what contributes to community member well-being. Below are some of the perspectives shared in community-led studies for the Project.

Sagkeeng First Nation

Connections are important to the well-being of Sagkeeng First Nation members. Connections include those among family, other community members, the natural world, and the landscape. Each type of connection provides members with the space and opportunity to embody and live their culture. The TKLU Study (Sagkeeng Aniciabe and Firelight Research Inc 2019), defines and describes Anicinabe pimatiwizin (Anicinabe life), which is the interconnectedness of Sagkeeng's sense of place, identity, culture, history, and knowledge transmission. Examples of the interconnectedness include the way intergenerational ties facilitate transfer of language and knowledge:

> *And I always tell my generation and the generation before me, I tell them, practice it. Practice it, because it's inside of us. You can say it's here. But to speak it, because there's that conditioning gets in the way of speaking our language. That's impacted a lot of us, and it's impacted all our children. So, it goes down generation from generation.* (Narratives Inc., p. 15)

The same bonds are also supported by sharing resources and knowledge within the community.

> *When I grew up … we weren't rich, but say if my neighbour killed a deer, well that was shared in the community. If there was fishing and you got abundance of fishing, that was shared in the community. The gardens were shared in the community. Milk was shared in the community. Butter that you made was shared in the community. I hate cottage cheese to this day because I ate so much of it. But that was all shared. Like just all shared. You didn't have to have money… Your neighbours fed you or you fed your neighbours.* (Narratives Inc. 2020, p. 16)

> *…taking the fish out of the nets and just spending time with my dad [are the fondest memories of Lake Winnipeg] … teaching me survival skills, you know? For my future if I had to live off the land … I still carry that.* (Sagkeeng Anicinabe and Firelight Research Inc, p.35)

Ceremony is a way to reinforce the spiritual connection with the natural world more broadly, and specific places, such as the WL site:

> *The importance [of ceremonies to the Sagkeeng way of life] is that our ancestors and ourselves have a direct connection with Mother Earth … We're all connected on way or the other. We need each other in order for us to sustain a livelihood here … for us it's a spiritual connection to all of creation and that's what this area [Whiteshell Laboratories] signifies for me because it reminds me of those things that were taken away from us long time ago (*Sagkeeng Anicinabe and Firelight Research Inc 2019 *p.68)*

Medicinal plants contribute to general community health, as well as the treatment of specific ailments. Accessing them is important to the Sakgeeng First Nation member's cultural identity and as such maintaining access to traditional health care is an important aspect of Sagkeeng wellness (Sagkeeng Anicinabe and Firelight Research Inc 2019).

> *So that's where they used to come and there was a lot of area around there [Brightstone]. I remember like they used to pick a lot of – my dad was – he was, I guess, in his own way, he was considered a medicine man. And I know we used to go – we used to walk out, I don't know, if it's Lee River, but there's one medicine that you only find in the muskeg. It's called a [maska-eg]. It'd for the heart – the heart medicine. So, we used to work way out. Way out. I used to help him quite a bit. I remember that. And it's only found, he said, in the muskeg. (p.50)*

Sagkeeng First Nation members shared their perspective on aspects of healthy behaviours and lifestyles, including the importance of a traditional diet and food security, which are supported by a healthy environment and traditional land and resource use activities. Food plants and game provide both fresh and preserved foods to maintain a healthy diet. Maintaining access to plants and game habitats plays an important role in the food security of community members for Sagkeeng First Nation members (Sagkeeng Anicinabe and Firelight Research Inc. 2019).

> *Say you shot a moose and it was canned and everything, jarred in, you know, it was canned, you know, and it was pickles and ... big gardens and stuff like that, everything was put away in the cellars, you know.* (p.57)

One Sagkeeng First Nation member shared the importance of their control over their diet and well-being.

> *Food sovereignty… is very important for us, to go back to the land. Because that's the only connection we have left, really. Money's not going to buy us happiness. It's going to be the land, still, and I really want to emphasise the food sovereignty part because it's healthy*. (Narratives Inc. 2020, p.17)

Sagkeeng First Nation members have expressed concern over psychosocial impacts as a result of the Project and the WL site. To better understand Sagkeeng's concerns regarding the psychosocial impacts that Sagkeeng associates with the WL site and effects that may result from the Project, Sagkeeng prepared a Psychosocial Impact Assessment Report (Narratives 2020). The overwhelming sentiment shared was regarding the confusion and fear related to nuclear in general; the expressed concerns about the use of a nuclear reactor and waste in Sagkeeng's territory; and the lack of engagement with Sagkeeng First Nation on the siting and operations of the WL site (Narratives 2020). One community member succinctly drew the connection between the secrecy and historic lack of consultation or engagement surrounding the WL site on the one hand, and negative feelings of self-worth, family cohesion, and traditional lifestyle on the other (Narratives 2020).

Black River First Nation, Brokenhead Ojibway Nation and Hollow Water First Nation

The Anishinaabe (or Ojibway) people of Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation, hold similar perspectives on health and wellness that are supported by traditional land use: water, harvesting plants, hunting/trapping, and preserving traditional lands and ways of life in the area. Alongside these values, the Anishinaabe people see other aspects of their environment as important to community health and wellness, namely, relationships with spirituality not considered in technical, western science (Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation 2019).

In their collective study, Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation (2019) members describe their culture as an important aspect of wellness, which includes interconnection and spirituality of all aspects of the world:

> *Although spiritual beings cannot be captured, they are actors in the environment, as 'real' as the plants, animals, and fish that are studied through western science. Even tangible objects on Mother Earth are not just physical, they are inherently spiritual. For example, the Anishinaabemowin word for rock, Asin, is an animate noun because rocks have the potential to carry spirits and to be animate.* (p. 16)

Culture is expressed in multiple ways, including medicines, ceremony, and harvesting (Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation 2019). A Brokenhead Ojibway Nation member shared how everything is a medicine for community members:

> *Everything is a medicine – even the air we breathe, what I'm speaking - it's medicine. A lot of our people are disconnected from this. Even those that walk with us and have their spirit name, they get their name and turn their backs on the Grandmother.* (Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation 2019, p.32)

Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation members shared their perspective on aspects of healthy behaviours and lifestyles, including the importance of a traditional diet and food security, which are supported by a healthy environment and traditional land and resource use activities. Harvesting from the land not only contributes to the fulfillment of cultural and family traditions amongst the Anishinaabe people but provides a source of nourishment and food security for the community year-round (Black River First Nation, Brokenhead Ojibway Nation, and Hollow Water First Nation 2019).

> *"That was their living. Everything was done seasonally. Rice picking, blueberry picking, fishing. Rice picking was the last [in the season]. Then they came home to the community."* (p.30)

Red River Métis

The Red River Métis perspective on health and wellness is linked the use of and harvesting of resources from both land and water sources. The historical family ties of the Red River Métis to tradition and culture in the area continue to influence their current connection to the land (Shared Value Solutions 2019). The Red River Métis have a distinctive culture that contributes to well-being that is expressed in part through their connection with the land and the water (SVS 2019). One citizen shared their family history and the connections it fostered:

> *I mean my family history—I come from the fur trade on my dad's side, and we come from Red River here—my great-great-great grandfather through Hudson Bay—were part of the fur trade. So, we were trappers and fur-traders, and same thing on the mother's side; they were as well voyageurs and stuff. So, my connection to it is very strong; I'm very proud of that, and that's the lifestyle that I live. I mean when I'm out there, I was raised out that—raised to trap, hunt, fish—and I've been very fortunate to have that. Same as my history, and as I look back and do it, it's such a colourful past that we were here. So, I mean there are very strong ties to the land there, and like I say, I live in between it—it was Dawson Trail and the Winnipeg River. It's the homeland. (p. 27)*

The harvesting of plants and animals provide the community with food and can also be a source of traditional medicine (SVS 2019).

6.9.5.2.7 Public Safety

6.9.5.2.7.1 Road Safety

Traffic volume near the WL site can be estimated through coverage count stations (CCS) surveyed by the Province of Manitoba on a three-year cycle. Table 6.9.5-24 presents the annual average daily traffic counts for the three CCS locations near the WL site. The CCS station (No. 692) on Highway 211, west of the WL site access road and east of Highway 11, showed an annual average daily traffic count of 1,420 vehicles in 2011, 1,440 vehicles in 2014, and 1,450 vehicles in 2017. The CCS station (No. 657) on Highway 11, north of Highway 211, showed an annual average daily traffic count of 1,310 vehicles in 2011, 1,380 vehicles in 2014, and 1,460 vehicles in 2017. The CCS station (No. 726) on Highway 11, north of Highway 307 and south of Highway 211, showed an annual average daily traffic count of 1,560 vehicles in 2011, 1,630 vehicles in 2014, and 1,690 vehicles in 2017 (Manitoba Infrastructure and University of Manitoba Transportation Information Group 2019).

Table 6.9.5-24: Traffic Statistics for Highways near the Whiteshell Laboratories Site

Highway and Coverage Count Station (CCS) number	2009	2011	2014	2017
Highway 211, CCS 692	1,340	1,420	1,440	1,450
Highway 11, CCS 657	1,340	1,310	1,380	1,460
Highway 11, CCS 726	1,590	1,560	1,630	1,690

Source: Manitoba Infrastructure and University of Manitoba Transportation Information Group 2019.

Outside of off-road vehicle collisions, Manitoba Public Insurance does not break out collisions based on geographic location in its reporting beyond urban centres and all rural locations. Overall, the level of traffic collisions in Manitoba decreased in 2020 by 19% as compared to 2019 and a decrease by 10% compared to the previous five-year annual average (2015 to 2019) (Manitoba Public Insurance 2020). The decrease in the total number of collisions in 2020 compared to 2019 is attributable to decreases in injury and property damage only (PDO) collisions. Traffic collisions in urban locations account for the majority of causalities overall. In 2020, 83% of all casualties result from traffic collisions in urban areas (Manitoba Public Insurance 2020). Traffic collisions in rural locations, however, account for 55% of people killed. In the previous five years (2015 to 2019) annual average, nearly 87% of all victims are from traffic collisions in urban locations, while 62% of people killed are from traffic collisions in rural locations (Manitoba Public Insurance 2020).

6.9.5.2.7.2 Site Access

Access to the WL site is restricted. There is a security program in place that provides access control, visual monitoring and patrolling. There is an extensive surveillance system at the WL site to detect and deter unauthorized entry and diversion of materials and equipment. Part of the system is the use of progressive zones to provide increasing levels of security that are specific to certain areas in the WL site. This is in accordance with the *Nuclear Security Regulations* SOR/2000209.

6.9.6 Project Interactions and Mitigation

6.9.6.1 Methods

This section describes the process by which interactions between Project components and activities and socio-economic VCs were identified and evaluated. Potential effect pathways are identified and mitigation options to eliminate and/or reduce effects are presented. A pathways analysis is then used to focus on key interactions between the Project and the environment by evaluating the different effect pathways to determine if, after incorporation of mitigation, there is still potential to cause residual effects. Where effects will be adequately mitigated and are not forwarded for further analysis (i.e., secondary pathways, or where mitigation will remove the pathway altogether), the reasons for concluding the assessment at this stage are articulated. Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in Section 6.9.6 Residual Effects Analysis. As such, this section helps to focus the remainder of the assessment on those interactions (effects pathways) likely to result in residual adverse effects.

The first part of the analysis was to identify the potential effects pathways for all stages of the Project. The pathways analysis considers interactions that may result during normal or routine activities. Potential effects from accidents and malfunctions are assessed in Section 7.0 Accidents and Malfunctions. The next step in the analysis was the development of environmental design features and mitigation practices that could be incorporated into the Project to eliminate and/or reduce effects to socio-economic VCs. Environmental design features included design elements, environmental best practices and management policies and procedures. Environmental design features and mitigation were developed through an iterative process between the engineering and environmental teams, combined with input from project-specific or regional engagement with other interested parties. The design features and/or mitigation activities were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified effect pathways.

After incorporation of mitigation, potential pathways were evaluated into the following categories using scientific knowledge, logic, experience with similar developments and the effectiveness of environmental design features and mitigation.

- **No linkage pathway** – pathway is removed by environmental design features or mitigation such that the Project would not be expected to result in a measurable environmental change to measurement indicators identified for socio-economic VCs relative to Base Case values, and therefore would have no residual effects to socio-economic VCs.
- **Secondary pathway** – the pathway could result in a measurable minor change to measurement indicators identified for socio-economic VCs, but would have a negligible residual effect on socio-economic VCs relative to Base Case values and is not expected to contribute cumulatively to other Project effects or to the effects of other past, present or reasonably foreseeable developments to cause a significant effect. Secondary pathways may also include Project effects that were identified as important to people during Project engagement, but that do not specifically fall under the requirements of the *Canadian Environmental Assessment Act, 2012* (CEAA 2012). This pathway includes direct or indirect socio-economic effects that are not expected to arise as a result of direct effects on the environment, but were included as a secondary pathway due to their importance to people, as required in paragraph 5(2)(b) of CEAA 2012.

- **Primary pathway** – the pathway is likely to result in an environmental change to measurement indicators identified for socio-economic VCs relative to the Base Case that could contribute to residual effects to socio-economic VCs. This includes direct and indirect effects stemming from changes to the environment, as required in paragraph 5(2)(b) of CEAA 2012.

Environmental design features and mitigation that have been or could be incorporated into the Project to eliminate and/or reduce adverse effects to socio-economic VCs were considered. Potential pathways that were completely removed due to implementation of environmental design or mitigation were not assessed further. Pathways that were assessed to be secondary and demonstrated to have a negligible residual effect to socio-economic VCs through simple qualitative or semi-quantitative evaluation of the pathway were also not advanced for further assessment. Primary pathways were carried forward for more detailed quantitative and qualitative effects analysis to characterize the residual effects of the Project on socio-economic VCs (see Section 6.9.6 Residual Effects Analysis).

6.9.6.2 Results

Pathways through which all stages of the Project may interact with and result in changes to measurement indicators for socio-economic VCs is provided in Table 6.9.6-1.

Table 6.9.6-1: Pathways Analysis for Socio-economic Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment

Expenditures associated with the overall preparation, grouting, removal and remediation of WR-1 and above-grade facilities	■ Changes to the current decommissioning plan will generate different employment opportunities.
	■ Changes to the current decommissioning plan will generate different contracting opportunities.
		■ CNL may contract with a Manitoba-based contractor for the grouting work provided one with the necessary qualifications is available.
		■ To the extent feasible, CNL will work with interested Indigenous Nations to provide employment opportunities during decommissioning activities. For example:
		  ▪ CNL worked to enhance options to better match capabilities of First Nation members and Red River Métis citizens with their contracting needs including adding provisions to its procurement process that encourages the use of Indigenous and local small and medium sized businesses
		  ▪ CNL shared information regarding the procurement and contracting opportunities and asked for specific capabilities that Indigenous Nations have, related to the Project.
		  ▪ CNL facilitated introductions between Indigenous Nations and the CNL procurement department.
		  ▪ To facilitate information sharing, capabilities and opportunities, CNL planned and executed three industry days, and invited Indigenous Nations.
		  ▪ CNL created a First Nation and Métis affairs summer student position that was advertised in Indigenous Nations interested in the Project.
		  ▪ During site visits Human Resources shares information about employment opportunities at the WL site and CNL will continue that practice.
		  ▪ CNL will continue to share job postings with Sagkeeng First Nation.
		  ▪ CNL has made a commitment to help job candidates find appropriate housing in the region.
		  ▪ Where feasible, introduce Indigenous individuals, contractors and community to CNL contractors to discuss mutual opportunities.
		■ CNL is willing to participate in Indigenous-led job and contracting events.
		■ To the extent feasible, CNL will fill positions with local qualified staff.
		■ CNL recognizes that the commute from the Wabaseemoong Independent Nations community is long and has made a commitment to help job candidates find appropriate housing in the region.
			Secondary (no direct or indirect change to the environment identified)

Table 6.9.6-1: Pathways Analysis for Socio-economic Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Overall activities associated with WL site preparation, ISD of WR-1 and above-ground facilities	■ The Project will result in changes to local and regional traffic volumes in connection with contractor and new employee traffic requirements. ■ The Project will reduce the amount of transport required for off-site waste disposal, which will reduce traffic volumes and risks to public safety in the RSA.	■ The handling and disposition of waste material resulting from decommissioning will be conducted in accordance with CNL company-wide requirements, the WL waste materials management procedure and existing regulatory requirements. ■ Disposal methods for non-radioactive waste materials will meet all provincial and municipal requirements, with the order of preferred disposition of reuse/recycle, disposal in the CNL landfill, or disposal in a licensed off-site landfill.	Secondary (no direct or indirect change to the environment identified)
Preparation for and implementation of institutional control	■ The presence of long-lived radioactive material as part of ISD may affect community well-being for Indigenous Nations through the changes to the suitability of the site for future uses, the continued inability to exercise stewardship and governance over land and resource management decisions.	■ CNL is committed to involving Indigenous Nations in the follow-up monitoring, including initiatives that considers Indigenous values. This would involve Indigenous Nations during the monitoring stage of the Project to assess potential effects on fish and wildlife resources and changes to vegetation and water quality upon which traditional uses are dependent. It would also involve discussions in post decommissioning monitoring. ■ CNL will work with Indigenous Nations so that relationships endure, grow and adapt to future activities. As such, CNL will work to establish contribution/relationship agreements with each engaged Indigenous community, which include liaison positions, and create mechanisms to develop and implement initiatives that will help address each Nation's unique interests and concerns related to the Project and the Whiteshell Laboratories Restoration Project. ■ Follow-up monitoring during the post-closure phase will be completed to verify effects predictions and to provide information for use in adaptive management to address potential unforeseen effects. Results will be shared with Indigenous Nations. ■ A long-term funded Sagkeeng community liaison position, and committee will be created. ■ Sagkeeng First Nation, AECL and CNL plan to complete a Long-term Relationship Agreement. ■ CNL and AECL will support the development of a Healing and Resiliency Action Plan[4] in relation to the WL site' effects over time on Sagkeeng members. ■ Maximize the areas available for future use using CCME criteria for land use.	Secondary (elevated from no linkage due to the importance to Indigenous Nations)

[4] Now called, Healing and Resiliency Action Plan (Formerly Trauma Informed Action Plan)

Table 6.9.6-1: Pathways Analysis for Socio-economic Valued Components

Project Activity	Effects Pathways	Management Practices and Mitigation Actions	Pathway Assessment
Preparation for and implementation of institutional control	■ The suitability of the site for future business ventures may change as a result of the presence of long-lived radioactive material as part of ISD. ■ The use of ISD as the decommissioning method for the WR-1 Building will change the proportion of the site that can be released with no restrictions on use.	■ Continued activities through the WL Community Regeneration Partnership to help the region develop economically. ■ Maximize the areas available for future use using CCME criteria for land use. ■ Communication of environmental monitoring results to confirm the safety of the WL site and lands around it. ■ Final ISD design so that projections of doses to members of the public are well below the average Canadian individual background dose rate. ■ Final ISD design will be done to maximize hazard reduction.	Secondary
Preparation for and implementation of institutional control	■ Changes to the overall decommissioning plan may accelerate changes to the sources of municipal revenue for Pinawa. ■ Changes to the overall decommissioning plan may affect municipal revenue sources, which will change the provision of infrastructure and services in Pinawa.	■ AECL will engage with the Province and Pinawa regarding municipal revenue that is currently provided by the grant-in-lieu of taxes and future use of the WL site.	Secondary (no direct or indirect change to the environment identified)

ISD = in situ disposal; RSA = Regional Study Area; AECL = Atomic Energy of Canada Limited.

6.9.6.2.1 No Linkage Pathway

There are no interactions with no linkage to residual direct or indirect effects on socio-economic VCs.

6.9.6.2.2 Secondary Pathways

In some cases, a Project source of effect and an interaction with an assessment endpoint exists but with mitigation is expected to cause minor changes to the environment and a negligible effect on the socio-economic environment relative to the existing Base Case. The following are expected to result in negligible effects on the socio-economic environment and will not be examined further in the EIS.

- **Changes to the current decommissioning plan will generate different employment opportunities.**
- **Changes to the current decommissioning plan will generate different contracting activities.**

As of July 31, 2021, there were 321 employees employed on-site, with almost all of them working directly on or supporting decommissioning projects. Positions included engineering, scientific and technical staff; licensed skilled trades; unskilled trades; managers; and administrative and business professionals. Of these employees, approximately 6 full-time equivalents work directly on WR-1 and approximately 14 full-time equivalents support the ongoing storage with surveillance of the WR-1. The decommissioning workforce has been maintained since July and is expected to increase to approximately 430 staff and then decline to less than 10 employees by 2031.

A large workforce is not required during institutional control (i.e., post-closure phase). Changes to the decommissioning of the WR-1 are not anticipated to substantively increase employment on the WL site relative to the previous decommissioning plan. In both scenarios, the employment generation is not anticipated to be considerable in relation to the surrounding population.

The CNSC approved the current decommissioning licence in 2002 and decommissioning are ongoing. CNL assumed responsibilities for day-to-day operations of the WL site in 2014. Current employment at the WL site is contractual and understood to be finite. The implications of the change in decommissioning activities associated with WR-1 does not necessarily alter the number of new employment and/or contracting opportunities during the closure phase, but rather indirectly changes the nature of the employment and/or contracting opportunities available. Previously, the above- and below-grade infrastructure of WR-1 would have been dismantled, packaged and dispositioned to appropriate disposal sites. This would have resulted in construction and transport opportunities. The proposed change will increase the requirements for engineering and construction, while decreasing the amount of transportation labour required. In addition, the Project creates an opportunity, which may go to a local contractor, to encase the below-grade structures with grout before constructing a concrete cap and engineered cover for the below-grade structure.

The change in decommissioning plan may also create additional employment and/or contracting opportunities for the Indigenous Nations in the LSA. Many Indigenous Nations have expressed interest in employment opportunities and in particular Sagkeeng First Nation has noted that some of its members are qualified to work on the Project in certain capacities (e.g., transportation). CNL is committed to hiring members of the Indigenous Nations where feasible and has completed a number of initiatives to support contracting opportunities, including the following.

- CNL has worked to enhance options to better match the Indigenous capabilities with their contracting needs including adding provisions to its procurement process that encourages the use of Indigenous and local small and medium sized businesses.
- CNL shared information regarding the procurement and contracting opportunities and asked for specific capabilities that communities have related to the Project.
- CNL facilitated introductions between the communities and the CNL procurement department.
- To facilitate information sharing, capabilities and opportunities, CNL planned and executed three industry days, and invited Indigenous Nations.
- CNL created a First Nation and Red River Métis affairs summer student position that was advertised in Indigenous Nations interested in the Project.
- During site visits Human Resources shared information about employment opportunities at the WL site.
- CNL has been sharing job postings and will continue to share job postings with Indigenous Nations.

CNL recognizes that the commute from the Wabaseemoong Independent Nations community is long and has made a commitment to help job candidates find appropriate housing in the region. This commitment has been included in the EIS.

CNL has worked to enhance options to better match Indigenous capabilities with their contracting needs, added provisions to its procurement process to encourage the use of Indigenous and local businesses, and considers single source contracting opportunities with Indigenous companies where well suited to the work. CNL has also adjusted the evaluation criteria for competitive bids to favour contracts that are Indigenous owned or have Indigenous employees.

CNL recognized the need for better information sharing regarding procurement and contracting opportunities and asked for specific capabilities that communities have related to the Project. This included CNL facilitating introductions between the communities and the CNL procurement department, as well a representative from CNL Human Resources sharing information about employment opportunities. In addition, CNL has conducted meetings with the Manitoba Métis Federation and Métis N4 Construction to learn more about their capabilities and CNL has meet with Métis businesses and shared employment and contracting opportunities for the Project.

To further facilitate information sharing, capabilities, and opportunities, CNL planned and executed three Industry Days, and invited Indigenous Nations. The Industry Days were held in Winnipeg, WL Site, and the SFN arena. CNL is currently considering how to provide training to First Nation members and Red River Métis Citizens, including an option to open vacant seats in CNL training courses. CNL has been sharing job postings and will continue to share job postings with Indigenous Nations.

CNL continues to explore the best ways to reach out to communities about employment opportunities. CNL also toured and engaged with the South East Regional Development Corporation as it was recommended as the best way to explore First Nations capabilities and procurement opportunities. CNL has created a First Nation and Red River Métis summer student position that was advertised in Indigenous Nations interested in the Project. CNL is also reviewing long-term economic opportunities in relation to Indigenous economic interest and capacity to determine where they may be in alignment. CNL has expressed an interest in creating an Indigenous Liaison Committee and proposed Indigenous membership on a WL site Indigenous Advisory Committee.

The termination of existing employment will be accelerated with the Project, including those science-based positions which typically pay at rates higher than the regional average. While the schedule for reducing employment has been accelerated, there is mitigation in place to enhance benefits for area communities and the Indigenous Nations in the LSA to the extent possible. Mitigation focuses on supporting current employees in transitioning to new work and helping foster business opportunities in the area to replace lost employment. For current employees, CNL has programming at the WL site to explore other employment and take advantage of training opportunities.

In terms of fostering economic development in the region, CNL provides support for the Community Regeneration Partnership, which has been established to create a feasible socio-economic plan for the region, facilitate economic development and hopefully provide high quality employment to replace the losses associated with the overall WL site closure. CNL has also provided substantial support to North Forge East, which offers services to entrepreneurs interested in establishing businesses in eastern Manitoba. The level of interest in participating in North Forge East has been higher than anticipated, and to date, North Forge East has accepted twenty proposals for their programming, which is above their initial target of six to nine proposals. These proposals are from a diverse range of sectors, including social media and manufacturing. Due to the different requirements from different sectors of the economy, these projects are moving forward on their own timelines (KPI Program 2016).

Considering the economic development activities undertaken by the municipalities and RMs in the LSA, the Project's indirect effects on employment and income, and business opportunities are expected to be negligible relative to the overall closure of the site despite the accelerated timeline.

- **The Project will result in changes to traffic volumes in the LSA in connection with contractor and new employee traffic requirements.**

Two factors are considered in determining the extent of effects changes to local traffic volumes could have: the size of the workforce and the capacity of transportation infrastructure near the WL site. The current peak of about 321 employees at WL has been maintained since July 2021 and is expected to increase to approximately 430 staff and then decline to less than 10 employees by 2031. Specific to the Project, CNL anticipates a mobilization of about 25 employees (mostly contractors) between when approvals are received and the peak workforce when grouting of below-grade systems and structures is anticipated to occur. After the below-grade structures are grouted, the size of the workforce will continue to reduce until institutional control begins, along with the overall WL site workforce reduction. While there will be a temporary increase during closure work, it is smaller in absolute terms when compared to the current workforce, or peak workforce on the WL site in 1984.

With respect to transportation infrastructure, the WL site can be accessed from the communities and RMs in the LSA via Roads and Transportation Association of Canada (RTAC) routes (with a carrying capacity of 63,500 kg), Class A1 highways or Class B1 highways. Since the WL site can be accessed using relatively major roadways (as opposed to smaller, more rural roadways), the temporary increase of 50 passenger vehicles is not anticipated to pose a problem to the transportation infrastructure between communities in the LSA and the WL site. This includes the transportation infrastructure between the reserve parcels of the First Nations in the LSA and the WL site.

When the small number of additional employees required by the Project and the capacity of roadways leading to the Project are considered together, the increase in traffic volumes associated with Project-related employment will have a negligible effect on the transportation in the LSA.

- **The Project will reduce the amount of transport required for off-site waste disposal, which will reduce traffic volumes and risks to public safety in the RSA.**

The Project currently involves transporting up to 2,000 loads of waste from the WL site to the appropriate disposal site. These shipments would occur over the course of four years, from 2022 to 2026. This means that there would be an increase in current traffic of between two to three trucks a day (weekdays only). The lowest class of highway heavy Project-related traffic would likely use are Class B1 highways (e.g., Highway 211), which can carry a maximum gross vehicle weight load of 47,630 kg. The Trans-Canada Highway and Highway 44, which will also be used to haul waste to the Chalk River Laboratories site, is a Roads and Transportation Association of Canada route with a load limit of 62,500 kg for vehicles not conforming to RTAC standards and 63,500 kg for vehicles that do conform. Highway 211 and Highway 44 have load restrictions between March 11 and May 31.

The Comprehensive Study Report for the previous decommissioning plan did not provide anticipated traffic volumes for transporting radioactive waste (AECL 2001) from the decommissioning of WR-1. Overall activities, however, included transporting low-level and intermediate-level radioactive material to permanent off-site disposal facilities, some of which would have been from the WR-1 Building. With ISD, there will be a reduced amount of radioactive waste transported, and thus a reduced amount of traffic generated.

The reduction in traffic will limit the potential for transportation incidents. The reduced potential for incidents will limit risks to public safety as the chance for injury and mortality will be reduced. Transportation of waste is routine and safe. Exposure to radioactive waste from transportation incidents was not considered a substantial risk to public safety as transportation involves specialized packaging and shipping containers.

This pathway is anticipated to have a negligible effect on regional transportation infrastructure since the capacity of the roadways in the region is good and the Project will result in lower traffic volumes than previously planned. Together, this will reduce the demands placed on infrastructure and reduce the probability that the public may be exposed to radioactive material.

- **The suitability of the site for future business ventures may change as a result of the presence of long-lived radioactive material as part of ISD.**
- **The use of ISD as the decommissioning method for WR-1 will change the proportion of the site for unrestricted use.**

The permanent presence of the WRDF will change the suitability of the WL site for future uses due to the restrictive land use categories that will be applied to the WL site. While the Project does not return the WL site to an area completely available for unrestricted use, no primary pathways were identified between the Project and the aquatic environment (Section 6.5 Aquatic Environment) or the terrestrial environment (Section 6.6 Terrestrial Environment). With negligible effects predicted to the biophysical environments, the assessment does not indicate the potential for direct or indirect effects to the well-being of Indigenous Nations. Similarly, the ecological and human health risk assessment (Section 6.7 Human and Ecological Health) concluded that residual effects from radiological and non-radiological contaminants are not significant. Even under an accidents and malfunctions scenario (i.e., a WRDF Barrier Failure Disruptive Event), all predicted radiological and non-radiological doses are well below their respective protective benchmark values indicating that no adverse residual effects are expected.

The availability of land for future uses does not stem directly from environmental effects of the Project, but rather from the indirect effect of zoning restrictions that will be required for the WL site into the distant future. Participants in the KPI Program expressed concern with the Project because it would limit the types of businesses and industries that could use the WL site for future operations and therefore reduce the number of economic development opportunities available to them. This is a major concern for communities in the LSA who have considered the operation of the WL site as an important economic contributor in the region, as expressed through the desire to recruit a new industry to the site.

The previous decommissioning plan assumed that radioactive wastes, except for those designated to remain in the Waste Management Area and a limited area of radioactive contaminated sediment in the Winnipeg River, would eventually be removed and placed in permanent disposal facilities (AECL 2001). The communities had assumed that this would provide them with the ability to recruit a new industry (and associated employment) to the WL site, which features ample land, connection to the power grid, access to water from the Winnipeg River system and reasonable transportation network connectivity (1.5 hours to the James Richardson International Airport in Winnipeg, 20 minutes to the nearest railway and 45 minutes to the TransCanada Highway). This was combined with the understanding that the overall site (beyond the Waste Management Area and a limited area of the Winnipeg River System) would eventually be available with no restrictions on use. The WL site will now have restriction on use in proximity to the WRDF over an indefinite period of time associated with institutional control.

CNL is currently working with the communities and RMs in the LSA by funding the activities of the Community Regeneration Partnership. The goal of the Community Regeneration Partnership is to develop a socio-economic plan for the region. CNL supported development of the regional socio-economic plan through the provision of in-kind technical resources and contracting of graphic arts services. The plan lays out the steps needed to facilitate future economic development of the region. Through the KPI Program, participants expressed hope that activities through the Community Regeneration Partnership would replace the employment lost at the WL site with stable, high-quality employment in the region. It was felt that as a result of this development, people would stay or move to communities in the LSA for employment and they would flourish (KPI Program 2016). CNL has displayed a renewed commitment to the group through staffing changes to support the development of the socio-economic plan, sponsoring travel for community representatives to similar sites in the US and designating a board member of the Canadian National Energy Alliance, which owns CNL, to advocate for the WL site (KPI Program 2016).

Future uses and zoning for the site have not been determined. Currently the WL site occupies four different land use designations in the LGD of Pinawa (2004), including general agriculture, heavy industrial, recreational/commercial, and natural area (Section 6.8.25.2.1 Whiteshell Laboratories Site). The land including the WL main campus, waste management area, and landfill are used for heavy industrial use. Although a small proportion of the WL site will have restrictions on use because of the Project (i.e., 0.07 ha), it is still anticipated that the majority of the site will be safe and appropriate for unrestricted use, and that future designations will seek to maximize the amount of lands available for other uses. While the Project does not return the WL site to an area completely available for unrestricted use, the restrictions are anticipated to have a negligible effect on the socio-economic VCs.

Although uncertainty remains about the timing and nature of a new industry being attracted to the site, CNL is encouraged by the interest that has been expressed to develop the site for alternative uses. In 2017, CNL offered an invitation to site a small modular reactor demonstration unit at one of its managed campuses, including the WL Site. By 2019, two organizations (out of 80 applications and 19 expressions of interest) advanced to the due diligence stage of assessment by CNL, which considers the technical and business merits of the applicants. Although this process is not an indication of project approval (which would require a separate review by the CNSC), it provides support to the attractiveness of the site for future development.

CNL will share information regarding future uses and access to the WL site with the Community Regeneration Partnership as it becomes available. This information will influence the actions described in the socio-economic plan that presents a feasible path forward containing realistic possibilities for future economic development. Depending on the future uses and access to the WL site, the plan is expected to help focus recruitment efforts or provide another route for achieving the same economic goals without reliance on the WL site. Consequently, suitability of the site for future business ventures and the portion of the site available for unrestricted use is anticipated to have a negligible effect on socio-economic VCs.

Communication around timelines and uses for the WL site are key for development of an implementable socio-economic plan. CNL will also support robust communication of environmental monitoring results to confirm the safety of the WL site and help address concerns and mitigate concerns about the site's suitability for future uses. Members of the Public Liaison Committee are currently expected to share monitoring results with residents of their respective home communities, and it is anticipated that they will have a substantial role with sharing monitoring results with community members once decommissioning is complete. CNL can provide communication support to committee members, to help disseminate monitoring results. Similar efforts for the sharing of monitoring results will be extended to Indigenous Nations.

CNL will continue to use a public website and direct engagement to share information and receive feedback from immediate local and Indigenous Nations. Communication efforts will build on the current Environmental Assessment Follow-up and Monitoring Program, which focuses on environmental monitoring, interim storage and future use support and communications. The public and Indigenous communication component of the Environmental Assessment Follow-up and Monitoring Program is to develop and maintain communication mechanisms during decommissioning that support ongoing communication (CNL 2016a). CNL will also consider other mechanisms for disseminating monitoring results that are suggested or requested by any interested parties, as they will help reduce the concerns associated with ISD. Sharing monitoring results, including activities that connect with whole communities and not just with leadership will be considered. CNL has developed several initiatives to improve how CNL communicates now, including incorporating country harvested foods into the current environmental monitoring programs, and has committed to supporting future initiatives, such as a guardian program called the Niigan Aki Program (see Section 11.4 Indigenous Engagement and Participation in Environmental Monitoring).

- **The presence of long-lived radioactive material as part of ISD may affect community well-being for Indigenous communities through the changes to the suitability of the site for future uses, the continued inability to exercise stewardship and governance over land and resource management decisions.**

The permanent presence of the WRDF will change the suitability of the WL site for future uses due to the restrictive land use categories that will be applied to the WL site. The Project represents a change from the previous decommissioning plan, which assumed that radioactive wastes, except for those designated to remain in the Waste Management Area and a limited area of radioactive contaminated sediment in the Winnipeg River, would eventually be removed and placed in permanent disposal facilities, (AECL 2001). The change is understood from an Indigenous perspective as having the potential to result in fear, stigma and anxiety associated with the long term presence of nuclear materials in the region. Given the importance of the topic to Indigenous Nations, CNL considers this to be a secondary pathway so that Sagkeeng First Nation concerns reflected are included in the assessment.

In the LSA, Indigenous Nations have commented on the ongoing adverse effects the presence of the WL site has had on their well-being (Section 6.9.5.2.1) since the site's establishment in the 1960s, including ongoing fear and trauma for Sagkeeng First Nation members, which they highlighted in their alternative means assessment report, "Mental stress, fear and stigma associated with Whiteshell has already had a significant effect on Sagkeeng people" (Sagkeeng Ancinabe and Firelight Research Inc. 2020, p. 35). Black River First Nation, Hollow Water First Nation, and Brokenhead Ojibway Nation have also noted that WL site, along with other historical industrial development in the LSA, have affected the communities' well-being by adversely affecting the environment.

All engaged communities expressed some level of concern over the proposed Project. The Sagkeeng First Nation specifically identified a preference for the full removal of the WR-1 reactor either immediately or in the future to address past and ongoing trauma (Section 2.8 Sagkeeng's Alternative Means Assessment). The presence of radioactive materials associated with the Project is identified as a source of distress for the community (Sagkeeng Ancinabe and Firelight Research Inc. 2020); however, the previous decommissioning plan against which the Project is being assessed, similarly assumed some radioactive materials would remain in place. As such the existing conditions, have contributed to the Sagkeeng First Nation identified effects.

While the Project does not return the WL site to an area completely available for unrestricted use, no primary pathways were identified between the Project and the aquatic environment (Section 6.5 Aquatic Environment) or the terrestrial environment (Section 6.6 Terrestrial Environment). Similarly, the ecological and human health risk assessment (Section 6.7 Human and Ecological Health) concluded it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of maximum potential contaminant releases associated with the Project. Even under an accidents and malfunctions scenario (i.e., a WRDF Barrier Failure Disruptive Event), all predicted radiological and non-radiological doses are well below their respective protective benchmark values indicating that no adverse residual effects are expected. With negligible effects predicted to the biophysical environments, the assessment does not indicate the potential for direct or indirect effects to the well-being of Indigenous Nations because of the Project-related changes to the environment.

Due to the importance of well-being to Indigenous Nations, CNL acknowledges that efforts to support dialogue and learning are central to the relationship going forward. While the Project may not be the preferred alternative of the Sagkeeng First Nation, CNL and AECL recognize and acknowledge the cumulative impacts and trauma experienced by Sagkeeng First Nation members in relation to the initial siting of the WL and are willing and committed to begin addressing this through community-led initiatives facilitated by the Technical Working Group. CNL and AECL have also entered into a contribution agreement with Sagkeeng First Nation that outlines CNL and AECL will work to address the psychosocial impacts identified by Sagkeeng First Nation. In 2022, SFN, AECL, and CNL signed an agreement to implement a first of its kind Sagkeeng-led Community Environmental Monitoring Program (CEMP), named Niigan Aki. The Niigan Aki Program, funded by CNL and AECL, and led by SFN includes a detailed workplan and scope of work.

In addition, CNL, Black River First Nation, and Hollow Water First Nation signed a two-year comprehensive relationship agreement, on April 6, 2021, which was later extended to the end of 2025 to support greater community involvement and engagement on the Project. The relationship agreement supports the establishment of a Core Engagement Team, a full-time community liaison position, a monthly meeting series, provides support to participate in the Indigenous Advisory Committee and provides capacity support to ensure the communities are able to continue to participate in discussions on other ongoing work at WL site, such as engagement on low level waste trenches, and Land use end state discussions. The BRFN/HWFN – CNL agreement also provides the capacity for the communities to participate and observe in CNL's on-site environmental monitoring, and to establish a community school program.

Through ongoing discussions CNL and the Manitoba Métis Federation identified initiatives that would help address the Manitoba Métis Federation's concerns of the Project. As a culmination of these discussions, in August 2023, the Manitoba Métis Federation and CNL signed a multi-year contribution agreement. This agreement established a series of ongoing engagement activities to improve communications between the parties, including an annual leadership meeting, the creation of a Manitoba Métis Federation liaison position, and invitation for Red River Métis participation in an Indigenous Advisory Committee. Other initiatives include the development of a communications protocol for reportable events, the development of plain language materials on CNL activities, and support to enable Manitoba Métis Federation participation in environmental monitoring and economic activities at the WL site.

In 2024 February, the MMF notified CNL of the MMF's decision to end the 2023 agreement. CNL respects the MMF's decision while continuing to share information and remains open and interested in discussions with the MMF. CNL aspires to rebuild a productive partnership with the MMF to enable full participation of Red River Métis Citizens in the various projects, licensing, economic benefits, and environmental protection opportunities. While

this agreement is no longer active, CNL has an open offer of capacity funding for different areas of Manitoba Métis Federation MMF interest related to participation on the environmental assessment for the Project.

Since the effects documented by Indigenous Nations in the LSA are linked to the historical presence of the WL site, there are no predicted changes to the biophysical environment, and CNL and AECL are committed to working with Indigenous Nations going forward, the assessment does not indicate the potential for direct or indirect effects to the well-being of Indigenous Nations.

- **Changes to the overall decommissioning may accelerate changes to the sources of municipal revenue for Pinawa.**
- **Changes to municipal revenue streams for Pinawa may change the provision of infrastructure and services in the community.**

In the 1960s, AECL and the Provincial Government signed a Master Agreement, which stipulates that AECL will pay Pinawa a grant-in-lieu of taxes. As a federal Crown corporation, AECL is exempt from property taxes and instead pays a grant-in-lieu of taxes. Under the Payments in Lieu of Taxes Act, AECL has obligations to pay amounts similar to what would otherwise be required in taxes, notwithstanding the Master Agreement. Upon closure of the site, the agreement states that the LGD will be incorporated as a municipality when it is economically feasible and desirable. The agreement, however, does not contain a defined strategy for ending the grant-in-lieu of taxes or a process for negotiating a different fiscal relationship between the signatories. Any changes negotiated to the Master Agreement may have an effect on municipal finances for Pinawa.

The proposed approach to decommission WR-1 contributes to an overall acceleration of the WL site decommissioning timeline. These timeline changes may necessitate finding additional sources of revenue to compensate for budget shortfalls sooner than previously considered. To date, Pinawa has been focused on developing economic development options to increase municipal revenue. Economic development activities are supported through the Community Regeneration Partnership, which is examining future uses for the WL site. In addition to this, efforts through North Forge East are intended to promote entrepreneurial initiatives in eastern Manitoba; potentially creating new jobs and other economic benefits. Pinawa-specific initiatives are also being explored through the Pinawa Community Development Corporation and are intended to diversify the area's economic drivers (KPI Program 2016). Overall, the Project is anticipated to have a negligible effect on the continued financial viability of the communities and rural municipalities in proximity to the Project.

6.9.6.2.3 Primary Pathways

There are no interactions with primary linkages to effects to the socio-economic VCs.

6.9.7 Monitoring and Follow-up

CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical. Monitoring and follow-up programs associated with effects on vegetation, wildlife, fish and water quality are critical to supporting community well-being, as the continued confirmation that the WRDF is safe will help ease concerns regarding the suitability of the site for future business ventures.

It is noted that data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. Within this framework, modifications to the program may be appropriate to confirm data

continue to fulfill program objectives. Any proposals for modifications to the monitoring program and the rationale for the modifications will be communicated to the CNSC prior to implementation.

During Project engagement activities, the First Nations and the Manitoba Métis Federation expressed concerns about the potential long-term effects of the Project on the environment. They indicated that the health of the environment, species relied on for fishing and harvesting, and the risk to people in the area of the WL site are of great concern. They also expressed an interest in being actively involved in the development and implementation of an ongoing monitoring program. This initiative would enable the involvement of Indigenous interests in CNL's monitoring programs and create a forum for direct participation in monitoring activities.

To reduce the potential effect of these concerns, CNL is committed to sharing information and working collaboratively with Indigenous Nations and the Partnership to help them develop a feasible socio-economic plan and development of robust communication plan to convey and confirm the Project's safety. It is assumed that the Public Liaison Committee and the Partnership will continue for the duration of the Project and provide a means through which CNL can disseminate information with the communities and RMs in the LSA. Communities and RMs in the LSA can also bring their concerns and issues regarding future use and access to the site forward to CNL. Communication efforts will build on the existing Environmental Assessment Follow-up and Monitoring Program at the WL site, which focuses on environmental monitoring, interim storage and end-state support and communications. The public communication component of the Environmental Assessment Follow-up and Monitoring Program for the WL site is to develop and maintain communication mechanisms during decommissioning that support ongoing communication (CNL 2016a).

As the WL site is undergoing decommissioning over the next several years, CNL will work with Indigenous Nations so that relationships endure, grow and adapt to future activities. As such, CNL is currently working on establishing contribution/relationship agreements with each engaged Indigenous Nation, which include liaison positions and create mechanisms to develop and implement initiatives that will help address each Nation's unique interests and concerns related to the Project and the Whiteshell Laboratories Restoration Project overall.

Public information activities required as part of CNL's Public Information Program (2024) will be part of the Environmental Assessment Follow-up and Monitoring Program for the Project and will be summarized as part of the annual Environmental Assessment Follow-up and Monitoring Program progress report.

6.9.8 Conclusions

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous Nations, or the public (The Agency 2018). The socio-economic VCs chosen for the Project to reflect identified concerns, professional judgement and/or standard practice in environmental assessment are:

- employment and income;
- business opportunities;
- government finances;
- community infrastructure and services;
- community well-being; and
- public safety.

With ISD, there will be a reduced amount of radioactive waste transported off-site, and thus a reduced amount of traffic generated. The reduction in traffic will limit the potential for transportation incidents and risks to public safety. Considering the small number of additional employees required by the Project and the reduced amount of waste transported off-site, changes to traffic volumes associated with Project employment will have a negligible effect on the transportation infrastructure in the local area and reduce the probability that the public may be exposed to radioactive material.

The permanent presence of the WRDF will change the suitability of a small portion(i.e., 0.07 ha) of the WL site for future uses due to the restrictive land use categories that will be applied to the Project site. However, it is still anticipated that the majority of the site will be appropriate for unrestricted use, and that future designations will seek to maximize the amount of lands available for other uses.

The availability of land for future uses does not stem directly from environmental effects of the Project, but rather from the indirect effect of zoning restrictions that will be required for the WL site into the distant future. The public expressed concern with the Project because it would limit the types of businesses and industries that could use the WL site for future operations and therefore reduce the number of economic development opportunities available to them. CNL provides support for the Community Regeneration Partnership, which has been established to create a feasible socio-economic plan for the region, facilitate economic development and hopefully provide high quality employment to replace the losses associated with the overall WL site closure. Depending on the future uses and access to the WL site, the plan is expected to help focus recruitment efforts or provide another route for achieving the same economic goals without reliance on the WL site.

The implications of the change in decommissioning activities associated with WR 1 does not necessarily alter the number of new employment and/or contracting opportunities, but rather indirectly changes the nature of the employment and/or contracting opportunities available and associated timeframe. The proposed change will increase the requirements for engineering and construction, while decreasing the amount of transportation labour required. While the schedule for reducing employment has been accelerated, the Community Regeneration Partnership is working to enhance benefits for area communities and the Indigenous Nations in the local area to the extent possible.

While the Project does not return the WL site to an area completely available for unrestricted use, no residual adverse effects were identified between the Project and the aquatic environment or the terrestrial environment. Similarly, the ecological and human health risk assessment concluded it is unlikely that there would be significant adverse effects on aquatic or terrestrial populations or communities as a result of maximum potential contaminant releases associated with the Project. Even under an accidents and malfunctions scenario (i.e., a WRDF Barrier Failure Disruptive Event), all predicted radiological and non-radiological doses are well below their respective protective benchmark values indicating that no adverse residual effects are expected. With negligible effects predicted to the biophysical environments, the assessment does not indicate the potential for direct or indirect effects to the well-being of communities.

Considering CNL's programming to support current employees in transitioning to new work, CNL's support of fostering economic development in the region, and the potential for attracting future industry to the WL site, the Project's indirect effects on employment and income, and business opportunities are expected to be negligible relative to the over closure of the site despite the accelerated timeline and change in land use restrictions.

Indigenous Nations have commented on the ongoing adverse effects the presence of the WL site has had on their well-being since the site's establishment in the 1960s, including ongoing fear and trauma for Sagkeeng First Nation

members. The Manitoba Métis Federation, Black River First Nation, Hollow Water First Nation, and Brokenhead Ojibway Nation have also noted that WL site, along with other historical industrial development in the LSA, have affected the communities' well-being by adversely affecting the environment.

The change in the decommissioning strategy for WR-1 is understood from an Indigenous perspective as having the potential to result in fear, stigma and anxiety associated with the long-term presence of nuclear materials in the region. Given the importance of the topic to Indigenous Nations, CNL acknowledges that efforts to support dialogue and learning are central to the relationship going forward. CNL and AECL recognize and acknowledge the cumulative impacts and trauma experienced by Sagkeeng First Nation members in relation to the initial siting of the WL and are willing and committed to begin addressing this through community-led initiatives facilitated by the Technical Working Group. In addition, CNL, Black River First Nation, and Hollow Water First Nation signed a comprehensive relationship agreement, on April 6, 2021, to support greater community involvement in the Project. Through ongoing discussions CNL and the Manitoba Métis Federation identified initiatives that would help address the Manitoba Métis Federation's concerns of the Project. As a culmination of these discussions, in August 2023, the Manitoba Métis Federation and CNL signed a multi-year contribution agreement. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of Manitoba Métis Federation interest related to participation on the environmental assessment for the Project.

The assessment does not indicate the potential for effects to the well-being of Indigenous Nations since the effects documented by Indigenous Nations in the LSA are linked to the historical presence of the WL site and there are no predicted changes to the biophysical environment. CNL and AECL are committed to working with Indigenous Nations going forward to develop programs and initiatives that provide meaningful mitigation to Indigenous Nations to address the issues of fear and stigma identified.

7.0 ACCIDENTS AND MALFUNCTIONS

This section of the Environmental Impact Statement (EIS) seeks to provide an understanding of the potential effects due to characterized malfunctions and accidents of the In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project). The three objectives of the effects assessment for accidents and malfunctions are as follows:

- identification of the primary hazards for potential accidents and malfunctions in the Project facilities that could affect the environment, public safety or worker safety;
- identification of planned mitigation, including prevention measures that would reduce the probability of these hazards from occurring, and control measures to mitigate the severity of consequences from an accident or malfunction; and
- estimation of the residual risks following the implementation of mitigation, and prioritization of the resources for risk management based on the levels of residual risks identified.

Accidents and malfunctions could take place as internally initiated events and externally initiated events. Internal events are defined as those that are initiated within the Whiteshell Reactor 1 (WR-1) Building and are under Canadian Nuclear Laboratories (CNL) direct control (e.g., equipment failures or other unplanned releases). External events are defined as those that are initiated outside the WR-1 Building and are outside of CNL's direct control (i.e., aircraft crash). This section of the EIS focuses on internal events and external man-made events. Natural events, such as extreme weather events, glaciation and seismic events, are assessed in Section 10 Effects of the Environment on the Project.

Hazards and accidents and malfunctions which result in consequences only over long time-frames (i.e., Post-closure Phase) are not included in the accident and malfunction assessment, as they are assessed in the Decommissioning Safety Assessment Report (Golder 2021), and encompassed by the bounding scenarios presented in Section 6.7.1.7 Residual Effects Analysis where human health is assessed.

7.1 Indigenous Engagement Feedback – Key Interests and Concerns

Information and concerns raised specifically by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the assessment of accidents and malfunctions are summarized in Table 7.1.1-1. Other general concerns and questions raised during the engagement are documented in Section 4.0 Indigenous Engagement.

Table 7.1.1-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Assessment of Accidents and Malfunctions

Interest and Concern	Inclusion Status	Additional information and Rationale
Interested in how accidental releases could be contained in the soil, and how CNL detects spills.	Included in the accident assessment	Spills and leak containment is described in Section 7.3.2 and Section 3.2.2.4 of the EIS
Interested in how accidental releases could affect the Winnipeg River.	Included in the accident assessment	Spills and leak containment is described in Section 7.3.2 and Section 3.2.2.4 of the EIS
Questions about which material will be sent to Chalk River for disposal and how it will be transported	Included in the accident assessment	Management of accidents resulting from off-site transportation are described in section 7.3.4

7.2 Methods

The environmental assessment for the Project is being carried out under the C*anadian Environmental Assessment Act*, *2012* (CEAA 2012). The environmental effects of accidents and malfunctions that could occur in connection with the Project are assessed in accordance with the Canadian Nuclear Safety Commission (CNSC) Generic Guidelines for the Preparation of an Environmental Impact Statement (CNSC 2021) and REGDOC-2.9.1 Environmental Protection: Environmental REGDOC-2.9.1 (CNSC 2020). The assessment was also conducted using the Systems Failure Modes and Effects Criticality Analysis approach, which is a standard risk assessment method (CSA Group 1991, 1997; ISO 2018, 2019).

The assessment criteria for accidents and malfunctions are different from the criteria that are used for the environmental effects assessments. Residual effects for accidents and malfunctions are defined in terms of risk. The risk characterization used to classify residual effects is based on both the likelihood of the postulated event, as well as the severity of the potential effects to the environment and public. The approach includes hazard identification (Section 7.2.1), risk measurement (Section 7.2.2) and risk evaluation (Section 7.2.3). The assessment of accidents and malfunctions identified for the Project is provided in Section 7.3, with a summary of the results of the risk evaluation in Section 7.4.

7.2.1 Hazard Identification

The assessment began by systematically identifying hazards associated with the Project components that could affect the environment, public safety or worker safety. A structured Hazard and Operability Study (HAZOP) was completed for the project at the early design stage to identify high-level risks and scenarios that could occur (Appendix 7.0-1). An Accidents and Malfunctions Report (Appendix 7.0-2) was also prepared to identify credible events which could arise during the WR-1 closure phase based on five work packages identified for the in situ disposal (ISD) of WR-1 (i.e., building systems, preparing reactor systems, grout installation and building demolition and site remediation), causing potential harm to people or the environment.

Additional accidents and malfunctions were identified through the following activities:

- review of CNL documentation related to the WR-1 Building, including annual reports and environmental monitoring reports;
- review of the Comprehensive Study Report (CSR; AECL 2001);
- review of EIS accidents and malfunctions reports for other similar facilities;
- review of lessons learned documents from previous decommissioning work, including operating experience; and
- engagement input collected as part of the *Public Information Program for Canadian Nuclear Laboratories* CNL (2024d), including public and Indigenous feedback regarding long-term waste storage options.

Where potential adverse effects are identified from an accident or malfunction, feasible environmental design features and/or mitigation practices are implemented to avoid and minimize these potential adverse effects. Mitigation actions were identified for each hazard scenario and include prevention measures that would minimize the probability of the scenarios occurring, and control measures to mitigate the severity of consequence from and accident or malfunction.

Essential to the assessment of potential accidents and malfunctions is identification of the sources of hazards currently present within the WR-1 Building. Internally or externally initiated events could result in radiological and/or non-radiological accidents. Radiological accidents refer to those that could result in the acute release of radioactivity to the environment and potentially affect the environment, the public or workers. Non-radiological accidents refer to those that involve only non-radiological substances and will not have any adverse radiological effects on the environment and humans (e.g., the spill of chemicals, lubricants and oils).

The hazards associated with the Project during the Closure Phase are thus grouped into two categories:

- radiological hazards; and
- non-radiological hazards.

A high-level overview of the waste inventories and other hazards anticipated to be encountered during Project activities is presented.

7.2.1.1 Radiological Hazards

Radiological hazards associated with decommissioning the WR-1 Building include potential exposure to beta, gamma and alpha-emitting radionuclides produced during the operational period of WR-1. These consist primarily of the following types of radiological hazards.

- **Fission products –** Fission products are normally contained within the fuel, although fuel defects or failures result in the release of fission products in small quantities, which are then circulated throughout the reactor core and heat transport system, during the operational life of the reactor.
- **Activation products –** Activation products are produced by irradiation of neutron absorbing materials, which become radioactive. They are most abundant in structures and components in or near the core of the reactor, such as the fuel channels.
- **Tritium –** Tritium is produced when heavy water captures neutrons. Residual moderator left from draining WR-1 is expected to contain tritium.
- **Corrosion products –** Corrosion products are small, mobile activation products, produced when small debris from corrosion is transported through the core (e.g., in the moderator or coolant) and are irradiated.

The dominant radionuclides associated with the main systems and components of the WR-1 Building are provided in Table 7.2.1-1. Derived radionuclide inventories for the main systems and components are described in detail in the ERA (EcoMetrix 2024) and are summarized in Section 6.7 Human and Ecological Health. The bulk of the remaining radioactivity is known to be within the reactor vessel (i.e., calandria, fuel channels, thermal shield and biological shield) (CNL 2020a).

Table 7.2.1-1: Radionuclides Associated with Main Systems and Components of the WR-1 Building

System/Component	Radionuclide
Reactor Core	Carbon-14, iron-55, cobalt-60, nickel-59, nickel-63, niobium-94
Primary Heat Transport	Caesium-137, strontium-90, cobalt-60, (small amounts of niobium-94, zirconium-95, antimony-125, europium-152, radium-226, americium-241), isotopic plutonium, technetium-99, iodine-129, curium-244
Biological Shield	Carbon-14, chlorine-36, calcium-41, nickel-63, cobalt-60, europium-152
Heavy Water and Helium System	Tritium, carbon-14
Corrosion products	Carbon-14, chlorine-36, iron-55, nickel-63, nickel-59, cobalt-60, niobium-94
Surface contamination	Caesium-137, strontium-90, cobalt-60

7.2.1.2 Non-radiological Hazards

Non-radiological hazards present during the decommissioning of the WR-1 Building include conventional industrial hazards, chemical hazards, biological hazards and fire hazards. Conventional industrial hazards associated with the decommissioning activities include working at heights, working in confined spaces, working with energized systems, hoisting and rigging and falling objects. Dismantling and demolition of the WR-1 Building will involve the use of cranes and movement of heavy loads. The use of saws, drills and compressors represent potential sources of physical injury to the operators. Changes in site conditions (e.g., excavations and trenching) also represent potential sources of physical injury. These conventional hazards are discussed further in Section 7.3.1. Hazardous materials present within the WR-1 Building include asbestos, lead, polychlorinated biphenyl compounds (PCBs), mercury, mould and various chemicals.

A select number of non-radiological contaminants are identified as a potential concern and are evaluated in ERA (EcoMetrix 2024). These include: potassium hydroxide, boron, lead, xylene, palladium, chromium, cadmium, organic coolant (HB-40) and mercury. The hazardous materials within the WR-1 Building are summarized in Table 7.2.1-2. Details on derived non-radiological waste inventories are provided in the ERA (EcoMetrix 2024).

No PCBs are planned to be left in place for ISD that exceed exemption quantities. CNL has conducted an examination to identify potential PCB containing equipment and materials (CNL 2021a). These PCB containing materials will be removed in accordance with CNL's Waste Management Program prior to grouting or demolition. If additional PCB-suspect materials are encountered, additional samples may be taken to confirm their exemption or identify them for removal. All PCB-containing waste material generated at Whiteshell Laboratories site (WL) site will be sent to an off-site hazardous waste processing facility for treatment and disposal. Waste with both radiological and other hazardous properties may require segregation or use of a treatment facility to be acceptable for disposal.

Asbestos containing materials located in the ISD portion of the WR-1 Building will be left in place and disposed of in situ. The asbestos containing material is primarily piping and tank insulation. The estimated amount of asbestos containing material to be disposed of in-situ is 1,000 m^3 (CNL 2021a). All asbestos containing material located in the portion of the building to be demolished will be removed following the CNL asbestos remediation procedure and adhering to provincial and federal regulations. The estimated amount of asbestos containing material to be removed from the WR-1 building is 801 m^3 (CNL 2021a). Most of this material will be considered radioactively contaminated waste and will be packaged for storage/disposal at the Chalk River Laboratories site.

With respect to the liquid drained from the reactor systems, an estimated residual percentage is assumed to remain in the system after draining/flushing.

In cases where hazardous materials could not be directly quantified (e.g., chromium plating on various components), conservative assumptions have been made to provide a reasonable estimate. For several contaminants (e.g., xylene), there is no confirmation of their presence within WR-1 and their inclusion in this inventory is precautionary, to ensure the effects of the discovery of detectable quantities is not significant. Any additional non-radiological contaminants of potential concern identified during decommissioning will be assessed and remediated as needed to ensure there are no significant effects to the environment.

Table 7.2.1-2: Non-radiological Hazards Associated with Main Systems and Components of the WR-1 Building

Chemical/Material	Expected Locations	Quantity (kg)	Form
HB-40[(a)]	Primary Heat Transport (PHT) System; Auxiliary Organic System and Gas System; Fuel Wash Down system, calandria tubes, tanks	87,700	Liquid in system low points
Lead	Throughout the WR-1 Building	40,800	Solid, Various shielding uses (sheets and bricks)
Xylene	Spent Fuel Handling and Storage System; Wash Down System – Trapped in system low points or blockages	1.9	Liquid/Vapour,
Boron	Heavy Water System; Auxiliary Systems, including Boron Addition System – Low points/Joints where residual solutes collect.	0.0009	Solids/Solutes
Palladium	Organic Supply System, Helium System – Low points/Joints where residual solutes collect	15.5	Solids/Solutes
Potassium Hydroxide	Chemical Addition Tank in the Concrete Cooling System –Low points/Joints where residual solutes collect	0.01	Solids/Solutes
Cadmium	Ion chamber Component and as plating on Fuel Storage Block	91.4	Solid/Plating
Chromium	Various Thermocouples and as Plating on various components (Condenser Tubes; Boiler Tubes)	148	Solid/Plating
Mercury	Drains low points and joints throughout the WR-1 Building	0.33	Liquid/Vapour
Beryllium	WR-1 – Fuel Elements	Limited	Trace solid residuals
Platinum	FLUX Detectors	Limited	Trace solid residuals
Magnesium Oxide	FLUX Detectors	Limited	Trace solid residuals
Gadolinium Nitrate	SLOWPOKE Demonstration Reactor Liquid Absorber Safety System	Limited	Trace solid residuals
Ozone Depleting Substances	Multiple systems	Limited	Trace solid residuals
Multiple Ion Exchange Columns	Heavy Water System, Distilled Water System, Spent Fuel Bay Circulation System, Concrete Cooling System, Boron Addition System, SLOWPOKE Demonstration Reactor Auxiliary Systems, WR-1 L2 Loop, Fast Neutron Loop	Limited	Trace solid residuals

Note:

a) Organic coolant, also known as OS-84 or HB-40, has been drained and properly disposed of; however, residual coolant anticipated to coat the PHT system, and found in some tanks and some calandria tubes. The used organic coolant is potentially contaminated from fuel failure events and corrosion products. The properties of the organic coolant are known to change with irradiation; therefore, residual amounts are expected to be in the form of a viscous liquid sludge, or a dried coating. The volume of organic coolant remaining was very conservatively estimated by assuming 30% of the total organic cooling system volume remains. Subsequent source term investigations indicate that the volume remaining is much lower.

7.2.2 Risk Measurement

After identifying accidents and malfunctions, the consequence severity and the likelihood (frequency) of occurrence associated with each scenario was estimated using a risk matrix that was developed for the Project. The matrix includes a *Likelihood Index* (Table 7.2.2-1) and a *Consequence Severity Index* (Table 7.2.2-2). Likelihood and consequence severity were estimated based on industry and operation experience, Project-specific conditions, and the knowledge base of the Project team.

The process of estimating the likelihood index includes consideration of past performance indicators and safety statistics for site operations and similar closure work performed at the WL site in the last 10 years. Likelihood can be described as how often the hazard scenario might occur (Table 7.2.2-1). The likelihood index ranges from a "Highly Unlikely" event to an "Almost Certain" event and is more formally defined through the events per year value. Order of magnitude of events per year values are defined for each likelihood level. For example, the "Possible" level ranges from more than 1 event in 100 years up to 1 event in 10 years. The categories selected for the likelihood index reflect the Project timescales and type of hazards that may arise. The likelihood of events occurring beyond 1000 years is more related to disruptive events during posts-closure, which is assessed in the DSAR (Golder 2021) and in Section 6.7 Human and Ecological Health.

Table 7.2.2-1: Likelihood Index

Index	A Almost Certain	B Very Likely	C Possible	D Unlikely	E Highly Unlikely
Events per Year	>1 occurrence in 1 year	≤1 occurrence in 1 year and >1 occurrence in 10 years	≤1 occurrence in 10 years and >1 occurrence in 100 years	≤1 occurrence in 100 years and >1 occurrence in 1,000 years	≤1 occurrence in 1,000 years

> = greater than; ≤ less than.

The process of estimating the consequence severity index includes a consideration of existing CNL programs, procedures and policies that are in place to mitigate potential hazards. The consequence severity index ranges from "Negligible" to "Very High," and is applied to two categories of consequences: 1) environment; and 2) worker and public safety. Therefore, there are a total of two risk matrices combined in the Project Risk Matrix. A description of the consequence levels from "Negligible" to "Very High" for each of the two categories is presented in Table 7.2.2-2. Consequence severity considers anticipated and public perceived risks, including longevity of consequences. For the environment, the consequence severity index also acts as a surrogate to describe the magnitude of an environmental effects.

Table 7.2.2-2: Consequence Severity Index

Category	1 Negligible	2 Low	3 Moderate	4 High	5 Very High
Environment	Negligible environmental effect	Short-term effects (<1 month; effects are restricted to on-site	Reversible or repairable effect (less than one year in duration); local effects, off site	Long-term effect (e.g., 10 years in duration), local or regional effect off-site	Long-lasting with long-lasting (> 10 years) or irreversible environmental effects
Worker and Public Safety	Medical treatment not required	Minor first aid injuries with no lost time	Reversible injury with lost time	Severe injuries with long-lasting effects and/or disability	Fatalities, or multiple disabilities

7.2.3 Risk Evaluation

As mentioned in Section 7.2.1, where potential adverse effects are identified from an accident or malfunction, feasible environmental design features and/or mitigation practices are implemented to avoid and minimize these potential adverse effects. Mitigation includes prevention measures that would minimize the probability of the scenarios occurring, and control measures to mitigate the severity of consequence from and accident or malfunction. Estimating the likelihood and consequence severity of an accident and malfunction includes consideration of the environmental design features and/or mitigation practices implemented for a particular hazard.

Each scenario is assigned a Risk Matrix Priority Level according to the likelihood and consequence severity ranking. Risk evaluation requires determining risk priority according to the Project Risk Level Matrix (Table 7.2.3-1). The colour ranking system for each risk level in the Project Risk Matrix and the associated management actions are shown in Table 7.2.3-2. The risks are ranked according to three priority levels, ranging from low (green) to moderate (yellow) to high (red). Evaluation of the individual identified accidents and malfunctions is presented in Section 7.3 and summarized in Section 7.4.

Table 7.2.3-1: Project Risk Level Matrix

Index		Consequence Severity				
		1 Negligible	2 Low	3 Moderate	4 High	5 Very High
Likelihood	A Almost Certain	Low	Moderate	Moderate	High	High
	B Very Likely	Low	Low	Moderate	High	High
	C Possible	Low	Low	Moderate	Moderate	High
	D Unlikely	Low	Low	Low	Moderate	High
	E Highly Unlikely	Low	Low	Low	Moderate	Moderate

Table 7.2.3-2: Risk Matrix Priority Levels

Risk Level		Management Action
	High	High-risk scenarios have High to Very High severity with likelihood ranging from Almost Certain to Unlikely. For high-risk scenarios, additional mitigation measures are required to lower the severity of the potential effects of an accident and malfunction.
	Moderate	Moderate-risk scenarios have Low to Very High severity with likelihood ranging from Almost Certain to Highly Unlikely. In many cases, risk reduction activities will reduce the risk associated with these scenarios, but may require monitoring and active management.
	Low	Low-risk scenarios have Negligible to Moderate severity with likelihood ranging from Almost Certain to Moderate. These risks may require monitoring in certain cases but are not considered to require active management.

7.3 Accidents and Malfunctions

The CSR (AECL 2001) outlined the accidents and malfunctions relevant to the overall decommissioning of WL, identified the expected effects of each scenario, and described mitigations to be put in place as part of the emergency response to those events. Closure activities for the proposed ISD of WR-1 are encompassed by current operating conditions and approved emergency preparedness and response planning identified in the CSR, specifically the Emergency Preparedness Program (CNL 2022b) and WL Site Emergency Response Plan (CNL 2023a), which form the basis of the CNSC-issued site decommissioning licence. The types of hazards anticipated during closure activities are aligned with similar hazards under existing conditions. The procedures, controls and proven mitigative measures in the Emergency Response Plan are considered to appropriately limit the consequence of these hazards such that they would not increase from existing conditions. If new hazards are identified during the execution of the Project, the WL Site Emergency Response Plan (CNL 2023a) will be updated accordingly.

7.3.1 Conventional Occupational Accidents

7.3.1.1 Hazard Identification

Potential worker accidents and injury may arise from non-radiological hazards such as conventional industrial hazards, including working at heights, working in confined spaces, working with energized systems, hoisting and rigging and the potential for falling objects. Dismantling and demolition of the WR-1 Building will involve extensive use of cranes and the movement of heavy loads, resulting in fall hazards and falling object hazards. Failure to isolate all energized systems (e.g., electrical, pressurized) during building isolation, either through improper isolation or accidental exclusion, may result in electrocution or physical shock hazards for workers. The use of saws, drills and compressors represent potential sources of physical injury to the operator, as well as changes in site condition (e.g., excavations).

In addition to the potential injury or accident itself, initiating incidents during decommissioning activities may result in increased exposures to other hazards present within the workplace. For example, if injured personnel require the assistance of rescuers or face delays in being removed from an unsafe location this could increase hazard exposure magnitude and timeframe. In particular, accidents or injuries in confined spaces increase potential exposure of the worker and rescuers to confined space hazards, such as exposure to poor air quality, chemicals and radiation. The hazard initiating the accident or injury may also pose a particular threat to rescuers.

The risk of occupational accidents, such as trips, fall, strains, electrocution, crushing and pinching are no different for the Project than at other industrial projects; these are likely to occur. Conventional industrial hazards associated with Project activities are limited to on-site personnel who are working on the Project under controlled and monitored conditions, and do not pose a threat to the public or the environment. Occupational health and safety

aspects of these types of industrial projects are heavily regulated and programs must be compliant with federal regulations, ensuring that occupational hazards are appropriately managed.

The non-radiological, industrial hazards are systematically identified and assessed through CNL's Occupational Safety and Health (OSH) Program. The WL site has demonstrated the ability to develop and implement effective health and safety procedures and training programs to reduce the occurrence of an accident and limit the potential extent of personnel injury. The work required as part of the Project will be carefully executed and will be completed in accordance with established CNL procedures. Furthermore, CNL has a rigorous Emergency Preparedness Program and personnel at the WL site are adequately trained to prevent and respond to occupational accidents, including on-site fire fighters who are trained in confined space rescue and procedures for dealing with injured workers.

Predicting the human factor that is central to occupational health and safety accidents is not always possible; however, assessment of human factors and performance and their influence on the work safety is a key part of the work planning process at CNL. WL Integrated Work Control (CNL 2024f) process provides that all work steps are identified and reviewed against possible risks. Occupational hazards and risks, including those influenced by human factors, associated with the work are identified, consequences are considered and appropriate engineered and procedural controls are applied. Proven workplace controls (e.g., job scope and safety analysis, signage, training, standard work procedures and controlled access where applicable) and Personal Protective Equipment and Clothing (PPE&C) (e.g., hard hats, gloves, fall protection and hearing protection) are expected to mitigate these hazards to an acceptable level. Over the past 10 years, decommissioning activities have been taking place on the WL site (e.g., SLOWPOKE demonstration reactor, Decontamination Centre and B300 R&D Laboratory). During this time period the WL site received a ranking from the CNSC of "Satisfactory" for Conventional Health and Safety.

The key performance measure for conventional Health and Safety is the Recordable Lost-time Injuries (i.e., an injury that takes place at work and results in the worker being unable to return to work for a period of time). Both the frequency and severity of incidents for every 200,000 person-hours is considered in the performance measure. A summary of WL injury rate data are provided in Table 7.3.1-1. It was noted in 2013 by the CNSC that although most injuries were minor (i.e., only requiring first aid) there was an increasing trend in the number of days required to return to work (i.e., increasing event severity). As such, CNL has since implemented improvements, which have been successful as shown by the decline in Recordable Lost-time Injuries and working days lost in Table 7.3.1-1 (CNL 2017, 2020a).

Table 7.3.1-1: Summary of Whiteshell Laboratories Injury Rate Data

Year	2013	2014	2015	2016	2017	2018	2019	2020
Person Hours Worked	860,250	883,500	741,000	684,450	706,000	688,000	642,000	584,030
Lost-time Injuries	7	4	0	1	3	1	0	1
Working Days Lost	62	54	0	5	27	5	0	4
Frequency[(a)]	1.6	0.9	0	0.29	0.85	0.28	0	0.34
Severity[(b)]	14.4	12.2	0	1.46	7.67	1.45	0	0.68

7.3.1.2 Risk Measurement and Evaluation

Potential worker incidents and injuries may arise from conventional industrial hazards such as working at heights, in confined spaces, with energized systems, hoisting and rigging systems, falling objects and heavy equipment. Management actions in place to reduce the likelihood and consequence of potential worker incidents are consistent with the safety management system and safety culture already in effect at the WL site, where regular assessment of safety performance is conducted and lessons learned from experience are applied. The likelihood of a worker injury is **Very Likely**, which is to be expected at an industrial operation. However, with the management systems currently in place, coupled with WL's strong safety culture that includes regular assessments of safety performance and human performance, the consequence of a worker injury is expected to be **Moderate** (i.e., reversible injury with lost time) as shown in Table 7.3.1-1. A consequence severity of **Moderate**, combined with a likelihood of **Very Likely**, results in a risk evaluation of **Moderate,** where appropriate management actions will reduce the risk associated with occupational accidents.

7.3.2 Spills and Leaks

7.3.2.1 Hazard Identification

Spills and leaks of hazardous substances are possible during all stages of Project activities, including hydraulic fluid or fuel leaks from vehicles or heavy equipment, failure of storage equipment (e.g., Low Level Waste Collection system). For example, during cutting and perforation of components and structures as part of preparation for grouting or other dismantling work, unknown or greater than expected quantities of radiological and non-radiological hazardous substances may be encountered. Accidental cuts or breaks of contaminated piping during decommissioning may also release radioactive substances from these systems. Non-radiological hazardous materials in excess of the regulated exemption quantities in the above-grade structure (as well as easily removed quantities in the WR-1 ISD envelope) will be removed and disposed of at an appropriate disposal site. However, spills and leaks are possible during removal and handling of these materials, including friable asbestos, lead, PCBs and chemicals of various degrees of toxicity.

The CNL Emergency Plan, as part of the Emergency Preparedness Program, provides an analysis of potential emergencies that could occur and focuses on planned response to a release of hazardous material. As part of the Emergency Preparedness Program, this plan is revised annually to identify any changes required to keep the plan current. WL employees have basic training in the management of emergencies, while other personnel at the WL site have been highly trained to respond to incidents involving contamination dispersion.

Risks associated with a spill or leak affecting the environment is mitigated through the implementation of engineering controls including use of secondary containment and spill trays that would be continued for the Project. During closure, operational procedures pertaining to spill response will also still be in effect (i.e., Emergency Preparedness Program including WL Emergency Plan). The use of appropriate PPE&C (e.g., chemical resistant gloves, eye protection), routine inspections of equipment, spill trays, spill kits and established emergency procedures will also be used to manage these hazards and mitigate the effects of spills and leaks to workers, the public and environment. With implementation of mitigation and the operation procedures in effect, spills and leaks of hazardous substances are expected to be contained within the WL site. On-site spills are not considered a risk to public safety given no public access within the WL site.

Essential to preventing spills and leaks is the consideration of contamination characterization (e.g., location and composition) during detailed work planning. All activities related to the Project will be covered by either CNL's work permits with completed Radiological Safety Assessments, as required, or through WL Integrated Work Control (CNL 2024f) procedure that ensures all work steps are identified and reviewed against possible risks.

A Work Permit System for all non-routine work involving potential health and safety hazards provides that hazards are evaluated and appropriate protective measures taken.

To minimize the potential effects of radiological spills and leaks, all work will be executed following the procedures and practices of CNL's Radiation Protection Program. Procedures developed under CNL's Environmental Protection Program, Waste Management Program and OSH Program will also aid in protecting workers and the environment from radiological and non-radiological hazards. CNL's Radiation Protection Program is designed and implemented to ensure CNL complies with, or exceeds, the level of radiation safety that is required by the relevant regulations pursuant to the *Nuclear Safety Control Act* and CNL's Health and Safety Policy.

The fundamental objectives of the CNL Radiation Protection Program are to:

- limit the doses to less than the regulatory limits;
- limit doses to employees and members of the public to levels As Low As Reasonably Achievable (ALARA), social and economic factors being taken into account; and
- prevent detrimental non-stochastic (deterministic) health effects caused in employees and members of the public by CNL's use of radiation.

At all WL facilities, these objectives are achieved through facility design, staff training, administrative exposure control procedures, contamination control requirements and work planning and supervision. A combination of Action Levels and dose management tools are used to keep radiation doses to employees below regulatory limits and ALARA (social and economic factors being taken into account).

CNL's Environmental Protection Program (CNL 2023b) provides compliance with applicable environmental regulatory requirements and requirements that CNL has adopted as a matter of policy. The program is registered under ISO 14001 (ISO 2015) and is designed to provide for the protection of the environment and the public in relation to CNL's activities.

The Environmental Protection Program incorporates the following key elements of the ISO 14001 Environmental Management System Standard:

- **Environmental Policy**
  - Commitment to pollution prevention.
  - Setting environmental objectives and targets to support continual improvement of environmental performance.
  - Complying with applicable laws, recognized standards and guidelines applicable to CNL activities.
  - Reviewing the effects of CNL facilities, projects, services and products on the environment.
- **Planning**
  - Identification and determination of significance of those environmental aspects associated with CNL's activities.
  - Establishment of environmental objectives and targets.
  - Development of appropriate plans and/or programs to achieve the objectives and targets.

- **Implementation and Operation**
  - Defining and documenting appropriate roles and responsibilities.
  - Establishment and maintenance of operational controls over environmental aspects.
- **Checking and Corrective Action**
  - Monitoring to verify environmental performance and compliance.
  - Maintaining non-conformance and corrective and preventative action procedures.
- **Management Review**
  - Periodic review by CNL's management to ensure the ongoing suitability, adequacy and effectiveness of the Environmental Protection Program.

CNL's Management of Waste Program (CNL 2022c) includes requirements and processes for CNL activities that involve planning for, handling, processing, packaging, transporting, storage and disposal of wastes to ensure that they are performed in a manner that complies with applicable regulatory and licence requirements and protects workers, the public and the environment. The Waste Management Plan at the WL site includes identification of waste inventory and the characteristics of the waste (radiological and hazardous non-radiological), waste segregation waste packaging and transfer requirements and the plan for storage or disposal of the wastes.

CNL's Occupational Safety and Health Program is designed to provide for the protection of workers and public health and safety in relation to CNL activities. CNL and its contactors will meet all applicable health and safety legislative requirements. CNL requires that contractors and their subcontractors maintain a level of safety equivalent to that of CNL employees while on-site.

From 2015 through 2019, there were no incidents requiring the initiation of the WL Site Emergency Plan, including no reportable spills (CNL 2018, 2019, 2020b, and 2021b). Table 7.3.2-1 summarizes the number and types of spills and leaks recorded at the WL site over the past five years. Definitions and examples of the four levels of incident categories are provided below:

- **Level 4 (Negligible) –** Non-reportable (i.e., unpublished internal data for trending performance) environmental incidents with no potential for, or actual generation of public concern. For example, an on-site release immediately contained by on-site controls or readily cleaned up resulting in pollution or degradation with a short-term (less than 3-month), reversible detrimental effect on the environment.
- **Level 3 (Minor) –** Non-reportable (i.e., unpublished internal data for trending performance) environmental incident with no potential for, or actual generation of public concern. For example, an environmental nuisance release resulting in pollution or degradation with a persistent (greater than 3-month), reversible detrimental effect on the environment.
- **Level 2 (Moderate) –** Reportable environmental incident that could generate public concern and/or negative press. Incident requiring significant company resources and likely additional resources, to clean-up. The incident poses a potential serious threat to natural are sources, the environment, or public property. There are on-site and off-site effects.

- **Level 1 (Major) –** Reportable environmental incident that generates a significant amount of public concern. Refers to pollution or degradation which has or may have irreversible detrimental effects on the environment. Catastrophic environmental (extends to a wide scale beyond the site) effect requiring a full-scale response by outside agencies and allocation of additional resources to conduct clean-up. Level 1 incidents may involve international boundaries; could seriously affect natural resources, the environment and/or public property; could have a major effect on production capability.

Table 7.3.2-1: Whiteshell Laboratories Recorded Spills and Leaks

Year	Level 1	Level 2	Level 3	Level 4	Total
2015	0	0	0	9	9
2016	0	0	0	20	20
2017	0	0	0	17	17
2018	0	0	0	26	26
2019	0	0	2	26	28

Note: Level 1 = Highly Significant Problem; Level 2 = Significant Problem; Level 3 = Problem / Minor Incident; and Level 4= Minor Problem / Improvement / Negligible Incident.

7.3.2.2 Risk Measurement and Evaluation

With implementation of mitigation and the operation procedures in effect, spills and leaks of hazardous substances are expected to be contained within the WL site. On-site spills are not considered a risk to public safety given no public access within the WL site. CNL's Emergency Preparedness Program, Radiation Protection Program, Environmental Protection Program, Management of Waste Program, and Occupational Safety and Health Program aid in protecting workers and the environment from radiological and non-radiological hazardous substances.

Based on the statistics presented in Table 7.3.2-1, the likelihood of a spills or leak during Project activities is **Very Likely**. From 2015 through 2019, there were no incidents requiring the initiation of the WL Site Emergency Plan, an all events were non-reportable (i.e., Level 3 and 4) environmental incidents with no potential for, or actual generation of public concern. As such, with the management systems currently in place, coupled with WL's strong safety culture that includes regular assessments of safety performance and human performance, the consequence of a spill or leak on the environment and to worker safety is **Low.** A consequence severity of **Low**, combined with a likelihood of **Very Likely**, results in a risk evaluation of **Low,** where implementation of appropriate mitigation will reduce the risk associated with spills and leaks. These mitigations are consistent with the safety system that would be in place during the closure phase.

7.3.3 Material Handling Accidents

7.3.3.1 Hazard Identification

Various ISD activities may involve lifting and moving of large, potentially contaminated materials. The heat exchangers from the PHT system may be placed inside the WRDF. Other contaminated items, such as fume hoods and active ventilation ducts that will not be placed within the WRDF, will be removed from the WR-1 Building and properly stored or disposed where licenced disposal facilities exist. All wastes collected during decommissioning activities will be placed in containers and properly stored or disposed.

Demolition activities will require handling of heavy loads. Drops of, or effects from, large objects pose physical hazards for workers nearby, and dropped objects could also damage other equipment or structures, resulting in leaks and spills. Cleanup or remediation required following such an incident could result in higher worker exposures. Dropping of contaminated rubble or concrete could cause fine, radioactive particles to be suspended in air, posing an internal exposure hazard. Drops and ruptures of waste containers, or contaminated equipment, such as fume hoods, could also spread contamination and cause it to become airborne.

During closure, operational procedures pertaining to the prevention of spreading contamination will be in effect (i.e., Radiation Protection planning and WL Integrated Work Control planning) and the waste collection system for the WR-1 Building will be operational (i.e., sump water collection, storage and treatment) for as long as it can be reasonably done. The establishment of adequate ventilation in the workplace and the confinement of sources of contaminants from the active ventilation system will curtail airborne releases. Contamination release as a result of accidents during the bulk of the demolition activities to be completed following ISD is anticipated to be limited because the majority of the contamination will be encased in the grout. In addition, the use of stabilizing and immobilizing agents prior to demolition can reduce the spread of any remaining contaminants present in the WR-1 Building. Adherence to the CNL procedures, including hoisting and rigging, will reduce the likelihood of a material handling accident. Therefore, the exposure hazards associated with a material handing accident are limited to on-site personnel who are working on the Project and accident do not pose a threat to the public or the environment.

CNL's Emergency Preparedness Program (CNL 2022b) will reduce the consequences of an accident if it occurs and is designed to respond to any emergency at the WL site. The Emergency Preparedness Program provides guidelines for CNL's emergency management staff to ensure that adequate staff and materials are available to meet the requirements of provincial and municipal emergency plans. A four-tier classification of emergencies is used to assist the Emergency Preparedness Program in making preparations and in implementing response. The classification ranges from:

- **Emergency Classification 1 –** an emergency condition relating to industrial workplace hazards within the facility boundary.
- **Emergency Classification 2 –** an emergency condition having the potential to create significant consequences within the facility boundary.
- **Emergency Classification 3 –** an emergency condition having the potential to create a significant consequence on-site, outside the facility boundary.
- **Emergency Classification 4 –** an emergency condition having the potential to create significant consequences off-site.

7.3.3.2 Risk Measurement and Evaluation

Contamination release as a result of a material handling accident is anticipated to be limited because the majority of the contamination will be encased in the grout. In addition, the use of stabilizing and immobilizing agents prior to demolition can reduce the spread of any remaining contaminants present in the WR-1 Building. As such, the likelihood of a material handling accident occurring, considering controls and mitigation, and adherence to the CNL procedures, is **Unlikely.** Although it is unlikely that a material handling accident would occur, the consequence severity of a loss of control on worker safety would be **High**. A consequence severity of **High**, combined with a likelihood of **Unlikely**, results in a risk evaluation of **Moderate.** Risk reduction activities will reduce the risk associated with a material handling accident, but monitoring and active management will be required. The required management actions are consistent with the safety management system and safety culture already in place at the WL site, where regular assessment of safety performance is conducted, and lessons learned from experience are applied.

7.3.4 Off-site Transportation Accidents

7.3.4.1 Hazard Identification

Non-radiological hazardous wastes not planned for encapsulation will be transported to an appropriate off-site waste facility. Radioactive wastes not planned for encapsulation will be managed in the Waste Management Area or transported off-site (e.g., CNL's Chalk River Laboratories in Ontario). In addition to exposing emergency response personnel from the WL site, transportation accidents involving vehicles carrying hazardous and radiological wastes off-site may expose the driver or other members of the public, or release contaminants to the environment.

Transport of waste is routine and safe. The movement of hazardous and radioactive materials off-site is governed by the *Packaging and Transport of Nuclear Substance Regulations, 2015* (SOR/2015-145), and WL staff and drivers are trained in response procedures. Transport containers for nuclear waste are designed taking into account foreseeable accidents. Packaging materials are tested to withstand conditions associated with fire, impact, wetting, pressure, heat and cold. Therefore, the risk of public exposure during transport is considered to be well known and controlled.

Procedures developed under CNL's Radiation Protection Program, Environmental Protection Program, Waste Management Program, Management of Non-Radiological Hazardous Chemical Waste and OSH Program will aid in protecting workers, the public and the environment, and reduce the risk of transportation accidents and their potential severity. In addition, WL Emergency Preparedness Program has emergency plans for off-site accidents. WL personnel at the WL site have been highly trained to respond to incidents involving contamination dispersion and there are proven procedures in place to protect workers, the public and environment during such an event requiring the management of radiological emergencies. Many Whiteshell Laboratories' workers have extensive training and experience in those aspects of radiation hazard control and environmental hazard control relevant during an emergency.

Any deployment of the off-site response team will result in the automatic activation of the Emergency Operations Centre (EOC) at CNL. The role of the EOC is to support the team with access to subject matter experts and additional CNL or contracted resources as required. The EOC is staffed by members of Occupational Safety and Health, Environmental Protection, Radiation Protection and Health Physicists and its' Facility Managers. All WL resources can be called upon by the EOC to support the emergency response and remediation activities. *Whiteshell Emergency Operations Centre Operating Procedure* (CNL 2024a) establishes the EOC Operations structure and response framework.

In 2012, it was reported that just over 107 million tonnes of dangerous goods were transported on Canadian highways (Statistics Canada 2015). In 2011, 385 reportable accidents occurred involving the transport of dangerous goods by air, boat, rail and road (18% increase from 2010, but 5% below the five-year average for 2006 to 2010). Over 70% of these accidents occurred during material handling at transportation facilities, while the remaining less than 30% occurred during transit (Transport Canada 2012). The six-year average reportable accident rate for road is 102 (2006 to 2011). In 2009, the total distance travelled by trucks carrying dangerous goods in Canada was estimated at 308 million vehicle kilometres (Statistic Canada 2015). This translates into an accident rate of 0.33 accidents per million vehicle kilometres travelled. From 2004 to 2012, the average distance of all dangerous good shipments trucked in Canada was estimated to increase from 608 to 632 km (Statistics Canada 2015). CNL, and Atomic Energy of Canada Limited (AECL) previously, have been transporting radioactive materials between sites across North America with no release of radioactive material to the environment. For this analysis the distance required for the Project (one-way trip to disposal facility) was assumed to be triple the average (1,896 km), translating into an accident likelihood of 0.0006 on-site and an accident likelihood off-site of 0.0002.

For CNL to ship radioactive materials in Canada (CNL 2021d), CNL maintains an emergency response assistance plan that is registered with Transport Canada (Filed in CANUTEC as ERAP Number 2-1456). As part of the emergency response assistance plan, both Chalk River Laboratories and the WL site maintain teams of Radiological Protection staff and response vehicles that can respond to off-site radiological emergencies. These teams operate under specific procedures to respond to accidents that have the potential to disperse contamination to people or the environment (i.e., CNL's environmental response plans *Transportation Accidents Involving Hazardous/Dangerous Goods* [CNL 2021c] and *Response to Off-Site Transportation Accidents Involving Radioactive Material* [CNL 2021d). Whether or not the materials are owned by CNL, the teams will support first responders in the area with radiological assessments and information/resources needed to protect the responders, the public and the environment. This response is part of the mutual aid response assistance agreement between CNL, Bruce Power, Ontario Power Generation, Hydro Quebec and New Brunswick Power (per the *Mutual Initial Response Assistance Agreement* [CNL 2018).

The CNL team is expected to report to the Local Authority having jurisdiction over the emergency (typically a local fire department or police service) and support them with the emergency response portion of the event. This includes performing ongoing radiological assessments as well as providing guidance on how to protect themselves, other responders and the public in general. The team will also be responsible for implementing mitigating measures to attempt to prevent the further spread of contamination to the environment. Once the emergency is dealt with, CNL will assume responsibility for the remediation of the site, employing decontamination practices determined appropriate for restoring the site to pre-accident conditions (CNL 2021c). Contaminated materials will be removed to a CNL location for proper long-term remediation and environmental monitoring of the site would continue as long as required to ensure the event has not had any adverse effects to the environment.

7.3.4.2 Risk Measurement and Evaluation

CNL, and AECL previously, have been transporting radioactive materials between sites across North America with no release of radioactive material to the environment. By applying the Transport Canada and Statistics Canada statistics to the Project translating into an accident likelihood on-site of 0.0006 and an accident likelihood off-site of 0.0002. As such, the likelihood of a transportation accident is considered to be **Highly Unlikely**.

Procedures developed under CNL's Radiation Protection Program, Environmental Protection Program, Waste Management Program, Management of Non-Radiological Hazardous Chemical Waste and OSH Program will aid in protecting workers, the public and the environment, and reduce the risk of transportation accidents and

their potential severity. In addition, the movement of hazardous and radioactive materials off-site is governed by the *Packaging and Transport of Nuclear Substance Regulations, 2015* (SOR/2015-145) and transport containers for nuclear waste are designed taking into account foreseeable accidents. Therefore, the consequence severity of such a loss of control is considered to be **Low** for both effects on the environment and public and worker safety. A consequence severity of **Low**, combined with a likelihood of **Highly Unlikely**, results in a risk evaluation of **Low.**

7.3.5 System and Equipment Failure

7.3.5.1 Hazard Identification

Equipment failure and malfunctions may result from improper operation or maintenance or loss of services. Safety-significant systems and equipment, including alarm and monitoring systems (e.g., continuous air monitors), contamination collection and confinement (e.g., Low Level Liquid Waste Collection system, active ventilation system, storage tanks), could potentially be affected. Such failures could result in the accumulation or release of airborne or liquid contaminants potentially affecting worker dose exposures. As secondary containment and Emergency Preparedness Plans already exist, these hazards associated with Project activities are limited to on-site personnel who are working on the Project and do not pose a threat to the public.

Procedures developed under CNL's Environmental Protection Program (CNL 2023b), and *Management and Monitoring of Emissions* (CNL 2022a), describe the use of secondary containment as standard design features of equipment containing hazardous materials. For instance, CNL's *Management and Monitoring of Emissions* (CNL 2022a) indicates that secondary containment systems shall be provided for containers or systems containing radioactive or non-radioactive contaminants (e.g., chemicals, oils, solvents, or other hazardous or nuclear substances) that are stored outdoors or indoors near a storm drain or open draining trench. The exact design of the containment varies from equipment to equipment, but in general takes the form of spill trays and ventilation ducts connected to effluent collection systems, or spill trays with sufficient volume capacity to contain the potential spill.

Failures of systems or equipment could result in radiological and non-radiological hazards through the accumulation or release of airborne and liquid contaminants, as well as increased worker exposure. Failure of alarm and monitoring systems could put workers at higher risks of exposures or fail to provide notification of unsafe conditions. Worker injuries and accidents are also possible with failed equipment or systems. Preventative maintenance is performed to prevent failures from occurring and to assure the continuing capability to perform designed function. Design of equipment with fail-safe modes, use of reliable power supplies, maintenance programs and Defence-in-Depth reduce the likelihood or effects of failures. Use of PPE&C and adherence to OSH procedures, contingency planning and safe back-out procedures provide protection to workers from system and equipment failure.

From 2011 to 2019, there were no instances where criteria were exceeded as a result of equipment failure (i.e., no serious process failures). In 2012, 2013 and 2014, there were short-duration issues with the WL outdoor emergency siren that was believed to be the result of freezing rain and high wind events. The WL outdoor emergency siren has been repaired to prevent such failures in the future. In 2013, there was one unplanned event of unavailability of monitoring data when the outfall sampling pump lost its prime due to maintenance being performed on the main supply pump. This potential consequence of the maintenance was known, and inspection of the outfall sampling pump was scheduled to occur; however, for 95 hours the pump was offline.

In 2015, there was one unplanned instance of failure of the Class 4 power affecting the WL site that was of sufficient duration to initiate the Class 3 emergency power generators. Instances of monitoring unavailability in 2017 included a planned 10-hour outage for WL Building 200 air monitoring (CNL 2018). Instances of air monitoring unavailability in 2018 included two instances of unplanned outage for the WR-1 Complex (total 57 hours) and two unplanned instances for Building 200 (104 hours) (CNL 2019). Three instances of unplanned unavailability of the outfall sampling pump in 2017 were due to equipment failure or electrical power issues, resulting in a total of 86 hours of unavailability. There were also seven instances of unplanned unavailability to the outfall sampling pump in 2018 due to equipment failure or electrical power issues, resulting in a total of 106 hours of unavailability. The outfall sampling pump also had two cases of planned unavailability, totaling 7 hours in 2018. In each instance an estimate of the release during unavailability was calculated as per procedure.

In 2019, there were 4 instances of planned unavailability to Outfall monitoring were due to required maintenance that affected the electrical power supply 3 times and the water flow once. The total time of monitoring unavailability in 2019 was 9.3 hours. In each instance, an estimate of the release during unavailability was calculated as per procedure. Monitoring unavailability also occurred during the fall discharge of the Lagoon when the auto sampler failed due to frozen sample lines. Although the daily grab samples provided a reasonable substitute for auto sampling, strictly speaking there was a loss of monitoring for the remainder of the discharge. The total time for loss of unplanned monitoring, was 107 hours.

7.3.5.2 Risk Measurement and Evaluation

From 2011 to 2019, there were no instances where criteria were exceeded as a result of equipment failure (i.e., no serious process failures). As such, the likelihood of a system and/or equipment failure causing radiological and non-radiological exposure hazards to workers is considered to be **Highly Unlikely**. Use of PPE&C and adherence to OSH procedures, contingency planning and safe back-out procedures provide protection to workers from system and equipment failure. Therefore, the consequence severity of a loss of system and equipment function would be **Moderate** for worker safety. A consequence severity of **Moderate**, combined with a likelihood of **Highly Unlikely**, results in a risk evaluation of **Low.** Management actions are already in place at the WL site and will continue for the Project, where regular assessment of safety performance is conducted and lessons learned from experience are applied.

7.3.6 Fires and Explosions

7.3.6.1 Hazard Identification

Fires

Risks to the environment during a fire and/or explosion at WR-1 can be categorized as potential emissions to air, deposition of air emissions to soil or surface water, or runoff of wastewater generated from fire suppression activities. Fires may result by ignition of combustible materials, hot work, equipment malfunction, and electrical faults and could result in on-site and off-site effects. A number of systems and components will require cutting or perforating during reactor systems preparation. The use of saws, grinders, cutting torches and drills pose a risk of ignition of combustible material. These hazards are consistent with decommissioning activities currently taking place within the WL site and are addressed through the WL Integrated Work Control process (CNL 2024f). From 2015 to 2019, there were no reportable fire events. In 2012, there was one reportable fire in Building 408 (an electrical fire in a heating unit, with no injuries or releases to the environment [AECL 2012]).

Adequate ventilation will be provided to prevent the build-up of volatile components. If the ventilation is adversely affected by a fire in the building, there is possibility that workers exposure to airborne contaminants could be increased. The building contains standard emergency response equipment and required PPE&C is provided. Small radioactive releases to the environment are also possible during fires from the burning of contaminated material. Waste generated from decontamination activities, such as wipes, protective clothing and HEPA filters introduces combustible contaminated material, which could be released to the atmosphere during a fire. Firefighting methods may spread contamination, primarily inside the WRDF, but also outside of the WRDF (e.g., contamination spread in the 600 and 700 level from sections of the PHT system and active ventilation system). The potential for contamination spread beyond the WRDF as the result of a fire would depend on the stage of decommissioning activities (e.g., if above-ground portions of PHT system have been dismantled and relocated below-grade). Since most of the reactor hall outside of the WRDF will be removed, cross-contamination in these areas will burden the removal process with greater decontamination effort.

Wastewater generated from fire suppression activities in the event of a fire would come from internal fire suppression activities or exterior suppression activities. Interior wastewater could result from the activation of sprinkler systems within the building or the application of portable hose streams. Controls are in place to limit the potential for liquid borne contamination as the result of firefighting to spread to the surrounding environment. Most rooms in the WR-1 Building have floor drains, allowing water to be collected and then sampled for non-radiological and radiological contaminants. The floor drains terminate in one of two sumps located in the WR-1 Building, the Organic Sump and the conventional sump. The organics sump is connected to the drains of any room that had organic coolant flowing in or through it to capture any potential releases of organic material separately from the main water collection system in the WR-1 Building. Based on analytical results, the water can either be transferred directly into barrels or filtered and pumped into the conventional sump system for final dispositioning. Water collected by the conventional sump system is transferred to wastewater reservoirs inside the WR-1 Building until it can be sampled. Once the samples are collected the water can be released as per protocol or held back for treatment. In this respect interior wastewater generated in the event of a fire is contained and controlled.

The other potential for wastewater generated would be from exterior fire response on the facility in the form of runoff. This is less likely considering there is very little material left in the building that is capable of burning or to burn for long enough to generate enough heat to create the conditions that require exterior fire suppression. The combination of the lack of fuel load and the fact that the structure is of non-combustible construction under negative air pressure means that fire in this location would likely only be fought with interior fire suppression activities. In the event of exterior fire response, runoff could make its way from the roof of the facility down the exterior walls to the ground around the building. Any soils around the WR-1 Building affected by a fire would be tested after the event against established Canadian Council of Ministers of the Environment (CCME) soil quality standards, and remediated accordingly.

As part of CNL's Environmental Protection Program, there are requirements and processes in place for the *Management of Land, Habitat and Wildlife* (CNL 2024c), which includes mitigation strategies and actions that are to be employed to prevent contaminated run-off from the site to receiving waters. For example, in cases where runoff is of sufficient quantity to reach the roadway, road drains, which are connected to the site storm sewer system would capture the runoff. The runoff would then be sent to the Outfall where runoff is continuously monitored. A post-closure storm water management plan is being developed for the Project and regular site inspection and grounds maintenance is included as tasks under Work Package #10 in the Environmental Assessment Follow-Up and Monitoring Program.

A fire could also result in radiological and non-radiological air emissions to the environment. The release of radiologically contaminated air from a fire inside of WR-1 has a low probability. The entire WR-1 structure operates under a negative air pressure ventilation system. This means all the air in the facility flows from the least contaminated areas to the most contaminated areas before being vented from the building. The building is equipped with a HEPA filtration system that would be engaged in the event of a fire in a contaminated space to filter the air prior to releasing it to the atmosphere. The air exiting the stack is also monitored to detect if any radiological releases have occurred to the environment. The effect of the soot and ash on the soils and flora would be evaluated against established soil quality standards and remediated accordingly, as per direction from CNL Environmental Protection Specialists.

Fire hazards can be reduced through further removal of combustibles and preferential use of cold cutting equipment. Sealed components will be carefully surveyed prior to cutting or perforation, and remote and cold cutting equipment will be used as necessary. Grout specification and formulation will take into account the potential of hydrogen generation and radiolysis of water trapped in the grout. Waste from decontaminated activities will be packaged and managed in compliance with WL Waste Material Management reducing the likelihood of ignition and good housekeeping will reduce the fuel available for a fire. Wastes from decontamination activities will be packaged and managed in compliance with WL materials management procedures to reduce the likelihood of ignition. Worker doses during cleanup following a fire can be kept to a safe level through radiation protection practices.

Under Environmental Incident Reporting, Investigation and Mitigation, unplanned events, such as fire, are investigated until the cause of the incident has been identified and any adverse effects to the environment have been documented, or until due diligence has been demonstrated. This document also outlines all reporting responsibilities placed on CNL in the event of a fire. The environmental impacts are then mitigated to the extent practical to minimize adverse environmental impacts. Mitigative actions shall be directed on a case-by-case basis by the Facility Authority in consultation with Environmental Management staff.

Implementation of WL Fire Protection/Prevention Program will reduce the potential for a fire and the duration and consequences of a fire. CNL maintains a separate procedure for fires involving radioactive material at the WL site. CNL also maintains an Emergency Preparedness Program that reduces consequences from fires and explosions. These plans are discussed in more detail below. Promoting fire safety and preventing fire losses at WL are the main objectives of the WL Fire Protection/Prevention Program. Program objectives are achieved by the following:

- **Promoting Fire Safety:** Provide fire safety information such as pamphlets, displays, presentations, newsletters and employee awareness bulletins, participate in facility safety meetings and provide portable fire extinguisher training to WL employees.
- **Monthly Fire Prevention Inspection:** Inspect all buildings at WL every month to identify and report fire deficiencies and infractions.
- **Monitoring:** Monitor the activities at WL to prevent fire, including the fire watch (for hot works), follow-up inspections following hot works, inspection of construction, demolition and renovation sites and fire prevention inspections to verify (visually) that identified deficiencies are rectified.
- **Fire Scene Investigation:** Examine the fire scene to determine the cause of fire by identifying physical evidence, and protect the scene until the investigation is complete and adopt measures to prevent re-occurrence.

- **Change Control:** Ensure that proposed changes on site are in line with governing fire and building code requirements and site operating licence conditions. Conduct fire screenings and provide recommendations to the Fire Protection Program Manager for consideration.
- **Training:** Training of on-site personnel, facility operations staff and Fire Prevention Inspector.
- **Documentation:** Maintain database to monitor fire prevention trends, compile a list of fire hazard analyses (FHAs) and update as required.

If a fire does occur, the Fire Response Involving Radioactive Material at WL manages the hazards for emergency personnel involved in fire suppression and/or rescue activities that potentially involve radioactive materials. The plan includes the following requirements:

- keep individual doses below CNSC Emergency Response Dose Limits;
- keep potential radiation doses to fire fighters as low as reasonably achievable;
- minimize the potential spread of contamination after the fire is extinguished; and
- prevent possible nuclear criticality excursions for fires involving special fissionable materials.

CNL's WL Site Emergency Response Plan (CNL 2023a) includes emergency preparedness strategies for both on and off-site incidents. In the extremely unlikely event of an on-site fire associated with WR-1 triggering an off-site forest fire, the Emergency Response Plan identifies external organizations which would work with CNL during such an event including the Manitoba Emergency Measures Organization and the Local Government District of Pinawa, Emergency Coordinator and Pinawa Fire Department.

At the WL site, a full-time well-trained fire protection team is employed to ensure rapid and appropriate response to fires involving or potentially involving radiological material. CNL's Emergency Preparedness Program (CNL 2022b) is designed to respond to any emergency at the WL site, including fire and explosions. The Emergency Preparedness Program provides guidelines for CNL's emergency management staff to ensure that adequate staff and materials are available to meet the requirements of provincial and municipal emergency plans, as well as training and exercise requirements. The program provides the earliest possible coordinated response to reduce the effects from an emergency to workers, the public and the environment, as well as restore normal operations as quickly as possible to site.

The monitoring system within the WR-1 Building underwent upgrades in 2011, and is monitored directly at the Security Monitoring Room, providing rapid notification for first responders of any fire event. The response time for the WL on-site Emergency Services Operations, which includes the fire brigade, is under the industry standard set by *CSA N393-13: Fire Protection for Facilities that Process, Handle, or Store Nuclear Substances* (CSA Group 2013), as verified by a third-party *Fire Response Needs Analysis* (Jensen Hughes 2019). The initial response to the facility would include one Fire Engine, one Pumper/Tanker and a minimum of 5 fire fighters. Upon a confirmed fire in any facility on site, all off-duty Emergency Services Operations members and the Pinawa Fire Department are called in for support. Further details on the fire protection staffing and response times are provided in the *Fire Response Needs Analysis* (Jensen Hughes 2019).

The Emergency Services Operations training is skills focused, diving into specific response topics. All members of the WL Emergency Services Operations undergo specialised "Group 4 Enhanced" radiological training, WR-1 Building orientation and specific radiological response procedures/guidelines training. This training is over and above their already rigorous industrial fire training (CNL 2024b) which meets or exceeds the NFPA 1081 *Standard for Facility Fire Brigade Member Professional* (NFPA 2018). Each member of the Emergency Services Operations

fire brigade is required to complete annual qualifications in various aspects of their training, including most aspects of the NFPA 1081 and On the Job Training topics. Each crew of first responders is required to participate in Environmental Monitoring and Protection Program exercises as required. The Environmental Monitoring and Protection program exercises focus on interoperability, combining the First Responder's response with various other groups to ensure smooth responses anywhere across the site. Both the Emergency Operations Center and Building Emergency Teams, including fire response teams, are tested and evaluated according to the WL exercise and drill plan, which is a five-year guideline from which the annual exercise schedule is created (CNL 2023a). These exercises serve to validate the expected effectiveness of the emergency preparedness procedures, and provide an opportunity to adjust the response procedures to better fit the risk levels. The Emergency Services Operations training is skills-focused, diving into specific response topics.

Along with the general skills and procedures that the Emergency Services Operations fire brigade use for their responses, the WR-1 Building has specific Pre-Fire Plans which are primarily used by the Incident Commander in establishing a safe and appropriate response to emergency events within the WR-1 Building (CNL 2024e). The few contaminated spaces within the building are locked and responders have no access to these spaces without a facility operator present. Most of these spaces also contain sprinkler systems that are activated via a fusible link. Several of these spaces also have fog nozzles that con be operated remotely as a back-up to the sprinkler systems.

Confirmed fire in the WR-1 Building would also result in the activation of the WL EOC. The role of the EOC is to support the Incident Commander in their operations at the emergency site and to look after all the other issues that arise outside the emergency site, both on and off the WL site. The WL EOC is structured based on the Incident Command System which is the industry standard across North America. In addition to the standard EOC positions, the WL EOC is also staffed by members of Occupational Safety and Health, Environmental Protection, Radiation Protection and Health Physicists and its' Facility Managers.

Explosions

The WR-1 Building is in a "Storage and Surveillance" state, with the reactor having been shut-down and de-fuelled for over 30 years. The building has had no fissile material in it for at least 20 years. When the last of the fuel was removed from the reactor, the organic coolant was also drained and removed. In the past 3 years, staff has been moved out of the building and offices and labs have been decommissioned. This decommissioning includes the removal of all office furniture, non-structural walls and partitions and flooring and ceiling materials. The building is now occupied only by the Project team and facility operators in a couple of office spaces next to the control room. Access to the building is controlled, with access to the reactor hall and below-grade areas controlled by locks. There is no superfluous material stored in the building and only a minimal amount of flammable materials stored in the appropriate storage cabinets for routine maintenance and compliance work.

Given the current state of the building and the lack of any material, nuclear or otherwise, capable of creating an 'explosive' atmosphere, the risk of an explosion in the WR-1 Building is not considered feasible. There is therefore no current risk posed to employees, the public or the environment from an explosion from the WR-1 Building. As there is no explosion hazard posed by the WR-1 Building there is no corresponding emergency preparedness procedures for this particular hazard. During decommissioning, cutting of sealed components, which may be specifically targeted so that grout will infiltrate them and reduce voids, may pose an explosion hazard if they contain combustibles. During grouting, metals and alloys (i.e., aluminium) exposed to high pH (e.g., an improperly specified or mixed grout) produce hydrogen, which could potentially reach an explosive concentration above the grout surface. As the introduction of these items could create a localised explosion hazard and an ignition

hazard for any remaining combustible products, special approval for these items will be provided within CNL's Fire Protection Program (CNL 2023c) and additional mitigation measures put in place.

Environmental monitoring of the site will continue as part of the WL Environmental Assessment Follow-up and Monitoring Program. During incident response, CNL will assess monitoring data against established limits for contaminants of potential concern based on information in the DSAR (Golder 2021), including the findings from the Environmental Risk Assessment (EcoMetrix 2024). These limits are concentrations that are well below established benchmarks for the protection of humans and the environment. Cessation of a monitoring activity would occur only once it can be shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant by regulatory requirements or community concerns. Any proposals on modifications to the monitoring program will be communicated to the CNSC. A progress report will be prepared each year and will include a summary of the environmental monitoring results and the safety considerations of the contaminants left in-situ.

7.3.6.2 Risk Measurement and Evaluation

A four-tier classification of emergencies is used to assist the Emergency Preparedness Program in preparing and implementing responses. From 2015 to 2019, there were no reportable fire events. Therefore, the likelihood of a fire or explosion occurring as a result of an accident or malfunction, considering the controls and mitigation in place, is **Highly Unlikely**. Controls are in place to limit the potential for liquid contamination to spread to the surrounding environment as the result of firefighting activities. For airborne emissions from a fire, the WR-1 building is equipped with a HEPA filtration system that would be engaged in the event of a fire to filter the air prior to releasing it to the atmosphere. The air exiting the stack is also monitored to detect if any radiological releases have occurred to the environment As such, the consequence severity of such an incident is considered to be **Low** for the environment and the public. The consequence of a fire or explosion is considered to be **High** for worker safety.

A consequence severity of **High**, combined with a likelihood of **Highly Unlikely**, results in a risk evaluation of **Moderate.** Monitoring and management actions are already in place at the WL site for these hazards and will continue for the Project.

7.3.7 Aircraft Crash

7.3.7.1 Hazard Identification

The WL site is about 13 km from the nearest airfield (Lac du Bonnet airport), and over 100 km away from the nearest international airport (Winnipeg Jameson Armstrong Richardson). As the local airports are small and relatively distant, the likelihood of an aircraft crashing into the WR-1 Building during closure or post-closure phase can be based on the general aircraft crash rate. The general risk factor of 10^{-4} per square mile (US DOE 2006) applies to the Project. Decommissioning activities are planned to begin in 2022 with demolition of the WR-1 Building complete in 2025. The footprint of the WR-1 Building is approximately 0.07 ha. Given the small size of the WR-1 Building and the small footprint of the WRDF that will be present throughout post-closure, the likelihood of an aircraft crash directly affecting the Project is remote. As part of the Emergency Preparedness Plan, a regularly updated site inventory (radiological and non-radiological hazardous materials) is maintained. This inventory is used to characterize hazards and informed the execution of emergency response teams. If a crash does occur, damage may occur to the concrete cap and engineered cover, potentially reducing the long-term performance of the WRDF.

7.3.7.2 Risk Measurement and Evaluation

Given the small footprint of the WRDF that will be present throughout post-closure, the likelihood of an aircraft crash directly affecting the Project is **Highly Unlikely**. Because the occurrence of an aircraft crash is outside of CNL's control, there are no mitigation that can be implemented to reduce the likelihood of an event occurring. If a crash does occur, damage may occur to the concrete cap and engineered cover.

The concrete cap and engineered cover designed to prevent human intrusion by providing a hard barrier to actively resist drilling and excavations should someone bypass the earth cover. Should the concrete cap and engineered cover be damaged or breaches, the wastes are further isolated through the grout used within the cavities of the WRDF. Therefore, the consequence severity of an aircraft crash would be **Low** for effects on the environment and **Low** for. Although the consequence severity of an aircraft crash and the direct effect to worker safety is considered to be **Very High,** effects to worker and public safety as a result of a breach of the concrete cap and cover are considered to be **Low**. The consequence severity of **Low** is considered in the risk evaluation as mitigation and management actions to be implemented would be related to the cap and cover. A consequence severity of **Low**, combined with a likelihood of **Highly Unlikely**, results in a risk evaluation of **Low.**

7.4 Summary of Risk Evaluation for Accidents and Malfunctions

The Project Risk Level Summary (Table 7.4-1) is a resource for communicating results, prioritizing risks for risk management and facilitating implementation of the most effective risk mitigation options. The risk management actions and mitigation for potential accidents and malfunctions, including applicable CNL processes and procedures to implement these actions and mitigation, are summarized in Table 7.4-1. Estimates of residual risk following the implementation of the management actions and mitigation is also provided in Table 7.4-1. Some hazards have both an Environment component and a Worker and Public Safety component that may have different consequence severity levels. The highest consequence severity between Environment and Worker and Public Safety was used to determine the Risk Matrix Priority Level.

None of the hazard scenarios in Table 7.4-1 were classified as High (red). The environmental design features and mitigation measures to be implemented are known to be effective based on past performance and safety statistics for site operations and similar closure work performed at the WL site in the last 10 years. The highest category is "Moderate" indicating that the risks may require monitoring and active management. This is done routinely for all work performed at CNL sites. All work at WL site is planned in accordance with WL Integrated Work Control (CNL 2024f) process that ensures that all work steps are identified and reviewed against possible hazards and risks, consequences are considered, and appropriate engineered and procedural controls are applied.

Conventional occupational accidents, material handling accidents, and fires and explosions were evaluated as Moderate priority level during closure. Spills and leaks, off-site transportation accidents, system and equipment failure, and aircraft crash were evaluated as Low priority level during closure. All of these potential hazards are well understood and encompassed by existing and proven engineering controls, management program and standard operating procedures at the WL site. The residual risks for these accidents and malfunctions are expected to be within regulatory requirements. In addition, no off-site effects are predicted for the accident and malfunction scenarios, including those identified by the public and Indigenous communities.

This page intentionally left blank

Table 7.4-1: Project Risk Level Summary

Accident/ Malfunction	Project Phase	Environmental Design Features and Mitigation	Likelihood	Consequence Severity		Risk Matrix Priority Level (after mitigation)[1]
				Environmental	Public and Worker Safety	
Conventional Occupational accidents	Closure	■ Implementation of CNL procedures for hoisting and lifting, working at heights, confined space entry and working with energized systems; use of cranes and movement of heavy loads; the use of saws, drills and compressors; and hazard identification regarding changing site conditions (e.g., excavations). ■ Workplace controls, and Personal Protective Equipment and Clothing (PPE&C)	Very Likely (B)	n/a	Public = n/a Worker = Moderate (3)	Moderate
Spills and leaks	Closure	■ Implementation of CNL's Radiation Protection Program, Environmental Protection Program, including Emergency Plan and Occupational Safety and Health Program ■ Adequate ventilation during decommissioning activities ■ PPE&C (e.g., chemical resistant gloves, eye protection) ■ Routine inspections of equipment ■ Spill trays and spill kits ■ Chemical protection suits and self-contained breathing apparatuses	Very Likely (B)	Very Low (1)	Public = n/a Worker = Low (2)	Low
Material handling accidents	Closure	■ Confinement from ventilation ■ Implementation of CNL procedures, including hoisting and rigging and Emergency Preparedness plans	Unlikely (D)	n/a	Public = n/a Worker = High (4)	Moderate
Off-site transportation accidents	Closure	■ Proper packaging and handling of hazardous waste ■ Use of CNL's procedures on Management of Non-Radiological Hazardous Chemical Waste and WL Waste Materials Management Emergency ■ Preparedness Program has emergency plans for off-site accidents	Highly Unlikely (E)	Low (2)	Public and Worker = Low (2)	Low
System and equipment failure	Closure	■ Design of equipment with fail-safe modes, use of reliable power supplies, maintenance programs, Defence-in-Depth minimize the likelihood or effects of failures ■ Use of PPE&C and adherence to Occupational Safety and Health procedures, contingency planning and safe back-out procedures provide protection to workers from system and equipment failure	Highly Unlikely (E)	n/a	Public = n/a Worker = Moderate (3)	Low
Fires and explosions	Closure and Post-closure	■ Wastes from decontamination activities will be packaged and managed in compliance with WL materials management procedures to reduce the likelihood of ignition ■ Implementation of WL Fire Protection Program and Emergency Preparedness Program ■ Removal of combustibles and preferential use of cold cutting equipment ■ Careful surveying prior to cutting and through preferential use of remote cutting equipment ■ This risk of hydrogen explosion is avoided through proper specification and formulation of the grout (i.e., appropriate pH, adequate ventilation) ■ Adequate ventilation during decommissioning activities ■ Worker doses during cleanup following a fire can be kept to a safe level through radiation protection practices	Highly Unlikely (E)	Low (2)	Public = Low (2) Worker = High (4)	Moderate
Aircraft crash	Closure and Post-closure	■ During closure implementation of WL Fire Protection Program and Emergency Preparedness Program	Highly Unlikely (E)	Low (2)	Public and Worker = Low (2)	Low

Note: Colour coding refers to the risk level in the Project Risk Matrix shown in Table 7.1.3-1.

a) The highest Consequence Severity between Environment and Worker and Public Safety was used to determine the Risk Matrix Priority Level.

n/a = not applicable. An assignment of n/a was included with respect to consequence severity in the table if it was considered that there was no potential or a negligible pathway of effect .

8.0 SUMMARY OF CUMULATIVE EFFECTS

8.1 Introduction and Approach

The *Canadian Environmental Assessment Act, 2012* requires that each environmental assessment of a designated project consider any cumulative environmental effects that are likely to result from the designated project in combination with the environmental effects of other physical activities that have been or will be carried out (The Agency 2015). The cumulative effects assessment is completed to evaluate the contribution of effects from the In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project; i.e., Application Case) in combination with previous, existing, or reasonably foreseeable projects or activities in the region (i.e., Reasonably Foreseeable Developments [RFD] Case) that may overlap spatially (i.e., the same geographic area) and temporally (i.e., over time). Projects or activities in the region that have not yet been approved or developments and activities that are currently under application review, or that have officially entered a regulatory application process, may be considered reasonably foreseeable.

The method for assessment of cumulative effects is outlined in Section 6.1 Environmental Assessment Approach and is consistent with the Canadian Nuclear Safety Commission (CNSC) *Generic Guidelines for the Preparation of an Environmental Impact Statement* (CNSC 2021b) and the Canadian Environmental Assessment Agency's *Assessing Cumulative Effects under the Canadian Environmental Assessment Act, 2012* (The Agency 2018). Cumulative effects are assessed using the same approach used for the Project-specific effects analysis. The approach follows the same five general steps outlined in the cumulative effects technical guidance document (The Agency 2018):

- **Step 1: Scoping:**
  - identifying valued components (VCs; see Section 6.1.3 Valued Components);
  - determining spatial boundaries (see Section 6.1.4.1 Spatial Boundaries);
  - determining temporal boundaries (see Section 6.1.4.2 Temporal Boundaries); and
  - examining physical activities that have been and will be carried out (see Section 6.1.4.3 Assessment Cases).
- **Step 2: Analysis** (see Section 6.1.6 Project Interactions and Mitigation and Section 6.1.7 Residual Effects Analysis);
- **Step 3: Mitigation** (see Section 6.1.6 Project Interactions and Mitigation and Section 6.1.7 Residual Effects Analysis);
- **Step 4: Significance** (see Section 6.1.9 Residual Effects Classification and Determination of Significance); and
- **Step 5: Follow-up** (see Section 6.1.10 Monitoring and Follow-up).

The decommissioning approach for the Whiteshell Laboratories (WL) site as described in the Comprehensive Study Report (CSR; AECL 2001) was to remove all facilities with the exception of low level waste trenches in the Waste Management Area (WMA), and existing contaminated river sediments, which would be managed through in situ disposal (ISD). Canadian Nuclear Laboratories (CNL) is proposing a revised approach to the Whiteshell Reactor 1 (WR-1) decommissioning that includes partial dismantling and demolition, along with passive,

permanent disposal of the below-grade portions of the facility. The disposal approach is ISD. In situ disposal is a proven nuclear decommissioning approach that increases worker safety, provides protection of the environment and the public, reduces interim storage and multiple handling, enables permanent nuclear liability reduction and uses fewer resources. Other decommissioning activities for the WL site, documented in the CSR, are unmodified. Removal of the east annex and service wing of the WR-1 Complex were assessed as part of the CSR and are covered under the CNL's existing decommissioning licence for the WL site (Licence No. NRTEDL-W5-8.00/2024). Activities required to prepare for ISD, such as isolation of the WR-1 Complex and targeted remediation of hazardous materials, are also covered under CNL's existing decommissioning licence for the WL site.

The closure phase for the Project includes preparation for ISD, grouting of below-grade structures and systems, removal of above-grade structures and systems, installation of the concrete cap and engineered cover over the grouted below-grade structures, environmental controls, final site restoration and preparation for institutional control. Closure activities last from 2026 to 2031.

The post-closure phase has two discrete periods: institutional control and post institutional control. Institutional control is estimated to last 100 years during which long term monitoring and maintenance activities will continue to demonstrate WRDF performance is in compliance with the safety case assumptions and performance modelling. The 100 year timeframe is not related to the design life of the WRDF barriers. The 100-year active monitoring period was selected to ensure that sufficient opportunity is provided to verify the WRDF is performing as expected. Additionally, beyond 100 years, there is less confidence that institutional controls, like access restrictions, can be relied upon. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed. Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

Valued components refer to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, scientists, government agencies, Indigenous Nations, or the public (The Agency 2018). The selection of appropriate VCs allows the assessment to be focused on those aspects of the natural and human environment that are of greatest importance to society. The VCs requiring an analysis under the RFD Case are determined by understanding whether the residual effects from the Project and one or more additional developments (or activities) overlap or interact with the temporal or spatial distribution of the VC. For some VCs, there is no potential for cumulative residual effects to environmental components, because there is no overlap with the effects of other developments.

The analysis of cumulative residual effects considers pathways that are likely to result in residual effects on VCs, after implementing environmental design features and mitigation. Pathways determined to have no linkage to a VC or those that are anticipated to have a negligible effect are not expected to result in significant effects on the VC, individually or cumulatively. Where potential cumulative residual effects from the RFD Case are identified for these VCs, these effects were assessed using the same approach used for the Project-specific effects analysis.

The residual effects classification of pathways that are likely to result in residual effects on VCs and the associated predicted changes in measurement indicators provide the foundation for determining the significance of incremental and cumulative residual effects from the Project and RFDs on VCs. For some VCs, there may be no RFD Case and the assessment is limited to determining the significance of residual effects from the Project and previous and existing developments (i.e., Application Case). For those VCs that may be influenced by forecasted

future developments, the assessment includes classifying and determining the significance of cumulative residual effects from all developments, including the Project (i.e., RFD Case). The significance of incremental (i.e., Application Case) and cumulative (i.e., RFD Case) residual effects are summarized in Section 9.0 Summary of Significance.

Monitoring and follow-up programs are proposed to address the uncertainties associated with the effects predictions and the performance of mitigation. In general, monitoring is used to verify the incremental and cumulative residual effects predictions. Monitoring is also used to identify any unanticipated residual effects and provide the implementation of adaptive management to limit these effects. Monitoring and follow-up programs identified to verify the incremental and cumulative residual effects predictions are summarized in Section 11.0 Summary of Monitoring and Follow-up Programs.

8.2 Reasonably Foreseeable Projects

As described in Section 8.1, the Project has the potential to interact with past, existing and reasonably foreseeable projects or activities in the region. Table 8.2-1 provides a summary of the other projects considered in the RFD Case.

As described in Section 1.0 Introduction, CNL is in the process of executing activities associated with the ultimate decommissioning of the WL site. As such, decommissioning and reclamation activities are the primary RFDs with the potential to act cumulatively with the Project. The CSR (AECL 2001), under the *Canadian Environmental Assessment Act* (1992), was completed for the decommissioning and reclamation of the entire WL site. The environmental assessment decision to approve the Project was announced by the Minister of the Environment in March 2002 and a decommissioning licence was issued to Atomic Energy of Canada Limited (AECL) and subsequently to CNL. Since receiving approval, various decommissioning and reclamation activities at the WL site have either been completed or are currently underway. As such, decommissioning and reclamation activities that have been already completed or that are currently underway at the WL site are considered as part of the Base Case. Future decommissioning and reclamation activities planned to continue and that will overlap spatially and temporally with decommissioning activities for the Project are considered as part of the RFD Case.

Table 8.2-1: Reasonably Foreseeable Developments Considered in the Assessment

Type of Project	Location	Description	Timeframe
Infrastructure Decommissioning	WL site	Decommissioning of remaining infrastructure on the WL site (includes ISD of the low-level waste trenches).	2016 to 2034
Environmental Remediation	WL site	Remediation of affected lands, except for the low-level waste trenches.	2016 to 2034

As part of CNL's Environmental Protection Program (CNL 2023), CNL practices responsible environmental management across all sites and facilities. All activities are reviewed holistically over the entire WL site, for their potential impact on the environment.

8.3 Summary of Cumulative Residual Effects

8.3.1 Atmospheric Environment

Potential for cumulative residual effects on air quality is considered at the regional scale, specifically within the atmospheric environment Regional Study Area (RSA). As described in Section 6.2 Atmospheric Environment, there are no RFDs expected in the atmospheric environment RSA other than the decommissioning of the remaining infrastructure and support facilities, and reclamation of affected areas at the WL site, as described in the CSR (AECL 2001).

Results of the air quality assessment completed as part of the CSR indicated that from time-to-time nuisance dust will be generated. Mitigation practices will be implemented to limit potential effects to air quality, including dust control measures (e.g., containment and active suppression [e.g., wetting prior to sidewalk and street sweeping]), curtailment of activities during periods of high winds and maintenance of on-site access routes (see Section 6.3.1 of AECL 2001). In addition, dust monitoring stations have been established on site to collect airborne particulate samples as part of environmental monitoring during decommissioning activities. Special enclosures to cover large areas are currently in use and additional ones may be implemented in the future to contain potential airborne emissions from decommissioning activities (e.g., decommissioning of the WMA). In addition, temporary ventilated enclosures that implement High-Efficiency Particulate Air (HEPA) filtration are used where airborne contamination is a potential hazard during work. This protects workers and the environment. The evaluation of effects to air quality from decommissioning and reclamation activities for the entire WL site concluded that release of air emissions is negligible (AECL 2001).

Project activities will result in emissions associated with the operation of vehicles and equipment, as well as material handling emissions from the demolition and grouting and temporary batch mixing plant or similar equipment. Mitigation practices will be implemented to limit potential effects to air quality, including CNL's *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring and dust management techniques. Predicted concentrations for the Application Case are below applicable air quality guidelines and/or standards.

The environmental effects of the activities related to the decommissioning of the reactor are expected to be less than those assessed in the CSR (AECL 2001) due to the change in decommissioning strategy from complete removal of the facility to ISD. Consequently, the Project is not anticipated to result in a change in the conclusions of the CSR (AECL 2001) related to air quality (Section 6.2.1 Air Quality). As such, the Project is not expected to contribute cumulatively to the effects of decommissioning of the remaining infrastructure and support facilities at the WL to cause a significant effect.

8.3.2 Physical Environment

Potential for cumulative residual effects on geology and hydrogeology is considered at the regional scale, specifically within the geology and hydrogeology RSA.

8.3.2.1 Geology

As described in Section 6.3.1 Geology, there are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the CSR (AECL 2001). The CSR indicated that existing effects on soils are limited to contaminated soils within affected lands on the WL site (see Section 6.3.4 of AECL 2001). Affected lands and associated contaminated soils will be remediated during the WL site decommissioning to meet the WL soil clean-up criteria and the non-radiological and radiological clearance and release criteria.

The assessment of potential pathways of effects for the Application Case in Section 6.3.1 determined there are no pathways that would lead to residual effects on geology VCs. Erosion and sediment control practices (e.g., silt fences, runoff management) applicable to the region and already in place at the WL site will be used during decommissioning activities around disturbed areas, where appropriate. The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-state. Overall, cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site, are anticipated to positively affect soil. As such, an RFD Case is not presented as part of this assessment.

8.3.2.2 Hydrogeology

As described in Section 6.3.2 Hydrogeology, there are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the CSR (AECL 2001). Results of the CSR (see Section 6.3.4 of AECL 2001) indicated that major alterations of groundwater flow regimes from the decommissioning activities are not expected. Following decommissioning of the building sumps, groundwater levels will approach static conditions similar to the local environment. On the WL main campus, groundwater heads indicate downward flow conditions exist. For the closure and post-closure phases, groundwater will flow downwards through the overburden and westward, ultimately discharging at the Winnipeg River. The closure of the WL site may slightly alter the drainage flow patterns to the Winnipeg River for a short period of time, but the changes are expected to be within the natural range of variation. Overall, cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site, are anticipated to have a negligible effect on groundwater quantity.

The CSR (AECL 2001) indicated that for effects to groundwater quality, the main area of concern was the low-level waste proposed to be managed in situ in the WMA. The evaluation of contaminant migration from the WMA trenches concluded that the nature of groundwater flow in the area around the WMA limits contaminant migration away from the WMA. There is no downward movement of groundwater flow from the WMA to the underlying permeable sandy zone, which has the potential to act as a transmission zone to the Winnipeg River (see Section 6.3.4 and Appendix C of AECL 2001). Generally, the natural hydraulic head at 10 m depth is higher, meaning that the hydraulic head gradient is upward, leading to potential water discharge towards the surface (i.e., artesian conditions).

Contaminant migration, if it were to occur, would be less than 10 cm over 20 years. Testing also provided no evidence of a “bathtub effect” (i.e., flooding of the trenches so that they have a higher conductivity than the trench wall) and associated near-surface lateral movement of contaminants, although further testing was recommended to support a future detailed safety analysis (AECL 2001).

The final safety assessment for the WMA has not been completed. Both the Project and the WMA are subject to the same regulatory requirements, which require that no member of the public receive a dose greater than 1 mSv/a. *REGDOC 2.11.1, Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2021a), specifies a 1 mSv/a limit, and also specifies that a lower dose rate target should be set to account for emissions from other sources. . The Project specified a 0.25 mSv/a target dose rate limit for the public and results of the assessment for the normal evolution indicates that the Project is well below this target. The expectation is that the final assessment of the WMA will demonstrate negligible dose rates compared to these targets. Consequently, there are negligible cumulative effects between the Project and previous activities at the WL site (i.e., effects from the WMA). In summary, there is no overlap of effects between WR-1 ISD and previous activities at the WL site (i.e., effects from the WMA) and changes to groundwater quality from the Project.

8.3.3 Surface Water Environment

Potential for cumulative residual effects on surface water is considered at the regional scale, specifically within the surface water RSA.

8.3.3.1 Hydrology

As described in Section 6.4.1 Hydrology, there are no RFDs expected in the surface water RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the CSR (AECL 2001). The CSR (see Section 6.3.3 of AECL 2001) indicated that alterations of surface water flow regimes from the decommissioning activities are not expected. The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-state. The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. The WL site will be graded to promote drainage to the Winnipeg River. Overall, cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site, are anticipated to have a negligible effect on hydrology.

8.3.3.2 Surface Water Quality

As described in Section 6.4.2 Surface Water Quality, there are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the CSR (AECL 2001). Decommissioning and reclamation of the entire WL site, including the Project, may alter drainage rates and flow patterns as current precipitation management is removed. Consequently, the discharge volume to Winnipeg River may change, which may alter surface water quality. The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. The drainage system for the reclaimed WL site will have the physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. The contribution to site runoff from the Project is expected to be minor relative to the entire decommissioned WL site. Although closure of the WL site may slightly alter the

drainage rates and flow patterns and discharge volume to the Winnipeg River; the changes are expected to be within the natural range of variation. As such, changes to discharge volume to from the closure of the WL site, including the Project, are predicted to have a negligible effect on the surface water quality in Winnipeg River.

The CSR (see Section 6.3.3 of AECL 2001) indicated residual effects on surface water, particularly the Winnipeg River, are related to discharges from the Active Liquid Waste Treatment Centre and the sewage lagoon. These discharges, currently well below applicable standards, will gradually diminish to almost zero following decommissioning. Re-suspension of contaminated sediments is also not expected to lead to a decrease in water quality (Section 7.0 AECL 2001).

The CSR (AECL 2001) also examined the potential for effects via groundwater quality from the low-level waste that may be managed in situ in the WMA, and their potential to affect the Winnipeg River (see also Section 6.3.2.5.2.4 Groundwater Quality). The assessment considered three general exposure pathways: upward migration (with potential contamination of soils and vegetation), near-surface lateral migration (with potential contamination to local discharge in perimeter and roadside ditches) and downward migration and contamination of the sand and gravel aquifer and subsequently the river. Only the near-surface lateral migration scenario was considered in further detail. With respect to downward migration and release to the river, it was determined that the general hydrology of the site limits or eliminates the potential for a residual effect.

Water concentrations in the ditch were predicted and compared to established guidelines for several of the contaminants in the WMA. Radionuclide modelling in the CSR (Appendix C of AECL 2001) indicated that three radionuclides have the potential to exit the WMA through migration over a 200-year period: tritium, technetium-99 and carbon-14. Only technetium-99 is potentially present in non-zero concentrations in the ditch adjacent to the WMA in as early as 20 years. The carbon-14 and tritium will be lost to the atmosphere. When this is modelled, there is no release of these radionuclides to the perimeter ditch. These predictions were considered further for their potential effect on human health (see Section 6.7.1.7 Residual Effects Analysis [Section 6.7 Human and Ecological Health]). With respect to non-radiological contaminants, some exceedances of applicable standards were predicted. Further refinement of the modelling and potential need for selective remediation to remove the hazard was recommended (AECL 2001).

The final safety assessment for the WMA has not been completed; however, both the Project and the WMA are subject to the same regulatory requirements, which require that no member of the public receive a dose greater than 1 mSv/a. *REGDOC 2.11.1, Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2021a), Section 6.2.1, specifies a 1 mSv/a limit, and also specifies that a lower dose rate target should be set to account for emissions from other sources. Therefore, a value of 0.3 mSv/a dose limit to public has been established for the WL site. The Project specified a 0.25 mSv/a target dose rate limit for the public and results of the assessment for the normal evolution indicates that the Project is well below this target. The expectation is that the final assessment of the WMA will demonstrate negligible dose rates compared to these targets. Consequently, there are negligible cumulative effects between the Project and previous activities at the WL site (i.e., effects from the WMA) and surface water quality in the Winnipeg River.

As part of CNL's licence with the CNSC, environmental monitoring around the WL site will continue for the Project in accordance with the Environmental Assessment Follow-up and Monitoring Program. Follow-up monitoring during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects. Consequently, changes to surface water quality from the closure of the WL site, are predicted to be negligible.

8.3.4 Aquatic Environment

As described in Section 6.5 Aquatic Environment, there are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the CSR (AECL 2001). Potential effects from the Project on the aquatic environment that may overlap spatially with decommissioning activities include activities resulting in changes to surface water quality, sediment quality and hydrology.

The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. The contribution to site runoff from the Project is expected to be minor relative to the entire decommissioned WL site. Similar to the decommissioning plan for the Project, the WL site will be graded to promote drainage to the Winnipeg River. Although closure of the WL site may slightly alter the drainage rates and flow patterns and discharge volume to the Winnipeg River, the changes are expected to be negligible and within the natural range of variation. As such, changes to hydrology from the closure of the WL site, including the Project, are predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

The CSR indicated that the potential effects to aquatic biota are also related to changes in surface water quality in the Winnipeg River from the presence of contaminated river sediments. No decrease in water quality is expected and effluent emissions to the Winnipeg River are expected to decline to virtually zero following decommissioning (see Section 7.0 of AECL 2001). Re-suspension of contaminated sediments is also not expected to lead to a decrease in water quality. Consequently, changes to surface water quality from the closure of the WL site, are predicted to have a negligible effect on the maintenance of self-sustaining and ecologically effective fish populations, including species at risk.

8.3.5 Terrestrial Environment

Potential for cumulative residual effects on the terrestrial environment is considered at the regional scale, specifically within the terrestrial RSA. As described in Section 6.6 Terrestrial Environment, there are no RFDs expected in the terrestrial RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the CSR (AECL 2001). The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the land use and landscape of the day. Results of the CSR (see Section 6.3.5 of AECL 2001) indicated that no effects were identified for terrestrial biota as natural vegetation will re-establish following completion of decommissioning and reclamation activities. Airborne emissions from decommissioning activities are likely to be less than in the past, therefore, no residual effects from air emissions are expected (see Section 6.3.5 of AECL 2001).

Overall, cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site are anticipated to positively affect the terrestrial environment. Once existing infrastructure is removed and the RSA is reclaimed the level of anthropogenic disturbance within RSA will be reduced, benefiting the terrestrial environment of the RSA. Species such as barn swallow may be negatively affected through the loss of anthropogenic habitat on site through the decommissioning of structures; however, implementation of habitat offsetting (e.g., installation of nesting structures for barn swallow in 2018) in advance of additional decommissioning is designed to proactively address this potential. Because cumulative effects from the Project in combination with the decommissioning and

reclamation of the affected areas at the WL site are considered through proactive offsetting measures or anticipated to be positive, an RFD Case is not presented as part of this assessment.

8.3.6 Human and Ecological Health

Potential for cumulative residual effects on human and ecological health is considered at the regional scale, specifically within the human and ecological health RSA, as represented by a number of receptor locations (see Figure 6.7.1-1).

8.3.6.1 Human Health

As described in Section 6.7.1 Human Health, there are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the CSR (AECL 2001). The CSR (see Section 6.3.8 of AECL 2001) indicated that no public health threats were predicted from the decommissioning and reclamation activities for the WL site. Releases are well within regulatory limits for the protection of human health and regular monitoring provides that any aberrations are detected immediately.

The CSR (AECL 2001) also examined the potential for effects via groundwater quality from the low-level waste that may be managed in situ in the WMA, and their potential to affect the Winnipeg River and human health (see also Section 6.4.2.6.2.2 Project Interactions and Mitigation [surface water quality assessment]). The assessment considered three general exposure pathways: upward migration (with potential contamination of soils and vegetation), near-surface lateral migration (with potential contamination to local discharge in perimeter and roadside ditches) and downward migration and contamination of the sand and gravel aquifer and subsequently the river. Only the near-surface lateral migration scenario was considered in further detail. With respect to downward migration and release to the river, it was determined that the general hydrology of the site limits or eliminates the potential for a residual effect.

Water concentrations in the ditch were predicted and compared to established guidelines for several of the contaminants in the WMA. Radionuclide modelling in the CSR (Appendix C of AECL 2001) indicated that three radionuclides have the potential to exit the WMA through migration over a 200-year period, namely tritium, technetium-99 and carbon-14. Only technetium-99 is potentially present in non-zero concentrations in the ditch adjacent to the WMA in as early as 20 years. The carbon-14 and tritium will be lost to the atmosphere, and when this is modelled there is no release of these radionuclides to the perimeter ditch. The preliminary exposure assessment for radiological contamination of the ditch, when these losses were conservatively ignored, resulted in a dose of 0.16 millisieverts per year (mSv/a) at the predicted peak concentration of technetium-99 (Section 6.7.1 Human Health; Appendix C of AECL 2001).

With respect to non-radiological contaminants, some exceedances of applicable standards were predicted. Further refinement of the modelling and potential need for selective remediation to remove the hazard was recommended (AECL 2001). Organic contaminants were also considered; it was concluded that the remaining concentrations of the solvents and dichlorodiphenyltrichloroethane (DDT) are very small and unlikely to present a residual hazard.

The final safety assessment for the WMA has not been completed; however, both the Project and the WMA are subject to the same regulatory requirements, which require that no member of the public receive a dose greater than 1 mSv/a. REGDOC-2.11.1, *Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2021a), Section 6.2.1, specifies a 1 mSv/a limit, and also specifies that a lower dose rate target should be set to account for emissions from other sources. Therefore, a value of 0.3 mSv/a dose limit to public has been established for the WL site. The Project specified a 0.25 mSv/a target dose rate limit for the

public, and results of the assessment for the normal evolution indicate that the Project is well below this target. Consequently, there are negligible effects between the Project and previous activities at the WL site (i.e., effects from the WMA) and changes to surface water quality in the Winnipeg River.

Current effects from the existing facilities and operations at the WL site are considered part of the Base Case (i.e., existing conditions), and as such an RFD Case is not applicable to the human health assessment and is not further discussed.

8.3.6.2 Ecological Health

As described in Section 6.7.2 Ecological Health, there are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as assessed in the CSR (AECL 2001). The CSR (see Section 6.3.3 of AECL 2001) indicated that no decrease in water quality is expected and effluent emissions to the Winnipeg River are expected to decline following decommissioning. Results of the assessment concluded that no effect on aquatic species is expected as doses were below the limit at which no effects on aquatic populations are expected (see Section 6.3.6 of AECL 2001). Current effects from the existing facilities and operations at the WL site are considered part of the Base Case (i.e., existing conditions). Consequently, cumulative effects of the Base Case and the potential effects from the Project are evaluated in the Application Case. As such, an RFD Case is not presented as part of this assessment.

8.3.7 Land and Resource Use

Section 6.8 Land and Resource Use seeks to understand and characterize the potential residual effects of the Project and past, present, and reasonably foreseeable developments on traditional land and resource use (Section 6.8.1) and other land and resource use (Section 6.8.2). The assessment of traditional land and resource use considers traditional land and resource use activities in proximity to the Project, including hunting, trapping, and gathering by Indigenous Nations, archaeological and cultural sites, and the overall importance of the Winnipeg River. The assessment of other land and resource use includes consideration of non-Indigenous commercial, municipal, and federal land and resource use activities in proximity to the Project. These activities include agriculture, forestry, mineral claims and leases, water use, and outdoor recreation and tourism, sport fishing, outfitting, hunting, trapping, and other winter activities.

Potential cumulative residual effects on traditional land and resource use (Section 6.8.1) and other land and resource use (Section 6.8.2) were considered at the regional scale (i.e., the RSA). As described in Section 6.8.1 and Section 6.8.2, there are no RFDs expected in the RSA other than the continued decommissioning of the remaining facilities at the WL site, as described in the CSR (AECL 2001). The CSR (Section 6.3.9 of AECL 2001) identified residual effects on land and resource use as a result of the long-term land use restrictions. Land and resource use activities have persisted adjacent to the site, including uses of the Winnipeg River. It is expected that all activities and land uses adjacent to the WL site will be able to continue in the future with the Project as the Project will have no effect on land tenure or usage beyond the site boundaries.

Future use of the WL site will depend on the ability to release parts of the site with no restriction on use upon completion of the Project. Future uses/zoning have not been determined, but the end-state plan for the WL site is to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-state. The criteria developed will prioritize the environment and safety while incorporating Traditional knowledge if provided. Indigenous community priorities will also be included provided they align with environmental and safety priorities. Some lands will have restrictions on the future use so that there are no adverse effects to people and the environment as assessed in

the safety assessment and modelling associated with the ISD of infrastructure and facilities, such as WR-1 and the Waste Management Area. These areas will require ongoing controls including institutional control, access restrictions and environmental monitoring. However, the amount of land associated with all of these areas is negligible relative to the size of the WL site that will have no restrictions on land use. CNL will be engaging Indigenous communities in a discussion on future uses for the WL site, with site closure planned for early 2031.

The following are the key roles and responsibilities to determine the future use of the WL site:

- AECL owns the site and has responsibility for all assets and liabilities.
- CNL is the contractor responsible to perform the decommissioning and site remediation of the WL site.
- CNL is preparing a WL Remediation Plan defining the end state criteria in collaboration with stakeholders, Indigenous Nations and the public, and will submit it to the CNSC for acceptance.
- CNL informs and engages the public, Indigenous, and other key stakeholders such as the Province of Manitoba.

Changes in the future uses of the site may affect the Local Government District of Pinawa's desire to develop economic activity at the WL site to offset lost jobs due to closure of the site, including nuclear and non-nuclear developments. As noted in Section 6.9 Socio-economic Environment, the previous decommissioning plan for WL, described in the Comprehensive Study Report (AECL 2001), assumed that radioactive wastes would eventually be removed and placed in permanent disposal facilities with the assumption that a national disposal facility for low level radioactive waste would be available by 2025 and a national disposal facility for intermediate-level waste operational by 2050 (CNSC 2002). Under the previous decommissioning plan for WL, described in the Comprehensive Study Report (AECL 2001), a smaller percentage of the site (the Waste Management Area) would have had restrictions on use than with the Project; however, the area with anticipated restrictions on use under the Project is still small when compared with the remainder of the WL site.

While the Project will change the proportion of the site with restricted access and future uses, decommissioning is designed with the environment and safety as a priority. Future use will incorporate Traditional knowledge and CNL will work with Indigenous Nations so their concerns can be considered and aspirations around the site incorporated where feasible. The Project will increase the amount of land available for future use; therefore, negligible residual effects were predicated for traditional land and resource use and other land and resource use.

The Project in combination with the decommissioning and reclamation of the WL site is also anticipated to contribute to positive effects on the environment, which will positively affect land and resource use within the RSA (e.g., less industrial activity that could affect outdoor recreation, hunting, fishing, trapping and plant and berry gathering). Consequently, cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site are anticipated to be negligible for both traditional land and resource use and other land and resource use.

The Project will also contribute to positive effects on the environment, which will positively affect land and resource use within the RSA (e.g., less industrial activity that could affect outdoor recreation, hunting, fishing, trapping and plant and berry gathering). Consequently, cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site are anticipated to be negligible for both traditional land and resource use and other land and resource use.

8.3.8 Socio-economic Environment

Similar to the other disciplines, the two potential RFDs to overlap with the socio-economic VCs are:

- Decommissioning of remaining infrastructure on the WL site (includes ISD of the low-level waste trenches); and
- Remediation of affected lands, with the exception of the low-level waste trenches.

No new workforce is required for these activities; therefore, there is no overlap of effects with the Project. As such, an RFD Case is not presented as part of the socio-economic assessment.

8.4 Summary

The Project is in a rural area, and no RFDs are expected to overlap spatially or temporally with the Project other than the continued decommissioning of the remaining facilities at the WL site, as described in the CSR (AECL 2001). The CSR (AECL 2001) indicated that closure of the WL site may slightly alter existing conditions; however, effects were predicted to be within applicable guidelines (e.g., air quality, surface water quality, human and ecological health) or negligible (e.g., hydrology, hydrogeology, aquatic environment, and land and resource use). The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the land use and landscape of the day. Therefore, decommissioning of remaining WL structures is also anticipated to result in positive effects for many VCs (e.g., geology, terrestrial environment and land and resource use).

Overall, cumulative effects predicted are anticipated to be negligible after implementation of mitigation measures. As such, there were no cumulative residual effects predicted for the RFD Case (i.e., no determination of significance). A summary of Sections 8.3.1 to 8.3.8 is provided in Table 8.4-1.

Table 8.4-1: Summary of Cumulative Residual Effects for Discipline Assessments

Discipline	Contributing Project Activity	Phase the Project Effect Occurs in	Proposed Mitigation[a]	Cumulative Residual Effect
Atmospheric Environment	Closure activities for the Project will overlap with decommissioning of the remaining infrastructure and support facilities at the WL site per the existing decommissioning licence.	Closure Phase	■ Use of dust control measure (e.g., containment and suppression) to control generation of airborne emissions and nuisance dust. ■ Curtailment of activities during periods of adverse meteorological conditions (e.g., during periods of high winds). ■ Maintenance of on-site access routes. ■ Continued implementation of the Environmental Assessment Follow-up and Monitoring Program for the WL site.	Cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities and reclamation of the affected areas at the WL site are anticipated to be negligible. Therefore, there are no cumulative residual effects predicted.
Physical Environment	Decommissioning and reclamation of the entire WL site, including the Project, may alter groundwater quantity.	Closure Phase	■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. ■ The WL site will be graded to promote drainage from the site to the Winnipeg River.	Cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities and reclamation of the affected areas at the WL site are anticipated to have a negligible effect on groundwater quantity. Therefore, there are no cumulative residual effects predicted.

Table 8.4-1: Summary of Cumulative Residual Effects for Discipline Assessments

Discipline	Contributing Project Activity	Phase the Project Effect Occurs in	Proposed Mitigation[a]	Cumulative Residual Effect
Surface Water Environment	Decommissioning and reclamation of the entire WL site, including the Project, may alter drainage rates and flow patterns, and consequently the discharge volume to Winnipeg River.	Closure Phase	■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. ■ The WL site will be graded to promote drainage from the site to the Winnipeg River.	Changes to discharge volume to from the closure of the WL site, including the Project, are predicted to have a negligible effect on the surface water quality in Winnipeg River. Therefore, there are no cumulative residual effects predicted.
Surface Water Environment	Decommissioning and reclamation of the entire WL site, including the Project, may alter drainage rates and flow patterns as current precipitation management is removed. Consequently, the discharge volume to Winnipeg River may change, which may alter surface water quality.	Closure Phase	■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. ■ The WL site will be graded to promote drainage from the site to the Winnipeg River.	Changes to drainage rates and flow patterns volume to from the closure of the WL site, including the Project, are predicted to have a negligible effect on the surface water quality in Winnipeg River. Therefore, there are no cumulative residual effects predicted.

Table 8.4-1: Summary of Cumulative Residual Effects for Discipline Assessments

Discipline	Contributing Project Activity	Phase the Project Effect Occurs in	Proposed Mitigation[a]	Cumulative Residual Effect
Aquatic Environment	Decommissioning and reclamation of the entire WL site, including the Project, may alter drainage rates and flow patterns, and subsequently fish and fish habitat.	Closure Phase	■ As part of CNL's licence with the CNSC, environmental monitoring around the WL site will continue for the Project. ■ Follow-up monitoring as part of the Environmental Assessment Follow-up and Monitoring Program during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities and reclamation of the affected areas at the WL site are anticipated to have a negligible on fish populations. Cumulative effects to surface water quality from the closure of the WL site, including the Project, are predicted to have a negligible effect on the fish populations, including species at risk. Therefore, there are no cumulative residual effects predicted.
	Release of chemical and radiological contaminants in the long-term from the closure of the entire WL site, in combination with the Project.	Post-closure Phase		
Terrestrial Environment	Decommissioning and reclamation of the entire WL site, including the Project.	Closure Phase	■ Follow-up monitoring as part of the Environmental Assessment Follow-up and Monitoring Program during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Effects of RFDs in the RSA are expected to be primarily positive, because activities will focus on decommissioning existing infrastructure. Therefore, an RFD Case is not presented as part of the terrestrial environment assessment.
Human and Ecological Health	Decommissioning and reclamation of the entire WL site, including the Project.	Closure Phase	■ Follow-up monitoring as part of the Environmental Assessment Follow-up and Monitoring Program during the post-closure phase will continue to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Current effects from the existing facilities and operations at the WL site are considered part of the Base Case (i.e., existing conditions), and as such an RFD Case is not applicable to the human and ecological health assessments.

Table 8.4-1: Summary of Cumulative Residual Effects for Discipline Assessments

Discipline	Contributing Project Activity	Phase the Project Effect Occurs in	Proposed Mitigation[a]	Cumulative Residual Effect
Land and Resource Use	Decommissioning and reclamation of the entire WL site, including the Project, may change the future land tenure and uses of the WL site.	Post-closure Phase	■ The end-state plan for the WL site will be to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. ■ Affected areas will be remediated to meet the WL screening soil cleanup and the non-radiological and radiological clearance and release criteria in accordance with the target end state of the associated land-use category.	Cumulative effects from the Project in combination with the decommissioning of the remaining infrastructure and support facilities, and reclamation of the affected areas at the WL site are anticipated to be negligible. Therefore, there are no cumulative residual effects predicted.
Socio-economic Environment	Decommissioning and reclamation of the entire WL site, including the Project.	Not applicable	■ Not applicable	No new workforce is required for these activities; therefore, there is no overlap of effects with the Project. As such, an RFD Case is not presented as part of the socio-economic assessment.

a) Some mitigation efforts are within the scope of the Project, and others are as identified for other projects (e.g., as identified in the CSR).

CNSC = Canadian Nuclear Safety Commission; CSR = Comprehensive Study Report.

9.0 SUMMARY OF SIGNIFICANCE OF RESIDUAL EFFECTS

9.1 Introduction and Approach

The following assessments were completed to evaluate the biophysical and human environment effects of In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project) and to satisfy the requirements of the review being undertaken under the *Canadian Environmental Assessment Act, 2012* (CEAA 2012):

- Section 6.2 Atmospheric Environment;
- Section 6.3 Geological and Hydrogeological Environment;
- Section 6.4 Surface Water Environment;
- Section 6.5 Aquatic Environment;
- Section 6.6 Terrestrial Environment;
- Section 6.7 Human and Ecological Health;
- Section 6.8 Land and Resource Use; and
- Section 6.9 Socio-economic Environment.

The approved decommissioning approach for the Whiteshell Laboratories (WL) site, as described in the Comprehensive Study Report (CSR; AECL 2001), was to remove all facilities with the exception of low level waste trenches in the Waste Management Area, and existing contaminated river sediments, which may be managed through on-site in situ disposal (ISD). Canadian Nuclear Laboratories (CNL) is applying for an amendment to the current decommissioning licence to carry out the Project, rather than dismantling and demolition as previously assessed in the CSR. The in situ disposal approach includes partial dismantling and demolition along with passive, permanent disposal of the below-grade portions of Whiteshell Reactor 1 (WR-1). In situ disposal is a proven decommissioning approach that increases worker safety, provides protection of the environment and the public, reduces interim storage and multiple handling, enables permanent nuclear liability reduction, and utilizes fewer resources.

The Project activities are limited to ISD of the WR-1 Building. Other decommissioning activities for the WL site, documented in the CSR, have not changed and do not need to be reassess. Removal of the east annex and south service wing of the WR-1 Complex were assessed as part of the CSR and are covered under the CNL's existing decommissioning licence for the WL site (Licence No. NRTEDL-W5-8.00/2024). Some activities required to prepare for ISD, such as isolation of the WR-1 Complex and targeted remediation of hazardous materials, are also covered under CNL's existing decommissioning licence for the WL site.

The closure phase for the Project includes preparation for and implementation of ESD, which includes grouting of below-grade structures and systems, removal of above-grade WR-1 Building structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031. The post-closure phase has two discrete periods: institutional control and post-institutional control. Institutional control is estimated to last a minimum of 100 years, during which long-term monitoring and maintenance activities will continue, to demonstrate compliance with the safety case assumptions. Although the duration of institutional control is estimated at a minimum of 100 years, it is recognized that it will continue until

the Canadian Nuclear Safety Commission (CNSC) agrees institutional controls are no longer needed. Post-institutional control occurs after year 2131 and continues indefinitely; however, the timeframe defined for the assessment of potential effects, as part of the normal evolution of the Project's safety assessment is 10,000 years. This timeframe (i.e., 10,000 years) encompasses the phase in which peak effects are anticipated.

A residual adverse environmental effect is an effect that remains, or is predicted to remain, after mitigation has been implemented (The Agency 2015). Therefore, they are the expected consequences of the Project for the selected valued components (VCs). Interactions (linkages) between Project components or activities and the corresponding potential effects on VCs are identified by a pathway or screening analysis (see Section 6.1.6 Project Interactions and Mitigation for a more detailed description of the pathway analysis). For some interactions, there are proven effective mitigation or best management practices that would eliminate or reduce the potential effect to a negligible level. These interactions are not advanced for further assessment. Interactions that require further analysis were advanced to the residual effects analysis step (see Section 6.1.7 Residual Effects Analysis for a detailed description). A matrix table is included in Appendix 6.1-1 summarizing Project interactions for each VC that are determined to be no linkage, secondary, or primary, after consideration of environmental design features and mitigation.

The residual effects analysis is based on the Project interactions that are determined to be primary in the pathway analysis. For primary pathways, the concept of assessment cases is applied to estimate the incremental and cumulative effects from the Project, as well as previous, existing and reasonably foreseeable developments. The residual effects analysis is completed for the Application Case and the Reasonably Foreseeable Developments (RFD) Case. This Application Case scenario represents predictions of the cumulative effects of the existing environment combined with the effects that may result from the Project. The RFD Case scenario includes the Application Case plus additional RFDs in the region. Developments and activities that are currently under application review or have officially entered a regulatory application process were considered reasonably foreseeable.

The residual effects classification of primary pathways provide the foundation for determining the significance of incremental and cumulative effects from the Project and other existing, approved and reasonably foreseeable developments on VCs. The purpose of the residual effects classification is to describe the residual incremental and cumulative adverse effects from the Project and other developments on VCs using a common set of criteria. The classification criteria provide definitions that permit a clear, thorough and unambiguous classification of residual effects such that reviewers and readers can follow and apply the logic used in the assessment. Effects are classified using the following criteria, which follows the *Generic Guidelines for the Preparation of an Environmental Impact Statement Pursuant to the Canadian Environmental Assessment Act, 2012* provided by the Canadian Nuclear Safety Commission (CNSC 2021) and the *Operational Policy Statement Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the Canadian Environmental Assessment Act, 2012* (The Agency 2015). The residual effects classification is then used to make significance determinations.

- **Direction –** Direction indicates whether the residual effect on a VC is negative, positive or neutral (i.e., no change). Neutral and positive changes are not assessed for significance.
- **Magnitude –** Magnitude is a measure of the intensity of a residual effect, or the degree of change caused by the Project (and other developments, if applicable) relative to baseline conditions, guidelines or threshold values. Magnitude is typically classified into three scales: negligible to low, moderate and high.

- **Geographic Extent –** This criterion refers to the spatial extent of the effect, and is different from the spatial boundary (i.e., study area) for the residual effects analysis. The geographic extent of residual effects can occur on multiple scales within the spatial boundary of the assessment. Geographic extent is often categorized into three scales: local, regional and beyond regional.
- **Duration –** Duration is defined as the amount of time (usually in years) from the beginning of a residual effect on a VC to when the residual effect is reversed and is expressed relative to Project phases. Duration has two components. It is the amount of time between the start and end of a Project activity or stressor (which is related to Project development phases), plus the time required for the residual effect to be reversed. Duration is often categorized as short-term, medium-term and long-term.
- **Reversibility –** After removal of the Project activity or stressor, reversibility is the likelihood that the Project will no longer influence a VC in a future predicted period. Reversibility usually has only two alternatives: reversible or irreversible. The period is provided for reversibility (i.e., duration) if a residual effect is reversible. Permanent residual effects are considered irreversible.
- **Frequency –** Frequency refers to how often a residual effect will occur and may be expressed as isolated, periodic or continuous. Frequency is explained more fully by identifying when the residual effect occurs (e.g., once at the beginning of the Project). If the frequency is periodic, then the length of time between occurrences and the seasonality of occurrences (if present) is discussed.
- **Likelihood –** Likelihood is the probability of an effect occurring and is described in parallel with uncertainty. This criterion may be influenced by a variety of factors, such as the likelihood of disturbance occurring or the likelihood of mitigation being successful. Four classification categories are typically used: unlikely, possible, likely and highly likely.

The intent of the environmental assessment is to predict if the Project is likely to cause a significant adverse effect on the environment or to cause public concern. Only residual effects that are adverse are considered in the determination of significance under CEAA 2012 (The Agency 2015). Consequently, neutral and positive residual effects are reported; however, they are not assessed for significance.

The classification of residual adverse effects and the determination of significance was completed only for those VCs that have assessment endpoints. Assessment endpoints are qualitative expressions used to assess the significance of residual effects on VCs. Assessment endpoints are typically not quantifiable and require the identification of one or more measurement indicators that can be directly linked to the assessment endpoint. Measurement indicators represent properties of the environment and VCs that, when changed, could result in or contribute to an effect on assessment endpoints. Measurement indicators may be quantitative (e.g., changes to ambient concentrations of criteria air contaminants) or qualitative (e.g., continued sustainability and overall well-being of communities in proximity of the Project). The significance of effects from the Project on VCs was evaluated by linking changes in measurement indicators to effects on the assessment endpoints. For example, changes to ambient concentrations of criteria air contaminants (measurement indicators) were used to assess the Project's performance against criteria and thresholds for the protection of human health and the environment (an assessment endpoint) to identify and classify residual adverse effects of the Project on the air quality VC.

The evaluation of significance for VCs considered the entire set of primary pathways that influence a particular assessment endpoint, which means that the relative contribution of each pathway was used to determine the significance of potential adverse effects of the Project and other developments on an assessment endpoint (see Section 6.1.9.2 Determination of Significance for additional detail on the approach).

All VCs have measurement indicators, but not every VC has an assessment endpoint (e.g., geology, hydrogeology and surface water). Valued components with no assessment endpoint were still analyzed for Project-specific and cumulative (if applicable) changes in measurement indicators, but the classification of residual effects and the determination of significance was not completed for these VCs. Instead, the results of the analysis for these VCs are provided to other disciplines (e.g., aquatic and terrestrial environment, human health) for inclusion in their residual effects analysis, where applicable (see Section 6.1.3 Valued Components and Figures 6.1.3-1 and 6.1.3-2 for additional detail on the approach).

9.2 Summary of the Significance of Residual Effects

9.2.1 Atmospheric Environment

9.2.1.1 Air Quality

Air quality was selected as a VC because there is a potential for the Project activities to release air emissions that could affect the local air quality. The assessment endpoint for air quality is performance against the criteria and thresholds for protection of human health and the environment. The measurement indicators for air quality include changes in ambient concentrations of indicator compounds in comparison to the provincial or federal ambient air quality criteria.

The assessment of effects of the Project on air quality involves two steps, namely the calculation of emission rates (which include the implementation of mitigation), and dispersion modelling to predict the resulting concentrations of indicator compounds. During the Application Case, Project activities will result in emissions associated with the operation of vehicles and equipment, as well as material handling emissions from the demolition and grouting and temporary batch mixing plant or other similar equipment.

Mitigation practices to limit predicted residual effects to air quality during the closure phase are available, including:

- implementation of CNL's Environmental Protection Program and Procedure for Management and Monitoring of Emissions, which includes operational control monitoring, air verification monitoring and environmental monitoring;
- implementation of dust management techniques;
- on-site vehicles and equipment engines will meet a minimum of Tier 3 emission standards, where possible, and be maintained in good working order;
- limit idling of vehicles on-site and limit speed on roads; and
- use of enclosures for raw material handling.

Air quality is predicted to be affected by the Project. Fugitive dust from vehicle movement on roads is the largest contributor to suspended particulate matter, particles nominally smaller than 10 micrometre (µm) in diameter, and particles nominally smaller than 2.5 µm in diameter (Section 6.2.1 Air Quality). Non-road equipment exhaust emissions are the largest contributors to oxides of nitrogen (as nitrogen dioxide) and carbon monoxide emissions. Finally, the largest contributor to sulphur dioxide emissions is fuel combustion for emergency power generators.

For an effect to be deemed significant for air quality, the effect on an indicator compound must be adverse, exceed relevant guideline/standard (high in magnitude), and extend beyond the air quality Local Study Area (LSA), but be contained within the air quality Regional Study Area (RSA; regional in geographic extent) and irreversible or only reversible following completion of the Project phases (long-term in duration). The direction is negative for all

indicator compounds; however, the magnitude of changes to indicator compound emissions are predicted to be low to moderate as the predicted concentrations of each indicator compound from the Application Case are below their relevant guideline/standard, with the exception of SPM and PM_{10} limited to a small area just outside the LSA; along Ara Mooradian Way north of 211 Rd in a restricted area. The predicted effects are limited to the air quality RSA, and therefore the geographic extent of changes to all indicator compounds is regional for the Application Case. Although there are planned stages for the closure phase beyond the Application Case (Phases 4 to 6), emissions of indicator compounds during these phases will be lower than the Application Case; therefore, the duration of effect is conservatively considered to be short-term. Criteria air contaminants will be emitted continuously or near-continuously during the Application Case and, therefore, the frequency of effect is frequent. The likelihood of emissions from the Project changing indicator compound concentrations for the Application Case is high.

Based on the low to moderate magnitude, the regional geographical extent of the effect and the short-term duration, the overall residual adverse effect of the Project on air quality is determined to be not significant (Section 6.2.1 Air Quality).

The Project is not anticipated to result in a change in the conclusions of the 2001 Comprehensive Study Report related to air quality. As such, the Project is not expected to contribute cumulatively to the effects of decommissioning of the remaining infrastructure and support facilities at the WL there is no cumulative effect predicted for the RFD case.

Implementation of CNL's *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring, will continue for the Project. In addition, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented (Section 11.0 Summary of Monitoring and Follow-up Programs). This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical. CNL will continue to proactively seek, engage, and support meaningful discussions with First Nations and the Manitoba Métis Federation and communities of interest on issues and opportunities related to the Project, including the monitoring and follow-up program.

9.2.1.2 Greenhouse Gases

Climate change was selected as a VC for the greenhouse gas (GHG) assessment as there is a potential for the Project activities to release GHGs that could contribute incrementally to climate change. The assessment endpoint for climate change is comparison to provincial and national totals. The measurement indicators considered in the climate change assessment include changes in concentrations of carbon dioxide, methane, and nitrous oxide. There are no Project activities that are expected to emit sulphur hexafluoride, perfluorocarbons or hydrofluorocarbons; therefore, these compounds are not included in the GHG assessment.

Project activities will result in GHG emissions associated with the operation of vehicles and equipment. Mitigation practices to limit GHG emission during the closure phase are available, including:

- implementation of CNL's Environmental Protection Program and Procedure for Management and Monitoring of Emissions, which includes operational control monitoring, air verification monitoring and environmental monitoring;

- on-site vehicles and equipment engines will meet a minimum of Tier 3 emission standards, where possible, and be maintained in good working order; and
- limit idling of vehicles on-site and limit speed on roads.

Project activities will result in greenhouse gas emissions associated with the operation of vehicles and equipment. The greenhouse gas emissions are estimated to be less than 0.1% of the total provincial greenhouse gas emissions and less than 0.01% of the total national greenhouse gas emissions. Based on the comparison between the estimated annual emission to both the federal and provincial greenhouse gas emissions, the Project will result in minor releases of greenhouse gases, but is predicted to have a negligible effect on climate change and will not impact Canada's emission reduction efforts. In 2015, Canada represented less than 2% of total global greenhouse gas emissions. Therefore, any greenhouse gas emissions from the Project may be considered negligible on a global scale. Based on these estimates, no primary pathways were identified for the GHG assessment (Section 6.2.2 Greenhouse Gases). Subsequently, there is no further residual effects classification and determination of significance of GHG.

9.2.2 Geology and Hydrogeology

9.2.2.1 Geology

Geology, which includes bedrock, soils and geomorphology, is recognized as an important component of the environment that may be affected by the Project. Acknowledging that changes to geology could lead to effects on other VCs, geology is referred to as an intermediate component (i.e., it does not have an assessment endpoint). The measurement indicators for geology include changes in soil quality, soil quantity, bedrock and geomorphology.

Potential effects on geology are limited to changes in soil quantity and quality as a result of construction of temporary supporting infrastructure, and changes to soil quality from air emissions and groundwater transport from the WRDF into the groundwater. The assessment of potential pathways of effects determined there are no primary pathways that would lead to residual effects on geology (Section 6.3.1 Geology). The results of the analysis of changes in measurement indicators for geology are provided to other VCs for inclusion in their assessment.

9.2.2.2 Hydrogeology

Hydrogeology is recognized as an important component of the environment that may be affected by the Project and changes to hydrogeology could, in turn, lead to effects on other VCs selected for assessment. Acknowledging that changes to hydrogeology is an important aspect of the natural and human environment, hydrogeology is referred to as an intermediate component (i.e., it does not have an assessment endpoint). The measurement indicators for hydrogeology include groundwater flow patterns and discharge rates, groundwater table elevations, and peak solute mass loadings of contaminant in groundwater to the Winnipeg River.

Changes to groundwater quality from the Project due to the release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time was identified as having a residual adverse effect on the hydrogeological environment. Environmental design features and mitigation implemented to reduce residual effects on groundwater quality include:

- installation of a concrete cap and engineered cover to mitigate moisture infiltration into the Whiteshell Reactor Disposal Facility (WRDF);
- removal of the service area and infilling in these areas with compacted clay-based soil;

- sealing of open conduits in the building foundation;
- grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation; and
- monitoring will be completed throughout the institutional control period for the Project to confirm that the cover and grout is functioning as intended and to confirm modelling predictions.

Groundwater flow and solute transport modelling was completed to provide estimates of solute mass loadings during the post-closure phase (Section 6.3.2 Hydrogeology). The Winnipeg River was identified by the post-decommissioning groundwater flow model as the principal receptor of groundwater discharge from the geological pathway. The Winnipeg River is also of high importance to Indigenous Nations.

Mass flux rates from 56 radiological parameters, along with 29 non-radiological elements, were simulated in the groundwater flow and transport modelling. The groundwater flow modelling indicated that the mean advective groundwater travel times to the Winnipeg River were an estimated 100 years. The peak total activity level from the simulations occurs after approximately 70 years and is principally related to the migration of tritium from WR-1. Due to dispersion, the finite amount of tritium in the source (grout) and the half-life associated with tritium (approximately 12 years), its peak arrival to the Winnipeg River occurs earlier than the mean advective groundwater travel time.

Because hydrogeology is an intermediate component, the hydrogeology assessment does not include a determination of significance; rather, results of the analysis of changes in measurement indicators for hydrogeology are provided to other disciplines for inclusion in their assessment. Results of the groundwater assessment are used in the surface water quality assessment (Section 6.4.2 Surface Water Quality) and the human and ecological health assessment (Section 6.7 Human and Ecological Health.

CNL will continue to implement the Environmental Assessment Follow-up and Monitoring Program for the WL site to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. CNL will provide First Nations and the Manitoba Métis Federation with the opportunity to participate in the implementation and review of mitigation measures. For monitoring requirements arising from the Project, but not covered in the Environmental Assessment Follow-up and Monitoring Program, appropriate procedures will be developed that will meet or exceed federal and provincial regulatory requirements. A post-closure monitoring program will also be developed that will provide the sampling and analysis objectives and procedures for sampling and testing the groundwater quality in the vicinity of the WR-1 Building.

9.2.3 Surface Water Environment

9.2.3.1 Hydrology

Hydrology, which includes surface water flow and drainage direction, is recognized as an important component of the environment that may be affected by the Project. Acknowledging that changes to hydrology could lead to effects on other VCs, hydrology is referred to as an intermediate component (i.e., it does not have an assessment endpoint).

The assessment considers the potential effects of the Project to the flows and water levels of the Winnipeg River. The WL site will be graded to promote drainage from the site to the Winnipeg River. Natural runoff from the decommissioned WL site will continue to discharge to the Winnipeg River during the post-closure phase. In addition, the overall contribution of WL site drainage to the Winnipeg River flow is negligible, thus no effects are

anticipated. The assessment of potential pathways of effects determined there are no primary pathways that would lead to residual effects on hydrology (Section 6.4.1 Hydrology). The results of the analysis of changes in measurement indicators for hydrology are provided to other disciplines for inclusion in their assessment.

9.2.3.2 Surface Water Quality

Surface water quality is recognized as an important component of the environment that may be affected by the Project. Acknowledging that changes to surface water quality could lead to effects on other VCs, surface water quality is referred to as an intermediate component (i.e., it does not have an assessment endpoint). The measurement indicators for surface water quality include changes to ambient levels of surface water contaminants.

During the post-closure phase, groundwater may encounter the Whiteshell Reactor Disposal Facility and then flow to the Winnipeg River, resulting in changes to surface water and sediment quality. The predicted maximum radionuclide concentrations in surface water at both the Nearfield and the Farm A Intake on the Winnipeg River are orders of magnitude lower than background groundwater concentrations. Predicted sediment concentrations of radionuclides are lower than their respective clearance levels.

Predicted maximum non-radionuclide concentrations in surface water and sediment are driven by current river concentrations and some parameters exceed available surface water or sediment guidelines. For example, the background concentration for lead exceeds the lowest available guidelines for surface water and sediment, but the maximum sediment concentrations at both the Nearfield and the Farm A intake in both surface water and sediment show no change from the background level as a result of the Project.

Overall, the assessment of potential effects determined there are negligible residual adverse effects on surface water and sediment quality from changes in groundwater quality (Section 6.4.2 Surface Water Quality). Because surface water quality is an intermediate component, the assessment does not include a determination of significance; rather, results of the analysis of changes in measurement indicators for surface water quality are provided to other disciplines for inclusion in their assessment.

CNL will continue to implement the Environmental Assessment Follow-up and Monitoring Program for the WL site to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. CNL will provide First Nations and the Manitoba Métis Federation with the opportunity to participate in the implementation and review of mitigation measures.

9.2.4 Aquatic Environment

For the aquatic environment, fish and fish habitat was selected as a VC as there is a potential for the Project activities to affect aquatic biota in the Winnipeg River. The fish and fish habitat valued component includes the fish species identified by the First Nations and the Red River Métis that are occurring in the Winnipeg River, as well as habitats supporting life history requirements including spawning, nursery, rearing and foraging. The assessment endpoint for the aquatic environment is the maintenance of self-sustaining and ecologically effective fish populations. The measurement indicators for the aquatic environment include measurable attributes that broadly represent various facets of the aquatic environment, including fish habitat (quality and quantity), benthic invertebrate community structure and fish community structure.

During closure, potential effects to fish and fish habitat include the transport of site surface water runoff to the Winnipeg River in the vicinity of the WL site, changes in drainage rates and flow patterns due to the installation of the concrete cap and engineered cover at the Whiteshell Reactor 1 Building, and deposition of air emissions from demolition activities. The Project is not anticipated to affect the physical habitat of the Winnipeg River. With Implementation of a storm water management plan and Canadian Nuclear Laboratories' *Management and Monitoring of Emissions*, site runoff and air and dust emissions are not predicted to impact the surrounding aquatic environment. As such, closure activities are predicted to have a negligible residual effect on fish and fish habitat.

An Ecological Risk Assessment was completed and for the post-closure phase, it evaluates the potential for adverse effects on aquatic health associated with exposure to chemical and radiological contaminant releases through the groundwater pathway from the WRDF in the long-term. There are no exceedances of the radiation benchmark for the aquatic biota in the Winnipeg River and all predicted doses are well below this level. Therefore, it is unlikely there would be significant adverse effects on aquatic populations or communities as a result of radionuclide releases in the long-term during the post-closure phase.

There are no exceedances of the hazard quotients identified for exposure of the aquatic receptors to non-radionuclides, with the exception of benthic invertebrates in groundwater. The hazard quotients for cadmium, lead and HB-40 exceeded 1 for the scenario where benthic invertebrates are exposed directly to groundwater. The assessment conservatively assumes the organisms spend their entire lives in the peak discharge zone, and that no dilution of the groundwater occurs in the shallow sediment layers where most benthic organisms reside. Moreover, the seepage area represents a small part of the benthic community habitat, and the maximum groundwater concentration assumed represents the worst-case period. As such, a realistic benthic invertebrate population is not likely to be at risk due to cadmium, lead and HB-40 exposure, and any adverse effects will be spatially and temporally limited. Overall, the changes in water quality and sediment quality are expected to result in a negligible residual effect to the benthic invertebrate population relative to existing conditions.

The assessment of potential pathways of effects determined there are no primary pathways that would lead to residual effects on the aquatic environment VCs. As such, there is no further residual effects classification and determination of significance for the aquatic environment (Section 6.5 Aquatic Environment).

Monitoring and follow-up programs for the aquatic environment are not identified specific to the Project as there are no predicted residual effects to fish and fish habitat. However, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as identified for other environmental components (e.g., groundwater quality and surface water quality) to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment Follow-up and Monitoring Program for the WL site, where practical.

9.2.5 Terrestrial Environment

Based on the nature of this project and limited pathways of effects on natural terrestrial ecosystems, the focus of this assessment is at a species-level and primarily focuses on wildlife species identified on Schedule 1 of the federal *Species at Risk Act*. All listed wildlife species with the potential to occur within the WL site (or with confirmed occurrence records) were considered as potential VCs at the species level. The VCs assessed for the terrestrial environment include barn swallow, golden-winged warbler, bats and snapping turtle due to their potential to be present within the local area. The assessment endpoint for the terrestrial environment is the maintenance of self-sustaining and ecologically effective populations. Habitat availability, habitat distribution and survival and reproduction were selected as the measurement indicators.

Traditional Knowledge and Land Use Studies and Indigenous engagement identified additional valued components (i.e., white-tailed deer, moose, elk, porcupine, furbearers, grouse, geese, ducks, and waterfowl) for consideration in the terrestrial effects assessment. Project activities occur within the WL site on previously disturbed areas; therefore, there are no direct effects to habitat availability and distribution for the above listed species. In addition, indirect effects of the building demolition works (noise, equipment use) was deemed to be of low risk to wildlife in natural areas adjacent to the fenced campus, and they were considered to be unlikely to occur within the fenced campus. Although, these species were not selected as valued components for the terrestrial assessment, they (or representative species) were included in the effects assessment for ecological health.

During closure, the Project will generate air and dust emissions from demolition activities. With implementation of CNL's *Management and Monitoring of Emissions*, there is predicted to be negligible effects on the terrestrial environment from the Project as a result of air and dust emissions. Sensory disturbance, road mortality, and loss of nest/roost substrate also have the potential to affect terrestrial VCs during closure. Surveys during the appropriate season, to be undertaken the year prior to initiation of decommissioning activities, will confirm whether nesting and/or roosting activity is occurring in the WR-1 Building. If evidence of nesting or roosting activity is found, appropriate mitigation in the form of deterrents will be implemented, under consultation with Environment and Climate Change Canada and in accordance with habitat protection provisions and the required permitting process under the *Species at Risk Act* and potentially the *Migratory Birds Convention Act*. The objective of the selected mitigation will be to prevent birds and bats from accessing the building during the period when it will be demolished. The potential for road mortality of snapping turtle will be addressed through adaptive management and ongoing monitoring and documentation of road mortalities. If road mortality of snapping turtle occurs, additional mitigation will be enacted, as required. Following implementation of mitigation and monitoring in an adaptive management framework, there is predicted to be negligible effects on the terrestrial environment as a result of the Project.

An Ecological Risk Assessment was completed and for the post-closure phase, it evaluates the potential for adverse effects on terrestrial biota associated with exposure to chemical and radiological contaminant releases in surface water through the groundwater pathway from the WRDF in the long-term. There are no exceedances of the radiation benchmark for terrestrial biota and all predicted doses are well below this level. There are also no exceedances of the hazard quotients identified for exposure of the terrestrial receptors to cadmium, lead, HB-40 and xylene. Therefore, changes in surface water quality through the groundwater pathway are expected to result in negligible residual effect to terrestrial populations or communities in the long-term during the post-closure phase. Because the Ecological Risk Assessment found the predicted doses would be far below any effect level, no significant effects are predicted for the VCs identified by Indigenous Nations.

Overall, the assessment of potential pathways of effects determined there are no primary pathways that would lead to residual effects on terrestrial VCs (Section 6.6 Terrestrial Environment). Although no residual effects on terrestrial VCs are predicted, monitoring programs are described as possible proactive mitigation by CNL and includes consideration of all future decommissioning and building demolition activities that will occur on the WL site. In addition, CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project as identified for other environmental components to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. This monitoring will be integrated with that for the existing Environmental Assessment and Monitoring Follow-up Program for the WL site, where practical.

9.2.6 Human and Ecological Health

9.2.6.1 Human Health

Specific to the Project, the human health risk assessment focused on public and Indigenous Nations' health and the health of WL site workers not involved in performing Project activities. Consistent with CSA N288.6-12, Nuclear Energy Workers directly involved in performing Project activities were not assessed because their potential doses are controlled through CNL's Radiation Protection Program. The assessment for public and Indigenous Nations' health considered locations where people are known to be present.

The assessment endpoint is the protection of human health. Measurement endpoints for the human health assessment include changes in air quality, groundwater quality and surface water quality. The receptors for the Human Health Risk Assessment were selected to be appropriate for assessment of both radiological and non-radiological stressors on human health. The most-affected off-site members of the public are defined as the "critical group", which include:

- Farms A and F (year-round occupants with livestock);
- On-site Farm (post-institutional control only); and
- Harvesters (traditional users of the area gathering local foods).

The residual effects analysis methods for the HHRA are different in some notable ways from those used by other VCs. Specifically, the assessment of potential effects to human health VCs results in the generation of risk factors that inherently consider the geographic extent, duration, frequency and other characteristics of the predicted changes to the environment that may result from Project activities. As such, these inherent attributes cannot be used to determine environmental significance, as they can with other components. Instead, significance for human health is evaluated based on: (i) the potential magnitude of the response, as indicated by the comparison to benchmarks and (ii) the degree of conservatism and uncertainty in the analysis.

For the closure phase, the relevant COPCs are expected to be released via atmospheric releases from the WR-1 Building as reactor systems are dismantled, transported off-site or disposed of in situ within the WRDF. The closure activities are well encompassed by existing engineering and administrative controls currently in place at the WL site. The calculated radiological doses for the human receptors during closure (i.e., Farm A, Farm F, and downstream Harvester) are all below the CNSC public dose limit of 1 mSv/a, as well as the dose constraint for the Project of 0.25 mSv/a. Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure to radioactive releases from Project activities. Doses to workers will be monitored and managed as part of CNL's Radiation Protection Program. The application of the Radiation Protection Program ensures that exposures will be kept ALARA and below the effective dose limit of 100 mSv over 5 years, and below 50 mSv in any single year.

The post-closure phase is not expected to result in airborne effluent, as the grouting will have been completed, the above-grade building will have been completely decommissioned and a concrete cap and engineered soil cover will have been installed over the WRDF. The relevant COPCs are expected to be released via groundwater to the surface water. The total radiation dose to human receptors during the post-closure phase (i.e., Normal Evolution Scenario) are below the Canadian Nuclear Safety Commission public dose limit of 1 mSv/a, as well as the dose constraint for the Project of 0.25 mSv/a. Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure of potential critical groups to radioactive releases from the WL site during post-closure.

The doses to human receptors that could be exposed to the non-radiological COPCs (i.e., cadmium and lead) in surface water during post-closure were calculated based on total concentration (background plus Project contribution). The hazard quotients derived for COPCs were below the protective benchmark for all receptors and pathways, other than the river drinking water pathway. If only the Project contribution is considered, the hazard quotients are well below the protective benchmark, indicating the Project contribution to the risk is minimal. Although uncertainties in the assessment exist, conservatism, such as using the highest release rates, has been included in the modelling so that residual effects are not greater than predicted.

A number of disruptive events were assessed to address uncertainties that arose during the definition of scenarios and conceptual models, with three bounding scenarios (disruptive events with the potential for greatest consequence) identified. These were:

- Inadvertent Human Intrusion: an exploration borehole drilled into the WRDF and exposure of wastes;
- Substantial Failure of In Situ Disposal Structure (WRDF Barrier Failure); and
- Well in Plume: an on-site resident drinking groundwater from a well capturing the plume from the WRDF.

For all bounding scenarios, the total radiation dose to human receptors during the post-closure phase are below the IAEA Upper Reference Level for Disruptive Events of 20 mSv/a. For exposure to non-radiological COPCs (i.e., cadmium and lead), the HQ exceeded the target values for some scenarios. However, the assessment was conservatively conducted to predict exposures to human receptors under these future unlikely conditions. Further, controls can be put in place to reduce the probability of the Disruptive Events (e.g., land use restrictions during post-institutional control period to reduce the likelihood of a human intrusion event).

A key concern of Indigenous Nations was effects to the health of harvesters from consuming fish, plants, and wildlife in the vicinity of the WL site. The approaches to exposure and toxicity assessment have ensured that the characterization of dose and risk has been undertaken in a manner that has not underestimated dose or risk. Overall, residual effects from radiological and non-radiological COPCs are considered to be not significant for all human health valued components, including harvesters, during the closure and post-closure phases (Section 6.7.1 Human Health).

As part of the CNL's licence (NRTEDL-W5-8.00/2024), environmental monitoring of the WL site is required. It is anticipated that for closure, the monitoring at the WL site and surrounding area will continue in accordance with CNL's existing Environmental Monitoring Program. The Environmental Assessment Follow-up and Monitoring Program for the Project will be undertaken during the closure and post-closure phases. Once the WL site has been decommissioned, monitoring to support institutional control will continue, as well as any other requirements identified in the Environmental Assessment Follow-up and Monitoring Program for the Project.

CNL has committed to working collaboratively with the First Nations and the Manitoba Métis Federation to support each Indigenous Nation to participate in environmental monitoring at the WL site. Some of the key elements of the initiative may include expansion and evolution of the monitoring program at WL, through incorporation of feedback, recommendations, Traditional Knowledge, capacity development, including training in environmental monitoring, and opportunities for monitors from each First Nation and the Red River Métis to collect samples on site and in the surrounding area.

9.2.6.2 Ecological Health

The scope of the Ecological Health Assessment focuses on evaluating the potential health effects to non-human biota (plants and animals) from Project activities. It is generally an impractical task to assess the effect of radiological and non-radiological emissions on every species of biota within a natural ecosystem, and specifically within the ecosystem around the WL site. Therefore, representative organisms are chosen for dose and risk analysis. These organisms are selected because they are known to exist on site and are representative of major taxonomic groups or exposure pathways or have a special importance or value. CNL verified the list of important species identified by each Indigenous Nation to confirm that each was adequately represented by the selected representative organisms. Based on feedback from Indigenous Nations during engagement activities, moose was added as a VC to the ecological health assessment given the species importance to Indigenous people.

An environmental transport and pathways model was used to evaluate the effects of contaminants on ecological receptors. During closure, the assessment focuses on land animals and birds because releases are only expected via atmospheric pathways. After decommissioning (i.e., post-closure phase), the focus is on the aquatic animals, because releases are expected to be via groundwater to surface water pathways.

The residual effects analysis methods for the Ecological Health Assessment are different from those used by other VCs. Specifically, the assessment of potential effects to ecological health VCs results in the generation of risk factors that inherently consider the geographic extent, duration, frequency and other characteristics of the predicted changes to the environment that may result from Project activities. As such, these inherent attributes cannot be used to determine environmental significance, as they can with other components. Instead, significance for ecological health is evaluated based on: (i) the potential magnitude of the response, as indicated by the comparison to benchmarks and (ii) the degree of conservatism and uncertainty in the analysis.

Results of the radiological dose assessment for the closure and post-closure phases indicate that doses to ecological health valued components are below their respective benchmark values. In addition, there are no exceedances of the HQs identified for exposure of the ecological receptors to cadmium, lead, HB 40 (with the exception of benthic invertebrates in groundwater) and xylene. Therefore, no significant adverse effects on either aquatic or terrestrial populations or communities as a result of these chemical releases are predicted.

The assessment indicates that there will be exceedances of the HQs for cadmium, lead and HB-40 for benthic invertebrates in groundwater. Benthic invertebrates were modelled assuming the organisms spend their entire lives in the peak discharge zone, and that no dilution of the groundwater occurs in the shallow sediment layers. This is conservative because a diffusion gradient will exist across the sediment-water interface, resulting in some degree of dilution into the top layer of sediment where most benthic organisms reside. Moreover, the seepage area represents a small part of the benthic community habitat, and the maximum groundwater concentration assumed represents the worst-case period. As such, a realistic benthic invertebrate population is not likely to be at risk due to cadmium, lead and HB-40 exposure, and any adverse effects will be spatially and temporally limited, such that the community as a whole is not expected to be significantly affected.

Most of the disruptive events modelled do not have an effects pathway to impact the ecological environment. The WRDF Barrier Failure Disruptive Event is the modelled scenario that demonstrated the greatest effect on the ecological health. For the WRDF Barrier Failure Disruptive Event, all predicted radiological and non-radiological doses are well below their respective protective benchmark values indicating that no adverse residual effects are expected. Therefore, it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of radionuclide and non-radionuclide releases under a barrier failure scenario.

A key concern of Indigenous Nations was long-term effects of the Project on fish, plants and wildlife important to Indigenous Nations. The approaches to exposure and toxicity assessment have ensured that the characterization of dose and risk has been undertaken in a manner that has not underestimated dose or risk. Overall, residual effects from radiological and non-radiological COPCs are considered to be not significant for all ecological valued components during the closure and post-closure phases (Section 6.7.2 Ecological Health).

9.2.7 Land and Resource Use

9.2.7.1 Traditional Land and Resource Use

Indigenous Nations have indicated their concerns about potential effects on wildlife, fish and plants and the resultant effect on traditional land and resource use that occurs in close proximity to the WL site. The assessment of traditional land and resource use considers hunting, trapping, and gathering by Indigenous Nations, archaeological and cultural sites, and the overall importance of the Winnipeg River. The valued components selected for traditional land and resource use are cultural and archaeological sites, traditional land and resource use by Indigenous Nations, and the Winnipeg River. The assessments of each VC has incorporated the community and/or traditional knowledge provided.

The measurement indicators for each traditional land and resource use valued component include:

Cultural and Archaeological Sites: value, quantity, and quality of cultural and archaeological sites.

Traditional Land and Resource Use by Indigenous Nations: relative abundance and distribution of fish, vegetation, and wildlife species; changes to vegetation, fish and wildlife habitat; relative abundance and distribution of vegetation and fish and wildlife habitat; changes to opportunities for traditional land use; and perceived and observed changes to the area's suitability for land use and/or quality of harvested resources.

Winnipeg River: changes to ambient levels of surface water parameters; relative abundance and distribution of fish and aquatic plant species; changes to aquatic vegetation and fish habitat; relative abundance and distribution of aquatic plant and fish habitat; expanded opportunities for traditional use; and perceived and observed qualities of water, aquatic plant species, fish, and aquatic habitat by traditional users.

The Project is also located in the homeland of the Red River Métis. The Red River Métis community members live in the region around the WL site and may use the lands nearby for traditional activities.

The tangible history of the Winnipeg River is documented by physical artifacts and features that are distributed over the landscape. Although there are currently no archaeological sites located on the WL site, there is a site located approximately 1,700 m south of the WL site and the Winnipeg River has been an important travel route throughout history. In addition, three important sites can be found approximately 3,500 m south at the confluence of the Whitemouth and Winnipeg Rivers.

The WL site has been operational since the 1960s, with public access generally restricted for safety and security reasons. Exceptions to this restriction include parcels of the WL site on the WL Laboratories site; however, traditional land and resource use activities have persisted adjacent to the site, including uses of the Winnipeg River. It is expected that all activities and land use adjacent to the site will be able to continue in the future as the Project will have no effect on land usage beyond the WL site boundaries.

The Project could affect traditional land use through effects to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River. Changes to these VC could result from a change in the abundance and distribution of resources, the quality of the resource, and the ability to access resources including fish, wildlife and vegetation. Any of these changes could subsequently affect the ability and the desire to engage in activities in the area of the WL site. Threshold exceedances in harvested receptors through atmospheric releases and waterborne dispersion of contaminants are not anticipated. In addition, the mitigation proposed to minimize Project effects on surface water quality, the aquatic environment, the terrestrial environment, human health and ecological health are anticipated to eliminate or mitigate any potential adverse effects to the resources on which traditional land and resource use are dependent.

In collaboration with the First Nations and the Manitoba Métis Federation, CNL is committed to meaningful and ongoing engagement on the WL site remediation and clean-up activities. Although a small proportion of the WL site will have restrictions on use because of the Project, it is still anticipated that the majority of the site will be safe and appropriate for unrestricted use. Overall, decommissioning of the WL site will result in an increase in the land available for future use in the LSA. Future uses/zoning have not been determined, but the end-state plan for the WL site is to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria. Consequently, the Project is expected to have a negligible effect on traditional land and resource use VCs .

The assessment of potential pathways of effects determined there are no primary pathways that would lead to residual effects on the traditional land and resource use VCs. As such, there is no further residual effects classification and determination of significance for traditional land and resource use (Section 6.8.1.5.2.2 Traditional Land Use by Indigenous Nations).

CNL is aware that each Indigenous Nation continues to have concerns about the potential effects of the Project and more broadly the WL site on traditional land and resource use. As such, CNL is committed to involving the First Nations and the Manitoba Métis Federation, and its citizens, in monitoring and to engaging with them over the long-term to address on-going concerns. CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. In addition, to mitigate perceptions related to the suitability for use of the WL site and the lands around it, CNL will support robust communication of environmental monitoring results to confirm the safety of the WL site and help address concerns about future uses.

9.2.7.2 Other Land and Resource Use

The assessment of other land and resource use includes consideration of non-Indigenous commercial, municipal, and federal land and resource use activities in proximity to the Project. These activities include agriculture, forestry, mineral claims and leases, water use, and outdoor recreation and tourism, sport fishing, outfitting, hunting, trapping, and other winter activities. The other land and resource use valued components chosen for the Project are land tenure, outdoor recreation and tourism, and the Winnipeg River. The assessments of each VC has incorporated community knowledge where available.

The measurement indicators for each other land and resource use valued component include:

Land Tenure: availability of portions of WL site for alternative future uses; and ability to maintain current land uses/tenures in proximity to the Project.

Outdoor Recreation and Tourism: relative abundance and distribution of fish and wildlife species; changes to fish and wildlife habitat; relative abundance and distribution of vegetation and fish and wildlife habitat; continued opportunity for recreational land use; and perceived suitability of area for outdoor recreation and tourism activities.

Winnipeg River: changes to ambient levels of surface water parameters; relative abundance and distribution of fish species; changes to fish habitat; and relative abundance and distribution of fish habitat.

The WL site has restricted public access. Exceptions to this restriction include parcels of the WL site on the west side of the Winnipeg River that have been continuously used for agricultural purposes under agreements with Atomic Energy of Canada Limited. No outdoor recreation and tourism activities are permitted on the WL site. Land and resource use activities have persisted adjacent to the site, including uses of the Winnipeg River. Land use in the region includes forestry, recreation and tourism, hunting, trapping and fishing and limited agriculture.

The Project could affect outdoor recreation and tourism activities through effects to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River. Changes to these VCs could result from a change in the abundance and distribution of resources, the quality of the resource, and the ability to access resources including fish, wildlife and vegetation. Any of these changes could subsequently affect the ability and the desire to engage in activities in the area. There are not anticipated to be any threshold exceedances in human receptors through atmospheric releases and waterborne dispersion of contaminants. In addition, the mitigation proposed to minimize Project effects on surface water quality, the aquatic environment, the terrestrial environment, human health and ecological health are anticipated to eliminate or mitigate any potential adverse effects to the resources on which recreation and tourism activities are dependent.

The WL site has been operational since the 1960s, and no outdoor recreation and tourism activities are permitted on the site. Other land and resource use activities have persisted adjacent to the WL site, including uses of the Winnipeg River. It is expected that all activities and land uses adjacent to the WL site will be able to continue in the future as the Project will have no effect on land tenure or usage beyond the WL site boundaries. Overall, with mitigation and engagement in place, Project effects on other land and resource use are expected to be negligible.

The assessment of potential pathways of effects determined there are no primary pathways that would lead to residual effects on the other land and resource use VCs. As such, there is no further residual effects classification and determination of significance for other land and resource use (Section 6.8.2 Other Land and Resource Use).

CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. In addition, to mitigate perceptions related to the suitability for use of the WL site and the lands around it, CNL will support robust communication of environmental monitoring results to confirm the safety of the WL site and help address concerns about future uses.

9.2.8 Socio-economic Environment

Socio-economics refers to the way social and economic factors influence one another in local communities and households. The socio-economic environment assessment considers potential effects of the Project on the people and communities who are part of the existing socio-economic environment in the immediate vicinity of the Project. The socio-economic VCs chosen for the assessment are employment and income, business opportunities, government finances, community infrastructure and services, community well-being and public safety. The assessments of each VC will incorporate community and/or traditional knowledge where available.

The measurement indicators for each socio-economic VC include:

Employment and Income: changes to local employment and income opportunities based on the change in decommissioning strategy for the Project and the ability to create future employment opportunities by attracting new businesses to the WL site.

Business Opportunity: incremental expenditures for procurement requirements created by the Project and implications to the existing industry and business profile in the local and regional study areas.

Government Finances: the continued financial viability of the communities and rural municipalities in proximity to the Project.

Community Infrastructure and Services: traffic volumes and road infrastructure will be considered in relation to employee traffic and waste hauling; and potential change in the municipal revenue stream because of changes in the grant-in-lieu could alter the level of services offered in the Local Government District of Pinawa.

Community Well-being: continued socio-economic sustainability and overall well-being of communities in proximity to the Project, with a particular focus on the Local Government District of Pinawa due to the community's historical ties with the WL site.

Public Safety: public safety for the Project is related to potential hazards associated with decommissioning activities including waste hauling and public access to the site during institutional control.

With in situ disposal, there will be a reduced amount of radioactive waste transported off-site, and thus a reduced amount of traffic generated. The reduction in traffic will limit the potential for transportation incidents and risks to public safety. Considering the small number of additional employees required by the Project and the reduced amount of waste transported off-site, changes traffic volumes associated with Project employment will have a negligible effect on the transportation infrastructure in the local area and reduce the probability that the public may be exposed to radioactive material.

The permanent presence of the WRDF will change the suitability of a small portion of the WL site for future uses due to the restrictive land use categories that will be applied to the Project site. Although a small proportion of the WL site will have restrictions on use because of the Project (i.e., 0.07 ha), it is still anticipated that the majority of the site will be safe and appropriate for unrestricted use, and that future designations will seek to maximize the amount of lands available for other uses.

The availability of land for future uses does not stem directly from environmental effects of the Project, but rather from the indirect effect of zoning restrictions that will be required for the Project site into the distant future. The public expressed concern with the Project because it would limit the types of businesses and industries that could use the WL site for future operations and therefore reduce the number of economic development opportunities available to them. CNL provides support for the Community Regeneration Partnership, which has been established to create a feasible socio-economic plan for the region, facilitate economic development and hopefully provide high quality employment to replace the losses associated with the overall WL site closure. Depending on the future uses and access to the WL site, the plan is expected to help focus recruitment efforts or provide another route for achieving the same economic goals without reliance on the WL site.

The implications of the change in decommissioning activities associated with WR-1 does not necessarily alter the number of new employment and/or contracting opportunities, but rather indirectly changes the nature of the employment and/or contracting opportunities available and timeframe. The proposed change will increase the

requirements for engineering and construction, while decreasing the amount of transportation labour required. While the schedule for reducing employment has been accelerated, the Community Regeneration Partnership is working to enhance benefits for area communities and the Indigenous Nations in the local area to the extent possible.

Considering CNL's programming to support current employees in transitioning to new work, CNL's support of fostering economic development in the region, and the potential for siting a small modular reactor on the WL site, the Project's indirect effects on employment and income, and business opportunities are expected to be negligible relative to the overall closure of the site despite the accelerated timeline and change in land use restrictions.

While the Project does not return the WL site to an area completely available for unrestricted use, no residual adverse effects were identified between the Project and the aquatic environment or the terrestrial environment. Similarly, the ecological and human health risk assessment concluded it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of maximum potential contaminant releases associated with the Project. Even under an accidents and malfunctions scenario (i.e., a WRDF Barrier Failure Disruptive Event), all predicted radiological and non-radiological doses are well below their respective protective benchmark values indicating that no adverse residual effects are expected. With negligible effects predicted to the biophysical environments, the assessment does not indicate the potential for direct or indirect effects to the well-being of communities.

The assessment of potential pathways of effects determined there are no primary pathways that would lead to residual effects on the socio-economic environment VCs. As such, there is no further residual effects classification and determination of significance for the socio-economic environment (Section 6.9 Socio-economic Environment).

Indigenous Nations have commented on the ongoing adverse effects the presence of the WL site has had on their well-being since the site's establishment in the 1960s, including ongoing fear and trauma for Sagkeeng First Nation members. The Manitoba Métis Federation, Black River First Nation, Hollow Water First Nation, and Brokenhead Ojibway Nation have also noted that WL site, along with other historical industrial development in the local area, have affected the communities' well-being by adversely affecting the environment. The change in the decommissioning strategy for WR-1 is understood from an Indigenous perspective as having the potential to result in fear, stigma and anxiety associated with the long-term presence of nuclear materials in the region.

Given the importance of the topic to Indigenous Nations, CNL acknowledges that efforts to support dialogue and learning are central to the relationship going forward. As the WL site is undergoing decommissioning over the next several years, Canadian Nuclear Laboratories will work with Indigenous Nations so that relationships endure, grow and adapt to future activities. As such, Canadian Nuclear Laboratories is currently working on establishing contribution/relationship agreements with each engaged Indigenous Nation, which include liaison positions and create mechanisms to develop and implement initiatives that will help address each Nation's unique interests and concerns related to the Project and the Whiteshell Laboratories Restoration Project.

The assessment does not indicate the potential for direct or indirect effects to the well-being of Indigenous Nations since the effects documented by local Indigenous Nations are linked to the historical presence of the WL site, there are no predicted changes to the biophysical environment, and CNL and Atomic Energy of Canada Limited are committed to working with the Manitoba Métis Federation and First Nations going forward to develop programs and initiatives that provide meaningful mitigation to Indigenous Nations to address the issues of fear and stigma identified.

9.3 Summary

Residual adverse effects were identified for air quality, hydrogeology, surface water quality, and human and ecological health. Mitigation and environmental design features implemented for the Project are well-understood and include existing practices at the WL site. Based on the evaluation, no significant adverse effects on human health or the environment were identified as a result of the Project.

CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented, provide information for use in adaptive management and demonstrate compliance with regulatory requirements. Additional details on the Environmental Assessment Follow-up and Monitoring Program are provided in Section 11.0 Summary of Monitoring and Follow-up Programs.

Table 9.3-1: Summary of Predicted Residual Effects on Valued Components and Significance – Application Case and Reasonably Foreseeable Developments Case

Discipline	Valued Component	Assessment Endpoint	Residual Effect	Project Phase the Effect Occurs in	Contributing Project Activity	Mitigation	Significance	
							Application Case	RFD Case

Atmospheric Environment	Air Quality	Performance against criteria and thresholds for protection of human health and the environment.	Closure activities will alter concentrations of indicator compounds, including:
			■ use of vehicles and equipment that combust fuel and emit indicator compounds;
			■ material handling, for grouting and demolition;
			■ vehicles travelling on roads; and
			■ operation of batch mixing plant or other similar equipment for grout production.
				Closure Phase	■ Stage 1: Preparation for In Situ Disposal
					■ Stage 2: Grouting of below-grade structures and systems
					■ Stage 3: Removal of above-grade WR-1 structures and systems
						■ Implementation of CNL's *Environmental Protection* (CNL 2023) and *Management and Monitoring of Emissions* (CNL 2022), which includes operational control monitoring, air verification monitoring and environmental monitoring.
						■ Implementation of dust management techniques to control dust generated by the Project, consistent with the current Environmental Assessment Follow-up and Monitoring Program.
						■ Use of contamination immobilization agents, containment, ventilation and HEPA filters to control generation of airborne emissions during decontamination or removal of contaminated systems or structures.
						■ Use of dust suppression methods during building demolition or soil remediation activities to control airborne emissions and nuisance dust during building demolition or soil remediation. Methods may include:
						  ▪ wetting techniques during demolition to limit mobility of dust;
						  ▪ wind restrictions during demolition to stop work or apply wetting techniques; and
						  ▪ hydro seeding during backfilling and landscaping to reduce soil erosion.
						■ Road watering and chemical dust suppressant when necessary. Dust suppressant is already used annually at the site for select unpaved roads.
						■ Removal of accumulations of particulates (e.g., dirt) on road as soon as possible.
						■ On-site vehicles and equipment engines will meet Tier 3 emission standards, where possible, and be maintained in good working order.
						■ Limit idling of vehicles on site and speed on roads.
						■ Use of tarps or 3-sided enclosures for raw material storage.
							Not Significant	Not applicable – no cumulative effect is predicted

Table 9.3-1: Summary of Predicted Residual Effects on Valued Components and Significance – Application Case and Reasonably Foreseeable Developments Case

Discipline	Valued Component	Assessment Endpoint	Residual Effect	Project Phase the Effect Occurs in	Contributing Project Activity	Mitigation	Significance	
							Application Case	RFD Case
Geological and Hydrogeological Environment	Hydrogeology (Groundwater Quality)	Intermediate component (i.e., it does not have an assessment endpoint).	Release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time may cause changes in groundwater quality.	Post-closure Phase	Post-closure Performance – Grout and reactor components gradually deteriorate over time	■ Installation of a concrete cap and engineered cover to mitigate moisture infiltration into the WRDF and hence limit release of solutes into the groundwater. ■ The planned decommissioning of the WR-1 Building includes: ▪ removal the service area and infilling in these areas with compacted clay-based soil; ▪ sealing of open conduits in the building foundation; and ▪ grouting the interior portion of the building (containing the remaining components of WR-1) to ground surface elevation. ■ Monitoring will be integrated into the overall CNL WL Groundwater Monitoring Program.	Significance is not determined as VC does not have an assessment endpoint.	Significance is not determined as VC does not have an assessment endpoint.
Surface Water Environment	Surface Water Quality	Intermediate component (i.e., it does not have an assessment endpoint).	Release of chemical and radiological contaminants in the long term during the post-closure phase from the Project, which can surface water and sediment quality.	Post-closure Phase	Post-closure Performance – Grout and reactor components gradually deteriorate over time	■ The planned decommissioning of the WR 1 Complex includes: ▪ removal the service area and infilling in these areas with compact soil; ▪ sealing of open conduits in the building foundation; and ▪ grouting the interior portion of the building (containing the remaining components of WR 1) to ground surface elevation. ■ As part of CNL's licence with the Canadian Nuclear Safety Commission (CNSC), environmental monitoring around the WL site is required and will continue for the Project during institutional control. ■ Follow up monitoring during institutional control will be completed to verify effect predictions and to provide information for use in adaptive management to address potential unforeseen effects.	Significance is not determined as VC does not have an assessment endpoint.	Significance is not determined as VC does not have an assessment endpoint.

Table 9.3-1: Summary of Predicted Residual Effects on Valued Components and Significance – Application Case and Reasonably Foreseeable Developments Case

Discipline	Valued Component	Assessment Endpoint	Residual Effect	Project Phase the Effect Occurs in	Contributing Project Activity	Mitigation	Significance	
							Application Case	RFD Case
Human and Ecological Health	Public Health	Protection of human health.	Closure activities will result in the atmospheric release of radiological and non-radiological compounds from the WR-1 Building, which can affect public health.	Closure phase	■ Stage 1: Preparation for In Situ Disposal ■ Stage 2: Grouting of below-grade structures and systems ■ Stage 3: Removal of above-grade WR-1 structures and systems	■ same as Air Quality VC	Not significant	An RFD Case is not applicable to the human health assessment
Human and Ecological Health	Public Health	Protection of human health.	Release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time may cause changes in groundwater quality; which could migrate towards the Winnipeg River, and affect public health. 10.0 ASSESSMENT OF EFFECTS OF THE ENVIRONMENT ON THE PROJECT

This section of the Environmental Impact Statement (EIS) discusses the effects of the environment on the In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project), in a manner consistent with Section 2(1) (c) of the *Canadian Environmental Assessment Act, 2012* (CEAA 2012), which defines "environmental effects," in part, as "any change to the Project that may be caused by the environment, whether any such change or effect occurs within or outside Canada." Accordingly, this section focuses on the effects of natural hazards (i.e., extreme weather events, forest fires and seismic events) and climate change on the Project. It summarizes the risks associated with each kind of environmental change, along with environmental design features, management practices and other mitigation to reduce the risks. Additional information on the mitigation actions is reported elsewhere in the EIS, as referenced. Whiteshell Reactor 1 (WR-1) is currently in a storage with surveillance period and protected by the WR-1 Building. Demolition of the above-grade WR-1 Building will be completed after the below-grade section of the building has been grouted, allowing the contaminants to be fully isolated and immobilized within the remaining Whiteshell Reactor Disposal Facility (WRDF).

10.1 Indigenous Engagement Feedback – Key Interests and Concerns

Interests and concerns raised specifically by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations during engagement related to the assessment of effects of the environment on the Project are summarized in Table 10.1-1. Other general concerns and questions raised during the engagement are documented in Section 4 Indigenous Engagement and Section 5 Public Engagement.

Table 10.1-1: Summary of Key Interests and Concerns Raised During Indigenous Engagement Activities Related to the Effects of the Environment on the Project

Interest and Concern	Inclusion Status	Additional information and Rationale
Concern about the potential for climate change and natural disasters to affect the integrity of the grouted encapsulation. How would it be constructed to ensure that it is safe?	Included in the assessment of effects of the environment on the Project.	Potential effects of climate change on the Project are evaluated in Section 10.5.2. Potential effects of earthquakes on the Project are evaluated in Section 10.4.
Concern about the potential effects of flooding on the Project	Included in the assessment of effects of the environment on the Project.	Potential effects of flooding on the Project are discussed in Section 10.2.2 Extreme Rainfall Events, Snowmelts and Flooding

10.2 Extreme Weather Events

Weather events can produce extreme conditions affecting the performance of facilities and management systems. These events include extreme temperature fluctuations, thunderstorms, flooding and tornadoes. In this section potential effects from extreme weather events and the associated mitigation to be implemented, are described. Potential effects from shifts in the frequency and/or intensity of extreme weather events due to climate change are discussed in Section 10.5 Climate Change.

10.2.1 Temperature Fluctuations

Temperature fluctuations and the effects of freeze-thaw cycles could damage the components of the WRDF, the end-state of the Project. The concrete cap and engineered cover for the WRDF will be designed to limit damage due to natural freeze-thaw cycles. To limit damage from freeze-thaw cycles, the engineered cover includes layers of granular/soil materials of sufficient thickness above the concrete cap to effectively avoid frost penetration. Meteorological records will be reviewed annually to confirm that performance of the concrete cap and engineered cover is not overloaded during the institutional control period (i.e., from 2031 to 2131). Annual review of meteorological records will be included in the Environmental Assessment Follow-up Program for Whiteshell Laboratories (CNL 2018).

10.2.2 Extreme Rainfall Events, Snowmelts and Flooding

During decommissioning, extreme rainfall events could result in worker safety issues, such as slippery surfaces, reduced visibility and increased electrical hazards. Consequences of potential extreme rainfall events, such as a power outage, are encompassed by Canadian Nuclear Laboratories (CNL's) Emergency Preparedness Program (CNL 2022a). Heavy downpours and runoff could increase the probability of a vehicle accident, as a result of reduced visibility and poor road conditions. During extreme rainfall events, activities will be carried out in accordance with CNL's existing Occupational Safety and Health Program and Environmental Protection Program to ensure risks are managed and may include suspension of decommissioning activities during extreme rainfall events when necessary to limit associated risks.

The end-state plan for the WL site, which includes the WRDF, will be to return lands disturbed by site activities to a condition that is physically stable, safe, and in keeping with the post-closure land use classification and release criteria to achieve the planned end-states. The drainage system for the reclaimed WL site will have the physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity.

Extreme rainfall events could result in an increase in surface water runoff and subsequently, erosion of the concrete cap and engineered cover. Snowmelt events could also lead to soil erosion on the engineered cover. The concrete cap and engineered cover system have been designed to cover the entire footprint surface of the WRDF and the engineered cover will be graded to promote drainage from the site to the Winnipeg River, similar to the rest of the WL site. The concrete cap and engineered cover were also designed to limit water infiltration, to direct infiltration water away from the grouted structure and to resist degradation by surface geologic processes and biotic activity (e.g., deters intrusion by burrowing animals).

Flooding of the WL site due to a rise in the Winnipeg River is remote and has been previously evaluated in the Comprehensive Study Report for the WL Decommissioning Project (AECL 2001). A failure of the Seven Sisters Dam, which is upstream of the WL site, is considered a bounding scenario for a potential rise in river levels due to extreme rainfall events (1 in 100-year precipitation event). Flood levels of the Winnipeg River at the WL site

following a failure of the Seven Sisters Dam were estimated to take 1.5 hours to reach a peak at 7 m above normal water levels (AECL 2001, Section 6.5). As such, a flooding incident of this magnitude would affect the shoreline of the Winnipeg River adjacent to the WL site, but it would not flood the WL site. The risk to the Project from flooding is therefore considered to be of low probability and of low consequence (negligible physical or biological effects). Consequences of potential flooding, such as a power outage, are encompassed by CNL's Emergency Preparedness Program (CNL 2022a).The assessment work concluded that B100/the WL site would not be flooded.

During the Closure Phase, decommissioning activities are encompassed by the existing Emergency Preparedness and Response plan, and the site design event (e.g., water conveyance structures and collection sumps) is a 1 in 100-year 24-hour precipitation event. The detailed design of the concrete cap and engineered cover have been prepared using the site design event consistent with that of recent, similar projects and commensurate with the 100 year design lifespan of the concrete cap and engineered cover. A rise in river level in response to ice jams or extreme rainfall events is considered a possible – occasional event (1 in 100 years to 1 in 1,000 years) based on historical occurrence data. Further, Manitoba Hydro has contingency plans for comprehensive notification, warning, and response systems in case an emergency condition is detected.

10.2.3 Heavy Snowfall

Heavy snowfall due to severe snowstorms are primarily a concern related to worker safety during the closure phase and throughout the institutional control period where workers will be occasionally present for environmental monitoring. Heavy snowfall and severe snowstorms are already encompassed by CNL's Emergency Preparedness Program. Heavy snowfall could affect vehicle operation at the site because of reduced traction and visibility and increase the probability of vehicle accidents. Safety procedures are in place to address worker safety including reduced traffic speeds, increased following distances, addressing road conditions (e.g., snow removal, sanding) as quickly as possible and, if necessary, issuing work stop orders. Consequences of potential heavy snowfalls, such as a power outage, are encompassed by CNL's Emergency Preparedness Program.

10.2.4 Tornado/Extreme Wind

Tornadoes are recognized as a hazard to the facilities on the WL site, including the Project. Between 1868 and 1990 at least 75 tornadoes or tornado groups have occurred in Manitoba with two of these tornadoes passing near the WL site in 1978 (AECL 2001, Section 6.5). Between 1980 and 2009 there were 283 confirmed tornadoes in Manitoba, two of which passed within 10 km of the WL site (2005 at Lac du Bonnet and 2007 at Seven Sisters Falls). Based on the most recent period of data available (1980 to 2009), the frequency for a tornado strike on the property is estimated to be 5.4×10^{-5} per year and a return period of 2×10^{5} years (Cheng et al. 2013). There is, therefore, a low probability of a tornado affecting the WL site. There is concern that climate change will increase the frequency and severity of summer storms, including tornadoes, hailstorms and lightning events (Peterson et al 2008). While it appears that these storms have already become more frequent (comparing the 1868 to 1990 and 1980 to 2009 data), reporting of tornadoes has increased significantly with increasing population density, resulting in a higher reporting rate than was previously possible (Government of Canada 2015). It is therefore uncertain, at this time, if the perceived increase in reported tornadoes is due to increased storm frequency or due to improved detection and reporting. Extreme storms are treated as moderately probable events and encompassed by CNL's Emergency Preparedness Program.

High winds, atmospheric pressure changes and wind induced missiles have the potential to cause structural damage and/or failure of infrastructure. In 2005, the 1995 National Building Code of Canada (NBCC) was updated

to include provisions for basic structural resilience under low end tornadic loads in areas of Canada defined as "tornado prone" (NBCC 2005). Environment Canada has also recently compiled an updated 30-year national tornado database (Cheng et al. 2013).

Tornadoes and extreme winds are primarily a concern related to worker safety during the closure phase and throughout the institutional control period, when workers will occasionally be present for environmental monitoring. During closure, the main hazards associated with tornadoes and extreme winds include flying debris, slippery surfaces and conditions and the collapse of the partially decommissioned WR-1 Building. Another hazard is the spread of contamination from the partially decommissioned WR-1 Building. Post-closure, it is unlikely that a tornado would have an effect on the concrete cap and engineered cover but it could damage the intrusion control infrastructure (e.g., fencing). This and other risks associated with tornadoes and extreme winds will be managed through CNL's management practices. For instance, during closure, when wind gusts are greater than 30 km/hr, CNL will stop work associated with higher risk activities (e.g., handling of hazardous materials) or activities where dust suppression techniques are not being used. When sustained wind speeds exceed 30 km/h, all demolition work will stop. Consequences of potential tornadoes and extreme winds, such as a power outage, are encompassed by CNL's Emergency Preparedness Program.

10.3 Forest Fires

The Project is located in an area that is primarily under treed cover (approximately 83% of the Terrestrial Environment Regional Study Area), representing a potential fire hazard; however, there is minimal treed cover in the immediate vicinity of the Project. Historical data for the 1980 to 2015 period from Natural Resources Canada (the most recent period for which data are available [NRCan 2017]) indicate that southern Manitoba is generally at lower risk of forest fires than more northerly parts of the province. Mapping from the Province of Manitoba indicates that wildfires occurred from 2015 to 2019 in areas nearby to the Project and the WL site, including Brookfield, Lee River and Lac du Bonnet. However, no wildfires occurred from 2015 to 2019 in the immediate vicinity of the Project or the WL site (Manitoba Sustainable Development 2019a,b). The closest fire to the WL site reported in the last five years occurred in 2018 approximately 2.5 km to the northeast of the WL site, covering an area of 3.3 ha (Manitoba Sustainable Development 2019a).

During closure, an effective response to fires will be facilitated through CNL's Emergency Preparedness Program and the Fire Protection Program. Risks associated with wildfires during closure (e.g., low visibility due to smoke) would continue to be managed through existing procedures and design criteria in the long-term. Based on regional conditions and historical data, the probability of such an event has been assessed as likely due to the occurrence of fires nearby the Project and the WL site per the Province of Manitoba data (Manitoba Sustainable Development 2019a,b), however, with a low consequence severity (i.e., short-term local effects) in consideration of the rapid fire-response procedures in the province and CNL's on-site fire protection services.

CNL's on-site fire protection services include trained firefighting staff and firefighting equipment to respond to fires. In addition, CNL has an existing Fire Protection Program at the WL site, which will continue to be implemented during closure phase. The Fire Protection Program is dedicated to providing the highest level of fire and life safety to all CNL employees and facilities, which subsequently also provides protection to the surrounding areas. The objectives of the Fire Protection Program include preventing fire losses, providing responsible fire protection management, demonstrating compliance to applicable fire protection codes and standards and providing reliable facilities from a fire protection perspective. The Fire Protection Program provides services including developing fire prevention processes and conducting fire safety inspections. Fire hazard analyses, code compliance reviews

and fire protection screenings are also conducted as part of the program. Consequences of a fire, such as a power outage and system failure, are encompassed by CNL's Emergency Preparedness Program and evaluated previously in in Section 7.0 Accidents and Malfunctions.

10.4 Seismic Events

Major earthquakes (i.e., seismic events) are related to movements at tectonic plate boundaries. The province of Manitoba is the least earthquake-prone area in Canada (AECL 2001). Seismic activity in the prairie region south of 60 degree north (°N) is predominantly confined to southern Saskatchewan in a zone that continues into Montana (AECL 2001). Furthermore, the Canadian Nuclear Fuel Waste Management Program studied seismic stability in Northwest Ontario and Eastern Manitoba and found, based on a detection level of 2.5 on the Richter scale that the WL site and the southern two-thirds of Manitoba are aseismic (Wetmiller et al. 1996). The conclusion was based on data collected by the Geological Survey of Canada and the AECL through the operation of a network of seven seismograph stations in eastern Manitoba and northern Ontario from 1982 to 1995.

Detailed information on earthquakes that have occurred in Canada is contained in publications of Earthquakes Canada of Natural Resources Canada and their predecessor organizations. A seismic zoning map for Canada has been developed on the basis of these studies and is used in the NBCC 2015 (NRCan 2019).

A seismic hazard analysis was completed for the WL site. In 1995, the NBCC placed the WL site (and all of Manitoba) within a Seismic Zone 0, a zone that has a probability of exceedance of 0.0021. The peak ground acceleration (PGA; i.e., the maximum acceleration that a rigid structure would experience if it was located on bedrock) data from NBCC was considered for the years 2005, 2010 and 2015. The trend since 2005 is that for every probability of exceedance, the seismic hazard at the WL site has decreased (NBCC 2015). For the 1 in 10,000-year probability of exceedance, the PGA is approximately 0.10 g. Comparatively, the 0.10 g PGA represents a light (almost moderate) earthquake for which one wouldn't normally expect structural damage for NBCC designed buildings and components (CNL 2022b).

Liquefaction occurs when vibrations or water pressure within a mass of soil cause the soil particles to lose contact with one another. As a result, the soil behaves like a liquid, has an inability to support weight and can flow down very gentle slopes. This condition is usually temporary and is most often caused by an earthquake vibrating water-saturated fill or unconsolidated soil. Liquefaction most often occurs when three conditions are met: loose, granular sediment or fill; saturation by groundwater and strong shaking. A similar process can occur in some types of low plasticity silts and clays termed cyclic loading for strong earthquakes. Liquefaction is possible for cohesionless soils for M=4 to 6 earthquakes, which can produce ground shaking levels up to VIII on the Modified Mercalli Intensity. Therefore, liquefaction is not seen as an issue for the WL site due to the essentially aseismic conditions of Eastern Manitoba, and the consolidated nature of the overburden geology (CNL 2022b). Furthermore, the WR-1 Building was constructed directly on bedrock, which further reduces the risk of liquefaction having an effect on the Project. Cone penetration testing has been completed at site to assess the liquefaction potential of the overburden soils at the WL site. In general, the high plastic clayey overburden soils present at the site are not susceptible to cyclic liquefaction (KGS Group 2019).

10.5 Climate Change

Changes in the global and regional climate could affect the Project during the closure and post-closure phases. The Canadian Nuclear Safety Commission (CNSC) requires that effects assessments take into account any potential effects of climate change on a project, including an assessment of whether the Project might be sensitive to changes in climate condition during its life span (CNSC 2017). As such, an effect assessment of climate change was originally completed that follows the guidance provided by the Federal Provincial Territorial Committee on Climate Change and Environmental Assessment (FPTCCCEA). This general guidance document is for practitioners incorporating climate change issues into an environmental assessment (FPTCCCEA 2003).

Since the original assessment using the FPTCCCEA, the *Strategic Assessment of Climate Change, Revised October 2020* (ECCC 2020) (SACC) has been issued. The SACC requires that a climate change resiliency assessment be conducted that takes into account the vulnerabilities under both the mean climate conditions and extreme climate events over project's lifetime from construction to decommissioning and includes more details than the FPTCCCEA. The resiliency assessment should be based on future climate projections and associated impacts and identifies how the project is resilient to the future climate. The general approach for conducting a climate change resiliency assessment can follow Infrastructure Canada's *Climate Lens - General Guidance* (Infrastructure Canada 2019).

Based on this new guidance, the effects assessment has been updated with a climate change resiliency assessment conducted for the Project based on the requirements of SACC 2020. The following sections provide a summary of the climate change trends used to support the climate change resiliency assessment as well as the climate change resiliency assessment.

10.5.1 Summary of Climate Change Trends

10.5.1.1 Climate Change Effects on the Project

Climate change may result in shifts in the frequency and/or intensity of the extreme weather events and forest fires. When evaluating the potential effects from climate change, Project design features and mitigation as well as management and monitoring practices are also considered. The effects of climate change are typically measured over longer periods, with the potential for climate change effects increasing as the period over which they are measured increases.

Shifts in the frequency and/or intensity of extreme weather events are expected to accompany the general warming of surface air temperatures. Increased evaporation will result in more moisture in the air and warmer air can hold more moisture, therefore, more intense precipitation events (i.e., rainstorms and snowmelts) are expected. The drainage system for the reclaimed WL site will have physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness and longevity. A multi-component concrete cap and engineered cover system will be designed over the entire surface of the decommissioned WR-1 Building, which will be graded to promote positive drainage from the site to the Winnipeg River, similar to the rest of the WL site. The annual snowfall for Canada has increased by about 4% over the time period of 1950 to 2009 (Mekis and Vincent 2011) and the current climate General Circulation Models for the Project indicate that snowfall is increasing further.

Climate change has the potential to greatly influence forests, since even small changes in temperature and precipitation can affect forest growth and survival. A small increase in temperature can result in a longer growing season, increased plant growth and a shift in tree species occurrence and abundance (NRCan 2004). None of

these biological changes could directly affect the Project; however, the probability of forest fires increases with dry conditions due to the warming of surface air temperatures and probability of lightning strike. A forest fire could affect the Project infrastructure and workers' safety during closure (see Section 10.3 Forest Fires).

During the closure phase and institutional control period of the post-closure phase, monitoring will be incorporated into the existing Environmental Assessment Follow-up Program for WL to help identify potential future climate change effects beyond what has been considered in the assessment. This would include evaluating long-term monitoring results, documented changes in the local climate and up-to-date climate change predictions.

Changes in temperature and precipitation, as well as frequency or magnitude of extreme events and erosion will be tracked through the existing Environmental Assessment Follow-up Program for WL to inform the need for adaptive management. Adaptive management to be integrated into post-closure planning could be a result of:

- climate changes (e.g., increased erosion rates) affecting the concrete cap and engineered cover system design;
- changes to temperature and precipitation affecting hydrology and subsequently hydrogeology (i.e., changes in water table) and surface geology (i.e., erosion) affecting the drainage system; or
- changes to temperature and precipitation affecting the vegetation used in the rehabilitation of the site affecting final site restoration.

The following sections provide further descriptions of the projected future climate change trends at the global, regional and site level. These more detailed projections, in addition to the climate discussion in this section, are used to support the climate resilience assessment presented in Section 10.5.2.

10.5.1.2 Global Climate Change Trends

The world's climate is changing due to a combination of natural and anthropogenic factors, and the changes over the 20th century can largely be attributed to human activities (AMAP 2011; IPCC 2021; Bush and Lemmen 2019). Human activities affect climate by changing the land surface and altering the composition of the atmosphere. Human influence on the climate system has resulted in an increase in global surface temperatures ranging from 0.8°C to 1.3°C with a best estimate of 1.07°C from 1850-1900 to 2010-2019. (IPCC 2021). Over the Canadian landmass the annual average surface air temperature warmed 1.7°C between 1948 and 2016 (Bush and Lemmen 2019). Also, Canada has generally become wetter in recent decades with an increase in annual precipitation of about 20% over the period from 1948 to 2012 (Vincent et al. 2015). Even if considerable measures to reduce greenhouse gas emissions are introduced today, it is projected that climate change will continue to have an environmental effect for centuries. It is recognized that these effects will not occur uniformly across the country but will vary regionally (Bush and Lemmen 2019).

Climate change projections are provided by mathematical models based on the physical laws governing the behaviour of the climate. Climate change scenarios, as summarized by the Intergovernmental Panel on Climate Change (IPCC), predict that mean global temperatures are likely to increase by 1.0°C to 5.7°C for the period of 2081 to 2100 as compared to the reference period from 1986 to 2005 (IPCC 2021). The IPCC is generally considered to be the definitive source of information related to past and future climate change, as well as climate science.

The Canadian Prairies are projected to have a greater warming trend than the Canadian average as well as all other Canadian regions excluding the north where the warming signal is most predominant (CCCS 2019). This warming is expected to vary on a seasonal basis, being greater in the winter than the other seasons, and nights warming more than days. As warm air can hold more moisture, changes in precipitation patterns and shifts in the frequency and intensity of extreme climate events are expected to accompany this warming (CSA 2019). Mean results for Canada show that even under lowered emission scenarios, summer and winter temperatures by the middle of the century are anticipated to warm by about 1.5°C to 2.5°C and 3°C to 7°C, respectively (NRCAN 2014).

10.5.1.3 Current Climate Trends

The current climate is based on available long-term daily meteorological observations from a climate station in the vicinity of the Project. In general, the current climate normals and trends indicate a current climate that has likely become warmer and wetter over time. The analysis of climate station data shows that temperatures are increasing, with the exception of spring, and the total seasonal precipitation show increasing trends for all seasons (Golder 2017).

An analysis of the Pinawa Whiteshell Nuclear Research Establishment (WNRE; Climate ID 5032162; ECCC 2016) climate station data were completed illustrating:

- increasing trend in total precipitation;
- increasing trend in spring total precipitation;
- increasing trend in summer total precipitation;
- increasing trend in winter total precipitation;
- increasing trend in total rainfall;
- increasing trend in the number of days with greater than 20 mm of rainfall; and
- increasing trend in average fall temperatures.

10.5.1.4 Future Climate Conditions

The projected future climate conditions provided within this section are updated from *Environmental Impact Assessment for the Whiteshell Laboratories Closure Project WR-1 In Situ Decommissioning, Appendix 10.0-1, Climate Change* (Golder 2017) to reflect the most recent available climate projections. These climate projections are provided to support the climate change resilience assessment, which is summarized in Section 10.5.2.3.

The key climate variables include identifying changes to temperature and precipitation along with associated indices, which were derived using an ensemble of 24 General Circulation Models (GCMs) and 3 emission pathways (i.e., Representative Concentration Pathways or RCPs [RCP 2.6, RCP 4.5, RCP 8.5]), available from *Climate Data for a Resilient Canada* (ClimateData 2021). An ensemble approach is used for this work by taking the mean projected changes from all models and emission pathways available to provide a more robust estimate of projected changes in climate. Two future time periods are used to estimate projected changes relative to a current period of 1991 through 2020, as recommended by the World Meteorological Organization (WMO 2017). The Mid Term (2041 through 2070) represents near the beginning of the post-closure institutional control phase (2031 onwards) and the Far Term (2070 through 2100) represents the continuation of the post-closure institutional control phase (Golder 2017). Climate projections were also considered for the Long Term (2100 through 3000) described using publicly available literature (Golder 2017).

The projected changes in temperature for the Near Term and the Far Term, compared to the 1991-2000 are provided in °C, while the projected changes in precipitation are provided in %. Providing the precipitation in terms of % accounts for variability in total precipitation between models, where the variability is related to representation of the climate system and not necessarily a change in climate (e.g., some climate models are more "wet" or have more precipitation than others). Both temperature and precipitation are projected to increase in the Mid Term and Far Term, compared to the current conditions (1991-2000, as represented in the climate models), as shown in Tables 10.5.1-1 and 10.5.1-2 below.

Table 10.5.1-1: Modelled Baseline and Future Mean for Project for the Mid Term (2041 – 2070)

Period	Projected Change in Temperature (°C)	Projected Change in Precipitation (%)
Annual	+2.3 (+1.2 to +3.5)	+4.1 (+2.4 to +4.3)
Spring	+2.0 (+1.4 to +2.9)	+7.6 (+7.1 to +10.0)
Summer	+2.1 (+0.9 to +3.3)	0.0 (-5.0 to +2.2)
Fall	+2.2 (+1.3 to +3.1)	+3.5 (-7.2 to +4.1)
Winter	+3.0 (+3.0 to +4.2)	+10.7 (+3.8 to +13.0)

Note: Values before parentheses are the average across all available projections for the selected time period. Values within the parentheses provide the lowest and highest available values to capture the range of available projections from ClimateData (2021).

Table 10.5.1-2: Modelled Baseline and Future Mean for Project for the Far Term (2071 – 2100)

Period	Projected Change in Temperature (°C)	Projected Change in Precipitation (%)
Annual	+3.4 (+1.1 to +6.4)	+4.1 (+1.7 to +10.0)
Spring	+2.9 (+1.1 to +5.2)	+12.6 (+7.0 to +23.0)
Summer	+3.1 (+0.9 to +6.1)	0.0 (-11.8 to +3.3)
Fall	+3.2 (+1.2 to +5.8)	+5.0 (+2.7 to +11.8)
Winter	+4.2 (+4.2 to +7.2)	+14.3 (+8.5 to +24.5)

Note: Values before parentheses are the average across all available projections for the selected time period. Values within the parentheses provide the lowest and highest available values to capture the range of available projections from ClimateData (2021).

For the Long Term, based on Representative Concentration Pathways described in IPCC's fifth assessment report, global temperatures are predicted to rise between 0.6°C and 7.8°C by the year 3000 (see Table 10.5.1-3 below; Golder 2017). The majority of the warming will occur before 2300. Changes in precipitation distribution and variability are anticipated to increase after 2100, with an estimated increase in global precipitation of 1% to 3% per degree Celsius of increase in temperature over the period from 2100 to 3000 (IPCC 2013).

Table 10.5.1-3: Projected Climate for the Mid Term, Far Term and Long Term

Period	Temperature (°C)	Precipitation
Current Climate Normal (1981 – 2010)	2.8	588.60 mm
Mid Term Projected Change (2041 – 2070)[a]	2.3	18.9 mm
Far Term Projected Change (2071 – 2100)[a]	3.3	25.9 mm
Long Term Projected Changes (2101 – 3000)[b]	0.6 to 7.8[b]	1 to 3%/°C[l]

a) Please note that projected changes represent changes above the current climate normal (1991 – 2020) for the Project region.

b) Please note that these projected changes represent the changes above the reference period of 1986 – 2005 and are global values. Project-specific information is not available.

c) Absolute change not provided by literature. Projected change in precipitation is dependent on the projected warming experienced.

Projected changes in climate extremes of temperature and precipitation can result in climate change effects on the Project and are an important consideration in a climate change resilience assessment. Projected changes in climate extreme indices were obtained from ClimateData (2021), and have been extracted for the Project location. Each of the climate extreme indices are described in Table 10.5.2-4 with projected changes for the Mid Term and Far Term periods relative to the modelled baseline presented in Table 10.5.1-4. The climate extreme indices considered in this assessment are important as they can be associated with climate events such as extreme temperature and precipitation events, growing season length, forest fires, and drought, which can have potential impacts on the Project. Evaluation of climate extreme indices require daily climate projections which are not available beyond 2100 from ClimateData (2021). Beyond 2100, the degree of uncertainty prevents reasonable projections for climate extreme indices.

Table 10.5.1-4: Model Projected and Reference Mean Climate Extreme Indices

Climate Extreme Indices	Description	Units
Very Cold Days	Annual count of days where daily minimum temperature is less than -25°C.	Days
Very Hot Days	Annual count of days where daily maximum temperature is greater than 30°C.	Days
Growing Degree Days (Base 5°C)	Annual (1st Jan to 31st Dec in the northern hemisphere) count between first span of at least 6 days with ground temperatures greater than 5°C and first span after July 1 of 6 days with ground temperatures less than 5°C.	Days
Heavy Precipitation Days (10mm)	Annual count of days when precipitation is greater than or equal to 10 mm).	Days
Freeze-Thaw Cycles	Annual count of days when the air temperature fluctuates between freezing (less than or equal to 0°C) and non-freezing (greater than 0°C) temperatures.	Days
Frost Days	Annual count when the daily minimum temperature is less than 0°C.	Days
Ice Days	Annual count when the daily maximum temperature is less than 0°C.	Days
Warmest Maximum Temperature	The highest temperature of the year.	°C
Coldest Minimum Temperature	The very coldest temperature of the year.	°C
Summer Days	Annual count when the daily maximum temperature is greater than 25°C.	Days

Table 10.5.1-4: Model Projected and Reference Mean Climate Extreme Indices

Climate Extreme Indices	Description	Units
Wet Days	Annual count of days where the daily precipitation is greater than or equal to 1 mm.	Days
Consecutive Dry Days	Maximum number of consecutive days with daily precipitation amount less than 1 mm.	Days
Max 1-Day Precipitation	Annual maximum 1-day precipitation.	mm
Max 5-Day Precipitation	Annual maximum consecutive 5-day precipitation.	mm

Table 10.5.1-5: Model Projected and Reference Mean Climate Extreme Indices

Climate Extreme Indices	Modelled Baseline	Median Projected Changes	
		Mid Term	Far Term
Very Cold Days (Days)	30.8 (17.1 – 44.9)	18.4 (4.1 – 36.4)	14.5 (0.0 – 36.1)
Very Hot Days (Days)	11.7 (2.7 – 22.1)	27.1 (7.6 – 52.3)	36.5 (6.4 – 81.7)
Growing Degree Days (Base 5°C) (Days)	1835.4 (1629.5 – 2053.3)	2228.9 (1820.5 – 2689.3)	2435.3 (1807.8 – 3327.3)
Heavy Precipitation Days (10mm) (Days)	13.1 (8.2 – 17.9)	14.0 (8.8 – 19.4)	14.2 (8.4 – 20.7)
Freeze-Thaw Cycles (Days)	60.1 (46.4 – 74.5)	55.9 (40.7 – 72.5)	54.7 (37.2 – 71.2)
Frost Days (Days)	183.1 (168.9 – 197.2)	163.8 (138.7 – 185.4)	155.2 (115.7 – 185.4)
Ice Days (Days)	111.4 (94.7 – 128.0)	97.4 (72.6 – 119.7)	90.5 (51.1 – 119.0)
Warmest Maximum Temperature (°C)	33.6 (31.2 – 36.1)	36.1 (32.6 – 40.0)	37.2 (32.2 – 43.2)
Coldest Minimum Temperature (°C)	-36.8 (-40.5 – -33.1)	-33.3 (-38.6 – -27.3)	-31.3 (-38.6 –-22.1)
Summer Days (Days)	52.4 (34.4 – 70.8)	75.8 (47.2 – 103.7)	85.9 (45.4 – 128.5)
Wet Days (Days)	95.5 (82.2 – 108.3)	97.0 (83.1 – 111.3)	97.3 (82.2 – 112.5)
Consecutive Dry Days (Days)	23.5 (16.0 – 32.8)	23.4 (15.8 – 32.7)	23.1 (15.6 – 32.6)
Max 1-Day Precipitation (mm)	38.9 (22.8 – 60.0)	41.1 (23.5 – 66.6)	41.7 (23.8 – 67.2)
Max 5-Day Precipitation (mm)	65.8 (41.1 – 96.5)	69.4 (41.9 – 104.2)	70.7 (42.3 – 111.7)

Note: Values before parentheses are the average across all available projections for the selected time period. Values within the parentheses provide the lowest and highest available values to capture the range of available projections from ClimateData (2021).

The projected changes in climate extreme indices are consistent with projected changes in mean temperature and precipitation (Table 10.5.1-5, in that future climate at the Project location is projected to become warmer and wetter, while also indicating the potential for more frequent and extreme precipitation and temperature events in the future. This is illustrated by fewer very cold days, freeze-thaw cycles, frost and ice days, greater warmest and coldest temperatures, and more summer days, along with more heavy precipitation and wet days, fewer consecutive dry days, and greater maximum 1- and 5-day precipitation depths. Projected changes in extreme climate indices could impact the Project through increased physical damage to infrastructure components and impacts to on-site water management and revegetation. Impacts to the Project due to climate change are further described in Section 10.5.2.3.

10.5.2 Climate Change Resilience Assessment

CNL plans to start the decommissioning activities (closure phase) in 2026 which would last till 2031. Following that the institutional control period will last at least for 100. Post-institutional control will occur indefinitely; however, the timeframe defined for the assessment of potential effects, as part of the normal evolution of the Project's safety assessment is 10,000 years.

As the closure phase has a shorter time frame (2026 to 2031), it has a smaller potential for meaningful interactions with the climate trends outside of the normal seasonal variation experienced in the region. The climate change resilience assessment includes identifying the effects of climate change on Project infrastructure during the institutional control period and post-institutional control period.

Though climate projections for mean temperature and mean precipitation are available till 2300, climate projections for extremes (e.g., extreme rainfall events, freeze-thaw cycles) are only available till 2100. Hence, the mid-century likelihood rankings represent the closure phase and early institutional control period, while the end-of-century rankings represent the post-closure phase in the long run. The climate projections between 2100 and 3000 indicate that temperatures will stabilize before 3000. In the absence of further projections, these projections could be applied qualitatively for the 10,000-year time frame of the Project's risk assessment. As climate science continues to progress, projections further into the future will become available with decreased uncertainty (e.g., past 2100 or 3000). As part of a continual improvement process, this updated climate science could be considered to identify risks to the Project beyond 3000 or for the post-institutional control period.

10.5.2.1 Approach for the Climate Change Resilience Assessment

The climate change resilience assessment employs a risk management approach that anticipates the future climatic conditions for the Project region, and anticipates how climate change related impacts may affect the Project. A qualitative approach has been used based on the available design information. For the assessment, the high-level principles of Infrastructure Canada's *Climate Lens - General Guidance* (Infrastructure Canada 2019) and Mining Association of Canada's *Guide on Climate Change Adaptation in the Mining Sector* (MAC 2021) have been used. The following methodology was used to complete the assessment:

Future Climate Projections: A review of the current and future projected changes in climate is completed to identify potential climate hazards relevant to the Project region.

Climate-Infrastructure Interactions: Inventory of on-site infrastructure components (concrete cap and engineered cover, drainage system, and final site restoration) which may interact with various climate hazards are identified. Based on the site infrastructure and identified hazards, a list of climate-infrastructure interactions is developed for further consideration.

Risk Ranking Assessment: Likelihood and consequence rankings of climate-infrastructure interactions are then estimated to identify climate risks under future climate conditions. Likelihood rankings are estimated under two future periods, mid-century (2050s) and end-of-century (2080s). The mid-century likelihood rankings represent the closure and early post-closure institutional control phase, while the end-of-century rankings represent the post-closure institutional control phase in the long run. In absence of projections past 3000, these projections could be applied qualitatively and reviewed as part of a continual improvement process when updated climate projections become available. The current mitigation measures identified for the Project have been considered for the likelihood rankings.

Current Mitigation Measures: Using available Project information, current mitigation measures that would be implemented are identified and used in the risk ranking process.

10.5.2.2 Likelihood, Consequence and Risk Ranking Scales

Climate-infrastructure interactions include any potential interaction of a climate event (e.g., heavy rainfall, extreme temperature, high winds, storms and lightning, snow) with a given infrastructure component. The likelihood in which the interaction may occur, and the consequence associated with this interaction are then assigned qualitatively using a categorical numeric scale. The likelihood rankings for this assessment have a scale from Very Low (1) to Very High (5) and are summarized in Table 10.5.2.2-1. The consequence rankings for this assessment have a scale from Very Low (1) to Very High (5) and are summarized in Table 10.5.2.2-2.

Table 10.5.2.2-1: Likelihood Scale for Climate Infrastructure Interactions [Modified from Climate Lens - General Guidance (Infrastructure Canada 2019)]

Qualitative Descriptor	Description
Very Low	Less than 1% annual probability of the event occurring, event is not likely to occur
Low	Between 1 to 10% annual probability of the event occurring
Moderate	Between 10% to 50% annual probability of the event occurring
High	Between 50% to 90% annual probability of the event occurring
Very High	More than 90% annual probability of the event occurring, event may occur multiple times a year

Table 10.5.2.2-2: Consequence Scale for Climate Infrastructure Interactions [Modified from Climate Lens - General Guidance (Infrastructure Canada 2019)]

Qualitative Descriptor	Description
Very Low	■ Likely to cause no impacts on the Project. ■ No damage to infrastructure.
Low	■ Likely to cause few to no impacts on the Project. ■ Minimal damage or repair costs.
Moderate	■ Likely to cause disruptions to facility, or manageable damage to infrastructure but repair costs would be higher than previously budgeted.
High	■ Likely to cause impacts that would disrupt the facility operations leading to closures, or damage infrastructure that would require replacement and high repair costs.
Very High	■ Likely to cause impact that may require full replacement of infrastructure.

The consequence and likelihood of climate interactions are used to identify key climate risks. If an interaction has a high consequence, but very low likelihood, the overall risk would be assessed as low. Conversely, if an interaction has a very low consequence but its likelihood is very high, the risk is assessed as a moderate. A risk matrix has been identified which illustrates this concept and is summarized in Table 10.5.2.2-3. This table has been used to identify climate risk based on the likelihood and consequence of an interaction. The risk rating descriptors are summarized in Table 10.5.2.2-4.

Table 10.5.22-3: Climate Risk Matrix Based on Consequence and Likelihood Scales [Source: Climate Lens - General Guidance (Infrastructure Canada 2019)]

Likelihood	Consequence				
	Very Low	Low	Moderate	High	Very High
Very High	Moderate	High	High	Extreme	Extreme
High	Low	Moderate	High	High	Extreme
Moderate	Low	Low	Moderate	High	High
Low	Negligible	Low	Low	Moderate	Moderate
Very Low	Negligible	Negligible	Low	Low	Low

Table 10.5.2-4: Risk Rating Definitions [Modified from Climate Lens - General Guidance (Infrastructure Canada 2019)]

Qualitative Description	Descriptor
Negligible Risk	An identified interaction between the climate hazard and Project component has a negligible risk if the hazard has: ▪ A very low/low likelihood of occurrence and a very low consequence; or ▪ A very low likelihood of occurrence and a low consequence. Negligible risk includes no permanent damage. Risks do not require further consideration.
Low Risk	An identified interaction between the climate hazard and Project component has a low risk if the hazard has: ▪ A moderate/high likelihood of occurrence and a very low consequence; ▪ A low/moderate likelihood of occurrence and a low consequence; ▪ A very low/low likelihood of occurrence and a moderate consequence; or ▪ A very low likelihood of occurrence and a high/very high consequence. Low risk includes minor damage. Actions might not be required.

Table 10.5.2-4: Risk Rating Definitions [Modified from Climate Lens - General Guidance (Infrastructure Canada 2019)]

Qualitative Description	Descriptor
Moderate Risk	An identified interaction between the climate hazard and Project component has a medium risk if the hazard has: ■ A very high likelihood of occurrence and a very low consequence; ■ A high likelihood of occurrence and a low consequence; ■ A moderate likelihood of occurrence and a moderate consequence; or ■ A low likelihood of occurrence and a high/ very high consequence. Medium risk includes limited damage to infrastructure/operations. Some adaptation actions might be required.
High Risk	An identified interaction between the climate hazard and Project component has a high risk if the hazard has: ■ A very high likelihood of occurrence and a low/moderate consequence; ■ A high likelihood of occurrence and a moderate/high consequence; or ■ A moderate likelihood of occurrence and a high/very high consequence. High risk may result in permanent damage to infrastructure, assets, operations. High priority adaptation actions need to be implemented.
Extreme Risk	An identified interaction between the climate hazard and Project component has an extreme risk if the hazard has: ■ A very high likelihood of occurrence and a high/very high consequence; or ■ A high likelihood of occurrence and a very high consequence. Extreme risk may result in permanent damage or loss of asset and operations. Immediate adaptation actions need to be implemented.

10.5.2.3 Climate-Infrastructure Interactions

Identifying potential interactions between site infrastructure and climate is an important step in assessing climate risk. Future climate projections indicate changes in temperature, precipitation, and extreme events, potentially interacting with different components of the Project. The closure phase takes place during a short time frame (6 years), which has a smaller potential for meaningful interactions with the climate trends outside of the normal seasonal variation experienced in the region. There is a larger potential for changes in both the climate mean and extreme weather events during the post-closure institutional control phase.

Table 10.5.2.3-1 identifies the potential climate events and change factors that may interact with the infrastructure components. The presence of a climate interaction for a given infrastructure category is denoted by a checkmark. Through this process, it is demonstrated that each infrastructure category may be affected by various climate related events having an impact on different aspects of site operation.

Increase in freeze-thaw cycles and extreme weather events such as droughts and forest fires could cause physical damage to the concrete cap and engineered cover. Changes in precipitation, including extreme rainfall events could cause changes to the on-site hydrology including increase in surface run-off leading to erosion of the concrete cap and engineered cover. Increased snowmelt events could also cause increase in the run-off events causing erosion of the concrete cap and the engineered cover. Changes to temperatures, precipitation, and

extreme events such as drought could affect the on-site hydrology and the hydrogeology, impacting the drainage system and causing on-site erosion. Lastly, changes to temperature, precipitation, and extreme events such as drought could impact the selections of plant species for revegetation programs during the post-closure phase. Increase in mean annual temperatures and extreme heat could impact selection of plant species, and more drought-resilient plant species might have to be selected for revegetation. Interactions with wind/ tornadoes are not considered as it is unlikely that they could affect the concrete cap and engineered cover and the drainage system.

Table 10.5.2.3-1: Climate-Infrastructure Interactions Matrix

Infrastructure Components	Potential Climate Events and Change Factors							
	Temperature				Precipitation		Extreme Events	
	Extreme Heat	Extended Cold Spell	Growing Season Length	Freeze-Thaw Cycles	Frequency/ Amount of Heavy Rainfall Events	Changes in Snowfall	Forest Fires	Droughts
Concrete Cap and Engineered Cover				✓	✓	✓	✓	
Drainage System	✓		✓		✓	✓		✓
Final Site Restoration (Planting/ Landscaping over the Site)	✓	✓	✓		✓		✓	✓

10.5.2.4 Climate Change Resilience Profile

A qualitative climate risk assessment based on likelihood and consequence rankings has been conducted and summarized in Table 10.5.2.4-1. The likelihood of climate-infrastructure interactions occurring are evaluated qualitatively using the likelihood scale presented in Table 10.5.2.2-1. The resulting likelihood rankings are provided for near-term (2050s) and far-term (2080s) time periods, that represent the closure and the post closure institutional control time frame for the Project. Due to the projected increasing frequency of temperature, precipitation, and extreme events, the likelihood rankings generally reflect an increase in likelihood from 2050s to 2080s. The consequence of climate-interactions is independent to their likelihood of occurrence and represent the severity of impacts if an interaction were to occur and are based on the consequence scales presented in Table 10.5.2.2-2. The likelihood and consequence rankings consider the mitigation measures that would be implemented for the Project to reduce the climate impacts. Risk rankings are then derived by combining the likelihood and consequence rankings for each climate-infrastructure interaction.

In the near future (2050s) and far future (2080s), most interactions seem to have a negligible to moderate risk due to changes to temperature, precipitation, and extreme events. Overall, the lower level of risk is due to the existing mitigation measures and the monitoring and surveillance plans that would be in place during the post-closure phase.

Table 10.5.2.4-1: Qualitative Climate Risk Assessment

Infrastructure	Climate Variable	Interaction Description	Current Mitigation Measures	Climate Rankings					
				Near-term (2050s)			Far-term (2080s)		
				Likelihood	Consequence	Risk	Likelihood	Consequence	Risk
Concrete Cap and Engineered Cover	Temperature	Increase in freeze-thaw cycles might cause physical damage to the concrete cap and engineered cover.	Changes in temperature will be tracked through the Environmental Assessment Follow-up Program for WL to inform the need for adaptive management. The concrete cap and engineered cover for the WRDF will be designed to limit damage due to natural freeze-thaw cycles. To limit damage from freeze-thaw cycles, the engineered cover includes layers of granular/soil materials of sufficient thickness above the concrete cap to effectively avoid frost penetration.	**Low**	**Low**	**Low**	**Very Low**	**Low**	**Negligible**
	Precipitation	Extreme rainfall events and increased snowfall could result in an increase in surface water runoff and subsequently cause erosion of the concrete cap and engineered cover.	The concrete cap and engineered cover system will be designed to minimize water infiltration, to direct infiltration away from the grouted structure and to resist degradation by surface geologic processes and biotic activity (e.g., deter intrusion by burrowing of animals). The concrete cap and engineered cover system have been designed to cover the entire footprint surface of the WRDF and the engineered cover will be graded to promote drainage from the site to the Winnipeg River, similar to the rest of the WL site.	**Very Low**	**Moderate**	**Low**	**Low**	**Moderate**	**Low**
	Extreme events	Forest fires could cause erosion of the soil cover and cause physical damage to the concrete cap and the engineered cover.	A Fire Protection Program would be implemented for the closure phase activities that would include preventing fire losses, providing responsible fire protection management, demonstrating compliance to applicable fire protection codes and standards and providing reliable facilities from a fire protection perspective. During post-closure, protection from forest fires will be provided by the 2.7 metres thick soil cover over the concrete cap, and it is unlikely for the forest fires to cause complete erosion of the soil cover. Period maintenance during institutional control period will be provided to control vegetation growth and erosion of the soil cover. Changes in extreme events, will be tracked through the Environmental Assessment Follow-up Program for WL to inform the need for adaptive management.	**Low**	**Low**	**Low**	**Low**	**Low**	**Low**
Drainage System	Temperature	Extreme heat could affect hydrology and subsequently hydrogeology (i.e., changes in water table). Increase in the growing season length could cause overgrowth in the ditches and impact the drainage system.	Changes in groundwater elevation will be tracked through the Environmental Assessment Follow-up Program for WL to inform the need for adaptive management.	**Low**	**Low**	**Low**	**Moderate**	**Low**	**Low**
	Precipitation	Extreme precipitation events and changes in snowfall could affect hydrology and subsequently hydrogeology (i.e., changes in water table) and surface geology (i.e., erosion).	Changes in precipitation will be tracked through the Environmental Assessment Follow-up Program for WL to inform the need for adaptive management.	**Low**	**Moderate**	**Low**	**Moderate**	**Moderate**	**Moderate**
	Extreme events	Increase in droughts could affect the site hydrology and subsequently hydrogeology (i.e., changes in water table).	Changes in groundwater elevation will be tracked through the Environmental Assessment Follow-up Program for WL to inform the need for adaptive management.	**Low**	**Moderate**	**Low**	**Moderate**	**Moderate**	**Moderate**

Table 10.5.2.4-1: Qualitative Climate Risk Assessment

Infrastructure	Climate Variable	Interaction Description	Current Mitigation Measures	Climate Rankings					
				Near-term (2050s)			Far-term (2080s)		
				Likelihood	Consequence	Risk	Likelihood	Consequence	Risk
Final Site Restoration	Temperature	Extreme heat or extended cold spells could impact the type of species selected for the restoration during the post-closure phase. Changes to the length of the growing season could impact the species selection and rehabilitation of vegetation.	Changes in temperature will be tracked through the Environmental Assessment Follow-up Program for WL to inform the need for adaptive management. Meteorological data will be collected on an annual basis to track local changes to hydrogeological and climatological processes during the institutional control period.	**Low**	**Low**	**Low**	**Moderate**	**Low**	**Low**
	Precipitation	Changes in extreme precipitation could impact the final site restoration and the type of species selected for the restoration during the post-closure phase.	Changes in precipitation, will be tracked through the Environmental Assessment Follow-up Program for WL to inform the need for adaptive management.	**Low**	**Low**	**Low**	**Moderate**	**Low**	**Low**
	Extreme events	Increased drought-like conditions could impact the type of species selected for the restoration during the post-closure phase. Forest fires could cause damage to the restored areas.	As identified in Section 10.3, CNL has an existing Fire Protection Program at the WL site, which will continue to be implemented during closure phase. The Fire Protection Program is dedicated to providing the highest level of fire and life safety to all CNL employees and facilities, which subsequently also provides protection to the surrounding areas. Changes in extreme events, will be tracked through the Environmental Assessment Follow-up Program for WL to inform the need for adaptive management.	**Low**	**Moderate**	**Low**	**Moderate**	**Moderate**	**Moderate**

10.5.2.5 Summary of Climate Change Resilience

A climate change resilience assessment was conducted for the Project to meet the requirements of the *Strategic Assessment of Climate Change, Revised October 2020* (Government of Canada 2020). The assessment follows the approach outlined in Infrastructure Canada's *Climate Lens - General Guidance* (Infrastructure Canada 2019). The assessment includes identifying climate-infrastructure interactions of the Project infrastructure with a range of climate variables for near term (2050s) and far term (2080s). The risk rankings assigned for the far term (2080s) would be applicable to the risks associated beyond 2100.

All the climate risks associated with the Project have negligible to moderate risks under the future climate. To ensure ongoing resiliency for the Project and reduce the climate impacts, ongoing monitoring will be implemented to monitor the performance of the infrastructure under the changing climate. Hence, based on the existing Project design and the monitoring and surveillance plans, the Project is resilient in the near term (2050s) and the far term (2080s) for a range of different climate variables.

10.6 Glaciation

Typically, glacial cycles are assumed to be approximately 100,000 years, with the glaciation phase lasting approximately 90,000 years and the deglaciation phase lasting approximately 10,000 years (Peltier 2011; Clark et al. 2009). The earth is currently in an interglaciation period, meaning that it is between ice ages. It is estimated that the current period, called the Holocene, began approximately 11,700 years ago (Clark et al. 2016). Records suggest that previous interglaciation periods have lasted anywhere from 10,000 to 20,000 years (Berger et al. 2003).

Global warming is anticipated to elongate the interglacial period and postpone the next glacial event by tens of thousands of years. The global warming projected until the year 2300 (0.6 to 7.8°C) represents a much higher warming rate than the rate seen at the end of the last glacial period (4°C over an estimated 8,000 years). This corresponds to a higher rate of increase in atmospheric carbon dioxide (CO_2) concentration than observed in previous periods (Clark et al. 2009; Berger et al. 2003). Coupling of climate change models and glaciation models predicts a relatively long interglacial period of about 55,000 years (Berger et al 2003) to 100,000 (Peltier 2011). Peltier (2011) also notes that if the concentrations of greenhouse gases remains similar to the present, another glacial event is unlikely due to the increased surface warmth. However, projections for atmospheric concentrations beyond 3,000 years let alone 100,000 after present are uncertain.

As the current climate trend will likely delay the interglacial period until 100,000 years after present, the scenario of human inhabitants returning to the area after the glacial retreat is projected to occur 140,000 years from the present. The assessment timeframe for the Decommissioning Safety Assessment Report (Golder 2021) is 10,000 years. The timeframe was determined using the criteria within *REGDOC-2.11.1, Waste Management: Volume III: Assessing the Long-Term Safety of Radioactive Waste Management* (CNSC 2018). The 10,000-year assessment timeframe encompasses the phase in which peak effects are anticipated. Glaciation may occur 100,000 years into the future, far beyond the timeframe that the facility is hazardous. Therefore, the Project is not expected to adversely affect human health or the environment following the next glaciation event. A detailed assessment of glaciation can be found in Section 5.4.3.2.6 of the Decommissioning Safety Assessment Report (Golder 2021).

10.7 Summary of Project Design Features and Mitigation

Table 10.7-1 summarizes the design features and mitigation implemented to reduce or eliminate potential effects of the environment on the Project components and activities.

Table 10.7-1: Environmental Factors That Can Affect the Project and Associated Mitigation

Project Component or Activity	Factors	Mitigation
Multi-component concrete cap and engineered cover	■ Rain ■ Extreme events	Extreme rainfall events could result in an increase in surface water runoff and subsequently, erosion of the concrete cap and engineered cover. The multi-component concrete cap and engineered cover system will be designed to cover the entire footprint of the decommissioned WR-1 Building and will be graded to promote drainage from the site to the Winnipeg River, similar to the rest of the WL site. The concrete cap and engineered cover will also be designed to minimize water infiltration, to direct infiltration away from the grouted structure and to resist degradation by surface geologic processes and biotic activity (e.g., deter intrusion by burrowing of animals). Meteorological records will be reviewed annually to confirm that performance of the concrete cap and engineered cover is not overloaded during the institutional control period. This will be included in the Environmental Assessment Follow-up Program for WL.
Decommissioning activities	■ Extreme events ■ Forest fires	Implementation of CNL's Emergency Preparedness Program and the Fire Protection Program will mitigate the consequences of a forest fire and other extreme events (e.g., storms, extreme rainfall and snow).
Long-term environmental monitoring	■ Temperature and precipitation ■ Extreme events ■ Climate change	Changes in temperature and precipitation, as well as frequency or magnitude of extreme events and erosion will be tracked through the Environmental Assessment Follow-up Program for WL to inform the need for adaptive management. Meteorological data will be collected on an annual basis to track local changes to hydrogeological and climatological processes during the institutional control period. This will be included in the Environmental Assessment Follow-up Program for WL.

11.0 SUMMARY OF MONITORING AND FOLLOW-UP PROGRAMS

11.1 Integrated Environmental Monitoring Program

Whiteshell Laboratories' (WL) Integrated Environmental Monitoring Program (CNL 2020) is designed to track radiological and non-radiological contaminants throughout the different compartments of the geosphere, atmosphere, and biosphere and consists of three distinct programs: the Effluent Verification Monitoring Program (EVMP), the Environmental Monitoring Program (EMP), and the Groundwater Monitoring Program (GWMP). The Management and Monitoring of Emissions, Environmental Protection Programs, Protection and Monitoring of Groundwater, and WL Environmental Assessment Follow-up and Monitoring Program (EAFMP) outline the general requirements of each of the three monitoring programs (i.e., EVMP, GWMP, EMP). Implementation of these three programs under the Integrated Environmental Monitoring Program achieves the following main tasks:

- Direct release monitoring via the (EVMP);
- Contaminant pathways monitoring (via the EVMP, GWMP, and EMP); and
- Biological effects monitoring (via the EMP).

This integrated approach to environmental monitoring means that the evaluation of impacts on the environment from WL facilities and operations is carried out in a logical, comprehensive manner and is used to demonstrate compliance and protection of the environment and health and safety of the public.

The basis for the Integrated Environmental Monitoring Program is the WL CSR (AECL 2001) along with the associated WL Site's Dose Model. The EAFMP described in Section 11.1.1 is used to confirm the effects predictions made in the CSR. The Integrated Environmental Monitoring Program is dynamic in nature meaning that it is continually evolving based on various sources of information received, such as:

- findings and conclusions from the WL Site-Wide Environmental Risk Assessment;
- results of the EAFMP;
- data generated from the routine monitoring itself (e.g., a trend of interest is identified resulting in the need to increase monitoring in that location);
- outcomes of both integrated and annual program reviews (e.g., the need for an additional monitoring location based on site past or present operations);
- changes made to regulatory documents and/or standards;
- findings identified through internal or external audits (e.g., recommendation for the use of a different analysis method);
- changes in the routine operations of the site which are periodically reviewed through the Environmental Aspect Assessment process (e.g., a new process is implemented resulting in a change to a facility's routine emissions; and
- reviews of non-routine operations through an environmental review and/or EA (such as this Project).

11.1.1 Environmental Assessment Follow-up Program

The existing EAFMP for the WL site (CNL 2018) is being implemented under Licence No. NRTEDL-W5-8.00/2024. The Program serves to evaluate the risk to relevant human and non-human biota receptors resulting from exposure to contaminants and stressors related to the WL site and its activities, and recommends further monitoring (i.e., through the EVMP, GWMP, and EMP) or assessment as needed based on the results, to clarify risks or reduce uncertainties.

The overall objectives of the EAFMP for the WL site are to:

- verify the accuracy of the Environmental Assessment (CSR and this EIS);
- determine the effectiveness of any mitigations measures that have been implemented;
- optimize the monitoring (i.e., EVMP, GWMP, EMP) and surveillance programs already in place at the WL site;
- verify/confirm that appropriate mitigation measures are implemented;
- verify effects predictions;
- identify effects of the Project that may not have been predicted;
- develop appropriate responses to unforeseen events;
- offset loss of potential nesting habitat of species at risk and monitor use of compensatory habitat;
- monitor wildlife mortality (including birds, reptiles and mammals) and use information for adaptive management; and
- communicate risks and other relevant information to First Nations, the Red River Métis and Stakeholders in meaningful ways.

The current EAFMP for the site has been updated with *"Work Package #10 Whiteshell Reactor Disposal Facility (WRDF) Enhanced Monitoring"* that includes work tasks for review and integration of WR-1 Project groundwater, environmental, and effluent monitoring requirements into the WL Integrated Environmental Monitoring Program, development of WR-1 specific monitoring and surveillance plan, and the preparation of remedial action plans for the Project in alignment with Environmental Protection Program Environmental Incident Reporting, Investigation and Mitigation (CNL 2021). This will provide remedial actions that can be executed in a timely manner in case of unexpected monitoring results.

CNL will develop a Monitoring and Surveillance Plan for the In Situ Decommissioning of WR-1 at the WL Site (the Project) and integrate it into the existing EAFMP for the WL site. The Monitoring and Surveillance Plan will document the EAFMP activities for the Project and will include sufficient information on the type, quantity and quality of information required to reliably verify effects predicted by the environmental assessment and confirm the effectiveness of mitigations. Wherever possible, existing programs (i.e., EMVP, GWMP, and EMP) will be adapted to meet the objectives of monitoring the prediction in the environmental assessment for the Project.

The Monitoring and Surveillance Plan and the EAFMP activities for the Project will be prepared consistent with the Canadian Standards Association's Standards, as applicable:

- N288.4-19 (Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills [CSA Group 2019]);

- N288.5-22 (Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills [CSA Group 2022]); and
- N288.7-23 (Groundwater Protection Programs At Class I Nuclear Facilities and Uranium Mines and Mills [CSA Group 2023]).

The current compliance and monitoring programs for the WL site are listed below (CNL 2022b):

- Radiation Protection Program;
- Environmental Protection Program (including the EAFMP for the WL site);
- Waste Management Program;
- Occupational Safety and Health Program;
- Emergency Preparedness Program;
- Nuclear Criticality Safety Program;
- Physical Security Program;
- Nuclear Materials and Safeguards Management Program;
- Fire Protection Program;
- Quality Assurance Program; and

In the discipline assessments undertaken in Section 6.0 (Environmental Effects) of the Environmental Impact Statement (EIS), CNL has proposed monitoring and follow-up activities to be undertaken during the closure and post-closure stages of the Project. The EAFMP activities presented in this section provides a preliminary description of the activities and the framework for monitoring proposed for the Project. Each of the discipline-specific assessments presented in Sections 6.2 Atmospheric Environment through 6.9 Socio-economic Environment of the EIS proposes conceptual monitoring to be undertaken by CNL during the closure phase and the post-closure phase (i.e., institutional control period) of the Project, which are summarized in Table 11.1-1 in this Section. The monitoring activities are defined by the relevant project phase, consisting of:

- **Closure Phase**: Preparation and implementation of in situ disposal (ISD) includes grouting of below-grade structures and systems, removal of above-grade Whiteshell Reactor 1 (WR-1) building structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration. These activities last from 2026 to 2031. During the closure phase, CNL will be responsible for implementing the commitments made in the EAFMP.

- **Post-closure Phase:** The post-closure phase has two discrete periods: institutional control and post-institutional control. Institutional control is estimated to last 100 years during which long-term monitoring and maintenance activities will continue to demonstrate compliance with the safety case assumptions. Passive controls such as access restrictions (e.g., physical barriers/fencing, signage, and land title instruments/deed restrictions) will remain in place until the end of the institutional control period. Although the duration of institutional control is estimated at 100 years, it is recognized that it will continue until the CNSC, or the appropriate authority at the time, agrees it is no longer needed.

  Post-institutional control occurs after year 2131 and continues indefinitely. The post-closure phase will continue indefinitely; however, the timeframe defined for assessment of potential effects as part of the normal evolution of the Project is 10,000 years. This time period encompasses the phase in which peak effects are anticipated.

Table 11.1-1 summarizes the conceptual monitoring to be included in the Monitoring and Surveillance Plan for the Project. If the environmental assessment produces a positive decision on the Project, CNL will work with the CNSC to enhance and finalize the Monitoring and Surveillance Plan for the Project and integrate it into the existing, wider WL Site EAFMP. CNL will continue to engage local municipal governments and regulators such as the Province of Manitoba, Fisheries and Oceans and Environment and Climate Change Canada. The CNSC, as the regulatory authority for the Project, will coordinate the review of the follow-up monitoring program with the interested Federal and Provincial agencies.

CNL will continue to engage with First Nations and the Manitoba Métis Federation on the inclusion of traditional knowledge in the EAFMP (Section 11.4). CNL has received interest from six Indigenous Nations on being involved in development of the program and execution of the monitoring and reporting. CNL will work with each Nation to determine how they choose to participate in the work.

As the proponent of the Project, CNL will be responsible for implementing and managing the proposed follow-up monitoring program. AECL, as the owner of the site, is responsible for providing funding to CNL for the management and operation of its sites as per contractual arrangement, including funding for the follow-up monitoring program, with these costs included in CNL's submission of a decommissioning financial guarantee and accompanying cost estimate that has been submitted to the CNSC as per the WL site licence. CNL will be responsible for the delegation of resources to develop, implement and integrate the programs identified in Table 11.1-1. The development and implementation of mitigations identified for the Project and housed in the monitoring and follow-up programs, are tracked in relevant management plans, with roles and responsibilities clearly defined in each plan.

Table 11.1-1: Environmental Assessment Follow-up and Monitoring Programs Proposed for the Project

EIS Section	Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Section 6.2 Atmospheric Environment	Air Quality	**Potential Source(s) of Effects:** ■ Closure activities will result in fugitive dust emissions. **Proposed Monitoring:** ■ Application of aggregate to unpaved roads – a record will be kept of the date of each application of aggregate to unpaved roads. ■ Dust Control on Roads – a record will be maintained of dust control treatment for roads. ■ Site inspection – during periods of high dust susceptibility, regular inspections will be carried out to monitor the efficacy of dust mitigation and any potential concerns with regards to fugitive dust, and if required implementation of mitigation will be recommended. Environmental conditions will be recorded. ■ Confirmatory monitoring of total suspended particulates (PM_{10}) and radioactivity will be conducted during demolition and other dust generating activities. **Trigger for Further Action:** ■ Investigation if parameters above predictions, applicable guidelines, thresholds or limits, or if actual number of vehicles/kilometres travelled exceeds the prediction on which emission estimates were based. ■ If high levels of dust are identified (qualitative), adjust dust suppression measures accordingly.	■ Verify that mitigation is being incorporated as planned and are effective. ■ Verify predictions are within air quality criteria. ■ Demonstrate compliance with regulatory requirements.	■ Throughout the closure phase.	■ Project air quality monitoring will be integrated into CNL's WL Effluent Verification and WL Environmental Monitoring Programs.
	Greenhouse Gases	**Potential Source(s) of Effects:** ■ Closure activities will result in increased greenhouse gas (GHG) emissions. **Proposed Monitoring:** ■ Fuel Usage – a record will be kept of the fuel usage related to the Project. **Trigger for Further Action:** ■ Investigation if parameters above applicable guidelines, thresholds or limits, or if actual number of vehicles/km travelled exceeds the prediction on which emission estimates were based.	■ Verify that GHG emission rates used in the assessment are reasonable, but conservative. Monitoring results will be used for GHG reporting requirements.	■ Annual estimations and GHG reporting, as required during the closure phase.	■ Monitoring of GHG emissions is already completed as part of CNL's WL Effluent Verification and WL Environmental Monitoring Programs. No new monitoring is required for Project-specific GHG emissions.

Table 11.1-1: Environmental Assessment Follow-up and Monitoring Programs Proposed for the Project

EIS Section	Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Section 6.3 Geological and Hydrogeological Environment	Geology	■ Monitoring and follow-up programs are not identified as there are no predicted residual effects to geology; rather, monitoring will be implemented for other disciplines (i.e., air quality and groundwater) to verify effects predictions for soil quality. For example, environmental monitoring will be completed throughout the institutional control period to confirm that the WRDF barriers are functioning as intended. This monitoring will be integrated into the overall CNL WL Groundwater Monitoring Program to verify that changes to soil quality as a result of groundwater are negligible. In addition, CNL's *Management and Monitoring of Emissions* will include monitoring objectives air quality to verify that air emissions during closure have a negligible effect on soil quality.			
	Hydrogeology	**Potential Source(s) of Effects:** ■ Changes to groundwater quality from the release of solutes into the groundwater as the grout and reactor components gradually deteriorate during post-closure phases. **Proposed Monitoring:** ■ Water elevation measurements to determine groundwater flow direction and gradients. ■ Sampling to confirm groundwater quality to detect potential releases of constituents from the WRDF. ■ Initial sampling frequency will likely be twice per year (spring and fall). **Trigger for Further Action:** ■ If groundwater parameters above applicable guidelines or upgradient groundwater, conduct soil and/or sediment sampling and analysis for contaminants of concern. ■ If significant unexpected changes to groundwater flow, employ geophysical methods to confirm integrity of the concrete cap and engineered barrier.	■ Verify effects predictions on groundwater from the Project. ■ Verify the effectiveness of mitigation. ■ Demonstrate compliance with regulatory requirements.	■ Groundwater monitoring will continue through closure and post-closure. Semi-annual water level measurement and water quality measurements will be completed; however, the frequency of recurrence of water sampling will be reviewed based on performance data. The number and location of wells, and parameters measured, may change based on an annual review of the data.	■ Project groundwater monitoring will be integrated into the overall CNL WL Groundwater Monitoring Program and will be compliant with *CSA N288.7-23: Groundwater Protection Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2023).
Section 6.4 Surface Water Environment	Hydrology	■ Monitoring and follow-up programs are not identified as there are no predicted residual effects to hydrology.			
	Surface Water Quality	**Potential Source(s) of Effects:** ■ Changes to surface water quality from the release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time during the post-closure phases. **Proposed Monitoring:** ■ Monitor the quality of water in the Winnipeg River to evaluate whether the quality of the water is affected by the WRDF. ■ Monitor the quality of water in the vicinity of the groundwater seepage flow path in the Winnipeg River prior to post-closure ■ Monitor the quality of water in on-site ditches to verify the hydrogeological model. **Trigger for Further Action:** ■ Benthic invertebrate analyses will be completed if parameters in water and/or sediment are above predictions and/or applicable guidelines.	■ Verify effects predictions related to surface water quality. ■ Demonstrate compliance with regulatory requirements.	■ Surface water and ditch system water will be sampled on a semi-annual basis at one upstream and two downstream locations. Frequency of recurrence will be assessed based on performance data. ■ Water quality monitoring will continue through closure phase and post-closure phase (i.e., during institutional control).	■ Surface water monitoring in the receiving environment is already completed through CNL's WL Environmental Monitoring Program, which is compliant with *CSA N288.4-19: Environmental Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* (CSA Group 2019). No new surface water quality monitoring is proposed for the Project.

Table 11.1-1: Environmental Assessment Follow-up and Monitoring Programs Proposed for the Project

EIS Section	Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Section 6.5 Aquatic Environment	Fish and Fish Habitat	■ Monitoring and follow-up programs for the Project specific to fish and fish habitat are not identified as there are no predicted residual effects to fish and fish habitat; rather, monitoring will be implemented for other disciplines (i.e., air quality, groundwater quality, and surface water quality) to verify effects predictions for fish and fish habitat. For example, environmental monitoring will be completed throughout the institutional control period to confirm that the WRDF barriers are functioning as intended. This monitoring will be integrated into the overall CNL WL Groundwater Monitoring Program to verify that changes to surface water quality, and subsequently fish and fish habitat, as a result of groundwater are negligible. In addition, CNL's *Management and Monitoring of Emissions* will include monitoring objectives air quality to verify that air emissions during closure have a negligible effect on surface water quality, and subsequently fish and fish habitat. ■ Although not required for the Project specifically, current EAFMP for the WL site includes water monitoring and collecting fish flesh at one location upstream and two locations downstream of the WL site. This monitoring will also verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implementedCNL will continue to carry out the existing EAFMP for the WL site as it is a requirement of CNL's current licence (NRTEDL-W5-8.00/2024) with the CNSC.			
Section 6.6 Terrestrial Environment	Vegetation	Monitoring and follow-up programs are not identified as there are no predicted residual effects to vegetation. Although not required for the Project specifically, current Environmental Assessment Follow-up Program for the WL site includes collection of vegetation within the vicinity of the WL site and garden crop samples upstream and downstream from the site. This monitoring will also verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. CNL will continue to carry out the existing Environmental Assessment Follow-up Program for the WL site as it is a requirement of CNL's current licence (NRTEDL-W5-8.00/2024) with the CNSC.			
	Barn swallow	**Potential Source(s) of Effects:** ■ Closure and Post-Closure: If barn swallows are confirmed to be using the WR-1 Building as habitat through pre-disturbance surveys, there will be incremental contribution of the Project and all future decommissioning activities to the loss of potential nesting habitat in the RSA. There is predicted to be negligible effects on barn swallow, if determined to be nesting in the WR-1 Building, through the implementation of habitat compensation. **Proposed Monitoring:** ■ Barn swallow nest structures were installed in 2018 at the WL site proactively in consideration of potential loss of barn swallow nesting habitat from future decommissioning activities. ■ Effectiveness monitoring of compensatory barn swallow nest structures will be conducted to determine if the compensatory nest habitat is being used. ■ This compensation model and follow-up monitoring would be consistent with what has been designed by the Ontario Ministry of Natural Resources and Forestry. Barn swallows are designated as "Threatened" on the Ontario *Endangered Species Act*'s Species at Risk in Ontario list. An equivalent protocol has not been developed for Manitoba (barn swallow are not currently designated on the provincial *Endangered Species and Ecosystems Act*). Barn swallow are designated as "Threatened" under the federal *Species at Risk Act and is proposed to be down-listed as a Special Concern species by COSEWIC*. **Trigger for Further Action:** If effectiveness monitoring shows that the barn swallow nest structure is not being used, it would be relocated to other suitable habitat on the site.	■ Offset the incremental contribution of the Project and all future decommissioning activity to the loss of potential nesting habitat in the RSA using compensatory nesting habitat. ■ Determine number of individuals using compensatory nesting habitat on an annual basis.	■ Annually (in June, July or August) for three years following installation.	■ Monitoring for barn swallow will be integrated into CNL's existing Environmental Protection Program. ■ A Biodiversity Plan will be developed and included in the EAFMP for the WL site.

Table 11.1-1: Environmental Assessment Follow-up and Monitoring Programs Proposed for the Project

EIS Section	Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Section 6.6 Terrestrial Environment	Bats	**Potential Source(s) of Effects:** ■ Closure and Post-Closure: If bats are confirmed to be using the WR-1 Building as habitat through pre-disturbance surveys, incremental contribution of the Project and all future decommissioning activity to the loss of potential anthropogenic maternity roosting habitat in the RSA. There is predicted to be negligible effects on bats, if determined to be roosting in the WR-1 Building, through the implementation of habitat compensation. **Proposed Monitoring:** In consultation with CNL biologists on other CNL sites to be decommissioned in the future, and in consideration of future losses of anthropogenic structures that may provide roosting habitat at the WL site, offsetting in the form of bat boxes may be required if bats are confirmed to be using the WR-1 Building as maternity roosthabitat. ■ Criteria for appropriate siting, if required, may include: accessibility of box locations for installation and future monitoring of utilization/effectiveness, avoidance of areas with radiological contamination in surface water features and appropriate distance to anthropogenic disturbances to avoid sensory effects (i.e., noise). Immature forested areas adjacent to larger waterbodies (i.e., Winnipeg River) and wetlands are high priority locations, because these forest types do not currently provide high quality tree roosting habitat and would be most benefited by installation of bat roost boxes to expand the spatial coverage of potential roosting habitat within the RSA. Final site selection would be at the discretion of CNL biologists. ■ Effectiveness monitoring may be conducted to determine if boxes are being used for three years post-installation. **Trigger for Further Action:** ■ If effectiveness monitoring shows that the bat boxes are not being used by the target species, they would be relocated to other suitable habitat on the site.	■ Offset the incremental contribution of the Project and all future decommissioning activity to the loss of potential anthropogenic maternity roosting habitat across the RSA. ■ Install bat boxes and determine number of individuals and species using bat boxes on an annual basis.	■ Bat boxes should remain in place throughout the Closure Phase at minimum. Monitoring should take place annually for three years post-installation.	■ Monitoring for bats will be integrated into CNL's existing Environmental Protection Program. ■ A Biodiversity Plan will be developed and included in the EAFMP for the WL site.

Table 11.1-1: Environmental Assessment Follow-up and Monitoring Programs Proposed for the Project

EIS Section	Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Section 6.6 Terrestrial Environment	Snapping turtle	**Potential Source(s) of Effects:** ■ Closure: Minor increase in mortality risk on snapping turtle as a result of vehicle collisions, and negligible residual effect, if mitigation is implemented. ■ CNL will implement a follow-up monitoring program to address the uncertainty regarding the effectiveness of proposed mitigation for protecting snapping turtle populations. **Proposed Monitoring:** Implementation of routine annual wildlife road surveys using protocols for road surveys available from other Canadian jurisdictions for similar species (e.g., Survey Protocol for Blanding's Turtle in Ontario [MNRF 2015]), to be conducted when snapping turtles are likely to cross (i.e., terrestrial life history period from May 1 to October 15). ■ Any road mortality or injury of snapping turtle (or other reptile species) will be reported and data will be compiled in a database that can be used to inform adaptive management for the site. **Trigger for Further Action:** ■ If, after mitigation and operational measures are shown to be ineffective and any mortality or injury of snapping turtle occurs, further mitigation will be considered in an adaptive management framework. This mitigation may take the form of: surveys of high-risk road crossing locations to determine if they are being used by turtles for crossing, potential upgrade of existing crossing culverts to enhance snapping turtle passage, consideration of the potential need to re-design or lengthen the existing amphibian and reptile fencing at the three most likely turtle crossings on Ara Mooradian Way, or consideration of the need to add fencing on any other roads where injuries or mortality of snapping turtle is recorded. ■ Based on results of routine wildlife road mortality surveys, evaluate implementation of traffic calming measures during the season when snapping turtles are expected to cross the road (i.e., terrestrial life history period from May 1 to October 15). These may include options such as further reduction of posted speed limit, installation of speed bumps, or other measures.	■ Track turtle observations during routine wildlife road surveys and use information for adaptive management.	■ Ongoing reporting and monitoring should take place annually over the active decommissioning period (until the start of institutional control).	■ Monitoring for snapping turtle will be integrated into CNL's existing Environmental Protection Program. ■ A Biodiversity Plan will be developed and included in the EAFMP for the WL site ■ Continuation of WL staff reporting of incidental wildlife observations.

Table 11.1-1: Environmental Assessment Follow-up and Monitoring Programs Proposed for the Project

EIS Section	Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Section 6.7 Human and Ecological Health	Human health and Ecological health	**Potential Source(s) of Effects:** ■ Closure activities will result in the release of airborne effluent from the WR-1 Building which could affect human and ecological health. ■ Release of solutes into the groundwater as the grout and reactor components gradually deteriorate over time during the post-closure phase may cause changes in groundwater quality, which could migrate towards the Winnipeg River and affect receptors along the Winnipeg River. **Proposed Monitoring:** ■ Monitoring for air quality as noted above (i.e., for dust, gross alpha, beta and gamma radiation monitoring of the filters). ■ Verification monitoring for tritium in air (post venting through WR-1 stack). ■ Passive tritium in air network monitoring (semi-annual change out) will be included as part of the EAFMP for the Project. Monitoring locations (approximately 4 of them) will be selected to be within the main upriver and downriver windrose sectors, at the site boundary and on-site mainly to monitor airborne tritium plumes potentially originating from the WRDF. ■ Estimate combustible gases (e.g., based on project-related traffic and equipment), as per atmospheric environment above. ■ Monitor contaminants of concern (e.g., lead, asbestos, tritium) in air displaced from grouting the below-grade structure, as per the atmospheric environment above. ■ Groundwater monitoring surrounding the WRDF, as noted above. **Trigger for Further Action:** ■ Investigation if parameters are above applicable guidelines identified.	■ Verify effects predictions related to air quality, groundwater quality and surface water quality to confirm no health effects are anticipated as a result of exposure to COPCs from the Project.	■ Dust monitoring would be carried out during the closure phase. ■ Monitoring of tritium in air will be initiated when the stack monitoring system is discontinued. This monitoring would be on-going during post-closure. The need for and duration of monitoring will be assessed based on annual review of monitoring data. ■ Groundwater and surface water quality monitoring would be on-going during closure and post-closure. The need for and duration of monitoring will be assessed based on an annual review of monitoring data. ■ WL currently conducts industrial hygiene assessments of lead, asbestos and mould within facilities as part of the decommissioning planning process.	■ Air quality monitoring for the Project will be captured through the implementation of CNL's WL Effluent Verification and WL Environmental Monitoring Programs. ■ Groundwater monitoring for the Project will be integrated into the overall CNL WL Groundwater Monitoring Program. ■ Surface water monitoring in the receiving environment is already completed through CNL's WL Environmental Monitoring Program. No new surface water quality monitoring is proposed for the Project.
Section 6.8 Land and Resource Use	■ Monitoring and follow-up programs are not specifically identified for land and resource use; rather, monitoring for environmental pathways noted above (i.e., air quality, groundwater quality, and surface water quality) will be implemented to verify effects predictions for land and resource use. ■ CNL is aware First Nations and the Manitoba Métis Federation have continuing concerns about the potential effects of the Project and more broadly the WL site and the potential effect on traditional land and resource use, and more specifically on water, wildlife, fish and plants upon which such use is based, and cultural and archaeological sites. As such, CNL is committed to involving First Nations and the Red River Métis in monitoring and will engage with them over the long-term to address on-going concerns. Beginning in 2019 the Manitoba Métis Federation had an Environmental Monitor observing CNL's environmental monitoring program. CNL has initiated discussions to also have First Nations and Métis Environmental Monitors who will report back to their communities. CNL will provide communication support to committee members, to help disseminate monitoring results. ■ CNL will continue to engage with local communities, municipalities and Indigenous Nations during the closure and post-closure phases.				

Table 11.1-1: Environmental Assessment Follow-up and Monitoring Programs Proposed for the Project

EIS Section	Valued Component	Project Phase, Potential Effect and Conceptual Monitoring Program	Monitoring Program Objective	Suggested Duration	Implementing Program
Section 6.9 Socio-economics	Government Finances Community Infrastructure and Services Community Well-being	There are no monitoring and follow-up programs specific to socio-economics; rather, concerns with respect to the Project are addressed through social commitments made by CNL. ■ CNL will proactively seek, engage and support meaningful discussion on issues and opportunities related to the Project. ■ CNL is currently working on establishing contribution/relationship agreements with each engaged Indigenous Nation, which include liaison positions and create mechanisms to develop and implement initiatives that will help address each Nation's unique interests and concerns related to the Project and the Whiteshell Laboratories Restoration Project overall. ■ CNL is committed to sharing information and working collaboratively with Indigenous Nations and the Partnership to help them develop a feasible socio-economic plan and development of robust communication plan to convey and confirm the Project's safety. ■ Public information activities required as part of CNL's Public Information Program (2021) will be part of the EAFMP for the Project and will be summarized as part of the annual EAFMP progress report			

CNL = Canadian Nuclear Laboratories; ISD = in situ decommissioning; CNSC = Canadian Nuclear Safety Commission; GHG = greenhouse gas; $PMR_{10}R$ = particles nominally smaller than 10 micrometres (µm) in diameter; NPRI = National Pollutant Release Inventory; WRDF = Whiteshell Reactor Disposal Facility; RSA = Regional Study Area; LSA = Local Study Area; COPC = contaminant of potential concern; LGD = Local Government District; the Partnership = Whiteshell Laboratories Community Regeneration Partnership; RM = Rural Municipality; EIS = Environmental Impact Statement; CEAA 2012 = *Canadian Environmental Assessment Act, 2012;* EAFMP = Environmental Assessment Follow-up and Monitoring Program.

This page intentionally left blank

11.2 Adaptive Management

CNL is committed to achieving continual improvement in environmental performance through its management systems. CNL manages environmental-related matters through an existing Environmental Protection Program. The Environmental Protection Program is registered within the requirements of the International Organization for Standardization 14001:2015 standard (ISO 2015). The Environmental Protection Program includes compliance and improvement systems to evaluate areas for improvement or trending. The Environmental Protection Program will continue to be implemented during the Project's closure and post-closure phases, and will be updated, as needed, as part of an annual management review process.

The development and implementation of mitigations identified for the Project and housed in EAFMP for the Project, will be tracked in relevant existing CNL plans. CNL's approach to adaptive management is defined in each plan. As site conditions and monitoring dictate, or as new technology emerges, CNL will adaptively manage site practices and monitoring programs to meet the defined objectives. For some programs, this involves regular evaluation of predictive models; which are clearly defined in each applicable plan.

Environmental monitoring of the entire WL site will continue as part of the EAFMP for the WL site. For the EAFMP for the Project, CNL will determine the initial monitoring locations and frequency of sampling based on the EIS, the WR-1 Environmental Risk Assessment and the Decommissioning Safety Assessment Report. The monitoring data will be assessed against established limits for concentrations of contaminants of potential concern. These concentration limits are well below established benchmarks for the protection of humans and the environment.

If the EAFMP for the Project identifies that adverse environmental effects are greater than predicted or results for any monitored contaminants of potential concern are above the established limits, then CNL will investigate the results, which may include additional sampling and analysis to help determine/confirm the source and extent of the contamination. CNL would also evaluate whether they result in changes to the conclusions in this EIS. If changes are confirmed, then CNL will evaluate the need for revised mitigation actions and management practices to manage effects, with engagement with First Nations and the Manitoba Métis Federation for openness and transparency. Any proposals on modifications to the monitoring program will be communicated to the CNSC. Where the need for revised mitigations is identified, they will be developed and implemented on a case-by-case basis by CNL staff, and may include soil removal and/or treatment of groundwater. As part of the EAFMP for the Project, CNL will prepare remedial action plans for responses to unexpected results as per the Environmental Protection Program Incident Reporting, Investigation and Mitigation (CNL 2021). This will ensure that remedial actions can be executed in a timely manner.

In addition to incorporating the monitoring actions of this EIS into the EAFMP for the site, CNL is committed to reviewing and adapting the existing EAFMP for the WL site to incorporate Traditional Knowledge that has been collected through the environmental assessment for the Project, as well as through ongoing engagement and relationship building, in order to provide each community with the information that is relevant and important to them. In particular, the program will be modified to include monitoring of traditional foods as identified by Indigenous Nations. For example, a recommendation on CNL's environmental protection program was to include mushroom collection into the sampling program. CNL has since adjusted its environmental protection program to include mushroom collection and CNL continues to look for additional ways to improve their monitoring program. CNL will continue to work with First Nations and the Red River Métis as the EAFMP for the Project evolves to address concerns and incorporate them into the program as appropriate.

A progress report will be prepared each year and will include a summary of the environmental monitoring results and the safety considerations of the waste left in situ. As part of CNL's engagement with the local municipal governments and regulators, the CNSC and First Nations and the Manitoba Métis Federation, CNL will incorporate their feedback on the monitoring program and expand it where appropriate.

Institutional controls are proposed to be in place for at least 100 years post closure, and the continuation of these controls would be based on regulatory input. Stopping a monitoring activity would occur once it can be shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant by regulatory requirements or community concerns. Any proposals on modifications to the monitoring program will be communicated to the CNSC.

11.3 Data Management

The development and implementation of mitigations identified for the Project and housed in the monitoring and follow-up programs, are tracked in relevant management plans, where data management, including collection, storage, standards and responsible roles, are defined. Data collected will meet the required guidelines for collection and quality assurance and control. CNL will store information generated from the environmental assessment monitoring and follow-up program in a robust database for future analysis and reporting. Analysis of results from the monitoring and follow-up program will be reported and submitted to the relevant regulatory agencies as required.

11.4 Indigenous Engagement and Participation in Environmental Monitoring

Section 11.1 explains how the monitoring activities for the Project will be incorporated into the WL Integrated Environmental Monitoring Program for the overall WL Closure project and Section 11.1.1 outlines the proposed monitoring activities required by the CNSC to verify the outcomes of the environmental assessment for the Project. CNL has committed to augment the overall monitoring program to suit the ongoing needs of the Project, stakeholders and First Nations and the Red River Métis.

During Project engagement activities (Section 4.0 Indigenous Engagement), the First Nations and the Manitoba Métis Federation expressed concerns about the potential long-term effects of the Project on the environment. They indicated that the health of the environment, species relied on for fishing and harvesting, and the risk to people around the WL site are of great concern. They also expressed an interest in being actively involved in the development and implementation of an ongoing monitoring program and made several recommendations on how the current monitoring program could be amended to include components significant to the First Nations and the Manitoba Métis Federation. The following section outlines ongoing engagements and commitments to support meaningful discussion of and participation in future environmental monitoring and follow-up programs (CNL 2024) for the Project and the WL site.

CNL recognizes that the First Nations and the Red River Métis are stewards of the land and holders of Traditional knowledge who have a great interest in participating in monitoring at the WL site. CNL has thus committed to:

- Engaging with each Nation and the Manitoba Métis Federation on their specific interest and concerns regarding monitoring for the Project and the existing WL site EAFMP;

- Engaging with each First Nation and the Manitoba Métis Federation to on their specific interest and concerns regarding future land use and end state criteria; and
- Working collaboratively with the engaged First Nations and the Manitoba Métis Federation to develop an initiative for Indigenous Nations to participate in environmental monitoring at the WL site.

The goal of the initiative is to help address concerns regarding protection of the environment, health of people, confidence in the health of country foods, and reduction of stigma associated with the Project. In general, key elements of the initiative may include:

- Expansion and evolution of the monitoring program at WL, through incorporation of feedback, recommendations, and Traditional knowledge.
- Opportunities for community monitors, youths and Elders from each First Nation and the Red River Métis to collect samples on site and in the surrounding area, including capacity development and training in environmental monitoring; and
- Collaborate on ecological restoration and address specific interests and concerns related to monitoring at the site.

Each Nation may have different preferences for how to participate in the initiative and CNL commits to development of a program that is flexible to the needs of each Nation. Some communities may be satisfied with CNL's annual reporting, while others may wish to participate by observing CNL monitoring or may wish to develop their own community-led monitoring programs, separate from CNL's program. CNL will encourage cooperation between communities to minimize redundancy and unnecessary duplication of effort and cost.

The initiative will also have a reporting and risk communication component to increase the level of awareness and participation from the wider community members and citizens. CNL currently provides updates on environmental monitoring activities to all First Nations and the Red River Métis and invites them to observe and participate. Further, CNL shares all the results of their annual environmental monitoring reports with all the communities and is in the process of developing a user-friendly document to share with Indigenous Nations. CNL will continually evaluate both the process and the outcome of the ongoing engagement and communication activities, to address and manage issues as they arise. Annual progress reports on the EAFMP for the WL site are prepared and will include a summary of the environmental monitoring results for the Project, as well as the safety considerations of the waste left in situ. The need for maintaining communication mechanisms during institutional control is recognized as being important. Public and Indigenous information activities required as part of CNL's Public Information Program will be part of the EAFMP for the Project and will be summarized as part of the annual progress report.

CNL has already been engaging with the First Nations and the Manitoba Métis Federation on this initiative, including participation in monitoring activities at the WL site and provided interested Nations with a demonstration of how comprehensive the program is, and to identify gaps in monitoring that may be best filled through the initiative. CNL is also providing the opportunity and funding for an environmental monitor from each community to observe CNL's environmental monitoring program in action, including collection of water, soil, and plant samples for analysis. CNL has also provided the communities with a list of upcoming monitoring activities and invited them to participate. CNL worked with each First Nation and the Red River Métis to support their involvement in the 2021 sampling collection.

CNL has committed to augment the overall EAFP based on how the First Nations and the MMF wish to be involved. The first is through a harvest sample collection plan to collect information wild foods, medicines, and wood to be led by the MMF and implemented collaboratively between the MMF and CNL staff. One of the anticipated benefits of the program is to provide near-term confidence in the harvested goods for the Red River Métis citizens through reporting. Further to this, CNL commits to continue its testing of wildlife in the vicinity of the WL site and has invited Red River Métis harvesters to participate in the donation of locally harvested meat for testing. CNL has also agreed to the MMF request to have an additional groundwater monitoring well installed at a location closer to the WRDF.

Through ongoing discussions CNL and the Manitoba Métis Federation identified initiatives that would help address the Manitoba Métis Federation's concerns of the Project. As a culmination of these discussions, in August 2023, the Manitoba Métis Federation and CNL signed a multi-year contribution agreement. This agreement establishes a series of ongoing engagement activities to improve communications between the parties, including an annual leadership meeting, the creation of an MMF liaison position, and invitation for Red River Métis participation in an Indigenous Advisory Committee. Other initiatives include the development of a communications protocol for reportable events, the development of plain language materials on CNL activities, and support to enable MMF participation in environmental monitoring and economic activities at the Whiteshell site. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project.

At this time, no specific agreement has been reached between CNL and the MMF for longer term arrangements; however, CNL has committed to involve the MMF in monitoring in a way that is most meaningful to them, such as offering opportunities to provide input to the site water management plan, including a ground water monitoring station closer to the reactor, and providing capacity to involve the MMF in review of the WL Remediation Plan (formerly Land Use and End State Plan), which is currently under development. CNL and the MMF will continue to discuss how best to ensure MMF involvement in monitoring, and commit that whatever agreement is reached, will identify the respective roles and responsibilities of CNL and the MMF, as well as the intended duration of the agreement and renewal periods.'

CNL and AECL have also entered into a contribution agreement with Sagkeeng First Nation that outlines commitments to Indigenous independent monitoring. A scope of work for a Community Environmental Monitoring Program (CEMP) led by Sagkeeng First Nation has been agreed upon and includes detailed work planning for the first three years of activities, and commitment to detailed work planning on an annual basis. The Sagkeeng First Nation CEMP can be used to better understand changes to traditional uses and cultural practices should Sagkeeng First Nation so choose to do work in that regard. This work will be undertaken by Niigan Aki, a program established by Sagkeeng First Nation through the contribution agreement to undertake the CEMP. CNL is committed to continuing to engage with Sagkeeng First Nation in the manner they so choose. An additional amended contribution agreement was also entered into by CNL, AECL and Sagkeeng First Nation to support Sagkeeng First Nation's participation in the Project, and to provide incremental benefit to WL Site.

CNL believes that the CEMP and communication of results of that monitoring in the community is intended in part to support the of the SAFN Healing and Resiliency Action Plan scope of work which was a recommendation of the psycho-social impact assessment. CNL has agreed to implement this Healing and Resiliency Action Plan in part to acknowledge the difference in the conclusions of the EIS held by SAFN, and to support learning and reconciliation. CNL staff have also participated in trauma-informed engagement training provided by SAFN and will continue to be involved in and learn from processes SAFN may want to implement into the future.

At this time, no specific agreement has been reached between CNL and the MMF or CNL and the SAFN for longer term arrangements; however, CNL has committed to involve the MMF and SAFN in monitoring in a way that is most meaningful to them. CNL and SAFN will continue to discuss how to best ensure the MMF's and SAFN's involvement in monitoring, and commit that whatever agreement is reached, will identify the respective roles and responsibilities of CNL and the MMF and SAFN, as well as the intended duration of the agreement and renewal periods.

This page intentionally left blank

12.0 CONCLUSIONS

12.1 Introduction

Canadian Nuclear Laboratories (CNL) is performing the decommissioning of the Whiteshell Laboratories (WL) nuclear research facility with site closure expected by 2027. CNL is licensed to perform this work under a Canadian Nuclear Safety Commission (CNSC) decommissioning licence (Licence No. NRTEDL-W5-8.00/2024). A Comprehensive Study Report (CSR) under the *Canadian Environmental Assessment Act* (1992) was completed for the decommissioning project in 2001.

CNL is applying for an amendment to the current decommissioning licence to carry out In Situ Decommissioning of Whiteshell Reactor-1 at the Whiteshell Laboratories Site (the Project), rather than dismantling and demolition as previously assessed in the CSR. The in situ disposal (ISD) approach includes partial dismantling and demolition along with passive, permanent disposal of the below-grade portions of Whiteshell Reactor 1 (WR-1). In situ disposal is a departure from the end-state defined in the CSR, and as a result, the Project qualifies as a designated project under Section 37(b) of the *Regulations Designating Physical Activities* (SOR/2012-147) of the *Canadian Environmental Assessment Act, 2012* (CEAA 2012), related to “the long-term management or disposal of irradiated fuel or nuclear waste”. A key element of the regulatory approvals process is the completion of an environmental assessment under the CEAA 2012, the results of which are documented in this Environmental Impact Statement (EIS).

The EIS includes an analysis of alternatives, a description of the process of public and Indigenous engagement, the results of studies of baseline conditions and a description and assessment of effects of the Project on the environment. The assessment was completed to demonstrate that proposed activities can be safely completed in compliance with the prescribed protective limits, including radiological doses to workers and members of the public, and the releases of radioactive material to the surrounding environment. The environmental assessment considers the closure phase (which includes decommissioning and site reclamation) and long-term monitoring during the post-closure phase of the Project. The EIS includes an assessment of likely cumulative effects of the Project in combination with other past, present or reasonably foreseeable projects. It describes the effects for normal conditions and as a result of accidents and malfunctions. The EIS also describes and assesses the likely effects of the environment on the Project.

12.2 Alternatives Analysis

The assessment considers only alternatives that can safely achieve the Project goals and are technically feasible. The recommended alternative for the decommissioning of WR-1, based on the alternatives analysis, is in situ disposal. In situ disposal allows CNL to decommission WR-1 and the WR-1 Building in a safe, cost effective manner, in a shorter timeframe and without interim storage of the resulting waste. In situ disposal is a safe option, reducing the risk to workers compared to full dismantling and providing long-term safety to the public and the environment. The in situ disposal approach also has the least reliance on undefined future disposal options or technologies.

CNL recognizes that Indigenous Nations would prefer to see other alternatives selected for the Project. All engaged First Nations and the Manitoba Métis Federation have expressed a varying level of concern over ISD or have expressed a preference for immediate dismantling and removal in order that the waste is taken out of their traditional territory. Sagkeeng First Nation provided the most extensive feedback of all Indigenous Nations,

including conducting their own alternative means analysis using their community values criteria and weighting. CNL has strongly considered First Nations and the Manitoba Métis Federation views, opinions and interests and have ongoing engagements and commitments that reflect their input on Alternative Means; especially in the area of trauma informed engagement and risk-informed communications to address psychosocial effects. CNL has invested and is committed to ongoing engagement with Indigenous Nations to discuss and resolve, where possible, their issues and concerns regarding the Project.

Based on an understanding of the hazards associated with WR-1, CNL believes that the Whiteshell Reactor Disposal Facility (WRDF) can be built to meet CNSC regulations, considering the recommendations from the international Atomic Energy Agency (IAEA) related to radiological waste disposal. CNL also believes that the safety case has been made that this dedicated facility can be used to permanently dispose of the waste with effective containment and isolation, rather than temporarily store it.

12.3 Project Description

For the Project, the concept for long-term waste management is based on the passive containment and isolation of the waste within the WRDF. The primary pathway for release of contamination from the WRDF is by groundwater that has infiltrated into the sub-surface structure, picked up contamination and then carried it out of the sub-surface structure to the surrounding environment. The WRDF is designed to provide passive containment and isolation of the wastes. Containment is achieved through robust design based on multiple barriers that includes using combined inherent natural and engineered barriers to provide safety following the decommissioning of WR-1. Systematically, the natural and engineered barriers include the reactor core and bioshield, grout fill, building foundation, concrete cap and engineered cover, and finally the geologic surround. Combined, the barriers form a rigorous system to provide long-term safety to the public and the environment, with environmental monitoring to be conducted to verify the effectiveness of the barriers.

The decommissioning activities for the Project include:

- preparation for ISD;
- grouting of below-grade structures and systems;
- removal of above-grade structures and systems;
- installation of a concrete cap and engineered cover;
- final site restoration; and
- preparation for institutional control.

CNL plans to start preparation and implementation of ISD in 2026, which includes grouting of below-grade structures and systems, removal of above-grade WR-1 structures and systems, installation of the concrete cap and engineered cover, and environmental controls and final site restoration (pending approval by the CNSC). The WRDF will be turned over to institutional control in 2031, which is assumed to last for a minimum of 100 years during which environmental monitoring and surveillance activities will be carried out. However, it is recognized that institutional control will continue until the CNSC agrees it is no longer needed.

12.4 Indigenous Engagement

Indigenous engagement is a key component of the environmental assessment process. As part of its corporate, environmental, and social responsibility, CNL encourages ongoing engagement and relationship building with the First Nations and the Manitoba Métis Federation throughout the course of the environmental assessment process for the Project and ongoing Whiteshell Laboratories restoration and monitoring work.

Engagement with Indigenous Nations for the Project began in 2016 and is ongoing. CNL has reached out to and/or engaged with Sagkeeng First Nation, the Manitoba Métis Federation, Black River First Nation, Brokenhead Ojibway Nation, Hollow Water First Nation, Wabaseemoong Independent Nations, Shoal Lake No.40 (Treaty No.3), Iskatewizaagegan No.39 Independent First Nation (Shoal Lake No.39 First Nation) (Treaty No.3), Northwest Angle No. 33 (Treaty No.3), and Grand Council Treaty #3. Although effort was made to reach out to all of the First Nations, the Manitoba Métis Federation, and Indigenous organizations identified, particular effort was placed on outreach to the Nations and organizations who expressed interest in the Project or that live and practice traditional activities in closest proximity to the WL site. These Nations are Sagkeeng First Nation, Black River First Nation, Brokenhead Ojibway Nation, Hollow Water First Nation, Wabaseemoong Independent Nations and the Red River Métis.

Feedback CNL has received during engagement with Indigenous Nations has been considered during the environmental assessment process. Key themes of the issues and concerns provided through feedback received to date on the Project include:

- relationship building;
- the ISD approach;
- alternative means assessment;
- psychosocial impacts;
- waste management;
- historical siting and operations of the WL site;
- valued components (VCs);
- accidents and malfunctions;
- incorporation of Traditional Knowledge;
- business and employment opportunities;
- future land use and tenure for the WL site; and
- participation in environmental monitoring;

The feedback on issues and concerns was incorporated into the EIS where applicable. CNL has taken steps to verify that issues and concerns expressed by First Nations and the Manitoba Métis Federation have been correctly documented and that information provided by the Nations, and the Nations' positions are correctly described and captured in the revised EIS and supporting documents. CNL has documented this and all other commitments it has made to the First Nations and the Manitoba Métis Federation in a consolidated Commitments List, to be submitted to the CNSC as part of the licence application. CNL appreciates all feedback received to date on the

Project and remains committed to continuing discussions with First Nations and the Manitoba Métis Federation after submission of the updated EIS, throughout the remaining environmental assessment steps, and during the remediation of the WL site.

12.5 Inclusion of Traditional Knowledge and Influence of Indigenous Engagement Feedback on the Environmental Assessment

Traditional knowledge influenced the environmental assessment for the Project. Traditional knowledge includes both traditional knowledge and feedback gathered through engagement and community-led studies. Traditional knowledge was primarily gathered through the Traditional Knowledge and Land Use Studies that were completed to further enable opportunities to capture and include traditional knowledge into the environmental assessment and the EIS by better understanding modern and traditional land and resource use near the WL site. Four Traditional Knowledge, Land Use and Occupancy Studies for the WL site were completed and shared with CNL for inclusion in the EIS. Examples include identification of VCs, defining spatial boundaries, descriptions of the environment, and identification and evaluation of Project interactions, and modification of and participation in the environmental monitoring programs.

The key interests and concerns raised by Sagkeeng First Nation; the Manitoba Métis Federation; Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation; and Wabaseemoong Independent Nations have been assembled from a number of sources provided by the community to Canadian Nuclear Laboratories. Sources of information include formally submitted comments to the Canadian Nuclear Safety Commission as part of the environmental assessment process, comments and questions sent to CNL regarding the Project, summaries of topics that have been discussed between CNL and each Indigenous Nation at meetings, site tours, workshops, benchmarking trips, and the Traditional Knowledge and Land Use Studies. For each interest and concern, CNL has included references to sections of the EIS relevant to addressing the Nation's interest or concern.

12.6 Public Engagement

Engagement with the public and stakeholder representatives is a key component of the environmental assessment process. CNL operates a Public Information Program to inform the public (i.e., general public, as well as stakeholder representatives) about ongoing activities at CNL sites and the potential effects of these activities on the public. Engagement activities for the Project have been completed under the guidance of this program. This Public Information Program forms the basis of communication efforts with the public and helps to direct the establishment of long-term, mutually beneficial working relationships with their communities in proximity to CNL sites.

Key topics of the feedback received to date on the Project include:

- regulatory process;
- alternative means assessment;
- lessons learned;
- design and engineering details;
- effectiveness of the grout;

- radiological inventory;
- VCs;
- protecting the Winnipeg River;
- effects of the environment on the Project;
- contingency planning;
- environmental monitoring; and
- future land use and economic opportunity.

CNL appreciates all feedback received to date on the Project and remains committed to continuing discussions with the general public and stakeholder representatives after submission of the updated EIS, throughout the remaining environmental assessment steps, and during the remediation of the WL site.

12.7 Scope of the Environmental Assessment and Approach

The Project activities assessed in this EIS are limited to in situ disposal of the below-grade portion of the WR-1 Building. Other decommissioning activities for the WL site, documented in the CSR, have not changed and do not need to be reassessed.

The environmental assessment approach for the Project was developed to meet the requirements of Canadian Environmental Assessment Act, 2012 and the Generic Environmental Impact Statement Guidelines developed by the CNSC. The overall assessment approach includes the following steps:

- define the scope of the assessment (including VCs, spatial and temporal boundaries, and assessment cases);
- describe the existing environment;
- evaluate Project interaction and mitigation;
- conduct an analysis for each VC to predict residual effects from the Project;
- evaluate and describe the level of certainty in the assessment;
- classify and determine the significance of predicted residual effects; and
- identify monitoring and follow-up programs.

The following sections summarize the findings of the environmental assessment completed for each of the VCs.

12.8 Atmospheric Environment

12.8.1 Air Quality

The scope of the air quality assessment focuses on predicting changes in indicator compounds emissions (as a result of the Project) and comparison of these changes to the applicable guidelines and standards. The indicator compounds emissions from the Project include suspended particulate matter (SPM), particles nominally smaller than 10 micrometres (µm) in diameter (PM_{10}), particles nominally smaller than 2.5 µm in diameter ($PM_{2.5}$), carbon monoxide (CO), sulphur dioxide (SO_2) and nitrogen oxides (NO_x) expressed as nitrogen dioxide (NO_2). Emissions of particulates (SPM, PM_{10} and $PM_{2.5}$), CO, SO_2 and NO_x have the potential to affect aquatic, human and terrestrial

wildlife health. Particulate emissions, which are also referred to as fugitive dust, can also be a nuisance issue over which the public or Indigenous Nations are concerned. Air Quality focused on predicting changes in the concentrations of above-mentioned indicator compounds emissions; radiological and non-radiological hazardous parameters are considered in the Human and Ecological Health assessment.

Project activities will result in emissions associated with the operation of vehicles and equipment, as well as material handling emissions from above-grade building demolition, grouting, and temporary batch mixing plant or similar equipment operations. Project mitigations will be implemented to limit potential effects to air quality including the application of measures from CNL's Environmental Protection Program and Procedure for Management and Monitoring of Emissions, which includes operational control monitoring, air verification monitoring and environmental monitoring.

Fugitive dust from vehicle movement on paved roads is the largest contributor to suspended particulate matter emissions, PM_{10} and $PM_{2.5}$. Non-road equipment exhaust emissions are the largest contributors to NO_x and CO emissions. Finally, the largest contributor to SO_2 is fuel combustion for emergency power generators. Predicted concentrations for the Application Case are below applicable air quality guidelines and/or standards, with the exception of SPM and PM_{10} limited to a small area just outside the LSA and contained within the RSA, along Ara Mooradian Way north of 211 Rd in a restricted area. Overall, the residual adverse effects from the Project on air quality was determined to be not significant.

12.8.2 Greenhouse Gases

Project activities will result in greenhouse gas (GHG) emissions (i.e., carbon dioxide, methane, and nitrous oxide) associated with the operation of vehicles and equipment. The GHG emissions are estimated to be less than 0.1% of the total provincial GHG emissions and less than 0.01% of the total national GHG emissions. Based on the comparison between the estimated annual emission to both the federal and provincial GHG emissions, the Project will result in minor releases of GHG, but is predicted to have a negligible residual effect on climate change and will not impact Canada's emission reduction efforts. Therefore, any GHG emissions from the Project may be considered negligible on a global scale.

12.9 Geological and Hydrogeological Environment

12.9.1 Geology

The scope of the assessment focuses on geology, which includes bedrock, soils and geomorphology. Potential effects on geology are limited to changes in soil quantity and quality as a result of construction of temporary supporting infrastructure, and changes to soil quality from air emissions and groundwater transport from the WRDF into the groundwater. Temporary infrastructure will be located within the WL main campus, which is previously disturbed and developed, limiting potential effects to soil quality and quantity. Concentration of air emissions are predicted to be lower than applicable air quality guidelines/standards, thus negligible changes to soil quality are anticipated. The concrete cap and engineered cover will be designed to mitigate moisture infiltration into the WRDF and hence limit leakage through the WRDF to groundwater and subsequent changes in soil quality. Overall, the assessment of potential effects determined there are negligible effects on geology.

12.9.2 Hydrogeology

The scope of the hydrogeology assessment focuses on changes to groundwater quality and quantity. Changes to groundwater quality from the Project due to the release of solutes into the groundwater as the grout and reactor components gradually deteriorate (post-closure) was identified as having a residual effect on the hydrogeological environment.

The Winnipeg River was identified by the post-decommissioning groundwater flow model as the principal receptor of groundwater discharge. The groundwater flow modelling indicates that the mean groundwater travel times from the WRDF to the Winnipeg River are an estimated 100 years. Overall, the residual adverse effects on hydrogeology are anticipated to be negligible.

In 2024, groundwater flow and solute transport modelling was completed to evaluate 11 additional sensitivity scenarios (Scenarios 19 through 29) to further assess the peak loadings to the Winnipeg River. Sensitivity analyses included consideration of an enhancement to the hydraulic conductivity of the grout, a fractured flow condition in the bedrock pathway, and upper and lower bound adsorption co-efficients for the bedrock geo-pathway. The modelling indicates that the expanded set of parameter inputs results in increased mass loading estimates to the environment for some scenarios relative to those assessed in the Draft EIS submitted December 2022. The overall impact of the increased mass loadings are evaluated in Section 6.7 to determine the potential impact of these results on human and ecological health.

Based on the Comprehensive Study Report, it was determined that the likelihood of contaminant transport beyond the Waste Management Area was very low and no effects on groundwater were anticipated from in situ decommissioning of the trenches; therefore, no overlap with the Project is expected.

12.10 Surface Water Environment

12.10.1 Hydrology

The scope of the hydrology assessment considers the potential effects of the Project to the flows and water levels of the Winnipeg River. Following the completion of closure activities, the WL site will be graded to promote drainage from the site to the Winnipeg River. In addition, run-off control for the engineered cover is designed to limit erosion and infiltration of water into the grouted structure. This is achieved by sloping the cover surface to maintain a slope toward the edges and the collection of water by the surface water management systems at the WL site. Natural runoff from the decommissioned WL site will continue to discharge to the Winnipeg River during the post-closure phase. Although the installation of the concrete cap and engineered cover at the WR-1 Building is expected to slightly alter the drainage rates and flow patterns; the changes are expected to be within the natural range of variation of flow in the Winnipeg River. As such, effects to hydrology are predicted to have a negligible effect on hydrology of the area.

12.10.2 Surface Water Quality

The scope of the surface water quality assessment considers the potential effects of the Project on surface water quality within the Winnipeg River. During the post-closure phase, groundwater may encounter the WRDF and then flow to the Winnipeg River, resulting in changes to surface water and sediment quality. The predicted maximum radionuclide concentrations in surface water at both the Nearfield (i.e., 50 m from the upstream edge of the groundwater seep) and the Farm A intake (i.e., 3,150 m downstream from the upstream edge of the groundwater seep) on the Winnipeg River are orders of magnitude lower than background groundwater concentrations. Predicted sediment concentrations of radionuclides are lower than their respective clearance levels.

Predicted maximum non-radionuclide concentrations in surface water and sediment are driven by current river concentrations and some parameters exceed available surface water or sediment guidelines. For example, the background concentration for lead exceeds the lowest available guidelines for surface water and sediment, but the maximum sediment concentrations at both the Nearfield and the Farm A intake in both surface water and sediment show no change from the background level as a result of the Project. Overall, the assessment of potential effects determined there are negligible residual adverse effects on surface water and sediment quality from changes in groundwater quality.

12.11 Aquatic Environment

The scope of the aquatic assessment focuses on the potential effects of the Project on the physical aspects of the aquatic environment. During closure, potential effects to the aquatic environment (which includes fish and fish habitat) include the transport of surface water runoff to the Winnipeg River in the vicinity of the WL site, changes in drainage rates and flow patterns due to the installation of the concrete cap and engineered cover at the WR-1 Building, and deposition of air emissions from demolition activities. The Project during the closure phase is not anticipated to affect the physical habitat of the Winnipeg River. With Implementation of a storm water management plan and CNL's *Management and Monitoring of Emissions*, site runoff and air and dust emissions are not predicted to impact the surrounding aquatic environment. As such, closure activities are predicted to have a negligible residual effect on fish and fish habitat.

An Ecological Risk Assessment was completed and for the post-closure phase, it evaluates the potential for adverse effects on aquatic health associated with exposure to chemical and radiological contaminant releases through the groundwater pathway from the WRDF in the long-term. There are no exceedances of the radiation benchmark for the aquatic biota in the Winnipeg River and all predicted doses are well below this level. Therefore, it is unlikely there would be significant adverse effects on aquatic populations or communities as a result of radionuclide releases in the long-term during the post-closure phase.

There are no exceedances of the hazard quotients identified for exposure of the aquatic receptors to non-radionuclides, with the exception of benthic invertebrates in groundwater. The hazard quotients for cadmium, lead and HB-40 exceeded 1 for the scenario where benthic invertebrates are exposed directly to groundwater. The assessment conservatively assumes the organisms spend their entire lives in the peak discharge zone, and that no dilution of the groundwater occurs in the shallow sediment layers where most benthic organisms reside. Moreover, the seepage area represents a small part of the benthic community habitat, and the maximum groundwater concentration assumed represents the worst-case period. As such, a realistic benthic invertebrate population is not likely to be at risk due to cadmium, lead and HB-40 exposure, and any adverse effects will be spatially and temporally limited. Overall, the changes in water quality and sediment quality are expected to result in a negligible residual effect to the benthic invertebrate population relative to existing conditions.

12.12 Terrestrial Environment

The scope of the assessment focuses on potential effects of the Project on the terrestrial environment, including potential effects on the ecological and biological processes that connect species with each other and their physical environment. During closure, the Project will generate air and dust emissions from demolition activities. With Implementation of CNL's *Management and Monitoring of Emissions*, there is predicted to be negligible effects on the terrestrial environment from the Project as a result of air and dust emissions. Sensory disturbance, road mortality, and loss of nest/roost substrate also have the potential to affect terrestrial valued components during closure. Surveys to confirm whether nesting and/or roosting activity is occurring in the WR-1 Building will be

conducted during the appropriate season the year prior to the initiation of decommissioning activities. If evidence of nesting or roosting activity is found, appropriate mitigation in the form of deterrents will be implemented under consultation with ECCC and in accordance with habitat protection provisions and the required permitting process under Species at Risk Act and potentially the *Migratory Bird Conservation Act*. The objective of the selected mitigation will be to prevent birds and bats from accessing the building during the period when it will be demolished. The potential for road mortality of snapping turtle will be addressed through adaptive management and ongoing monitoring and documentation of road mortalities. If road mortality of snapping turtle occurs, additional mitigation will be enacted, as required. Following implementation of mitigation and monitoring in an adaptive management framework, there is predicted to be negligible effects on the terrestrial environment during the closure phase as a result of the Project.

An Ecological Risk Assessment was completed and for the post-closure phase, it evaluates the potential for adverse effects on terrestrial biota associated with exposure to chemical and radiological contaminant releases in surface water through the groundwater pathway from the WRDF in the long-term. There are no exceedances of the radiation benchmark for terrestrial biota and all predicted doses are well below this level. There are also no exceedances of the hazard quotients identified for exposure of the terrestrial receptors to cadmium, lead, HB-40 and xylene. Therefore, changes in surface water quality through the groundwater pathway are expected to result in a negligible residual effect to terrestrial populations or communities in the long-term during the post-closure phase.

12.13 Human and Ecological Health

12.13.1 Human Health Assessment

Specific to the Project, the human health risk assessment focused on public and Indigenous Nations' health and the health of WL site workers not involved in performing Project activities. Consistent with CSA N288.6-12, Nuclear Energy Workers directly involved in performing Project activities were not assessed because their potential doses are controlled through CNL's Radiation Protection Program. The assessment for public and Indigenous Nations' health considered locations where people are known to be present.

The receptors for the Human Health Risk Assessment were selected to be appropriate for assessment of both radiological and non-radiological stressors on human health. The most-affected off-site members of the public are defined as the "critical group", which include:

- Farms A and F (year-round occupants with livestock);
- On-site Farm (post-institutional control only); and
- Harvesters (traditional users of the area gathering local foods).

For the closure phase, the relevant COPCs are expected to be released via atmospheric releases from the WR-1 Building as reactor systems are dismantled, transported off-site or disposed of in situ within the WRDF. The closure activities are well encompassed by existing engineering and administrative controls currently in place at the WL site. The calculated radiological doses for the human receptors during closure (i.e., Farm A, Farm F, and downstream Harvester) are all below the CNSC public dose limit of 1 mSv/a, as well as the dose constraint for the Project of 0.25 mSv/a. Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure to radioactive releases from Project activities. Doses to workers will be monitored and managed as part of CNL's Radiation Protection Program. The application of the Radiation

Protection Program ensures that exposures will be kept ALARA and below the effective dose limit of 100 mSv over 5 years, and below 50 mSv in any single year.

The post-closure phase is not expected to result in airborne effluent, as the grouting will have been completed, the above-grade building will have been completely decommissioned and a concrete cap and engineered soil cover will have been installed over the WRDF. The relevant COPCs are expected to be released via groundwater to the surface water. The total radiation dose to human receptors during the post-closure phase (i.e., Normal Evolution Scenario) are below the Canadian Nuclear Safety Commission public dose limit of 1 mSv/a, as well as the dose constraint for the Project of 0.25 mSv/a. Since the dose estimates are a small fraction of the public dose limit, no discernable health effects are anticipated due to exposure of potential critical groups to radioactive releases from the WL site during post-closure.

The doses to human receptors that could be exposed to the non-radiological COPCs (i.e., cadmium and lead) in surface water during post-closure were calculated based on total concentration (background plus Project contribution). The hazard quotients derived for COPCs were below the protective benchmark for all receptors and pathways, other than the river drinking water pathway. If only the Project contribution is considered, the hazard quotients are well below the protective benchmark, indicating the Project contribution to the risk is minimal. Although uncertainties in the assessment exist, conservatism, such as using the highest release rates, has been included in the modelling so that residual effects are not greater than predicted.

A number of disruptive events were assessed to address uncertainties that arose during the definition of scenarios and conceptual models, with three bounding scenarios (disruptive events with the potential for greatest consequence) identified. These were:

- Inadvertent Human Intrusion: an exploration borehole drilled into the WRDF and exposure of wastes;
- Substantial Failure of In Situ Disposal Structure (WRDF Barrier Failure); and
- Well in Plume: an on-site resident drinking groundwater from a well capturing the plume from the WRDF.

For all bounding scenarios, the total radiation dose to human receptors during the post-closure phase are below the IAEA Upper Reference Level for Disruptive Events of 20 mSv/a. For exposure to non-radiological COPCs (i.e., cadmium and lead), the HQ exceeded the target values for some scenarios. However, the assessment was conservatively conducted to predict exposures to human receptors under these future unlikely conditions. Further, controls can be put in place to reduce the probability of the Disruptive Events (e.g., land use restrictions during post-institutional control period to reduce the likelihood of a human intrusion event).

For the fractured geo-pathway and the modified well in plume scenarios, the total radiation dose to all human receptors during post-closure is predicted to be well below the regulatory public dose limit of 1 mSv/yr, with the exception of the 3-month-old in the modified well in plume scenario. The HQs for all receptors in the fractured geo-pathway are well below the acceptable risk level of 0.2; therefore, no discernable health effects are anticipated. For the modified well in plume scenario, risk could not be ruled out for the on-site farm residents drinking groundwater in the plume of WRDF. However, the assessment was conservatively conducted to predict exposures to the on-site farmer under these unlikely conditions.

A key concern of Indigenous Nations was effects to the health of harvesters from consuming fish, plants, and wildlife in the vicinity of the WL site. The approaches to exposure and toxicity assessment have ensured that the characterization of dose and risk has been undertaken in a manner that has not underestimated dose or risk.

Overall, residual effects from radiological and non-radiological COPCs are considered to be not significant for all human health valued components, including harvesters, during the closure and post-closure phases.

12.13.2 Ecological Health Assessment

The scope of the Ecological Health Assessment focuses on evaluating the potential health effects to non-human biota (plants and animals) from Project activities. An environmental transport and pathways model was used to evaluate the effects of contaminants on ecological receptors. During closure, the assessment focuses on land animals and birds because releases are only expected via atmospheric pathways. After decommissioning (i.e., post-closure phase), the focus is on the aquatic animals, because releases are expected to be via groundwater to surface water pathways.

Results of the radiological dose assessment for the closure and post-closure phases indicate that doses to ecological health valued components are below their respective benchmark values. In addition, there are no exceedances of the HQs identified for exposure of the ecological receptors to cadmium, lead, HB 40 (with the exception of benthic invertebrates in groundwater) and xylene. Therefore, no significant adverse effects on either aquatic or terrestrial populations or communities as a result of these chemical releases are predicted.

The assessment indicates that there will be exceedances of the HQs for cadmium, lead and HB-40 for benthic invertebrates in groundwater. Benthic invertebrates were modelled assuming the organisms spend their entire lives in the peak discharge zone, and that no dilution of the groundwater occurs in the shallow sediment layers. This is conservative because a diffusion gradient will exist across the sediment-water interface, resulting in some degree of dilution into the top layer of sediment where most benthic organisms reside. Moreover, the seepage area represents a small part of the benthic community habitat, and the maximum groundwater concentration assumed represents the worst-case period. As such, a realistic benthic invertebrate population is not likely to be at risk due to cadmium, lead and HB-40 exposure, and any adverse effects will be spatially and temporally limited, such that the community as a whole is not expected to be significantly affected.

Most of the disruptive events modelled do not have an effects pathway to impact the ecological environment. The WRDF Barrier Failure Disruptive Event is the modelled scenario that demonstrated the greatest effect on the ecological health. For the WRDF Barrier Failure Disruptive Event, all predicted radiological and non-radiological doses are well below their respective protective benchmark values indicating that no adverse residual effects are expected. Therefore, it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of radionuclide and non-radionuclide releases under a barrier failure scenario.

For the fractured geo-pathway sensitivity scenario, there are no predicted exceedances of the 9.6 mGy/d radiation dose benchmark for aquatic biota or of the 2.4 mGy/d radiation dose benchmark for terrestrial and riparian biota during Project post-closure. Therefore, it is unlikely that there would be potential adverse effects on terrestrial or aquatic populations or communities as a result of radionuclide releases from the Project for this sensitivity analysis. All HQs are below 1 indicating no adverse ecological effect is anticipated.

A key concern of Indigenous Nations was long-term effects of the Project on fish, plants and wildlife important to Indigenous Nations. The approaches to exposure and toxicity assessment have ensured that the characterization of dose and risk has been undertaken in a manner that has not underestimated dose or risk. Overall, residual effects from radiological and non-radiological COPCs are considered to be not significant for all ecological valued components during the closure and post-closure phases.

12.14 Land and Resource Use

12.14.1 Traditional Land and Resource Use

The assessment of traditional land and resource use considers hunting, trapping, and gathering by Indigenous Nations, archaeological and cultural sites, and the overall importance of the Winnipeg River. The Project could affect traditional land use through effects to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River. Changes to these VCs could result from a change in the abundance and distribution of resources, the quality of the resource, and the ability to access resources including fish, wildlife and vegetation. Any of these changes could subsequently affect the ability and the desire to engage in activities in the area of the WL site.

Threshold exceedances in harvested receptors through atmospheric releases and waterborne dispersion of contaminants are not anticipated. In addition, the mitigation proposed to minimize Project effects on surface water quality, the aquatic environment, the terrestrial environment, human health and ecological health are anticipated to eliminate or mitigate any potential adverse effects to the resources on which traditional land and resource use are dependent.

In collaboration with First Nations and Manitoba Métis Federation and the public, CNL is committed to meaningful and ongoing engagement on the WL site remediation and clean-up activities. Although a small proportion of the WL site will have restrictions on use because of the Project, it is still anticipated that the majority of the site will be safe and appropriate for unrestricted use. Overall, decommissioning of the WL site will result in an increase in the land available for future use in the local area. Future uses/zoning have not been determined, but the end-state plan for the WL site is to return lands disturbed by site activities to a condition that is physically stable, safe and in keeping with the post-closure land use classification and release criteria. Consequently, the Project is expected to have a negligible effect on traditional land and resource use VCs.

CNL is aware that the First Nations and the Manitoba Métis Federation have continuing concerns about the potential effects of the Project and more broadly the WL site on traditional land and resource use. As such, CNL is committed to involving First Nations and the Red River Métis in monitoring and to engaging with them over the long-term to address on-going concerns. CNL will implement a WR-1 Environmental Assessment Follow-up and Monitoring Program to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. In addition, to mitigate perceptions related to the suitability for use of the WL site and the lands around it, CNL will support robust communication of environmental monitoring results to confirm the safety of the WL site and help address concerns about future uses.

12.14.2 Other Land and Resource Use

The assessment of other land and resource use includes consideration of non-Indigenous commercial, municipal, and federal land and resource use activities in proximity to the Project. These activities include agriculture, forestry, mineral claims and leases, water use, and outdoor recreation and tourism, sport fishing, outfitting, hunting, trapping, and winter activities.

The Project could affect outdoor recreation and tourism activities through effects to vegetation, fish and wildlife and their habitats, and surface water quality in the Winnipeg River. Changes to these valued components could result from a change in the abundance and distribution of resources, the quality of the resource, and the ability to access resources including fish, wildlife and vegetation. Any of these changes could subsequently affect the ability and the desire to engage in activities in the area.

There are not anticipated to be any threshold exceedances in human receptors through atmospheric releases and waterborne dispersion of contaminants. In addition, the mitigation proposed to minimize Project effects on surface water quality, the aquatic environment, the terrestrial environment, human health and ecological health are anticipated to eliminate or mitigate any potential adverse effects to the resources on which recreation and tourism activities are dependent.

The WL site has been operational since the 1960s, and no outdoor recreation and tourism activities are permitted on the site. Other land and resource use activities have persisted adjacent to the WL site, including uses of the Winnipeg River. It is expected that all activities and land uses adjacent to the WL site will be able to continue in the future as the Project will have no effect on land tenure or usage beyond the WL site boundaries. Overall, with mitigation and engagement in place, Project effects on other land and resource use are expected to be negligible.

CNL will implement an Environmental Assessment Follow-up and Monitoring Program for the Project to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. In addition, to mitigate perceptions related to the suitability for use of the WL site and the lands around it, CNL will support robust communication of environmental monitoring results to confirm the safety of the WL site and help address concerns about future uses.

12.15 Socio-economic Environment

Socio-economics refers to the way social and economic factors influence one another in local communities and households. The socio-economic environment assessment considers potential effects of the Project on the people and communities who are part of the existing socio-economic environment in the immediate vicinity of the Project. The socio-economic VCs chosen for the assessment are employment and income, business opportunities, government finances, community infrastructure and services, community well-being and public safety.

With in situ disposal, there will be a reduced amount of radioactive waste transported off-site, and thus a reduced amount of traffic generated. The reduction in traffic will limit the potential for transportation incidents and risks to public safety. Considering the small number of additional employees required by the Project and the reduced amount of waste transported off-site, changes traffic volumes associated with Project employment will have a negligible effect on the transportation infrastructure in the local area and reduce the probability that the public may be exposed to radioactive material.

The permanent presence of the WRDF will change the suitability of a small portion of the WL site for future uses due to the restrictive land use categories that will be applied to the Project site. Although a small proportion of the WL site will have restrictions on use because of the Project (i.e., 0.07 ha), it is still anticipated that the majority of the site will be safe and appropriate for unrestricted use, and that future designations will seek to maximize the amount of lands available for other uses.

The availability of land for future uses does not stem directly from environmental effects of the Project, but rather from the indirect effect of zoning restrictions that will be required for the Project site into the distant future. The public expressed concern with the Project because it would limit the types of businesses and industries that could use the WL site for future operations and therefore reduce the number of economic development opportunities available to them. CNL provides support for the Community Regeneration Partnership, which has been established to create a feasible socio-economic plan for the region, facilitate economic development and hopefully provide high quality employment to replace the losses associated with the overall WL site closure. Depending on the future

uses and access to the WL site, the plan is expected to help focus recruitment efforts or provide another route for achieving the same economic goals without reliance on the WL site.

The implications of the change in decommissioning activities associated with WR-1 does not necessarily alter the number of new employment and/or contracting opportunities, but rather indirectly changes the nature of the employment and/or contracting opportunities available and timeframe. The proposed change will increase the requirements for engineering and construction, while decreasing the amount of transportation labour required. While the schedule for reducing employment has been accelerated, the Community Regeneration Partnership is working to enhance benefits for area communities and the Indigenous Nations in the local area to the extent possible.

Considering CNL's programming to support current employees in transitioning to new work, CNL's support of fostering economic development in the region, and the potential for siting a small modular reactor on the WL site, the Project's indirect effects on employment and income, and business opportunities are expected to be negligible relative to the overall closure of the site despite the accelerated timeline and change in land use restrictions.

While the Project does not return the WL site to an area completely available for unrestricted use, no residual adverse effects were identified between the Project and the aquatic environment or the terrestrial environment. Similarly, the ecological and human health risk assessment concluded it is unlikely that there would be significant adverse effects on either aquatic or terrestrial populations or communities as a result of maximum potential contaminant releases associated with the Project. Even under an accidents and malfunctions scenario (i.e., a WRDF Barrier Failure Disruptive Event), all predicted radiological and non-radiological doses are well below their respective protective benchmark values indicating that no adverse residual effects are expected. With negligible effects predicted to the biophysical environments, the assessment does not indicate the potential for direct or indirect effects to the well-being of communities.

Indigenous Nations have commented on the ongoing adverse effects the presence of the WL site has had on their well-being since the site's establishment in the 1960s, including ongoing fear and trauma for Sagkeeng First Nation members. The Manitoba Métis Federation, Black River First Nation, Hollow Water First Nation, and Brokenhead Ojibway Nation have also noted that WL site, along with other historical industrial development in the local area, have affected the communities' well-being by adversely affecting the environment. The change in the decommissioning strategy for WR-1 is understood from an Indigenous perspective as having the potential to result in fear, stigma and anxiety associated with the long-term presence of nuclear materials in the region. Given the importance of the topic to Indigenous Nations, CNL acknowledges that efforts to support dialogue and learning are central to the relationship going forward.

CNL and Atomic Energy of Canada Limited recognize and acknowledge the cumulative impacts and trauma experienced by Sagkeeng First Nation members in relation to the initial siting of the WL site. As the WL site is undergoing decommissioning over the next several years, CNL will work with Indigenous Nations so that relationships endure, grow and adapt to future activities. As such, CNL is currently working on establishing contribution/relationship agreements with each engaged Indigenous Nation, which include liaison positions and create mechanisms to develop and implement initiatives that will help address each Nation's unique interests and concerns related to the Project and the Whiteshell Laboratories Restoration Project.

The assessment does not indicate the potential for direct or indirect effects to the well-being of Indigenous Nations since the effects documented by local Indigenous Nations are linked to the historical presence of the WL site, there are no predicted changes to the biophysical environment, and CNL and Atomic Energy of Canada Limited are committed to working with the Manitoba Métis Federation and First Nations going forward to develop programs and initiatives that provide meaningful mitigation to Indigenous Nations to address the issues of fear and stigma identified.

12.16 Accidents and Malfunctions

This section of the EIS focuses on accidents and malfunctions that could occur during the closure phase of the Project. Hazards, accidents and malfunctions that result in consequences only over long timeframes (i.e., post-closure phase) are not included in the accident and malfunction assessment, as they are assessed in the Decommissioning Safety Assessment Report and are encompassed by the bounding scenarios for the human and ecological health assessment.

To identify potential accident and malfunction events during the closure phase, as well as the potential health and environmental effects that may occur, the Project used a systematic and comprehensive approach. Credible events were identified through a review of Project activities to identify hazards, which were then assigned a likelihood and consequence severity ranking, and an overall risk priority level. The process of estimating the consequence severity index includes a consideration of existing CNL programs, procedures and policies that are in place to mitigate potential hazards.

Conventional occupational hazards are typical of a major construction project and evaluated to be controlled by human performance; thus, CNL has put in place provisions including training, procedures and oversight of contractors to achieve as-low-as-reasonably possible accident and malfunction rates. Events such as spills and leaks, off-site transportation accidents, system and equipment failure, fire and explosions are well understood and encompassed by existing and proven engineering controls, management program and standard operating procedures at the WL site. The residual risks for these accidents and malfunctions are expected to be within regulatory requirements. In addition, no off-site effects are predicted for the accident and malfunction scenarios, including those identified by the public and Indigenous Nations.

Management systems and safety culture already in effect at the WL site, where regular assessment of safety performance is conducted and lessons learned from experience are applied, will continue to be applied during the Project. Therefore, if an accident or malfunction situation occurs, CNL has procedures in place that address requirements for immediate response and post-event clean-up or remediation.

12.17 Effects of the Environment on the Project

The assessment focused on the effects of natural hazards (e.g., extreme weather events, forest fires, seismic events) and climate change on the Project. It summarized the risks associated with each kind of environmental change, along with environmental design features, management practices and other mitigation to reduce the risks.

Implementation of CNL's Emergency Preparedness Program and the Fire Protection Program will mitigate the consequences of a forest fire and other extreme events (e.g., storms, extreme rainfall, and snow) during the closure phase. During the post-closure phase, the concrete cap and engineered cover will be designed to limit water infiltration and to direct water away from the WRDF towards the Winnipeg River. The end-state plan for the WL site, which includes the WRDF, is to return lands disturbed by site activities to a condition that is physically

stable, safe, and in keeping with the post-closure land use classification and release criteria. The drainage system for the reclaimed WL site will have the physical characteristics similar to natural drainage systems in the general geographic region in terms of dynamic stability, robustness, and longevity.

The Province of Manitoba is the least earthquake-prone area in Canada. Furthermore, the Canadian Nuclear Fuel Waste Management Program studied seismic stability in Northwest Ontario and Eastern Manitoba and found, based on a detection level of 2.5 on the Richter scale that the WL site and the southern two-thirds of Manitoba are aseismic. Liquefaction is not seen as an issue for the WL site due to the essentially aseismic conditions of Eastern Manitoba, and the consolidated nature of the overburden geology. The probability of earthquake damage from such low ground acceleration approaches zero in this area.

Climate change may result in shifts in the frequency and/or intensity of the extreme weather events, temperature precipitation and forest fires. When evaluating the potential effects from climate change, Project design features and mitigation as well as management and monitoring practices are also considered. The climate change resilience assessment completed for the Project indicates that the Project design is resilient to changes in climate. However, although the Project design is resilient, ongoing monitoring will be implemented as part of an adaptive management plan to monitor the performance of the infrastructure under the changing climate.

12.18 Monitoring and Follow-up Programs

Canadian Nuclear Laboratories will implement an Environmental Assessment Follow-up and Monitoring Program for the Project that will be integrated with the existing Environmental Assessment Follow-up and Monitoring Program for the WL site (being implemented under Licence No. NRTEDL-W5-8.00/2024). The purpose of the Environmental Assessment Follow-up and Monitoring Program for the Project is to verify the accuracy of environmental effects and determine the effectiveness of mitigation measures that have been implemented. The Environmental Assessment Follow-up and Monitoring Program for the Project will include sufficient information on the type, quantity and quality of information required to reliably verify effects predicted by the environmental assessment and confirm the effectiveness of mitigations. Wherever possible, existing programs (Effluent Monitoring Verification Program, the Groundwater Monitoring Program, and the Environmental Monitoring Program) will be adapted to meet the objectives of monitoring the predictions made in the environmental assessment for the Project.

A post-closure monitoring program will be developed as part of the Environmental Assessment Follow-up and Monitoring Program for the Project that will provide the sampling and analysis objectives and procedures for sampling and testing in the vicinity of the Whiteshell Reactor Disposal Facility during the institutional control period. Data generated by the monitoring program will be evaluated on an ongoing basis within an adaptive management framework. If the Environmental Assessment Follow-up and Monitoring Program for the Project identifies that environmental effects are greater than predicted, then CNL will evaluate whether they result in changes to the conclusions in this EIS that describes the Project and assesses the likely effects of the Project on the environment. If changes are confirmed, then CNL will evaluate the need for revised mitigation actions and management practices to manage effects. Where the need for revised mitigation is identified, it will be developed and implemented. Conversely, cessation of a monitoring activity might be appropriate once it has been shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant with respect to regulatory requirements or community concerns. Any proposals on modifications to the monitoring program will be communicated to the Canadian Nuclear Safety Commission.

In addition to incorporating the monitoring actions of this EIS into the Environmental Assessment Follow-up and Monitoring Program for the Project, CNL is committed to reviewing and adapting the existing Environmental Assessment Follow-up and Monitoring Program for the WL site to incorporate Traditional Knowledge that has been collected through the environmental assessment for the Project, as well as ongoing engagement and relationship building, in order to provide each community with the information that is relevant and important to them.

Canadian Nuclear Laboratories is committed to achieving continual improvement in environmental performance through its management systems. Canadian Nuclear Laboratories manages environmental-related matters through an existing Environmental Protection Program that includes compliance and improvement systems to evaluate areas for improvement or trending. The Environmental Protection Program will continue to be implemented during the Project's closure and post-closure phases, and will be updated, as needed, as part of an annual management review process.

Recognizing that the First Nations and the Red River Métis are stewards of the land who have a great interest in participating in monitoring at WL site, CNL has committed to engaging with each Nation on their specific interest and concerns regarding monitoring for the Project and the existing Whiteshell Laboratories Site Environmental Assessment Follow-up and Monitoring Program. Some of the key elements of the initiative may include expansion and evolution of the monitoring program at WL, through incorporation of feedback, recommendations, Traditional knowledge, capacity development, including training in environmental monitoring, and opportunities for monitors from each First Nation and the Red River Métis to collect samples on site and in the surrounding area. The goal of the initiative is to help address concerns regarding protection of the environment, health of people, confidence in the health of country foods and to reduce stigma associated with the Project. It is also an opportunity to involve youth and Elders, collaborate on ecological restoration, and address Nation-specific interests and concerns related to monitoring at the site. Each Nation may have different preferences for how to participate in the initiative and CNL commits to development of a program that is flexible to the needs of each Nation.

Canadian Nuclear Laboratories currently provides updates on environmental monitoring activities to all First Nations and the Manitoba Métis Federation and invites them to observe and participate in the monitoring activities. Further, CNL shares all the results of their annual environmental monitoring reports with all the communities and is in the process of developing a user-friendly document to share with Indigenous Nations. Canadian Nuclear Laboratories will continually evaluate both the process and the outcome of the ongoing engagement and communication activities, to address and manage issues as they arise.

12.19 Conclusion

This EIS describes the Project, the existing environmental conditions on the WL site, and assesses the likely effects of the Project on the environment. The EIS includes an assessment of likely cumulative effects of the Project in combination with other past, present or reasonably foreseeable projects, as applicable. It describes the effects for normal conditions and as a result of accidents and malfunctions. The EIS also describes and assesses the likely effects of the environment on the Project.

Residual adverse effects were identified for air quality, hydrogeology, surface water quality, and human and ecological health. Mitigation and environmental design features implemented for the Project are well-understood and include existing practices at the WL site. Canadian Nuclear Laboratories will implement an Environmental Assessment Follow-up and Monitoring Program for Whiteshell Reactor 1 to verify the accuracy of environmental effects and determine the effectiveness of mitigation that has or is to be implemented. Based on the evaluation, no significant adverse effects on human health or the environment were identified as a result of the Project.

Overall, the EIS confirms that the ISD approach provides a permanent, passive decommissioning end state, and incorporates proven technologies and best industry practices, including documented international experience. ISD is a safe technique, reducing the risk to workers compared to dismantling and provides long-term safety to the public and the environment. The Project design has been optimized to remain below the assessment criteria established to be protective of the environment and to demonstrate long-term safety of the workers, the public and the environment. In addition, institutional controls, including restrictions on land use and a program for monitoring will be implemented to verify and validate these conclusions.

14.0 GLOSSARY, ABBREVIATIONS AND UNITS

14.1 Glossary

Table 14.1-1: Glossary Of Terms

Term	Definition
Acceptable Risk	A risk which is so small, whose consequences are so slight, or whose associated benefits (perceived or real) are so great, that persons or groups in society are willing to take or be subjected to that risk.
Activation Product	A radionuclide produced by activation. Often used in distinction from fission products. For example, in decommissioning waste comprising structural materials from a nuclear facility, activation products might typically be found primarily within the matrix of the material, whereas fission products are more likely to be present in the form of contamination on surfaces
Acute	With reference to toxicity, having a sudden onset, lasting a short time (usually within hours or days). With reference to a stimulus, severe enough to rapidly induce a response.
Acute Toxicity	Adverse effects occurring following oral or dermal administration of a single dose of a substance, or multiple doses given within 24 hours, or an inhalation exposure of 4 hours.
Adaptive Management	A management approach that involves the monitoring and evaluation of a reclaimed area's performance followed by any necessary actions to achieve the intended performance objectives. Adaptive management also allows information to be fed back into the planning and design process so that future reclaimed areas will meet the intended objectives.
Anthropogenic	Coming from or having been caused by man.
Anticipated Operational Occurrences	An operational process deviating from normal operation which is expected to occur at least once during the operating lifetime of a facility but which, in view of appropriate design provisions, does not cause any significant damage to items important to safety nor lead to accident conditions.
Archaeological Resources	Any material remains of past human life or activities which are of archaeological interest.
As Low As Reasonably Achievable (ALARA)	An optimization tool in radiation protection used to keep individual, workplace and public dose limits as low as reasonably achievable, social and economic factors being taken into account. ALARA is not a dose limit; it is a practice that aims to keep dose levels as far as possible below regulatory limits.
Background Radiation	The dose, dose rate or an observed measure related to the dose or dose rate, attributable to all sources other than the one(s) specified.
Batholith	A large mass of intrusive igneous rock (also called plutonic rock) formed from cooled magma deep in the Earth's crust.
Bioaccumulation Factor (BAF)	Bioaccumulation factor (BAF) is the quotient obtained by dividing the concentration of a substance in tissue by its concentration in a specified exposure medium, for example, air, food, sediment, soil, water.
Becquerels	The SI (International System) unit of radioactivity, corresponding to one disintegration per second.
Best Management Practice	Operating practice that enhances the sustainability of the resource to which the practice relates. Must be practical and economically achievable.
Beta Radiation	The emission of a beta particle from the nucleus of an atom.

Table 14.1-1: Glossary Of Terms

Term	Definition
Bioavailability	The amount of chemical which is actually available to the target tissues following exposure.
Chronic	Involving stimulus that is lingering or continues for a long time; often signifies periods from several weeks to years, depending on the reproductive life cycle of the species. Can be used to define either the exposure or the response to an exposure (effect). Chronic exposure typically induces a biological response of relatively slow progress and long continuance.
Contaminated Areas	An area where the condition or state of soil, water, or air caused by a substance release or escape results in an impairment of, or damage to, the environment, human health, safety, or property.
Contamination	(1) Radioactive substances on surfaces, or within solids, liquids or gases (including the human body), where their presence is unintended or undesirable, (2) the presence of such substances in such places or (3) the process giving rise to their presence in such places.
Cooling	A term used to describe the process of allowing radioactivity to decay and the rate of heat generation to decrease as in the case of vitrified HLW and spent fuel.
Corporate Social Responsibility	A business approach that contributes to sustainable development by delivering economic, social and environmental benefits for all stakeholders.
Crown Corporation	Any corporation that is established and regulated by a country's state or government.
Datum	A fixed starting point of a scale or operation.
Decommissioning	Administrative and technical actions taken to allow the removal of some or all of the regulatory controls from a facility. This does not apply to a repository or to certain nuclear facilities used for mining and milling of radioactive materials, for which closure is used.
Decontamination	The complete or partial removal of contamination by a deliberate physical, chemical or biological process.
Deep Geological Repository	A facility for disposal of radioactive waste located underground (usually several hundred metres or more below the surface) in a geological formation to provide long term isolation of radionuclides from the biosphere.
Diffusion	The movement of atoms or molecules from a region of higher concentration of the diffusing species to regions of lower concentration, due to a concentration gradient
Dismantling	The disassembly and removal of any structure, system or component during decommissioning. Dismantling may be performed immediately after permanent retirement of a nuclear facility or it may be deferred
Drainage Basins	Area draining to a lake, stream, reservoir or other body of water.
Duty To Consult	In Canada, the duty to consult and accommodate with Aboriginal peoples arises when the Crown contemplates actions or decisions that may affect an Aboriginal person's Aboriginal or Treaty rights.
Effluent	Liquid waste or sewage discharged into a river, lake or the sea.
Environmental Assessment	A planning tool used to identify the possible environmental effects of a proposed project and to determine if the adverse effects can be mitigated.
Environmental Impact Statement	A document that provides a detailed review of an environmental assessment and related studies.
Environmental Management System	Refers to the management of an organization's environmental programs in a comprehensive, systematic, planned and documented manner. It includes the organizational structure, planning and resources for developing, implementing and maintaining policy for environmental protection.

Table 14.1-1: Glossary Of Terms

Term	Definition
Eutrophic	A lake or other body of water that is rich in nutrients and supporting a dense plant population, the decomposition of which kills animal life by depriving it of oxygen.
Fission	The division of a heavy nucleus into two (or, rarely, more) parts with masses of equal order of magnitude; usually accompanied by the emission of neutrons and gamma radiation.
Friable	Material that can be readily reduced to dust or powder by hand or moderate pressure.
Fugitive Dust	Small airborne particulate matter which generally comes from soil. Fugitive dust is suspended in the air by wind action and human activities.
Gamma Radiation	Gamma rays are the most energetic form of electromagnetic radiation, with a very short wavelength of less than one-tenth of a nanometer. Gamma radiation is the product of radioactive atoms.
Gamma Spectroscopy	The quantitative study of the energy spectra of gamma-ray sources, in the nuclear industry, geochemical investigation, and astrophysics. Most radioactive sources produce gamma rays, which are of various energies and intensities.
Geiger Tube	It is a gaseous ionization detector and uses the Townsend avalanche phenomenon to produce an easily detectable electronic pulse from as little as a single ionising event due to a radiation particle.
Greenhouse Gases	A gas in the atmosphere that absorbs and emits radiation within the thermal infrared range. The primary greenhouse gases in the Earth's atmosphere are water vapor, carbon dioxide, methane, nitrous oxide, and ozone.
Hazardous Materials	Materials that are potentially hazardous to human health and/or the environment due to their nature and quantity and that require special handling and storage techniques.
High Level Waste	Includes used nuclear fuel and other wastes (e.g., reprocessing wastes) that have been declared as radioactive waste that generate significant heat via radioactive decay. Used nuclear fuel is associated with penetrating radiation and contains significant quantities of long-lived radionuclides.
Hydraulic Conductivity	Symbolically represented as K, is a property of vascular plants, soils and rocks that describes the ease with which a fluid (usually water) can move through pore spaces or fractures.
Hydrofluorocarbons	Organic compounds that contain fluorine and hydrogen atoms, are the most common type of organofluorine compounds. They are commonly used in air conditioning and as refrigerants.
Infrared Radiation	A type of electromagnetic radiation, as are radio waves, ultraviolet radiation, X-rays and microwaves. Infrared light is the part of the electromagnetic spectrum that people encounter most in everyday life, although much of it goes unnoticed. It is invisible to human eyes, but people can feel it as heat.
Intermediate Level Waste	Typically exhibits levels of penetrating radiation sufficient to require shielding during handling and interim storage and contains significant quantities of long lived radionuclides.
Ion Exchange	A usually reversible exchange of one ion with another, either on a solid surface, or within a lattice. A commonly used method for treatment of liquid waste.
Ionizing Radiation	A form of radiation that is capable of adding or removing electrons as it passes through matter (such as air, water, or living tissue).
Lc_{50}	LC_{50} is the lethal concentration of a toxin that is required to kill 50% of the population.
Low Level Waste	Contains material with radionuclide content above established clearance levels and exemption quantities, but generally has limited amounts of long lived activity. Low-level waste requires isolation and containment for up to a few hundred years.
Metasedimentary	Sediment or sedimentary rock that appears to have been altered by metamorphism.

Table 14.1-1: Glossary Of Terms

Term	Definition
Mixed Waste	Radioactive waste that also contains hazardous substances.
Molybdenum	The chemical element of atomic number 42, a brittle silver-gray metal of the transition series, used in some alloy steels.
Near Surface Disposal Facility	A facility for disposal of radioactive waste located at or within a few tens of metres from the earth's surface.
Nitrate	A salt or ester of nitric acid, containing the anion NO_3^- or the group —NO_3.
Nitrification/Denitrification	The biological oxidation of ammonia or ammonium to nitrite followed by the oxidation of the nitrite to nitrate. The transformation of ammonia to nitrite is usually the rate limiting step of nitrification. Nitrification is an important step in the nitrogen cycle in soil.
Nitrite	A salt or ester of nitrous acid, containing the anion NO_2^- or the group —NO_2.
Noble Gases	Any of the gaseous elements helium, neon, argon, krypton, xenon, and radon, occupying Group 0 (18) of the periodic table. They were long believed to be totally unreactive but compounds of xenon, krypton, and radon are now known.
Nuclear Facility, Sites	A facility and its associated land, buildings and equipment in which radioactive materials are produced, processed, used, handled, stored or disposed of on such a scale that consideration of safety is required.
Perfluorocarbons	Organofluorine compounds with the formula CxFy, i.e., they contain only carbon and fluorine.
Polychlorinated Biphenyls (PCBs)	Any of a class of toxic aromatic compounds, often formed as waste in industrial processes, whose molecules contain two benzene rings in which hydrogen atoms have been replaced by chlorine atoms.
Radiation Field	Represents the energy lost from the source radiator to space.
Radioactive Decay	The process by which the nucleus of an unstable atom loses energy by emitting radiation, including alpha particles, beta particles, gamma rays, and conversion electrons.
Radioactive Waste	For legal and regulatory purposes, waste that contains or is contaminated with radionuclides at concentrations or activities greater than clearance levels as established by the regulatory body. It should be recognized that this definition is purely for regulatory purposes and that material with activity concentrations equal to or less than clearance levels is radioactive from a physical viewpoint — although the associated radiological hazards are considered negligible.
Radiological	Involving radioactive materials
Radionuclide	A nucleus (of an atom) that possesses properties of spontaneous disintegration (radioactivity). Nuclei are distinguished by their mass and atomic number.
Reasonably Foreseeable Developments	Industrial or construction projects and developments that are approved or under approval, and are likely to commence in the reasonably foreseeable future.
Remediation	Any measures that may be carried out to reduce the exposure from existing contamination through actions applied to the contamination itself (the source) or to the exposure pathways to humans.
Residual Effects	Environmental effects predicted to remain after the application of mitigation outlined in an environmental assessment. The predicted residual effects are considered for each Project phase.
Shielding	A material interposed between a source of radiation and persons, or equipment or other objects, in order to absorb radiation and thereby reduce radiation exposure.

Table 14.1-1: Glossary Of Terms

Term	Definition
Sievert	The SI unit of absorbed radiation dose in living organisms modified by radiation type and tissue weighting factors. The sievert is the unit of dose measuring the “equivalent dose" and “effective dose". It replaces the classical radiation unit the rem. Multiples of sievert used in practice include millisievert (mSv) and microsievert (µSv).
Sorption	The interaction of an atom, molecule or particle with the surface of a solid. A general term including absorption (sorption taking place largely within the pores of a solid) and adsorption (surface sorption with a non-porous solid). The processes involved may also be divided into chemisorption (chemical bonding with the substrate) and physisorption (physical attraction, for example by weak electrostatic forces).
Source Term	The amount and isotopic composition of material released (or postulated to be released) from a nuclear facility.
Stochastic Effects	A term used to group radiation-induced health effects (such as cancer or inheritable diseases) which have a statistical risk. For these diseases, the probability of their occurrence increases proportionally to the radiation dose received: the higher the dose, the higher the probability of occurrence.
Subsurface Water	Water that flows or collects beneath the Earth's surface.
Sulphur Hexafluoride	Organic, colorless, odorless, non-flammable, extremely potent greenhouse gases, which are excellent electrical insulators.
Surface Water	Surface water is water collecting on the ground or in a stream, river, lake, wetland, or ocean.
Total Suspended Solids	Solids in water that can be trapped by a filter. TSS can include a wide variety of material, such as silt, decaying plant and animal matter, industrial wastes, and sewage. High concentrations of suspended solids can cause many problems for stream health and aquatic life.
Tritium	An isotope that occurs both naturally and as a by-product in nuclear reactors. Tritium is a radioactive isotope of hydrogen having two neutrons and one proton in its nucleus; hydrogen, by comparison, has only one proton. Tritium decays by emitting an electron (beta radiation) and has a half-life of 12.33 years.
Valued Component	Refers to environmental features that may be affected by a project and that have been identified to be of concern by the proponent, government agencies, Aboriginal peoples, or the public.
Volatile Organic Compounds	Organic compounds that easily become vapors or gases.
Waste Acceptance Criteria	Quantitative or qualitative criteria specified by the regulatory body, or specified by an operator and approved by the regulatory body, for radioactive waste to be accepted by the operator of a repository for disposal, or by the operator of a storage facility for storage.
Waste Streams	The total flow of solid waste from homes, businesses, institutions, and manufacturing plants that is recycled, burned, or disposed of in landfills, or segments thereof.

1.0 TABLE OF CONCORDANCE TO THE CNSC GENERIC EIS GUIDELINES

Section in Generic Guideline	Requirement	Section in the EIS
Part 1	**BACKGROUND**	
1.0	**Introduction**	
	The purpose of this document is to provide information to proponents on the requirements for the preparation of an environmental impact statement (EIS) for a designated project to be assessed pursuant to the *Canadian Environmental Assessment Act, 2012* (CEAA 2012). This document specifies the nature, scope and extent of the information required. Part 1 of this document provides guidance and general instruction on the preparation of the EIS, and part 2 outlines the information that must be included in the EIS.	■ Not Applicable
	Section 5 of the CEAA 2012 requires an assessment of the proposed project's potential environmental effects: 5. (1) For the purposes of this Act, the environmental effects that are to be taken into account in relation to an act or thing, a physical activity, a designated project or a project are: a) a change that may be caused to the following components of the environment that are within the legislative authority of Parliament: i. fish and fish habitat as defined in subsection 2(1) of the *Fisheries Act* ii. aquatic species as defined in subsection 2(1) of the *Species at Risk Act* iii. migratory birds as defined in subsection 2(1) of the *Migratory Birds Convention Act*, 1994 iv. any other component of the environment that is set out in Schedule 2 b) a change that may be caused to the environment that would occur: i. on federal lands ii. in a province other than the one in which the act or thing is done or where the physical activity, the designated project or the project is being carried out iii. outside Canada c) with respect to Aboriginal peoples, an effect occurring in Canada of any change that may be caused to the environment on: i. health and socio-economic conditions ii. physical and cultural heritage iii. the current use of lands and resources for traditional purposes iv. any structure, site or thing that is of historical, archaeological paleontological or architectural significance	■ Not Applicable

Section in Generic Guideline	Requirement	Section in the EIS
Part 1	**BACKGROUND**	
1.0	**Introduction**	
	5. (2) However, if the carrying out of the physical activity, the designated project or the project requires a federal authority to exercise a power or perform a duty or function conferred on it under any Act of Parliament other than this Act, the following environmental effects are also to be taken into account: a) a change, other than those referred to in paragraphs (1)(a) and (b), that may be caused to the environment and that is directly linked or necessarily incidental to a federal authority's exercise of a power or performance of a duty or function that would permit the carrying out, in whole or in part, of the physical activity, the designated project or the project b) an effect, other than those referred to in paragraph (1)(c), of any change referred to in paragraph (a) on: i. health and socio-economic conditions ii. physical and cultural heritage iii. any structure, site or thing that is of historical, archaeological, paleontological or architectural significance	
	The Canadian Nuclear Safety Commission (CNSC) will use the proponent's EIS and other information received during the environmental assessment (EA) process to prepare an EA report that will inform the issuance of a decision statement by the Commission. Therefore, the EIS must include a full description of the changes the project will cause to the environment that may result in potential effects on areas of federal jurisdiction (i.e., section 5 of the CEAA 2012) – including changes that are directly linked or necessarily incidental to any federal decisions that would permit the project to be carried out. The EIS should also include a list of key mitigation measures that the proponent proposes to undertake in order to avoid or minimize any adverse environmental effects of the project. It is the proponent's responsibility to provide sufficient data and analysis on potential changes to the environment.	■ Not Applicable

Section in Generic Guideline	Requirement	Section in the EIS
2.0	**GUIDING PRINCIPLES**	
2.1	**Government of Canada Interim Measures**	
	On January 27, 2016, the Minister of Environment and Climate Change Canada and the Minister of Natural Resources Canada announced an interim approach that includes principles and plans for major projects. These principles are the first part of a broader strategy to review and restore confidence in Canada's EA processes. In particular, the Government of Canada has introduced the principle that direct and upstream greenhouse gas emissions linked to the projects under review will be assessed. The proponent is expected to take the necessary steps to provide sufficient information and evidence in accordance with this principle. For more information on assessing greenhouse gas emissions, refer to Section 5.1 (part 2).	■ Section 6.2.2 Greenhouse Gases
2.2	**EA as a Planning Tool**	
	An EA is a planning tool used to ensure that projects are considered in a careful and precautionary manner in order to avoid or mitigate possible environmental effects and to encourage decision makers to take actions that promote sustainable development.	■ Not Applicable
2.3	**Public Participation**	
	One of the purposes identified in the CEAA 2012 is to ensure opportunities for meaningful public participation during an EA. The CNSC ensures that the public is provided with opportunities to participate in the EA. Meaningful public participation is best achieved when all parties have a clear understanding of the proposed project as early as possible in the review process. The proponent is required to provide current information about the project to the public and especially to the communities likely to be most affected by the project.	■ Section 5.0 Public Engagement

Section in Generic Guideline	Requirement	Section in the EIS
2.4	**Indigenous Engagement**	
	A key objective of the CEAA 2012 is to promote communication and cooperation with Aboriginal peoples, which include First Nations, Inuit and Métis. The proponent is expected to engage with Aboriginal groups that may be affected by the project, as early as possible in the project planning process. The proponent will provide Aboriginal groups with opportunities to learn about the project and its potential effects, to communicate their concerns about the project's potential effects, and to discuss measures to mitigate those effects. The proponent is strongly encouraged to work with Aboriginal groups in establishing an engagement approach that is reasonable to both parties. The proponent will make reasonable efforts to consider traditional Aboriginal knowledge into the assessment of environmental impacts. For more information on considering Aboriginal traditional knowledge, refer to Section 3.3.2 (part 1). Information gathered through the EA process and associated engagement by the proponent with Aboriginal groups will be used to inform decisions under the CEAA 2012. In providing information to the CNSC, the proponent will ensure any confidential information shared with them by Aboriginal groups is treated in the appropriate manner. This information will also contribute to the Crown's understanding of any potential adverse impacts of the project on potential or established Aboriginal or Treaty rights and the effectiveness of measures proposed to avoid or minimize those impacts, and will assist the Crown in meeting its duty to consult obligations. The proponent is encouraged to consult the following resources: ■ REGDOC-3.2.2, Indigenous Engagement (CNSC); and ■ Aboriginal and Treaty Rights Information System (Indigenous and Northern Affairs Canada).	■ Section 4.0 Indigenous Engagement
2.5	**Application of the Precautionary Approach**	
	In documenting the analyses included in the EIS, the proponent will demonstrate that all aspects of the project have been examined and planned in a careful and precautionary manner in order to avoid significant adverse environmental effects. The Canadian Privy Council Office's *A Framework for the Application of Precaution in Science-based Decision Making About Risk* (refer to bibliography) sets out guiding principles for the application of precaution to science-based decision making.	■ Section 3.4 Project Requirements ■ Section 6.1 Environmental Assessment Approach
3.0	**Preparation and Presentation of the EIS**	
3.1	**Guidance**	
	The proponent is encouraged to consult the CNSC's draft REGDOC-2.9.1, Environmental Principles, Assessments and Protection Measures for additional guidance on the preparation of the EIS. The proponent may also consider consulting the relevant EA policy and guidance documents provided on the Canadian Environmental Assessment Agency website. The proponent is further encouraged to consult with the CNSC and, if applicable, other federal authorities, during the planning and development of the EIS and supporting documentation.	■ All EIS sections and Appendices

Section in Generic Guideline	Requirement	Section in the EIS
3.2	**Study Strategy and Methodology**	
	The proponent is expected to respect the intent of these guidelines and to consider the effects that are likely to arise from the project (including situations not explicitly identified in these guidelines), the technically and economically feasible mitigation measures that will be applied, and the significance of any residual effects. Except where specified by the CNSC, the proponent has the discretion to select the most appropriate methods to compile and present data, information and analysis in the EIS as long as the methods are transparent, justifiable and replicable. These guidelines may include matters that the proponent does not deem relevant or significant to the project. If such matters are omitted from the EIS, the proponent will clearly indicate it and provide a justification so that the CNSC, federal authorities, Aboriginal groups, the public and any other interested party will have an opportunity to comment on this decision. Where the CNSC disagrees with the proponent's decision, it will require the proponent to provide the specified information. The proponent must explain and justify methods used to predict impacts of the project on each valued component (VC) (see Section 5.2.1 in part 2 of this document for the definition of valued component). VCs include biophysical and socioeconomic components, the interactions among them, and their relationships within the environment. The information presented must be substantiated; in particular, the proponent must describe how the VCs were identified and what methods were used to predict and assess the project's potential adverse environmental effects on these components. The value of a component not only relates to its role in the ecosystem, but also to the value that humans place on it. The culture and way of life of the people using the area affected by the project may be considered VCs themselves. The EIS will also explain and justify methods used to identify mitigation measures and follow-up program elements. The EIS will document how scientific, engineering, traditional and local knowledge were used to reach conclusions. Assumptions will be clearly identified and justified. All data, models and studies will be documented such that the analyses are transparent and reproducible. All data collection methods will be specified. The uncertainty, reliability and sensitivity of models used to reach conclusions must be indicated. The sections in the EIS regarding the existing environment and the potential adverse environmental effects predictions and assessment must be prepared, using best available information and methods, to the highest standards in the relevant subject area. All conclusions must be substantiated. The EIS will identify all significant gaps in knowledge and understanding related to key conclusions, and the steps to be taken by the proponent to address these gaps. Where the conclusions drawn from scientific, engineering and technical knowledge are inconsistent with the conclusions drawn from traditional and local knowledge, the EIS will contain a balanced presentation of the issues and a statement of the proponent's conclusions.	■ Section 6.1 Environmental Assessment Approach ■ Section 6.2 Atmospheric Environment ■ Section 6.3 Geological and Hydrogeological Environment ■ Section 6.4 Surface Water Environment ■ Section 6.5 Aquatic Environment ■ Section 6.6 Terrestrial Environment ■ Section 6.7 Human and Ecological Health ■ Section 6.8 Land and Resource Use ■ Section 6.9 Socio-economic Environment

Section in Generic Guideline	Requirement	Section in the EIS
3.3	**Use of Information**	
3.3.1	**Federal Coordination of Information or Knowledge**	
	Section 20 of the CEAA 2012 requires that every federal authority with specialist or expert information, or knowledge with respect to a project subject to an EA, make that information or knowledge available to the CNSC. The CNSC will coordinate the involvement, and notify the proponent, of federal departments and other jurisdictions with expert and specialist knowledge specific to the EA.	■ Not Applicable
3.3.2	**Community Knowledge and Aboriginal Traditional Knowledge**	
	Subsection 19(3) of the CEAA 2012 states that "the environmental assessment of a designated project may take into account community knowledge and Aboriginal traditional knowledge". The proponent will consider community and Aboriginal traditional knowledge to which it has access or that is acquired through Aboriginal and public engagement activities, in keeping with appropriate ethical standards and obligations of confidentiality. Agreement should be obtained from Aboriginal groups regarding the use, management and protection of their existing traditional knowledge information during and after the EA. Where community and Aboriginal traditional knowledge has been considered by the proponent, the EIS will document the following: ■ the traditional knowledge information gathered ■ how the traditional knowledge information was gathered (e.g., interviews with key community leaders and elders, collaborative field research, Aboriginal traditional knowledge studies, etc.) ■ the source of the traditional knowledge information ■ how the traditional knowledge information gathered was taken into consideration by the proponent in the assessment, including both methodology (e.g., identifying VCs, establishing spatial and temporal boundaries, defining significance criteria) and analysis (e.g., baseline characterization, effects prediction, development of mitigation measures)	■ Section 4.3 Influence of Traditional Knowledge on the Environmental Assessment ■ Section 6.4.2 Surface Water Quality ■ Section 6.5 Aquatic Environment ■ Section 6.6 Terrestrial Environment ■ Section 6.7 Human and Ecological Health ■ Section 6.8.1 Traditional Land and Resource Use by Indigenous Nations ■ Section 6.9 Socio-economic Environment
N3.3.3	**Existing Information**	
	In preparing the EIS, the proponent is encouraged to make use of existing information relevant to the project. When relying on existing information to meet requirements of the EIS guidelines, the proponent will either include the information directly in the EIS or clearly direct the reader to where it may obtain the information (i.e., through cross-referencing). When relying on existing information, the proponent will also comment on how the data were applied to the project, separate factual lines of evidence from inference, and state any limitations on the inferences or conclusions that can be drawn from the existing information.	■ All EIS Sections and Appendices

Section in Generic Guideline	Requirement	Section in the EIS
3.3.4	**Confidential Information**	
	In implementing the CEAA 2012, the CNSC is committed to promoting public participation in the EA of projects and providing access to the information on which EAs are based. All documents prepared or submitted by the proponent or any other stakeholder in relation to the EA are posted or referenced on the Canadian Environmental Assessment Registry and/or the CNSC's website and made available to the public upon request. For this reason, the EIS should not contain information that: ■ is sensitive or confidential (i.e., financial, commercial, scientific, technical, personal, cultural or other nature) in accordance with the Privacy Act and the Access to Information Act, that is treated consistently as confidential, and the person affected has not consented to the disclosure ■ may cause harm to a person or harm to the environment through its disclosure If the EIS contains information that should be treated as "confidential" or "protected" in accordance with the Privacy Act and the Access to Information Act, the proponent should identify and request to the CNSC that such information be treated accordingly.	■ All EIS Sections and Appendices

Section in Generic Guideline	Requirement	Section in the EIS
Part 2	**EIS CONTENT AND STRUCTURE** Part 2 of this document provides specific instructions for the content of each section in the EIS. The EIS as a whole must reflect the guiding principles in part 1 of this document.	
1.0	**Presentation and Organization of the EIS**	
	To facilitate the identification of the documents submitted, the title page of the EIS and its related documents will contain the following information: ■ project name and location ■ title of the document, including the term “environmental impact statement” ■ subtitle of the document ■ proponent name and contact information ■ date	■ EIS Cover Page
	The EIS will be written in clear, precise language. A glossary of technical words, acronyms and abbreviations will be included. It will include charts, diagrams, tables, maps and photographs, where appropriate, to clarify the text. Perspective drawings that clearly convey the various components of the project will also be provided. Wherever possible, maps will be presented in common scales and datum to allow for comparison and overlay of mapped features. For purposes of brevity and to avoid repetition, cross-referencing within the EIS is preferred. The EIS may make reference to the information that has already been presented in other sections of the document, rather than repeating it. Detailed studies (including all relevant and supporting data and methodologies) will be provided in separate appendices and will be referenced by appendix, section and page in the text of the main document. The EIS will explain how information is organized in the document. This will include a list of all tables, figures, and photographs referenced in the text. A complete list of supporting literature and references will also be provided. A table of concordance, which cross references the information presented in the EIS with the information requirements identified in the EIS guidelines, will be provided. The proponent will provide copies of the EIS and its summary for distribution, as directed by the CNSC, including paper and electronic version in an unlocked, searchable PDF format.	■ All EIS Sections and Appendices

Section in Generic Guideline	Requirement	Section in the EIS
2.0	**Executive Summary**	
	For efficiency, the proponent may consider preparing a summary of the EIS in both of Canada's official languages (French and English), which is to be provided to the CNSC at the same time as the EIS. The proponent is also encouraged to consider making the executive summary available in the language(s) spoken by Aboriginal communities in close proximity to the project (e.g., Cree, Dene). The summary will include the following: ■ a concise description of all key components of the project and related activities ■ a summary of the consultation conducted with Aboriginal groups, the public, and government agencies, including a summary of the issues raised and the proponent's responses ■ an overview of the key environmental effects of the project and proposed technically and economically feasible mitigation measures ■ the proponent's conclusions on the residual environmental effects of the project after taking mitigation measures into account and the significance of those effects The summary will be provided as a separate document and will have sufficient details for the reader to learn and understand the project, potential environmental effects, mitigation measures, the significance of the residual effects and follow-up program.	■ Executive Summary
3.0	**Introduction and Overview**	
3.1	**Project Overview**	
	The EIS will describe the project, key project components and associated activities, scheduling details, the timing of each phase of the project and other key features. If the project is a part of a larger sequence of projects, the EIS will outline the larger context. The overview is to identify the project's key components, rather than providing a detailed description, which will follow in section 4 (part 2) of this document.	■ Section 1.2 Project Overview

Section in Generic Guideline	Requirement	Section in the EIS
3.2	**Project Location**	
	The EIS will contain a description of the geographical setting where the project will take place. This description should include those aspects of the project and its setting that are key to understanding the project's potential adverse environmental effects, including: ■ geographical maps of the project location (at an appropriate scale) including project components, project boundaries of the proposed site with the Universal Transverse Mercator (UTM) coordinates – the lease boundary, site study area, local study area, regional study area, the major existing infrastructure, adjacent land uses and any important environmental features ■ current land use in the area ■ distance of the project facilities and components to any federal lands ■ the environmental significance and value of the geographical setting in which the project will take place and the surrounding area ■ environmentally sensitive areas, such as national, provincial and regional parks, ecological reserves, wetlands, estuaries, and habitats of federally (Schedule 1 of Species at Risk Act) or provincially listed species at risk and other sensitive areas ■ description of local and Aboriginal communities ■ traditional Aboriginal territories, treaty lands, and Indian reserve lands and Métis harvesting regions and/or settlements	■ Section 1.3 Project Location
3.3	**Regulatory Framework and the Role of Government**	
	The EIS should identify: ■ the environmental and other regulatory approvals and legislation, including CEAA 2012, that are applicable to the project at the federal, provincial, regional and municipal levels ■ government policies, resource management plans, planning or study initiatives pertinent to the project and/or EA and their implications ■ any treaty or self-government agreements with Aboriginal groups that are pertinent to the project and/or EA ■ any relevant land use plans, land zoning, or community plans ■ regional, provincial and/or national objectives, standards or guidelines that have been used by the proponent to assist in the evaluation of any predicted environmental effects	■ Section 1.6 Regulatory Framework

Section in Generic Guideline	Requirement	Section in the EIS
4.0	**Project Description**	
4.1	**Purpose of the Project**	
	The EIS will describe the purpose of the project by providing the rationale for the project, explaining the background, the problems or opportunities that the project is intended to satisfy and the stated objectives from the perspective of the proponent. If the objectives of the project are related to broader private or public sector policies, plans or programs, this information should also be included.	■ Section 2.3 Purpose of the Project
4.2	**Alternative Means of Carrying out the Project**	
	The EIS will identify and consider the effects of alternative means of carrying out the project that are technically and economically feasible as described in appendix A, section A.3.2 Alternative means for carrying out the project, of the CNSC's draft REGDOC-2.9.1, Environmental Principles, Assessments and Protection Measures. The proponent will complete the following procedural steps for addressing alternative means: ■ Identify and describe in sufficient detail the alternative means to carry out the project: ■ develop criteria to determine the technical and economic feasibility of the alternative means ■ identify those alternative means that are technically and economically feasible ■ Identify the effects of each technically and economically feasible alternative means: ■ identify those elements of each alternative means that could produce effects in sufficient detail to allow a comparison with the effects of the project ■ the effects referred to above include both environmental effects and potential adverse impacts on potential or established Aboriginal and Treaty rights and related interests ■ Describe the methodology used for the analysis of alternative means and the conclusion reached (i.e., preferred means). For further information regarding the "purpose of" and "alternative means", please consult the Agency's operational policy statement, titled Addressing "Purpose of" and "Alternative Means" under the Canadian Environmental Assessment Act, 2012". The CNSC recognizes that projects may be in the early planning stages when the EIS is being prepared. Proponents are strongly encouraged to conduct an environmental effects analysis where they have not made final decisions about the placement of project infrastructure, the technologies to be used, or if several options exist for various project components.	■ Section 2.5 Alternative Means of Carrying Out the Project

Section in Generic Guideline	Requirement	Section in the EIS
4.3	**Scope of Project**	
	The scope of project for the purposes of the EA includes all the phases, components, activities and federal decisions proposed by the proponent as described in the project description that has been determined to meet the requirements of the Prescribed Information for the Description of a Designated Project Regulations. The CNSC's Commission may also determine that other components and/or activities in relation to the project are to be included in the project scope. The proponent will consider all phases, components, activities and federal decisions identified in the scope of project as part of the effects assessment.	■ Section 3.0 Project Description
4.3.1	**Project Components**	
	The EIS will describe the project by presenting the project components, associated and ancillary works, and other characteristics that will assist in understanding the environmental effects.	■ Section 3.1.1 Project Overview ■ Section 3.4.5 Project Components
4.3.2	**Project Activities**	
	The EIS will include descriptions of each phase associated with the proposed project. This will include descriptions of the activities to be carried out during each phase, the location of each activity, expected outputs and an indication of the activity's magnitude and scale. Although a complete list of project activities should be provided, the emphasis will be on activities with the greatest potential to have environmental effects. Sufficient information will be included to predict environmental effects and address concerns identified by the public and Aboriginal groups. Highlight activities that involve periods of increased environmental disturbance or the release of materials into the environment. The EIS will include a summary of the changes that have been made to the project since originally proposed, including the benefits of these changes to the environment, Aboriginal peoples, and the public. The EIS will include a schedule including time of year, frequency, and duration for all project activities.	■ Section 3.1.2 Project Schedule ■ Section 3.4.6 In Situ Disposal ■ Section 3.4.7 Temporary Supporting Infrastructure ■ Section 3.4.8 Waste Generation and Management ■ Section 3.4.9 End-State and Post-Closure Activities

Section in Generic Guideline	Requirement	Section in the EIS
5.0	**Scope of the Environmental Assessment**	
5.1	**Factors to be Considered**	
	Scoping establishes the EA's parameters and focuses the assessment on relevant issues and concerns. The EA of the designated project must take into account the following factors, as listed in subsection 19(1) of the CEAA 2012: a) the section 5 environmental effects of the designated project (such as changes to fish and fish habitat, aquatic species, migratory birds), including the environmental effects of malfunctions or accidents that may occur in connection with the designated project, and any cumulative environmental effects likely to result from the designated project in combination with other physical activities that have been or will be carried out b) the significance of those environmental effects c) comments from the public that are received in accordance with the CEAA 2012 d) mitigation measures that are technically and economically feasible and that would mitigate any significant adverse environmental effects of the designated project e) the requirements of the follow-up program in respect of the designated project f) the purpose of the designated project g) alternative means of carrying out the designated project that are technically and economically feasible and the environmental effects of any such alternative means h) any changes to the designated project that may be caused by the environment i) the results of any relevant study conducted by a committee established under section 73 or 74 of the CEAA 2012 j) any other matter relevant to the EA that the CNSC requires to be taken into account, in accordance with the *Nuclear Safety and Control Act* Pursuant to subsection 19(2) of the CEAA 2012, the scope of the factors to be taken into account under paragraphs 19(1)(a), (b), (d), (e), (g), (h) and (j) is determined by the CNSC, as the responsible authority.	■ Section 2.0 Purpose of the Project and Alternatives to the Project ■ Section 3.0 Project Description ■ Section 4.0 Indigenous Engagement ■ Section 5.0 Public Engagement ■ Section 6.1 Environmental Assessment Approach ■ Section 6.2 Atmospheric Environment ■ Section 6.3 Geological and Hydrogeological Environment ■ Section 6.4.2 Surface Water Environment ■ Section 6.5 Aquatic Environment ■ Section 6.6 Terrestrial Environment ■ Section 6.7 Human and Ecological Health ■ Section 6.8 Land and Resource Use ■ Section 6.9 Socio-economic Environment ■ Section 7.0 Accidents and Malfunctions ■ Section 8.0 Summary of Cumulative Effects ■ Section 9.0 Summary of Significance of Residual Effects ■ Section 10.0 Assessment of Effects of the Environment on the Project ■ Section 11.0 Summary of Monitoring and Follow-up Programs

Section in Generic Guideline	Requirement	Section in the EIS
5.1	**Factors to be Considered**	
	To implement the Government of Canada interim measure with respect to upstream greenhouse gas emissions, the CNSC may require consideration of these types of emissions in the scope of the EA. On March 19, 2016, a definition of upstream GHG emissions was published by Environment Canada and Climate Change in the Canada Gazette. The proposed definition of upstream includes "*all industrial activities from the point of resource extraction to the project under review*." The processes that are to be considered as upstream activities will vary by the type of resource and the nature of the project under assessment. In general, upstream activities will include extraction, processing and handling as well as transportation. Where there is a reliable and feasible methodology for calculating upstream greenhouse gas emissions that are linked to the project, the proponent will be required to provide sufficient information to estimate these types of emissions. This information should be presented by individual pollutant and should be summarized in CO_2 equivalent units per year. If upstream greenhouse gas emissions are not considered in the assessment, the proponent will provide a rationale in the EIS.	■ Section 6.2.2 Greenhouse Gases

Section in Generic Guideline	Requirement	Section in the EIS
5.2	**Scope of Factors**	
5.2.1	**Valued Components to be Examined**	
	Valued components (VCs) refer to environmental biophysical or human features that may be impacted by a project. The value of a component not only relates to its role in the ecosystem, but also to the value people place on it. For example, it may have scientific, social, cultural, economic, historical, archaeological or aesthetic importance. The EIS will identify the VCs linked to section 5 of the CEAA 2012, including the ones identified in section 9.2 (part 2) that may be affected by changes in the environment, as well as species at risk and their critical habitat as per the requirement outlined in section 79 of the Species at Risk Act (SARA). Under section 73 of SARA, the Minister of Environment and Climate Change Canada may grant permits authorizing an activity affecting a listed wildlife species or any part of its residence or critical habitat that would otherwise be prohibited. Should the proponent identify a listed wildlife species or any part of its residence or critical habitat that would be affected by the project activities, the proponent should consult directly with the Canadian Wildlife Service as early as possible in the process. The final list of VCs to be presented in the EIS will be completed according to the evolution and design of the project and reflect the knowledge on the environment acquired through public consultation and Aboriginal engagement. The EIS will describe what methods were used to predict and assess the potential adverse environmental effects of the project on these components. The VCs will be described in sufficient detail to allow the reviewer to understand their importance and to assess the potential for environmental effects arising from the project activities. The EIS will provide a rationale for selecting specific VCs and for excluding any VCs or information specified in these guidelines. Challenges with particular exclusions may arise, so it is important to document the information and criteria used to make each determination. Examples of justification include primary data collection, computer modelling, literature references, public consultation, expert input or professional judgement. The EIS will identify those VCs, processes, and interactions that were identified to be of concern during any workshops or meetings held by the proponent, or that the proponent considers likely to be affected by the project. In doing so, the EIS will indicate to whom these concerns are important and the reasons why, including environmental, Aboriginal, social, economic, recreational, and aesthetic considerations. If comments are received on a component that has not been included as a VC, these comments will be summarised and the rationale for excluding the VC will be provided.	■ Section 6.1.3 Valued Components ■ Section 6.2.1.3 Valued Components – Air Quality ■ Section 6.2.2.3 Valued Components – Greenhouse Gases ■ Section 6.3.1.3 Valued Components – Geology ■ Section 6.3.2.3 Valued Components – Hydrogeology ■ Section 6.4.1.3 Valued Components – Hydrology ■ Section 6.4.2.3 Valued Components – Surface Water Quality ■ Section 6.5.3 Valued Components – Aquatic Environment ■ Section 6.6.3 Valued Components – Terrestrial Environment ■ Section 6.7.1.3 Valued Components – Human Health ■ Section 6.7.2.3 Valued Components – Ecological Health ■ Section 6.8.1.3 Valued Components – Traditional Land and Resource Use ■ Section 6.8.2.3 Values Components – Other Land and Resource Use ■ Section 6.9.3 Valued Components – Socio-economic Environment

Section in Generic Guideline	Requirement	Section in the EIS
5.2.2	**Spatial and Temporal Boundaries**	
	The spatial and temporal boundaries used in the EA may vary depending on the VC and will be considered separately for each VC. The proponent is encouraged to consult with the CNSC, federal and provincial government departments and agencies, local government and Aboriginal groups, and take into account public comments when defining the spatial boundaries used in the EIS. The EIS will describe the spatial boundaries, including local and regional study areas, of each VC to be used in assessing the potential adverse environmental effects of the project and provide a rationale for each boundary. Spatial boundaries will be defined by taking into account, but not limited to, the following criteria: a) the physical extent of the proposed project, including any offsite facilities or activities b) the extent of aquatic and terrestrial ecosystems potentially affected by the project c) the extent of potential effects arising from noise, light and atmospheric emissions d) the extent to which traditional land use or treaty rights could potentially be affected by the project e) current land and resource use for residential, commercial, industrial, recreational, cultural and aesthetic purposes by communities whose areas include the physical extent of the project f) the size, nature and location of past, present and reasonably foreseeable projects and activities which could interact with items (b), (c), (d) and (e) g) community and Aboriginal traditional knowledge, ecological, and technical considerations The following geographic study areas should serve as the basis for developing project specific and effect-specific study areas: ■ **Site study area:** The site study area is the project footprint (i.e., where project activities would be undertaken including the project's proposed facilities, buildings and infrastructure). ■ **Local study area:** The local study area is defined as that area existing outside the site study area boundary, where measurable changes to the environment resulting from the proposed activities from any phase of the project, either through normal activities, or from possible accidents or malfunctions, may be anticipated. The boundaries must change if appropriate following an assessment of the spatial extent of potential effects. The geographic boundary will depend on the factor being considered (e.g., a local study area defined for the aquatic environment will differ from that defined for the atmospheric environment). ■ **Regional study area:** The regional study area is defined as the area within which the potential effects of this project may interact with the effects of other projects, resulting in the potential for cumulative effects. The geographic boundary for the regional study areas are also specific to the factor being considered.	■ Section 6.1.4 Spatial Boundaries ■ Section 6.2.1.4 Assessment Boundaries – Air Quality ■ Section 6.2.2.4 Assessment Boundaries – Greenhouse Gases ■ Section 6.3.1.4 Assessment Boundaries – Geology ■ Section 6.3.2.4 Assessment Boundaries – Hydrogeology ■ Section 6.4.1.4 Assessment Boundaries – Hydrology ■ Section 6.4.2.4 Assessment Boundaries – Surface Water Quality ■ Section 6.5.4 Assessment Boundaries – Aquatic Environment ■ Section 6.6.4 Assessment Boundaries – Terrestrial Environment ■ Section 6.7.1.4 Assessment Boundaries – Human Health ■ Section 6.7.2.4 Assessment Boundaries – Ecological Health ■ Section 6.8.1.4 Assessment Boundaries – Traditional Land and Resource Use ■ Section 6.8.2.4 Assessment Boundaries – Other Land and Resource Use ■ Section 6.9.4 Assessment Boundaries – Socio-economic Environment

Section in Generic Guideline	Requirement	Section in the EIS
5.2.2	**Spatial and Temporal Boundaries (cont'd)**	
	Within the aforementioned study areas, the boundary of concern will extend to a depth that will include the full extent of the surface water and groundwater. The EA's temporal boundaries will span all phases of the project determined to be within the scope of the project as specified under section 4.3 above. If impacts are predicted after project decommissioning, this should be taken into consideration in defining boundaries. At a minimum, the assessment is expected to include the period of time during which the maximum impact is predicted to occur. Community and Aboriginal traditional knowledge should factor into decisions around temporal boundaries. If the temporal boundaries do not span all phases of the project, the EIS will identify the boundaries used and provide a rationale.	
6.0	**Public and Stakeholder Consultation**	
	In accordance with CNSC's REGDOC-99.3, Public Information and Disclosure, the EIS will describe the ongoing and proposed participation activities that the proponent will undertake or that it has already conducted on the project. It will describe efforts made to distribute project information, as well information and materials that were distributed during the public consultation process. The EIS will indicate the methods used, where the consultation was held, the persons and organizations consulted, the concerns voiced and the extent to which this information was incorporated in the design of the project as well as in the EIS. The EIS will provide a summary of key issues raised related to the Project and its potential environmental effects, as well as describe any outstanding issues and ways to address them.	■ Section 5.2 Project-specific Public Engagement Methods and Activities

Section in Generic Guideline	Requirement	Section in the EIS
7.0	**Aboriginal Engagement**	
	In accordance with the CNSC's REGDOC-3.2.2, Indigenous Engagement, the EIS will describe the proponent's engagement activities with potentially affected Aboriginal groups. The EIS will include, and the proponent should consider engaging with potentially affected Aboriginal groups to obtain their views on, the following: ■ the objectives of and the methods used for Aboriginal engagement activities ■ each Aboriginal group's potential or established rights including geographical extent, nature, frequency, timing and maps and data sets (e.g., fish catch numbers) when this information is provided by a group to the proponent or available through public records ■ comments, specific issues and concerns raised by Aboriginal groups and how the key concerns were responded to or addressed ■ the potential adverse impacts of the project on potential or established Aboriginal or treaty rights effects of changes to the environment on Aboriginal peoples (health and socioeconomic conditions; physical and cultural heritage, including any structure, site or thing that is of historical, archaeological, paleontological or architectural significance; and current use of lands and resources for traditional purposes) pursuant to paragraph 5(1)(c) of the CEAA 2012 ■ VCs suggested by Aboriginal groups for inclusion in the EIS, whether they were included, and the rationale for any exclusions ■ measures identified to mitigate or accommodate potential adverse impacts of the project on the potential or established Aboriginal or treaty rights and effects of changes to the environment on Aboriginal peoples, including suggestions raised by Aboriginal groups A suggested format for providing the information above is the creation of a tracking table of key issues raised by each Aboriginal group, including the concerns raised related to the project, proposed mitigation options, and where appropriate, a reference to the proponent's analysis in the EIS.	■ Section 4.2.2 Summary of Engagement

Section in Generic Guideline	Requirement	Section in the EIS
8.0	**Description of the Environment**	
8.1	**Baseline Environment**	
	The EIS will include a description of the environment, including the components of the existing environment and environmental processes, their interrelations and interactions as well as the variability in these components, processes and interactions over time scales appropriate to the EIS. In characterizing the environmental effects of the project, the proponent will consider the current baseline environment and environmental trends within the project area. The description of the existing baseline and the environmental trends should include a consideration of past projects and activities carried out by the proponent and/or others within the project area. Based on the scope of project described in section 4.3 (part 2), the EIS will present baseline information in sufficient detail to enable the identification of how the project could affect the VCs and an analysis of those effects. Should other VCs be identified during the conduct of the EA, the baseline condition for these components will also be described in the EIS. The baseline description should include results from studies done prior to any physical disruption of the environment due to initial project activities (e.g., site preparation). The proponent will use the information in appendix B of the CNSC's draft REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures* to develop the characterization of the baseline environment. If a federal decision (as per section 5(2) of the CEAA 2012) in relation to the project may result in environmental changes such as changes on federal lands, outside the province or Canada, the proponent will use the information in appendix A, section A.3.7, Socio-economic environment, of the CNSC's draft REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures*, to describe the baseline conditions in relation to these potential changes.	■ Section 6.1.5 Description of the Environment ■ Section 6.2.1.5 Description of the Environment – Air Quality ■ Section 6.2.2.5 Description of the Environment – Greenhouse Gases ■ Section 6.3.1.5 Description of the Environment – Geology ■ Section 6.3.2.5 Description of the Environment – Hydrogeology ■ Section 6.4.1.5 Description of the Environment – Hydrology ■ Section 6.4.2.5 Description of the Environment – Surface Water Quality ■ Section 6.5.5 Description of the Environment – Aquatic Environment ■ Section 6.6.5 Description of the Environment – Terrestrial Environment ■ Section 6.7.1.5 Description of the Environment – Human Health ■ Section 6.7.2.5 Description of the Environment – Ecological Health ■ Section 6.8.1.5 Description of the Environment – Traditional Land and Resource Use ■ Section 6.8.2.5 Description of the Environment – Other Land and Resource Use ■ Section 6.9.5 Description of the Environment – Socio-economic Environment

Section in Generic Guideline	Requirement	Section in the EIS
9.0	**Effects Assessment**	
9.1	**Predicted Changes to the Physical Environment**	
	The assessment will include a consideration of the predicted changes to the environment as a result of the project being carried out or as a result of any powers, duties or functions that are to be exercised by the federal government in relation to the project. These predicted changes to the environment are to be considered in relation to each phase of the project (i.e., construction, operation, decommissioning) and are to be described in terms of the following: ■ magnitude ■ geographic extent ■ timing ■ frequency ■ duration, ■ reversibility As changes to various parts of the physical environment may be inter-related as part of an ecosystem, the EIS will explain and describe the connections between the changes described. The proponent will use the information in Appendix C of the CNSC's draft REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures*, to assess the environmental effects of the project.	■ Section 6.1.9 Residual Effects Classification and Determination of Significance ■ Section 6.2.1.9 Residual Effects Classification and Determination of Significance – Air Quality ■ Section 6.3.2.7 Residual Effects Analysis – Hydrogeology ■ Section 6.4.2.7 Residual Effects Analysis – Surface Water Quality ■ Section 6.7.1.9 Residual Effects Classification and Determination of Significance - Human Health ■ Section 6.7.2.9 Residual Effects Classification and Determination of Significance - Ecological Health
9.2	**Predicted Effects on Valued Components**	
	Based on the predicted changes to the environment identified in section 9.1 (part 2) above, the proponent is to assess the environmental effects of the project on the VCs identified as per section 5.2.1 (part 2). Based on the changes to the environment that have been identified in section 9.1 (part 2), additional VCs are to be selected based on the following: ■ If there is the potential for the project to result in environmental changes on federal lands, another province, or another country, then VCs of importance not already identified above are to be listed in this section. ■ If federal decisions about the project will lead to an environmental change, then these environmental changes are to be considered stand-alone VCs. All interconnections between VCs and between changes to multiple VCs will be described.	■ Section 6.1.7 Residual Effects Analysis ■ Section 6.2.1.7 Residual Effects Analysis – Air Quality ■ Section 6.3.2.7 Residual Effects Analysis – Hydrogeology ■ Section 6.4.2.7 Residual Effects Analysis – Surface Water Quality ■ Section 6.7.1.7 Residual Effects Analysis – Human Health ■ Section 6.7.2.7 Residual Effects Analysis – Ecological Health

Section in Generic Guideline	Requirement	Section in the EIS
9.3	**Accidents and Malfunctions**	
	The proponent will use the information in appendix A, section A.3.4, Malfunctions and accidents, of the CNSC's draft REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures*, to assess the potential health and environmental effects from postulated accident and malfunction scenarios.	■ Section 7.0 Accidents and Malfunctions
9.4	**Cumulative Effects**	
	The proponent will use the information in appendix A, section A.3, Cumulative effects, of the CNSC's draft REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures*, to assess the project's potential cumulative effects.	■ Section 8.0 Summary of Cumulative Effects
9.5	**Socio-economic Environment**	
	The proponent will use the information in appendix A, section A.3.7, Socio-economic environment, of the CNSC's draft REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures*, to assess the project's indirect socio-economic effects.	■ Section 6.9 Socio-economic Environment
9.6	**Effects of the Environment on the Project**	
	The proponent will use the information in appendix A, section A.3.9, Assessment of effects of the environment on the project, of the CNSC's draft REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures*, to assess the effects of the environment on the project (i.e., severe weather events).	■ Section 10.0 Assessment of Effects of the Environment on the Project

Section in Generic Guideline	Requirement	Section in the EIS
10.0	**Mitigation Measures**	
	Every EA conducted under the CEAA 2012 will consider measures that are technically and economically feasible and that would mitigate any significant adverse environmental effects of the project. Measures that are technically and economically feasible include application of best industry practices, pollution prevention principles such as best available technology and techniques economically achievable (BATEA), and radiation protection principles such as keeping radiation exposure and doses as low as reasonably achievable (ALARA). Under the CEAA 2012, mitigation includes measures to eliminate, reduce or control the adverse environmental effects of a project, as well as restitution for damages to the environment through replacement, restoration, compensation or other means. Each measure will be specific, achievable, measurable and verifiable, and described in a manner that avoids ambiguity in intent, interpretation and implementation. Mitigation measures may be considered for inclusion as conditions in the EA decision statement and/or in other compliance and enforcement mechanisms provided by other authorities' permitting or licensing processes. As a first step, the proponent is encouraged to use an approach based on the avoidance and reduction of the effect(s) at the source. Such an approach may include the modification of the design of the project or relocation of project components. The EIS will describe the standard mitigation practices, policies and commitments that constitute technically and economically feasible mitigation measures and that will be applied as part of standard practice regardless of location (including the measures directed at mitigating adverse socio-economic effects). The EIS will then describe the project's environmental protection plan and its environmental management system, through which the proponent will deliver this plan. The plan will provide an overall perspective on how potentially adverse effects would be minimized and managed over time. The EIS will further discuss the mechanisms the proponent would use to require its contractors and sub-contractors to comply with these commitments and policies and with auditing and enforcement programs. The EIS will then describe mitigation measures that are specific to each environmental effect identified. Measures will be written as specific commitments that clearly describe how the proponent intends to implement them and the environmental outcome the mitigation is designed to address. The EIS will describe mitigation measures in relation to species and/or critical habitat listed under the Species at Risk Act (SARA). These mitigation measures will be consistent with any SARA permit, applicable recovery strategy and/or action plan.	■ Section 6.1.6 Project Interactions and Mitigation ■ Section 6.2.1.6 Project Interactions and Mitigation – Air Quality ■ Section 6.2.2.6 Project Interactions and Mitigation – Greenhouse Gases ■ Section 6.3.1.6 Project Interactions and Mitigation – Geology ■ Section 6.3.2.6 Project Interactions and Mitigation – Hydrogeology ■ Section 6.4.1.6 Project Interactions and Mitigation – Hydrology ■ Section 6.4.2.6 Project Interactions and Mitigation – Surface Water Quality ■ Section 6.5.6 Project Interactions and Mitigation – Aquatic Environment ■ Section 6.6.6 Project Interactions and Mitigation – Terrestrial Environment ■ Section 6.7.1.6 Project Interactions and Mitigation – Human Health ■ Section 6.7.2.6 Project Interactions and Mitigation – Ecological Health ■ Section 6.8.1.6 Project Interactions and Mitigation – Traditional Land and Resource Use ■ Section 6.8.2.6 Project Interaction and Mitigation – Other Land and Resource Use ■ Section 6.9.6 Project Interactions and Mitigation – Socio-economic Environment

Section in Generic Guideline	Requirement	Section in the EIS
10.0	**Mitigation Measures (cont'd)**	
	The EIS will specify the actions, works, minimal disturbance footprint techniques, best available technology, corrective measures or additions planned during the project's various phases to eliminate or reduce the significance of potential adverse effects. The impact statement will also present an assessment of the effectiveness of the proposed technically and economically feasible mitigation measures. The reason(s) for determining if the mitigation measure reduces the significance of a potential adverse effect will be made explicit. The proponent is also encouraged to identify mitigation measures for effects that are adverse although not significant. The EIS will indicate what other technically and economically feasible mitigation measures were considered, and explain why they were rejected. Trade-offs between cost savings and effectiveness of the various forms of mitigation will be justified. The EIS will identify who is responsible for the implementation of these measures and the system of accountability. For proposed mitigation measures for which there is little experience or that have questionable effectiveness, the potential environmental risks and effects – should those measures not be effective –will be clearly and concisely described. In addition, the EIS will identify the extent to which technological innovations will help mitigate environmental effects. Where possible, it will provide detailed information on the nature of these measures, their implementation and management and how these are integrated in the follow-up program.	
11.0	**Conclusion on Significance**	
	The proponent will use the guidance and information in Appendix A, Section A.3.6, Significance of residual effects, of the CNSC's draft REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures*, for the preparation of this section of the EIS.	■ Section 9.0 Summary of Significance of Residual Effects

Section in Generic Guideline	Requirement	Section in the EIS
12.0	**Follow-up Program**	
	The proponent will use the guidance and information in Appendix A, Section A.3.10 EA follow-up program, of CNSC's draft REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures* for the preparation of this section of the EIS. Where applicable, the proponent will describe how the follow-up program relates to the project's environmental protection plan and environmental management system as mentioned in section 10 above. Environmental assessment effects predictions, assumptions and mitigation actions that are to be tested in the follow-up program must be converted into field-testable monitoring objectives. The monitoring design must include a statistical evaluation of the adequacy of existing baseline data to provide a benchmark for testing project effects, and the need for any additional pre-construction or pre-operational monitoring to establish a firmer project baseline. The proponent will propose a schedule for the follow-up program. The schedule should indicate the timing, frequency and duration of effect monitoring. This schedule would be developed after statistical evaluation of the length of time needed to detect effects given estimated baseline variability, probable environmental effect size and desired level of statistical confidence in the results (type 1 and type 2 errors). The description of the follow-up program will include any contingency procedures or plans or other adaptive management provisions as a means of addressing unforeseen effects, or for correcting exceedances, as required, so as to comply with benchmarks, regulatory standards or guidelines. The follow-up program will describe roles and responsibilities for the program and its review process, by both peers and the public. The EIS should provide discussion on the follow-up program's requirements, and include: ■ objectives and structure of the follow-up program and the VCs targeted by the program ■ tabular summary and explanatory text of the main components of the program including: ■ a description of each monitoring activity under that component ■ which of the two generic program objectives the activity is relevant to (e.g., verify EA predictions, determine effectiveness of mitigation measures) ■ the specific statement from the EA that goes along with that generic objective and will be the focus for that activity (e.g., program objective: verify predicted effects; environmental assessment effect: no potential adverse effects) ■ the specific monitoring objective for that activity ■ planned schedule	■ Section 6.1.10 Monitoring and Follow-up ■ Section 6.2.1.10 Monitoring and Follow-up – Air Quality ■ Section 6.2.2.8 Monitoring and Follow-up – Greenhouse Gases ■ Section 6.3.1.7 Monitoring and Follow-up – Geology ■ Section 6.3.2.9 Monitoring and Follow-up – Hydrogeology ■ Section 6.4.1.7 Monitoring and Follow-up – Hydrology ■ Section 6.4.2.9 Monitoring and Follow-up – Surface Water Quality ■ Section 6.5.7 Monitoring and Follow-up – Aquatic Environment ■ Section 6.6.7 Monitoring and Follow-up – Terrestrial Environment ■ Section 6.7.1.10 Monitoring and Follow-up – Human Health ■ Section 6.7.2.10 Monitoring and Follow-up – Ecological Health ■ Section 6.8.1.7 Monitoring and Follow-up – Traditional Land and Resource Use ■ Section 6.8.2.7 Monitoring and Follow-up – Other Land and Resource Use ■ Section 6.9.7 Monitoring and Follow-up – Socio-economic Environment ■ Section 11.0 Summary of Monitoring and Follow-up Programs

Section in Generic Guideline	Requirement	Section in the EIS
12.0	**Follow-up Program (cont'd)**	
	■ roles and responsibilities to be played by the proponent, regulatory agencies, Aboriginal people, local and regional organizations and others in the design, implementation and evaluation of the program results ■ possible involvement of independent researchers ■ program funding sources ■ information management and reporting (reporting frequency, methods and format) ■ possible opportunities for the proponent to include the participation of the public and Aboriginal groups, during the development and implementation of the program The follow-up program plan should be sufficiently described in the EIS to allow independent judgment as to the likelihood that it will deliver the type, quantity and quality of information required to reliably verify predicted effects (or absence of them) and confirm the effectiveness of mitigation measures.

2.0 TABLE OF CONCORDANCE TO THE CNSC REGDOC 2.9.1 ENVIRONMENTAL PRINCIPLES, ASSESSMENTS, AND PROTECTION MEASURES

Section in REGDOC 2.9.1	Requirement	Section in the EIS
Appendix A	**Environmental Assessments under the Canadian Environmental Assessment Act, 2012**	
A.3	**Specific CEAA 2012 Environmental Assessment Requirements**	
	Where the information is common to both the EIS and the licence application, the applicant may provide the information in either the application or the EIS, with appropriate cross-referencing between the submissions. The applicant shall clearly indicate where the requirements of both the NSCA and CEAA 2012 are addressed. The EA of a designated project shall take into account the following factors as listed in subsection 19(1) of CEAA 2012: a) the environmental effects of the designated project, including the environmental effects of malfunctions or accidents that may occur in connection with the designated project and any cumulative environmental effects that are likely to results from the designated project in combination with other physical activities that have been or will be carried out b) the significance of those environmental effects c) comments from the public that are received in accordance with CEAA 2012 d) mitigation measures that are technically and economically feasible and that would mitigate any significant adverse environmental effects of the designated project e) the requirements of the follow-up program in respect of the designated project f) the purpose of the designated project g) alternative means of carrying out the designated project that are technically and economically feasible and the environmental effects of any such alternative means h) any changes to the designated project that may be caused by the environment i) the results of any relevant study conducted by a committee established under section 73 or 74 of CEAA 2012 j) any other matter relevant to the EA that the responsible authority requires to be taken into account Pursuant to subsection 19(2) of CEAA 2012, the scope of the factors to be taken into account under paragraphs 19(1)(a), (b), (d), (e), (g), (h) and (j) is determined by the Commission, as a responsible authority. The EIS and supporting technical studies are completed to meet the requirements of CEAA 2012, paragraphs 19(1)(a), (b), (d), (e), (f), (g), (h) and, if appropriate, (i) and (j) in accordance with the scope of these factors as determined by the CNSC. The completion of the EIS and, as necessary, supporting technical studies is typically delegated to the applicant in accordance with section 23 of CEAA 2012. This regulatory document provides requirements and guidance to support project planning and early development of these documents by the applicant. These requirements and guidance do not negate the importance of pre-project engagement or the potential for project-specific EA guidelines.	■ All EIS Sections and Appendices

Section in REGDOC 2.9.1	Requirement	Section in the EIS
A.3.1	**Purpose of the Project**	
	Paragraph 19(1)(f) of CEAA 2012 states that the EIS shall identify the purpose of the project (defined as what is to be achieved by carrying out the project). For further guidance, consult *Addressing "Purpose of" and "Alternative Means" under the Canadian Environmental Assessment Act, 2012* [17].	■ Section 2.3 Purpose of the Project
A.3.2	**Alternative Means for Carrying out the Project**	
	Paragraph 19(1)(g) of CEAA 2012 states that the EIS shall identify and describe alternative means to carry out the project that are, from the perspective of the applicant, technically and economically feasible. As identified by the proponent, the alternative means include options for locations, development, and implementation methods, routes, designs, technologies, mitigation measures, and so on. Alternative means may also be related to the construction, operation, expansion, decommissioning and abandonment of a physical work. The approach and level of effort applied to addressing alternative means is established on a project-by-project basis taking into consideration: ■ the characteristics of the project ■ the environmental effects associated with the potential alternative means ■ the health or status of valued components (VCs) that may be impacted by the alternative means ■ the potential for mitigation and the extent to which mitigation measures may address potential environmental effects ■ the level of concern expressed by the public and Indigenous groups The EIS should also describe the environmental effects of each alternative means. The criteria used to identify alternative means as unacceptable, and how these criteria were applied, should be described, as should the criteria used to examine the environmental effects of each remaining alternative means to identify the preferred alternative. For further guidance, consult *Addressing "Purpose of" and "Alternative Means" under the Canadian Environmental Assessment Act, 2012* [17].	■ Section 2.5 Alternative Means of Carrying Out the Project

Section in REGDOC 2.9.1	Requirement	Section in the EIS
A.3.3	**Environmental Effects**	
	Paragraph 19(1)(a) of CEAA 2012 states that the EA must take into account the environmental effects of the designated project. The environmental effects that must be considered in an EA under CEAA 2012 are also requirements under the NSCA. As described in section 4, the applicant should conduct an ERA in accordance with CSA 288.6, *Environmental risk assessment at Class I nuclear facilities and uranium mines and mills* [6].	■ Section 6.1 Environmental Assessment Approach ■ Section 6.2 Atmospheric Environment ■ Section 6.3 Geological and Hydrogeological Environment ■ Section 6.4 Surface Water Environment ■ Section 6.5 Aquatic Environment ■ Section 6.6 Terrestrial Environment ■ Section 6.7 Human and Ecological Health ■ Section 6.8 Land and Resource Use ■ Section 6.9 Socio-economic Environment

Section in REGDOC 2.9.1	Requirement	Section in the EIS
A.3.4	**Malfunctions and Accidents**	
	Paragraph 19(1)(a) of CEAA 2012 states that malfunctions and accidents shall be assessed in the EA. Malfunctions and accidents should be separated into radiological and non-radiological (conventional). The applicant should provide an assessment of potential health and environmental effects resulting from postulated radiological and conventional malfunctions or accidents. The EIS should also include any mitigation measures such as monitoring, contingency, clean-up or restoration work in the surrounding environment that would be required during or immediately following the postulated malfunction and accident scenarios. The EIS should provide a description of postulated malfunction and accident sequences leading to a radiological or non-radiological release considering, as appropriate, internal events, external events and human-induced events, including their frequency and an explanation of how these events were identified, and any modeling that was performed. The applicant can use a bounding approach or use facility- or activity-specific information (for example, design, operation, projected environmental releases) in the assessment of radiological accidents and malfunctions. If a bounding approach is used, the applicant should provide a detailed rationale for the selection of each bounding scenario. The EIS should include the source, quantity, mechanism, pathway, rate, form and characteristics of contaminants and other materials (physical and chemical) likely to be released to the surrounding environment during the postulated malfunctions and accidents. **Note:** Malfunctions and accidents are reviewed in depth under the NSCA for licensing purposes (for example, under REGDOC-2.4.1, *Deterministic Safety Analysis* [18], REGDOC-2.4.2, *Probabilistic Safety Assessments for Nuclear Power Plants* [19] and RD-346, *Site Evaluation for New Nuclear Power Plants* [20]). These scenarios should be taken into consideration by the applicant when designing environmental protection measures (see section 4). If applicable, the applicant should use operating experience (OPEX) to identify any past abnormal operations, accidents and spills to the extent that they are relevant to the current assessment for the purposes of identifying malfunction and accident scenarios to be assessed.	■ Section 7.2 Methods ■ Section 7.2.1.1 Radiological Hazards ■ Section 7.2.1.2 Non-Radiological Hazards ■ Section 7.3 Accidents and Malfunctions ■ Section 7.4 Risk Evaluation of Accidents and Malfunctions
A.3.5	**Cumulative Effects**	
	Paragraph 19(1)(a) of CEAA 2012 states that the applicant shall assess any residual adverse environmental effects of the project in combination with other past, present or reasonably foreseeable projects and/or activities within the study area. The applicant should explain the approach and methods used to identify and assess cumulative effects. The approach and methods should be consistent with *Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012* [21].	■ Section 8.0 Summary of Cumulative Effects

Section in REGDOC 2.9.1	Requirement	Section in the EIS
A.3.6	**Significance of Residual Effects**	
	Paragraph 19(1)(b) of CEAA 2012 states that the applicant shall assess the significance of any residual effects that persist, taking into consideration the proposed mitigation measures. These residual effects are identified during the ERA or a characterization of the environmental effects. In the EIS, the applicant should include a detailed analysis of the significance of each residual effect. The applicant should clearly explain the method and definitions used to describe the level of the residual adverse effect (for example, low, medium, or high) for each of the issues. The applicant should also describe any cumulative environmental effects that are likely to result from the designated project in combination with other physical activities that have been or will be carried on and how these levels were combined to reach an overall conclusion on the significance of the adverse effects for each valued component (VC). **Guidance** Some specific issues to be assessed are: ■ magnitude of the effect ■ spatial extent of the effect ■ duration and frequency of the effect ■ degree to which the effect can be reversed or mitigated ■ ecological importance The method used to describe the level of the adverse effect should be transparent and reproducible. The EIS should identify additional criteria used to assign significance ratings to any predicted adverse effects. It should contain clear and sufficient information to enable the CNSC and the public to understand and review the applicant's judgement of the significance of effects. The applicant should define the terms used to describe the level of significance. In assessing significance against the criteria, the EIS should, where possible, employ relevant existing regulatory documents, environmental standards, guidelines or objectives such as prescribed maximum levels of emissions or discharges of specific hazardous substances into the environment or maximum acceptable levels of specific hazardous substances in the environment.	■ Section 9.0 Summary of Significance of Residual Effects
A.3.7	**Socio-economic Environment**	
	The applicant should characterize the socio-economic environment and identify all indirect socio-economic effects. An indirect effect is a secondary environmental effect that occurs as a result of a change that a project may cause to the environment. Paragraph 5(2)(b) of CEAA 2012 refers to any change to the environment caused by the project on health and socio-economic conditions, physical and cultural heritage, or any structure, site or thing that is of historical, archaeological, paleontological or architectural significance. For additional guidance, refer to *Technical Guidance for Assessing Physical and Cultural Heritage or any Structure, Site or Thing that is of Historical, Archeological, Paleontological or Architectural Significance under the Canadian Environment Assessment Act, 2012* [22].	■ Section 6.9 Socio-economic Environment

Section in REGDOC 2.9.1	Requirement	Section in the EIS
A.3.8	**Community and Aboriginal Traditional Knowledge**	
	Subsection 19(3) of CEAA 2012 states that community and Aboriginal traditional knowledge may be considered in the EA. CNSC staff will provide guidance to the applicant at the earliest possible stage in the EA process concerning the extent to which community and Aboriginal traditional knowledge shall be considered in the EA. For additional information, refer to: ■ *Considering Aboriginal traditional knowledge in environmental assessments conducted under the Canadian Environmental Assessment Act, 2012* [23] ■ REGDOC-3.2.2, *Indigenous Engagement* [10] (for further information on the CNSC's expectations of applicants for Indigenous engagement)	■ Section 4.3 Influence of Traditional Knowledge on the Environmental Assessment ■ Section 6.4.2 Surface Water Quality ■ Section 6.5 Aquatic Environment ■ Section 6.6 Terrestrial Environment ■ Section 6.7 Human and Ecological Health ■ Section 6.8.1 Traditional Land and Resource Use by Indigenous Nations ■ Section 6.9 Socio-economic Environment
A.3.9	**Assessment of Effects of the Environment on the Project**	
	Paragraph 19(1)(h) of CEAA 2012 states that the EIS shall take into account how the environment could adversely affect the project. The applicant shall also take into account any potential effects of climate change on the project, including an assessment of whether the project might be sensitive to changes in climate conditions during its lifecycle. Some adverse environmental conditions are flooding, severe weather, biophysical hazards (such as algae), geotechnical hazards and seismic events.	■ Section 10.0 Assessment of Effects of the Environment on the Project

Section in REGDOC 2.9.1	Requirement	Section in the EIS
A.3.10	**EA Follow-up Program**	
	Paragraph 19(1)(e) of CEAA 2012 states that the EIS shall include a framework or preliminary program upon which EA follow-up actions will be managed throughout the life of the project. The applicant should design the follow-up program to verify the accuracy of the EA predictions and to determine the effectiveness of the measures implemented to mitigate the potential adverse environmental effects of the project. The applicant should also design the follow-up program to incorporate pre-project information that would provide the baseline data; compliance data such as established environmental quality criteria; regulatory documents, standards or guidelines; and real-time data consisting of observed data gathered in the field. As part of the follow-up program, the applicant should describe the compliance reporting methods to be used, including reporting frequency, methods and format. **Note:** The CNSC, in collaboration with other federal authorities (where applicable), verifies and monitors all EA follow-up activities through the CNSC licensing and compliance process. EA follow-up monitoring activities may be integrated within the applicant's environmental protection measures.	■ Section 6.1.10 Monitoring and Follow-up ■ Section 6.2.1.10 Monitoring and Follow-up – Air Quality ■ Section 6.2.2.8 Monitoring and Follow-up – Greenhouse Gases ■ Section 6.3.1.7 Monitoring and Follow-up – Geology ■ Section 6.3.2.9 Monitoring and Follow-up – Hydrogeology ■ Section 6.4.1.7 Monitoring and Follow-up – Hydrology ■ Section 6.4.2.9 Monitoring and Follow-up – Surface Water Quality ■ Section 6.5.7 Monitoring and Follow-up – Aquatic Environment ■ Section 6.6.7 Monitoring and Follow-up – Terrestrial Environment ■ Section 6.7.1.10 Monitoring and Follow-up – Human Health ■ Section 6.7.2.10 Monitoring and Follow-up – Ecological Health ■ Section 6.8.1.7 Monitoring and Follow-up – Traditional Land

Section in REGDOC 2.9.1	Requirement	Section in the EIS
		and Resource Use ■ Section 6.8.2.7 Monitoring and Follow-up – Other Land and Resource Use ■ Section 6.9.7 Monitoring and Follow-up – Socio-economic Environment ■ Section 11.0 Summary of Monitoring and Follow-up Programs

Section in REGDOC 2.9.1	Requirement	Section in the EIS
Appendix B	**Characterization of the Baseline Environment for an Environmental Assessment under CEAA 2012**	
B.1	**Atmospheric Environment**	
	The atmospheric environment includes the climate conditions at the site and in the local and regional study areas. It includes the seasonal variations in weather conditions within the study areas, to allow the assessment of effects on the facility or activity. The applicant or licensee should provide a description of the existing ambient air quality in the study areas, with emphasis on characterizing radiological and non-radiological analytes. The description should include meteorological information such as air temperature, relative humidity, precipitation, wind speed and direction, atmospheric pressure, and solar radiation. It should also include the occurrence of weather phenomena (for example, lightning, temperature inversions and fog). Special consideration should be given to the analysis of extreme and rare meteorological phenomena (for example, tornadoes).Uncertainties should be described and taken into account when discussing the reliability of the information presented. The description should also include current ambient daytime and nighttime noise levels at the site and local study areas, and include information on its source(s), geographic extent and temporal variations. The description should provide ambient noise levels for other areas that could be affected by the facility or activity. Some examples are: ■ increased traffic along transportation corridors to and from the site during construction ■ receptors at residences and sensitive sites (such as hospitals, schools, daycare facilities, seniors' residences, and places of worship) The applicant or licensee should describe the influence of regional topography or other features that could affect weather conditions in the study areas. The baseline information should be sufficient to support the use of an atmospheric dispersion model to conduct the site-specific ERA and to support an assessment of the effects of the environment on the project (for example, tornadoes).	■ Section 6.2.1.5 Description of the Environment – Air Quality ■ Section 6.2.2.5 Description of the Environment – Greenhouse Gases

Section in REGDOC 2.9.1	Requirement	Section in the EIS
B.2	**Surface Water Environment**	
	The surface water environment includes all surface water features and hydrology that affect surface water at the site or in the local and regional study areas. The applicant or licensee should include delineation of drainage basins at appropriate scales. When documenting the water quality of all surface water, the applicant or licensee should demonstrate the use of appropriate sampling and analytical protocols, for the range of analytical parameters with the potential to be influenced by the facility or activity. This information should be presented using tables, maps and figures to provide an understanding of surface water characteristics and conditions at the site and in the local and regional study areas. The applicant or licensee should describe hydrological regimes within the drainage basin, including seasonal fluctuations and year-to-year variability of all surface waters. The applicant or licensee should assess normal flow, flooding and drought properties of water bodies as well as the interactions between surface water and groundwater flow systems. The applicant or licensee should describe all water sources used for drinking water in the area, including source water intakes for drinking water treatment facilities. The baseline information should be sufficient to support the use of an aquatic dispersion model to conduct the site-specific ERA and to support an assessment of the effects of the environment on the facility or activity (for example, flooding). The applicant or licensee should document the sediment quality of all water bodies to be affected by the facility or activity, demonstrating the use of appropriate sampling and analytical protocols, for the range of analytical parameters with the potential to be influenced by the facility or activity. This information should provide an appropriate understanding of sediment characteristics and conditions on the site and in the local and regional study areas. The study design should be fully described, including the allocation of samples in space and time, measurement methods and results. The applicant or licensee should include an assessment of any limitations or gaps in the quality and extent of baseline data and methods, as well as the method(s) by which they have been addressed.	■ Section 6.4.1.5 Description of the Environment – Hydrology ■ Section 6.4.2.5 Description of the Environment – Surface Water Quality

Section in REGDOC 2.9.1	Requirement	Section in the EIS
B.3	**Aquatic Environment**	
	The aquatic environment includes the aquatic and wetland species at the site and within the local and regional study areas, including the flora, fauna and their habitats. The applicant or licensee should seek information from relevant authorities (such as Environment and Climate Change Canada (ECCC), Fisheries and Oceans Canada (DFO) and provincial or territorial authorities) on aquatic and wetland species and habitat for the local and regional study areas. The applicant or licensee should also undertake independent studies to gather the necessary information. The applicant or licensee should include a description of the food chain and food web dynamics as a habitat component as this relates to fish populations, and potential effects resulting from the facility or activity (such as impingement and entrainment). The applicant or licensee should provide detailed habitat mapping that demonstrates habitat usage by fish within the study areas. This information should include depth profiles, substrate mapping, water temperature profiles, and a description of known and potential habitat usage (such as spawning, nursery, rearing, feeding and migratory) by fish that occur in the study areas. The applicant or licensee should identify any biological species of natural conservation status (that is, rare, vulnerable, endangered, threatened or uncommon at a federal, provincial or municipal level) and their critical habitats, if identified. The applicant or licensee should provide baseline characterization of radionuclide and hazardous substance levels in aquatic biota to support human and ecological risk assessment. The applicant or licensee should fully describe the study design, including the allocation of samples in space and time, measurement methods and results. The applicant or licensee should include an assessment of any limitations or gaps in the quality and extent of baseline date and methods, as well as the method(s) by which they have been addressed.	■ Section 6.5.5 Description of the Environment – Aquatic Environment

Section in REGDOC 2.9.1	Requirement	Section in the EIS
B.4	**Geological and Hydrogeological Environment** The geological and hydrogeological environment includes the bedrock and overburden geology at both the local and regional scales.	
B.4.1	**Geology**	
	The applicant or licensee should characterize the geomorphology, topography, quaternary geology and soil characteristics, structural geology, petrology, geochemistry, economic geology and hydrogeology. The applicant or licensee should also describe the geomechanical properties that apply to the region and at the site that will be disturbed. The applicant or licensee should provide the geotechnical properties of the overburden, including shear strength and liquefaction potential, to allow for the assessment of slope stability and bearing capacity of foundations under both static and dynamic conditions. The description of the structural geology should include regional, local and site-specific documentation of fractures and faults. It should include a description of primary geological features and deformation fabrics both at the site and within the local and regional study areas. If applicable, the applicant or licensee should describe the coastal geomorphology and should include the characteristics of any lakefront or ocean bluffs, shoreline, and both near-shore zone and offshore zones. The baseline characterization should be sufficient to assess effects of the environment on the facility or activity (for example, seismic effects). The applicant or licensee should present a geological model that incorporates all overburden and bedrock information. If extrapolation is required to derive the stratigraphy, the applicant or licensee should explicitly discuss the uncertainties and the need for additional field investigations to reduce those uncertainties. The applicant or licensee should describe the geotechnical and geophysical hazards including the consideration of subsidence, uplift, seismicity (and active faulting), and consider the potential for movement at the ground surface (including co-seismic rupture) and earthquake ground motions. A seismic hazard assessment should be provided. Where appropriate, the narrative descriptions should be supplemented by geological maps, figures, cross-sections, borehole logs and photographs (with specific location information).	■ Section 6.3.1.5 Description of the Environment – Geology

Section in REGDOC 2.9.1	Requirement	Section in the EIS
B.4.2	**Hydrogeology**	
	The applicant or licensee should describe the hydrogeology at the site and in the local and regional study areas. The description should characterize the physical and geochemical properties of all overburden and bedrock hydrogeological units (from the ground surface to the uppermost basement unit, which is site dependent). Units may be characterized as aquifers or aquitards, and unit descriptions should include their geochemical characteristics, vertical and lateral permeabilities, transport mechanism (diffusion versus advection) and directions of groundwater flow. The applicant or licensee should identify the groundwater recharge and discharge areas, and describe in detail the groundwater interactions with surface waters. The applicant or licensee should present a conceptual and numerical hydrogeological model that discusses the hydrostratigraphy and groundwater flow systems. The applicant or licensee should provide a description of baseline groundwater quality at the site and in the local study area. The applicant or licensee should also describe local and regional potable groundwater supplies, including their current use and potential for future use.	■ Section 6.3.2.5 Description of the Environment – Hydrogeology

Section in REGDOC 2.9.1	Requirement	Section in the EIS
B.5	**Terrestrial Environment**	
	The terrestrial environment includes flora and fauna, their habitats, any wildlife corridors and the soil. The applicant or licensee should describe the terrestrial species at the site and within the local and regional study areas, including flora, fauna and their habitat. The applicant or licensee should identify all biological species at risk (that is, endangered, threatened, special concern, extirpated at a federal, provincial or municipal level) known to occur in the area or where the site is within the range of the species. The applicant or licensee should describe the presence and importance of wildlife habitat within the study areas, including critical habitats for listed species (if identified). The applicant or licensee should also describe any wildlife corridors and physical barriers to movement. The applicant or licensee should identify all protected and conservation areas established by federal, provincial and municipal jurisdictions (for example, wilderness areas, parks, sites of historical or ecological significance, nature reserves, federal migratory bird sanctuaries and wildlife management areas). The applicant or licensee should describe the existing soil quality (including hazardous and radiological substance concentrations) for all study areas, as well as any additional soil quality parameters potentially relevant for modelling purposes (such as transport and bioavailability of contaminants of potential concern). The applicant or licensee should provide baseline characterization of radionuclide and hazardous substance levels in vegetation and other non-human biota to support human and ecological risk assessment. The characterization should also take into consideration the baseline conditions of other applicable environmental components (such as the atmospheric environment). The applicant or licensee should undertake independent studies to gather the necessary information as appropriate. The applicant or licensee should describe field studies in terms of representativeness of the target populations where possible. The applicant or licensee should fully describe the design of the study, including the allocation of samples in space and time, measurement methods and results. The applicant or licensee should include an assessment of any limitations or gaps in the quality and extent of baseline data and methods, as well as the method(s) by which they have been addressed.	■ Section 6.6.5 Description of the Environment – Terrestrial Environment

Section in REGDOC 2.9.1	Requirement	Section in the EIS
B.6	**Ambient Radioactivity**	
	The ambient radioactivity arises from the sources, their activity levels and their origin, for all applicable environmental media (including air, soil, food, water, aquatic sediments and plant or animal tissue). The applicant or licensee should describe the ambient radiological conditions at the site and in the local and regional study areas. The applicant or licensee should include information on the existing conditions, including an inventory of sources, their activity levels and their origin (natural or anthropogenic), for all applicable environmental media. The applicant or licensee should fully describe the design of the study, including the allocation of samples in space and time, measurement methods and results. The description should include an assessment of any limitations or gaps in the quality and extent of the baseline data and methods, as well as the method(s) by which they have been addressed.	■ Section 6.7.1.5 Description of the Environment – Human Health ■ Section 6.7.2.5 Description of the Environment – Ecological Health
B.7	**Human Health**	
	The potential effects of the facility or activity on human health include both radiological sources and non-radiological contaminants. The applicant or licensee should describe the current health profiles of the communities likely to be affected by the facility or activity, including information on population health of the communities in the local and regional study areas. The applicant or licensee should provide, to the extent available, information on current consumption of locally grown harvests and country foods, and the quality by food type, amounts consumed, parts consumed (whole body or specific organs).	■ Section 6.7.1.5 Description of the Environment – Human Health
B.8	**Aboriginal Land Use**	
	Indigenous land and resource use includes lands, waters and resources of specific value; traditional activities and lifestyle; and traditional dietary habits. Traditional land use may include areas where traditional activities such as establishing seasonal camps, camping, travel on traditional routes, gathering of country foods and medicines (hunting, fishing, trapping, planting and harvesting) are being carried out. Traditional land use also includes spiritual sites of significance to Indigenous people. The applicant or licensee should identify the lands, water and resources of specific social, economic, archaeological, cultural or spiritual value to Indigenous people, including established and asserted Indigenous or treaty rights that may be affected by the facility or activity. The applicant or licensee should describe Indigenous land and resource use at the site and in the local and regional study areas. The applicant or licensee should identify traditional activities, including activities for food, social, ceremonial and other cultural purposes, in relation to such lands, waters and resources with a focus on the current use of lands, waters and resources for traditional purposes. The applicant or licensee should describe the traditional dietary habits and dependence on country foods and harvesting for other purposes, including harvesting of plants for medicinal purposes. The analysis should focus on the identification of potential adverse effects of the facility or activity on the ability of future generations of Indigenous people to pursue traditional activities or lifestyle.	■ Section 6.8.1 Traditional Land and Resource Use by Indigenous Nations

Section in REGDOC 2.9.1	Requirement	Section in the EIS
Appendix C	**Environmental Effects for an Environmental Assessment under CEAA 2012**	
C.1	**Atmospheric Environment**	
	The licensee should characterize the effects of the facility or activity on the atmospheric environment during all phases of the lifecycle for the facility or activity, including postulated accident and malfunction scenarios. The licensee should identify and characterize all atmospheric emissions (radiological and non-radiological) expected to be generated during all phases of the lifecycle for the facility or activity, including postulated accident and malfunction scenarios. This information should include average and maximum emissions from planned discharges, point sources and fugitive (non-point source) releases (including greenhouse gases). The licensee should complete modelling that incorporates baseline (or existing ambient) air quality in combination with the predicted site-specific atmospheric characteristics (such as shoreline fumigation) to assess potential effects on air quality, the transport of atmospheric contaminants and any associated exposure to humans and non-human biota receptors. The licensee should describe predicted effects of noise on terrestrial and aquatic species as well as on nearby residents and communities. The description should include both daytime and nighttime noise levels and tonal noise. The predicted sound levels should be compared against baseline levels and any guidelines published by recognized organizations.	■ Section 6.2.1.7 Residual Effects Analysis – Air Quality ■ Section 6.2.2.6 Project Interactions and Mitigation – Greenhouse Gases
C.2	**Surface Water Environment**	
	The licensee should describe the effects of the facility or activity on the surface water environment during all phases of the lifecycle for the facility or activity, including accident and malfunction scenarios. The licensee should identify and characterize all liquid effluents that could be generated during all phases of the facility or activity. Some examples are: ■ average and maximum emissions from point sources (concentrations/activity levels and volumes) ■ planned discharges ■ fugitive releases ■ deposition from airborne particulates ■ surface runoff	■ Section 6.4.1.6 Project Interactions and Mitigation – Hydrology ■ Section 6.4.2.7 Residual Effects Analysis – Surface Water Quality

Section in REGDOC 2.9.1	Requirement	Section in the EIS
C.3	**Aquatic Environment**	
	For all phases of the lifecycle for the facility or activity, the licensee should describe the effects of the facility or activity on aquatic flora and fauna, and include a full accounting of effects on species of natural conservation status and their habitat. This evaluation should be based on results of field monitoring studies or predictions from an ecological risk assessment. The description should be clear on how predicted effects to the biota exposed to the stressor compare to the expected reference condition for unexposed biota on a biological population basis, taking natural variation into account. Predictions of effects should include sufficient detail to allow follow-up verification. Some potential effects are: ■ effects on habitat, including aquatic vegetation and sensitive areas such as spawning grounds, nursery areas, winter refuges and migration corridors ■ effects on aquatic species, including rare or sensitive species ■ effects of blasting on fish and fish habitat on local aquatic systems ■ contaminant exposures through environmental and food-chain transport ■ effects on aquatic biota due to impingement and entrainment ■ effects of infilling on loss of fish habitat and changes to productive capacity ■ effects of thermal plume(s) on fish and fish habitat ■ effects on wetlands Under the NSCA, the CNSC assesses the ongoing operation of nuclear facilities and activities to ensure protection of the environment and the health and safety of persons. Under the Memorandum of Understanding between CNSC and Fisheries and Oceans Canada (DFO), the CNSC is responsible for conducting reviews of licence applications to assess the potential effects on fish and fish habitat, and to ensure that the assessment process considers the intent and requirements of the *Fisheries Act*, the *Species at Risk Act* and their associated regulatory and policy frameworks.	■ Section 6.5.6 Project Interactions and Mitigation – Aquatic Environment

Section in REGDOC 2.9.1	Requirement	Section in the EIS
C.4	**Geological and Hydrogeological Environment** The geological and hydrogeological environment includes the bedrock and overburden geology at both the local and regional scales.	
C.4.1	**Geology**	
	The licensee should fully describe any changes to the geology and geomorphology resulting from the facility or activity, including any interrelationships with the groundwater regime. The licensee should describe any changes to the environment resulting from the removal of bedrock and/or unconsolidated deposits. The licensee should also describe the disturbance of soils or sediments that may be stockpile, used for construction purposes or otherwise perturbed. The licensee should include an assessment of changes made that would affect coastal processes and features (such as changes to the shoreline morphology due to construction, erosion or sediment transport).	■ Section 6.3.1.6 Project Interactions and Mitigation – Geology
C.4.2	**Hydrogeology**	
	The licensee should describe and assess any effects the facility or activity may have on the groundwater regime including the quantity and quality of groundwater and how these effects may influence surface waters. The licensee should carry out modelling as needed to develop and test the predicted effects.	■ Section 6.3.2.7 Residual Effects Analysis – Hydrogeology
C.5	**Terrestrial Environmental**	
	The licensee should describe the effects of the facility or activity on terrestrial fauna and flora and include a full accounting of effects on species with elevated conservation status and their habitat. This evaluation should be based on results of field monitoring studies or predictions from an ecological risk assessment. The description should be clear on how predicted effects to the biota exposed to the stressor compare to the expected “reference condition” for unexposed biota on a biological population basis taking into account natural variation. Predictions of the effects should include sufficient detail to allow follow-up verification. Some potential effects that should be considered are: ■ loss of terrestrial habitat and the quality of lost habitat for relevant species ■ disturbance of feeding, nesting or breeding habitats ■ physical barriers to wildlife ■ disruption, blockage, impediment and sensory disturbance (such as light effects, noise and vibration) of daily or seasonal wildlife movements (such as migration or home ranges) ■ direct and indirect wildlife mortality ■ reduction in wildlife productivity ■ contaminant exposures through environmental and food-chain transport ■ effects on biodiversity	■ Section 6.6.6 Project Interactions and Mitigation – Terrestrial Environment

Section in REGDOC 2.9.1	Requirement	Section in the EIS
C.6	**Ambient Radioactivity**	
	The licensee should describe the effects of the facility or activity on ambient radioactivity. Humans and non-human biota exposed to ambient radioactivity should be assessed for all relevant routes of exposure (both internal and external exposure scenarios). To support the assessment of human health (see section 3.2.7), the licensee should provide information on radiation levels to which members of the public may be exposed, including consideration of consumers of country food whose exposure pathways may differ due to cultural norms; for example, any dietary characteristics of Indigenous peoples.	■ Section 6.7.1.7 Residual Effects Analysis – Human Health ■ Section 6.7.2.7 Residual Effects Analysis – Ecological Health
C.7	**Human Health**	
	The licensee should describe the potential effects of the facility or activity on the physical well-being of Indigenous groups and other people resulting from biophysical effects, including the effects of the facility or activity on all environmental components (for example, atmospheric environment) and the resulting effects on human health. Some examples are: ■ an analysis of the effects of the facility or activity on the health and safety of the public, including the possible effects from malfunctions and accidents (radiological and conventional) ■ the predicted radiation doses to members of the public resulting from activities within the scope of the facility or activity and any resulting health effects ■ a description of quantitative risk assessment modeling conducted, where necessary, for any malfunctions and accidents ■ an assessment of the potential effects on human health from all non-radiological contaminants released from the facility or activity, through all potential exposure pathways ■ potential effects of noise generated from the facility or activity on human receptors within the study area(s)	■ Section 6.7.1.7 Residual Effects Analysis – Human Health
C.8	**Indigenous Land and Resource Use**	
	The licensee should identify any change that the facility or activity is likely to cause in the environment and any effect of any such change on the health and socio-economic conditions, physical and cultural heritage and on the current use of lands and resources for traditional purposes by any Indigenous group including effects on hunting, trapping, fishing and gathering. The licensee should identify any concerns raised by Indigenous people about the facility or activity in relation to any Indigenous or treaty rights. For further information on the CNSC's expectations of licensees for Indigenous engagement, see REGDOC-3.2.2, *Indigenous Engagement*. Table 1: Interrelation Between Whiteshell Reactor 1 (WR-1) In Situ Disposal Project Documents

Technical Supporting Document or Supplemental Support Document	Portion of Information or Data Applying to WR-1 In-Situ Disposal Project	How Information/Data are Applied; Outline of Assumptions, Limitations or Differences	Distinguish Factual Evidence from Inference
Stakeholder Engagement Report (WLDP-26000-REPT-010) CNL 2024a	■ Information on public engagement activities related to the Project, including timing and location of public information sessions, presentation materials, and feedback received during the sessions.	■ Information is used to demonstrate how CNL has engaged with communities that are interested in and potentially affected by the Project.	■ Factual evidence based on interactions and feedback received from stakeholders during engagement activities.
Indigenous Engagement Report (WLDP-26000-REPT-002) CNL 2024b	■ Information on Indigenous engagement activities related to the Project, including timing and location of engagement activities, presentation materials, and feedback received during the sessions.	■ Information is used to demonstrate how CNL has engaged with Indigenous peoples that are interested in and potentially affected by the Project.	■ Factual evidence based on interactions and feedback received from Indigenous peoples during engagement activities.
Decommissioning Safety Assessment Report (WLDP-26000-SAR-001) Golder 2021a	■ The DSAR provides evidence that the overall performance of the decommissioned WR-1 is safe and identifies institutional controls that will be needed in the long-term to demonstrate protection of human health and the environment. Applicable sections of the DSAR include: ▪ Site Description ▪ Project Description ▪ Safety Strategy ▪ Assessment Approach ▪ WR-1 Building Closure Safety Assessment ▪ Post Closure Safety Assessment ▪ Results Evaluation ▪ CNL WR-1 In Situ Disposal Hazards Identification and CNL WR-1 Decommissioning Activities Accidents and Malfunctions	■ Information is used to support the assessment of effects in the EIS. ■ There is uncertainty in the estimated inventory of radioactive material that could be encountered during the cutting and perforation of components, during grouting preparation activities, or dismantling of the WR-1 Building. As such, reactor characterization and radiological surveys have been completed to verify model inputs and assumptions. In addition, a building condition assessment and grout characterization and test plan work are underway, the results of which will also be used to verify model inputs and assumptions. ■ There is uncertainty in the radiological release rates to the atmosphere; however, the estimates are expected to be conservative. ■ For the ERA, both maximum and average quantities estimated for non-radionuclides were assessed. ■ For the groundwater flow and solute transport modelling, the models were configured based on measured input parameters and (in the absence of measured data) conservative assumptions. Uncertainty in model inputs was addressed through sensitivity analyses. Model components evaluated through the sensitivity analysis included geological pathways, the WR-1 concrete cap and engineered cover, foundation and grout failure modes and timeframes associated with failure, adsorption-partition coefficients, source mass inventory, corrosion of the reactor components, hydraulic conductivity of the backfill and bedrock, stage of the Winnipeg River.	■ Report is based on factual information; a summary of site characteristics, facility structures, systems, components and safety features, facility operations, and maintenance and relevant compliance programs.

Table 1: Interrelation Between Whiteshell Reactor 1 (WR-1) In Situ Disposal Project Documents

Technical Supporting Document or Supplemental Support Document	Portion of Information or Data Applying to WR-1 In-Situ Disposal Project	How Information/Data are Applied; Outline of Assumptions, Limitations or Differences	Distinguish Factual Evidence from Inference
Detailed Decommissioning Plan (WLDP-26400-DDP-001) CNL 2021a	■ The DDP describes plans for the decommissioning of the WR-1 Building. It provides a bounding scope document for the EIS that describes the work to be done, lays out the high-level work breakdown structure, and provides a high-level hazard assessment. Applicable sections of the DDP include: ▪ Description of Site and Facility ▪ Current Status ▪ Decommissioning End-State ▪ Requirements for Institutional Control ▪ Hazards Assessment ▪ Decommissioning Strategy ▪ Decommissioning Work Packages ▪ Waste Management Plan ▪ Public Consultation ▪ Radiological Status of Rooms in B100 (WR-1 Complex) ▪ Summary of Evaluation of Alternative Decommissioning Strategies	■ Information is used to support the selected approach to decommission the WR-1 Building and to determine how the equipment associated with the WR-1 Building should be managed (above-grade; below-grade; level of radioactivity). All information supports the assessment of effects in the EIS. ■ There is uncertainty in the estimated inventory of radioactive material that could be encountered during the cutting and perforation of components, during grouting preparation activities, or dismantling of the WR-1 Building. As such, reactor characterization and radiological surveys have been completed to verify model inputs and assumptions. In addition, a building condition assessment and grout characterization and test plan work are underway, the results of which will also be used to verify model inputs and assumptions. ■ There is uncertainty in the radiological release rates to the atmosphere; however, the estimates are expected to be below the release criteria. The WRDF is expected to prevent over 97% of the initial radioactivity in the WRDF from being released to the environment. ■ The worker dose estimates are based on dose rates from WR-1 radiological hazard surveys and WL Projects resource estimates. ■ While it is not possible to anticipate every potential decontamination problem during the Project planning phase, the ISD approach needs to be sufficiently flexible to accommodate the expected field conditions encountered. ■ During ISD activities, various hazards may be encountered: ▪ Radiation fields; ▪ Radioactive contamination; ▪ Environmental contamination to the geosphere and biosphere; ▪ Conventional hazards (biological, physical, chemical); ▪ Radioactive sources not included in the inventory; ▪ Leaking radioactive sources or loss of shielding; ▪ Leaks of liquids produced during decommissioning; ▪ Piping systems containing radioactive and/or chemically hazardous liquids or sediments; ▪ Buried pipes with highly contaminated liquids that might be broken; ▪ Tanks with liquids or contaminated sludge that will require draining; ▪ Accumulation of radioactive dust present in ventilation and filtration systems; ▪ Accumulation of a significant radioactive inventory typically in the form of contaminated and activated tools and materials/waste; ▪ Clean areas can be contaminated due to loss of containment; e.g., opening of closed systems, such as ventilation ducts and tanks; ▪ Decontaminated zones can be recontaminated due to personnel movement and material handling; ▪ Elevated tritium levels; ▪ Components coated with organic coolant. ■ The final end-state for the WR-1 will be a permanent, passive, multilayered disposal system that applies a Defence-in-Depth strategy. Environmental monitoring wells are expected to be installed in strategic places in the surrounding area to monitor the performance of the WRDF during the institutional control period.	■ Factual information about the facility.
Groundwater Flow and Solute Transport Modelling Report (WLDP-26000-REPT-005) Golder 2021b	■ Groundwater flow and solute transport models have been developed and used to simulate the current and future (post-closure) conditions of the WL facilities. Model calculations were completed to estimate long-term mass loadings to environmental receptors following site decommissioning. Applicable sections of the report include: ▪ Post Decommissioning Simulations ▪ Sensitivity Analysis	■ Information is used to support the EIS and the DSAR. ■ The models were configured based on measured input parameters and (in the absence of measured data) conservative assumptions. Uncertainty in model inputs was addressed through sensitivity analyses. Model components evaluated through the sensitivity analysis included geological pathways, the WR-1 concrete cap and engineered cover, foundation and grout failure modes and timeframes associated with failure, adsorption-partition coefficients, source mass inventory, corrosion of the reactor components, hydraulic conductivity of the backfill and bedrock, stage of the Winnipeg River.	■ Groundwater flow is calculated based on fact-based evidence and assumptions based on site knowledge.

Table 1: Interrelation Between Whiteshell Reactor 1 (WR-1) In Situ Disposal Project Documents

Technical Supporting Document or Supplemental Support Document	Portion of Information or Data Applying to WR-1 In-Situ Disposal Project	How Information/Data are Applied; Outline of Assumptions, Limitations or Differences	Distinguish Factual Evidence from Inference
Hydrogeological Study Report (WLDP-26000-REPT-004) Dillon 2018	■ The Hydrogeological Study Report has been developed and used to meet CNSC EIS regulatory baseline hydrogeological requirements, to identify data uncertainties and to assess their relevance/significance to the Project. Applicable sections of the report include: ▪ Geology and Hydrogeology ▪ Analytical Results ▪ Summary Tables	■ The Hydrogeological Study Report has been prepared in support of the EIS. Extensive hydrogeological studies have been performed around the WMA, the lagoons, landfill areas, and the main campus within the WL site. This report provides baseline data for refining the conceptual hydrogeological model for the site, which was used in developing and calibrating a three-dimensional (3-D) groundwater flow and transport model. ■ The results of this hydrogeological study have confirmed previous site hydrogeological observations and hypotheses: WR-1 is situated primarily within an overburden setting, draining westerly towards the Winnipeg River. Horizontal groundwater gradients observed are consistent with those observed across the WL site. Vertical hydraulic gradients were predominately downwards, and were dominant in the fine-grained soils overlying coarser grained basal sand and fractured bedrock. Groundwater flow was generally assumed to be horizontal in the basal sand and shallow bedrock and may be influenced by regional hydraulic controls (e.g., Natalie Lake hydro dam reservoir, Winnipeg River). Horizontal flow in these two units is influenced locally by the operation of the sumps at the WR-1 Building. Deeper bedrock flows (e.g., greater than 30 mbgs [metres below-ground surface]) were also expected to be under discharge conditions in the WR-1 study area, given the proximity to the Winnipeg River.	■ Values are calculated based on fact-based evidence, up-to-date available parameters (e.g., reactor characterization), sensitivity analyses, and conservative assumptions of unknown parameters.
Geosynthesis for WR-1 Environmental Impact Statement Report (WLDP-26400-041-000) CNL 2022	■ The Geosynthesis Report has been developed and used to meet CNSC EIS regulatory baseline geological and hydrogeological requirements and to identify geoscientific data uncertainties and assess their relevance/significance to the Project. Applicable sections of the report include: ▪ Hydrogeological Summary ▪ Geomechanical Framework ▪ Future Evolution of the WL Site ▪ REGDOC-2.9.1 Requirements (CNSC 2020) ▪ Geoscience Verification Plan	■ The Geosynthesis Report has been prepared in support of the EIS. The report presents site geological, hydrogeological and geomechanical data and information. The descriptive geosphere site model of the WL site is outlined based on the descriptive geological, hydrogeological and geomechanical models provided in Sections 2.7, 3.3 and 4.8 of the report, respectively. The descriptive geosphere site model of the WL site includes geological, hydrogeological and geomechanical elements. The geosynthesis identified areas of data uncertainty, the rationale for identification of the uncertainty and recommendations to address the uncertainties, as shown in Table 6-2 of the report.	■ Values are calculated based on fact-based evidence, up-to-date available parameters (e.g., reactor characterization), sensitivity analyses, and conservative assumptions of unknown parameters.

Technical Supporting Document or Supplemental Support Document	Portion of Information or Data Applying to WR-1 In-Situ Disposal Project	How Information/Data are Applied; Outline of Assumptions, Limitations or Differences	Distinguish Factual Evidence from Inference
WR-1 Reactor Radiological Characterization Summary and Radionuclide Inventory Estimates Report (WLDP 26100-041-000) CNL 2020	■ The Reactor Characterization Report describes the current radiological conditions of WR-1. Applicable sections of the report include: ▪ Reactor Description ▪ Potential Contaminants of Concern ▪ Reactor Core Estimated and Characterization Inventories ▪ Reactor Biological Shield Estimated and Characterization Inventories ▪ Outside Core Reactor Systems Estimated and Characterization Inventories ▪ Non-Radiological Hazardous Materials ▪ Appendix: Radiological Characteristics of Potential Contaminants of Concern ▪ Non-Radiological Hazards in WR-1 ▪ Calculated Exposure Rates – Calandria Vessel and Fuel Channels ▪ Summary of Radiological Hazard Survey Results for WR-1 Rooms ▪ WR-1 Reference Documents	■ The Reactor Characterization Report summarizes the data collected to describe the current conditions of WR-1. This data has been used in many of the other supporting documents for the EIS, including the DDP, DSAR, ERA, the Groundwater Flow and Solute Transport Modeling Report. Results from sampling have also been compared with modelled values.	■ Factual information from sampling and testing.
Building Condition Assessment Report (WLDP-26000-REPT-011) Golder 2022b	■ The building condition assessment evaluated the integrity of the existing subsurface concrete foundation and bottom slab of WR-1. A condition assessment of the exposed and accessible concrete elements of the substructure, supplemented with laboratory testing of recovered cores was completed to establish the condition and properties of the concrete. Applicable sections of the report include: ▪ Summary of Significant Findings ▪ Need for a Repairs Work Program ▪ Laboratory Test Results	■ The building condition assessment program included the following tasks: ▪ Review of available WR-1 facility construction documentation and hydrogeological data. ▪ Visual assessment of the exposed portions of internal subsurface concrete foundation walls and the related concrete floor structure. The visual assessment included surface deterioration mapping and a delamination survey. ▪ Concrete coring investigation of the concrete foundation walls and concrete floor from the inside of the structure. ▪ Laboratory testing on the extracted concrete core samples. ▪ Preparation of a report describing the factual results of the investigation and providing recommendations for potential repairs for any condition issues which could affect the long-term integrity of the structure that were identified during the investigation. ■ Results of the assessment were used to verify the assumptions of the Groundwater Flow and Solute Transport Modelling Report.	■ This report presents a factual record of the current structure condition based on a visual inspection, core sampling and laboratory testing.

Table 1: Interrelation Between Whiteshell Reactor 1 (WR-1) In Situ Disposal Project Documents

Technical Supporting Document or Supplemental Support Document	Portion of Information or Data Applying to WR-1 In-Situ Disposal Project	How Information/Data are Applied; Outline of Assumptions, Limitations or Differences	Distinguish Factual Evidence from Inference
Environmental Risk Assessment (WLDP-26000-REPT-006) EcoMetrix 2024	■ Prediction and assessment the risk to relevant human and ecological receptors resulting from exposure to radiological and non-radiological substances expected to be released throughout the closure and post-closure periods of the Project. Applicable sections of the ERA report include: ▪ Site Description ▪ Source Term Characterization ▪ Human Health Risk Assessment - Closure ▪ Human Health Risk Assessment – Post-Closure ▪ Ecological Risk Assessment - Closure ▪ Ecological Risk Assessment – Post-Closure ▪ Ecological Receptor Profiles ▪ Evaluation of Disruptive Scenarios	■ The ERA uses the expected source terms of atmospheric and liquid releases to predict the transport of these substances through the environment, exposure and dose to the public, exposure and effects on representative ecological receptors, and changes in habitat and effects on species that rely on that habitat. ■ The IMPACT^{TM} model was used to predict dose to identified human and ecological receptors during the closure and post-closure period. ▪ Human Health Risk Assessment: – Exposure factors were based on best-available information from literature with preference for exposure factors identified in CSA N288.1-14 (CSA Group 2014). For parameters that did not have exposure factors in CSA N288.1-14, surrogate parameters were identified. – The Harvester Model in the ERA uses the average intake rates from the 2018 Aboriginal Food Intake Survey and is considered to be a conservative reflection of potential health effects to Indigenous peoples. ▪ Ecological Health Assessment: – Uncertainties in the exposure assessment include the representativeness of the predicted concentrations used in the assessment at each location. Maximum concentrations are considered to overestimate exposure for all mobile receptors. – BAFs were used to calculate uptake into tissues. The BAFs used for the exposure assessment were taken from reputable sources (e.g., N288.1-14) and are considered to be representative of the conditions found at the site. – Reputable sources are used for wildlife exposure factors, such as intake rates and diets. They are a potential source of uncertainty, but are considered to be representative for the organisms assessed. – Dose coefficients were obtained from reputable sources for reference organisms, but have not been derived specifically for all the organisms assessed. Dose coefficients for surrogate organisms were often used.	■ Screening indices are values calculated based on fact-based evidence, up-to-date available parameters and conservative assumptions of unknown parameters.
Environmental Assessment Follow-Up Program for Whiteshell Laboratories (WL-509246-STD-001) CNL 2018	■ The scope of the framework is described in Section 11 of the EIS. In addition, an overview of WL's Integrated Environmental Monitoring Program was included in Section 11 of the EIS. Applicable sections of the document include: ▪ Goals and Monitoring Objectives for Whiteshell Reactor Disposal Facility ▪ Whiteshell Reactor Disposal Facility Work Package Status ▪ Proposed Schedule for Decommissioning Activities	■ Information is used to provide context for and to describe purpose of the Project's EAFP. ■ The enhanced monitoring work package associated with the WRDF, as described in this report, includes: ▪ Review effluent verification monitoring for WR-1 and integrate any enhanced monitored required by the EIS for the WRDF into the WL effluent verification monitoring plan. ▪ Maintain the acquisition of pertinent meteorological data. ▪ Integrate the enhanced groundwater monitoring (including WR-1 near field wells) required by the EIS for the WRDF into the WL groundwater monitoring plan. ▪ Review environmental (e.g., surface water [Winnipeg River]) monitoring for WR-1 and integrate any enhanced monitored required by the EIS for the WRDF into the WL environmental monitoring plan. ▪ Prepare a Monitoring and Surveillance Plan for post-closure following guidance in IAEA SSG 31 (IAEA 2014) and CSA N292.6-18 (CSA Group 2018) (Annex A.13) and related CSA N288 standards. ▪ Implement, maintain, and report on the results from the monitoring and surveillance plan for post closure. ▪ Evaluate compliance, groundwater effects, and refine and enhance monitoring program. ▪ Ensure measures to prevent erosion/subsidence/deterioration at the WRDF are considered in the WL site flood/storm water management plan. This should also include an inspection and GPS measurement of the Winnipeg River bank in the vicinity of the WL site. ▪ Prepare remedial action plan for responses to unexpected results as per CNL's Environmental Incident Reporting, Investigation and Mitigation (CNL 2018b). ▪ Maintain regular reporting requirements and public information activities. ■ The follow-up monitoring plan presented in the EIS provides a preliminary description of the activities and framework for monitoring proposed for the Project. The follow-up monitoring program will be further detailed as the Project design is finalized. In addition, input from regulatory agencies, Indigenous peoples, and the public will be considered. The detailed follow-up monitoring plan will include sufficient information on the type, quantity and quality of information required to reliably verify predicted effects (or absence of them) and confirm the effectiveness of mitigation. These plans will also be prepared consistent with relevant CSA N288 standards.	■ Factual evidence based on the existing WL Integrated Environmental Monitoring Program.

Table 1: Interrelation Between Whiteshell Reactor 1 (WR-1) In Situ Disposal Project Documents

Climate Change Assessment (WLDP-26000-REPT-007) Golder 2017	■ This document provides an assessment of changing climate considerations. The assessment follows the guidance provided by the Federal-Provincial-Territorial Committee on Climate Change and Environmental Assessment (FPTCCCEA), which has prepared a general guidance document for practitioners to use when incorporating climate change issues into environmental assessments (FPTCCCEA 2003). Applicable sections of the Climate Change Assessment Report include: ▪ Future Climate Conditions Until 2100 ▪ Future Climate Conditions Post 2100 ▪ Project Specific Climate Factors and Extreme Events	■ This document provides a quantitative assessment of the current climate analysis and future climate projections up to the year 2100. A qualitative assessment of climate change projections past 2100, through to the year 3000, is also provided. ■ Based on the historical climate parameters and climate data analyzed up to 2100, climate factors have been developed to further analyse the potential climate infrastructure interactions for the Project region. The climate factors include changes to rainfall, temperature and extreme events (e.g., storms). These factors are further subdivided into specific event type factors that describe long-term changes, such as increasing temperatures or extreme events such as increased storms with intense precipitation. Where information is available from Section 4.0 Future Climate Conditions Post 2100, the climate factor trends will be extended out to the year 3000. ■ Climate factor trends for the Project are described in Table 5.0-1 of the report. The future trends of the climate factors were analysed using the climate model projections in Section 3.0 Future Climate Conditions until 2100. If climate projections were not available from Section 3.0 Future Climate Conditions until 2100, literature values were referenced to discuss the projected change in climate.	■ Values are calculated based on fact-based evidence, up-to-date available parameters (e.g., transfer factors), and conservative assumptions of unknown parameters.
Grout Formulation Testing Report (WLDP-26000-REPT-012) Golder 2022a	■ This document provides the methodology, results, and conclusions of the testing program used to develop a grout formula for the ISD of WR-1 based on requirements developed by Savannah River National Laboratory from their experiences with ISD.	■ The key property of the grout used in the WR-1 solute transport modelling is the hydraulic conductivity. CNL has specified that the grout used in the decommissioning of WR-1 must have a hydraulic conductivity of less than 9.5×10^{-10} m/s (CNL 2017). To support the selection of this value, CNL provided reference materials for grout specifications that were used in the ISD of a nuclear reactor at the Savannah River National Laboratories site in the southern United States. In addition, a literature review of the hydraulic conductivity of other grout mixtures was completed (Golder 2018). ■ Recognizing that not all of the areas within the WR-1 Building will be fully penetrated by the grout, and some voids will remain after final grout placement, a higher value of 5×10^{-8} m/s was selected for the grout in the WR-1 ISD assessment (i.e., a factor of 50 times greater than the maximum value specified by CNL and 50 times greater than the maximum measured value at Savannah River). Results of testing (Golder 2022a) performed on a preferred grout formula indicated a hydraulic conductivity of 0.0004 m/yr (1.27E-11 m/s) (Golder 2022a) which is more than 50 times below the target.	■ This report presents a factual record of the grout formula testing program.
Safety Case Report (WLDP-26000-SAR-002) CNL 2023	■ The Safety Case demonstrates that in situ disposal, post closure activities, and long-term disposal of the WR-1 Building can be safety undertaken. Applicable sections of the Safety Case include: ▪ Safety Strategy ▪ System Description ▪ Safety Assessment ▪ Iteration and Design Optimization ▪ Limits, Controls and Conditions ▪ Comparison of Safety Case Sections to REGDOC-2.11.1 (CNSC 2018) ■ The Safety Case is supported by the EIS and DSAR.	■ Information is used to support the safety case for the ISD of WR-1 and the mapping of the design and safety documents to the regulatory requirements is provided to demonstrate that all elements of the safety case are met by the suite of Project documents.	■ Report is primarily based on factual information; a summary of site characteristics, facility structures, systems, components and safety features, radiological and non-radiological inventories, natural and anthropological analogues, and maintenance and relevant compliance programs.

3-D = three-dimensional; BAF = bioaccumulation factor; CNL = Canadian Nuclear Laboratories; CNSC = Canadian Nuclear Safety Commission; CSA = Canadian Standards Association; DDP = Detailed Decommissioning Plan; DSAR = Decommissioning Safety Assessment Report; EAFP = Environmental Follow-up Program; EIS = Environmental Impact Statement; ERA = Environmental Risk Assessment; FPTCCCEA = Federal-Provincial-Territorial Committee on Climate Change and Environmental Assessment; GPS = Global Positioning System; IAEA = International Atomic Energy Agency; ISD = In Situ Disposal; REGDOC = Regulatory Document; WMA = Waste Management Area; WR-1 = Whiteshell Reactor 1; WRDF = Whiteshell Reactor Disposal Facility.

1.0 SUMMARY OF SECTION 4.0 APPENDICES

The following contain two sets of information for each Indigenous Nation on the Project. The first set of information provides a summary of engagement with each Nation which is described in detail in subsection 1.1 'Summary of Indigenous Engagement Tables.'

The second set of information outlines the summary of key interest and concerns organized by each Indigenous Nation which is described in detail in subsection 1.2 'Summary of Interests and Concerns Tables.' Both sets of tables are organized by each Indigenous Nation in subsection 1.3 'Summary of Indigenous Engagement Tables and Summary of Interests and Concerns Tables.'

1.1 Description of the Summary of Indigenous Engagement Tables

The Summary Tables of Indigenous Engagement provide a record of key engagement activities of the Project between CNL and each First Nation and the Manitoba Métis Federation from June 2016 to July 2024. The record includes the date and method of the communication/ engagement, the topics discussed and the role or title of participants. Note that CNL's record of engagement format was revised in October 2022 to include expanded information on engagement activities and align with CNL's internal practices and other environmental assessments. The updated Indigenous engagement tables retain all required record information for the environmental assessment.

The following is a list of key topics related to the Project that Indigenous communities were engaged on:

- **Baseline Conditions:**

  Information on the existing Whiteshell Laboratories site and study areas for the Project – site characterization, facility description, description of the existing environment.

- **Alternative Means Assessment:**

  Information on the various alternative options for disposing of the waste liabilities at the Whiteshell Laboratories site.

- **Project components and related activities:**

  Information on the purpose of the project, scope of the project, proposed project phases, how the project would be carried out (i.e., grouting), waste inventory and strategy, as well as information on the proposed schedule.

- **Effects assessment, including VC, Spatial and temporal boundaries for the assessment:**

  Information on the EA process, the EIS, valued components (VC), site location, and project timeline and effects assessment.

- **Proposed Mitigation Measures**

  Information on proposed mitigation measures, such as dust suppression during decommissioning execution.

- **Residual Effects**

  Information on the residual effects (impacts directly from the Project after mitigation measures are applied).

- **Follow-up Monitoring Program**

  Information on the proposed follow-up monitoring program for the WL Site.

- **Aboriginal and Treaty Rights / Traditional Land Use**

  Information on effects and potential impacts to Indigenous rights.

- **Specific Interests and Concerns of the Community**

  Information related to (and in response to) any or all of the particular topics or issues raised by the Indigenous community in either their comments on the Project Description or versions of the draft EIS or during engagement activities with CNL. A list of these interests for each community is found in Appendix 4.0-1 of Section 4,0 of the EIS.

- **Engagement Methods**

  Discussions with communities on structuring Indigenous engagement activities to ensure Indigenous engagement activities are appropriate to the community's needs. Engagement can be performed in a number of manners, including through face-to-face meetings, phone calls, video calls, sharing of documentation, and written communication. Each of these methods of engagement can be a source of Indigenous knowledge, perspectives, as well as issues and concerns expressed by Indigenous groups.

1.2 Description of the Summary of Interests and Concerns Tables

The Summary of Interests and Concerns tables summarize the key interests and concerns that each Indigenous community or organization has raised to date on the WR-1 In situ Decommissioning Project.

These summary tables represent an amalgamation of: the formally submitted comments as part of the Environmental Assessment (EA) process; formally submitted comments and questions to CNL (not submitted as part of the formal EA process); and summaries of topics that have been discussed between CNL and each Indigenous Nation or organization but were not part of a formal submission including project-specific studies; and all information shared by the Indigenous Nations to date. CNL has prepared these tables to provide a picture of the interests and concerns that have been raised by each Indigenous Nation or organization. These tables also reflect the evolving relationship between each community or organization and CNL. Narrative summaries of each table up to July 31, 2024 are included in Section 4 of the draft EIS.

CNL has worked with each Indigenous Nation to confirm that the Summary of Interests and Concerns tables accurately reflect the high-level key interests and concerns of Nations as well as the status of each interest and concern. The Summary of Interests and Concerns tables were updated and the tables re-verified by the corresponding Indigenous Nation following feedback CNL received from the CNSC on CNL's Nuclear Power Demonstration EIS Submission Package. In addition, the interactive validation process has occurred, most recently, in the fall of 2024.

These tables are current as of July 2024.

The Tables consist of four columns:

- Column 1 summarizes the key interests or concerns and why they are important in terms of effects under Section 5(1)(c) of the Canadian Environmental Assessment Act 2012 and/or impacts to Aboriginal and/or treaty rights, claims or interests.
- Column 2 summarizes how the interests or concerns are being addressed by CNL.
- Column 3 identifies where in the EIS the interests or concerns are addressed, changes made to the EIS as a result of the interests or concerns and any changes to the EIS outcomes (if applicable); and,
- Column 4 is the "Status". This column describes the status of each interest or concern and whether the community has verified that CNL has addressed the interest or concern. Not all concerns can be quickly or easily resolved as some concerns go beyond the scope of the Project or there may remain a difference of opinion on certain interests or concerns. The table indicates when an interest or concern is out of the scope of the EA process.

1.3 Summary of Indigenous Engagement Tables and Summary of Interests and Concerns Tables

1.3.1 Sagkeeng First Nation Engagement

Date	Activity	Attendance	Description	Key EA Topics									
				Baseline Conditions	Alternative Means Assessment	Project Components	Effects Assessment	Proposed Mitigation Measures	Residual Effects	Follow-up Monitoring Program	Aboriginal and Treaty Rights / Traditional Land Use	Specific Topics of Interest	Engagement Methods
April 1, 2016	Teleconference	Chief, Sagkeeng First Nation 4 representatives from CNL 5 representatives from CNSC 1 representative from AECL 1 CNL contractor	CNSC initiated teleconference and two-way dialogue with Chief Derick Henderson from Sagkeeng First Nation. Chief Henderson confirmed his preferred point of contact for the community and expressed an interest in reviewing the environmental baseline conditions, WR-1 in-situ design, environmental monitoring, and economic opportunities.	✓		✓	✓			✓			
May 18, 2016	In-person meeting	5 members of Sagkeeng First Nation 3 representatives from CNL 1 CNL contractor	Introductions of the Sagkeeng First Nations and the CNL representatives and discussion of the preliminary concerns and how Sagkeeng First Nation would like to be involved in the future.	✓		✓		✓	✓	✓		✓	✓
August 3, 2016	Email/Letter	Sagkeeng First Nation	CNL sent a Project Introductory Letter to all Indigenous communities in the area and request for community input on any potential adverse impacts from project activities. The letter requested meaningful feedback on the following: Whether the project may have environmental effect on any lands and/or resources currently used by Indigenous peoples for traditional purposes; Whether the project may have any perceived impacts on Aboriginal and Treaty Rights; Whether local and traditional knowledge can assist in describing the existing environment; and, The view of Indigenous communities on proposed valued ecosystems components (environmental attributes) that have been identified for the assessment.										✓
January 25, 2017	In-person Meeting	4 representatives from Sagkeeng First Nation (Chief and Council) 3 representatives from CNL	CNL provided an overview of the proposed Project and responded to questions directly from the community. Sagkeeng and CNL discussed how best to engage Sagkeeng on the Project.			✓			✓			✓	✓
January 25, 2017	Open House	3 First Nations members 2 members of the public	CNL presentation providing an overview of CNL and WR-1. There were discussions on the WR-1 design, clean up criteria of the site, environmental monitoring, procurement opportunities for Indigenous people, and a discussion about Aboriginal and treaty rights. The discussions were guided by the community's interest in the topics presented in a PowerPoint presentation. This was a two-way dialogue between Sagkeeng and CNL.			✓			✓	✓	✓		
May 17, 2017	In-person meeting	5 representatives from Sagkeeng First Nation 2 representatives from Wabaseemoong Independent Nations 4 representatives from CNSC 6 representatives from CNL 2 representatives from AECL 1 CNL contractor	CNSC led meeting about engagement and presented on the CNSC's role and the Project.	✓		✓			✓		✓		✓
July 4, 2017	Site Tour	7 representatives from Sagkeeng First Nation 9 Sagkeeng First Nation students 4 representatives from CNL 1 CNL contractor	CNL welcomed Sagkeeng's Chief and Council and Sagkeeng's summer students for a tour and hands on demonstration of tools followed by a period for questions and two-way discussion. Topics covered included CNL's environmental protection program, WR-1 design, and the waste management area.	✓		✓				✓			
July 6, 2017	In-person event - Industry Day	2 CNL contractors 3 representatives from CNL	CNL hosted an industry day, presentation of Whiteshell Laboratories.									✓	

Date	Activity	Attendance	Description	Key EA Topics									
				Baseline Conditions	Alternative Means Assessment	Project Components	Effects Assessment	Proposed Mitigation Measures	Residual Effects	Follow-up Monitoring Program	Aboriginal and Treaty Rights / Traditional Land Use	Specific Topics of Interest	Engagement Methods
October 5, 2017	Email/Letter	Sagkeeng First Nation	CNL sent a mass notification of public and Indigenous comment period on the draft EIS and invitation to engage to all Indigenous communities.										✓

CNL held a booth and provided demonstrations by the CNL Fire Department and Security.	In Person event
2024 July 31	This email from CNL Indigenous Relations Advisor to SAFN Manager of the Niigan Aki Program is to confirm if the scheduled meeting to be held on 2024 August 08 will go ahead as planned to discuss the Nuclear Power Demonstration (NPD) Project. CNL requested an update for a new date for the meeting and provided options.	Email

1.3.2 Sagkeeng First Nation (Sagkeeng) – Key Interests and Concerns

It should be noted that several interest and concerns, within the scope of the Whiteshell Laboratories Site, will be discussed, and addressed within the parameters of the future relationship between Sagkeeng Anicinabe First Nation (SAFN), CNL and AECL. As such, the status column will indicate an “ongoing” status.

Additionally, CNL has been working diligently to develop a draft list of commitments from the Project to SAFN regarding WR-1. SAFN and CNL have not arrived at a set list of sufficiently detailed commitments at this time but do expect that to change over the coming months, as CNL and SAFN continue to engage and discuss. As such, the status column will indicate an “ongoing” status.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Relationship-Building			
At the start of the Whiteshell Reactor 1 (WR-1) Project, the relationship between Sagkeeng Anicinabe First Nation (SAFN) and Canadian Nuclear Laboratories (CNL) was limited in scope. Although SAFN was concerned about the limited opportunities for their involvement in the Environmental Assessment (EA) process, they were also interested in a positive respectful relationship with CNL to help SAFN and CNL work together on topics such as the Project and to ensure that SAFN’s interests, concerns, and Aboriginal and treaty rights are considered by CNL in its activities. This is both a project-specific and site-wide interest.	This interest and concern has been addressed via the 3-year extension of the contribution agreement signed, August 2023. The agreement which provides funding for multiple avenues including a Community Liaison position and Healing and Resiliency Action Plan (HRAP), Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameters for the leadership table between SAFN, CNL and AECL. In 2022 October, CNL, AECL, and SAFN signed a contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the SAFN Indigenous monitoring guardianship program, which is in place and called the Niigan Aki Program. In addition to the Technical Working Group, CNL and SAFN are building their relationship through grass- roots engagements like environmental monitoring, community engagement such as the 2024 Summer Tree Planting, and mushroom collections, and through joint public engagement such as the 2023 September Nuclear Waste Management Decommissioning and Environmental Restoration (NWMDER) conference held in Niagara Falls, ON where Niigan Aki presented on Indigenous-led environmental monitoring on Nuclear sites, Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized. CNL will continue engagement with SAFN to address or resolve outstanding issues or concerns to the extent possible regarding the Project and has demonstrated its commitment to ongoing engagement and relationship-building to support discussions regarding the future land use of the Whiteshell site.	Section 4.2.4.1: SAFN was updated to include CNL’s commitment to working with SAFN through the Technical Working Group to develop and implement initiatives that would help address SAFN’s concerns on the Project.	Ongoing CNL’s relationship with SAFN has improved since a CNL, AECL, and SAFN leadership meeting on April 6, 2021. The relationship is growing positively and is currently being managed through tripartite discussions at the Technical Working Group. SAFN has expressed that the relationship needs to be ratified through meaningful long-term commitments to SAFN monitoring and management roles in relation to the WR-1 and the WL, and to support for healing and resiliency improvements and evidence of benefit to offset long-term and likely future impacts at and around the WR-1 facility.
Site Management Structure/Roles and Responsibilities			
SAFN expressed an interest in reviewing the nature of the contractual relationship and financial terms between Canada and the Canadian National Energy Alliance (CNEA), with emphasis on any incentives or penalties related to the schedule and budget of the proposed undertaking. SAFN wants to understand how incentives or penalties may impact site decisions and, in turn, may impact their Aboriginal and treaty rights to use lands and resources near the WL site. This is both a project-specific and site-wide concern.	CNL provided formal responses and had direct engagement with SAFN in 2020 and 2021, to explain and discuss the contractual relationship between AECL and CNEA. CNL indicated that it could not disclose the detailed financial terms between Canada and CNEA as that information is confidential and commercially sensitive. However, CNL provided SAFN with a redacted copy of the Contract between AECL and CNEA. CNL reiterated that regardless of the contractual and financial terms, CNL will remain responsible for carrying out the Project and the overall WL site closure in accordance with all federal regulations, international best practices, and with public safety as a primary concern.	Sections 1.0: Introduction and 1.4: Proponent were revised to clarify the relationships and history between CNL, Atomic Energy of Canda Limited (AECL), and the Canadian National Energy Alliance (CNEA).	This interest/concern has been addressed. SAFN and CNL have differing perspectives on this matter. At this time SAFN does not accept CNL's position that the financial terms of the CNEA contract cannot be disclosed. SAFN has proposed entering into confidentiality agreements and other possible arrangements to allow for the confidential and “for-purpose” disclosure of the requested information.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
SAFN was interested in the history of, relationship between, and responsibilities of CNL, AECL, the WL site, Canada, CNEA, and other parties responsible for the environmental liabilities at the WL site now and in the future. Specifically, they want to know who will be accountable for any impacts to their Aboriginal and treaty rights to use lands and resources near the WL site. This is both a project-specific and site-wide interest.	CNL provided formal responses and had direct engagement with SAFN to explain the roles, relationships, and responsibilities of CNL, AECL, and CNEA. CNL explained that CNL and AECL operate under a Government-owned, Contractor-operated (GoCo) model, whereby the site, facilities, and assets remain the property of AECL, but are operated by CNL. Management of CNL was awarded to CNEA, a private sector consortium that represents some of the world's most experienced nuclear engineering and management firms. The GoCo model is set up so that CNL remains the operator and licensee of all AECL sites regardless of whether a new contractor is selected. AECL could award a new contract for the management and operation of CNL to a different consortium after 2025 and CNL would remain responsible for the management and operation of all AECL sites. CNL defers conclusions on the impacts to Aboriginal and Treaty Rights to the CNSC. CNL reiterated that it will remain responsible for the Project, the WL site closure, the ongoing monitoring activities, and for any remedial actions resulting from the CNSC Rights Impact Assessment, should they be required. The federal government, through AECL, will remain responsible for funding CNL throughout the closure work and ongoing post-closure monitoring.	Sections 1.0: Introduction and 1.4: Proponent were revised to clarify the relationships and history between CNL, AECL, and CNEA. CNL documented its commitment to and responsibility for the future monitoring of the WL site and the WR-1 facility, and AECL commitment to funding the monitoring program in Section 11.2: Adaptive Management. CNL's responsibility for remedial actions is documented in Section 11.3: Data Management.	This interest/concern has been addressed within the scope of the WR-1 project, pending completion of the CNSC's Rights Impact Assessment. SAFN has expressed appreciation for the information provided about present and future nuclear liability responsibility, and has noted that the question of what degree of harm to SAFN rights and interests has already occurred prior to the Project, and how much harm will occur in a future with and without the Project, remains an open issue,
Engagement			
In January 2018, SAFN expressed concern with the lack of meaningful and responsive engagement by CNL. SAFN has also indicated that technical results are difficult to understand and that CNL should work with Chief and Council to promote future engagement activities and go door to door to invite on-reserve members. SAFN is interested in improving its community members' understanding of the Project so community members can come to their own conclusions about impacts to the environment and fully exercise their right to be consulted on projects that might adversely impact their Aboriginal and treaty rights. This is a project-specific concern.	This interest and concern has been addressed via the 3-year extension of the contribution agreement signed, August 2023. The agreement provides funding for multiple avenues including a Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameters for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki.	Section 4.2.4.1: SAFN was updated to provide information on all engagement activities with SAFN since 2016 and to include key next steps to help address SAFNs concerns with the Project.	Ongoing CNL will continue to engage meaningfully with SAFN Chief and Council, community members, their engagement team, and their Liaison through the lifecycle of this Project. SAFN has expressed that for engagement to be meaningful, it must be ongoing. SAFN acknowledges that CNL has meaningfully engaged with it on the WR-1 Project, enabling SAFN's participation in the environmental assessment and licensing process and expects that engagement to continue. SAFN has expressed that for engagement to be meaningful, it must be ongoing.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
SAFN expressed interest in a greater role in reviewing draft documentation related to the WR-1 Environmental Impact Statement (EIS) as they want to ensure their Aboriginal and treaty rights, their interests, and their concerns are properly reflected and assessed. This is a project-specific interest.	This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides formal funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. In 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Niigan Aki. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program designed to improve Indigenous understanding of the site and vicinity risk to the health and edibility of country food and water sources (including radiation, impact pathway identification, monitoring results, and plain language reporting about the safety of country food and water sources), as well as sharing CNL's annual reports with the community. In February 2024, CNL shared the draft EIS Indigenous Engagement Report with SAFN for their review. CNL received SAFN written feedback for incorporation. CNL and SAFN have also engaged through a subcommittee focused on verifying that EIS documentation accurately reflects SAFN's interests and position. SAFN has been included as a member of the Federal Provincial Indigenous Review Team (FPIRT) with the CNSC, responsible for formal review of the EIS and supporting documentation.	The following sections of the draft EIS were influenced and modified based on feedback from SAFN: Section 2.8: Sagkeeng's Alternative Means Assessment – Approach and Findings. CNL created Section 2.8: Sagkeeng's Alternative Means Assessment – Approach and Findings to capture SAFN's alternative means study and CNL analysis of SAFN's findings. Section 4.0: Indigenous Engagement, particularly 4.2.4.1: SAFN, which details SAFN engagement and interests and 4.2.4.1.4: Sagkeeng First Nation's Psychosocial Impact Assessment. Table 4.4-1: Summary of Issues Raised During Engagement Activities that Influenced the Scope of the Environmental Assessment (EA) provides other impacts on the EIS from engagement activities. Section 6.7: Human and Ecological Health. CNL added moose as a Valued Component (VC) for the post-closure phase and assessed the effects of the Project on moose, and Indigenous peoples harvesting moose. Section 6.8: Land and Resource Use. CNL revised the assessment boundaries in Section 6.8: Land and Resource Use based on SAFN's feedback to expand the Regional Study Area (RSA) to extend downstream of the Winnipeg River and beyond the outlet into Lake Winnipeg. CNL confirmed that the land use RSA encompasses the EA areas from Sections 6.2: Atmospheric Environment through 6.7: Human and Ecological Health. Section 6.9: Socio-economic Environment. CNL elevated psychosocial aspects of the Project from a no linkage pathway to a secondary pathway in Section 6.9: Socio-economic Environment to include this concern in the assessment due to its importance to Indigenous Nations. Section 11.0: Summary of Monitoring and Follow-up Programs. Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring was added to outline ongoing engagements and commitments to support meaningful discussion on the monitoring and follow-up programs and includes CNL's commitment to an independent SAFN Guardianship Program.	Ongoing CNL recognizes that this interest will likely apply to future versions as well and is committed to ongoing engagement and provision of capacity to support SAFN in future review. SAFN notes that CNL made some revisions to the EIS based on SAFN comments and chose not to make revisions based on SAFN comments in some instances. SAFN has informed CNL that it will provide further comments on the EIS upon its acceptance by the CNSC.
SAFN is concerned that the site may impact the environment in the future. SAFN wants to be involved in the planning, assessment, remediation, and monitoring of WR-1 and the Waste Management Area trenches to ensure their Aboriginal and treaty rights to use lands and resources near the WL site is not impacted in the future. This is both a project-specific and site-wide concern.	CNL agreed to engage SAFN on how they would like to participate in the In Situ Disposal (ISD) of WR-1 if approved. CNL also agreed to provide the Environmental Risk Assessment, Detailed Decommissioning Plans and final safety assessment for the remediation of trenches at the WL site, and other relevant documents, once drafted and to engage SAFN on the institutional control framework for the Waste Management Area trenches. In August 2023, SAFN received the Land Use End State (LEUS) draft document. In early 2024 SAFN informed CNL that they would be working on the *SAFN Vision for Long-Term Land Use* report which will be the avenue to address the LUES. Spring 2024 CNL commissioned a "plain language" version of the LUES document. June 2024 CNL hosted a CNL Regional Gathering of Leaders; Project Discussion 2024 which provided an overview of the End State Plan and sought consultation on 3 options for low-medium level nuclear waste management. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized. Unclear why CNL's formal, funded agreement with to support an independent SAFN Guardian Program is not reflected in this section, but rather in the impact to EIS section.	Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring was added to outline ongoing engagements and commitments to support meaningful discussion on the monitoring and follow-up programs and includes CNL's commitment to an independent SAFN Guardianship Program.	Ongoing CNL's perspective is that this concern cannot be fully addressed until a licensing decision is made on the WR-1 ISD Project as WR-1 decommissioning cannot occur before that time. SAFN recognizes that CNL has entered into a formal, funded agreement to support a Community Environmental Monitoring Program with SAFN. SAFN views this as a positive development. In addition, SAFN notes that questions of SAFN's role in planning and assessment of WR-1 and the WL site have yet to be addressed through concrete commitments by CNL or AECL.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
SAFN expressed concern that consultation with the Crown will still need to occur to discuss and determine any potential impacts on Aboriginal and Treaty rights and, where appropriate, accommodation in addition to the engagement CNL and SAFN are undertaking. This is a project-specific concern.	For questions related to consultation and the Nation-to-Nation relationship, CNL responded providing its understanding of the roles of the Canadian Nuclear Safety Commission (CNSC) and AECL, and also referred SAFN to the CNSC and Crown. CNL has offered to have the regulator and AECL join meetings to help address this concern. CNL has and will consider how traditional land and resource uses (such as trapping, hunting, fishing, gathering, and culture) might be different among the various Indigenous Nations. Certainly, each Indigenous Nation will describe how it undertakes traditional land and resource use in a somewhat different way and CNL has to the best of its ability described that. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	Section 6.8: Land and Resource Use was revised based on feedback from SAFN to improve the description of SAFNs traditional land and resource use.	Ongoing SAFN has expressed its expectation that AECL, as an agent of the Crown, the owner of the WL site, and entity primarily responsible for the nuclear liabilities, will play a role in facilitating consultation and ensuring accommodation.
SAFN is interested in improving its community members' understanding of the WL site, through an Indigenous-led risk communication program and sharing CNL's annual reports, to improve understanding of the site and vicinity risk to the health and edibility of country food and water sources (including radiation, impact pathway identification, monitoring results and plain language reporting about the safety of country food and water sources). This would support community members to develop their own conclusions about impacts to the environment and fully exercise their right to be consulted on projects that might adversely impact their Aboriginal and treaty rights. This is both a project-specific and site-wide interest.	This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. CNL and SAFN have prioritized the Indigenous-led risk communication program to improve Indigenous understanding of the site and vicinity risk to the health and edibility of country food and water sources (including radiation, impact pathway identification. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	Section 4.2.4.1: SAFN was revised to include CNL's commitment to support a risk communication program.	Ongoing
SAFN expressed concern that CNL had not engaged in a meaningful way to establish a baseline, conduct an effects assessment, or consider SAFN VCs. SAFN expressed the position that the spatial boundaries of the assessment are inappropriate for assessing potential impacts to the Current Use of Lands and Resources for Traditional Purposes (CULRTP). SAFN wants to ensure their Aboriginal and treaty rights, their interests, and their concerns are properly reflected and assessed. SAFN believes the traditional land and resource use impacts of the Project should be compared to conditions prior to the establishment of the WL site rather than to current conditions. The siting and operations of the WL site had the potential to adversely impact SAFN's Aboriginal and treaty rights and SAFN believes this needs to be factored into the remediation of WR1. This is a project-specific concern.	CNL engaged with SAFN on how the baseline was established and on revisions CNL made based on SAFN input through engagements and incorporating SAFN's Traditional Knowledge Land Use and Occupancy Study into the draft EIS. For example, CNL revised the Land and Resource Use assessment spatial boundaries based on SAFN's feedback to expand the RSA to extend downstream of the Winnipeg River and beyond the outlet into Lake Winnipeg. CNL clarified that the Project is being assessed under the framework of the Canadian Environmental Assessment Act (CEAA) 2012 and Section 5 (1) (c) of the CEAA 2012 states that the assessment of effects is limited to *"the current use of lands and resources for traditional purposes"*. CNL explained that while ISD does not undo the historic developments in the area, it is an appropriate approach because it reduces the nuclear liabilities at the WL site by disposing of WR-1 in a design-reviewed, safety assessed facility without the need for major demolition and nuclear waste extraction and transportation work. This minimizes the impact to the surrounding environment and in turn builds confidence that the rights, cultural practices, and traditional land and resource use by SAFN and other Indigenous Nations will not be impacted at the present or the future time. CNL provided SAFN with the effects assessments sections of the draft EIS for their review and feedback. CNL reviewed SAFN's studies and feedback on the draft EIS and incorporated SAFNs feedback where appropriate. This helped ensure the assessment reflects the results of the engagement and covers the elements of the environment relevant to SAFN. Based on the feedback received during engagement activities and SAFN studies, CNL also prepared a list of VCs for SAFN in a format that compared the SAFN VCs to the Project VCs. CNL requested a review and comment by SAFN on this table. For each SAFN VC, CNL either: ▪ Confirmed it was encompassed by the assessment. ▪ Added it to the assessment. ▪ Added it to the model to be assessed. ▪ Did not add it to the assessment, with rationale provided.	CNL revised the assessment sections (Sections 6.2: Atmospheric Environment through 6.9: Socio-economic Environment) to include a summary describing how Indigenous VCs, interests, and land use practices, including those provided by SAFN, were considered in that specific assessment. CNL revised the assessment boundaries in Section 6.8: Land and Resource Use based on SAFN's feedback to expand the RSA to extend downstream of the Winnipeg River and beyond the outlet into Lake Winnipeg. CNL confirmed that the Land and Resource Use RSA encompasses the EA areas from Sections 6.2: Atmospheric Environment through 6.7: Human and Ecological Health. CNL revised Section 6.8.1.5.2.2.1: Historical and Present-Day Traditional Land Use to provide additional information on traditional land use by SAFN and include discussion of impacts on communities as a result of establishment of the WL site, among other developments in the area. CNL revised the conclusions of section 6.9 to reclassify the results from 'No Linkage" to "Secondary Pathway" based on the importance of the pathway to SAFN.	This interest/concern has been addressed within the scope of the WR-1 project. CNL and SAFN continue to disagree on the approach taken to develop the baseline and no resolution is imminent.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Historical Siting and Operations of the WL Site			
SAFN expressed concern over the lack of engagement during the siting and operations of the WL site as this adversely impacted their Aboriginal and treaty rights. This is a site-wide concern.	CNL has taken steps to address this concern by incorporating feedback from SAFN on historical siting issues and committing to discussions between AECL, SAFN, and CNL on the historic siting of the WL site and will continue to engage SAFN on the Project and closure of the WL site. CNL and SAFN have worked through a subcommittee to review EIS documentation to incorporate SAFN's feedback as much as possible. Regarding SAFN's concern on historical cumulative effects, the issue remains outstanding and unresolved as SAFN disagrees that adequate steps have been taken on this issue.	Section 4.2.4.1: SAFN was revised to include CNL's commitment to working with SAFN through the Technical Working Group to develop and implement initiatives that will help address SAFN's interests and concerns related to the WL site. Section 6.8.1.5.2.2.1: Historical and Present-Day Traditional Land Use was revised to provide additional information on traditional land use by SAFN and include discussion of impacts on communities as a result of establishment of the WL site, among other developments in the area.	Ongoing CNL has taken steps to address this concern by incorporating feedback from SAFN on historical siting issues and committing to discussions between AECL, SAFN, and CNL on the historic siting of the WL site and will continue to engage SAFN on the Project and closure of the WL site. SAFN disagrees that adequate steps have been taken on this issue, as no facilitated discussions between AECL and SAFN on historic effects or past practices have occurred, or discussions on accommodations and reconciliation have occurred to date.
SAFN believes the traditional land and resource use impacts of the Project should be compared to conditions prior to the establishment of the WL site rather than current conditions. The siting and operations of WL adversely impacts SAFN's Aboriginal and treaty rights and SAFN believes this needs to be factored into the remediation of WR1. This is a project-specific concern.	CNL believes that, while ISD does not undo the historic developments in the area, it is an appropriate approach because it reduces the nuclear liabilities at the WL site by disposing of WR-1 in a design-reviewed, safety assessed facility without the need for major demolition and nuclear waste extraction and transportation work. This minimizes the impact to the surrounding environment and in turn builds confidence that the rights, cultural practices, and traditional land and resource use by SAFN and other Indigenous Nations will not be impacted at the present or the future time. The Project is being assessed under the framework of the CEAA 2012 and Section 5 (1) (c) of the CEAA 2012 states that the assessment of effects is limited to *"the current use of lands and resources for traditional purposes*." To confirm that there would be no effects in the future, CNL is committed to a minimum of 100 years of institutional control and environmental monitoring. CNL is also committed to working in collaboration with Indigenous Nations, including SAFN, on developing a post-closure monitoring program that ensures that environmental aspects important to Indigenous Nations are monitored and timely results provided.	Section 6.8.1.5.2.2.1: Historical and Present-Day Traditional Land Use was revised to provide additional information on traditional land use by SAFN and include discussion of impacts on communities as a result of establishment of the WL site, among other developments in the area. Section 6.9.6.2.2: Secondary Pathways has been revised to make the effects of WR-1 on Indigenous well-being a secondary pathway, acknowledging that the long-term presence of nuclear materials in the region, along with other historical industrial developments in the local study area, had the potential to result in fear, stigma, and anxiety, and that psychosocial effects are legitimate impact pathways affecting the Indigenous community well-being. CNL created Section 2.8: Sagkeeng's Alternative Means Assessment – Approach and Findings to capture SAFNs alternative means study and CNL analysis of SAFN's findings. CNL confirmed in Section 2.8.5.4: Conclusion of CNL's Consideration of SAFN's Assessment that it would not consider any alternative it believed was not safe for the public, the environment, or its workers.	Ongoing CNL's perspective is that this concern is out of scope of the WR-1 EA; SAFN disagrees. CNL and SAFN continue to disagree on the approach taken to assess cumulative effects for the project and no resolution is imminent.
Free, Prior, and Informed Consent (FPIC)			
SAFN holds the perspective that Article 29(2) of the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) and customary international law creates a legally binding requirement to secure SAFNs FPIC prior to proceeding with the proposed ISD Project. This is a project-specific concern.	In February 2021, SAFN, AECL, and the CNSC held a leadership teleconference that included a discussion about the application of FPIC on the Project; CNL participated as an observer. During the meeting, all three parties shared the same view that it is important to engage and seek consensus and consent; ensure a genuine intention to address concerns; and ensure the government makes a responsible decision. There were differing views on the idea that CNL and AECL require SAFN's consent. Reaching consent is a goal of any collaboration, engagement or consultation process, along with identifying mutually acceptable benefits and opportunities, even where consent is not achieved. CNL shared with SAFN that CNL is working towards achievement of the FPIC principle with a goal of SAFN moving closer towards consent, and that CNL is following the EA process for a final decision on the Project. CNL and SAFN have signed a number of Contribution Agreements to support SAFNs engagement in the EA process. CNL continues to seek direction from the community, and work closely with the Liaison Officer, to strengthen engagement with SAFN community members. SAFN continues to hold that the development of a permanent hazardous waste disposal facility is a special, heightened factor re: the importance of FPIC. CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	Section 4.2.4.1: SAFN was updated to state SAFNs position regarding FPIC and the WR-1 EA process.	Ongoing

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Rights Impact Assessment			
SAFN expressed concern that potential impacts to their Aboriginal and treaty rights were not being adequately assessed by the Project. This is a project-specific concern.	CNL has incorporated three SAFN-led studies into the EIS. These studies include SAFN's Traditional Knowledge, Land Use and Occupancy Study, Alternative Means Assessment Report, and Psychosocial Impact Assessment Report. These reports include information on SAFN's rights and key points on their ability to practice their rights in the future. Key findings of these documents and CNL's considerations of them are included in the revised draft EIS. CNL has also included a summary table of SAFN's VCs and how they were considered in each assessment section (i.e., 6.X) in the revised EIS. CNSC REGDOC 3.2.2 provides guidance on Indigenous engagement for proposed projects that may raise the Crown's duty to consult. The regulatory document also encourages the building of long-term relationships and provides guidance on how proponents can address concerns and mitigate potential impacts to Aboriginal and treaty rights. CNL has made significant efforts, through support and review of traditional use studies and overall engagement, to be respectful of Aboriginal and treaty rights, to gain a better understanding of Aboriginal and treaty rights, and to seek understanding of any potential infringement to those rights. CNL has indicated that the CNSC is responsible for making determinations on any impacts to Aboriginal and treaty rights. As the CNSC develops the rights impact assessment for the Project, there is an opportunity for SAFN to work with the CNSC on that assessment of rights. CNL is committed to engaging with SAFN to gain a better understanding of SAFN's concerns related to their Aboriginal and treaty rights. CNL and SAFN have established a Technical Working Group to move forward on key initiatives to help address outstanding concerns SAFN has with the Project and collaborate on areas of interest. This is intended to help mitigate SAFN's concern about their ability to practice their rights and traditional land and resource use in the future that stem from fear of the site. CNL has responded to this concern and endeavored to carry out the Project with careful consideration of Indigenous interests and Aboriginal and treaty rights. CNL awaits the outcome of the CNSC's rights impact assessment to determine whether further action is required. SAFN notes that what it considers to be inaccurate findings re: impacts from the Project on traditional land and resource use is an outstanding issue that is pertinent to the rights impact assessment. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; consent seeking process is a priority of these discussions.	CNL added Section 4.2.4.1.4: Sagkeeng First Nation's Psychosocial Impact Assessment, including the following: *"CNL defers to the results of the rights impact assessment process for a conclusion on whether Aboriginal and treaty rights are impacted by this Project"*. CNL has documented various aspects of Traditional Land and Resource Use by Indigenous Peoples and Archaeological and Cultural Sites in Section 6.8.1.5.2: Results and assessed the impact of the Project on those aspects in Section 6.8.1.6.2: Results. The assessment determined that there would be negligible effect on Traditional Land and Resource Use or Archaeological and Cultural Sites. CNL also reflected the differing opinions of the Indigenous communities in its consideration of residual effects and accuracy of scientific predictions in Section 6.8.1.6.2.2: Secondary Pathways.	Ongoing SAFN notes that what it considers to be inaccurate findings re: impacts from the Project on traditional land and resource use is an outstanding issue that is pertinent to the rights impact assessment.
Psychosocial Impact Assessment			
SAFN has expressed concern that, as described in SAFNs Psychosocial Impact Assessment Report, fear and stigma associated with ISD will prevent or limit future exercising of Aboriginal and treaty rights by SAFN members and will cause an impact to the well-being of the SAFN . The SAFN Assessment further states that CNL must address impacts resulting from past trauma, including the 1960s construction of the WL, the perception of environmental effects, and the perception that illnesses may be connected with environmental effects. This is a project-specific concern.	Through engagements. CNL has worked with SAFN to understand the findings and recommendations of SAFN's Psychosocial Impact Assessment Report (2020) and to adequately incorporate the information provided in the EIS. SAFN reviewed the Psychosocial Impact Assessment subsection that was added to the draft EIS and provided an overview of the report and also reviewed CNL's considerations of the report in the effects assessment. CNL incorporated SAFN's 's feedback into the draft EIS. CNL staff have also taken trauma-informed engagement training with the authors of SAFNs Psychosocial Impact Assessment Report to help gain further perspective on this important matter. During meetings with SAFN, CNL shared that assessment of psychosocial impacts could not be considered a primary pathway under the CEAA 2012 because it was not tied to an environmental effect and expressed an interest in finding alternative ways to address SAFN's concern. CNL and SAFN discussed proposed next steps. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. CNL is committed to working collaboratively with SAFN on developing and implementing the initiatives that will help address SAFN's concerns. These initiatives include the development of a healing and resiliency action plan, which can include or be closely tied to a community-driven risk communication program focused on the health of country foods and waters; an independent SAFN Community Environmental Monitoring Program; a community liaison committee; and a leadership table. CNL, AECL and SAFN have entered discussions on the parameters of their future relationship with the implementation of an Indigenous-led risk communications program a priority.	CNL added a new subsection 4.2.4.1.4: Sagkeeng First Nation's Psychosocial Impact Assessment to describe the findings of SAFNs Psychosocial Impact Assessment Report and CNL's considerations of the report. SAFN reviewed the subsection and CNL incorporated SAFN's revisions into the draft EIS. CNL also improved Section 6.9.6.2.2: Secondary Pathways, acknowledging that the long-term presence of nuclear materials in the region has the potential to result in fear, stigma, and anxiety, and that psychosocial effects are legitimate impact pathways. CNL is working with SAFN to minimize any potential or lasting effects.	Ongoing SAFN's notes that CNL has made a nominal commitment to support a SAFN healing and resiliency action plan. However, the scope and duration of that program that CNL and AECL are willing to support has yet to be defined. This information is material to the likelihood of success of any such initiative.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Valued Components			
SAFN expressed concern that the draft EIS does not fully consider all of SAFN's VCs identified within the SAFN Traditional Knowledge and Land Use Study (TKLUS): water; medicine, berries and other food plants; hunting and trapping; and Anicinabe Pimatiziwin, ranging from the direct presence of traditionally hunted animals and gathered plants, to continued habitation, travel, and cultural activities on the land. This is a project-specific concern. SAFN chose these VCs to represent the critical conditions or elements for the continued practice of SAFN culture and livelihoods, which may be impacted by the Project.	CNL drafted a list of SAFN specific VCs based on information from SAFN-led studies and engagement activities. CNL verified this list of VCs with SAFN and for each VC, CNL either: ▪ Confirmed it was encompassed by the assessment. ▪ Added it to the assessment. ▪ Added it to the model to be assessed. ▪ Did not add it to the assessment, with rationale provided. VCs selected for terrestrial and aquatic assessments were confirmed to be representative of many other species, including all species identified by SAFN. VCs chosen for the land and resource use assessment were confirmed to capture archaeological and cultural sites and traditional land use as important VCs identified by all of the Indigenous Nations engaged on the Project. CNL assessed community well-being by adding "the continued use of the area by Indigenous community members for traditional land and resource use" as an assessment endpoint for the Community Well-Being VC and assessing the potential impact to community well-being resulting from fear, stigma and anxiety associated with the long-term presence of nuclear materials in the region. With negligible effects predicted to the biophysical environments, the assessment does not indicate potential for direct or indirect effects to the well-being of Indigenous communities because of the Project-related changes to the environment; however, CNL made the Community Well-Being VC a secondary pathway in the community socio-economic well-being assessment due to its importance to Indigenous communities. Secondary pathways require mitigation measures to be in place to address potential measurable changes. The mitigation measure in this case is CNL and AECL recognizing and acknowledging the cumulative impacts and trauma experienced by SAFN members in relation to the initial siting of WL and committing to begin addressing this through community-led initiatives facilitated by the Technical Working Group. In respect to the SAFN Value of Anicinabe Pimatiziwin, CNL has captured it as one of the SAFN Site-Specific Values in Section 6.8.1.5.2.2.1 and continues to work with SAFN through the Technical Working Group table to address SAFN's outstanding concerns related to the Project and Whiteshell Laboratories Closure Project (WLCP). CNL collected SAFN species and topics of interest from their TKLUS, Alternative Means Assessment, Psychosocial Impact Assessment, general engagement, and verification discussions. CNL worked with SAFN to verify the list of VCs accurately captures, to the extent possible, SAFN's species and topics of interest. SAFN provided two rounds of feedback and met with CNL in July August 2021, to revise the list based on SAFN's feedback. Any revisions to this table will be reported in the IER for the public record. CNL has revised subsection of Section 6.0 to clearly reflect how VCs from First Nations and the Manitoba Métis Federation were considered for each effects assessment, where applicable. SAFN has reviewed and provided feedback on this section, which was incorporated into the current version of the EIS. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	Section 4.2.4.1.2: Interests and Concerns was revised to include a verified list of SAFN's VCs. Sections 6.5.3: Valued Components, , 6.7.2.3: Valued Components, and 6.8.1.3: Valued Components were updated to reflect the input into VC selection resulting from Indigenous Traditional Knowledge and Land Use Studies, including the study submitted by SAFN. Sections 6.6.3: Valued Components and 6.7.2.3: Valued Components were specifically revised to discuss how the assessment encompasses the Indigenous VCs, how the assessment was expanded to include the Indigenous VCs (for example: moose), or the rationale for not including the Indigenous VCs (for example: wild rice). Section 6.8.1.5.2.2.1: Historical and Present-Day Traditional Land Use was updated to include the Site-Specific Values identified by SAFN to ensure that the assessment reflects these values. Section 6.9.6.2.2: Secondary Pathways has been revised to make the effects of WR-1 on Indigenous well-being a secondary pathway, acknowledging that the long-term presence of nuclear materials in the region, along with other historical industrial developments in the local study area, had the potential to result in fear, stigma, and anxiety, and that psychosocial effects are legitimate impact pathways affecting the Indigenous community well-being.	Ongoing

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Business and Employment Opportunities			
SAFN expressed interest in knowing more about CNL's procurement and employment policies, potential economic participation opportunities, potential priority contracts and employment, and qualification requirements for work associated with the WLCP. This is a site-wide interest in enabling SAFN's community members to participate in the socio-economic benefits resulting from the WL site.	On May 11-12, 2017, CNL organized a two-day business conference to help SAFN and other First Nations learn more about CNL's procurement policies as well as employment and contracting opportunities for the Whiteshell Laboratories Restoration Project CNL asked for specific capabilities SAFN has related to the Whiteshell Laboratories Restoration Project and indicated their interest in examining SAFN recommended contractors. CNL sent a listing of current and potential future external vacancies as well as criteria for security clearances to SAFN. CNL adjusted the evaluation criteria for competitive bids to encourage greater economic participation by contractors that are Indigenous owned or have Indigenous employees or subcontractors. SAFN forwarded a procurement strategy discussion paper in 2021 for consideration. Since that time, CNL is considering this paper in the context of developing an Indigenous procurement strategy to support greater participation of Indigenous owned business and support more Indigenous people in CNL's workforce. CNL has been sending job postings to SAFNs since the mid-1990s. CNL would welcome applicants from SAFN and will continue to work with SAFN to see how CNL can improve interest and success in recruiting, and in creating further economic benefit to SAFN from the Whiteshell Laboratories Restoration Project In 2023, CNL developed and shared a draft Indigenous Relations Procurement Strategy with SFN. SFN provided feedback on the strategy and CNL and SFN met on November 15, 2023, to discuss SFN feedback. SFN's feedback on this strategy included recommendation that CNL review the CNL Indigenous Relations Procurement Strategy within the context of the SAFN-CNL Procurement Policy Discussion Paper-Precedence Analysis Document. SAFN found that CNL's corporate strategy did not meaningfully enhance Indigenous participation in CNL Procurement, or adequately consider the relationship with SAFN, the future of the Whiteshell site and CNL's intention to complete the closure of the site within the decade. While CNL views this feedback as going beyond the scope of the WR-1 Project, CNL is continuing to work with SAFN to determine an adequate path to addressing this feedback. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized. SAFN, CNL and AECL have established a Technical Working Group to resolve outstanding concerns and work collaboratively on areas of interest.	CNL acknowledges contracting and employment as a priority area of interest for SAFN and has revised Section 4.2.4.1.2: Interests and Concerns to reflect this. Employment and business opportunities for Indigenous Nations and the Red River Métis (RRM) have been added to the project VCs in Section 6.9.3: Valued Components. CNL updated Section 6.9.6.2.2: Secondary Pathways and added a discussion of Project impacts on the employment and contract opportunities for Indigenous communities and the RRM as well as mitigations that were put in place by CNL.	Ongoing
Future Land Use and Tenure (End-State Planning for the WL Site)			
SAFN is interested in future compensation for the Local Government District (LGD) of Pinawa and the First Nation since portions of the WL site is located in Treaty 1 territory. This is a site-wide interest in the socio-economic impacts of the Whiteshell Closure Project (WLCP).	During engagement, CNL explained that AECL pays a grant in lieu of taxes to the LGD of Pinawa as the site falls within the municipal boundary of the LGD. The payment supports the municipal services of the community and is not compensatory for past siting. There is no compensation paid to any community for the siting of the WL site. AECL, in the past, and CNL, currently, have been a positive socio-economic development for the area, providing employment and contracts for the local supply chain. With the closure of the WL site, there are mitigations in place to enhance benefits for area communities and the Indigenous Nations in the Local Study Area to the extent possible. Mitigations focus on supporting current employees in transitioning to new work and helping foster business opportunities in the area to replace lost employment. CNL has worked to enhance options to better match Indigenous capabilities with their contracting needs, added provisions to its procurement process to encourage the use of Indigenous and local businesses, and considers single source contracting opportunities with Indigenous companies where well suited to the work. CNL has also adjusted the evaluation criteria for competitive bids to favour contracts that are Indigenous owned or have Indigenous employees. CNL also explained that a community regeneration partnership was formed to develop both nuclear and non-nuclear opportunities for the WL site after the site is decommissioned to help support the socio-economic development of the region. CNL participates in and supports the partnership. CNL invited Indigenous Nations to join. In August 2023 SAFN received the most recent Land Use End Sate (LUES) document. In early 2024 SAFN informed CNL that they would be working on the *SAFN Vision for Long-Term Land Use* report which will be the avenue to address the LUES. Spring 2024 CNL commissioned a "plain language" version of the LUES document. June 2024 CNL hosted a CNL Regional Gathering of Leaders; Project Discussion 2024 which provided an overview of the End State Plan and sought consultation on 3 options for low-medium level nuclear waste management. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	Section 4.2.4.1.6: Next Steps was revised to include a commitment that CNL will engage SAFN on the land use and end-state of the site. Section 6.9.6.2.2: Secondary Pathways was revised to add various measures that CNL, in collaboration with Indigenous Nations and local municipalities, took to mitigate socio-economic impacts resulting from the accelerated decommissioning schedule.	Ongoing SAFN notes that this concern is outstanding given that there is no evidence of benefit to the First Nation from employment and business opportunities, or evidence that there are "mitigations in place to enhance benefits for Indigenous Nations" with the closure of the WL site.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
SAFN is concerned that the WL site may impact the environment in the future. SAFN wants to be involved in: the development of site clean-up and release criteria, the planning, assessment, and remediation of the trenches, and any end-state deviations to ensure their Aboriginal and treaty rights to use lands and resources near the WL site is not impacted in the future. This is both a project-specific and site-wide concern.	The Project incorporates multiple barriers to ensure the environment remains safe in the future and the EIS assesses the Project's long-term impact on the environment and determined the environment will remain safe. Likewise, the trenches will undergo a rigorous safety assessment to ensure the long-term safety of the environment. CNL committed to setting up a workshop to discuss the end-state of the site including clean-up and release criteria, remediation of the waste management areas including the trenches, and future land use. In August 2023 SAFN received the most recent Land Use End Sate (LUES) document. CNL committed to engaging bilaterally with SAFN and other interested parties to co-develop future land use objectives, as well as engage on the end-state of the Whiteshell site as part of Whiteshell Laboratories Closure Project. CNL, SAFN, and AECL have established a Technical Working Group to resolve outstanding concerns and work collaboratively on areas of interest. CNL will continue to engage meaningfully with SAFN Chief and Council, community members, their engagement team, and their Liaison through the lifecycle of this Project. CNL and AECL have also affirmed their commitment to engage beyond the WR-1 project and are already engaging with SAFN on issues regarding the Whiteshell site more broadly and land use and end state. In early 2024 SAFN informed CNL that they would be working on the *SAFN Vision for Long-Term Land Use* report which will be the avenue to address the LUES. *SAFN* Spring 2024 CNL commissioned a "plain language" version of the LUES document. June 2024 CNL hosted a CNL Regional Gathering of Leaders; Project Discussion 2024 which provided an overview of the End State Plan and sought consultation on 3 options for low-medium level nuclear waste management. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized. CNL has explained that the liability and land remain the long-term responsibility of AECL. CNL and AECL continue to engage SAFN to discuss potential future uses of the Whiteshell site.	CNL verified that there will be no impact on the environment through the assessment and documented the results of the assessment in Section 9.3: Summary. Section 4.2.4.1.6: Next Steps was revised to include a commitment that CNL will engage SAFN on the land use and end-state of the site.	Ongoing
SAFN expressed interest in the potential for siting of a small modular reactor on the WL site as this has the potential to impact their Aboriginal and treaty rights. This is a site-wide interest.	CNL had a dialogue with the community regeneration partnership, which includes SAFN, on a vision for the WL site that includes the potential for on-going industrial use in some areas of the site, with other areas available for agriculture or recreation. A small modular reactor could potentially fit in the proposed end-state in the area identified as "industrial use." CNL explained that any new nuclear project on the WL site, such as a small modular reactor, would need to go through a rigorous licensing process that would include Indigenous engagement. In August 2023 SAFN received the most recent Land Use End Sate (LUES) document. In early 2024 SAFN informed CNL that they would be working on the *SAFN Vision for Long-Term Land Use* report which will be the avenue to address the LUES. Spring 2024 CNL commissioned a "plain language" version of the LUES document. June 2024 CNL hosted a CNL Regional Gathering of Leaders; Project Discussion 2024 which provided an overview of the End State Plan and sought consultation on 3 options for low-medium level nuclear waste management. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized. SAFN reinforced the importance of an Indigenous Liaison or Monitor to provide information back to the community on how the legacy low-level waste trenches will be decommissioned.	Section 4.2.4.1.6: Next Steps was revised to include a commitment that CNL will engage SAFN on the land use and end-state of the site.	Ongoing

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Waste Management			
SAFN is concerned that the radioactive waste remaining on the WL site and the radioactive waste being transported off-site will contaminate the environment. SAFN was interested in more detailed information about how much radioactive waste would remain on the WL site and where the radioactive waste being transported off-site will be stored as they want to ensure their Aboriginal and treaty rights to use land and resources near the WL site are not impacted. This is both a project-specific and site-wide concern.	During engagements, CNL explained that all waste materials produced at the WL site are sorted, characterized, verified, and packaged into licensed containers for transport. SAFN was informed that the vast majority of radioactive materials from the WL site will be transported to the Chalk River Laboratories (CRL) site in Ontario for interim storage or disposal in the proposed Near Surface Disposal Facility. This disposition pathway remains contingent upon the EA for the Near Surface Disposal Facility Project, which is currently underway. Approximately 2,800 m^3 (4,000 Mg) of radioactive waste will remain in the WR-1 disposal facility and approximately 3,000 m^3 (5,400 Mg) of radioactive waste from the WR-1 building will be transported to the CRL site. For waste remaining in the WR-1 disposal facility, the Project incorporated multiple engineered barriers into the ISD design to ensure the radioactive waste does not contaminate the environment and the EIS assessed the Project's impact on the environment and determined the environment will remain safe. Likewise, the Waste Management Area trenches will undergo a rigorous safety assessment to ensure the safety of the environment. Depending on the type of waste may be transported to a licensed hazardous waste management facility. Shipping of used fuel and waste from projects outside of WR-1 have been assessed in the Comprehensive Study Report and are out of the scope of this Project's assessment. New facilities have recently been built at the WL site to temporarily store radioactive waste generated from decommissioning activities until they can be shipped to the CRL site. CNL explained that any shipment of nuclear materials is a highly regulated process. CNL has procedures in place to ship the waste in accordance with the federal Packaging and Transport of Nuclear Substances Regulations. CNL maintains a response plan and team that works together with the Transport Canada emergency services to respond to any road accident involving nuclear materials. CNL explained that the WL site possesses over 50 years of experience in shipping and receiving radioactive material and have never experienced an incident that compromised the safety of workers, the public, or the environment. Through the SAFN Alternative Means Assessment, SAFN expressed that it would be best if all waste from WR-1 were removed from the Whiteshell site. In general, SAFN expressed substantial and consistent concerns regarding deviation from the Comprehensive Study Report (AECL 2001), which proposed full removal of WR-1. In August 2023 SAFN received the most recent Land Use End Sate (LUES) document. In early 2024 SAFN informed CNL that they would be working on the *SAFN Vision for Long-Term Land Use* report which will be the avenue to address the LUES. *SAFN* Spring 2024 CNL commissioned a "plain language" version of the LUES document. June 2024 CNL hosted a CNL Regional Gathering of Leaders; Project Discussion 2024 which provided an overview of the End State Plan and sought consultation on 3 options for low-medium level nuclear waste management. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	EIS assessments concluded there would be no impact on the environment through the EIS assessment as documented in Section 9.3: Summary. CNL confirmed that the risks resulting from transportation of Project radiological waste off-site are already captured and assessed in Section 7.3.4: Off-site Transportation Accidents. The assessment indicates that the risk and consequence severity of transportation accidents involving nuclear materials is low due to existing controls on transport of nuclear materials and the requirements for waste packaging. No changes to the assessment were required. CNL updated Section 3.4.8: Waste Generation and Management with a reference to the Detailed Decommissioning Plan as this is where the waste volume estimates are documented.	Ongoing

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
SAFN expressed interest in CNL's waste transportation methods and how information about waste transportation is communicated to potentially affected communities. SAFN is concerned about a potential waste transportation accident impacting human health and the environment. This is a project-specific and site-wide concern.	CNL explained that waste is transported in packages that are selected based on the nature, form, and quantity or radioactivity of the waste. There are design requirements that apply to all package types to ensure that they can be handled safely and easily, secured properly, and are able to withstand routine transport conditions. There are also federal regulations for how nuclear materials can be shipped and CNL maintains a set of procedures for packaging and transporting nuclear materials. CNL explained that it maintains a response plan and team that works together with the Transport Canada emergency services to respond to any road accident involving nuclear materials. CNL explained that the WL site possesses over 50 years of experience in shipping and receiving radioactive material and have never experienced an incident that compromised the safety of workers, the public, or the environment. The EIS assessed the risks resulting from transportation of Project waste off-site and determined that the risk and consequence severity of transportation accidents involving nuclear materials is low due to existing controls on transport of nuclear materials and the requirements for waste packaging. For security reasons, information about individual shipments of nuclear materials is kept confidential. CNL explained that the proposed ISD of the Project requires far less shipping of nuclear materials to interim storage, as it provides a securely designed disposal facility for the most radioactive parts of the WR-1, thus helping to ensure public safety. SAFN In August 2023 SAFN received the most recent Land Use End Sate (LUES) document. In early 2024 SAFN informed CNL that they would be working on the *SAFN Vision for Long-Term Land Use* report which will be the avenue to address the LUES. *SAFN* Spring 2024 CNL commissioned a "plain language" version of the LUES document. In June 2024, CNL hosted a CNL Regional Gathering of Leaders; Project Discussion 2024 which provided an overview of the End State Plan and sought consultation on 3 options for low-medium level nuclear waste management. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized. CNL has responded to this concern in detail. CNL acknowledges that waste transportation is an ongoing area of concern and will continue to respond to ongoing questions as they may arise and will be working with SAFN and AECL through the Technical Working Group to resolve them.	CNL confirmed that the risk and consequence severity of transportation accidents involving nuclear materials was assessed to be low in Section 7.3.4: Off-site Transportation Accidents. CNL confirmed in Section 2.5.4: Assessment of Alternatives that the proposed ISD alternative reduces the overall amount of radioactive waste shipment compared to the original full dismantling proposal.	Ongoing
SAFN was interested in how water treatment on the WL site worked as they want to ensure the Winnipeg River is safe downstream of the site and protect their Aboriginal and treaty rights to use the river. This is a site-wide interest.	CNL explained how various potentially radiologically-contaminated water effluent streams on site are collected, tested, and treated before they are released back to the Winnipeg River through the outfall station, where the water is tested again. Additionally, the WL site maintains a lagoon system to treat water from domestic drains (sinks, toilets, showers, laundry). CNL documents water testing results and releases to the river from the site outfall station in an annual compliance report that is available to the public and Indigenous communities. CNL has supported Niigan Aki participation in on – site monitoring.	Section 3.2.2.4: Active Drainage System was revised to clarify the description of the wastewater treatment process in the WR-1 building and the sources of potentially radioactive liquid waste.	Ongoing

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Future Monitoring			
SAFN expressed a keen interest in knowing more about and participating in future site monitoring, including providing input on additional fish and water monitoring locations relevant to SAFN. SAFN wants to ensure the Winnipeg River and the fish are safe and protect their Aboriginal and treaty rights to fish and use the river. This is both a project-specific and site-wide interest.	CNL explained the current WL site-wide environmental monitoring program and the proposed future monitoring program for the Project. CNL will continue operating its site-wide monitoring program that currently tests fish at one upstream and two downstream locations from the WL site. Fish monitoring carried out to date has shown that the fish have been safe to consume, with the monitoring results provided in an annual report available to the public. CNL explained that after WR-1 is decommissioned, the only way contamination could enter the environment is through releases to groundwater and groundwater movement to the Winnipeg River. CNL undertook a detailed analysis of how the WR-1 disposal facility will perform in the long-term and determined that based on the negligible amounts of radioactivity or hazardous materials released to the environment, no measurable health effects are predicted and all doses to humans and animals are orders of magnitude below federal guidelines. CNL plans to monitor the expected performance of the WR1 disposal facility using groundwater monitoring wells for at least 100 years, at which point the performance of the facility is expected to be confirmed. CNL will stop monitoring only when the CNSC finds it acceptable. To enable this monitoring, CNL has created a monitoring well network, which will be used to detect any movement of radioactive or hazardous materials from the WR-1 disposal facility towards the river. CNL has already committed to additional groundwater monitoring well(s) as recommended during Indigenous engagements. Because the earliest way to detect emissions from the facility is through groundwater monitoring, CNL does not intend to test the river water specifically for the WR-1 facility. However, river water monitoring as part of the overall WL site monitoring will continue as part of the overall site closure monitoring to confirm that there are no residual effects on the environment from historic operation of the WL site. Additionally, CNL has committed to an independent SAFN Guardianship Program through the Technical Working Group that will incorporate country food monitoring and risk communication. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Niigan Aki staff began initial onsite monitoring activities in 2023. Monitoring has continued into 2024, and work planning for the future continues. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	Sections 6.7.1.7: Residual Effects Analysis and 6.7.2.7: Residual Effects Analysis describe the pathways by which releases can get into the environment. Section 11.0: Summary of Monitoring and Follow-up Programs was updated to better describe the current proposal for the closure and post-closure monitoring activities, integration of the Project monitoring into the existing site-wide program, and commitments to include Indigenous Nations in ongoing environmental monitoring. CNL has specifically revised Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring to include its commitment to an independent SAFN Guardianship Program.	Ongoing
SAFN expressed concern with CNL's environmental monitoring due to a lack of Indigenous knowledge, explaining that Indigenous environmental monitoring is a critical element of SAFN's stewardship and Indigenous-led risk communication with members. SAFN requested a commitment from CNL for an independent, long-term future monitoring program to be designed and led by Indigenous peoples, including SAFN. SAFN wants to ensure the environment is safe and protect their Aboriginal and treaty rights to use lands and resources near the WL site. This is both a project-specific and site-wide concern.	CNL and SAFN have agreed that incorporation of Indigenous knowledge and SAFN's participation in the monitoring program could help address concerns and reduce the fear and stigma associated with the proposed ISD of WR-1. CNL has committed to reviewing and adapting the existing EA Follow-up Program for the WL site to incorporate Indigenous traditional knowledge that has been collected through the EA for the Project. SAFN will review the Follow-up Monitoring Program and provide feedback to CNL. Based on Indigenous feedback, CNL has adjusted its environmental monitoring to include collecting and analyzing mushrooms. CNL continues to look for additional ways to improve their environmental monitoring, including participation in monitoring by SAFN. CNL has committed to an independent SAFN Guardianship Program through the Technical Working Group that will incorporate country food monitoring and risk communication. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Niigan Aki staff began initial onsite monitoring activities in 2023. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	Section 11.2: Adaptive Management was revised with the commitment to review and adapt the existing EA Follow-up Program to incorporate Indigenous traditional knowledge and expand the program to include monitoring of traditional foods as identified by Indigenous peoples. Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring was added to outline ongoing engagements and commitments to support meaningful discussion on the monitoring and follow-up programs and includes CNL's commitment to an independent SAFN Guardianship Program.	Ongoing

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
SAFN is concerned that WR-1's close proximity to the river will contaminate the river and the fish in the long-term. SAFN wants to ensure their Aboriginal and treaty rights to fish and use the river are not impacted by the Project. This is a project-specific concern.	CNL acknowledges the importance of fish, fish habitat and the Winnipeg River to SAFN as it pertains to the exercise of Aboriginal and Treaty Rights. CNL engaged with SAFN on their list of VCs and confirmed fish and fish health were included in the EIS assessment. CNL included the Winnipeg River as a VC in its assessment. CNL has modelled the long-term performance of the WR-1 disposal facility for both the expected evolution of the site and extreme events and in both cases, the assessment indicates no measurable effect on water quality or fish. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Niigan Aki staff began initial onsite monitoring activities in 2023. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized. SAFN notes that this issue is related not just to monitoring but also to the different approaches preferred by SAFN (Full Removal) and CNL (ISD) for WR-1 decommissioning, which have differential long-term effects on real and perceived risk of contamination of fish and the Winnipeg River.	CNL confirmed there have been no measurable effects on water quality or fish. CNL also confirmed that the assessment predicts no impact to the water quality (Section 6.4.2.7.2: Application Case Results) or fish (Section 6.7.2.7.2.2: Results) and fish habitat (Section 6.5.6.2.2: Secondary Pathways). Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring was added to outline ongoing engagements and commitments to support meaningful discussion on the monitoring and follow-up programs and includes CNL's commitment to an independent SAFN Guardianship Program.	Ongoing: SAFN notes that this issue is related not just to monitoring but also to the different approaches preferred by SAFN (Full Removal) and CNL (ISD) for WR-1 decommissioning, which have differential long-term effects on real and perceived risk of contamination of fish and the Winnipeg River.
SAFN expressed concern about perceived deterioration of fish quality in the Winnipeg River since establishment of the WL site, noting observation of unusual sores on some fish. SAFN expressed interest in being more involved in water quality and fish monitoring on-site. SAFN wants to ensure their Aboriginal and treaty rights to fish and use the river have not been impacted. This is a site-wide concern.	CNL has been testing fish upstream and downstream of the WL site for decades and testing shows that the radioactivity (< 0.001 mGy/d) is well below the benchmark recommended by the CNSC (0.6 mGy/d). Through ongoing engagement CNL provided SAFN with information on the Winnipeg River Task Force; the information provided included the following: ▪ In late 1994, the Winnipeg River Task Force was created. Representatives from Indian and Northern Affairs Canada, Environment Canada, Health Canada, and SAFN took part in the Task Force. ▪ The objective of the Task Force was to look at potential sources of Winnipeg River water quality degradation near the community of SAFN. ▪ The Task Force report concluded that the drinking water quality met Canadian guidelines and that it was unlikely that the WL site had ever posed or would pose a significant threat to the health of SAFN community members. The CNSC conducted an independent monitoring campaign in 2017 with assistance from SAFN. This independent program included collecting and analyzing fish caught near SAFN. The results of the assessment conclude that the public and the environment in the vicinity of WL are protected and there are no expected health impacts. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Niigan Aki staff began initial onsite monitoring activities in 2023. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	Section 6.5.5.2.3: Radioactivity in Fish was revised to compare fish testing results with an applicable benchmark. Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring was added to outline ongoing engagements and commitments to support meaningful discussion on the monitoring and follow-up programs and includes CNL's commitment to an independent SAFN Guardianship Program. CNL documented the engagements with SAFN on water quality and fish monitoring in Section 4.2.4.1.1: Engagement to demonstrate CNL's desire to include SAFN in these programs.	Ongoing

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Regulatory Process			
SAFN expressed concern regarding limited funding provided by the CNSC for review and participation in the Project. SAFN expressed interest in further opportunities for involvement in the Project. This is a project-specific concern.	In order to enable meaningful engagement on the Project, CNL provided capacity funding and support to SAFN beyond the funding provided by the CNSC and committed to providing funding to SAFN as needed throughout the EIS review process. Examples include, but are not limited to the following: ▪ Access to CNL technical experts. ▪ Reimbursement of reasonable out-of-pocket expenses to participate in engagement activities such as site visits, tours, regional community open houses, and Indigenous community open houses. ▪ CNL entered into seven contribution agreements with SAFN to help fund participation. To date, funds have supported legal counsel, consultants to review the EIS on SAFN's behalf, support for a traditional knowledge study, other technical studies, stipends for a food intake study, benchmarking, ceremony, and other community-based events. ▪ CNL supported a three-day alternative means assessment workshop and supported a SAFN-led alternative means study. ▪ CNL provided top-up funding to the CNSC-supported Psychosocial Impacts Assessment Report. Additional efforts in support of involvement can be read in the topics of Relationship Building and Engagement above in this Table. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL.	Section 4.2.4.1.1: Engagement documents engagement activities with SAFN and the funding provided for SAFN's participation in the Project. Various EIS sections were sent to SAFN for review and feedback; CNL worked to address or incorporate SAFN's feedback where appropriate.	Ongoing CNL has taken steps to address this concern and will be working with SAFN and AECL through the Technical Working Group to further involve SAFN in the Project.
SAFN is concerned that the Project is being evaluated under CEAA 2012 and not the 2019 Impact Assessment Act (IAA). This is a project-specific concern.	SAFN and CNL have discussed the matter of the regulatory review process during engagements, and the parties recognize that CNL has no authority to make any requested changes related to the regulatory process and will proceed with the environmental assessment under CEAA 2012. While the Project is being reviewed within CEAA 2012 legislation, CNL has made efforts to exceed these requirements and move towards the requirements of IAA (2019). CNL acknowledges that the long-term presence of nuclear materials in the region has the potential to result in fear, stigma, and anxiety, and has included psychosocial effects as a legitimate impact pathway to reflect SAFN's concerns in the assessment.	Section 1.6.1: Federal Review Process explains why the EA for the ISD of WR-1 will continue under CEAA 2012. Section 6.9.6.2.2: Secondary Pathways was revised to acknowledge that the long-term presence of nuclear materials in the region has the potential to result in fear, stigma, and anxiety, and to include psychosocial effects as a legitimate impact pathway.	CNL considers this concern addressed by the provisions within the IAA legislation. CNL and SAFN continue to disagree on the approach taken on the regulatory approval process for the project and no resolution is imminent. The Project will continue under CEAA 2012 while working to exceed requirements and work collaboratively with SAFN to address their concerns. SAFN continues to consider this issue as outstanding because several aspects of the assessment did not meet requirements that would have been required had it been conducted using requirements of IAA 2019 (e.g., but not limited to, inclusion of impacts on Indigenous health, social and economic well-being beyond those caused by physical changes to the environment).

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
SAFN is concerned that the Project may impact the environment in the future. SAFN was interested in understanding how the WR-1 facility will be grouted, how it will maintain its long-term integrity and safety, and the potential for and impact of climate change and natural disasters as they want to ensure their Aboriginal and treaty rights to use lands and resources near the WL site are not impacted in the future. This is a project-specific concern.	CNL provided detailed responses on the process used to design the grout recipe, the extensive testing carried out, and the plans for how the facility will be grouted. CNL also clarified that the key to long-term safety and performance of the grouted facility is the fact that a significant portion of the contaminants are contained in the metals of the reactor, which will corrode very slowly and prevent major releases of contaminants to the environment. Barriers such as the foundation walls, grout, and the concrete cap and engineered cover provide additional protection. The specific function of grout is to resist structural subsidence of the facility and resist human intrusion into the facility. CNL explained that the normal evolution of the disposal facility over 10,000 years was assessed as well as any credible abnormal event or disaster that could affect the safety of the disposal facility and subsequent safety of the human and ecological environment around it. The assessment included climate change forecasts in the normal evolution scenario and considered the effects of an unlikely major seismic event. CNL confirmed that even if some future event, including climatic or natural disaster, causes significant damage to the disposal facility, there would be no negative effects on human and ecological health because there is no credible event that can cause faster release of contaminants from reactor metals. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Niigan Aki staff began initial onsite monitoring activities in 2023. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	CNL has been working on finalizing the grout recipe and placement designs and carrying out additional testing. Sections 3.4.6.2: Grouting of Below-Grade Structures and Systems and 3.4.9.1.2: Grout were revised to update the description of the grout material and placement methods with the latest design and testing work. CNL confirmed the long-term safety of the WR1 disposal facility against climate change and natural disasters in Section 10.0: Assessment of Effects of the Environment on the Project. CNL also confirmed that the assessment scenarios in Section 6.7.1.7.2.2: Results encompass the potential effects of natural disasters described in Section 10.0: Assessment of Effects of the Environment on the Project and that human and ecological health are protected even under severe adverse conditions such as glaciation, earthquakes, or rapid degradation of materials.	Ongoing
SAFN is concerned that the Project may impact the environment. SAFN members expressed interest in the existence of similar ISD projects, the cost differences between full removal and ISD, and the safety of ISD in connection with the environment as they want to ensure their Aboriginal and treaty rights to use lands and resources near the WL site are not impacted in the future. This is a project-specific concern.	During engagements, CNL explained that the design and assessment of the ISD of WR-1 incorporates all applicable Canadian regulations as well as guidelines and best practices used at similar decommissioning projects internationally. CNL explained that while this type of decommissioning has not yet been undertaken for a reactor in Canada, there are reactors around the world that have been decommissioned in a similar in situ process. CNL has shared a list of these projects with SAFN. Other countries, such as the United Kingdom, are assessing ISD for suitable legacy sites. CNL visited the United States Department of Energy's Savannah River site in Georgia that was decommissioned using the ISD methods. CNL looked at the lessons learned from these sites and the monitoring programs/ processes in place and incorporated a number of the lessons learned into the WR-1 ISD design, particularly on the grout development. CNL organized a site tour of an in situ disposed (entombed) reactor in Hallam, Nebraska and provided the opportunity for SAFN and other Indigenous Nations to participate. SAFN members were invited but did not attend; however, SAFN's consultant attended the trip and reported back to the community. Additionally, in 2019, CNL supported the SAFN Independent Evaluation of the CNL Alternative Means Assessment, and a series of engagements on CNL's Alternative Means Assessment. CNL provided information on costs associated with ISD as well as other alternatives, including costs for ongoing and future monitoring. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Niigan Aki staff began initial onsite monitoring activities in 2023. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	CNL considered international guidelines and best practices when preparing and assessing the design of the ISD as described in Section 3.0: Project Description of the Decommissioning Safety Assessment Report. Section 2.5.4.3.1: Technical provides some information on other reactors around the world that have undergone ISD. CNL provided the cost differences between all feasible alternatives in Section 2.6.2: Economic Feasibility.	CNL has addressed this concern to the extent practical at this time. .

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
SAFN expressed concerns about incidents and accidents that affect the decommissioning of WR-1 or the safety of the WR-1 disposal facility after closure. These incidents and accidents can affect the safety of people and the environment and could affect SAFN's Aboriginal and treaty rights to use lands and resources near the WL site. This is a project-specific concern.	CNL shared with SAFN that they had assessed the accidents and malfunctions that could occur during the process of decommissioning WR-1 and construction of the disposal facility. The assessment indicates that existing CNL health and safety, and work control procedures adequately address the risks and that CNL has sufficient programs in place to address any likely accident. CNL explained that the normal evolution of the disposal facility over 10,000 years was assessed as well as any credible abnormal event or disaster that could affect the safety of the disposal facility and subsequent safety of the human and ecological environment around it. The assessment included climate change in the normal evolution scenario and considered the effects of unlikely events, such as a major earthquake or glaciation.	CNL confirmed that the assessment scenarios in Section 6.7.1.7.2.2: Results encompass the potential effects of various disruptive events, human actions and natural disasters, and that human and ecological health are protected even under severe adverse conditions such as glaciation, earthquakes, or rapid degradation of materials. CNL updated Section 7.0: Accidents and Malfunctions to clarify the analysis of accidents and malfunctions during closure.	This interest/concern has been addressed within the scope of the WR-1 project. Ongoing
Traditional Knowledge and Land Use and Cultural Heritage			
SAFN expressed interest in conducting a traditional use study as they identified traditional uses, specifically collecting wild rice and medicinal plants, in proximity to the Project study area and the larger WL site. SAFN wants to ensure their interests and Aboriginal and treaty rights are well understood by CNL and adequately assessed for impacts from the Project. This is a project-specific interest.	CNL supported SAFN's 2018 Traditional Knowledge Land Use and Occupancy Study and incorporated the findings into the updated draft EIS. The study helped CNL confirm that its assessment VCs, physical boundaries, pathways, and receptor models (harvester specifically) are appropriately representing the interests and practices of Indigenous peoples in the area. CNL sent draft sections (6.8, 6.7, and 6.9) of the EIS to SAFN for their review and comment, and incorporated SAFN's feedback into the updated draft EIS where appropriate. CNL will await the outcome of CNSC's Rights Impact Assessment for SAFN and will continue working with SAFN and AECL through the Technical Working Group to seek a resolution. In February 2024, CNL shared the draft EIS and Indigenous Engagement Report with SAFN for their review. CNL received SAFN written feedback for incorporation, and CNL made changes to the EIS that reflect the feedback from the IER.	CNL used SAFN's TKLUS to validate the Traditional Harvester model in Sections 6.7.1.7.1: Application Case – Closure Phase and 6.7.1.7.2: Application Case – Post-closure Phase of the assessment. CNL revised the assessment boundaries for the Land and Resource Use assessments in Section 6.8: Land and Resource Use based on SAFN's feedback to expand the RSA to extend downstream of the Winnipeg River and beyond the outlet into Lake Winnipeg. CNL also confirmed that this Land and Resource Use assessment boundary encompasses all of the other EA boundaries in Sections 6.2: Atmospheric Environment through 6.7: Human and Ecological Health. CNL revised Section 6.8.1.5.2.2.1: Historical and Present-Day Traditional Land Use to provide additional information on traditional land use by SAFN and include discussion of impacts on communities as a result of establishment of the WL site, among other developments in the area.	Ongoing
SAFN expressed interest in conducting a traditional knowledge study, explaining that it would be a useful resource for the Species-at-Risk Field Guide used by CNL Environmental Monitoring. SAFN wants to ensure that species of importance to SAFN are accounted for and protected, and that their Aboriginal and treaty rights for wildlife harvesting are protected. This is both a project-specific and a site-wide interest.	CNL supported SAFN's Traditional Knowledge Land Use and Occupancy Study and incorporated the findings into the updated draft EIS. CNL incorporated SAFN's feedback on the revised effects assessment sections that were revised to include a summary of how Indigenous VCs were considered in the assessment. CNL shared both hard copies and a digital copy of their Species-at-Risk Field Guide with SAFN for review and feedback. CNL and SAFN are currently in the process of expanding SAFN's participation in monitoring at the site, which will include integration of traditional knowledge into CNL's existing program. To help address SAFN's broader concern on ensuring that species of importance to SAFN are protected, CNL committed to collaboratively developing an independent SAFN Guardianship Program that includes integrating traditional knowledge into CNL's own Environmental Protection Program as well as risk communication. This interest and concern has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Niigan Aki staff began initial onsite monitoring activities in 2023. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized.	CNL revised Section 4.2.4.1.2: Interests and Concerns to include the following commitment: *"CNL committed to establishing a Guardianship Program with SAFN. CNL has agreed to work with SAFN through a Technical Working Group to establish this Guardianship Program that will include Indigenous risk communication and country foods monitoring with SAFN members."* CNL revised Section 11.2: Adaptive Management to include a commitment to review and adapt the existing Environmental Monitoring programs to include traditional knowledge and monitoring of animals and foods significant to local Indigenous Nations.	Ongoing This interest remains outstanding until the mitigations and commitments are in place.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Alternative Means Assessment			
SAFN expressed concern that CNL's alternative means assessment does not adequately consider SAFN's unique values and criteria or the psychosocial impact of ISD. CNL's alternatives means study arrives at an alternative that is not acceptable to SAFN and deviates from the full dismantling approach proposed in the 2001 Comprehensive Study Report. Only full and immediate dismantling is accepted by SAFN. SAFN is concerned that the proposed ISD of WR-1 does not fully remove the danger and liability from the WL site and does not return the land for traditional use and practice of Aboriginal and treaty rights. This is a project-specific concern.	To understand SAFN's unique values and criteria regarding the WR-1 alternative means assessment, CNL held an alternative means workshop, teleconferences, and in-person meetings with SAFN to discuss the alternative means assessment for WR-1. CNL explained the alternative means assessment to SAFN and acknowledged SAFN's concerns and strong preference for full dismantling of WR-1 instead of the proposed ISD. CNL has shared with SAFN findings that point to ISD as an appropriate approach because of its effectiveness to reduce the nuclear liabilities at the WL site by disposing of the WR-1 in a design-reviewed, safety-assessed facility without the need for major demolition and nuclear waste extraction and transportation work. To better understand SAFN's position and provide SAFN an opportunity to meaningfully express their values and preferred alternatives, CNL supported a SAFN-led Alternative Means Assessment Report. CNL also supported SAFN's Traditional Knowledge Land Use and Occupancy Study and incorporated the findings into the EIS. These studies were important to CNL's assessment because they provided insight into SAFN culture and values and provided clarity on the historical and contemporary interests of SAFN, including VCs. CNL reviewed and documented the findings from these studies in its assessment to demonstrate that it has considered SAFN's values. CNL's used SAFN's Alternative Means Assessment to conduct a critical review and reflection of CNL's own alternative means assessment and working assumptions. CNL concluded that its own alternative means assessment and findings remain valid because the proposed ISD approach fulfills the wider objectives for the project than simply removing the radioactive material from the WL site. CNL revised the draft EIS in Section 2.0: Purpose of the Project and Alternatives to the Project by including a new subsection that focuses on presenting the key finding of SAFN's Alternative Means Assessment and CNL's consideration of the report. CNL also revised Section 4.0: Indigenous Engagement to clearly state SAFN's preferred preference towards full dismantlement. These additions were reviewed by SAFN and CNL incorporated SAFN's revisions into the draft EIS. CNL has been clear that full dismantling, as described in the 2001 Comprehensive Study Report, is not a guarantee of removal of all waste from the WL site because there currently is no available storage facility at the CRL site. Dismantling will therefore not ensure immediate removal of waste from the site, full access to the lands, or necessarily a reduction in stigma. CNL also reviewed its assessment against SAFN's TKLUS and updated the assessment modelling with traditional knowledge and specific SAFN values from the TKLUS. The assessment confirmed that the ISD alternative is not predicted to have a measurable effect on the environment.	CNL created Section 2.8: SAFN's Alternative Means Assessment – Approach and Findings that outlines SAFN's Alternative Means Assessment. Section 2.8.5: CNL Consideration of SAFN's Alternative Means Assessment provides a detailed description of how CNL considered SAFN's Alternative Means Assessment. CNL documented SAFN's preference for complete removal of WR-1 and the outcomes of the SAFN-led Alternative Means Assessment in Section 2.8: Sagkeeng's Alternative Means Assessment = Approach and Findings. CNL validated the Traditional Harvester model in the assessment using SAFN's TKLUS in Sections 6.7.1.7.1: Application Case – Closure Phase and 6.7.1.7.2: Application Case – Post-closure Phase. CNL revised Section 6.8.1.5.2.2.1: Historical and Present-Day Traditional Land Use to provide additional information on traditional land use by SAFN and include discussion of impacts on communities as a result of establishment of the WL site, among other developments in the area. CNL confirmed through its assessment of Human and Ecological Health (Section 6.7), Land and Resource Use (Section 6.8) and Socio-economic Environment (Section 6.9) that no significant adverse effects are anticipated on SAFN's interests, Aboriginal and treaty rights, or land use practices.	Ongoing .

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
SAFN is concerned that their interests and Aboriginal and treaty rights are not being fully considered and protected by the proposed WR-1 ISD Project. SAFN wants Canada to honour its prior commitment to remove the radioactive wastes from SAFN lands and expressed the position that the WR-1 ISD Project is inconsistent with the federal government's commitment to meaningful reconciliation with Indigenous peoples. This is a project-specific concern.	Through engagement with SAFN, CNL provided that the current EA and license application for the ISD of WR-1 was completed with the full intent of securing the radioactive waste and ensuring that the safety, interests, and Aboriginal and treaty rights of Indigenous Nations are fully considered and protected using a safe decommissioning approach and international best practices. CNL has considered all potential physical effects and impacts from the WR-1 disposal facility in its EA, which concluded that adverse effects on human or ecological health, or the socio-economic conditions of the surrounding communities are not likely. Therefore, CNL does not believe that Aboriginal and treaty rights will be impacted but defers to the CNSC who will make a determination regarding impact to Aboriginal and Treaty rights. To better understand SAFN's position and provide SAFN an opportunity to meaningfully express their concerns and preferred alternatives, CNL supported a SAFN-led Alternative Means Assessment. CNL's review of SAFN's Alternative Means Assessment provided a critical review and reflection of CNL's own alternative means assessment and working assumptions. CNL concluded that its own alternative means assessment and findings remain valid because the proposed ISD approach fulfills the wider objectives for the project than simply removing the radioactive material from the WL site. CNL revised the draft EIS in Section 2.0: Purpose of the Project and Alternatives to the Project by including a new subsection that focuses on presenting the key finding of SAFN's Alternative Means Assessment and CNL's consideration of the report. This I&C has been addressed via the 3-year extension agreement signed (August 2023) which provides funding for multiple avenues including the Community Liaison position and HRAP, Technical working group meetings, capacity for reviewing the draft EIS sections, and the community environmental monitoring program. These programs and initiatives have been identified by SAFN as being important to address this concern. The contribution agreement also outlines the parameter for the leadership table between SAFN, CNL and AECL. Additionally, in 2022 October, CNL/AECL and SAFN signed the contribution agreement for the Community Environmental Monitoring Program to fulfill the scope of the independent SAFN guardianship program, which is in place and called Nigaan Aki. Additionally, CNL, AECL and SAFN have entered discussions on the parameters of their future relationship; the implementation of an Indigenous-led risk communications program has been prioritized. CNL has responded to this concern by carefully considering SAFN feedback and their Alternative Means Assessment. CNL respects that SAFN has an independent and different opinion on the most suitable decommissioning approach for WR-1, and that therefore this is an outstanding issue. CNL maintains that the proposed ISD alternative is its preferred option and will await the outcome of the CNSC's decision on the Project.	CNL confirmed through its assessment of Human and Ecological Health (Section 6.7), Land and Resource Use (Section 6.8) and Socio-economic Environment (Section 6.9) that no significant adverse effects are anticipated on the environment or the public. CNL also documented SAFN's preference for complete removal of WR-1 and the outcomes of the SAFN-led Alternative Means Assessment in Section 2.8 Sagkeeng's Alternative Means Assessment – Approach and Findings. CNL revised Section 4.2.4.1: SAFN to include CNL's commitment to working with SAFN through the Technical Working Group to develop and implement initiatives that would help address SAFN's concerns on the Project.	Ongoing CNL recognizes that SAFN considers this issue to be outstanding, given SAFN has predicted residual adverse effects on traditional land and resource use and culture in the Project case, which have not been incorporated into the EIS. In addition, SAFN has noted that commitments made re: a Healing and Resiliency Action Plan require more detail before their value as mitigation for impacts on SAFN values can be stated with confidence.

2023 December 15	This email from a CNL Consultant to all engaged Indigenous Nations, communities, organizations and Governments is to follow up on the invite to the CNL Whiteshell Laboratories Virtual Public Liaison Committee Meeting - CNL 2023 WRAP-UP. Manitoba Métis Federation - CNL Liaison confirmed their attendance. Note- Manitoba Métis Federation did not attend.	Email
2023 December 17	This email from the Manitoba Métis Federation Senior Director of Energy, Infrastructure and Resource Management to CNL is to request a date change for the Manitoba Métis Federation & CNL January monthly touch base meeting. CNL sent a proposed date. Manitoba Métis Federation confirmed and CNL sent a meeting invite for 2024, January 15.	Email
2023 December 18	This email from the Manitoba Métis Federation, Manitoba Métis Federation - CNL Liaison to CNL Manager, Communications and Engagement is to follow up on CNL's interest in participating in the Red River Métis Climate Symposium being held in 2023 February.	Email
2023 December 18	This email from Manitoba Métis Federation Stewardship Coordinator to CNL Manager, Communications and Engagement is to follow up on CNL's interest in participating in the Red River Métis Climate Symposium being held in 2023 February. CNL Communications Officer confirmed CNL's interest.	Email
2023 December 20	This email from the Manitoba Métis Federation, Manitoba Métis Federation – CNL Liaison to CNL Manager, Communications and Engagement is to request information on the required PPE for CNL Whiteshell Site Visits, and on-site monitoring activities.	Email
2024 January 04	This email from CNL Indigenous Relations Contractor to Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to follow up on the Manitoba Métis Federation WR-1 Commitments list and propose the topics for the 2024 January 15 CNL - Manitoba Métis Federation January monthly meeting, and to request a separate time to meet to discuss some of the outstanding commitments for WR-1. Manitoba Métis Federation confirmed 2024 January 15.	Email
2024 January 09	This email from CNL Indigenous Engagement Coordinator to all engaged Indigenous Nations, communities, organizations and Government is to provide the CNL posting for the role of Indigenous Engagement officer. Manitoba Métis Federation confirmed receiving the posting.	Email
2024 January 09	This email from Manitoba Métis Federation Nuclear Energy Specialist to CNL is to follow up on CNLs interest in attending the 2024 February Red River Métis Climate Symposium.	Email
2024 January 09	This email from Manitoba Métis Federation Nuclear Energy Specialist to CNL is to follow up on CNLs 2024 Environmental Monitoring schedule. CNL confirmed that it would be ready soon and be sent over. Manitoba Métis Federation shared the Climate Symposium information.	Email
2024 January 10	This email from CNL Indigenous Engagement Coordinator to the Manitoba Métis Federation Nuclear Energy Specialist, and Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to provide the draft agenda for the Manitoba Métis Federation-CNL monthly meeting being held on 2024 January 15.	Email
2024 January 11	This email from CNL Indigenous Engagement Coordinator to all engaged communities is to notify them of the change in leadership at the Whiteshell site.	Email
2024 January 12	This email from Manitoba Métis Federation Nuclear Energy Specialist to CNL Manager of Communications and Engagement is to request information on the PPE email sent before the Christmas Break. CNL Consultant noted being unable to respond. CNL Manager of Communications and Engagement responded noting being able to order through CNL Stores.	Email
2024 January 12	This email from Manitoba Métis Federation Nuclear Energy Specialist to CNL is to follow-up about the 2024 Monitoring schedule. CNL Indigenous Engagement Coordinator noted that the 2024 Monitoring schedule is not complete yet.	Email
2024 January 15	This meeting between the Manitoba Métis Federation (including Manitoba Métis Federation Senior Director of Energy, Infrastructure and Resource Management, Nuclear Energy Specialist, and SVS Consultant) and CNL (including, Indigenous Engagement Coordinator, Manager of Communications and Engagement, Indigenous Relations Consultant, Director of WR-1, Manager of Licensing, and Director of End- State and Environmental Specialist) is to act as the January monthly meeting. Discussion included the WR-1 commitments and WR-1 Information Requests.	Virtual Meeting
2024 January 15	This call from CNL Manager of Communications and Engagement to the Manitoba Métis Federation Nuclear Energy Specialist is to follow up on the Manitoba Métis Federation's email in 2023 December about approved PPE.	Email
2024 January 15	This email from CNL Manager of Communications and Engagement to Manitoba Métis Federation Nuclear Energy Specialist is to follow up on the telephone conversation and confirm the purchase of PPE.	Email
2024 January 17	This email from Manitoba Métis Federation Nuclear Energy Specialist to CNL Indigenous Engagement Coordinator is to request a 2024 bi-weekly meeting invite. CNL sent a series of meeting invites.	Email

Date	Event	Event / Activity
2024 January 21	This email from CNL Director of WR-1 is to invite the Manitoba Métis Federation Nuclear Energy Specialist, and Director to dinner at the NEI decommissioning conference being held in California. Manitoba Métis Federation accepted the invitation.	Email
2024 January 23	This meeting between the Manitoba Métis Federation (including the Nuclear Energy Specialist) and CNL (including, the Indigenous Engagement Coordinator, Manager of Communications and Engagement, and Environmental Specialist, and Indigenous Relations Consultant) is to touch base bi-weekly on Manitoba Métis Federation and CNL updates. Discussion included Manitoba Métis Federation Workplan, Manitoba Métis Federation harvesting samples, the climate symposium on Ice in Gimli, and the Decommissioning conference being held in California.	Virtual Meeting
2024 January 23	This email from CNL Environmental Analyst to Manitoba Métis Federation is to follow-up from the bi-weekly meeting held on 2024 January 23rd to discuss updates. CNL requested information for the Manitoba Métis Federation Harvester sample schedule.	Email
2024 January 24	This email from CNL Indigenous Engagement Coordinator to the Manitoba Métis Federation is to provide the draft CNL Environmental monitoring field sample schedule. CNL proposed discussing dates for the Manitoba Métis Federation to participate at the next bi-weekly on 2024 February 06.	Email
2023 January 29	This telephone call from CNL Indigenous Relations Contractor to Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to inform the Manitoba Métis Federation that CNL will be sending the draft workplan documents meant to be a starting point to flesh-out action items and key leads on the work that will address the outstanding commitments sought by the Manitoba Métis Federation. CNL also proposed the 2024 February 07 Working Group meeting be focused on starting the workplan.	Telephone Call
2024 January 29	This email from CNL Indigenous Relations Contractor to Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to provide the Manitoba Métis Federation with the draft work plan documents meant to be a starting point to flesh out action items and key leads on the work that will address the outstanding commitments sought by the Manitoba Métis Federation. CNL also proposed the 2024 February 07 Working Group meeting be focused on starting the work plan.	Email
2024 January 30	This email from CNL Manager of Communications and Engagement to the Manitoba Métis Federation Nuclear Energy Specialist, and Energy, Infrastructure & Resource Management Coordinator is to follow up on the conversation about CNL sponsoring the Manitoba Métis Federation Symposium that was held at the 2024 January 15 Manitoba Métis Federation- CNL Bi-weekly touch base meeting. CNL confirmed sponsoring the coffee/ hot chocolate break. CNL provided the Manitoba Métis Federation with a poster for the sponsorship.	Email
2024 January 31	This email from CNL Indigenous Engagement Coordinator to all engaged Indigenous Nations, communities, organizations and Governments is to provide the link for the CNL Public Disclosure Notice.	Email
2024 February 05	This email from CNL Indigenous Relations Contractor to the Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to follow up on the email sent on 2024 January 29 to confirm the 2024 February 07 Manitoba Métis Federation- CNL Monthly Meeting.	Email
2024 February 05	This email from CNL Indigenous Relations Contractor to Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to provide the Manitoba Métis Federation with the second batch of Manitoba Métis Federation Information Requests.	Email
2024 February 06	This email from Manitoba Métis Federation Nuclear Energy Specialist to CNL Indigenous Engagement Coordinator is to request that the 2024 February 06 Manitoba Métis Federation- CNL Bi-weekly meeting be moved to 2024 February 07.	Email
2024 February 07	This email from the Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management to CNL WL GM and Site License Holder is to request that the 2024 February 07 Manitoba Métis Federation- CNL monthly meeting be re-scheduled. CNL confirmed.	Email
2024 February 15	This email from Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management to CNL WL GM and Site License Holder is to inform of Manitoba Métis Federation's request to terminate the CNL- Manitoba Métis Federation Contribution agreement. CNL requested a meeting to discuss the proposed termination as per the contribution agreement.	Email
2024 March 21	This email from CNL WL - GM Site License Holder to Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management to advise that CNL is seeking a 3-year license reviewal from CNSC. CNL Advised the hearing will be held in 2024 October and information about the hearing and public engagement is included in the attachment.	Email
2024 March 22	This virtual meeting between CNL (including, Director of Communications and Engagement, and Director of WR-1) and the Manitoba Métis Federation (including, Senior Director Energy, Infrastructure and Resource Management) is to discuss the CNL - Manitoba Métis Federation relationship.	Virtual Meeting
2024 March 25	This email from CNL WL - GM Site License Holder to Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to confirm Manitoba Métis Federation will continue to be informed on the Environmental Assessment for the WR-1 Project. CNL requested confirmation of Manitoba Métis Federation's continued participation in the submission of their review and feedback of the Indigenous Engagement Report by 2024 April 19. Manitoba Métis Federation confirmed receipt.	Email

Date	Event	Event / Activity
2024 April 02	This email from CNL Manager of Communications and Engagement to Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to invite Manitoba Métis Federation to participate in the Regional Gathering 2024 June 06.	Email
2024 April 03	This email from CNL Indigenous Engagement Officer to Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to advise of CNL's webinar on Gentilly-1 Decommissioning Project and the Whiteshell Laboratories Restoration Program on 2024 April 09. Registration links provided.	Email
2024 April 04	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations and Governments, Organization, and Governments is to inform them of the funding for Indigenous Capacity Support, of the CNSC's Indigenous and Stakeholder Capacity Fund.	Email
2024 April 23	This email from CNL Manager of Communication and Engagement to Manitoba Métis Federation Senior Director Energy, Infrastructure and Resource Management is to inform the Manitoba Métis Federation of the change in venue for the Regional Gathering being held on 2024 June 04. CNL also provided additional information about the draft agenda and registration will be provided by the end of day on 2024 May 03.	Email
2024 April 29	This email from CNL Executive Assistant to Manitoba Métis Federation Senior Director of Energy, Infrastructure and Resource Management is to cancel the monthly meetings between CNL & Manitoba Métis Federation, until further notice.	Email
2024 May 02	This email from CNL Manager of Communication and Engagement to Manitoba Métis Federation Senior Director of Energy, Infrastructure and Resource Management is to inform the Manitoba Métis Federation of event registration logistics for the Regional Leadership Gathering being held in Beausejour on 2024 June 04.	Email
2024 May 15	This email from CNL Indigenous Engagement Officer to Manitoba Métis Federation Senior Director of Energy, Infrastructure and Resource Management is to inform the Manitoba Métis Federation that on 2024 February 15, CNL submitted an application to CNSC to renew the Whiteshell Laboratories site licence for a period of three years. CNL also noted that there will be a public hearing on this application held on 2024 October 23 and 24. CNL proposed that Manitoba Métis Federation review the Indigenous engagement section of the CNL draft Commission Member Document (CMDCNL is preparing the CMD section on Indigenous engagement, which will be available for review from participants in 2024 June. CNL requested CMD review from Manitoba Métis Federation by 2024 July 05 in order to make changes to the CMD before the submission deadline (2024 July 18).	Email
2024 May 21	This email from CNL Manager of Communications and Engagement to Manitoba Métis Federation Senior Director of Energy, Infrastructure and Resource Management is to provide Manitoba Métis Federation with the "First Nation and Métis Affairs Coordinator Student" employment opportunity with CNL. CNL shared the Job description, deadlines and link for application.	Email
2024 June 10	This email from CNL Indigenous Engagement Officer to Manitoba Métis Federation Senior Director of Energy, Infrastructure and Resource Management is to provide the Manitoba Métis Federation the draft Commission Member Document (CMD) for the WL site re-license, and Indigenous Engagement Section for review and comment. CNL requested feedback by 2024 July 05. The Manitoba Métis Federation confirmed receipt of the email and noted follow-up to discuss next steps.	Email
2024 June 18	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations and Governments is to inform them of the CNL June webinars on Douglas Point Decommissioning, Nuclear Power Demonstration Closure Project- Fact or Fiction, and the Facilities Decommissioning Projects Update.	Email
2024 June 20	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations and Governments is to inform them of the funding available through the Indigenous and Stakeholder Capacity Fund.	Email
2024 June 25	This webinar was to provide an opportunity for Manitoba Métis Federation to learn about the Douglas Point Decommissioning, Nuclear Power Demonstration Closure Project- Fact or Fiction, and the Facilities Decommissioning Projects Update. This webinar was part of a series of CNL ERM 2024 June Webinars.	Virtual Meeting
2024 June 25	This email from CNL Director of Communications and Indigenous Engagement provided the Manitoba Métis Federation with a letter on staff changes at the Whiteshell Site.	Email
2024 June 27	This email from Manitoba Métis Federation Nuclear Energy Specialist to a CNL Indigenous Engagement Officer is to provide CNL with the Manitoba Métis Federation comments and edits to the Whiteshell Site re-license CMD. The Manitoba Métis Federation noted that the CMD required edits to more accurately reflect the current Manitoba Métis Federation- CNL relationship	Email
2024 July 02	This email from CNL Indigenous Engagement Officer to Manitoba Métis Federation Nuclear Energy Specialist is to provide Manitoba Métis Federation with the received comments and edits incorporated into the Whiteshell Site re-license CMD.CNL requested any additional feedback by 2024 July 05.	Email
2024 July 03	This email from Manitoba Métis Federation Energy ad Infrastructure Portfolio Lead to the CNL Indigenous Engagement Officer is to request a deadline extension for the review and feedback of the Whiteshell Site re-license CMD. CNL confirmed a deadline extension of 2024 July 09.	Email

Date	Event	Event / Activity
2024 July 03	This telephone call from CNL Indigenous Engagement Officer to the Manitoba Métis Federation Energy and Infrastructure Portfolio Lead is to confirm CNL's ability to provide the Manitoba Métis Federation with an extension on the 2024 July 05 deadline for the Manitoba Métis Federation review of the CNL Whiteshell Site re-license Commission Member Document (CMD). CNL extended the deadline to 2024 July 09 to ensure an accurate representation of the CNL - Manitoba Métis Federation relationship is included in the CMD.	Telephone
2024 July 08	This email from CNL WL Site License Holder and GM to Manitoba Métis Federation Energy and Infrastructure Portfolio Lead is to inquire if Manitoba Métis Federation would be receptive to an in-person event for the WL Licence Renewal Hearing.	Email
2024 July 08	This email from Manitoba Métis Federation Nuclear Energy Specialist to CNL Indigenous Engagement Officer is to provide CNL with the Manitoba Métis Federation final edits to the Whiteshell Site re-license CMD.	Email
2024 July 09	This email from CNL Indigenous Engagement Officer to Manitoba Métis Federation Nuclear Energy Specialist is to provide confirmation of receipt of Manitoba Métis Federation final edits to the Whiteshell Site re-license CMD, and to offer support to Manitoba Métis Federation's participation in the hearing in October.	Email

1.3.4 Manitoba Métis Federation (MMF) – Key Interests and Concerns

In February 2024, the MMF notified CNL of the MMF's decision to end the 2023 agreement. CNL respects the MMF's decision while continuing to share information. CNL remains open and interested in discussion with the MMF. CNL aspires to rebuild a productive partnership with the MMF to enable full participation of Red River Métis Citizens in the various projects, licensing, economic benefits and environmental protection opportunities. In late summer 2024, CNL and the MMF began to engage at the working - level on the 2024 WL site re-license, and environmental monitoring.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Long-Term Relationship			
The Manitoba Métis Federation (MMF) is interested in a positive and collaborative relationship with Canadian Nuclear Laboratories (CNL). Strengthening the relationship will help the MMF and CNL work together on the Whiteshell Reactor 1 (WR-1) Project and will ensure that the Red River Métis's Section 35 and harvester rights, as well as the rights, interests, and claims more broadly are addressed by CNL and Atomic Energy of Canada Limited (AECL) in their activities, and the Canadian Nuclear Safety Commission (CNSC) in its regulatory oversight of the facility. This is both a project-specific and site-wide interest.	CNL has made efforts to improve relations with the MMF since 2017 and have been responsive in addressing immediate concerns and interests on the Project. CNL has ensured that the MMF have economic and technical capacity to support the Project. A 5-year Contribution Agreement was signed in March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison position), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, and worked with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes. The sought commitments are intended to address the interests and concerns of the MMF. Additionally, MMF has been included as a member of the Federal Provincial Indigenous Review Team (FPIRT) with the CNSC, responsible for formal review of the EIS and supporting documentation.	Engagement activities with the MMF regarding developing a relationship agreement were included in Section 4.2.4.2.1: Engagement.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next steps:** CNL is committed to build on their relationship to ensure that the MMF is engaged in a respectful and meaningful manner in respect of the Project and that the MMF has the capacity to be meaningfully engaged about their rights, claims and interests on the Project. CNL will continue to engage the MMF on the Project and closure of the WL site throughout the licensing process and project implementation. **Commitments Sought:** MMF-7: CNL is prepared to fully enable MMF engagement in activities relating to the federal environmental assessments for the Project by providing funding for such activities as agreed to by the Parties, including jointly establishing an MMF Liaison position and MMF-CNL Monthly meetings, which is a venue for: ▪ WR-1 Project updates to the MMF community through construction and decommissioning. ▪ MMF to express areas of concern with respect to the project for discussion and potential action. ▪ Confirming appropriate implementation of WR-1-specific mitigation, monitoring, and compensatory commitments related to MMF rights and interests. ▪ Discuss with MMF, any Reportable Events ▪ CNL primary point of engagement with MMF during the planning, construction, and decommissioning of the Project. MMF-8: CNL will continue to hold and resource regular update meetings with representatives from MMF on the Project and restoration of the Whiteshell site. MMF-9: MMF and CNL to develop a risk communication protocol to ensure MMF has the information it needs to communicate information about the project to Citizens. MMF-10: CNL will continue to follow proper protocol and inform MMF if an event should occur as per their Resolution #8 as well as provide any additional information about CNL's response.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
The Health of the Winnipeg River and Confidence in Métis Harvesting near the WL Site			
The Red River Métis is concerned that the Project may impact the environment including plants, wildlife, and in turn impact current land uses by Red River Métis harvesters and Citizens, the health of Red River Métis Citizens, and economic systems associated with traditional land use. As the MMF's Citizens use the land around the WL site for harvesting, the MMF want to ensure that the Section 35 rights, harvesting rights, and interests to use lands, resources and water near the Whiteshell Laboratories (WL) site by the Red River Métis Citizens is not impacted by the Project. This is a project-specific concern.	Through engagement activities and questions from the MMF, CNL provided information on the WR-1 In Situ Disposal (ISD) design and its uses of a multi-barrier approach to safely isolate contaminants from the environment. The environmental assessment of the normal evolution, extreme events, and accident scenarios concluded that there are no impacts on the environment, including plants and wildlife relied on by the Red River Métis, and that the Métis Citizens can safely practice traditional activities near the WL site. CNL used information from engagement activities and MTKLUOS to confirm that Project's Valued Components (VCs) and assessment adequately capture Red River Métis interests and ensured the harvester receptor was conservative compared to the Red River Métis harvester consumption data as part of the Project's human health risk assessment. This confirms that CNL's assessment accurately reflects Red River Métis land and resource use practices. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In 2023, the MMF began expanded sampling and monitoring at the Whiteshell site through the MMF-led Harvester Sampling Plan. Engagement and monitoring/sampling with the MMF will continue to inform environmental protection for the Project and at the site. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes. The sought commitments were intended to address the interests and concerns of the MMF.	CNL used the MTKLOUS and Métis harvester food intake study to validate and refine its Harvester receptor model in the assessment of human health in Section 6.7.1.7: Residual Effects Analysis. Each subsection of Section 6.0: Environmental Effects was revised to include a table of Indigenous Interests and concerns, and how they were considered under each particular assessment. CNL specifically confirmed that fish and fish habitat (the Winnipeg River) health is captured in Section 6.5: Aquatic Environment, and that the health of fish, waterfowl, aquatic plants, and humans that consume them is captured in Section 6.7: Human and Ecological Health. To provide additional monitoring requested by the MMF, CNL revised Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring to include a commitment to add additional groundwater well(s) in between WR1 and the Winnipeg River, and to include additional river water and country food monitoring in its Environmental Monitoring program.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. CNL has committed to ongoing engagement with the MMF regarding environmental monitoring, including further discussion about the concept of MMF-led monitoring. **Commitments Sought:** MMF-11: Agree to a path forward on how to incorporate Métis interests and feedback into the current wildlife and environmental monitoring program for the Whiteshell Laboratories Site. MMF-12.1: CNL will continue to engage with MMF on environmental monitoring for WR-1, for site wide monitoring, and to discuss environmental monitoring initiatives MMF is pursuing to determine how we can work together. MMF-12.2: CNL shall support the MMF Pilot Harvester Sample Collection Plan (HCSP), an MMF led and guided harvesting plan that includes a target species list developed through consultation with harvesters in the area and a block-based harvesting schedule to approximate target species availability. MMF-14: CNL will work with the Community Liaison and the MMF to share monitoring results/outcomes to the communities in ways that are appropriate for community distribution. MMF-15: CNL will continue to monitor fish tissues annually during the closure phase. MMF-17: CNL will assess monitoring data against established limits for parameters/contaminants of potential concern based on information in the Detailed Safety Analysis Report including the findings from the WR- 1 Ecological Risk Assessment. MMF-19: CNL will perform additional modeling using moose as a VC. CNL will make the results of the analysis available to all interested parties. MMF-20: CNL commits to continuing its testing of wildlife killed in the vicinity of Whiteshell Laboratories.
The MMF is concerned that the site's discharge to the Winnipeg River, (including the potential for a discharge license to trigger an environmental assessment) and if the site's discharge has any effects on Manitoba Hydro operations. This is a site-wide concern.	During engagements, the MMF indicated that the health of the environment, plants, and wildlife relied on for harvesting activities as well as the risk to people in the area of the Project site are of great concern to the Manitoba Métis Community. The MMF also had a series of questions on the Whiteshell site's discharge to the Winnipeg River, including the potential for their discharge license to trigger an environmental assessment and if the site's discharge has any effects on Manitoba Hydro operations. In the response, CNL stated that the general water discharge from the WL site is covered under the original site environmental assessment – the Comprehensive Study Report (CSR). Water discharges from the WL site are approximately 5000 gallons/minute; however, water intake from the Winnipeg River is of a similar volume – it operates like a loop. As such, discharges from the site have no effect on the overall volumes of water in the river. For accuracy, CNL clarified that 1.36 gigalitres (GL) of water was pumped from the river over 2015. The total discharge volume in 2015 was 1.34 GL. All discharges are monitored, and the results are shared publicly every year. The performance of WL site environmental emissions controls is very good and there is documented scientific evidence that there are no impacts to the environment or the public. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes.	The impact of the WL site on river water quality is documented in Section 6.4.2.5.2.2: Surface Water and Sediment Quality. CNL confirmed no impact to local hydrology as a result of the Project in Section 6.4.1.6.2: Results.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. CNL has committed to ongoing engagement with the MMF regarding environmental monitoring, including further discussion about the concept of MMF-led monitoring. **Commitments Sought:** MMF-18: CNL will continue to monitor ground and surface water (Winnipeg River) for comparison with background levels and guidelines including Health Canada's Canadian Drinking Water Guidelines and the Canadian Council of Ministers of the Environment guidelines for the protection of aquatic life. .

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
The MMF is concerned that the Section 35 rights of the Red River Métis may be impacted by construction-related disturbances on the WL site. The MMF has requested to be notified of construction activities within 21 days before the activity is due to start. This will allow the MMF to inform harvesters of potential impacts and wildlife disturbances. This is both a site-wide and project-specific concern.	CNL agreed to notify the MMF of any construction related activities on-site that would impact nearby harvesting activities. To help to address these concerns, CNL has committed to collaborating on a MMFs wildlife and environmental monitoring program for the Whiteshell site, during a technical wrap up meeting in May 2021, to address concerns regarding the health of the environment. These initiatives will improve communication about site activities and support alleviating concerns about the Project. In addition, CNL has committed to establishing a communication protocol for reportable events with the MMF so that Métis harvesters are notified in the unlikely event of any off-site effects such as noise or other activities that may impact harvesting activities. This commitment was affirmed during a workshop in November 2020. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes.	CNL documented its commitment to establishing a communication protocol for reportable events with the MMF so that Métis harvesters are notified in the unlikely event of any off-site effects such as noise or other activities that may impact harvesting activities in Section 4.2.4.2.2: Interests and Concerns.	**Next Steps:** CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. CNL has committed to ongoing engagement with the MMF regarding environmental monitoring, including further discussion about the concept of MMF-led monitoring. **Commitments Sought:** MMF-14: CNL will work with the Community Liaison and the MMF to share monitoring results/outcomes to the communities in ways that are appropriate for community distribution.
Regulatory Process			
The MMF expressed a concern regarding participant funding from the CNSC within the Environmental Assessment process for the Project to date. The MMF wants to ensure that they have capacity, resources, and opportunity to exercise their right to be consulted on and participate in projects that might adversely impact their Section 35 rights. The MMF also wants to ensure that the rights, interests, and claims of the Red River Métis more broadly are being upheld. This is a project-specific concern.	CNL has provided capacity funding and committed to supporting MMF participation in the environmental assessment process beyond the funding provided by the CNSC. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes. Additionally, MMF has been included as a member of the Federal Provincial Indigenous Review Team (FPIRT) with the CNSC, responsible for formal review of the EIS and supporting documentation.	A description of engagement with the MMF, including participant and capacity funding commitments was documented in the revised Section 4.2.4.2: MMF.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL is committed to build on their relationship to ensure that the MMF are engaged in a respectful and meaningful manner in respect of the Project and that the MMF have the capacity to be meaningfully engaged about their rights, claims and interests on the Project. CNL will continue to engage the MMF on the Project and closure of the WL site throughout the licensing process and project implementation. **Commitments Sought:** MMF-7: CNL is prepared to fully enable MMF engagement in activities relating to the federal environmental assessments for the Project by providing funding for such activities as agreed to by the Parties, including jointly establishing an MMF Liaison position and MMF-CNL Monthly meetings, which is a venue for: ▪ WR-1 Project updates to the MMF community through construction and decommissioning. ▪ MMF to express areas of concern with respect to the project for discussion and potential action. ▪ Confirming appropriate implementation of WR-1-specific mitigation, monitoring, and compensatory commitments related to MMF rights and interests. ▪ Discuss with MMF, any Reportable Events ▪ CNL primary point of engagement with MMF during the planning, construction, and decommissioning of the Project.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
The MMF expressed interest in the list of Valued Components (VCs) for the Project and provided a list of requested additions to the VCs list as a method of ensuring the rights, interests, and claims of the Red River Métis were appropriately considered in the assessment for the Project. These additional VCs were important for the MMF to see included in the EIS as a method for ensuring that factors that could impact the both the rights and well-being of the Red River Métis were considered as part of the assessment. In addition, the MMF also want to ensure, the exercising of rights by Métis Citizens is avoided, Métis specific mitigations implemented, or Métis specific accommodation are provided. This is a project-specific concern.	CNL, with support from the CNSC, funded the Whiteshell Reactor #1 Decommissioning: Manitoba Métis TKLUOS (SVS 2019). CNL has incorporated information from the TKLUOS into the draft EIS. CNL has subsequently revised the draft EIS and included elements of the TKLUOS in Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Peoples. CNL's view is that the steps CNL has taken adequately addresses this area of interest to the extent possible. In June 2021 CNL provided a list of VCs for the Project to the MMF. CNL then proceeded to draft a list of the MMF's VCs based on information from engagement activities with the MMF, the MMF's MTKLUOS, and the Red River Métis's harvester consumption survey. CNL verified the VCs with the MMF and for each VC, either: ▪ Confirmed it was encompassed by the assessment. ▪ Added it to the assessment. ▪ Added it to the model to be assessed. ▪ Did not add it to the assessment, with rationale provided. CNL confirmed that potential impacts to the environment that could impact Aboriginal rights and claims are considered under the Traditional Land and Resource Use VC in Section 6.8.1.3. Specific to the Aboriginal Rights interests, and claims, CNL has indicated that the CNSC is responsible for making determinations on and assessing any impacts to Aboriginal and Treaty rights. As the CNSC develops the Rights Impact Assessment for the Project, there is an opportunity for the MMF to work with the CNSC on that assessment of rights. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes.	Each subsection of Section 6.0: Environmental Effects was revised to include a table of Indigenous Interests and concerns, and how they were considered under each particular assessment. Table 4.41: Summary of Interests and Concerns Raised During Engagement Activities That Influenced the Environmental Assessment identifies where VC related feedback has resulted in the addition of a new VC.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL will continue to ensure the MMF and Red River Métis values, interests, and traditional knowledge are meaningfully incorporated into the Project. One way this is being done is through the implementation of the MMF-led Harvester Sampling Plan which was enabled through the 2023 MOA. The parties will consider these concerns to be fully addressed once the MMF and CNL can assess the success of the implemented commitments and confirm they address the MMF's concerns. **Commitments Sought:** MMF-12.2: CNL shall support the MMF Pilot Harvester Sample Collection Plan (HCSP), an MMF led and guided harvesting plan that includes a target species list developed through consultation with harvesters in the area and a block-based harvesting schedule to approximate target species availability. MMF-19: CNL will perform additional modeling using moose as a VC. CNL will make the results of the analysis available to all interested parties.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Monitoring and Control of the Proposed WR-1 Disposal Facility and the Decommissioned WL Site			
The MMF raised a concern about monitoring and control of the WL site over the long-term to ensure human and ecological health and Red River Métis Section 35 rights to use lands and resources near the WL site are not impacted by the WL site operations or the Project. CNL has the responsibility for facility monitoring and accountability in case effects on the environment are detected.	CNL provided information on the environmental assessment and explained that the environmental assessment of normal evolution and extreme events and accident scenarios concluded there are no impacts on the environment, including plants and wildlife relied on by Red River Métis, and that the Métis Citizens can safely practice traditional activities near the WL site with no impact to traditional land use. The assessment shows that the final disposal facility is passively safe and is not reliant on monitoring or human control to be effective in protecting people and the environment. The institutional control period for the WR-1 facility, will last for a minimum of 100 years after closure of the facility. CNL explained that they remain responsible for control and monitoring of the site until the CNSC agrees that it is no longer needed. Institutional controls will include access restrictions, ongoing observation and maintenance of the soil cover and vegetation, and ongoing environmental monitoring. The purpose of the institutional controls and the monitoring are to verify the performance of the disposal facility over time and build confidence that the passive safety of the system will ensure the safety of people and the environment well into the future. CNL has re-iterated that it will remain responsible for implementing and managing the monitoring program, including Red River Métis environmental monitoring, as well as any remedial actions required at the WL site, and Atomic Energy of Canada Limited (AECL) is responsible for funding to CNL for the follow-up monitoring program. This funding is part of the financial guarantees submitted to CNSC as part of the WL site license. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, intended to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes.	CNL clarified the post-closure activities and responsibilities for monitoring in Section 3.4.9.2: Post-Closure Activities. Section 11.0: Summary of Monitoring and Follow-up Programs was updated to provide a better description of the long-term monitoring planned for the Project. CNL has clarified its commitment and responsibility for the on-going monitoring program and AECL funding in Section 11.1: Integrated Environmental Monitoring Program.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL has committed to supporting the MMF's participation in environmental monitoring and will be collaborating with the MMF to ensure CNL aligns with the MMF's expectations and interests. CNL has also committed to collaborating in the development of a post closure monitoring program. **Commitments Sought:** MMF-12.2: CNL shall support the MMF Pilot Harvester Sample Collection Plan (HCSP), an MMF led and guided harvesting plan that includes a target species list developed through consultation with harvesters in the area and a block-based harvesting schedule to approximate target species availability. MMF-19: CNL will perform additional modeling using moose as a VC. CNL will make the results of the analysis available to all interested parties. MMF-22.1: Establish Surface Water monitoring in closer proximity to the release point in the Winnipeg River MMF-22.2: Include a ground water monitoring station closer to the reactor. MMF-26.1: Update the Environmental Assessment Follow- up Program to clearly state the commitment for monitoring fish tissue will continue annually during the closure phase. MMF-26.2: Incorporate a water sample collection in the final post-closure monitoring plan.
The MMF expressed concerns about containment of waste in the WR-1 disposal facility and groundwater monitoring in the vicinity of the WR-1 facility, as it has a potential to release radioactive and hazardous materials into the environment, endangering human and ecological health, as well as Red River Métis Section 35 rights to use lands and resources near the WL site, including the Winnipeg River as an ecologically and culturally significant area to the Red River Métis. This is a project-specific concern.	CNL carried out the environmental assessment and determined that the amount of radioactive and hazardous material that would be released from the WR-1 facility would be sufficiently low to not endanger human or ecological health. To confirm this modelling, CNL proposes a network of groundwater monitoring wells around the WR1 facility, in addition to the site's existing broader environmental monitoring program. In 2021, the MMF and CNL participated in a series of technical workshops on specific areas of interest. Workshops included an overview of the in-situ design, proposed groundwater monitoring program, the broader site's environmental protection program, the WR-1, Alternative Means Assessment, and opportunity for collaboration. The workshops facilitated greater understanding of the concerns and interest of the MMF. As a result of the workshops, CNL committed to incorporating an additional ground monitoring station between WR-1 and the river as part of their post-closure monitoring program. This was a recommendation from the Red River Métis . A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes. The sought commitments were intended to address the interests and concerns of the MMF.	CNL updated Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring to include CNL commitments to working with the First Nations and the MMF to involve them in environmental monitoring of the site after closure, as well as adding ground water monitoring well(s) between WR-1 and the river as requested by the MMF.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Nest Steps:** CNL has committed to supporting the MMF's participation in environmental monitoring and will be collaborating with the MMF to ensure CNL aligns with the MMF's expectations and interests. **Commitments Sought:** MMF-18: CNL will continue to monitor ground and surface water (Winnipeg River) for comparison with background levels and guidelines including Health Canada's Canadian Drinking Water Guidelines and the Canadian Council of Ministers of the Environment guidelines for the protection of aquatic life. MMF-22: Include an additional groundwater monitoring well in the proposed WR-1 post-closure monitoring program. MMF-22.1: Establish Surface Water monitoring in closer proximity to the release point in the Winnipeg River MMF-22.2: Include a ground water monitoring station closer to the reactor.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
The MMF is concerned that the WL site activities may impact wildlife in the area. The MMF wants to work alongside CNL in the development of a wildlife mortality monitoring and adaptive management program to address impacts to wildlife important to the MMF to ensure the Red River Métis's Section 35 rights to hunt and for trade and commerce in their harvesting territory are not impacted by WL site activities. This is both a site-wide and project-specific concern.	In March 2020, CNL hosted a workshop with the MMF on the site's Environmental Protection Program that included a dialogue on the wildlife mortality monitoring and adaptive management program. The MMF said they would consider this issue addressed by CNL, if CNL established a wildlife mortality monitoring plan that takes into consideration timing and seasonality (for example: monitoring focused on nesting snapping turtles in spring/summer, white-tailed deer more of a concern in the fall), and that specifies mortality thresholds, as well as adaptive management measures to be implemented in the event a threshold is exceeded. CNL's Environmental Protection team provided a summary of the current Wildlife Mortality Plan and clarified that the Environmental Protection Program is in the process of addressing concerns that were discussed. All wildlife mortality is monitored on the plant road and the results of this monitoring are included in the annual Environmental Monitoring report. Since the program was initiated in 2014, no mortalities of species at risk have been recorded. The current ongoing Wildlife Mortality Monitoring Plan was implemented in 2021, recording any wildlife mortalities on site. Currently wildlife awareness road signage and ditch monitoring are underway. Road inspections by the Emergency Services team and notification of any wildlife fatalities are ongoing. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought sought at this time, to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes.	CNL assessed the Project's impact on terrestrial species in Section 6.6: Terrestrial Environment, including mitigation measures to reduce species mortality and loss of habitat for species at risk in Section 6.6.6.2.2: Secondary Pathways) CNL has documented the commitment to monitor wildlife mortality to help inform adaptive management practices as part of the Environmental Assessment Follow-up Program for the WL site in Section 11.1: Integrated Environmental Monitoring Program.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Nest Steps:** CNL has committed to supporting the MMF's participation in environmental monitoring and will be collaborating with the MMF to ensure CNL aligns with the MMF's expectations and interests. **Commitments Sought:** MMF-12.1 : CNL will continue to engage with MMF on environmental monitoring for WR-1, for site wide monitoring, and to discuss environmental monitoring initiatives MMF is pursuing to determine how we can work together. MMF-20: CNL commits to continuing its testing of wildlife killed in the vicinity of Whiteshell Laboratories.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
The MMF is concerned that the Project may impact the environment and the perceived safety of the site by Métis harvesters through potential psycho-social impacts of the Project. The MMF is interested in more active involvement in planning and execution of environmental monitoring activities on site as they want to ensure their Section 35 rights to use lands and resources near the WL site are not impacted by the Project. This is both a project-specific concern and a site-wide interest.	In 2021, the MMF and CNL participated in a series of technical workshops on specific areas of interest. Workshops included an overview of the in-situ design, proposed groundwater monitoring program, the broader site's environmental protection program, the WR-1, Alternative Means Assessment, and opportunity for collaboration. The workshops facilitated a greater understanding of the concerns and interests of the MMF. As a result of the workshops, CNL committed to incorporating an additional ground monitoring station between WR-1 and the river as part of their post-closure monitoring program. At the workshops, CNL presented information on the WR-1 ISD design and stated the WR-1 ISD design uses a multi-barrier approach to safely isolate contaminants from the environment. The environmental assessment of the normal evolution, extreme events, and accident scenarios concluded that there are no impacts on the environment, including plants and wildlife relied on by the Red River Métis, and that the Métis Citizens can safely practice traditional activities near the WL site. To demonstrate that the WR-1 ISD is safe, CNL proposed that monitoring for the Project will be incorporated into the overall WL site monitoring program, which already monitors a number of the terrestrial and aquatic species. CNL provided opportunity, training, and capacity for an MMF Monitor to directly observe and participate in environmental monitoring activities on the site to build familiarity and confidence that CNL is effectively monitoring the environment to ensure protection of people and the environment. The Métis Monitor has visited the site eight times and participated in river water collection, lagoon discharge monitoring, fish monitoring, collection of traditional foods/plants for monitoring, and other activities. The Métis Monitor provides activity reports directly back to Manitoba Métis Citizens, ensuring trusted sharing of information about CNL's operations and protection of the environment. CNL has adapted its environmental monitoring program based on feedback provided by the MMF. During the fall 2020 monitoring season, the Métis Monitor walked the site with CNL Environmental Monitoring Technologists to identify plants of importance to Métis Harvesters. CNL gathered mushrooms for analysis and will search for berries in season. The results will be incorporated to the Annual Safety Compliance Report. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes.	No changes were made to the assessment; however, CNL confirmed that there will be no impact on the environment through the assessment and documented the results of the assessment in Section 9.3 : Summary. Engagement activities with the MMF in regard to participation in environmental monitoring activities on site were added to the revised Section 4.2.4.2.1: Engagement. Section 11.2: Adaptive Management was updated with a CNL commitment to review and adapt the existing Environmental Assessment Follow-Up Program for the WL site to incorporate Indigenous Traditional Knowledge that has been collected through the environmental assessment for the Project. Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring was updated to include CNL commitments to working with the First Nations and the MMF to involve them in environmental monitoring of the site after closure.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Nest Steps:** CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. CNL has committed to ongoing engagement with the MMF regarding environmental monitoring, including further discussion about the concept of MMF-led monitoring. **Commitments Sought:** MMF-11: Agree to a path forward on how to incorporate Métis interests and feedback into the current wildlife and environmental monitoring program for the Whiteshell Laboratories Site. MMF-12.1: CNL will continue to engage with MMF on environmental monitoring for WR-1, for site wide monitoring, and to discuss environmental monitoring initiatives MMF is pursuing to determine how we can work together. MMF-12.2:CNL shall support the MMF Pilot Harvester Sample Collection Plan (HCSP), an MMF led and guided harvesting plan that includes a target species list developed through consultation with harvesters in the area and a block-based harvesting schedule to approximate target species availability. MMF-14: CNL will work with the Community Liaison and the MMF to share monitoring results/outcomes to the communities in ways that are appropriate for community distribution. MMF-17: CNL will assess monitoring data against established limits for parameters/contaminants of potential concern based on information in the Detailed Safety Analysis Report including the findings from the WR- 1 Ecological Risk Assessment.
Whiteshell Site Environmental Remediation and Incorporation of Métis Information			
The MMF expressed interest in providing Métis input into the grass seed mix and revegetation measures including tree and bush planting for site remediation areas to ensure species of importance to the Métis are considered and to avoid species that may conflict with Métis harvest practices. This is both a site-wide and project-specific concern. The MMF wants to ensure the rights, interests, and claims of the Red River Métis, including Section 35 rights to use lands and resources near the WL site are not impacted by site and Project activities.	CNL committed to using only native species in the grass seed mix for remediation of the WL site. CNL shared the current seed mix with the MMF to seek their feedback on it. CNL committed to providing the MMF with the detailed site revegetation plan once it has been drafted. CNL committed to only using native seeds in our revegetation efforts. CNL held discussions in fall 2020 with the MMF on input to tree species for site re-forestation. CNL held discussions with the MMF on potentially procuring trees and bush plants from the Red River Métis. The MMF is currently exploring the establishment of a tree nursery business. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes.	Section 3.4.6.5: Final Site Restoration was updated with a commitment to use a grass seed mixture native to the area.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Nest Steps:** CNL will continue to engage with the MMF on input to and potential sourcing of seeds, bushes, and trees for site re-vegetation activities. CNL will continue to meaningfully engage the MMF on all matters pertaining to the WR-1 application and the Whiteshell Laboratories site in general, to ensure their rights, claims, and interests are adequately considered. Through the signed Agreement, CNL and MMF have put in place a forum to share information, hear knowledge-holder perspectives, and make efforts to address residual areas of concern related to ISD of the WR-1. **Commitments Sought:** MMF-11: Agree to a path forward on how to incorporate Métis interests and feedback into the current wildlife and environmental monitoring program for the Whiteshell Laboratories Site. MMF-13: CNL will support MMF participation in regular CNSC on-site inspections by a Red River Métis Citizen Monitor.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Economic Opportunities (Business, Capacity Building, etc.)			
The MMF stated Red River Métis Citizens must be able to equitably participate in the economic benefits and opportunities associated with the construction, operations, and maintenance of the Project. The MMF specified CNL needs to support Red River Métis employment to ensure MMF is able to participate in the environmental monitoring and management of the Project in all stages.	CNL has worked to enhance options to better match Indigenous capabilities with CNL contracting needs, added provisions to CNL procurement process to encourage the use of Indigenous and local businesses, and considers single source contracting opportunities with Indigenous companies where well suited to the work. CNL has also adjusted the evaluation criteria for competitive bids to favour contracts that are Indigenous owned or have Indigenous employees. CNL exhibited at the 2018 and 2019 Manitoba Métis Federation Annual General Assembly in order to meet Métis businesses and share employment and contracting opportunities with the Whiteshell Laboratories Closure Project. In 2023 CNL developed and shared a draft Indigenous Relations Procurement Strategy with the MMF. The MMF provided feedback on the strategy and CNL and the MMF met on November 6, 2023, to discuss MMF feedback. CNL also shared the Indigenous Vendors Portal in the fall of 2023. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes.	Engagement activities with the MMF in regard to developing a relationship agreement are included in Section 4.2.4.2.1: Engagement. CNL revised Section 6.9.6.2.2: Secondary Pathways to add various measures that CNL took in collaboration with Indigenous communities to enhance Indigenous capacity and participation in contracting and employment opportunities at the WL site.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL will continue to engage on the matter of contracting and employment with the MMF. CNL will continue to work to remove the barriers Indigenous Peoples may face in applying for positions in the interest of increasing Indigenous participation in the project. **Commitments Sought:** MMF-2: CNL will establish a mechanism to send job postings to the MMF on an ongoing basis. MMF-3: CNL will meet with the MMF to discuss the best approach to supporting Indigenous employment at CNL. Factors to consider include the format of job postings, education requirements, on-the-job training opportunities and in-community recruitment. MMF-5: CNL will work proactively with the MMF to identify economic opportunities in relation to the decommissioning and site remediation of the Whiteshell Laboratories Site. CNL commits to direct contracting work relating to its Whiteshell Laboratories Site operations to Métis businesses that meet the definitions of Indigenous businesses, provided that they meet all safety, technical and qualification standards and allow CNL to maintain its requirements applicable to its site and its operations, including provision of appropriate economic value to CNL, taking into account the social value of achieving CNL's Indigenous Procurement Strategy and the terms of this agreement. MMF-6: CNL shall employ the following initiatives in furtherance of its efforts to achieve its Indigenous Procurement Objectives and contract appropriate work to the Red River Métis Citizens in support of its Indigenous Procurement Strategy: MMF-6.1: CNL shall provide and see that its subcontractors provide advance information on Whiteshell Laboratories work which Métis businesses may be interested in, in advance of undertaking a public request for proposal process. MMF-6.2: Under this agreement, CNL and MMF will discuss upcoming work that MMF may have the interest and capacity to undertake and could potentially be provided to MMF businesses on a sole-source or other basis, subject to the MMF business being qualified in respect of satisfying all technical, performance, safety and other qualifications set out by CNL for each contract. MMF-6.3: CNL will share information regarding Red River Métis owned businesses to potential or selected contractors that may subcontract a portion of work to qualified Indigenous businesses. MMF-6.4:Where CNL believes appropriate, CNL will encourage opportunities, including partnerships, joint ventures and relationships, between Red River Métis owned businesses and potential CNL contractors and proponents within CNL's supply chain community who may competitively bid on future work associated with decommissioning and reclamation, to support skills transfer and capacity building, and in support of mutual business interests.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Traditional Land Use			
The MMF is concerned that the Project may have potential negative impacts on socio-cultural and economic systems associated with traditional land use, including the trade and sharing of resources or products from traditional land-use practices in the surrounding area. This is a project-specific concern.	CNL, with support from the CNSC, funded the Whiteshell Reactor #1 Decommissioning: Manitoba Métis TKLUOS (SVS 2019). CNL has incorporated information from the TKLUOS into the draft EIS. CNL has subsequently revised the draft EIS and included elements of the TKLUOS in Section 6.8.1.5.2.2 Traditional Land and Resource Use by Indigenous Peoples. CNL incorporated Red River Métis traditional land use practices and traditional food consumption data into WR-1 environmental assessment and confirmed there are no predicted negative effects to Red River Métis traditional land users. The environmental assessment of the normal evolution, extreme events, and accident scenarios concluded that there are no impacts on the environment, including plants and wildlife relied on by the Red River Métis, and that the Métis Citizens can safely practice traditional activities near the WL site. CNL also agreed to notify the MMF of any construction related activities on-site that would impact nearby harvesting activities. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, to address the interests and concerns and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes.	Engagement activities with the MMF in regard to developing a relationship agreement are included in Section 4.2.4.2.1: Engagement documented its commitment to establishing a communication protocol for reportable events with the MMF so that Métis harvesters are notified in the unlikely event of any off-site effects such as noise or other activities that may impact harvesting activities in Section 4.2.4.2.2: Interests and Concerns. CNL used the MTKLOUS and Métis harvester food intake study to validate and refine its Harvester receptor model in the assessment of human health in Section 6.7.1.7: Residual Effects Analysis. CNL has confirmed that Traditional Land and Resource Use by Indigenous People is a VC in the assessment in Section 6.8: Land and Resource Use and that it assessed continued opportunity for, and willingness to engage in, traditional activities such as hunting, fishing, swimming, drinking surface water, trapping and plant, berry, wild rice and medicine gathering by Indigenous Peoples with no detrimental effects.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL has partially addressed this matter within the Project context through the incorporation of TKLUOS information and will continue to ensure the MMFand Red River Métis values, interests, and traditional knowledge are meaningfully incorporated into the Project. One way this is being done is through the implementation of the MMF-led Harvester Sampling Plan which was enabled through the 2023 MOA. **Commitments Sought:** MMF-1: Incorporate Red River Values and Interests. MMF-1.1: Incorporate Red River Métis values and feedback into the current wildlife and environmental monitoring program for the Whiteshell Laboratories Site during the closure period until a Post Closure monitoring is agreed to between the MMF and CNL. MMF-1.2: Incorporate Red River Métis traditional knowledge and land use information in the EIS. MMF-1.3: Document the uniqueness of the MMF MMF governance structure and cultural in the EIS. MMF-1.4: Document MMF's position in the EIS (i.e. the complete removal of the WR-1 facility should be undertaken).
The MMF noted that regulators may notice and flag the absence of Métis Traditional Knowledge in the EIS. The MMF has a catalogue of Traditional Knowledge but does not have the capacity to analyze it for gaps and relevance to the WL site. The MMF notes that a Traditional Knowledge study should be undertaken as neither the previous Comprehensive Study Report nor the current monitoring reports consider Métis harvesting. The species of traditional importance identified in the MTKLUOS should be thoroughly assessed for any effects. This is both a site-wide and project-specific concern. The MMF wants to ensure their Section 35 rights to use lands and resources near the WL site are considered by CNL and to have confirmation that they are not impacted by site and Project activities.	CNL, with support from the CNSC, funded the WR1 Decommissioning Manitoba Métis TKLUOS. In addition, CNL supported a Red River Métis harvester consumption survey. CNL incorporated information from both studies into the draft EIS. This includes confirming that species of traditional importance identified by the Red River Métis Citizens were either already included in the assessment through representative species or added to the assessment, such as moose. In cases where species were not included in the assessment, CNL provided an explanation of why they were not. CNL also verified a list of VCs for the Red River Métis with the MMF and incorporated the VCs into the assessment chapters of the EIS. The ecological health assessment results indicate that there would be no negative effects on the health or population of the representative species, and thus no effect to the species of importance to Red River MétisCitizens. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes. The sought commitments were intended to address the interests and concerns of the MMF.	Section 6.6.3: Valued Components was updated to include the assessment of species of importance to the Indigenous communities, including the Red River Métis, and how they were represented in the assessment. The assessment model for the Harvester, representing a traditional land use receptor, was updated and validated using the results of the MTKLOUS Section 6.7.1.7.1.1: Methods and 6.7.1.7.2.1: Methods. Section 6.7.2: Ecological Health was updated with assessment results for moose, as well as confirmed that there is not likely to be any effects on the representative species due to the Project. Traditional Land and Resource Use by Indigenous People is a VC in the assessment in Section 6.8: Land and Resource Use and it assesses continued opportunity for, and willingness to engage in, traditional activities such as hunting, fishing, swimming, drinking surface water, trapping and plant, berry, wild rice and medicine gathering by Indigenous Peoples with no detrimental effects. Section 6.8.1: Traditional Land and Resource Use was updated with the relevant information on traditional land use from the Red River Métis TKLOUS.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL has partially addressed this matter within the Project context through the incorporation of TKLUOS information and will continue to ensure the MMFand Red River Métis values, interests, and traditional knowledge are meaningfully incorporated into the Project. One way this is being done is through the implementation of the MMF-led Harvester Sampling Plan which was enabled through the 2023 MOA. **Commitments Sought:** MMF-1: Incorporate Red River Values and Interests. MMF-1.1: Incorporate Red River Métis values and feedback into the current wildlife and environmental monitoring program for the Whiteshell Laboratories Site during the closure period until a Post Closure monitoring is agreed to between the MMF and CNL. MMF-1.2: Incorporate Red River Métis traditional knowledge and land use information in the EIS. MMF-1.3: Document the uniqueness of the MMF , MMF governance structure and cultural in the EIS. MMF-1.4: Document MMF's position in the EIS (i.e. the complete removal of the WR-1 facility should be undertaken).

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
The MMF indicated that CNL should include culturally important terrestrial species in its monitoring program to confirm that the WL site and Project do not affect the health of the environment through radiological releases. This is both a site-wide and project-specific concern. The MMF wants to ensure that Red River Métis Section 35 rights to use lands and resources near the WL site are not impacted by site and Project activities.	Monitoring for the Project will be incorporated into the overall WL site program, which already monitors a number of terrestrial and aquatic species. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. As a result of engagement with the MMF, CNL has added mushrooms, berries and wild rice to the current environmental monitoring program as a result of engagement with the MMF. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes. The sought commitments were intended to address the interests and concerns of the MMF.	Section 11.2: Adaptive Management was updated with CNL commitment to reviewing and adapting the existing Environmental Assessment Follow-up Program for the WL site to incorporate Indigenous Traditional Knowledge that has been collected through the environmental assessment for the Project. Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring was updated to include CNL commitments to working with the First Nations and the MMF to develop an Indigenous stewardship monitoring initiative.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL is committed to Incorporating Métis interests and feedback into the current wildlife and environmental monitoring program for the Whiteshell Laboratories Site. **Commitments Sought:** MMF-1: Incorporate Red River Values and Interests. MMF-1.1: Incorporate Red River Métis values and feedback into the current wildlife and environmental monitoring program for the Whiteshell Laboratories Site during the closure period until a Post Closure monitoring is agreed to between the MMF and CNL. MMF-1.2: Incorporate Red River Métis traditional knowledge and land use information in the EIS. MMF-1.3: Document the uniqueness of the MMF , MMF governance structure and cultural in the EIS. MMF-1.4: Document MMF's position in the EIS (i.e. the complete removal of the WR-1 facility should be undertaken).
In Situ Disposal			
The MMF has a project-specific concern about the ISD approach and stated that they prefer complete removal of the facility from the WL site so there would be no potential for impacts on human and ecological health and the land would be fully available for traditional use and practice of Section 35 rights.	CNL assessed all the economically and technically feasible WR-1 decommissioning options and chose ISD as the preferred alternative. CNL explained the alternative means assessment conducted by CNL to the MMF, including its findings that ISD is an appropriate approach because it reduces the nuclear liabilities at the WL site by disposing of WR-1 in a safety assessed facility without the need for major demolition and nuclear waste extraction and transportation work. CNL explained the alternative means assessment conducted by CNL to the MMF. CNL prepared a safety case and a decommissioning safety assessment that examine the ISD approach as proposed and demonstrates that it will effectively contain and isolate the waste, ensuring protection of human and ecological health. CNL also assessed the impacts to traditional land use around the WL site. The assessments indicate that Métis Citizens can safely practice traditional activities near the WL site with no impact to traditional land use. CNL and the MMF met to discuss the details of the proposed ISD Project during a technical workshop on February 9, 2021. This included a detailed walkthrough of the proposed in situ design and the protective barriers in place to protect the environment. A 5-year Contribution Agreement was signed March 2023 and encompasses 14 Articles that lay the foundation for commitments between CNL and MMF that address building community capacity (Community Liaison), communications and the development of an Environmental Assessment Follow-up Monitoring Program. While this agreement is no longer active, CNL has an open offer of capacity funding for different areas of MMF interest related to participation on the environmental assessment for the Project. In December 2023, MMF verified and agreed to the MMF commitments sought at this time, and were working with CNL on protocols and processes that further addressed the outstanding commitments sought by MMF, i.e. communications protocol, intellectual property, MMF recruitment and procurement processes. The sought commitments were intended to address the interests and concerns of the MMF.	To acknowledge the MMF's concerns, CNL included the MMF's position on the proposed ISD and their preferred alternative (full dismantlement) has been noted in Section 2.7: Conclusion. CNL assessed human and ecological health in Section 6.7: Human and Ecological Health and confirmed no effects. CNL has confirmed that Traditional Land and Resource Use by Indigenous People is a VC in the assessment in Section 6.8: Land and Resource Use and that it assessed continued opportunity for, and willingness to engage in, traditional activities such as hunting, fishing, swimming, drinking surface water, trapping and plant, berry, wild rice and medicine gathering by Indigenous Peoples with no detrimental effects.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to MMF as referenced in the WR-1 Environmental Impact Statement Commitments. **Nest Steps:** While CNL and the MMF do not agree on the method of decommissioning, the parties had agreed to continue to work collaboratively to ensure any outstanding concerns are resolved to the extent possible. **Commitments Sought:** MMF-1: Incorporate Red River Values and Interests. MMF-1.1: Incorporate Red River Métis values and feedback into the current wildlife and environmental monitoring program for the Whiteshell Laboratories Site during the closure period until a Post Closure monitoring is agreed to between the MMF and CNL. MMF-1.2: Incorporate Red River Métis traditional knowledge and land use information in the EIS

1.3.5 Black River First Nation, Hollow Water First Nation, and Brokenhead Ojibway Nation Engagement

Date	Activity	Attendance	Description	Key EA Topics									
				Baseline Conditions	Alternative Means	Project Components	Effects Assessment3	Proposed Mitigation Measures	Residual Effects	Follow-up Monitoring Program	Aboriginal and Treaty Rights / Traditional Land Use	Specific Interests and Concerns	Engagement Methods
August 3, 2016	Email/Letter	Brokenhead Ojibway Nation Black River First Nation Hollow Water First Nation	Project Introductory Letter and request for community input on any potential adverse impacts from project activities.								✓		✓
December 15, 2016	In-person meeting	7 representatives from the First Nations 4 representatives from CNL 1 representative from CNL contractor	Discussed project engagement regarding overall closure plans for Whiteshell Laboratories, and specifically to review the proposed changes to the WR-1 Reactor and associated EA process.			✓	✓	✓		✓	✓	✓	
February 21, 2017	In-person meeting	13 members from Brokenhead Ojibway Nation 11 members from Black River First Nation 13 members from Hollow Water First Nation 6 representatives from CNL 1 representative from CNL Contractor	Discussed WR-1 In-situ decommissioning. CNL presented about the overall site and closure plan. Review of the Student Job Description.	✓		✓		✓	✓				
February 22, 2017	Site Visit and WR-1 tour	13 members from Brokenhead Ojibway Nation 11 members from Black River First Nation 13 members from Hollow Water First Nation 6 representatives from CNL 1 representative from CNL Contractor	Participants were invited to the site to tour the facility and learn about the WR-1 In-Situ Decommissioning Project. Participants and CNL HR staff also discussed job advertising.	✓		✓		✓	✓	✓			
June 27, 2017	In-person Meeting	5 representatives from Black River First Nation 2 representatives from CNSC 1 representative from AECL 2 representatives from CNL	CNL, CNSC and AECL presented on the WR-1 In-Situ Decommissioning Project to Black River and Hollow Water First Nation's Chief and Councils.			✓		✓					
June 28, 2017	In-person meeting	5 representatives from Brokenhead Ojibway Nation 2 representatives from CNSC 1 representative from AECL 1 representative from CNL	The CNSC led a meeting with Brokenhead Ojibway Nation to discuss the Project and to discuss the environmental assessment process.	✓		✓			✓	✓			
July 6, 2017	In-person meeting	Open to all Indigenous communities	CNL hosted an industry day, presentation of Whiteshell Laboratories.									✓	
October 5, 2017	Email/Letter	Brokenhead Ojibway Nation Black River First Nation Hollow Water First Nation	Notification of public comment period on the draft EIS and invitation to engage.										✓

1.3.5.1 Brokenhead Ojibway Nation October 2022-July 2024

CNL has divided these records of engagement between Brokenhead Ojibway Nation, Black River First Nation, and Hollow Water First Nation, as they three First Nations have ceased to engage together. As of July 2024, Black River First Nation and Hollow Water First Nation had signed an agreement with CNL and were engaging jointly with CNL, and Brokenhead Ojibway Nation was in communication with CNL directly and independently from the other two First Nations.

Date	Event	Event / Activity
Brokenhead Ojibway Nation (BON)		
2022 October 21	This email from CNL Indigenous Engagement Contractor to BON Chief is to provide BON with an attached a letter from Canadian Nuclear Laboratories providing an update on the status of the WR-1 Environmental Impact Statement in Relation to the Whiteshell Decommissioning Project located near Pinawa Manitoba. 2024 May 02	This in-community event between (Indigenous Engagement Officer, Facility Authority) and HWFN/BRFN (Project coordinator and HWFN Councillor) was for CNL to present a Science and Physics presentation to the Grade 8 & 9's at Hollow Water First Nation School on 2024 May 02.	In Person Meeting
2024 May 02	This in-person meeting between CNL (including, Manager of Communication and Engagement, the WR-1 Manager, Director End State Strategy, Environmental Analyst, Indigenous Engagement Officer) and BRFN/HWFN (including, BRFN/HWFN Project Coordinator, HWFN Councillor, and community members) in Hollow Water First Nation is to attend the Core Engagement Meeting. Discussion and presentations included, overview of WR-1 Project, Environmental Protection and Monitoring, Land Use End State and Q & A with community members.	In Person Meeting
2024 May 02	This email from CNL Consultant to HWFN Chief and Councillor is to provide registration information for the Regional Leadership Gathering on 2024 June 04 in Beausejour.	Email
2024 May 02	This email from CNL Consultant to BRFN Chief is to provide registration information for the Regional Leadership Gathering on 2024 June 04 in Beausejour.	Email
2024 May 07	This email from CNL Indigenous Engagement Officer to BRFN/HWFN is to provide BRFN/HWFN with the action recorded at the 2024 May BRFN/HWFN - AECL - CNL Core Engagement Team meeting held in Hollow Water First Nation on 2024 May 02.	Email
2024 May 06	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator is to propose new dates for the CNL & BRFN/HWFN Milkweed walkdown. BRFN/HWFN Project Coordinator provided 2024 June 19 as preferred option.	Email
2024 May08	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator, BRFN/HWFN Consultant and BRFN Councillor is to request the names of attendees for Community Engagement Mushroom Picking event to be held on 2024 May 22 at CNL Whiteshell.	Email
2024 May 08	This email from BRFN/HWFN Consultant to CNL Indigenous Engagement Officer is to provide feedback on the WR-1 Draft BRFN/HWFN on IER Section 3.4.3.	Email
2024 May 08	These text messages between CNL Indigenous Engagement Officer and BRHW/HWFN Project Coordinator is to request action items from 2024 May 02 CNL- AECL - BRFN/HWFN Core Engagement team meeting.	Telephone

.Date	Event	Event / Activity
2024 May 09	This email from BRFN/HWFN Project Coordinator to CNL Indigenous Engagement Officer is to confirm the names of participants from Black River First Nation for the in person mushroom picking event to be held on 2024 May 22.	Email
2024 May 09	This email from BRHN/HWFN Project Coordinator to CNL Indigenous Engagement Officer is to provide CNL with the video recording of 2024 May 02 CNL- AECL - BRFN/HWFN Core Engagement team meeting.	Email
2024 May 14	This email from CNL Indigenous Relations Advisor to BRFN/HWFN Project Coordinator is to request an update on logistical information for tree planting event in BRFN/HWFN to be held on 2024 June 11 & 12, and the BRFN and HWFN high school graduations. BRFN/HWFN Project Coordinator provided logistical details and a presentation deck to be shared on 2024 June 15. A follow up email was sent on 2024 May 16 from CNL Indigenous Relations Advisor to BRFN/HWFN Project Coordinator.	Email
2024 May 15	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Manager and Hollow Water First Nation Councillor is to inform BRFN/HWFN that on 2024 February 15 CNL submitted an application to CNSC to renew the Whiteshell Laboratories site licence for a period of three years. CNL also noted that there will be a public hearing on this application held on 2024 October 23 and 24. CNL proposed that BRFN/HWFN review the Indigenous engagement section of the CNL draft Commission Member Document (CMD). CNL to submit a final CMD to the CNSC by 2024 July 18. CNL is preparing the CMD section on Indigenous engagement, which will be available for review from participants in 2024 June. CNL requested CMD review from BFN/HWFN by 2024 July 05 to make changes to the CMD before the submission deadline (2024 July 18).	Email
2024 May 15	This email from BRFN/HWFN Project Coordinator to CNL Indigenous Engagement Officer is to confirm the names of participants from Hollow Water First Nation for the in person mushroom picking event to be held on 2024 May 22.	Email
2024 May 15	These text messages from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator is to confirm the names of attendees for 2024 May 22 mushroom picking event to be held on WLRP off site in greater Whiteshell area.	Telephone
2024 May 16	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator is to provide an agenda for the in -person event to be held on 2024 May 22 and general best practices for mushroom collection. BRFN/HWFN Project Coordinator provided updates on event attendees for visitor passes.	Email
2024 May 21	These emails between CNL Indigenous Relations Advisor and BRFN/HWFN Consultant and BRFN/HWFN Project Coordinator is to discuss the logistics for the 2024 June 11 & 12 BRFN and HWFN tree planting events.	Email
2024 May 21	This email from CNL Indigenous Relations Advisor to BRFN/HWFN Project Coordinator is to provide BRFN/HWFN with the "First Nation and Métis Affairs Coordinator Student" employment opportunity with CNL. CNL shared the Job description, deadlines and link for application.	Email
2024 May 21	This telephone call from CNL Indigenous Relations Advisor to BRFN/HWFN Project Coordinator is to finalize logistic details for the Tree Planting event in BRFN/HWFN being held on 2024 June 11 & 12. Confirmed dates and times for BRFN/HWFN High School graduations provided.	Telephone
20204 May 22	This telephone call from CNL Indigenous Relations Advisor to BRFN/HWFN Project Coordinator is to confirm logistics and volunteer coordination for the 2024 June 11 & 12 Tree Planting events in BRFN and HWFN.	Telephone
2024 May 22	This in person event held on site at WLRP between BRFN/HWFN (including, Project Coordinator, Project Consultant, Black River First Nation Elders, Black River First Nation community members, Hollow Water First Nation community members) and CNL (including, Indigenous Engagement Officer, Environmental Specialists, Environmental technicians) is to conduct mushroom collection for environmental field sampling. The event provided and opportunity for CNL to learn about cultural practices and uses of the species in the WL area. The event included a tour of the WLRP collection analysis lab and produced an opportunity to share CNL sampling documents to support community based environmental monitoring and sampling collection activities and documentation.	In Person Meeting
2024 May 22	This email from BRFN/HWFN Project Coordinator to Black River First Nation Elders, Black River First Nation community members, Hollow Water First Nation community members and CNL is to thank everyone who participated in the in- person mushroom collection event held on 2024 May 22 at WLRP.	Email
2024 May 27	This telephone call from CNL Indigenous Relations Advisor to BRFN Councillor is to request contact information for the BRFN Fire Department for the in-community tree planting event to be held on 20204 June 11. BRFN Councillor provided guidance to the BRFN/HWFN Project Coordinator to liaise with the HWFN Councillor to provide logistical information, information regarding procedures and event attendees.	Telephone
2024 May 27	These emails between from CNL Indigenous Relations Advisor and BRFN/HWFN Project Coordinator is to the CNL Environmental Awards at the high school graduations to be held on 2024 June 22 for Powerview/Pine Falls and 2024 June 25 for Hollow Water First Nation. CNL and BRFN/HWFN coordinated logistics.	Email
2024 May 28	This virtual meeting between CNL (including, CNL Indigenous Relations Advisor and Indigenous Engagement Officer) and BRFN/HWFN (including, BRFN/HWFN Consultant) is to act as the BRFN/HWFN - CNL bi-weekly touch base meeting. Discussion included the logistical details for the tree planting events in Hollow Water First Nation on 2024 June 12 and Black River First Nation on 2024 June 11.	Email

.Date	Event	Event / Activity
2024 May 28	This email from CNL Indigenous Relations Advisor to BRFN/HWFN Project Coordinator is to provide a summary of the virtual meeting agenda items of the tree planting events in BRFN and HWFN on 2024 June 11 & 12 and to request confirmation of the names of the students who will receive the Environmental Award at the High School graduation to be held on 2024 June 25.	Email
2024 May 28	This telephone call from BRFN/HWFN Project Coordinator to CNL Indigenous Relations Advisor is to confirm remaining logistics for the tree planting events on 2024 June 11 & 12 as discussed in the Bi-weekly meeting.	Telephone
2024 May 29	This telephone call from BRFN/HWFN Project Coordinator to CNL Indigenous Relations Advisor is to confirm remaining logistics discussed in the virtual bi-weekly meeting held on 2024 May 28.	Telephone
2024 May 30	This email from BRFN/HWFN Project Coordinator to CNL Indigenous Relations Advisor is to provide a digital map of locations for the tree planting sites in Black River First Nation and Hollow Water First Nation for the events to be held on 2024 June 11 & 12.	Email
2024 June 04	CNL hosted the second annual in-person Regional Leaders Gathering held in Beausejour. This event was attended by Black River First Nation(including Chief, BRFN/HWFN Project Coordinator, BRFN/HWFN Project Manager, Waste Management Coordinator and Community Elder) Hollow Water First Nation (including Councillor, Prevention Land Based Coordinator, Income Assistance Coordinator) Peguis First Nation, SAFN, and CNL (including, Culture and Employee Experience Officer, General Manager of WL site, General Manager and WL Site License Holder, Director of End State Strategy, Environmental Analyst, Environmental Specialist, Manager of Regulatory Approval, Manager of Communication and Engagement, Facility Authority, Manager of Licensing and End State, Indigenous Engagement Officer, Indigenous Relations Advisor, Vice-President of Corporate Affairs, Vice-President of Environmental Remediation Management, Director of Indigenous Relations, and Consultant). The Regional Leaders Gathering is to facilitate discussions on CNL projects, Environmental Monitoring, and to gather feedback on Trenches and Land Use End State. The Regional Leaders Gathering included presentations on the WL End Use Strategy, CNL Environmental Monitoring Program, Keynote and fireside discussion highlighting Indigenous Participation.	In Person Meeting
2024 June 05	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator and BRFN/HWFN Waste Management Coordinator is to request the names of participants for the Milkweed Walkdown event to be held on 2024 June 19 at the Whiteshell site for the purpose of creating visitor passes for participants. CNL provided confirmation that lunch will be provided. BRFN/HWFN Project Coordinator to create list of names of confirmed participants and shared the poster to be distributed in community for the event.	Email
2024 June 07	This email from CNL Consultant to BRFN/HWFN Project Coordinator is to provide an invitation to a post event survey for the 2024 June 04 Regional Gathering held in Beausejour.	Email
2024 June 10	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator, Waste Management Coordinator and BRFN/HWFN Consultant is provide an update on the CNL lead for the tree planting events to be held in Black River First Nation on 2024 June 11th and Hollow Water First Nation on the 2024 June 12. BRFN/HWFN Project Coordinator provided maps with directions to band offices and school and arranged transport to community in CNL vehicle for 2024 June 11.	Email
2024 June 10	This email from CNL Indigenous Engagement Officer to BRFN/HWFN is to provide SAFN with CNL staff updates.	Email
2024 June 10	This email from CNL Indigenous Engagement Officer to BRFN/HWFN is to provide BRFN/HWFN with the draft Commission Member Document for the WL site re-license, and Indigenous Engagement Section for review and comment. CNL requested feedback by 2024 June 05.	Email
2024 June 11	This in person event held at Black River First Nation was attended by BRFN (including, BRFN/HWFN Project Coordinator and BRFN/HWFN Consultant and students from Black River Community School) and CNL (including Indigenous Engagement Officer, Environmental technicians, fire department personnel and health and safety personnel). The event is to provide an opportunity to plant trees with the students and host a BBQ for participants. A fire prevention demonstration was provided by CNL.	In Person Event
2024 June 10	This email from CNL Indigenous Engagement Officer to BRFN/HWFN is to provide BRFN/HWFN with the draft Commission Member Document (CMD) for the WL site re-license, and Indigenous Engagement Section for review and comment. CNL requested feedback by 2024 June 05.	Email
2024 June 11	This in person event held at Black River First Nation was attended by BRFN (including, BRFN/HWFN Project Coordinator and BRFN/HWFN Consultant and students from Black River Community School) and CNL (including Indigenous Engagement Officer, Environmental technicians, fire department personnel and health and safety personnel). The event is to provide an opportunity to plant trees with the students and host a BBQ for participants. A fire prevention demonstration was provided by CNL.	In Person Event
2024 June 13	This in person event held at Hollow Water Nation was attended by HWFN (including, BRFN/HWFN Project Coordinator and school students from Hollow Water school) and CNL (including, Indigenous Engagement Officer, Environmental technicians and Emergency Management Officer). This event is to provide and opportunity to plant trees and host a BBQ for participants.	In Person Event
2024 June 13	These text messages between CNL Indigenous Engagement Officer and BRHW/HWFN Project Coordinator is to confirm logistics for the BRFN/HWFN Tree Planting Days.	Telephone
2024 June 16	This email from BRFN/HWFN Project Coordinator to CNL Indigenous Engagement Officer to is to request CNLs sponsorship of the BRFN/HWFN golf tournament. CNL requested additional information. CNL noted not being able to sponsor a team entry but offered to sponsor the Treaty Days as whole.	Email

.Date	Event	Event / Activity
2024 June 18	This email from BRFN/HWFN Project Coordinator to CNL Indigenous Engagement Office is to provide CNL with the names of participants attending Milkweed walkdown event being held on 2024 June 19th at the WL site.	Email
2024 June 18	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations, and Governments is to inform them of the CNL ERM June Webinars on Douglas Point Decommissioning, Nuclear Power Demonstration Closure Project- Fact or Fiction, and the Facilities Decommissioning Projects Update.	Email
2024 June 19	This in person event held onsite at WLRP between BRFN/HWFN (including, BRFN/HWFN Project Coordinator and community member), SAFN and CNL (Including, Indigenous Engagement Officer and Environment Specialist and technician) is to conduct field monitoring and mapping activities for Milkweed locations.	In Person Event
2024 June 20	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations, and Governments is to inform them of the funding available through the Indigenous and Stakeholder Capacity Fund.	Email
2024 June 24	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator is to request permission to use the photo taken at the 2024 January BRFN/HWFN and SAFN Core Engagement Team meeting for the CNL Commission Member Document (CMD) for our 2024 Whiteshell site re-license. BRFN/HWFN confirmed the use of the photo for the CMD.	Email
2024 June 25	This email from CNL Director of Communications and Indigenous Engagement is to provide BRFN/HWFN with a letter on Staff Changes at the Whiteshell Site.	Email
2024 June 26	This email from BRFN/HWFN Consultant to CNL Indigenous Engagement Officer is to request a telephone call. CNL provided contact information.	Email
2024 June 26	This email from BRFN/HWFN Project Coordinator to CNL Indigenous Engagement Officer is to provide information for the upcoming Treaty Days in the community in early July and to request sponsorship for the Black River First Nation Treaty Days Golf Tournament.	Email
2024 July 02	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator is to extend and invitation to the WR-1 Bat Exit Survey to be held on 2024 July 18.	Email
2024 July 03	This virtual meeting between BRFN/HWFN (including, Consultant and Project Coordinator) and CNL (including, Indigenous Engagement Officer) is to serve as the weekly touch base meeting.	Virtual Meeting
2024 July 03	This email from CNL Indigenous Engagement Officer to BRFN is to provide sponsorship form for the Black River First Nation Treaty Days Golf Tournament to be held on 2024 July 25.	Email
2024 July 04	This email from CNL Indigenous Engagement Officer to BRFN/HWFN is to request to participate in the BRFN/HWFN Treaty Days events.	Email
2024 July 04	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Councillor, Project Coordinator and BRFN/HWFN Consultant is to provide the proposed agenda for the BRFN/HWFN Monthly Meeting to be held on 2024 July 10.	Email
2024 July 09	This virtual meeting between BRFN/HWFN (including, Consultant) and CNL (including, Indigenous Engagement Officer) is to serve as the weekly touch base meeting.	Virtual Meeting
2024 July 10	This virtual meeting between CNL (including, Indigenous Engagement Officers, Manager of Regulatory Approval, Director of End Use State Strategy), and BRFN/HWFN (including, Project Manager, Project Coordinator, and Lands Management in Training) is to act as the 2024 July Monthly Meeting. Discussion included community updates, upcoming in person event to be held at WL, CNL updates of the WL WR-1 site re-licensing, Trenches project engagement, review of CMD for the WL site re-licensing, BRFN and HWFN Treaty Days events, and feedback from the Regional Gathering.	Virtual Meeting
2024 July 10	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator is to provide a document with information about the WR-1 Bat Exit Survey with the purpose of creating a poster for community information of the event. BRFN/HWFN also provided the names of 3 participants.	Email
2024 July 10	This email from BRFN/HWFN Project Coordinator to CNL Indigenous Engagement Officer is to provide the contact information for the BRFN/HWFN Lands Manager in training.	Email
2024 July 10	This email from CNL Indigenous Engagement Officer to BRFN/HWFN is to provide the meeting information for the monthly meeting being held on 2024 August 14.	Email
2024 July 11	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Consultant is to request that BRFN/HWFN review and provide any feedback on the CMD for the WL Site re-licensing hearing to be held in 2024 October. CNL provided an explanation that the review of the CMD was drafted based on BRFN/HWFN's content the WR-1 IER, and this CMD draft is different and shorter than the IER section on engagement.	Email
2024 July 15	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator is to provide the actions recorded at the 2024 July 10 BRFN/HWFN – CNL Monthly Meeting.	Email
2024 July 16	This email from BRFN/HWFN Consultant to CNL Indigenous Engagement Officer is to inform CNL that BRFN/HWFM have no further updates for the Whiteshell Site Re-licensing CMD. CNL provided an update to inform BRFN/HWFN that their comments on the WR-1 EIR were used to write the CMD, and CNL thanked BRFN/HWFN for the follow-up.	Email

.Date	Event	Event / Activity
2024 July 16	This virtual meeting between BRFN/HWFN (including, Consultant) and CNL (including, Indigenous Engagement Officer) is to serve as the weekly touch base meeting. Discussion included School Program and availability of BRFN/HWFN Project Coordinator.	Virtual Meeting
2024 July 17	This email from CNL Indigenous Engagement Officer to HWFN Councillor is to follow up on a verbal conversation on 2024 June 13 to determine if HWFN would like CNL to attend Black Island Days to be held between 2024 July 21 and July 26.	Email
2024 July 17	This telephone call from HWFN Councillor to CNL Indigenous Engagement Officer is to extend an invitation to the Black Island Days event and provide logistics information to attend. CNL confirmed attendance.	Telephone Call
2024 July 17	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Consultant is to confirm the receipt of feedback on the CMD and to provide and update on the CMD documentation status, which has moved ahead prior to receiving feedback from BRFN/HWFN. CNL also informed BRFN/HWFN of the intended submission of the WL relicensing Indigenous Engagement Report (IER) for the hearing and provided a timeframe of mid/late August.	Email
2024 July 17	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Manager, Project Coordinator, Project Consultants, and Lands Manager in training, and AECL is to follow up on action item from the Monthly meeting and to extend the invitation for the Core Engagement Team meeting to be held in person at CNL's office in Pinawa on 2024 August 21. BRFN/HWFN confirmed date.	Email
2024 July 18	This in-person event held at WLRP between HWFN (including, Prevention Coordinator and Income Assistance Manager), SAFN and CNL (including, Environmental technicians, environmental specialist, and Indigenous Engagement Officer) to is conduct the WR-1 Bat Exit Survey.	In Person Event
2024 July 19	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Project Coordinator is to provide the action items from the 2024 July 10 Monthly meeting with BRFN/HWFN.	Email
2024 July 19	This email from CNL Indigenous Engagement Officer to HWFN Councillor is to confirm attendance to the Black Island Days in Hollow Water.	Email
2024 July 19	This telephone call from HWFN Councillor to CNL Indigenous Engagement Officer is to provide a timeframe for logistics to attend Black Island days on 2024 July 24.	Telephone
2024 July 23	This virtual meeting between BRFN/HWFN (including, Consultant and Project Coordinator) and CNL (including, Indigenous Engagement Officer) is to serve as the weekly touch base meeting. Discussion included availability of BRFN/HWFN Project Coordinator.	Virtual Meeting
2024 July 24	This in person event hosted by Hollow Water First Nation and attended by CNL Indigenous Engagement Officer is for the Black Island Days.	In Person Meeting
2024 July 19	This telephone call from HWFN Councillor to CNL Indigenous Engagement Officer is to provide a timeframe for logistics to attend Black Island days on 2024 July 24.	Telephone
2024 July 24	This email from CNL Indigenous Engagement Officer to HWFN Councillor is to thank HWFN for the invitation and participation of Black Island Days.	Email
2024 July 25	This email from CNL Indigenous Engagement Officer to BRFN/HWFN Consultant is to request confirmation to cancel the bi-weekly liaison touch base meetings until the BRFN/HWFN Project Coordinator returns to office. BRFN/HWFN Consultant agreed to postpone the meetings until the project Coordinator becomes available to attend.	Email
2024 July 29	This email from CNL Indigenous Engagement Officer to HWFN Councillor is to provide information on how to implement travel per diems and honoraria payments for HWFN participants to the WR-1 Bat Exit Survey held on 2024 July 18. CNL confirmed capacity.	Email

1.3.6 Black River First Nation (BRFN), Hollow Water First Nation (HWFN), and Brokenhead Ojibway Nation (BON) – Key Interests and Concerns

In the fall of 2020, the BON notified CNL of its decision to discontinue engagement with CNL at this time. CNL noted its continued interest in engaging with BON and re-establishing the relationship at a future date. CNL continues to share information on Project updates.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Business and Employment Opportunities			
Brokenhead Ojibway Nation (BON), Hollow Water First Nation (HWFN), and Black River First Nation (BRFN) expressed an interest in Canadian Nuclear Laboratories' (CNL's) procurement requirements for Indigenous businesses. Recognizing that no BRFN, HWFN or BON community members are currently employed at Whiteshell Laboratories (WL), the Nations also expressed an interest in further information regarding employment or business opportunities at the WL site, the potential for directly negotiated contracts with Indigenous businesses, and a concern about their ability to compete with larger businesses for opportunities at the Whiteshell Laboratories Closure Project (WLCP). This is a site-wide interest in enabling BON, HWFN, and BRFN members to participate in the socio-economic benefits resulting from the WL site and the WLCP.	Regarding the WL site's procurement requirements, CNL adjusted the evaluation criteria for competitive bids to encourage greater economic participation by contractors that are Indigenous owned or have Indigenous employees or subcontractors. This was also completed to help address the Nations' concern raised about their ability to compete with larger businesses for contracts at the site. As of 2021, CNL is working to develop an Indigenous procurement strategy to support greater participation of Indigenous owned business and support more Indigenous people in CNL's workforce. The Nations recommended that CNL meet with the Southeast Regional Development Corporation (SERDC) as the best method to explore First Nation capabilities and CNL procurement opportunities. CNL toured SERDC at the WL site, provided details on CNL's procurement requirements, and discussed opportunities for contracting and employment. As a result of engagement with SERDC, SERDC has partnered with Golder Associates Inc. to increase their ability to contract to CNL. In 2023 April, CNL and BRFN/HWFN signed a contribution agreement amendment. The CNL – BRFN/HWNF Contribution Agreement provides funding for multiple avenues including the Community Liaison position, working group meetings, capacity for reviewing the draft EIS sections, environmental monitoring, and the Core Engagement Team. These programs and initiatives have been identified by BRFN/HWFN as being important to address this concern. In 2023 March CNL shared the CNL Indigenous Relations Procurement Strategy with BRFN and HWFN and requested feedback. CNL received initial feedback at the April and May monthly meetings. Later in 2023, CNL received feedback from BRFN and HWFN on the Strategy. In 2024 January, CNL met with BRFN/HWFN to discuss their feedback. CNL is working to incorporate feedback received from all First Nations, Organizations and Governments into the first revision of the CNL Indigenous Relations Procurement Strategy. In 2023 September, CNL shared the Indigenous Vendors Portal, and Indigenous Business network; an initiative that stems from the CNL Indigenous Relations Procurement Strategy. To support the Nations' interest in employment opportunities at the site, CNL provided a list of employment opportunities at the WL site and added the Nations' representatives to the employment mailing list to receive updates on employment opportunities at the WL site.	Employment and business opportunities for Indigenous Nations and the Red River Métis (RRM) have been added to the Project VCs in Section 6.9.3: Valued Components. CNL updated Section 6.9.6.2.2: Secondary Pathways and added a discussion of Project impacts on the employment and contract opportunities for Indigenous communities and the Red River Métis (RRM) as well as mitigations that were put in place by CNL to help address socio-economic impacts resulting from the accelerated decommissioning schedule. CNL acknowledges contracting and employment opportunities as priority areas of interest for BON, HWFN, and BRFN and has revised Section 4.2.4.3.5: Interests and Concerns to reflect this.	CNL is addressing this interest/concern within the scope of the WR-1 project through CNL's commitments to BRFN/HWFN as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL and BRFN/HWFN will utilize the monthly working groups as an avenue for continued discussions around employment and procurement. To support the Nations' interest in employment opportunities at the site, CNL will continue to share updates on employment opportunities at the WL site. **Commitments Sought:** BRHWFN- 1: CNL will continue to engage on the matter of contracting and employment with the Nations. CNL will continue to work to remove the barriers community members may face in applying for positions and seek opportunities to increase Indigenous participation in the project.
BON expressed a concern that the Environmental Impact Statement (EIS) does not include data on BON's labour force, employment, and income conditions in the regional baseline and does not inherently link community well-being to the land. This is a project-specific concern by BON that the Whiteshell Reactor-1 (WR-1) Project does not adequately represent BON in the socio-economic assessment and may affect their socio-economic well-being or their Aboriginal and treaty rights.	BON provided a technical report on the Revised Draft EIS in 2020 September. In the report BON provide feedback on six Socio-economic VCs related to this topic CNL provided responses to BON's Technical Report on the Revised EIS for the Project in September 2020 and identified it would revise the EIS with current socio-economic data and include data from BON on labour force, employment, and income conditions where available. CNL linked Indigenous well-being to land use by including the concern that the Indigenous communities expressed about the Project potentially limiting their participation in land and resource use activities, which would affect their well-being through the ability to express their culture or exercise Aboriginal and treaty rights in the Community Well-Being Valued Component (VC). CNL then assessed this VC by analyzing any effects the presence of long-lived radioactive material in the In Situ Disposal (ISD) may have on community well-being by assessing the changes to the suitability of the site for future uses, the continued inability to exercise stewardship, and governance over land and resource management decisions. The assessment indicated that there would be no significant residual effects on the community well-being as a result of the presence of WR-1 ISD. In 2023 March CNL shared the CNL Indigenous Relations Procurement Strategy with BRFN and HWFN and requested feedback. CNL received initial feedback at the April and May monthly meetings. Later in 2023 CNL received feedback from BRFN and HWFN on the Strategy. In 2024 January CNL met with BRFN/HWFN to discuss their feedback. CNL is working to incorporate feedback received from all First Nations, Organizations and Governments into the first revision of the CNL Indigenous Relations Procurement Strategy.	CNL revised Section 6.9.5.2.3.2: Employment by Sector to include all available data on BON's labour force, employment, and income conditions into the regional baseline, as well as noting community well-being is inherently linked to the land. CNL revised Section 6.9.3: Valued Components to link Indigenous communities' well-being to their ability to express their culture and exercise Aboriginal and treaty rights though participation in land and resource use activities. Section 6.9.6.2.2: Secondary Pathways has been revised to make the effects of WR-1 on Indigenous well-being a secondary pathway, acknowledging that the long-term presence of nuclear materials in the region, along with other historical industrial developments in the local study area, had the potential to result in fear, stigma, and anxiety, and that psychosocial effects are legitimate impact pathways affecting the Indigenous community well-being.	CNL is addressing this interest/concern within the scope of the WR-1 project through CNL's commitments to BRFN/HWFN as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL and BRFN/HWFN will utilize the monthly working groups as an avenue for continued discussions around employment and procurement. **Commitments ought:** BRHWFN- 1: CNL will continue to engage on the matter of contracting and employment with the Nations. CNL will continue to work to remove the barriers community members may face in applying for positions and seek opportunities to increase Indigenous participation in the project.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Future Land Use and Tenure of the WL Site			
The Nations are interested in knowing if the WL site land and its resources will be safe, healthy, and available in the future for Indigenous people to re-establish connection to this land for traditional use or economic development using the seven generations approach to land stewardship subsequent to the decommissioning process. This is a site-wide interest.	Through engagement activities, CNL explained that the liability and land remain with the federal government (Atomic Energy of Canada Limited (AECL)). Decisions on future uses of the land of the whole site are not under the scope of the WR-1 Environmental Assessment (EA) and license amendment. The EIS (and other supporting studies) have demonstrated that there are no predicted impacts to the accessibility or safety of the WR-1 site in the long term based on several different future use scenarios, including self-sufficient Indigenous receptors. These findings, which will be confirmed by monitoring, may reduce concerns about loss of connection to land and water, and about food safety. In 2023 April, CNL and BRFN/HWFN signed a contribution agreement amendment. The CNL – BRFN/HWNF Contribution Agreement provides funding for multiple avenues including the Community Liaison position, working group meetings, capacity for reviewing the draft EIS sections, environmental monitoring, and the Core Engagement Team. These programs and initiatives have been identified by BRFN/HWFN as being important to address this concern. In 2020 September, as part of BON's Technical Report of the Revised Environmental Impact Statement for the Project they requested engagement with CNL and AECL to discuss future land use and tenure plans and agreements. In August 2021 and as response to the request, CNL invited BON to participate in discussions on future land use and end state when they begin. In 2023 May, CNL hosted a Land Use and End State Conference in community and shared a draft Land Use End State document for input. CNL began engaging on the future of the site more actively in 2023. The monthly working groups, and core engagement team meetings are an avenue by which CNL and BRFN/HWFN have discussions around updated LUES. In August 2023, CNL shared the draft Land Use and End State document for review and comment. CNL also shared that a plain language version of the report would also be published. BRFN/HWFN provided CNL with feedback on the LUES in November 2023. In June 2024 CNL hosted a CNL Regional Gathering of Leaders: Project Discussion 2024, which provided an overview of the End State Plan. BRFN/HWFN attended the event.	CNL revised Section 4.2.4.3.5: Interests and Concerns to discuss this interest and to indicate that CNL is committed to engagement on future land use and end-state planning of the site. Section 6.9.6.2.2: Secondary Pathways was also revised to describe the comprehensive relationship agreement signed with BRFN and HWFN to help communities participate in discussions on future land use of the WL site.	CNL is addressing this interest/concern within the scope of the WR-1 project, through CNL's commitments to BRFN/HWFN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to engage BRFN/HWFN on the LUES plans. **Next Steps:** CNL will continue to welcome BRFN / HWFN members to the Whiteshell Laboratories site to build an understanding of the site and potential future uses. CNL will facilitate discussions with the Nations, AECL, and other stakeholders on planning for the end state of the site, including use and access **Commitments Sought:** BRHWFN-2: While future land use and tenure is out of scope for the assessment for WR-1, CNL will be contacting the communities to participate in discussions on the site-wide end state. BRHWFN-3: CNL has acknowledged the historical lack of engagement on siting the Whiteshell Laboratories and will continue to facilitate dialogue between CNL, AECL, and the Nations in this regard via the Core Engagement team meetings, and the monthly meeting series CNL will continue to engage the Nations on the Project and closure of the WL site.
The Nations expressed an interest in discussions with the Federal Government about the future of the WL site and potential accommodation, because the WL site occupies a large parcel of land that was removed from Treaty 1 territory without adequate consultation, and the current proposal does not return it in its past condition for unrestricted traditional land use. Future land use decisions, therefore, have the potential to impact their Aboriginal and treaty rights. This is a site-wide interest.	CNL acknowledged that engagement practices in the past were below today's engagement standards and CNL and the Nations agreed that the primary duty to consult on this Project lies with the Crown (Canadian Nuclear Safety Commission (CNSC)). To help address historical concerns with WL siting and future land use, CNL is committed to helping facilitate discussions between CNL, AECL, and the Nations. In 2023 April, CNL and BRFN/HWFN signed a contribution agreement amendment. The CNL – BRFN/HWNF Contribution Agreement provides funding for multiple avenues including the Community Liaison position, working group meetings, capacity for reviewing the draft EIS sections, environmental monitoring, and the Core Engagement Team. These programs and initiatives have been identified by BRFN/HWFN as being important to address this concern. The monthly working groups, and core engagement team meetings are an avenue by which CNL and BRFN/HWFN have discussions around updated Land Use End State.	Section 4.2.4.3.5: Interests and Concerns was revised to discuss this interest and to indicate that CNL is committed to engagement on future land use and end-state planning of the site. Section 6.9.5.2.1.1: Indigenous Community Perspectives on and Observations of the Whiteshell Laboratories Site was created to recognize First Nations' and RRM's perspectives on the establishment of the WL site.	CNL is addressing this interest/concern within the scope of the WR-1 project, through CNL's commitments to BRFN/HWFN as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL will continue to welcome BRFN / HWFN members to the Whiteshell Laboratories site to build an understanding of the site and potential future uses. CNL will facilitate discussions with the Nations, AECL, and other stakeholders on planning for the end state of the site, including use and access **Commitments Sought:** BRHWFN-2: While future land use and tenure is out of scope for the assessment for WR-1, CNL will be contacting the communities to participate in discussions on the site-wide end state. BRHWFN-3 CNL has acknowledged the historical lack of engagement on siting the Whiteshell Laboratories and will continue to facilitate dialogue between CNL, AECL, and the Nations in this regard. CNL will continue to engage the Nations on the Project and closure of the WL site.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
BRFN and HWFN wanted to know more about potential plans for a small modular reactor on the WL site. Use of the site for this purpose has the potential to impact their Aboriginal and treaty rights and to prevent or delay restoration of the site to natural conditions. BRFN and HWFN said it was essential that they were engaged as part of this process. This is a site-wide interest.	CNL discussed a potential on-going industrial use and other areas available for agriculture or recreation. A small modular reactor could potentially fit in the proposed end state in the area identified as “industrial use”. CNL explained that any new nuclear project on the WL site, such as a small modular reactor, would need to go through a full licensing process that would include Indigenous engagement. CNL provided BRFN and HWFN with the contact of the Regeneration Partnership Committee who is looking into the potential for having a small modular reactor on site. The monthly working groups, and core engagement team meetings are an avenue by which CNL and BRFN/HWFN have discussions around updated Land Use End State. CNL began engaging on the future of the site more actively in 2023. The monthly working groups, and core engagement team meetings are an avenue by which CNL and BRFN/HWFN have discussions around updated LUES. In August 2023, CNL shared the draft Land Use and End State document for review and comment. CNL also shared that a plain language version of the report would also be published. BRFN/HWFN provided CNL with feedback on the LUES November 2023. June 2024 CNL hosted a CNL Regional Gathering of Leaders: Project Discussion 2024 which provided an overview of the End State Plan and sought consultation on 3 options for low-medium level nuclear waste management.	Section 4.2.4.3.3: Interests and Concerns was revised to include a commitment that CNL will engage the Nations on the land use and end state of the site. Section 6.9.6.2.2: Secondary Pathways was revised to include a description of potential small modular reactors at the WL site and to state that any such development would require a separate review and approval by CNSC, which would involve Indigenous consultation.	This interest/concern falls outside the scope of the WR-1 Project.
Potential Impacts on Winnipeg River Water Quality			
The Nations expressed a concern that the WL site experienced radiological releases in the past, as well as the potential for the Project to release hazardous and radiological materials into the Winnipeg River, which would endanger human and ecological health. The Nations’ holistic worldview highlights the site’s connection to waters and beings along the river system, and the potential for wide-spread impacts from site activities. The Winnipeg River is part of the Nations’ traditional territories where the Nations exercise Aboriginal and treaty rights. Most of the community’s concerns about the historical spills were that people in the community were not aware of these until recently and that past releases from the site have reduced the Nations’ confidence in scientific predictions about its future safety. This is a project-specific and a site-wide concern.	In the fall 2017 BON/ BRFN/ HWFN Engagement Update, and through regular engagement, CNL explained that the Project assessed the effects resulting from maximum potential releases of radionuclides from the WR-1 disposal facility, taking into account existing sediment contamination from historical releases, and found that there were no expected health effects, as all potential human and ecological doses were orders of magnitudes below regulatory limits. CNL also confirmed that while historical releases were typically liquid, the WR-1 waste consists primarily of reactor metals, and the release of radiological and hazardous materials is controlled by the slow metals corrosion rate. The Project therefore cannot release significant volumes of liquid waste that would be mobile in the environment and endanger human or ecological health. Movement of the radionuclides from the WR-1 facility through the environment would be detected through groundwater monitoring long before reaching the river or any receptors. CNL explained that the assessments for the Project use conservative estimates for all aspects of the Project, ensuring that the worst case scenarios are assessed. The assessment indicated that even using a conservative modeling approach, human and ecological health will not be endangered in the future by the presence of WR-1. CNL explained that there were releases to the river in the past, and that the river sediments were investigated and assessed during the 2001 Comprehensive EA. The assessment concluded that using the most conservative methods, doses to humans and non-human biota are below accepted guidelines. The analysis methodology and results were peer-reviewed and are available in the open publication of the Comprehensive Study Report. In the fall 2017 BON/ BRFN/ HWFN Engagement Update, and through regular engagement, CNL has provided the Nations with a short summary report of the historical spills, which have now been shared with the Core Engagement Teams and CNL is working on preparing infographics for the communities to better communicate information like this to community members in the future. The Summary report on the historic spills consisted of information on an independent task force that consisted of Sagkeeng First Nation, Indian and Northern Affairs, Health Canada, and Environment Canada that assessed the impact from WL site. In its 1995 report, the Task Force concluded that *“it is unlikely that the AECL Whiteshell Laboratories has ever posed a significant threat to the health of Sagkeeng residents, nor is there apparently any prospect of such a threat in the future.”* The CNSC conducted an independent monitoring campaign In 2017 with assistance from Sagkeeng First Nation. This independent program included collecting and analyzing fish caught near Sagkeeng First Nation. The results of the assessment conclude that the public and the environment in the vicinity of WL are protected and there are no expected health impacts. CNL also explained how it proposes to use future groundwater monitoring to confirm the modeling predictions and verify that the releases to the environment pose no danger. In 2023 April, CNL and BRFN/HWFN signed a contribution agreement amendment. The CNL – BRFN/HWNF Contribution Agreement provides funding for multiple avenues including the Community Liaison position, working group meetings, capacity for reviewing the draft EIS sections, environmental monitoring, and the Core Engagement Team. These programs and initiatives have been identified by BRFN/HWFN as being important to address this concern. The monthly working group meetings and Core Engagement Team meetings are an avenue by which CNL and BRFN/HWFN have discussions around information sharing and the WR-1 Project.	CNL had previously assessed past releases from the WL site and included a summary in Section 6.7: Human and Ecological Health of the EIS. The radiological inventory was confirmed to be localized in the reactor core metals and is presented in Section 3.3.3: Waste Classification, Inventory and Characterization of the EIS. CNL had already identified water quality as a VC (Section 6.5: Aquatic Environment of the EIS) and considered various pathways for radionuclide release in Section 6.7: Human and Ecological Health of the EIS. CNL expanded the description of the proposed monitoring program in Section 11: Summary of Monitoring and Follow-up Programs of the EIS and included Section 11.4 Indigenous Engagement and Participation in Environmental Monitoring, which includes the CNL commitment to involve BRFN and HWFN in long-term monitoring at the WL site.	CNL is addressing this interest/concern within the scope of the WR-1 project, through CNL’s commitments to BRFN/HWFN as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL will work with the Community Liaison and the Nations to share monitoring results/outcomes to the communities in ways that are appropriate for community distribution. CNL is facilitating opportunities for members of the Nations to take part in monitoring activities. CNL will engage with BRFN / HWFN to explore the development and implementation of an Indigenous-led independent monitoring program by BRFN / HWFN. The parties will work collaboratively to determine the most effective way to share monitoring results with the Communities. CNL will provide resources to support ongoing participation in monitoring activities. CNL will facilitate opportunities for members of the Nations to take part in monitoring activities, including an Indigenous-led independent monitoring program for BRFN / HWFN. **Commitments Sought:** BRHWFN-7: CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. BRHWFN-8: CNL has committed to ongoing engagement with the Nations regarding environmental monitoring, including further discussion about the concept of Indigenous-led independent monitoring.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
The Nations were concerned that the close proximity of the WL site and the Project to the river will contaminate the river through contamination of the soil. They were also interested in the CNL spill detection process. The Nations want to ensure their traditional lands as well as their Aboriginal and treaty rights to use lands, water, and resources are not impacted by site and Project activities. Again, the Nations' holistic worldview highlights the site's connection to waters and beings along the river system, and the potential for wide-spread impacts from site activities. Past releases have reduced the Nations' confidence in scientific predictions about its future safety. This is both a site-wide and project-specific concern.	CNL explained that the Project provides multiple barriers to ensure that the environment and the river remain safe and that the EIS assesses the Project's impact on the river and determined it will remain safe. CNL explained that the soil properties at the WL site determine how well releases are contained in the soil and that for ISD of WR-1, contaminant releases are primarily limited by a significant portion of the contaminants being contained within the metals of the reactor, which corrode very slowly. CNL further explained that other barriers (such as the low-permeability clays surrounding the WR-1) provide additional resistance to contaminant movement. CNL explained that groundwater monitoring wells around the ISD facility would be the primary means of monitoring for contaminant releases. CNL has modelled how much contaminants will be released during normal life of the facility, and if contaminants are being released in quantities of concern above the expected amount, this would show up in the groundwater monitoring and remedial actions would be taken. With respect to the rest of the WL site, all radioactive waste at the site is safely and securely stored in the site's Waste Management Area (WMA) and are covered by the 2001 Comprehensive Study Report, which assessed their impact on the river and determined it will remain safe. In 2023 April, CNL and BRFN/HWFN signed a contribution agreement amendment. The CNL – BRFN/HWNF Contribution Agreement provides funding for multiple avenues including the Community Liaison position, working group meetings, capacity for reviewing the draft EIS sections, environmental monitoring, and the Core Engagement Team. These programs and initiatives have been identified by BRFN/HWFN as being important to address this concern. The monthly working group meetings and Core Engagement Team meetings are an avenue by which CNL and BRFN/HWFN have discussions around the CNL Environmental Monitoring Program. Additionally, in both 2023 and 2024, CNL has extended an open invite to BRFN/HWFN to participate in any Environmental Monitoring Field Sampling occurring on the WL site. To date, BRFN/HWFN participants have attended numerous monitoring activities including mushroom collection. At the 2024 January Core Engagement Team meeting CNL presented its proposed plain language quarterly environmental monitoring report, which will be shared with the nations on a quarterly basis. CNL received feedback from BRFN/HWFN, on additions that would be meaningful for the communities to have related to environmental monitoring results. CNL and will continue to work with BRFN/HWFN on the development of future plain language quarterly environmental monitoring reports. Additionally, CNL continues to share timely Community Bulletins, and disclosures to support the increased confidence towards CNL.	CNL confirmed that the assessment predicts no impact to the river in Section 6.4.2.7.2: Application Case Results. Section 6.3: Geological and Hydrogeological Environment of the EIS confirms the low permeability of the surrounding geosphere. CNL also assessed the likelihood and consequence of spills in Section 7.3.3: Material Handling Accidents of the EIS and confirmed that if spills do occur during closure activities, CNL has sufficient experience and controls in place to limit negative effects on human health and the environment. CNL expanded the description of the proposed monitoring program in Section 11: Summary of Monitoring and Follow-up Programs of the EIS and included Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring, which includes the CNL commitment to support BRFN and HWFN in long-term monitoring at the WL site.	CNL is addressing this interest/concern within the scope of the WR-1 project, through CNL's commitments to BRFN/HWFN as referenced in the WR-1 Environmental Impact Statement Commitments. **Next Steps:** CNL will work with the Community Liaison and the Nations to share monitoring results/outcomes to the communities in ways that are appropriate for community distribution. CNL is facilitating opportunities for members of the Nations to take part in monitoring activities. CNL will engage with BRFN / HWFN to explore the development and implementation of an Indigenous-led independent monitoring program by BRFN / HWFN. The parties will work collaboratively to determine the most effective way to share monitoring results with the Communities. CNL will provide resources to support ongoing participation in monitoring activities. CNL will facilitate opportunities for members of the Nations to take part in monitoring activities, including an Indigenous-led independent monitoring program for BRFN / HWFN. **Commitments Sought:** BRHWFN-7: CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. BRHWFN-8: CNL has committed to ongoing engagement with the Nations regarding environmental monitoring, including further discussion about the concept of Indigenous-led independent monitoring.

Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
The Nations expressed that some of their primary concerns with the Project relate to the potential for the contamination of groundwater which, due to its close proximity to the Winnipeg River, could also contaminate the river. The Nations exercise their Aboriginal and treaty rights to use lands and resources along the Winnipeg River and adjacent lands. The Nations have recommended independent Indigenous-led monitoring to confirm and build trust in scientific monitoring results. This is a project-specific concern.	Since 2019 CNL has hosted the Nations on site for tours six times. During site tours with the Nations, and in the in the fall 2017 BON/ BRFN/ HWFN Engagement Update, CNL explained that the Project incorporates multiple barriers to ensure the river remains safe and the EIS assesses the Project's impact on the river and determined it will remain safe. In their Technical Report BON re-enforced the importance of water and protecting it and shared many comments and recommendations pertaining to water. Key themes included the potential for future groundwater contamination, recommendation for more wells for groundwater testing, concerns about proper sealing of conduits, and that the Proponent develop closure-specific runoff control measures, as well as sediment and erosion control measures, to minimize site surface water and sediment entering the river. On August 16, 2021, CNL provided responses to questions from BON's Technical Report of the Revised Environmental Impact Statement for the Project. CNL provided additional rational and clarity on specific topics under this theme. This did not result in any updates to the revised draft EIS. During the institutional control period, surface water and ditch system water is planned to be sampled on a semi-annual basis at one upstream and two downstream locations, with frequency of recurrence being assessed based on the data collected. Predicted groundwater concentrations of non-radiological contaminants were screened against various federal and provincial drinking and aquatic life water quality guidelines, with cadmium, HB-40, lead, and xylene being the only contaminants requiring further investigation. Further investigation identified that the predicted groundwater concentrations would be protective of humans and animals. Groundwater concentrations of radionuclides were not directly assessed as there is no realistic pathway for humans or animals to come into contact with contaminated groundwater; however, river water concentrations were assessed and shown to be protective of humans and animals. The unlikely scenario of a farmer having a groundwater well halfway between WR-1 and the Winnipeg River was assessed as an upset conditions and was found be acceptable. CNL has committed to adding additional groundwater monitoring well(s) between WR-1 and the river as a result of Indigenous engagement and welcomes a discussion with the Nations on preferred locations. CNL has prepared a memo that includes a complete list of openings and services that penetrate through the building foundation, material recommendations, and recommended procedures to sever these services and seal the penetrations. This memo will guide the contractor responsible for the grout filling of the WR-1 building, who will prepare detailed engineering designs to execute this work. During initial engagement in late 2016, and early 2017, CNL explained that that during closure activities, there is a very low potential for the transport of uncontrolled site runoff to the Winnipeg River. Any liquid effluent collected inside the WR-1 building during decommissioning activities will be held, tested, and processed by the Low Level Liquid Waste Treatment System. Any effluent coming through groundwater sumps is routed through the storm water system to the outfall station, where all liquid effluent from the WL site is sampled and tested. Surface water from around the WR-1 building is intercepted by a series of road gutters, where it is captured and routed through the site storm water system. After the WR-1 building systems are taken offline, any construction sump water will be collected and tested prior to release. At community meetings and site tours, CNL has explained the proposed decommissioning process and how the proposed ISD facility uses many barriers to safely contain the waste. In 2023 April, CNL and BRFN/HWFN signed a contribution agreement amendment. The CNL – BRFN/HWNF Contribution Agreement provides funding for multiple avenues including the Community Liaison position, working group meetings, capacity for reviewing the draft EIS sections, environmental monitoring, and the Core Engagement Team. These programs and initiatives have been identified by BRFN/HWFN as being important to address this concern. Additionally, in both 2023 and 2024, CNL has extended an open invite to BRFN/HWFN to participate in any Environmental Monitoring Field Sampling occurring on the WL site. To date, BRFN/HWFN participants have attended numerous monitoring activities including mushroom collection. At the 2024 January Core Engagement Team meeting CNL presented its proposed plain language quarterly environmental monitoring report, which will be shared with the nations on a quarterly basis. CNL received feedback from BRFN/HWFN, on additions that would be meaningful for the communities to have related to environmental monitoring results. CNL and will continue to work with BRFN/HWFN on the development of future plain language quarterly environmental monitoring reports.	CNL confirmed that the health of the Winnipeg River and those who depend on it is a VC for the Project and was determined to be safe through the assessment of: ▪ Section 6.4.2 (Surface Water Quality) ▪ Section 6.5 (Aquatic Environment) ▪ Aquatic biota in Section 6.7.2.7.2 (Application Case – Post-closure Phase). ▪ Health of humans that consume aquatic biota, drink Winnipeg River water, and may be exposed to groundwater through a well in an unlikely case in Section 6.7.1.7.2 (Application Case – Post-closure Phase). CNL added Section 11.4 (Indigenous Engagement and Participation in Environmental Monitoring), which includes CNL's commitment to support BRFN and HWFN's participation in long-term monitoring at the WL site, as well as commitments to improve CNL's environmental monitoring program by providing additional groundwater well(s) and sampling and monitoring of country harvested food.	CNL is addressing this interest/concern within the scope of the WR-1 project, through CNL's commitments to BRFN/HWFN as referenced in the WR-1 Environmental Impact Statement Commitments. **Next steps:** CNL will work closely with the First Nations and the Manitoba Métis Federation to support their involvement in environmental monitoring at the Whiteshell site. This initiative will extend beyond the timeline and scope of the environmental assessment for WR-1 and will be a part of the larger site environmental remediation Project. CNL has committed to ongoing engagement with the Nations regarding environmental monitoring, including further discussion about the concept of Indigenous-led independent monitoring. CNL will continue to share and invite input from BRFN / HWFN on annual monitoring plans. Where possible, CNL will incorporate Indigenous perspectives and approaches in shaping their own monitoring program on site. CNL will facilitate opportunities for members of the Nations to take part in monitoring activities. CNL will work with the Community Liaison and the Nations to share monitoring results/outcomes to the communities in ways that are appropriate for community distribution. CNL will provide reasonable funding for the development and implementation of an Indigenous-led independent monitoring program by BRFN / HWFN. **Commitments Sought:** BRHWFN-7: CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. BRHWFN-8: CNL has committed to ongoing engagement with the Nations regarding environmental monitoring, including further discussion about the concept of Indigenous-led independent monitoring.

1.3.7 Wabaseemoong Independent Nations Engagement

Date	Activity	Attendance	Description	Key EA Topics[4]

				Baseline Conditions	Alternative Means	Project Components	Effects assessment[5]	Proposed Mitigation Measures	Residual Effects	Follow-up Monitoring Program	Aboriginal and Treaty Rights / Traditional Land Use	Specific Topics of Interest	Engagement Methods
June 9, 2021	Phone Call	1 representative from Wabaseemoong Independent Nations 1 representative from CNL	Wabaseemoong's representative updated CNL on their participation in the Indigenous Advisory Committee, and agreed to join as an observer until permission from the Chief is received. CNL requested a timeline for the review of the Summary Table of Interests and Concerns, Wabaseemoong confirmed that the review could be completed by the end of the week. CNL also offered capacity funding to support the review.										✓
July 20, 2021	Teleconference	1 representative from Wabaseemoong Independent Nations 2 representatives from CNL	CNL and Wabaseemoong Independent Nations met via teleconference and walked through the community's summary table of interests and concerns. The community representative provided feedback during the meeting which was also incorporated during the meeting.	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
July 22, 2021	E-mail	1 representative from Wabaseemoong Independent Nations 2 representatives from CNL 1 representative from CNSC	CNL provided a revised copy of the community's summary of interests and concerns table to the community to show how CNL had incorporated the community's feedback from the July 20th, 2021 meeting.										✓
July 23, 2021	Phone Call	1 representative from Wabaseemoong Independent Nations 1 representative from CNL	CNL provided a revised copy of the community's list of valued component to the community to show how CNL had incorporated the community's feedback from a phone call earlier that day, July 23, 2021.										✓
July 23, 2021	E-mail	1 representative from Wabaseemoong Independent Nations 2 representatives from CNL 1 representative from CNSC	CNL provided a revised copy of the community's list of valued component to the community to show how CNL had incorporated the community's feedback from a phone call earlier that day, July 23, 2021.				✓						
September 9, 2021	E-mail	CNL Wabaseemoong Independent Nations	CNL sent Wabaseemoong Independent Nations a thank you letter for their participation in verifying that CNL had adequately characterized their interests and concerns.										✓

Date	Event	Event / Activity
Wabaseemoong Independent Nation (WIN)		
2022 October 04	This email from a CNL Administrative Assistant to WIN Information Resource Officer is to provide WIN with attached the letter from Whiteshell General Manager in regard to "Canadian Nuclear Laboratories (CNL) Submission of Whiteshell Laboratories 2021 Annual Compliance Monitoring Reports" and the following reports: Whiteshell Laboratories-509243-ACMR-2021 - Environmental Monitoring in 2021 at Whiteshell Laboratories, Rev.0. Whiteshell Laboratories-509246-ACMR-2021 - 2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories, Rev.0, and Whiteshell Laboratories-514300-ACMR-2021 - Whiteshell Annual Compliance Monitoring Report for 2021, Rev.1	Email
2022 October 19	This email from CNL Indigenous Engagement Contractor to WIN Information Resource Officer is to inform WIN that CNL has made some changes and updates to the EIS based on recent feedback from the CNSC. CNL noted it will be sending WIN relevant portions of Section 4 and the Interests and Concerns Table.	Email
2022 October 21	This email from Indigenous Engagement Contractor to WIN Information Resource Officer is to provide the WIN relevant portions of Section 4 and the updated appendices can be found, for WIN review and validation. CNL requested a meeting to discuss further.	Email
2022 November 03	This email from CNL Indigenous Engagement Contractor to WIN Information Resource Officer is to follow-up on CNL's email sent on 2022 October 21. CNL looked to discuss any thoughts or concerns WIN may have on the updates to the EIS. CNL proposed a meeting to discuss further.	Email
2022 November 11	This email from CNL Indigenous Engagement Contractor to WIN Information Resource Officer is to follow-up on CNL's email sent on 2022 October 21. CNL looked to discuss any thoughts or concerns WIN may have on the updates to the EIS. CNL proposed a meeting to discuss further. CNL also noted CNL has been moving through the regulatory process since 2016 and with these updates CNL will be resubmitting the EIS to the Canadian Nuclear Safety Commission (CNSC), anticipated before the year's end. At that time, CNL anticipates the EIS will be accepted for CNSC Technical Review, which will involve Indigenous representatives, and wanted to ensure WIN validation and verification through their review of the EIS. CNL also noted a new Indigenous Relations Advisor had joined the CNL team and provided their contact information.	Email
2022 November 23	This email from CNL Indigenous Engagement Contractor to WIN Information Resource Officer is to follow-up on CNL's email sent on 2022 October 21. CNL noted requested feedback by 2022 November 23. CNL noted that they continue to finalize EIS updates and will be resubmitting the EIS soon, moving the EIS into the Technical Review Process if accepted by the CNSC. CNL indicated the importance of WIN Verification on the interest and concerns they captured.	Email
2022 December 05	This email from CNL Indigenous Engagement Contractor to WIN Information Resource Officer is to follow-up on CNL's email sent on 2022 October 21. CNL noted requested feedback by 2022 November 23. CNL noted that they continue to finalize EIS updates and will be resubmitting the EIS soon, moving the EIS into the Technical Review Process if accepted by the CNSC. CNL indicated the importance of WIN Verification on the interest and concerns they captured. CNL noted continued updates on the progress of the EIS submission.	Email
2022 December 16	This email from CNL Indigenous Engagement Contractor to WIN Information Resource Officer and Chief is to inform WIN that yesterday afternoon CNL submitted an updated draft Environmental Impact Statement (EIS) for the proposed in situ disposal of the WR-1 reactor.	Email
2023 January 16	This email from CNL Indigenous Engagement Contractor to WIN Resources Information Officer is to inform WIN that on Friday January 13, 2023, CNL received a letter from the CNSC informing them that the EIS for the WR-1Project has been accepted for Technical Review.	Email
2023 March 10	This email from CNL Indigenous Engagement Contractor to GCT#3 is to provide GCT#3 with a copy of the CNL Indigenous Relations Procurement Strategy. CNL noted that in response to Call to Action #92 in the Truth and Reconciliation report to actively promote economic opportunity for Indigenous Businesses, CNL has developed the Indigenous Relations Procurement Strategy. AECL, the federal Crown corporation that provides oversight of CNL, has reviewed and endorsed the Strategy. CNL offered a meeting to discuss this further.	Email
2023 April 11	This email CNL Indigenous Relations Advisor to WIN Resource Information Officer is to provide more information on the upcoming webinars in 2023 May and to confirm that Wabaseemoong Independent Nation is still not interested in engagement on the Whiteshell Laboratories restoration project. WIN Resource Information Officer confirmed their engagement with CNL through Grand Council treaty #3.	Email
2022 June 14	This email from CNL Consultant is to all Land Use End State Conference attendees on behalf of CNL to provide them with an update on the Land Use End State Plan to incorporate attendees' feedback.	Email
2023 July 04	This email from CNL Indigenous Relations Advisor to actively engaged Indigenous Nations, communities, organizations, and Governments is to provide them with the updated Land Use End State Plan. CNL requested any comments be sent to CNL by the end of 2023 August.	Email
2023 July 13	This email from CNL Indigenous engagement coordinator to GCT#3 Is to provide GCT#3 with a draft agenda for the 2023 18 July monthly meeting, WIN confirmed receipt of the meeting agenda	Email
2023 July 21	This email from CNL Indigenous Engagement Coordinator to WIN Resource Information Officer is to invite them to the 2023 September 07 Industry Day at the CRL site.	Email

Date	Event	Event / Activity
2023 July 21	This email from CNL Indigenous Engagement Coordinator to WIN Resource Information Officer is to invite them to a meeting to discuss WIN Resource Information Officer commitments. WIN confirmed meeting date for 2023 August 09.	Email
2023 July 27	This email from CNL Indigenous Engagement Advisor to WIN Resource Information Officer is to confirm that WIN is included in the job posting distribution list.	Email
2023 August 09	WIN Resource Information Officer did not attend the scheduled meeting to discuss the WIN WR-1 Draft Commitment List.	Virtual Meeting
2023 August 10	This email from CNL Indigenous Relations Advisor to WIN Resource Information Officer is to provide them with a copy of the WIN WR-1 Draft Commitments list as WIN did not attend the 2023 August 09 CNL-WIN meeting.	Email
2023 September 19	This email from CNL Indigenous Engagement Coordinator to all engaged Indigenous Nations, communities, organizations, and Governments is to provide the links to the newly launched CNL Indigenous Vendors Portal, and Indigenous Business network; an initiative that stems from the CNL Indigenous Relations Procurement Strategy.	Email
2023 September 19	This virtual meeting held between CNL (Indigenous Relations Advisor, Indigenous Engagement Coordinator, manager of Communications and Engagement, Environmental Specialist, Manager Licensing and End State and Administrative Assistant) and WIN (including, WIN Resource Information Officer) and GCT#3 (including, Junior Policy Analyst) is to act at the September monthly meeting. Discussion included, the CNL Whiteshell Safety Stand Down, WR-1 Update, Land Use and End State Updates, Independent Environmental Monitoring Program, Communities Update, and an update from Wabaseemoong.	Virtual Meeting
2023 September 20	This email from CNL Indigenous Engagement Coordinator to all engaged Indigenous Nations, communities, organizations, and Governments is to provide the job posting for the Director of Indigenous Relations.	Email
2023 October 05	This email from CNL Indigenous Engagement coordinator to all engaged Indigenous Nations, communities, organizations, and Governments is to provide the 6-month update/ feedback request for the Indigenous Relations Procurement Strategy. CNL requested to meet in 2023 November to incorporate feedback.	Email
2023 October 11	This email from CNL Indigenous Engagement coordinator to all engaged Indigenous Nations, communities, organizations and Governments is to provide the posting for the CNL Indigenous Relations Advisor Roles and the links to apply.	Email
2023 October 20	This email from CNL Indigenous Engagement coordinator to all engaged Indigenous Nations, communities, organizations and Governments is to provide them with the importance notice of CNLs Administrative Penalty from the CNSC. CNL attached a link to the CNSC Public disclosure and provided information in a PDF.	Email
2023 November 01	This email from CNL Indigenous Engagement coordinator to all engaged Indigenous Nations, communities, organizations and Governments who CNL had not already coordinated a review meeting is to provide the 6-mont update/ feedback request for the Indigenous Relations Procurement Strategy. CNL requested to meet in 2023 November to incorporate feedback. WIN noted a lack of capacity as WIN is currently going through Chief and Council elections. CNL offered to touch-base in the new Year.	Email
2023 November 01	This email from CNL Indigenous Engagement coordinator to WIN Resource Information Officer is to request a meeting to discuss the WR-1 Commitment List. CNL also noted that if WIN was happy with the draft commitment list presented, WIN could make the verification via email.	Email
2023 November 20	This email from CNL Indigenous Engagement coordinator to WIN Resource Information Officer is to follow-up to request a meeting to discuss the WR-1 Commitment List. CNL also noted that if WIN was happy with the draft commitment list presented, WIN could make the verification via email.	Email
2023 November 21	This email from CNL Indigenous Engagement coordinator to all engaged Indigenous Nations, communities, organizations and Governments is to provide them with an invite to the 2023 December 19 Public Liaison Community meeting being held Virtually.	Email
2023 December 04	This email from CNL Manager, Communications and Engagement to all engaged Indigenous Nations, communities, organizations, and Governments is to inform them of CNLs intention to begin exploring options and meaningful input on the cleanup of some of the waste facilities in the near future.	Email
2024 January 02	This email from CNL Indigenous Engagement coordinator to WIN Resource Information Officer is to request a meeting to discuss the WR-1 Commitment List. CNL also noted that if WIN was happy with the draft commitment list presented, WIN could make the verification via email.	Email
2024 January 09	This email from CNL Indigenous Engagement Coordinator to all engaged Indigenous Nations, communities, organizations and Governments is to provide the CNL posting for the role of Indigenous Engagement officer.	Email
2024 January 11	This email from CNL Indigenous Engagement Coordinator to all engaged communities is to notify them of the change in leadership at the Whiteshell Laboratories site.	Email
2024 January 31	This email from CNL Indigenous Engagement Coordinator to all engaged Indigenous Nations, communities, organizations, and Governments is to provide the link for the CNL Public Disclosure Notice.	Email

Date	Event	Event / Activity
2024 February 09	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations and Governments is to provide them with an information Bulletin on Routine Maintenance Work Restarting at Whiteshell Laboratories Site.	Email
2024 February 13	This email from CNL Indigenous Engagement Officer to all engaged communities is to invite them to the 2024 February 20 ERM Bi-monthly webinars on NPD and the WLRP.	Email
2024 March 11	This email from CNL Indigenous Engagement Officer to WIN is to inform them of the CNL Whiteshell Laboratories Licence Renewal. CNL provided links to the CNSC's Notice of Hearing, and information on the CNSC's Participant Funding Program. CNL also proposed a meeting to discuss further if the community is interested.	Email
2024 March 20	This email from CNL Indigenous Engagement Officer to WIN is to provide WIN First Nation with a copy of the Indigenous Engagement Report (IER). CNL looked to verify that the submitted IER reflects the understanding of both WIN and CNL on WR-1 engagements. CNL requested verification by 2024 April 17.	Email
2024 April 03	This email from CNL Indigenous Engagement Officer to WIN is to advise of CNLs webinar on Gentilly-1 Decommissioning Project and the Whiteshell Laboratories Restoration Program on 2024 April 09. Registration links provided.	Email
2024 April 04	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations and Governments, Organization, and Governments is to inform them of the funding for Indigenous Capacity Support, of the CNSC's Indigenous and Stakeholder Capacity Fund.	Email
2024 April 05	This email from CNL Indigenous Engagement Officer to WIN is to request meeting to continue discussions surrounding the draft commitments list for the WR-1 project at the CNL Whiteshell site. Request made to share and review commitments list with Chief and Council.	Email
2024 April 17	This email from CNL Indigenous Engagement Officer to WIN is to provide the action items from the 2024 April 16 monthly meeting.	Email
2024 May 01	This email from CNL Consultant to WIN is to provide a Save the Date reminder for the Regional Leadership Gathering on 2024 June 04 in Beausejour.	Email
2024 May 02	This email from CNL Consultant to WIN is to inform WIN of event registration for the Regional Leadership Gathering on 2024 June 04 in Beausejour.	Email
2024 May 09	This email from CNL Indigenous Relations Advisor to WIN is to provide the draft agenda for the upcoming 2024 May GCT#3 - CNL monthly meeting on 2024 May 21.	Email
2024 May 15	This email from CNL Indigenous Engagement Officer to WIN is to inform WIN that on 2024 February 15 CNL submitted an application to CNSC to renew the Whiteshell Laboratories site licence for a period of three years. CNL also noted that there will be a public hearing on this application held on 2024 October 23 and 24. CNL proposed that WIN review the Indigenous engagement section of the CNL draft Commission Member Document (CMD). CNL to submit a final CMD to the CNSC by 2024 July 18. CNL is preparing the CMD section on Indigenous engagement, which will be available for review from participants in 2024 June. CNL requested CMD review from WIN by 2024 July 05 in order to make changes to the CMD before the submission deadline (2024 July 18).	Email
2024 May 21	This email from CNL Consultant to WIN is to inform WIN of event registration for the Regional Leadership Gathering on 2024 June 04 in Beausejour.	Email
2024 May 21	This email from CNL Indigenous Relations Advisor to WIN is to provide WIN with the "First Nation and Métis Affairs Coordinator Student" employment opportunity with CNL. CNL shared the Job description, deadlines, and link for application.	Email
2024 June 10	This email from CNL Indigenous Engagement Officer to WIN is to provide the draft Commission Member Document (CMD) for the WL site re-license, and Indigenous Engagement Section for review and comment. CNL requested feedback by 2024 June 05.	Email
2024 June 18	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations and Governments is to inform them of the CNL ERM June Webinars on Douglas Point Decommissioning, Nuclear Power Demonstration Closure Project- Fact or Fiction, and the Facilities Decommissioning Projects Update.	Email
2024 June 20	This email from CNL Indigenous Engagement Officer to WIN is to follow up the CNL email sent on 2024 June 10 on the review of the Commission Member Document (CMD) that CNL will be submitting to the Canadian Nuclear Safety Commission (CNSC) in July. CNL requested feedback by 2024 July 05.	Email
2024 June 20	This email from WIN to CNL Indigenous Engagement Officer is to inform CNL to engage on the 2024 WL Re-license through GCT#3. CNL confirmed receipt.	Email
2024 June 25	This email from CNL Director of Communications and Indigenous Engagement is to provide WIN with a letter on Staff Changes at the Whiteshell Site.	Email
2024 July 09	This email from GCT#3 Policy Manager to CNL Indigenous Engagement Officer is to provide feedback on the draft Commission Member Document (CMD) for the Whiteshell Site re-license with no changes to the entry noted. CNL confirmed receipt of the feedback.	Email
2024 July 16	This virtual meeting between GCT#3 (including, Policy Manager, Environmental Manager and Junior Policy Analyst) and CNL (including, Indigenous Engagement Officers, Administrative Assistant, Manager of Regulatory Approvals) and AECL (including, Indigenous Relations Coordinator) is to act as the 2024 July monthly meeting. Discussion included WR-1 re-licensing, LUES, Trenches community updates, and environmental monitoring schedule.	Virtual Meeting

Date	Event	Event / Activity
2024 July 22	This email from GCT#3 Policy Manager to CNL Indigenous Relations Advisor is to request a response to questions posed by a GCT#3 community member regarding Fuel Consolidation and Waste transportation from the Whiteshell facility. CNL confirmed a response will be provided. GCT#3 also requested if there were privacy issues to share the monthly meeting notes. CNL responded that sharing monthly meeting notes was at the discretion of GCT#3.	Email

1.3.8 Wabaseemoong Independent First Nations (WIN) – Key Interests and Concerns

In 2024 April, CNL received unofficial communication that engagement with WIN should go through GCT#3. CNL continues to engage with GCT3 both to provide information to them as representatives of the Treaty 3 Nations, but also to use GCT#3 as an avenue to engage with WIN as per the unofficial request of WIN. CNL recognizes that engagement with GCT#3 without official notification from WIN Chef and Council, is not a replacement for direct engagement with WIN, and CNL continues to reach out to WIN to attempt to reestablish direct engagement.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Regulatory Process			
Wabaseemoong Independent Nations (WIN) expressed concern that they were not consulted during the siting of Whiteshell Laboratories (WL) and not consulted earlier in the Whiteshell Reactor 1 (WR-1) Project as they have a right to be consulted on projects that might adversely impact Aboriginal and treaty rights. This is both a site-wide and project-specific concern.	Canadian Nuclear Laboratories (CNL) acknowledged that engagement practices in the past were well below today's engagement standards. CNL has undertaken activities to conduct meaningful engagement and develop relationships with Nations. Since 2016 CNL has been sharing information with the community. In August 2016, CNL sent a letter to all identified Indigenous Nations, including WIN, introducing the Project and inviting them to engage in the Project. CNL followed up with WIN via telephone and emails to determine their interest in participating in engagement activities. Communication between WIN and CNL has improved since initial outreach on the Project in 2016. In May 2017, CNL, AECL, and the CNSC met with WIN to discuss the Project. One month later, in June, WIN representatives participated in a site tour at the Whiteshell site and had a follow-up discussion on the Project. Other engagement highlights include an information session in the community, sharing documents, the Hallam site visit to see a completed In Situ Disposal (ISD) Project. A representative from WIN participated in the two exploratory discussions on developing an Indigenous Advisory Committee for the Whiteshell site. The two sessions were held in August and September 2021. WIN also submitted a Traditional Knowledge and Environmental Impact Assessment, which was submitted to the CNSC on January 8, 2018. CNL provided responses to the EIS review. Through 2020 and 2021 CNL and WIN met to ensure CNL had accurately captured the community's interest and concerns and list of valued components. CNL continues to provide regular updates on the Project by teleconference and email and offers capacity funding to support WIN's participation in the Environmental Assessment (EA) process for WR-1.	There were no changes to the outcome of the assessment; a summary of engagement with WIN is provided in Section 4.2.4.4: Wabaseemoong Independent Nations.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. CNL – GCT #3 – AECL and WIN have a standing monthly meeting to which WIN maintains an open invitation to attend. The draft agenda and meeting actions are distributed for each meeting. **Next Steps:** CNL will continue to send information on the Project and will seek the direction of WIN's Chief and Council related to engagement with their membership. CNL will continue to make efforts to meaningfully engage WIN on matters pertaining to the WR-1 application and the Whiteshell Laboratories site in general, to ensure their rights, claims and interests are adequately considered. CNL is working with the Grand Council of Treaty #3 to accommodate WIN's request to work through the Grand Council. **Commitments Sought:** WIN-2: CNL wishes to build on their relationship with WIN and to ensure that WIN are engaged in the Project in a respectful and meaningful manner and have the capacity to be meaningfully engaged about the potential impacts of the Projects.
Engaging the Community			
WIN expressed interest in having an engagement event in their home community with CNL, Atomic Energy of Canada Limited (AECL), and the CNSC as they want their membership to be informed during the regulatory process for the Project so that their knowledge, interests, concerns, and Aboriginal and treaty rights are considered in the EA. This is a project-specific interest.	On 2017 June 28, at a CNL Whiteshell tour, WN indicated an interest in having in-community engagement. In August 2017, CNL, AECL, and the CNSC participated in a one-day event to discuss the Project in the WIN community. Discussion included a presentation on the Whiteshell Laboratories site, waste transportation, and WR-1. In October 2017, CNL sent a letter to WIN notifying them of the public comment period for the draft Environmental Impact Statement (EIS) and invited them to review and submit comments. In November 2017, CNL sent a hard copy of the draft EIS executive summary to the community. WIN provided comments on the draft EIS at that time. In August 2020, CNL provided WIN with CNL's responses to Wabaseemoong's comments on the 2017 draft Environmental Impact Statement (EIS) for the proposed in-situ disposal of WR-1. CNL also shared WIN's list of proposed Value Components for WIN review. CNL proposed a follow-up meeting and site tour. WIN did not provide additional follow-up on CNL's responses. CNL has continued to reach out to WIN at critical milestones in the Project's development to encourage WIN's continued participation in the regulatory process.	CNL revised Sections 6.2:Atmospheric Environment through 6.9: Socio-economic Environment to include WIN's feedback, interests, and concerns in the Indigenous Engagement Feedback tables and confirmed that the feedback, interests, and concerns were addressed in the assessment or provided the rationale for why they were not applicable. CNL updated Section 6.8.1: Traditional Land and Resource Use to capture WIN's traditional knowledge provided to CNL through WIN's Traditional Knowledge and Environmental Impact Assessment Report.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** Once CNL has submitted the revised EIS, CNL will send out invitations to the First Nations and the Manitoba Métis Federation to continue engagement on the key components of the EIS, including baseline studies, WR-1 end state, follow-up monitoring, and other items of importance to that Community. Proposed commitment: CNL wish to build on their relationship with WIN and to ensure that WIN are engaged in the Project in a respectful and meaningful manner and have the capacity to be meaningfully engaged about the potential impacts of the Projects. CNL will continue to make efforts to meaningfully engage WIN on matters pertaining to the WR-1 application and the Whiteshell Laboratories site in general, to ensure their rights, claims and interests are adequately considered. CNL is working with the Grand Council of Treaty #3 to accommodate WIN's request to work through the Grand Council. **Commitments Sought:** CNL wishes to build on their relationship with WIN and to ensure that WIN are engaged in the Project in a respectful and meaningful manner and have the capacity to be meaningfully engaged about the potential impacts of the Projects.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Business and Employment Opportunities			
WIN expressed interest in employment opportunities at the WL site, including seasonal employment and the proportion of the workforce that is Indigenous, in the interest of increasing their economic participation. WIN noted that employment at the WL site may be difficult for members due to the distance between the community and the WL site. This is a site-wide interest.	CNL updated WIN's community employment contacts and provides WIN with information on employment opportunities, including seasonal employment when they become available. CNL created an Indigenous summer student position to provide a youth employment opportunity at the site. CNL explained that approximately 13% of the WL workforce has self-identified as Indigenous. CNL has worked to enhance options to better match Indigenous capabilities with CNL contracting needs, added provisions to CNL procurement process to encourage the use of Indigenous and local businesses, and considers single source contracting opportunities with Indigenous companies where well suited to the work. CNL has also adjusted the evaluation criteria for competitive bids to favor contracts that are Indigenous owned or have Indigenous employees. CNL acknowledged the long commute from WIN and offered to help any job candidates find appropriate housing in the region. March 2023 CNL shared the Indigenous Relations Procurement Strategy with WIN.	CNL revised Section 6.9.6.2.2: Secondary Pathways to provide more information on CNL initiatives to support Indigenous contracting opportunities. CNL revised Section 6.9.5.2.3.1: CNL Whiteshell Laboratories Employment to provide information on the proportion of the WL workforce that has self-identified since 2017. This interest does not affect the outcome of the EA.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Nest Steps:** CNL will continue to share job postings and opportunities for employment as they become available. **Commitments Sought:** WIN-1: CNL will continue to seek efforts to increase Indigenous participation in the economics of the project.
Ecological Health			
WIN is concerned that animals may be impacted by the Project. WIN wants to ensure their Aboriginal and treaty rights to hunt, fish, and gather are not impacted by the Project. This is a project-specific concern.	The Project incorporates multiple barriers to ensure that animals remain safe and that the EIS assesses the Project's impact on terrestrial and aquatic animals, and determined they will remain safe under normal and upset conditions. The EIS (and other supporting studies) have demonstrated that, there are no predicted impacts to the accessibility or safety of the WR-1 site in the long term based on several different future use scenarios, including self-sufficient Indigenous receptors. These findings, which will be confirmed by monitoring, may reduce concerns about loss of connection to land and water, and about food safety. CNL acknowledged that animals do not obey the same boundaries as humans and explained that there were no Project activities or outcomes that would result in a residual adverse effect to wildlife so species of importance to traditional land and resources use will not be affected. In 2018, WIN participated in a trip to Hallam, Nebraska to see a completed In Situ Disposal (ISD) Project. The group had a discussion on environmental monitoring and saw that the results from monitoring showed no levels of radioactivity. CNL has been sharing information on the monitoring programs with WIN. For example, on October 31, 2017, CNL's Annual Safety Reports were distributed to each First Nation community including the "Environmental Monitoring in 2016 at Whiteshell Laboratories" report, and the "2016 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories". CNL also provided an invitation to engage on these documents. CNL has also invited WIN to participate in monitoring activities on site. CNL sent a copy of CNL's monitoring program schedule August 2022 and requested WIN identify any activities of interest. CNL recognizes that much of the concern expressed will need to be addressed through participation in ongoing monitoring and has committed to supporting Indigenous participation in long-term monitoring at the WL site.	CNL confirmed that the assessment predicts no impact to terrestrial or aquatic animals Sections 6.7.2.7.1: Application Case – Closure Phase and 6.7.2.7.2: Application Case – Post-closure Phase. CNL added Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring, which includes CNL's commitment to support Indigenous participation in long-term monitoring at the WL site.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL will continue to engage with WIN on environmental monitoring for WR-1, for site wide monitoring, and to discuss environmental monitoring initiatives. CNL continues to encourage engagement with WIN and are making efforts to encourage WIN participation through dialogue with the Grand Council of Treaty #3. CNL will provide resources to support WIN participation in monitoring activities. **Commitments Sought:** WIN-3: CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. CNL has committed to ongoing Indigenous engagement, including with WIN, should they choose to remain involved with the project, including involvement in environmental monitoring.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Monitoring			
WIN is concerned that WR-1's close proximity to the river will contaminate the river and the fish, now and over time. WIN was interested in knowing more about fish monitoring as WIN members use the Winnipeg River to fish and would like to ensure their Aboriginal and treaty rights to fish are not impacted by the Project. This is a project-specific concern.	Over the course of engagement with WIN, CNL has explained via in-person meetings, and virtual meetings how the ISD design incorporates multiple barriers to ensure that the river and the fish remain safe and the EIS assesses the Project's impact on the river and the fish, and determined they will remain safe. In August 2017, CNL, AECL, and the CNSC participated in a one-day event to discuss the Project in the WIN community. WL's monitoring program. Fish are caught at one location upstream of the WL site (Sylvia Lake; upstream of the Seven Sisters Falls Hydro Dam) and two locations downstream (2.0 km and 5.0 km downstream). The length and weight of the fish are recorded, and the fish are filleted and sent to an external laboratory for analysis. Contaminants can accumulate over time, but recent fish monitoring results show that the radioactivity (< 0.001 mGy/d) is well below the benchmark recommended by the CNSC (0.6 mGy/d). In 2018, WIN participated in a trip to Hallam, Nebraska to see a completed ISD Project. The group had a discussion on environmental monitoring and saw that the results from monitoring showed no levels of radioactivity. After the Hallam Trip, CNL prepared a trip summary report, WIN confirmed accuracy of trip summary and findings. In September 2020, CNL sent an invitation to WIN inviting them to participate in CNL's fall monitoring activities, which include fish monitoring. CNL sent a "What We Hear Report" to WIN that included questions and responses on monitoring. WIN indicated a community evacuation due to wildfires; WIN did not participate in the activities.	CNL confirmed that the assessment predicts no impact to the river Section 6.4.2.7.2: Application Case Results or fish Section 6.7.2.7.2: Application Case – Post-closure Phase. CNL added Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring, which includes CNL's commitment to support Indigenous participation in long-term monitoring at the WL site.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL will continue to engage with WIN on environmental monitoring for WR-1, for site-wide monitoring, and to discuss environmental monitoring initiatives. CNL will continue to monitor fish tissues annually during the closure phase. CNL will consider the suggestion to monitor fish every ten years during post-closure. CNL will have adaptive management plans in place to include fish monitoring more frequently if water quality data indicates the need. CNL continues to encourage engagement with WIN and are making efforts to encourage WIN participation through dialogue with the Grand Council of Treaty #3. CNL will provide resources to support WIN participation in monitoring activities. **Commitments Sought:** WIN-3: CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. CNL has committed to ongoing Indigenous engagement, including with WIN, should they choose to remain involved with the project, including involvement in environmental monitoring.
WIN expressed interest in the WL air emissions monitoring practices as there is the potential for contamination to be released to the atmospheric environment during Project demolition work. This could impact the health of WIN members and the environment. This is a project-specific concern.	In August 2017, CNL, AECL, and the CNSC participated in a one-day event to discuss the Project in the WIN community, provided information on WL's monitoring program. CNL explained where air monitoring occurs, both on- and off-site, and explained the historic WL site results and the low impact of the site. CNL pointed to where the annual results are available online and provided information on the CNSC independent monitoring program that confirmed the low impact of the site. CNL explained the proposed demolition approach for the WR-1 building, the results of the atmospheric assessment for the Project, and that no impacts to the environment are predicted. CNL confirmed that past monitoring verified the protection of wildlife, and that the assessment indicates there will be no impact to wildlife from airborne emissions. CNL has been sharing information on the monitoring programs with WIN. For example, on October 31, 2017, CNL's Annual Safety Reports were distributed to each First Nation community including the "Environmental Monitoring in 2016 at Whiteshell Laboratories" report, and the "2016 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories". CNL also provided an invitation to engage on these documents. CNL has also invited WIN to participate in monitoring activities on site. CNL sent a copy of CNL's monitoring program schedule August 2022 and requested WIN identify any activities of interest. CNL invited WIN to participate in environmental monitoring during the 2020 summer and fall seasons. WIN indicated a community evacuation due to wildfires; WIN did not participate in the activities.	CNL confirmed that the assessment predicts no impact to the atmospheric environment Section 6.2.1.7.2: Application Case Results, human health Section 6.7.1.7.1: Application Case – Closure Phase, or the health of wildlife Section 6.7.2.7.1: Application Case – Closure Phase. CNL added Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring, which includes CNL's commitment to support Indigenous participation in long-term monitoring at the WL site.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL will continue to engage with WIN on environmental monitoring for WR-1, for site wide monitoring, and to discuss environmental monitoring initiatives.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
WIN is concerned that the Project may impact the environment in the long-term. WIN was interested in learning more about CNL's long-term monitoring plan for WR-1 to ensure their Aboriginal and treaty rights to use lands and resources near the WL site is not impacted by the Project for generations to come. This is a project-specific concern.	Throughout WR-1 engagement, and overview presentations, CNL has provided information on how the Project incorporates multiple barriers to ensure that the environment remains safe in the long-term and the EIS assesses the Project's long-term impact on the environment and determines the environment will remain safe. After WR-1 is decommissioned, the only way contaminants can enter the environment is through releases to groundwater and groundwater movement to the Winnipeg River. CNL plans to monitor the expected performance of the WR-1 Disposal Facility using groundwater monitoring wells for at least 100 years, at which point the performance of the facility is expected to be confirmed. CNL will stop monitoring only when the CNSC finds it acceptable. To enable this monitoring, CNL has created a groundwater monitoring well network that will be used to detect any movement of contaminants from the WR-1 Disposal Facility towards the river. CNL has already committed to additional groundwater monitoring well(s) as recommended during Indigenous engagements. CNL has been sharing information on the monitoring programs with WIN. For example, on October 31, 2017, CNL's Annual Safety Reports were distributed to each First Nation community including the "Environmental Monitoring in 2016 at Whiteshell Laboratories" report, and the "2016 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories". CNL also provided an invitation to engage on these documents. CNL has also invited WIN to participate in monitoring activities on site. CNL sent a copy of CNL's monitoring program schedule August 2022 and requested WIN identify any activities of interest. In 2018, WIN participated in a trip to Hallam, Nebraska to see a completed ISD Project. The group had a discussion on environmental monitoring and saw that the results from monitoring showed no levels of radioactivity. CNL has committed to Indigenous participation in long-term monitoring at the WL site.	CNL confirmed that the assessment predicts no impact to the environment Section 9.3: Summary. Sections 6.7.1.7: Residual Effects Analysis and 6.7.2.7: Residual Effects Analysis describe the pathways by which releases can get into the environment. CNL updated Section 11.0: Summary of Monitoring and Follow-up Programs)to better describe the current proposal for the closure and post-closure monitoring activities as well as the integration of the Project monitoring into the existing site-wide program. CNL added Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring, which includes CNL's commitment to support Indigenous participation in long-term monitoring at the WL site.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL will continue to engage with WIN on environmental monitoring for WR-1, for site wide monitoring, and to discuss environmental monitoring initiatives.
Future Land Use and Tenure			
WIN requested more information about the proportion of the land that would be available post-closure of the WL site as they are interested in re-establishing connection within the WL site for traditional use purposes as this land base has been unavailable since the site was established in the early 1960s. This is a site-wide interest.	In August 2017, CNL, AECL, and the CNSC participated in a one-day event to discuss the Project in the WIN community. WIN was provided a draft map of the Whiteshell site that would be potentially available for future use. CNL explained at that time that discussions on future land use and final clean-up criteria are forthcoming between WIN – AECL – CNL CNL began engaging on the future of the site more actively in 2023. In August 2023 CNL shared the draft Land Use and End State document for review and comment. CNL also shared that a plain language version of the report would also be published. In June 2024 CNL hosted a CNL Regional Gathering of Leaders; Project Discussion 2024 which provided an overview of the End State Plan and sought consultation on 3 options for low-medium level nuclear waste management. WIN did not attend the gathering. CNL did not receive a response. On 2022 November 11, CNL informed WIN of an upcoming letter to the WIN indicating the more formal kick-off of LUES discussions. WIN participation at the May 30th, LUES workshop. Outreach will be ongoing. CNL also invited WIN to the Virtual Public Liaison Committee 2023 Wrap – up Meeting.	CNL revised Section 4.2.4.4.2: Interests and Concerns to discuss engagement on future land use and end-state planning for the WL site. Engagements on future land use and tenure will not impact the conclusions of the EIS.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** While future land use and tenure is out of scope for the assessment for WR-1, CNL will be contacting WIN to participate in discussions on the site-wide end state. CNL will continue to send information on the Project and will seek the direction of WIN's Chief and Council related to engagement with their membership.
Management of the Whiteshell Laboratories Site			
WIN expressed interest in the history of CNL and how it is related to AECL and the WL site as WIN wanted to understand the different roles and responsibilities of each company to ensure they were dealing with the appropriate party in regard to their interests and concerns. This is both a project-specific and site-wide interest.	During engagement activities with WIN, CNL explained that AECL, a federal Crown corporation, is responsible for managing Canada's radioactive waste and decommissioning liabilities and enabling nuclear science and technology. At the 2017 August community meeting, AECL presented an overview presentation and touched on AECL's responsibilities for managing Canadas radioactive waste. Following a restructuring process, AECL now operates under a Government Owned, Contractor Operated model. Under this model, while AECL retains ownership of the sites, facilities, assets, and liabilities, it delivers its mandate through a long-term contract with the private sector for the management and operation of its sites. AECL has a contract with CNL for the decommissioning and closure of the WL site as well as the operations of other sites across Canada (including the Chalk River Laboratories in Ontario, which remains an active nuclear science and technology complex).	There were no changes to the outcome of the assessment; information on the relationship between CNL, AECL, and the WL site is provided in Section 1.4: Proponent.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL will continue to send information on the Project and will seek the direction of WIN's Chief and Council related to engagement with their membership.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Waste Management			
WIN expressed concern with the transport of waste off-site as transportation accidents could impact the health of the public and the environment. WIN was interested in more detailed information about how much radioactive waste would remain on the WL site and where the radioactive waste that was being transported off-site would be stored as this waste has the potential to impact their Aboriginal and treaty rights to use lands and resources near the WL site. This is both a project-specific and site-wide concern.	On June 28, 2017, CNL hosted WIN for a tour of their waste management facilities and answered questions about waste management and transportation of waste. CNL provided information to the community on waste management at the site and proposed plans for waste transportation. During engagement activities with WIN CNL explained that the vast majority of radioactive materials from the WL site will be transported to the Chalk River Laboratories site in Ontario for interim storage or disposal in the proposed Near Surface Disposal Facility. Disposal in the proposed Near Surface Disposal Facility remains contingent upon approval of the EA for that Project, which is under review. The WL site possesses over 50 years of experience in shipping and receiving radioactive material and has never had an incident that compromised the safety of workers, the public, or the environment. The shipment of nuclear materials is a highly regulated process. CNL has procedures in place to ship the waste in accordance with the federal Packaging and Transport of Nuclear Substances Regulations. CNL maintains a response plan and a team that works together with the Transport Canada emergency services to respond to any road accident involving nuclear materials. All waste is transported in packages that are selected based on the nature, form, quantity, and radioactivity of the waste. There are design requirements that apply to all waste package types to ensure that they can be handled safely and easily, secured properly, and withstand routine transport conditions. The EIS assesses the risks resulting from the transportation of Project waste off-site and determined that the risk and consequence severity of transportation accidents involving nuclear materials is low due to existing controls on transport of nuclear materials and the requirements for waste packaging. Likewise, the Waste Management Area trenches will undergo a rigorous safety assessment to ensure the safety of the environment. Approximately 2,800 m^3 (4,000 Mg) of radioactive waste is estimated to remain on the WL site as part of the Project.	CNL confirmed that the risk and consequence severity of transportation accidents involving nuclear materials was assessed to be low in Section 7.3.4: Off-site Transportation Accidents; no changes to the assessment were required. CNL updated Section 3.4.8: Waste Generation and Management with a reference to the Detailed Decommissioning Plan as this is where the waste volume estimates are documented.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL will continue to send information on the Project and will seek the direction of WIN's Chief and Council related to engagement with their membership.
WIN expressed interest in CNL's waste transportation methods and how waste transportation is communicated to potentially affected communities. WIN is concerned about a potential waste transportation accident near their reserve and on their traditional territory impacting human health and the environment, particularly the potential impact on the water, as there are many water crossings of the highway near their traditional and treaty territory. This is both a project-specific and site-wide concern.	In June 2017, CNL hosted WIN for a tour of their waste management facilities and answered questions about waste management and transportation of waste. CNL provided information to the community on waste management at the site and proposed plans for waste transportation. CNL provided information on waste transportation include that all waste is transported in packages that are selected based on the nature, form, quantity, and radioactivity of the waste. There are design requirements that apply to all waste package types to ensure that they can be handled safely and easily, secured properly, and withstand routine transport conditions. There are also federal regulations for how nuclear materials can be shipped and CNL maintains a set of procedures for packaging and transporting nuclear materials. CNL maintains a response plan developed and maintained in accordance with CNL's company-wide Emergency Preparedness Program that has been accepted to meet the CNSC's requirements (under REGDOC-2.10.1), and a team that works together with the Transport Canada emergency services to respond to any road accident involving nuclear materials. CNL explained that the WL site possesses over 50 years of experience in shipping and receiving radioactive material and has never had an incident that compromised the safety of workers, the public, or the environment. The EIS assesses the risks resulting from the transportation of Project waste off-site and determined that the risk and consequence severity of transportation accidents involving nuclear materials is low due to existing controls on transport of nuclear materials and the requirements for waste packaging. For security reasons, information about individual shipments of nuclear materials is kept confidential.	CNL confirmed that the risk and consequence severity of transportation accidents involving nuclear materials was assessed to be low in Section 7.3.4: Off-site Transportation Accidents; no changes to the assessment were required.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL will continue to send information on the Project and will seek the direction of WIN's Chief and Council related to engagement with their membership.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
Accidents and Malfunctions			
WIN was interested in past releases and the potential for future releases of hazardous and radioactive material into the Winnipeg River as they are concerned that the close proximity of the WL site to the river will contaminate the river. WIN uses the Winnipeg River for traditional harvesting activities and wants to ensure their Aboriginal and treaty rights to use lands and resources near the WL site are not impacted by site activities. This is both a project-specific and site-wide concern.	In the Fall 2017 WIN Engagement Report Update, CNL responded to WIN's questions regarding CNL's detection systems, past spills, and prevention of future spills. CNL developed plain language materials to support their communication of past spills. The EIS (and other supporting studies) have demonstrated that, there are no predicted impacts to the accessibility or safety of the WR-1 site in the long term based on several different future use scenarios, including self-sufficient Indigenous receptors. These findings, which will be confirmed by monitoring, may reduce concerns about loss of connection to land and water, and about food safety. CNL has committed to involving First Nations and the Manitoba Métis Federation in the development and implementation of an Indigenous post-closure monitoring program. In the Fall 2017 WIN Engagement Report Update, CNL provided WIN with information on how the Project incorporates multiple barriers to ensure that the river remains safe, and the EIS assesses the Project's impact on the river and determined it will remain safe. Other activities on the WL site are covered by the 2001 Comprehensive Study Report, which assesses their impact on the river and determined it will remain safe. CNL explained that any events that occurred in the past were reported to the CNSC (or previously the Atomic Energy Control Board) and that no employees or members of the public have been negatively affected by the operation emissions of the WL site. As part of AECL's application to the CNSC for a decommissioning license in 2001, AECL conducted a Comprehensive Environmental Assessment. This included an investigation of the surrounding environment and the Winnipeg River sediments to look for any radioactive contamination that may have occurred over the history of the site. River sediments were surveyed for radioactivity at hundreds of locations. The assessment concluded that *"using the most conservative dose estimation methods, doses to non-human biota and humans are below accepted guidelines."* The analysis methodology and results were peer-reviewed, presented in public meetings, and are available in the open publication of the Comprehensive Study Report. CNL continues to monitor the river sediment near the site and downstream. CNL also explained that in late 1994, the Winnipeg River Task Force was created. Representatives from Indian and Northern Affairs Canada, Environment Canada, Health Canada, and Sagkeeng First Nation took part in the Task Force. The objective of the Task Force was to look at potential sources of Winnipeg River water quality degradation near the community of Sagkeeng. The Task Force report concluded that the drinking water quality met Canadian guidelines and that it was unlikely that the WL site had ever posed or would pose a significant threat to the health of Sagkeeng community members. CNL developed plain language materials to support their communication of past spills.	CNL confirmed that the assessment predicts no impact to the river (Section 6.4.2.7.2: Application Case Results. CNL added Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring, which includes CNL's commitment to support Indigenous participation in long-term monitoring at the WL site.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL continues to look for ways to improve its environmental monitoring program. CNL will continue to invite WIN to participate in CNL's monitoring activities. CNL has also committed to engagement with each Indigenous community on the development and implementation of a post-closure monitoring plan that will include an Indigenous-led monitoring program.
WIN was interested in how releases could be contained in the soil and how CNL detects spills as they are concerned that the close proximity of the WL site to the river will contaminate the river through contamination of the soil. WIN wants to ensure their Aboriginal and treaty rights to use lands and resources near the WL site is not impacted by site activities. This is a site-wide concern.	In the Fall 2017 WIN Engagement Report Update, CNL provided information on how the Project incorporates multiple barriers to ensure that the river remains safe, and the EIS assesses the Project's impact on the river and determines it will remain safe. Other activities on the WL site are covered by the 2001 Comprehensive Study Report, which assesses their impact on the river and determined it will remain safe. The properties of a site determine how well releases are contained in the soil; however, for ISD of WR-1, contaminant releases are primarily limited by a significant portion of the contaminants being contained within the metals of the reactor, which corrode very slowly. Other barriers (such as the building walls, the grout, and the concrete cap and engineered cover) further limit contaminant releases and the low-permeability clays surrounding the WR-1 building provide additional resistance to contaminant movement. Groundwater monitoring wells around the ISD facility will be the primary means of monitoring for contaminant releases. If contaminants are being released in quantities of concern, this would show up in the groundwater monitoring and remedial actions would be taken.	CNL confirmed that the assessment predicts no impact to the river Section 6.4.2.7.2: Application Case Results. CNL assessed the likelihood and consequence of spills in Section 7.3.2: Spills and Leaks and confirmed that if spills do occur during closure activities, CNL has sufficient experience and controls in place to limit negative effects on human health and the environment. CNL added Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring, which includes CNL's commitment to support Indigenous participation in long-term monitoring at the WL site.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL will continue to send information on the Project and will seek the direction of WIN's Chief and Council related to engagement with their membership. CNL continues to look for ways to improve its environmental monitoring program. CNL will continue to invite WIN to participate in CNL's monitoring activities. CNL has also committed to engagement with each Indigenous community on the development and implementation of a post-closure monitoring plan that will include an Indigenous-led monitoring program.

Key Interest/Concern	How the Interest/Concern is Being Addressed	Impact on the Environmental Impact Statement	Status
WIN expressed the view that potential adverse impacts on fisheries from the Project would negatively impact the ability of WIN members to collect fishery resources and damage their relationship with them. Moreover, changes to concentrations of contaminants in fish tissues (for example, from nuclear spills) could have negative consequences on human health. WIN is concerned that the close proximity of WR1 to the river will contaminate the river and the fish. As stewards of the land, members of WIN have a responsibility to protect ecosystems and ensure ecosystem function including trophic impacts of contamination. WIN wants to ensure their Aboriginal and treaty rights to fish is not impacted by the Project. This is a project-specific concern.	In the Fall 2017 WIN Engagement Report Update, CNL provided information on how the Project incorporates multiple barriers to ensure that the river and the fish remain safe, and the EIS assesses the Project's impact on the river and the fish, and determined they will remain safe. CNL shared that radioactivity levels for WR-1 are within the range of other reactors that have safely gone through the ISD process. In 2018, WIN participated in a trip to Hallam, Nebraska to see a completed ISD Project. The group had a discussion on environmental monitoring and saw that the results from monitoring showed no levels of radioactivity. In September 2020, CNL sent an invitation to WIN inviting them to participate in CNL's fall monitoring activities, which include fish monitoring. CNL has committed to supporting WIN's participation in monitoring at the site.	CNL confirmed that the assessment predicts no impact to the river Section 6.4.2.7.2: Application Case Results or fish Section 6.7.2.7.2: Application Case – Post-closure Phase. CNL added Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring, which includes CNL's commitment to support Indigenous participation in long-term monitoring at the WL site.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Seps:** CNL continues to look for ways to improve its environmental monitoring program. CNL will continue to invite WIN to participate in CNL's monitoring activities. CNL has also committed to engagement with each Indigenous community on the development and implementation of a post-closure monitoring plan that will include an Indigenous-led monitoring program. Through the GCT#3 CNL will engage with WIN on the Environmental Assessment Follow-up Monitoring Plan. CNL will continue to engage with WIN on environmental monitoring for WR-1, for site wide monitoring, and to discuss environmental monitoring initiatives. **Commitments Sought:** WIN-3: CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. CNL has committed to ongoing Indigenous engagement, including with WIN, should they choose to remain involved with the project, including involvement in environmental monitoring.
Long-Term Safety			
WIN expressed concern about the longevity of the nuclides and the long-term nature of the Project. WIN is concerned that the Project may impact the environment in the long-term and wants to ensure their Aboriginal and treaty rights to use lands and resources near the WL site is not impacted by the Project. This is a project-specific concern.	In the Fall 2017 WIN Engagement Report Update, CNL provided information on how the WR-1 Disposal Facility is designed in accordance with all applicable Canadian codes and standards as well as international best practices to ensure protection of the environment and safety throughout the life of the facility. CNL shared that radioactivity levels for WR-1 are within the range of other reactors that have safely gone through the ISD process. In 2018, WIN participated in a trip to Hallam, Nebraska to see a completed ISD Project. The group had a discussion on environmental monitoring and saw that the results from monitoring showed no levels of radioactivity. CNL has committed to supporting WIN's participation in long-term monitoring at the WL site.	CNL confirmed that the assessment predicts no impact to the environment Section 9.3: Summary. CNL added Section 11.4: Indigenous Engagement and Participation in Environmental Monitoring, which includes CNL's commitment to support Indigenous participation in long-term monitoring at the WL site.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next steps:** CNL continues to look for ways to improve its environmental monitoring program. CNL will continue to invite WIN to participate in CNL's monitoring activities. CNL has also committed to engagement with each Indigenous community on the development and implementation of a post-closure monitoring plan that will include an Indigenous-led monitoring program. **Commitments Sought:** WIN-3: CNL respects the importance of both Indigenous Knowledge and western science in understanding and managing the environment on the Whiteshell Laboratories site. CNL has committed to ongoing Indigenous engagement, including with WIN, should they choose to remain involved with the project, including involvement in environmental monitoring.
WIN expressed concern that climate change or natural disasters could affect the integrity of the grouted encapsulation and result in un-anticipated releases of hazardous material, which could impact their Aboriginal and treaty rights to use lands and resources near the WL site. WIN wanted to know how the disposal facility would be constructed to ensure that it is safe. This is a project-specific concern.	CNL provided information to WIN on how the normal evolution of the disposal facility was assessed over 10,000 years along with credible abnormal event or disaster that could affect the safety of the disposal facility. The assessment considered climate change in the normal evolution scenario and considered the effects of an unlikely major seismic event. Even if some future event causes significant damage to the disposal facility, the assessment determined that there would be no negative effects on the environment. The WR-1 Disposal Facility is designed in accordance with all applicable Canadian codes and standards as well as international best practices to ensure protection of the environment and safety throughout the life of the facility. WIN participated in a Hallam trip to see a fully decommissioned ISD reactor and see how effective ISD was at protecting the environment. A post-trip survey found that almost everyone had a better understand of ISD and that their confidence in this technique increased.	CNL confirmed that the assessment scenarios in Section 6.7.1.7.2: Application Case – Post-closure Phase encompass the potential effects of natural disasters described in Section 10.0: Assessment of Effects of the Environment on the Project, and that human and ecological health is protected even under severe adverse conditions such as glaciation or earthquakes.	This interest/concern has been addressed within the scope of the WR-1 project, through CNL's commitments to WIN as referenced in the WR-1 Environmental Impact Statement Commitments. CNL continues to contact WIN to verify the commitments. **Next Steps:** CNL will continue to send information on the Project and will seek the direction of WIN's Chief and Council related to engagement with their membership.

1.3.9 Shoal Lake #40 First Nation Engagement

Date	Activity	Attendance	Description	Key EA Topics[6]									
				Baseline Conditions	Alternative Means	Project Components	Effects assessment including VCs[7]	Proposed Mitigation Measures	Residual Effects	Follow-up Monitoring Program	Aboriginal and Treaty Rights / Traditional Land Use	Specific Topics of Interest of the community	Engagement Methods

7 including VC, spatial and temporal boundaries for the assessment, and adverse impacts to rights

Date	Event	Event / Activity
Shoal Lake First Nation (SLFN)		
2022 October 21	This email from CNL Indigenous Engagement Contractor to SLFN Chief is to provide SLFN with an attached a letter from Canadian Nuclear Laboratories providing an update on the status of the WR-1 Environmental Impact Statement in Relation to the Whiteshell Decommissioning Project located near Pinawa Manitoba. CNL proposed a meeting to discuss further.	Email
2022 November 16	This email from CNL Indigenous Engagement Contractor to SLFN Chief is to provide SLFN with a letter that provides an update and next steps for the Land use end state community engagement for the CNL Whiteshell site.	Email
2022 December 19	This email from CNL Indigenous Engagement Contractor to SLFN Chief is to provide SLFN with a letter that outlines updates on the Whiteshell Restoration Project, and the CNL re-submission of the EIS.	Email
2023 January 16	This email from CNL Indigenous Engagement Contractor to SLFN Chief is to notify SLFN that Friday January 13, 2023, CNL received a letter from the CNSC informing them that the EIS for the WR-1Project has been accepted for Technical Review.	Email
2023 March 10	This email from CNL Indigenous Engagement Contractor to IIIIFN is to provide SLFN with a copy of the CNL Indigenous Relations Procurement Strategy. CNL noted that in response to Call to Action #92 in the Truth and Reconciliation report to actively promote economic opportunity for Indigenous Businesses, CNL has developed the Indigenous Relations Procurement Strategy. AECL, the federal Crown corporation that provides oversight of CNL, has reviewed and endorsed the Strategy. CNL offered a meeting to discuss this further.	Email

In Person Meeting
2024 June 06	This email from CNL Indigenous Relations Advisor to Peguis Consultant Lead/HR Designate is to request an outstanding invoice from Peguis Finance for the WL site tour event held on 2024 April 23. Peguis First Nation shared form and CNL notified that payment would be sent.	Email
2024 June 07	This email from CNL Consultant to Peguis Director of Special Projects and Consultant Lead/HR Designate is to provide an invitation to a post event survey for the 2024 June 04 Regional Gathering held in Beausejour.	Email
2024 June 10	This email from CNL Indigenous Engagement Officer to Peguis Consultant Lead/HR Designate is to provide Peguis with CNL staff updates. Peguis First Nation confirmed receipt on 2024 June 18.	Email
2024 June 10	This email from CNL Indigenous Engagement Officer is to provide Peguis First Nation with the draft Commission Member Document (CMD) for the WL site re-license, and Indigenous Engagement Section for review and comment. CNL requested feedback by 2024 June 05.	Email
2024 June 18	This email from Peguis Consultant Lead/HR Designate to CNL Indigenous Engagement Officer is to inform CNL that Peguis First Nation will not provide comments feedback on the draft Commission Member Document and the WR-1 draft EIS Indigenous Engagement Report Section until consultation is formally established between Peguis and CNL. Peguis noted no response from CNL on the consultation package sent to CNL for consideration on 2024 April 17.	Email
2024 June 18	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations and Governments is to inform them of the CNL ERM June Webinars on Douglas Point Decommissioning, Nuclear Power Demonstration Closure Project- Fact or Fiction, and the Facilities Decommissioning Projects Update.	Email
2024 June 19	This email from CNL Indigenous Engagement Officer to Peguis Consultant Lead/HR Designate is to provide confirmation that CNL will review Peguis First Nation's proposed workplan and Budget. CNL to provide a draft engagement plan.	Email
2024 June 20	This email from CNL Indigenous Engagement Officer to all engaged Indigenous Nations, communities, organizations and Governments is to inform them of the funding available through the Indigenous and Stakeholder Capacity Fund.	Email
2024 June 25	This email from CNL Director of Communications and Indigenous Engagement is to provide Peguis FN with a letter on Staff Changes at the Whiteshell Site.	Email
2024 July 03	This email from CNL Indigenous Engagement Officer to Peguis Consultant Lead/HR Designate is to provide Peguis FN with an update regarding the draft engagement Contribution agreement and workplan. CNL also extended a one-time offer of capacity support for Peguis FN's review of the CMD. CNL provided the draft Commission Member Document (CMD) for the WL site re-license, and Indigenous Engagement Section for review and comment.	Email
2024 July 04	This email from Peguis Director, Consultation & Special Projects to CNL Whiteshell General Manager is to request a meeting with CNL Senior Leadership regarding the involvement of Peguis in the Whiteshell site decommissioning project. CNL confirmed receipt of the email and provided a timeframe to Peguis regarding an adequate response.	Email
2024 July 23	This email from CNL Indigenous Relations Advisor to Peguis Consultant Lead/HR Designate and Director, Consultation & Special Projects is to provide CNL's proposed Contribution agreement Draft Schedule A and Draft WR-1 EIS Technical Review Workplan. CNL requested a meeting with Peguis Chief and Council to provide an overview of the Whiteshell Restoration Project, the WR-1 Reactor Environmental Assessment, and the future work CNL is performing as the contractor on the AECL federal site, and review CNL's obligation and commitment to Indigenous people's engagement.	Email
2024 July 31	This email from CNL Indigenous Relations Advisor to Peguis Consultant Lead/HR Designate and Director, Consultation & Special Project is to follow up on the request for a meeting with Peguis Chief and Council and to extend an invitation to the Whiteshell site as the location for the proposed meeting. A meeting date of 2024 August 27 was agreed upon.	Email

1.0 INTRODUCTION

This Appendix was prepared to support the Environmental Impact Statement (EIS) for the proposed Canadian Nuclear Laboratories (CNL) In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project). This Appendix presents the meteorology and air quality baseline data used in the assessment to predict changes in non-radiological indicator compound emissions. The available ambient air quality monitoring data from air quality monitoring stations (Figure 1) located near the Project, as well as the meteorological conditions at the Whiteshell Laboratories (WL) site and surrounding area. As described in Section 6.2.1.4.1 Spatial Boundaries of the EIS, the Local Study Area (LSA) is defined to encompass activities and sources of emissions associated with the Project. The LSA is equivalent to approximately 8-kilometre (km) by 8 km square that includes the Site Study Area (SSA) and the WL site. The Regional Study Area (RSA) is defined as the area within which the potential effects of the Project may interact with the effects of other existing or reasonably foreseeable projects. The RSA is equivalent to approximately a 12 km by 12 km square surrounding the LSA, centered on the WL Site. The SSA, LSA and RSA are presented on Figure 2.

This Appendix documents the methods, data and assumptions that were used to assess the non-radiological background meteorology and air quality at the Project and in the LSA and RSA. The background meteorology documented in this Appendix provides a summary of the review of the:

- climate data sources; and
- weather parameters, including; temperature, relative humidity, precipitation, wind speed and direction, atmospheric pressure and solar radiation.

The background air quality assessment was carried out by:

- identifying the non-radiological indicator compounds expected to be emitted from the Project;
- identifying and comparing non-radiological air quality guidelines in Manitoba and Canada for the indicator compounds;
- identifying existing emission sources located within 50 km of the SSA with shared indicator compounds;
- assessing air quality data sources for use in the background air quality assessment; and
- comparing air quality monitored data to the applicable air quality guidelines.

2.0 METEOROLOGY BASELINE ASSESSMENT

This section summarizes the current climate conditions at the WL site. Meteorological parameters analyzed include temperature, precipitation, wind speed and direction, relative humidity, atmospheric pressure, solar radiation and the occurrence of extreme and rare meteorological phenomena, as required by REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures*, for the characterization of the atmospheric baseline environment (CNSC 2020).

2.1 Climate Normals Data Sources

Climate normals are used to summarize and describe the average climatic conditions of a particular location, using long-term averages (typically 30 years) of observed climate data that meet the data quality standards. Climate normals from Environment and Climate Change Canada (ECCC) climate stations located near the Project are used to describe the long-term record of climatic conditions in the region. Additional information on climate change and climate projection is available in the Golder (2017) report. The most recent climate normals available from ECCC are for the period from 1981 through 2010.

The Comprehensive Study Report (AECL 2001) completed the Climate and Meteorology Baseline assessment using climate normals from the climate station located at the WL site (closed in 1998) for periods ranging from 1964 to 1997. This station was considered for the Meteorology Baseline Assessment; however, this station was not retained for the current assessment due to insufficiency data availability for the most recent climate normals from 1981 through 2010.

For this study, the nearest climate station with published normals for the 1981 through 2010 period is the Pinawa WNRE station (Climate ID 5032162) located on the WL site, and is less than 1 km away from the WR-1 Building. The Pinawa WNRE station only has temperature and precipitation monitoring data and therefore for meteorological parameters required by CNSC REGDOC-2.9.1 without long-term data, the next closest station with the required parameters for climate normals, Winnipeg James Armstrong Richardson International Airport (Winnipeg Airport), was used for the assessment (Climate ID 5023222; ECCC 2016a). Table 1 presents the location of climate stations used in this assessment and Table 2 presents the available parameters at each station.

Table 1: Location of Climate Stations

Station Name	Climate ID	Distance and Direction from WR-1 [km]	Elevation [m]	Normal Period[(b)] [Years]
Pinawa WNRE[(a)]	5032162	0.25 NE	267	1981 – 2010
Winnipeg Airport[(a)]	5023222	104.45 SW	239	1981 – 2010

a) ECCC 2016a.
b) Normal period as defined by ECCC.

Table 2: Availability of Climate Normals for Meteorological Parameters at the Climate Stations

Station Name	Available Parameter						
	Wind Speed	Wind Direction	Temperature	Precipitation	Relative Humidity	Atmospheric Pressure	Solar Radiation
Pinawa WNRE	No[a]	No[a]	Yes	Yes	No	No[a]	No
Winnipeg Airport	Yes	Yes	Yes	Yes	Yes	Yes	Yes

a) Some data are available but there is insufficient data for a climate normal as per the ECCC data quality standards.

The purpose of the air quality baseline assessment in this Appendix is to present the local climate and meteorology conditions in the area surrounding the Project. This assessment was not used to assess the suitability of meteorological data for dispersion modelling, as the model used for the Project's air quality assessment does not require input of meteorological data. The Pinawa 503B1ER station has hourly meteorological data for all parameters, but the data are not available for the full 30-year period (only 6 years were available for the period considered [i.e., 1981 to 2010]); therefore, the Winnipeg Airport station was used for the unavailable parameters. As discussed below, the Winnipeg Airport station may be considered representative of conditions in the vicinity of the Project based on comparable temperature and precipitation data, as well as similar predominant wind direction.

2.2 Climate and Meteorology for the Project

This section presents the closest available climate normal. The expected values of weather parameters, including temperature, precipitation, wind speed and direction, relative humidity, atmospheric pressure and solar radiation, can be expressed in terms of normal values obtained from the long-term averages.

2.2.1 Temperature

A summary of the monthly temperature distribution for the climate normals from the Pinawa WNRE station is shown in Table 3. The daily average temperature in the winter season is approximately -14.3°C, while the daily average temperature in the summer season is approximately 18.0°C. The extreme minimum temperature during the 30-year period was -47.8°C while the extreme maximum temperature during the 30-year period was 37.5°C. Temperatures below -10°C have typically occurred between November and April, while temperatures above 30°C occur occasionally between May through August.

For comparison purposes, a summary of the monthly temperature distribution for the climate normals from the Winnipeg Airport station is shown in Table 4. The Winnipeg annual daily average, maximum and minimum temperatures are comparable to the Pinawa WNRE station.

Table 3: Monthly Temperature Distribution for the Pinawa WNRE Station

Climate Normals Parameters	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual[(a)]
Daily Average [°C]	-16.6	-13.2	-5.7	3.9	11.2	16.4	19.3	18.2	12.3	5.1	-4.5	-13.1	2.8
Standard Deviation [°C]	4	4.3	2.9	2.7	2	1.9	1.4	1.8	1.4	1.7	3.4	4.2	1.3
Daily Maximum [°C]	-11.1	-7.3	0.2	10.3	17.7	22.5	25.2	24.3	18	9.7	-0.7	-8.5	8.4
Daily Minimum [°C]	-22.1	-19	-11.6	-2.5	4.6	10.3	13.2	12	6.7	0.4	-8.3	-17.6	-2.8
Extreme Maximum [°C]	9.5	12	20	32.5	34.5	37.5	37	36	36	28.5	23.3	10	—
Extreme Minimum [°C]	-44	-47.8	-40.5	-28.9	-13.9	-3.9	-0.6	-1.5	-6.7	-15.5	-34.5	-40	—
Days with Maximum Temperatures Above 30°C	0	0	0	0	0.5	1.5	2.8	2.7	0.23	0	0	0	7.7
Days with Minimum Temperatures Below -10°C	26.9	21.6	15.1	2.7	0	0	0	0	0	0.56	10.4	22.6	99.9

a) The annual data average may not match the average of the presented monthly values due to rounding; however, the annual number days with maximum temperatures above 30°C and below -10°C would match the total of the monthly values.

Table 4: Monthly Temperature Distribution for the Winnipeg Airport Station

Climate Normals Parameters	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual[(a)]
Daily Average [°C]	-16.4	-13.2	-5.8	4.4	11.6	17	19.7	18.8	12.7	5	-4.9	-13.2	3
Standard Deviation [°C]	4.1	4.2	3.1	2.7	2.1	2	1.4	1.9	1.3	1.8	3.6	4.4	1.2

Days with Maximum Temperatures Above 30°C	0.0	0.0	0.0	0.1	1.2	2.5	4.1	4.7	0.7	0.0	0.0	0.0	13.3
Days with Minimum Temperatures Below -10°C	27.4	21.9	14.6	2.2	0.04	0	0	0	0	0.93	11.8	23.5	102.2

a) The annual data average may not match the average of the presented monthly values due to rounding; however, the annual number days with maximum temperatures above 30°C and below -10°C would match the total of the monthly values.

2.2.2 Precipitation

A summary of the monthly and seasonal precipitation data for the climate normals from the Pinawa WNRE station are shown in Table 5 and Table 6, respectively. The 30-year climate normal from the Pinawa WNRE station calculates an average annual precipitation of approximately 578 millimetres equivalent (mm[eq]) for the region, with the highest precipitation occurring in the summer at 253.2 mm[eq]. The greatest extreme daily precipitation also occurs in summer at 168.4 mm[eq]. Approximately 94% of the precipitation in winter is attributed to snow. Winter extreme daily precipitation is 35 mm[eq].

Table 5: Monthly Precipitation Summary for the Pinawa WNRE Station

Month	Rainfall (mm)	Snowfall (cm)	Total Precipitation (mm[eq])[(a)]	Extreme Daily Precipitation (mm)	Days with Measurable Precipitation[(b)]
January	0.3	21.4	21.7	23.9	9.2
February	2.1	14.6	16.7	26	6.5
March	11	14.9	25.8	44.4	7.5
April	19.7	9.4	29.1	48	6.9
May	64.5	2.1	66.6	65	12.4
June	98.8	0	98.8	168.4	13.9
July	89.1	0	89.1	63.5	12.9
August	65.3	0	65.3	77.2	11.7
September	61.4	0.5	61.9	75.2	12.8
October	40.3	7.9	48.2	56.5	11.5
November	10.3	19.2	29.5	21.2	9.4
December	1.6	24	25.6	35	9.8
Annual	**464.3**	**113.9**	**578.3**	**—**	**124.5**

a) Total precipitation in mm [eq] is calculated by adding the snowfall in cm (a ratio of 10:1 to convert snow to rain) to the rainfall in mm.
b) Greater or equal to 0.2 mm.
mm[eq] = millimetres equivalent

Table 6: Seasonal Precipitation Summary for the Pinawa WNRE Station

Season	Total Precipitation (mm)
Winter (December – February)	64.0
Spring (March – May)	121.5
Summer (June – August)	253.2
Fall (September – November)	139.6
Total	**578.3**

For comparison purposes, a summary of monthly and seasonal precipitation for the climate normals from the Winnipeg Airport station are shown in Table 7 and Table 8, respectively. The Winnipeg Airport station annual total precipitation amount is slightly lower than the Pinawa WNRE station annual total precipitation amount, due to a lower amount of annual rainfall. The amount of annual snowfall at each station is comparable.

Table 7: Monthly Precipitation Summary for the Winnipeg Airport Station

Month	Rainfall (mm)	Snowfall (cm)	Total Precipitation[a] (mm[eq])	Extreme Daily Precipitation (mm)	Days with Measurable Precipitation[b]
January	0.2	23.7	19.9	22.5	12.2
February	2.7	12.5	13.8	23.6	8
March	9.7	16.5	24.5	35.6	9.2
April	19.2	10.6	30	44.1	7.2
May	54.1	2.6	56.7	60.2	11.5
June	90	0	90	69.8	13.3
July	79.5	0	79.5	83.6	11.4
August	77	0	77	83.8	10.7
September	45.5	0.3	45.8	65	10.4
October	32.7	4.8	37.5	74.4	9.4
November	6.9	19.9	25	27.7	10.3
December	1.5	23	21.5	21.8	11.8
Annual	**418.9**	**113.7**	**521.1**	—	**125.3**

a) Total precipitation in mm [eq] is calculated by adding the snowfall in cm (a ratio of 10:1 to convert snow to rain) to the rainfall in mm.
b) Greater or equal to 0.2 mm.
mm[eq] = millimetres equivalent.

Table 8: Seasonal Precipitation Summary for the Winnipeg Airport Station

Season	Total Precipitation (mm[eq])
Winter (December – February)	55.2
Spring (March – May)	111.2
Summer (June – August)	246.5
Fall (September - November	108.3
Total	**521.2**

mm[eq] = millimetres equivalent.

2.2.3 Wind Speed and Direction

Climate normals for wind were not available at the Pinawa WNRE station; therefore, wind climate normals from the Winnipeg Airport station were used to present the long-term wind data from the surrounding area. The long-term average of wind speed and most frequent direction from the Winnipeg Airport station is provided in Table 9. Winds were from the south at the Winnipeg Airport station, with an annual average wind speed of 17 km/hr.

Table 9: Monthly Wind Meteorology Data from the Winnipeg Airport Station

Month	Season	Average Wind Speed (km/hr)	Most Frequent Direction
January	Winter	17.4	S
February		16.9	S
March	Spring	18	S
April		18.5	S
May		18.4	S
June	Summer	16.3	S
July		14.6	S
August		15.4	S
September	Fall	16.9	S
October		18	S
November		17.9	S
December	Winter	17.4	S

S = south.

The Pinawa area is generally characterized by winds predominantly blowing from the south-southeast or north-northwest directions, which may be visualized by an annual wind-rose using hourly wind data obtained from ECCC for the most recent six-year period (January 2010 to December 2015; ECCC 2016b). As seen on Figure 3, there is variation in the annual wind speeds and direction in the area around the WR-1 Building, with winds predominantly from the south and south-southeast and slightly less predominantly from the north-northwest and northwest. Over the six-year period, there were no recorded wind speeds defined as “calms,” having a wind speed of less than 0.2 m/s. Some “model calms” were identified, these are defined as hours having a wind speed less than 3.6 km/hr or 1 m/s. Winds from the south were generally of lower wind speeds than winds from the northwest.

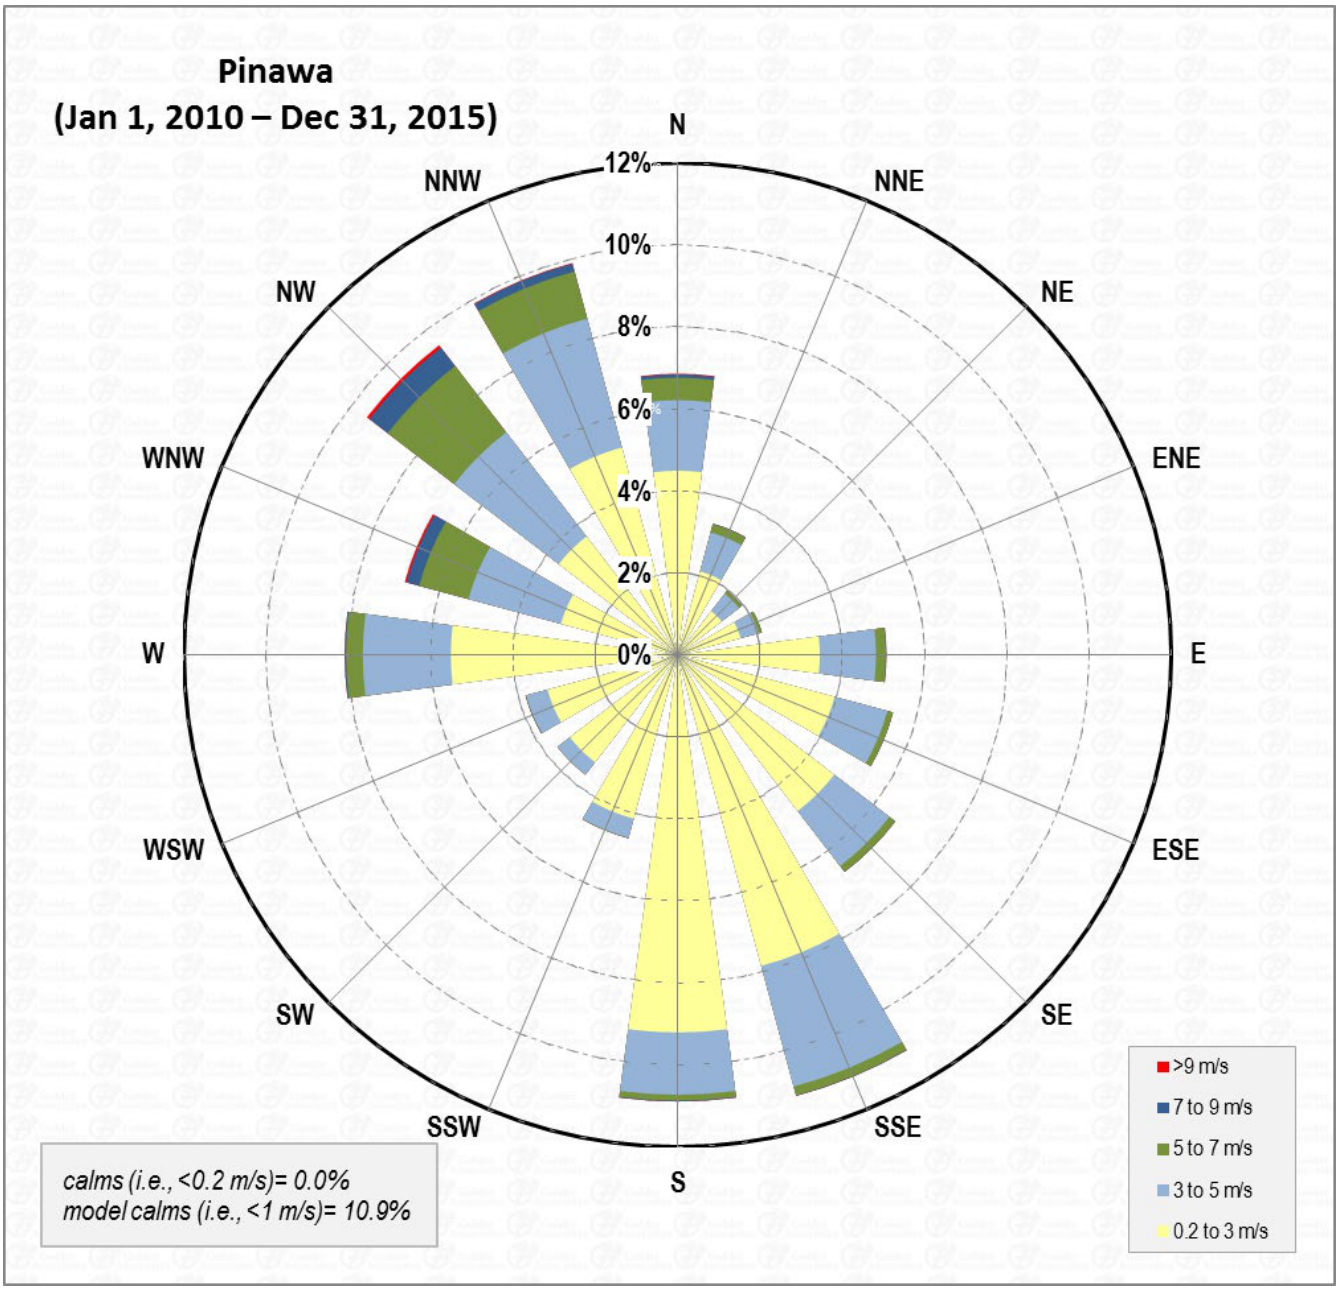

Figure 3: Annual Wind-Rose for the Pinawa WNRE Station (January 2010 to December 2015)

2.2.4 Relative Humidity

Relative humidity is the ratio of the actual water vapour in the air to the maximum amount the air can hold at a given temperature (ECCC 2016a). Table 10 presents the monthly average relative humidity climate normals from the Winnipeg Airport station recorded for 6:00 a.m. and 3:00 p.m. local time. Although the Winnipeg Airport station is located just over 100 km from the Project, it has been used as a regional comparison as there is no closer station reporting long-term relative humidity climate normals.

Table 10: Monthly and Annual Average Relative Humidity from the Winnipeg Airport Station

Month	Average Relative Humidity (%)	
	6:00 a.m.	3:00 p.m.
January	76.9	72.7
February	78.3	71.7
March	81.7	68.5
April	79.1	49.1
May	78.3	46.7
June	83.4	54.5
July	87.7	55.6
August	87.8	52.4
September	87.4	54.8
October	84.3	60.1
November	84.5	72
December	80	75.1
Annual	**82.4**	**61.1**

2.2.5 Atmospheric Pressure

Atmospheric pressure is the force per unit area exerted by the atmosphere on a surface. The higher the altitude, the lower the atmospheric pressure will be as less force will be applied on the surface. The monthly average atmospheric pressure from the Winnipeg Airport station is presented in Table 11. Although the Winnipeg Airport station is located just over 100 km from the Project, it has been used as a regional comparison, as there is no closer station reporting long-term (1981 to 2010) atmospheric pressure climate normals. The atmospheric pressure in Pinawa is comparable to Winnipeg as the stations are located at similar elevations.

Table 11: Monthly and Annual Average Atmospheric Pressure from the Winnipeg Airport Station

Month	Atmospheric Pressure (kPa)
January	98.9
February	98.9
March	98.9
April	98.7
May	98.5
June	98.3
July	98.4
August	98.5
September	98.5
October	98.6
November	98.7
December	98.8
Annual	**98.6**

kPa = kilopascal.

2.2.6 Solar Radiation

Solar radiation data from the Pinawa WNRE station is provided in Table 12. The solar radiation data are available through RETScreen (Natural Resources Canada 2013). RETScreen allows the user to select an ECCC station and provides the site reference conditions for the station selected, including daily solar radiation based on data from the National Aeronautics and Space Administration (NASA).

Table 12: Daily Solar Radiation for the Pinawa WNRE Station

Month	Daily Solar Radiation – Horizontal (kWh/m^2/day)
January	1.20
February	2.13
March	3.38
April	4.57
May	5.56
June	5.84
July	5.85
August	5.02
September	3.43
October	2.23
November	1.35
December	0.94
Annual	**3.47**

kWh/m^2/day = kilowatt-hour per square metre per day.

2.3 Extreme Weather Phenomena

Extreme weather conditions, including extreme temperature (either high or low), precipitation and winds, have been discussed in the previous sections. In addition, the CNSC REGDOC-2.9.1 indicates that extreme weather phenomena should also be included in the air quality assessment. The Comprehensive Study Report (AECL 2001) identified tornadoes as an extreme weather phenomenon and noted that there is a moderate probability of a tornado affecting the WL site. It was estimated that in a given 1 km^2 area within the southern area of Manitoba (approximately 190 km), there is a probability of a tornado strike of 0.00048 per year (AECL 2001).

2.4 Summary of Meteorology

The meteorological parameters discussed above characterize the meteorological climate for the baseline environment, as required by REGDOC-2.9.1. Of the parameters discussed in the sections above; temperature, precipitation, wind speed, wind direction, relative humidity, atmospheric pressure and solar radiation influence the atmospheric dispersion of the indicator compounds emitted in the study areas and from the Project. Results from the air quality assessment will incorporate meteorological effects.

3.0 AIR QUALITY BASELINE ASSESSMENT

This section summarizes the current air quality baseline for non-radiological indicator compounds at the WL site. The results presented in this section represent the Base Case air quality concentrations that are used in the EIS to assess changes to air quality from the Project.

3.1 Non-Radiological Criteria Air Contaminants

The assessment of air quality focused on predicting changes in the concentrations of selected non-radiological indicator compounds. These indicator compounds represent non-radiological compounds that are expected to be emitted from the Project, and include relevant compounds identified in the Comprehensive Study Report (AECL 2001). These compounds are generally accepted as indicators of changing air quality and for which relevant air quality criteria exist. The selected non-radiological indicator compounds fall into the following three categories:

- **particulate matter**: suspended particulate matter (SPM), particles nominally smaller than 10 µm in diameter (PM_{10}) and particles nominally smaller than 2.5 µm in diameter ($PM_{2.5}$); and
- **combustion gases**: nitrogen oxides (NO_X) represented by nitrogen dioxide (NO_2), sulphur dioxide (SO_2) and carbon monoxide (CO).

These compounds are associated with various Project activities. Particulate matter is typically associated with airborne dust from demolition and decommissioning activities including the mobile concrete batching plant, vehicles travelling over on-site paved roads, as well as material loading and unloading activities. Products of combustion (NO_2, SO_2 and CO) are associated with the exhaust from on-site vehicles.

While ozone (O_3) is not directly emitted into the atmosphere from the Project, it is associated with the reaction of NO_X and volatile organic compounds (VOCs) to create NO_2 (MOE 2010). Ozone will be assessed as part of baseline conditions due to the availability of air quality monitoring data; however, emissions of ozone will not be quantified for the Project's air quality assessment Ozone baseline data will be used to calculate the NO_2 emissions from the Project. The VOCs, while a criteria air contaminant, are not considered indicator compounds for this Project. VOCs are not expected to be emitted from the decommissioning activities with the exception of some VOC emissions from fuel combustion; and therefore, were not retained for the air quality baseline assessment.

3.1.1 Applicable Guidelines

The relevant air quality criteria used for screening air quality effects in the region include the Manitoba Air Quality Criteria. The Province of Manitoba, Department of Sustainable Development, Climate Change and Air Quality Branch (Manitoba) has set guidelines related to ambient air concentrations and are summarized in *Objectives and Guidelines for Various Air Pollutants: Ambient Air Quality Criteria* (AAQC) (Government of Manitoba 2005). The Manitoba AAQCs are maximum concentration levels set for the protection and preservation of ambient air quality within Manitoba. The criteria are classified as objectives, guidelines or Canada-wide Standards. The Canada-wide Standards were updated in 2012 and are now known as Canadian Ambient Air Quality Standards (CAAQSs). The Manitoba AAQC are characterized as maximum tolerable, acceptable or desirable level concentrations in ambient air, and intend to serve as guidance for air quality assessment.

The Manitoba AAQC document states the following:

- Maximum Acceptable Levels are not to be exceeded in any urban centre including areas that are in the vicinity of industries with atmospheric emissions;
- within rural areas, it is in the goal to maintain pollutant concentrations at or below Maximum Desirable Levels; and
- Maximum Tolerable Levels are only for evaluation purposes to identify the severity of an anthropogenic or natural phenomenon in order to protect human health and institute appropriate corrective action.

As the Project is located in a rural area, the Maximum Desirable Levels were used to assess background air quality conditions if available; where the Maximum Desirable Levels were not available, the Maximum Acceptable Levels were used.

There are two sets of federal objectives and criteria: the National Ambient Air Quality Objectives (NAAQOs) and the Canadian Ambient Air Quality Standards (CAAQSs; formerly Canada Wide Standards or National Ambient Air Quality Standards [NAAQS]). Similar to the Manitoba AAQCs, the NAAQOs are benchmarks that can be used to facilitate air quality management on a regional scale, and provide goals for outdoor air quality that protect public health, the environment, or aesthetic properties of the environment (Canadian Council of Ministers of the Environment [CCME] 1999).

The NAAQOs are not regulatory criteria rather federal government has established the following levels of NAAQOs (Health Canada 1994):

- the Maximum Desirable Level defines the long-term goal for air quality and provides a basis for an anti-degradation policy for unpolluted parts of the country and for the continuing development of control technology; and
- the Maximum Acceptable Level is intended to provide adequate protection against adverse effects on soil, water, vegetation, materials, animals, visibility, personal comfort and well-being.

The CAAQSs have been developed under the *Canadian Environmental Protection Act* (CEPA) and include standards for $PM_{2.5}$, NO_2, SO_2 and ozone that must be achieved by 2020, as well as more stringent standards for NO_2, SO_2 and ozone that must be achieved by 2025. In 2015 the standard was phased in, with the final standard phase in date in 2025 (Government of Canada 2020). Similar to the NAAQOs the CAAQSs are not regulatory limits but, rather, are used as national targets for $PM_{2.5}$, NO_2, SO_2 and ozone, excluding Quebec (CCME 2014).

Monitoring data in Canada periodically exceeds these criteria, objectives, and standards at different locations for different periods of time. Measured concentrations above these values does not necessarily result in an immediate effects but serves as a guidance for areas where air quality could potentially be improved and to take actions to reduce or limit exposure.

A summary of the applicable Manitoba and federal objectives and criteria is listed in Table 13.

Table 13: Manitoba and Canadian Regulatory Air Quality Objectives and Criteria

Contaminant	Criteria Classification	Averaging Period	Manitoba AAQC[a] (µg/m³)			Canada-wide Standards[b]	Canadian Ambient Air Quality Standards[c] (µg/m³)	National Ambient Air Quality Standards and Objectives[d] (µg/m³)	
			Tolerable	Acceptable	Desirable			Desirable	Acceptable
SPM	Objective	24-hr	400	120	—	—	—	—	120
SPM	Objective	Annual	—	70	60	—	—	60	70
PM_{10}	Guideline	24-hr	—	50	—	—	—	—	—

SO_2	Guideline	Annual	—	60	30	—	10.5	30	60

a) Manitoba AAQC (Government of Manitoba 2005).

b) Canada-wide Standard as published in the Manitoba AAQC (2005) (updated in 2012 to CAAQS).

c) CAAQS published in the Canada Gazette Volume 147, No. 21 - May 25, 2013. Final standard phase in date of 2020 used.

d) CCME (1999).

e) The 24-hour CAAQS for $PM_{2.5}$ is based on the three-year average of the annual 98th percentile of the daily averaged monitored data. The annual CAAQS for PM2.5 is based on the three-year average of annual averaged monitored data.

f) The 1-hour CAAQS for NO_2 is based on the 3-year average of the annual 98th percentile of the daily maximum 1-hour average concentrations.

g) The 1-hour CAAQS for SO_2 is based on the 3-year average of the annual 99th percentile of the SO_2 daily maximum 1-hour average concentrations.

µg/m³ = micrograms per cubic metre; SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; CO = carbon monoxide; NO_2 = nitrogen dioxide; O_3 = ozone; SO_2 = sulphur dioxide; — = No guideline available.

3.1.2 Existing Emissions Sources

There are three industrial facilities that report indicator compounds releases, disposals and transfers for recycling under Part 1A to the National Pollutant Release Inventory (NPRI) within 55 km of the Project (ECCC 2016c). These emissions contribute to the local air quality and the consideration of cumulative effects. Reporting facilities and emission totals are summarized in Table 14. These sources are minor contributors to the Projects indicator compounds provincial totals, as their total emissions for the six indicator compounds contribute from less than 1% to 3% to their respective provincial total emissions.

Table 14: 2014 Air Emission Totals for Industry Reported to National Pollutant Release Inventory within 55 km of the Project

Company Name	Distance to the Project (km)[a]	Direction from the Project	Emissions (tonnes)					
			NO_X	SO_2	CO	SPM	PM_{10}	$PM_{2.5}$
			11104-93-1	7446-09-5	630-08-0	NA-M08	NA-M09	NA-M10

Percent Facilities Total of Manitoba Total			<1%	<1%	<1%	3.0%	2.0%	<1%

a) Approximate distance from WR-1 as reported to NPRI

b) NO_X, SO_2 and CO emissions for WL are reported as part of the Annual Safety Review Report.

SE = southeast; NW = northwest; NE = northeast; NO_X = nitrogen oxides; SO_2 = sulphur dioxide; CO = carbon monoxide; SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; — = Below NPRI reporting threshold.

3.2 Data Sources

In Manitoba and throughout Canada, regional air quality is monitored through a network of air quality monitoring stations operated by the ECCC NAPS. These stations are operated under strict quality assurance and quality control procedures. Existing air quality was characterized using background air concentrations from monitoring data sources near the Project. The Comprehensive Study Report (AECL 2001) included an air quality baseline assessment that used monitoring stations that are no longer in operation or have been relocated (i.e., Winnipeg's station ID 9119); therefore, the data from these stations was not considered in this assessment.

There are no air quality monitoring stations within the RSA; however, six air quality monitoring stations are located within 1,100 km of the Project: Winnipeg (65 Ellen Street), Experimental Lakes, Brandon Assiniboine Community College (Assiniboine) and Flin Flon in Manitoba and Estevan and Buffalo Narrows in Saskatchewan. The 65 Ellen Street station was the only air quality monitoring station located within 100 km of the Project[1]. The 65 Ellen Street station includes all indicator compounds with the exception of SPM. The 65 Ellen Street station is

[1] The second monitoring station in Winnipeg was not selected for this assessment as it monitors less

located approximately 84 km from the Project, in an urban area and approximately 60 km to 70 km away from two large bodies of water.

The second closest station, Experimental Lakes is located approximately 180 km away from the Project and is situated in one of the largest research areas for freshwater lakes that is managed by the International Institute for Sustainable Development (IISD 2016). The data from this station is heavily influenced by the more than 50 surrounding freshwater lakes and the station only monitors ozone which makes it difficult to compare with the other data sets. The limited data from this station are not considered representative of the air quality within the LSA and RSA, and therefore, were not used in the air quality assessment.

The next closest air quality monitoring station is located in Brandon Assiniboine Community College (Assiniboine) and includes all indicator compounds with the exception of CO, SO_2 and SPM. The Assiniboine station is located approximately 280 km from the Project.

The Flin Flon, Estevan and Buffalo Narrows air quality monitoring stations are located approximately 645 km, 512 km and 1,036 km away from the project, respectively. These stations are the three closest stations in proximity to the project location that are located in areas more characteristic of the Project location in terms of population, urbanization, and land use and that include all indicator compounds, with the exception of CO and SPM.

Ideally, an air quality monitoring station would be within close proximity of the Project with a similar geographical siting and similar influences; however, the NAPS program focuses on areas that are affected by local sources and not on remote un-affected areas like the WL site. Therefore, for the Project, all six of the stations, except for Experimental Lake, will be considered in the assessment to produce a range of background air quality concentrations that will be used in the assessment.

The relative locations of the five air monitoring stations selected to describe the background air quality for the LSA and RSA (i.e., 65 Ellen Street, Assiniboine, Flin Flon, Estevan and Buffalo Narrows) are provided in Table 15 and the station locations are shown on Figure 1. For this assessment, data from 2009 to 2013 was used for the 65 Ellen Street and Assiniboine stations, which is the most recent five-year period at the time of the original assessment for which all data are available and quality assured by ECCC. For the Flin Flon, Estevan and Buffalo Narrows stations, data from 2017-2021 was used which is the most recent five-year period at the time of the updated assessment for which all data are available and quality assured by ECCC.

Table 15: Location of Air Monitoring Stations to the Project

City	NAPS Station ID	Location	Latitude and Longitude	Distance to the Project[(a)] (km)	Direction
Winnipeg	70119	Outside Regional Study Area	49.89809, -97.14652	84	Southwest
Brandon	70203	Outside Regional Study Area	49.83918, -99.9206	280	Southwest
Estevan	80502	Outside Regional Study Area	49.132350, -102.98499	512	Southwest
Flin Flon	70301	Outside Regional Study Area	54.76852, -101.87747	645	Northwest
Buffalo Narrows	82002	Outside Regional Study Area	55.834566, -108.403332	1,036	Northwest

a) Approximate distance from WR-1.

NAPS = National Air Pollution Surveillance

The air flow into the WL site varies in direction but is predominantly blowing from the south and south-southeast and slightly less predominantly from the north-northwest and northwest. The Project is located in a fairly remote area, with very few industrial emission sources that influence the airshed surrounding the Project.. As the 65 Elle Street and Assiniboine monitoring stations are located in more industrial and urban areas, the air quality data from these two stations can be considered to provide conservative air quality estimates and are likely to be greater than the existing conditions in the RSA. As the Flin Flon, Estevan and Buffalo Narrows stations are located in areas more characteristic of the project location in terms of population, urbanization, and land use, the air quality data from these three stations can be considered to provide representative air quality estimates of the existing conditions in the RSA.

Table 16 provides a summary of the monitoring data available from each of the five selected stations for the period from 2000 through 2021. At the time of the original assessment, complete datasets were available up until 2013, with only partial information available for 2014 and 2015 at the 65 Ellen Street and Assiniboine stations. At the time of the updated assessment, compete datasets were available up until 2021 at the Flin Flon, Estevan and Buffalo Narrows stations. Not all compounds have the same data availability period for a given station, as additional compounds are added to the station at different dates as required by the ECCC (e.g., SO_2 was only monitored starting in 2008).

Table 16: Availability of Ambient Air Quality Data (Years)

Compound	65 Ellen Street Station	Assiniboine Station	Buffalo Narrows Station	Flin Flon Station	Estevan Station
SPM	—	—	—	—	—
PM_{10}	2006 - 2013	2006 - 2013	2017-2021	2002-2021	2017-2021
$PM_{2.5}$	2000 - 2002, 2013	2001 - 2002, 2013	2017-2021	2002-2021	2017-2021
NO_2	2000 - 2013	2000 - 2010, 2012 - 2013	2017-2021	2002-2021	2017-2021
NO	2000 - 2013	2000 - 2013	—	—	—
SO_2	2008 - 2013	—	2017-2021	2008-2021	2017-2021
CO	2006 - 2013	—	—	—	—
O_3	2000 - 2013	2000 - 2013	2017-2021	2002-2021	2017-2021

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; CO = carbon monoxide; NO_2 = nitrogen dioxide; NO = nitrogen oxide; O_3 = ozone; SO_2 = sulphur dioxide; — = data for the parameter were not available at that station.

3.3 Assessment of Background Air Quality

The continuous monitoring stations listed in Table 15 were used to reflect the existing conditions in the RSA. The existing air quality levels based on background air concentrations from available monitoring stations are summarized in the following sections. The available air monitoring data represents the combined effect of emissions from sources near to each of the monitoring stations, as well as the effect of the emissions transported into the region.

Although gaseous monitoring equipment records concentrations in units of parts per million parts (ppm) or parts per billion parts (ppb), regulatory criteria are established on the basis of micrograms per cubic metre (µg/m³). In this section, monitoring results for gaseous compounds are presented in the units of µg/m³, to facilitate the comparison of monitoring to criteria. The conversion from ppm to µg/m³ is unique to each compound, based on

the molecular weight of the compound and standard atmospheric conditions (1 atmosphere of pressure and 25°C). In contrast, particulate monitoring equipment records concentrations in units of µg/m³, allowing for direct comparison to the regulatory criteria.

3.3.1 Comparison of Monitored Data by Indicator Compound

The graphs in the following sections present simplified box-and-whisker plots showing the available concentration data. The box on the figures represents the bounds of the middle 50% of the data points. The top of the box represents the 75th percentile concentration, while the bottom of the box represented the 25th percentile concentration. The line through the middle of the box represents the median, or 50th percentile concentration. The orange diamond represents the average concentration, and the green circle represents the 90th percentile. On these figures, the whiskers extend up to the maximum and down to the minimum concentration.

The 90th percentile of the 1-hour, 8-hour and 24-hour measurements are typically used to represent the background air quality value when conducting an effects assessment as this value is exceeded only 10% of the time. The annual average concentration is used for annual background levels (AESRD 2013) and based on the measurement data. The average concentration for the shorter time periods provides an indication of what air quality would typically be at the location. The 75th percentile provides an indication of the concentration below which most of the existing air quality readings occurred. Significant differences between the average and 75th percentile readings provide an indication that the background air quality is dominated by infrequent, increases in measured concentration.

Particulate Matter (SPM, PM_{10} and $PM_{2.5}$)

Particulate emissions occur due to anthropogenic activities (e.g., industrial, transportation and residential sources), as well as natural sources. Suspended particulate matter is classified based on its aerodynamic particle size, primarily due to the different health effects that can be associated with the particles of different diameters.

There is no monitoring data available for SPM at any of the five stations in this assessment, however, an estimate of the background SPM concentrations can be estimated from the available PM_{10} monitoring results. Because PM_{10} is a subset of SPM, it is reasonable to assume that the ambient concentrations of SPM will be greater than corresponding PM_{10} levels. The mean levels of PM_{10} in Canadian locations are found to be approximately 50% of the SPM concentrations (Brook et al. 2011). By applying this ratio, it is possible to estimate the background SPM concentrations for the RSA. The average and 90th percentile 24-hour SPM estimated from PM_{10} monitoring results did not exceed the Manitoba AAQC (Acceptable Level) at any monitoring station.

Monitoring data for PM_{10} was available at all monitoring stations. There were no PM_{10} values that are above the Manitoba AAQC (Acceptable Level) at the 65 Ellen Street station; however, the maximum monitored PM_{10} data are above the AAQC at the other four stations, as shown on Figure 4.

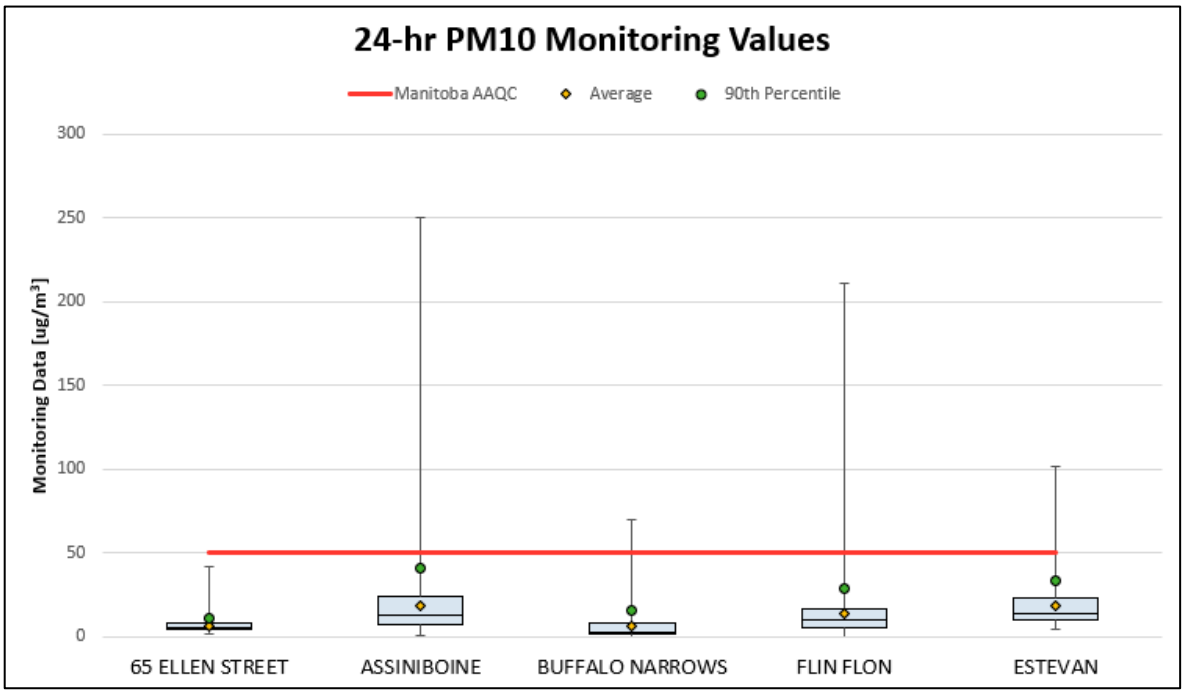

Figure 4: PM_{10} Monitoring Data for 2009 through 2013 (65 Ellen Street & Assiniboine) and 2017 through 2021 (Flin Flon, Estevan & Buffalo Narrows)

In Manitoba, fine particulate matter ($PM_{2.5}$) emissions have been demonstrating a steady decline since 1990 (ECCC 2016d). While the maximum 24-hour value of $PM_{2.5}$ at 65 Ellen Street, Flin Flon, Estevan and Buffalo Narrows may be above the CAAQS (to be phased-in in 2020; as shown on Figure 5), the standards are calculated as the 98th percentile of the annual monitored data averaged over three years of measurements. At the time of this assessment, at the 65 Ellen Street and Assiniboine stations, there were no periods of three consecutive years with monitored data after 2008. Therefore, there is insufficient data quantity for an assessment against the 24-hour CAAQS. Similarly, an assessment of the annual of the CAAQS could not be completed for these stations due to insufficient data quantity; however, a background value based on the annual average of the 2013 monitoring data were calculated to be 6.64 µg/m³ at the 65 Ellen Street station. Table 17 presents the 24-hour $PM_{2.5}$ ambient monitoring results calculated according to the methodology for the Flin Flon, Estevan and Buffalo Narrows stations. The CAAQS have been exceeded for two three-year periods at Flin Flon and one three-year period at Estevan.

Table 17: Summary of 3-year average 24-Hour $PM_{2.5}$ Monitoring Results for Comparison to the CAAQS

Years	24-Hour $PM_{2.5}$ [ug/m^3]		
	Flin Flon	**Estevan**	**Buffalo Narrows**
2017 – 2019	39.41	19.71	29.37
2018 – 2020	24.64	20.93	27.94
2019 – 2021	—	20.17	26.71

Nitrogen Oxides and Nitrogen Dioxide (NO_x and NO_2)

The oxides of nitrogen (NO_x) are emitted in two primary forms: nitric oxide (NO) and nitrogen dioxide (NO_2 The NO reacts with ozone in the atmosphere to create NO_2. The air quality assessment was complete for NO_2, which has a Manitoba AAQCs. The primary source of NO_x and NO_2 in the region is the combustion of fossil fuels. Emissions of NO_X and NO_2 result from the operation of stationary sources such as, boilers and generators, as well as the operation of mobile sources such as vehicles, haul trucks and other equipment.

The annual mean concentrations of NO_2 in Manitoba have been decreasing slowly since 1990 (ECCC 2016e). There was NO_2 monitoring available at all monitoring stations and there were no data above the 24-hour Manitoba AAQC (Acceptable Level) for NO_2 (Figure 6). While the maximum 1-hour values of NO_2 at the 65 Ellen Street, Assiniboine and Estevan stations may be above the CAAQS (to be phased-in in 2025; as shown on Figure 6), the standards are calculated as the 98th percentile of the annual monitored data averaged over three years of measurements (Figure 6). At the time of this assessment, at the 65 Ellen Street and Assiniboine stations, there were no periods of three consecutive years with monitored data after 2008. Therefore, there is insufficient data quantity for an assessment against the 1-hour CAAQS. Similarly, an assessment of the annual of the CAAQS could not be completed for these stations due to insufficient data quantity. Table 18 presents the 1-hour NO_2 ambient monitoring results calculated according to the CAAQS methodology for the Flin Flon, Estevan and Buffalo Narrows stations. The CAAQS have not been exceeded using this method at any of the three stations.

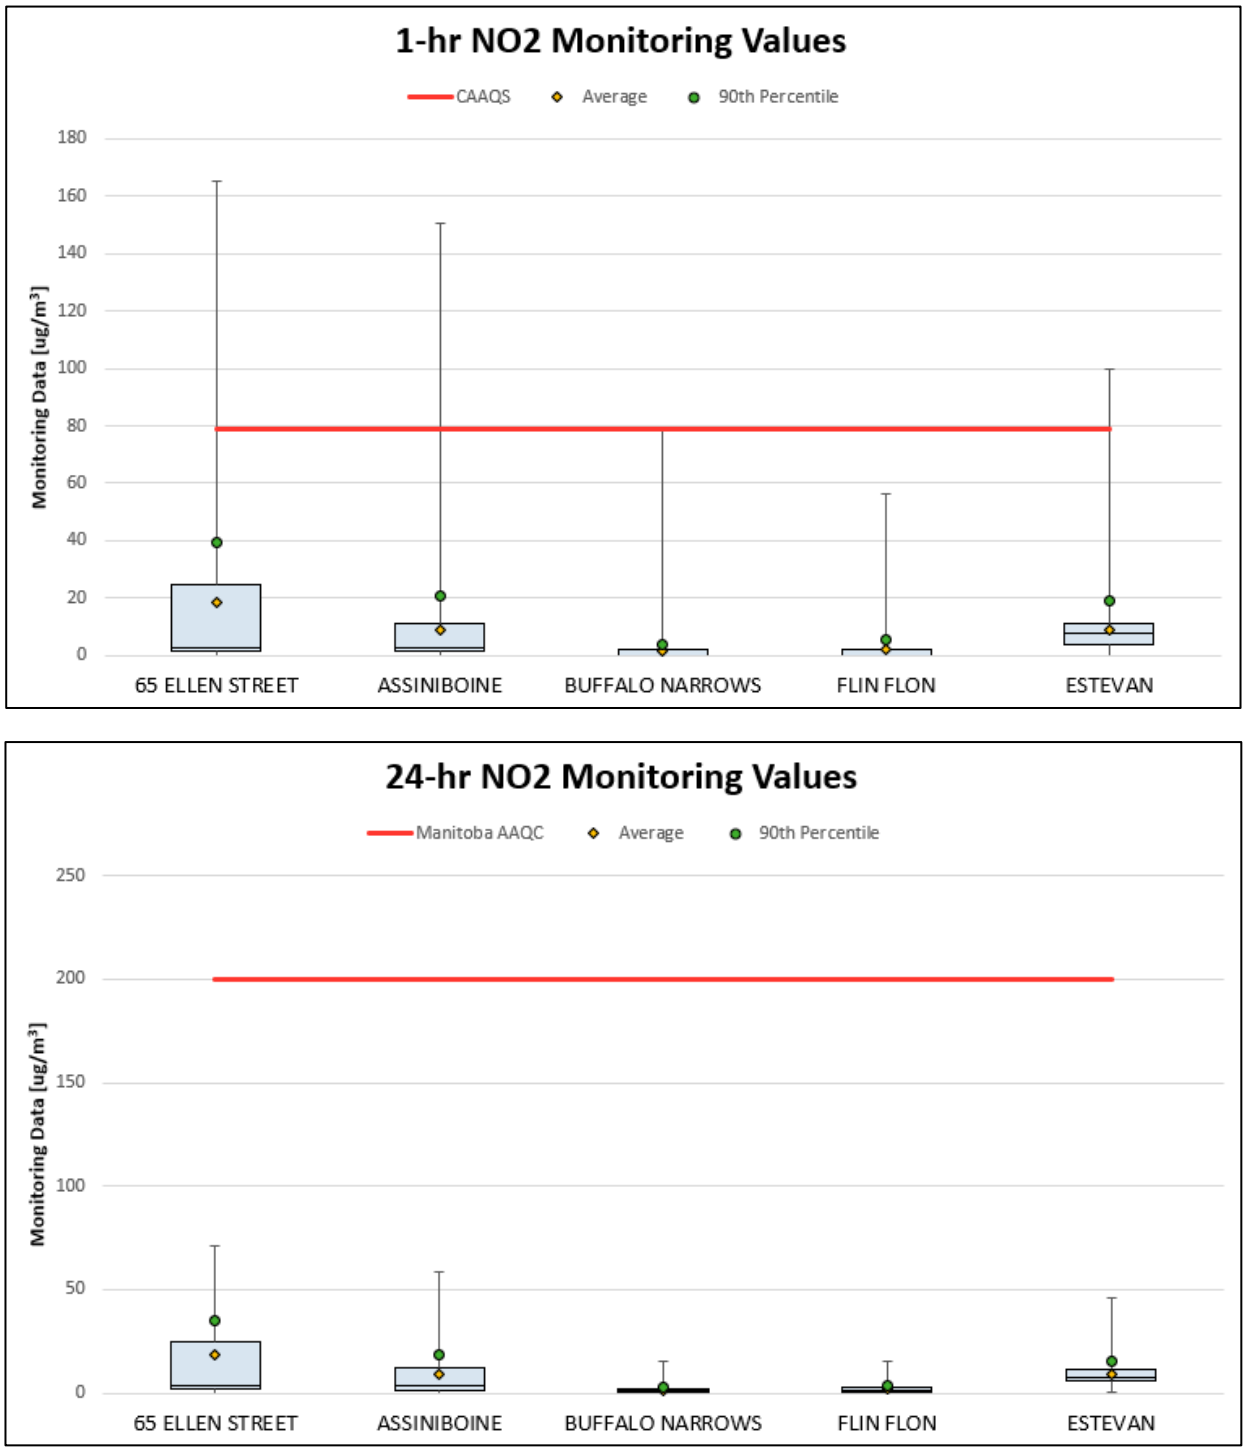

Figure 6: *NO_2 Monitoring Data for 2009 through 2013 (65 Ellen Street & Assiniboine) and 2017 through 2021 (Flin Flon, Estevan & Buffalo Narrows)*

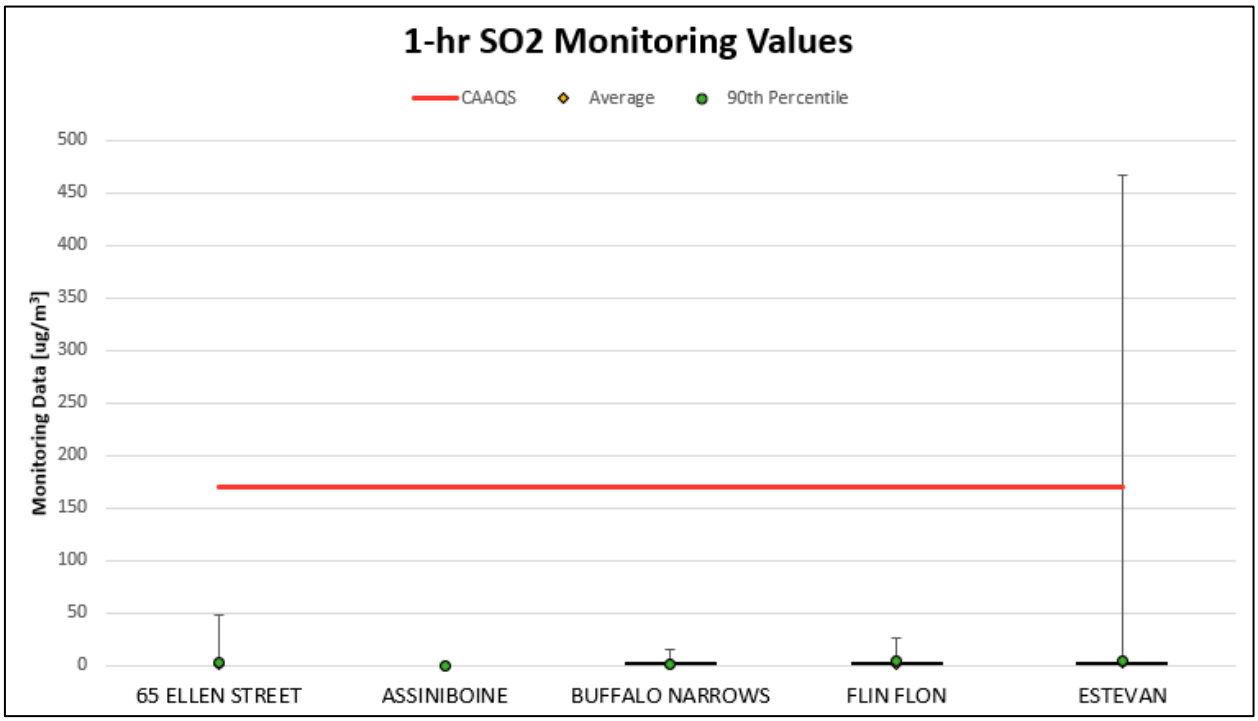
Table 18: Summary of 3-year average 1-Hour NO_2 Monitoring Results for Comparison to the CAAQS

Years	1-Hour NO_2 [ug/m^3]		
	Flin Flon	Estevan	Buffalo Narrows
2017 – 2019	—	54.07	13.05
2018 – 2020	—	62.66	17.44
2019 – 2021	—	61.36	16.36

Sulphur Dioxide (SO_2)

The primary source of sulphur dioxide (SO_2) is the combustion of fossil fuels in a variety of sectors such as the electricity and smelter sectors. In Manitoba, emissions have decreased significantly due to the phase out of coal-fired generating stations in the province. A summary of the monitored SO_2 concentrations are summarized on Figure 7. While SO_2 monitoring was not available at the Assiniboine station, only Estevan recorded an SO_2 value above the 1-hour CAAQS while no stations recorded monitoring data above the 24-hour AAQC (Desirable Level) for SO_2. While the maximum 1-hour values of SO_2 at the Estevan station may be above the CAAQS (to be phased-in in 2025; as shown on Figure 7), the standards are calculated as the 99th percentile of the annual monitored data averaged over three years of measurements (Figure 7). At the time of this assessment, there were no periods of three consecutive years with monitored data available after 2008 from the 65 Ellen Street and Assiniboine stations,. Therefore, there is insufficient data quantity for an assessment against the 1-hour CAAQS. Similarly, an assessment of the annual CAAQS could not be completed for these stations due to insufficient data quantity. Table 19 presents the 1-hour SO_2 ambient monitoring results calculated according to the CAAQS methodology for the Flin Flon, Estevan and Buffalo Narrows stations. The CAAQS have been exceeded for all three-year periods at the Estevan station but the have been no exceedances at the Flin Flon or Buffalo Narrows stations.



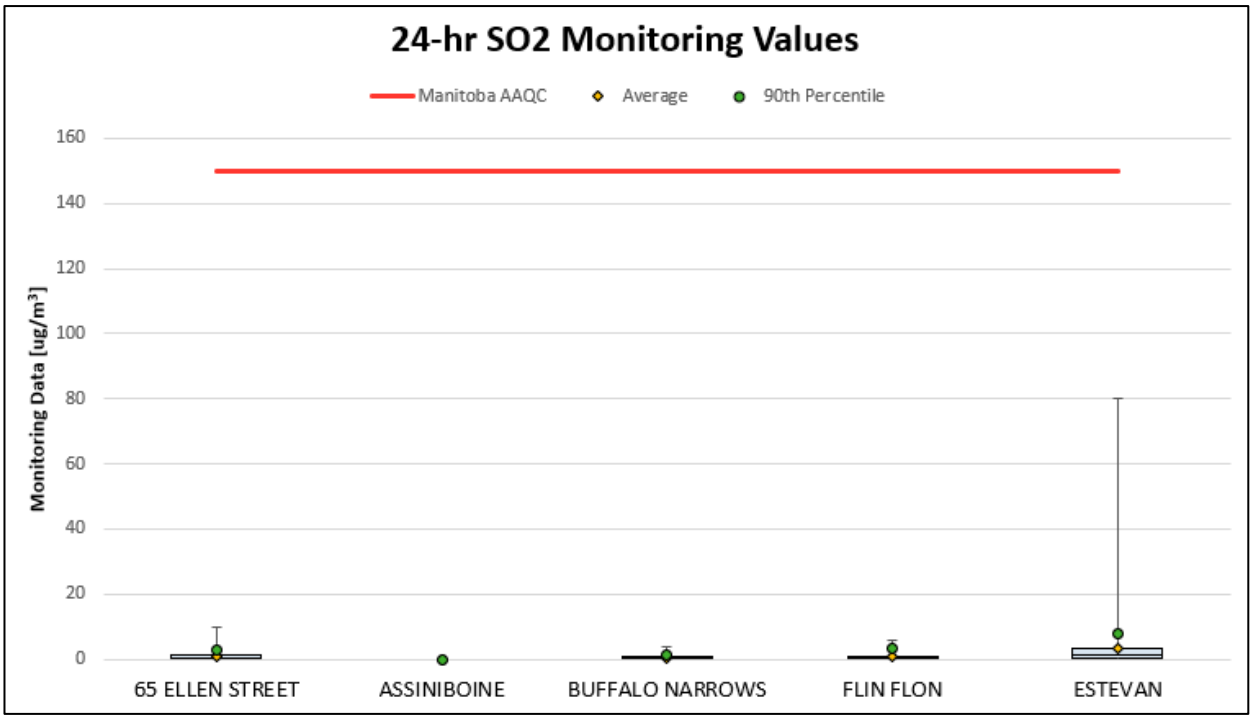


Figure 7: *SO_2 Monitoring Data for 2009 through 2013 (65 Ellen Street & Assiniboine) and 2017 through 2021 (Flin Flon, Estevan & Buffalo Narrows)*

Table 19: Summary of 3-year average 1-Hour SO_2 Monitoring Results for Comparison to the CAAQS

Years	1-Hour SO_2 [ug/m^3]		
	Flin Flon	Estevan	Buffalo Narrows
2017 – 2019	7.10	208.05	6.72
2018 – 2020	8.70	251.12	6.56
2019 – 2021	—	257.31	6.53

Carbon Monoxide (CO)

Carbon monoxide (CO) is a colourless, odourless, tasteless and, at high concentrations, toxic gas. It is produced primarily from the incomplete combustion of fossil fuels, as well as natural sources. Emissions of CO have been decreasing since 1990, mainly due to transportation emission reductions (ECCC 2016f). While CO monitoring was not available at the Assiniboine, Flin Flon, Estevan or Buffalo Narrows stations, there were no values above the 1-hour or 8-hour AAQC (Desirable Level) for CO recorded at the 65 Ellen Street station between 2009 and 2013 (Figure 8).

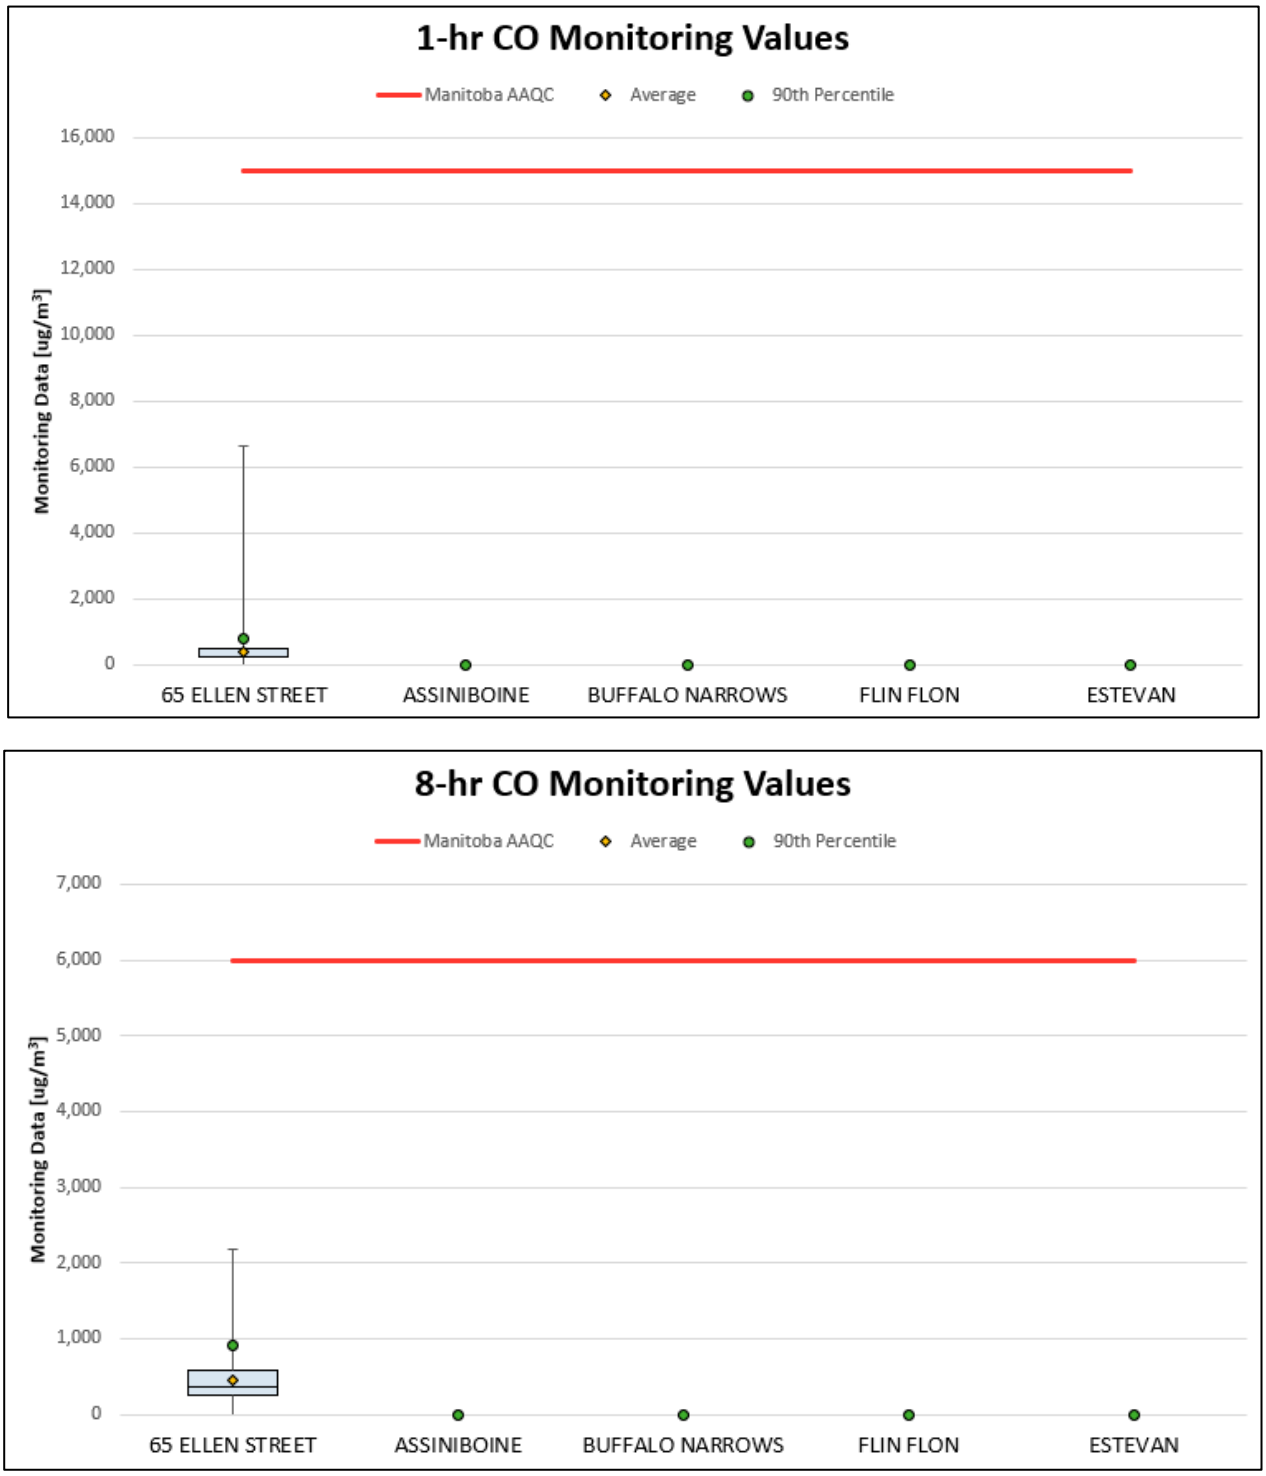

Figure 8: CO Monitoring Data for 2009 through 2013 (65 Ellen Street & Assiniboine) and 2017 through 2021 (Flin Flon, Estevan & Buffalo Narrows)

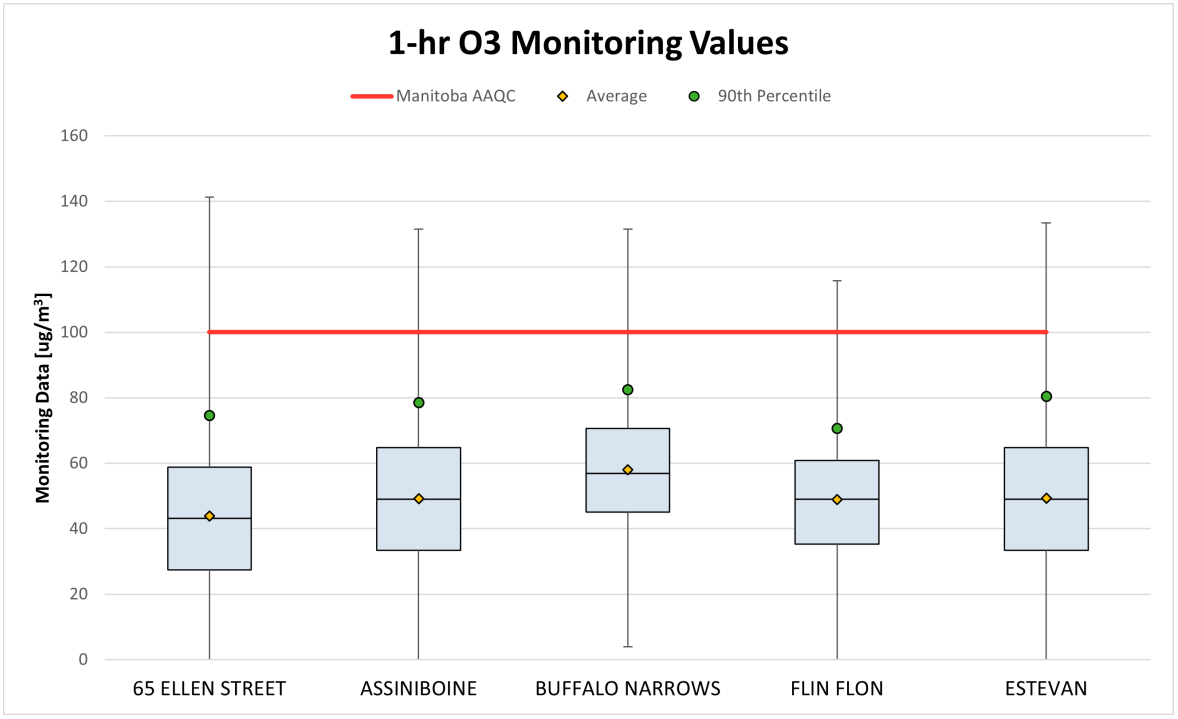
Ozone (O_3)

Ground-level ozone (O_3) is formed when NO_x and VOCs react in the presence of sunlight. A summary of the monitored O_3 concentrations is provided on Figure 9. Although the maximum 1-hour concentrations of O_3 were above the Manitoba AAQC (Desirable Level), the average and 90th percentile concentrations were below this Manitoba AAQC. Overall, O_3 values above the 1-hour Manitoba AAQC were measured at the 65 Ellen Street station and Assiniboine station 5% and 6% of the time (equivalent to 100 and 109 days in 5 years), respectively, throughout the period of 2009 to 2013 and, at most, 8% of the time in one of the years at both stations (equivalent to approximately 29 days per year). Ozone values above the 1-hour Manitoba AAQC were measured at the Flin Flon, Estevan and Buffalo Narrows stations 0.43%, 1.9%, and 1.3% of the time (equivalent to 8, 34, and 24 days in 5 years), respectively, throughout the period of 2017 to 2021 and, at most, 4.1% of the time in one of the years at any of the three stations (equivalent to approximately 15 days per year).

Currently there is no 8-hour Manitoba AAQC for O_3, but there is a CAAQS, which has been used for comparison to the data. The maximum 8-hour concentration of O_3 was above the standard at the 65 Ellen Street station, Assiniboine station and Buffalo Narrows station but was just below this standard at the Flin Flon and Estevan stations. However, compliance with the CAAQS is based on the fourth highest 8-hour value annually, averaged over a 3-year period. At all five stations, the most recent average 4th highest concentrations were below the CAAQS. Tables 20 and 21 present a summary of the 3-year averaging method using 8-hour O_3 ambient monitoring results.



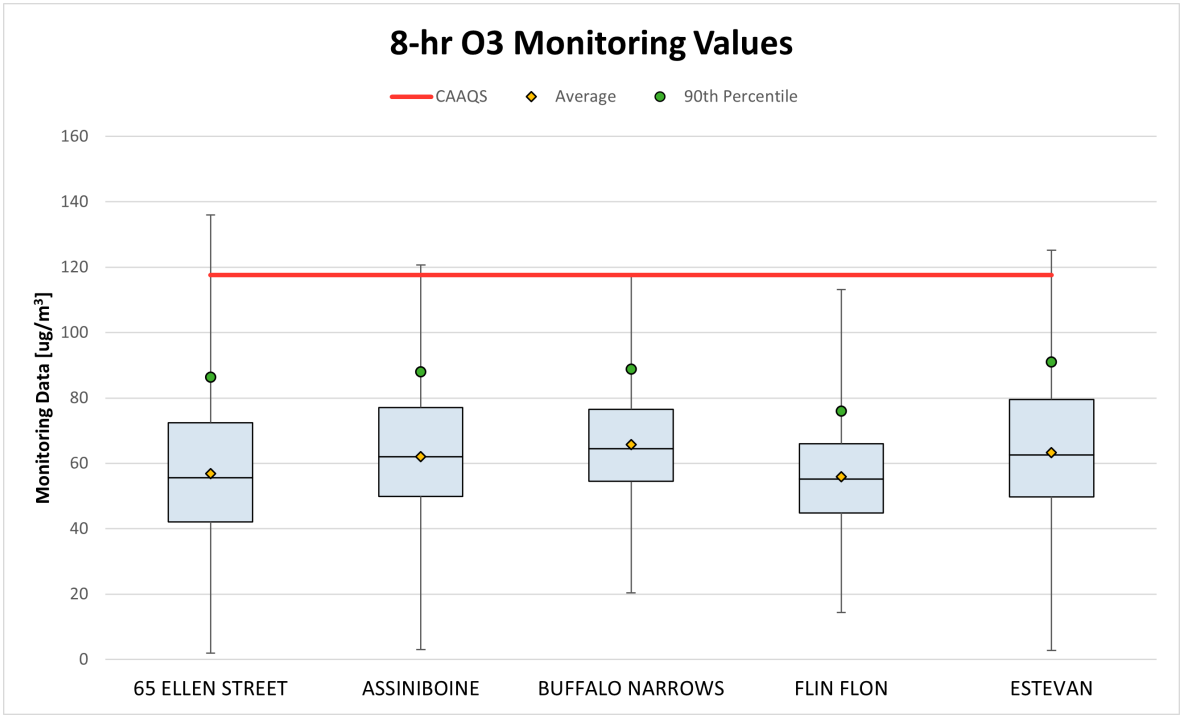


Figure 9: *O_3 Monitoring Data for 2009 through 2013 (65 Ellen Street & Assiniboine) and 2017 through 2021 (Flin Flon, Estevan & Buffalo Narrows)*

Years	8-Hour Ozone [µg/m³]

3.4 Summary of Monitored Data by Station

For each of the five stations, monitoring data for the years 2009 through 2013 (65 Ellen Street and Assiniboine) and for the years 2017-2021 (Flin Flon, Estevan and Buffalo Narrows) were summarized by indicator compound for the averaging period relevant to the AAQC. As discussed above, to provide an understanding of the variability of the monitoring data, the average, 75th percentile, 90th percentile and maximum values for both stations are summarized in Tables 22 through 26.

Table 22: Summary of Background Air Quality at the 65 Ellen Street Station (2009 – 2013)

CAC	Averaging Period	Average (µg/m³)[a]	75th (µg/m³)[a]	90th (µg/m³)[a]	Max (µg/m³)[a]
SPM[b]	24-hour	13.63	16.23	22.46	83.25
	Annual	13.72	—	—	19.45
PM_{10}	24-hour	6.81	8.11	11.23	41.63
$PM_{2.5}$	24-hour	6.65	8.29	11.58	33.46
	Annual	6.64	—	—	6.64
NO_2	1-Hour	18.45	24.45	39.50	165.53
	24-Hour	18.48	24.62	35.41	71.23
	Annual	18.48	—	—	21.86
SO_2	1-Hour	0.74	0.00	2.62	47.15
	24-Hour	0.75	1.09	2.62	9.79
	Annual	0.75	—	—	1.30
CO	1-Hour	373.75	458.10	801.67	6642.40
	8-Hour	453.79	588.98	916.19	2192.32
O_3	1-Hour	43.85	58.87	74.57	141.30
	8-Hour	56.88	72.37	86.35	135.90

a) Data measured in parts per billion (ppb) or parts per million (ppm), were converted to µg/m³ assuming standard temperature and pressure (25°C and one atmosphere of pressure).

b) SPM concentrations were calculated using PM_{10} concentrations.

CAC = criteria air contaminant; µg/m³ = microgram per cubic metre; SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; CO = carbon monoxide; O_3 = ozone.

Table 23: Summary of Background Air Quality at the Assiniboine Station (2009 – 2013)

Indicator	Averaging Period	Average[a] (µg/m³)	75th[a] (µg/m³)	90th[a] (µg/m³)	Max[a] (µg/m³)

3.5 Summary of Background Air Quality

This section summarizes the existing air quality for the RSA, which is considered as background air quality. The 65 Ellen Street station is the only air quality monitoring station located within 100 km of the Project, but both the 65 Ellen Street station and the Assiniboine station are located in urban settings that could have elevated background air quality concentrations that are over-conservative for this assessment. The Flin Flon, Estevan and Buffalo Narrows stations are all located in rural areas more characteristic of the project location in terms of population, urbanization, and land use but are each located over 500 km from the Project. As a result, minimum and maximum background concentrations from all five stations were considered to be the most representative background air quality for non-radiological indicator compounds in the RSA. The background air quality values retained for the assessment are presented below in Table 27 and are based on the minimum and maximum values from all five stations. The existing concentrations are below the respective provincial and federal criteria for each indicator compound, suggesting that the region has generally good air quality.

Table 27: Background Air Quality Values (90th Percentile, Average for Annual Only)[a]

Indicator	Averaging Period	65 Ellen Street (84 km SW)	Assiniboine (280 km SW)	Flin Flon (645 km NW)	Estevan SK (512 km SW)	Buffalo Narrows SK (1,036 km NW)	Background (Minimum Base Case)	Background (Maximum Base Case)
SPM	24-hour	22.46	81.61	58.38	67.33	32.16	**22.46**	**81.61**
	Annual	13.72	38.26	29.05	37.57	12.44	**12.44**	**38.26**
PM_{10}	24-hour	11.23	40.80	29.19	33.67	16.08	**11.23**	**40.80**
$PM_{2.5}$	24-hour	11.58	11.79	15.00	11.84	8.67	**8.67**	**15.00**
	Annual	6.64	6.47	6.53	6.81	5.70	**5.70**	**6.81**
NO_2	1-Hour	39.50	20.69	5.64	18.81	3.76	**3.76**	**39.50**

1.0 INTRODUCTION

This Appendix was prepared to support the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project). The following sections summarize the emission calculation methods followed to quantify the air quality emissions for use in the non-radiological dispersion modelling for indicator compounds as well as greenhouse gas (GHG) emissions. The emission estimation methods described within this Appendix follow generally accepted practices for conducting Environmental Assessments and, where appropriate, guidance in Appendix C of REGDOC-2.9.1, *Environmental Principles, Assessments and Protection Measures* (CNSC 2020). Scientifically accepted by Manitoba Sustainable Development (Draft Guidelines) and well-documented emission factors, such as AP-42 from the United States Environmental Protection Agency (US EPA) were used to estimate maximum and average emission rates.

2.0 ASSESSMENT OF COMPOUNDS AND ACTIVITIES

The assessment of air quality focused on predicting changes in the concentrations of selected non-radiological indicator compounds. The GHG assessment focused on predicting the emissions of GHGs and comparing them to provincial and federal emissions.

2.1 Air Quality Assessment

2.1.1 Air Quality – Indicator Compounds

The selected non-radiological indicator compounds fall into two categories:

- **particulate matter**: suspended particulate matter (SPM), particles nominally smaller than 10 micrometres (µm) in diameter (PM_{10}) and particles nominally smaller than 2.5 µm in diameter ($PM_{2.5}$); and
- **combustion gases**: nitrogen oxides (NO_X) represented by nitrogen dioxide (NO_2), sulphur dioxide (SO_2) and carbon monoxide (CO).

These compounds are associated with various Project activities. Particulate matter is typically associated with airborne dust from demolition and decommissioning activities including the mobile concrete batching plant, non-road equipment (such as construction vehicles) and vehicles travelling over on-site paved roads, as well as material handling activities. Products of combustion (NO_2, SO_2 and CO) are associated with the exhaust from on-site vehicles. Ozone was assessed as part of baseline conditions, to calculate the NO_2 emissions from the Project. Emissions of ozone are not quantified for the Project's activities as it is not directly emitted into the atmosphere from the Project.

Emissions were assessed for the Project activities during the various stages of the closure phase. Scientifically accepted and well-documented emission factors, such as AP-42 from the US EPA were used to estimate maximum and average emission rates. Compounds that will be emitted from the Project in negligible amounts and/or activities that discharge a compound in a negligible amount were excluded from further analysis.

The rationale for these exclusions is provided in Section 2.2.2. Table 1 provides a summary of the activities for which emissions were calculated in the air quality assessment (i.e., considered in the Application Case), as well as a summary of the compounds expected to be released from the Project. The Application Case includes Project Stages 1 to 3, and therefore, the emissions and associated effects during these stages of the Project represent the bounding cases.

Table 1: Activities and Non-Radiological Indicator Compounds Released/Expected During the Closure Phase

Project Stage	Duration	Project Component		Application Case? [Y/N]	Emission Source Type	Non-Radiological Indicator Compounds					
						SPM	PM_{10}	$PM_{2.5}$	NO_x	SO_2	CO

1) Compounds from this activity were considered to be negligible in comparison to the other activities occurring on-site.

2) Activities not included in the Application Case air quality assessment as worst-case conditions occur during the overlapping years of Stages 1 to 3.

3) For the emissions estimate, it was assumed that clean asbestos would be disposed of at the WL Landfill; however, some clean asbestos may be disposed of offsite.

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; CO = carbon monoxide; Y = yes; N = No.

2.1.2 Activities Not Considered in the Air Quality Assessment

There are many activities associated with the Project that produce emissions; however, not all activities produce emissions for any or all compounds that are relevant to the overall emissions assessment. All activities that potentially produce emissions were evaluated to assess their relevance; however, only activities that were considered to be relevant were included in the assessment. The following lists rationale as to why certain activities and/or emissions of certain compounds can be excluded from the assessment:

- the emission rates of certain compounds are very small relative to the overall emissions at the Project;
- the emissions of certain sources are known to not be relevant due to the type of operations in the assessment; and
- the location of the source relative to the rest of the sources on-site (i.e., the source is located far away from any potential receptors).

Table 2 lists the activities that were not assessed and the accompanying rationale.

Table 2: Emissions Not Included in the Air Quality Assessment

Activity/Compound	Rationale for Excluding from the Air Quality Assessment
Emergency power equipment	Emissions from the emergency power equipment were only included for contaminants with averaging period of 1 hour (NO_2, CO, SO_2). Other averaging periods for NO_2, CO, SO_2 exclude the generators emissions. Other contaminants with longer averaging periods (particulates) are excluded from the emergency power equipment assessment. The generators only operate periodically during monthly routine maintenance testing and a duration of one hour per month, rather than continuously. Additionally, the emergency power generators will only be used to supply electricity during power outage when other equipment is not in operation. Therefore, only routine maintenance of one hour per month is included in the representative scenario.
Snow removal equipment	Emissions from this equipment occur seasonally and are infrequent (i.e., only during the winter following a snowfall), and therefore, are not included in the representative scenario.
Operations support activities, such as maintenance activities	Emissions from these sources are infrequent, relatively small and do not occur at all times compared to the other activities that are occurring regularly and/or continuously. For example, these activities may include minor vehicles maintenance.
Combustion from Propane Space Heating	At the time of the assessment, it is unknown when the electric building heating systems will be taken offline for the WR-1 Building and replacement heating using propane has not been confirmed. The possible emissions from the combustion of propane used to replace the electric space heating would account for less than 5% of the total emissions from the Project and were not included in the representative scenario.
Removal of the Primary Heat Transport system	Releases from dust or gaseous emissions from removal of the PHT system are expected to be negligible because these particulates are anticipated to be captured in the remnant organics (oil), within the system. In addition, the structure is made of steel not concrete, which also inhibits the collection of dust and particulates on the PHT system. Regardless of the decontamination and dismantling techniques used for the WR-1, best practices will be implemented and will follow the Environmental Protection Plan. Releases of radiological emissions from the removal of the PHT system are evaluated in Section 6.7 Human and Ecological Health.
Non-road nuisance dust	Potential sources of dust not already included in the assessment will be managed through the *Management and Monitoring of Emissions* (CNL 2018a).

Table 2: Emissions Not Included in the Air Quality Assessment

Activity/Compound	Rationale for Excluding from the Air Quality Assessment
Non-dust fugitive emissions	■ Materials such as insulating material and asbestos are handled through existing strict procedures outlined in the Management Control Procedure, Controlling Asbestos Hazards (CNL 2017b) and are therefore not included in the assessment. ■ The bulk of the residual organic coolant that is in piping in tanks has been drained out, with the remainder to be filled as practical in place. This coolant, OS-84, has a negligible evaporation rate and its vapour pressure is lower than 0.001 hPa. Therefore, the coolant's components are not volatile and are not expected to be released to the atmosphere in measurable amounts.

NO_2 = nitrogen dioxide; SO_2 = sulphur dioxide; CO = carbon monoxide; PHT = primary heat transport; hPa = hectopascal pressure unit

2.2 Greenhouse Gas Assessment

2.2.1 Greenhouse Gas Compounds

There is no provincial GHG regulatory program specific to Manitoba currently in place; however, Manitoba is in the process of developing a mandatory reporting of GHG emissions regulation (IISD 2015). While is the regulation is under development, Manitoba continues to rely on the federal GHG Reporting Program (GHGRP) to collect GHG data for the large emitters and other GHG sources Manitoba covered through the National Inventory Report for Canada (ECCC 2014).

Only direct GHG emissions from the Project have been considered in this assessment. Direct emissions include emissions that are owned or controlled by CNL, such as fuel use. Indirect GHG emissions, such as electricity, are emissions that are a consequence of the CNL activities but occur at sources owned or controlled by another entity, and therefore, are excluded from the assessment. The Project is not expected to require a large amount of electricity, as the Project activities are mainly powered by fuel.

The GHG emissions included the following:

- carbon dioxide (CO_2);
- methane (CH_4); and
- nitrous oxide (N_2O).

There are no Project activities which are expected to emit sulphur hexafluoride (SF_6), perfluorocarbons (PFCs) or hydrofluorocarbons (HFCs); therefore, these compounds are not included in the GHG assessment.

The GHG emissions were calculated from the stationary combustion sources, including the boiler's propane combustion and emergency power equipment diesel combustion, and mobile equipment based on the equipment/vehicle information provided by CNL for the closure phase. The GHG emission estimation assumptions are documented in Section 3.0. The GHG emissions were calculated using methods described in the guidance documents for the Environment and Climate Change Canada (ECCC) GHGRP.

2.2.2 Activities Not Considered in the Greenhouse Gas Assessment

There are many activities associated with the Project that produce GHG emissions; however, not all activities produce emissions for any or all compounds that are relevant to the overall emissions assessment. All activities that potentially produce emissions were evaluated to assess their relevance; however, only activities that were considered to be relevant were included in the assessment. Table 3 lists the activities that were not considered to be relevant (e.g., not included in the assessment) and the accompanying rationale.

Table 3: Emissions Not Included in the Greenhouse Gas Emissions Assessment

Activity/Compound	Rationale for Excluding from the GHG Assessment
Emissions from electricity consumption	Emissions from the electricity consumption from the Project are excluded from the greenhouse gas (GHG) assessment. This is consistent with the Greenhouse Gas Reporting Program (GHGRP) as only direct GHG emissions from sources operating at the facility are reported. Emissions from electricity consumption are considered as indirect emissions.
Emissions from transportation that occurred outside the Whiteshell Laboratories (WL) Site boundary	The transportation emissions to and from the site are excluded and should not be reported in accordance to the GHGRP. Only emissions from machinery used for the on-site transportation of materials or products used in the Project activities are included in the GHG assessment.
Snow removal equipment	Emissions from this equipment occur seasonally and are infrequent (i.e., only during the winter following a snowfall), and therefore, are not included in the representative scenario.
Upstream GHG emissions	A March 19, 2016 Notice in the Canada Gazette presented ECCC's proposed method for estimating the upstream GHG emissions associated with projects undergoing federal environmental assessments. Upstream GHG emissions are those resulting from all industrial activities from the point of resource extraction to the Project. The specific processes will vary by resource but generally include extraction, processing, handling and transportation. The final block volume of 15,000m^3 of grout is not planned to enable new soil or clay extraction or cement production facilities. Rather, the Project will be a customer for existing soil or clay supply and cement facilities and is unlikely to affect the Provincial supply and demand for these materials. Therefore, these indirect and upstream emissions have been excluded from the assessment. An upstream GHG assessment has been conducted and the resulting GHG emissions estimates are considerably lower than the ECCC's Strategic Assessment of Climate Change (ECCC 2020) threshold for requiring an upstream GHG assessment, therefore, the upstream GHG assessment has not been included in this report but is available as a standalone document.
Land Clearing (Carbon Sinks)	There is no land clearing associated with the Project and therefore no negative impact on carbon sinks. During the Final Site Restoration stage, the reclaimed WL site will have a vegetative grass cover producing an overall positive impact on carbon sinks for the Project. The area of the reclaimed land will not result in a significant change in GHG emissions, and therefore, an assessment has not been conducted
Emissions from Accidents or Malfunctions	There are no potentially large sources of GHG emissions from accidents or malfunctions associated with the Project, and therefore, are not included in the assessment.
Emissions Intensity	There are no products manufactured as part of the Project to estimate an emissions intensity, and therefore, an intensity estimate is not included in the assessment.
Net-Zero Plan	A Net-Zero Plan is not required as the Project is not planning to operate beyond 2050.

m^3 = cubic metres

3.0 ASSUMPTIONS

Table 4 documents the assumptions made as part of the estimation of non-radiological indicator compounds and GHG emission rates.

	Generator Rating	250	kW	CNL
Miscellaneous				
Wind Speed		5.04	m/s	This is the average daily wind speed between 2010 and 2015, based on the hourly wind data obtained from the Pinawa Meteorological Station.

Note: For the purposes of this assessment, it is conservatively assumed that a batch mixing plant will be used.
1) For the emissions estimate, it was assumed that clean asbestos would be disposed of at the WL Landfill; however, some clean asbestos may be disposed of offsite.
hr = hour; m³ = cubic metre; kg = kilogram; Btu = British thermal units; gr/100 ft³ = grains per 100 feet; yr = year; Mg = megragram; g/m² = grams per square metre; km/hr = kilometres per hour; m = metre; kW = kilowatt; m/s = metres per second; hp = horsepower.

4.0 CALCULATIONS

The emission calculations expected during the closure phase were estimated as per REGDOC-2.9.1 (CNSC 2020), including average and maximum emission rates from the planned sources associated with the Project. Sample calculations are provided to demonstrate how the emission estimates were developed.

The emission rates for the non-radiological indicator compounds are expressed in units of grams per seconds (g/s), which are required for the dispersion models. The dispersion model assumes the emission rate is constant over an hourly period, which is the smallest time-step within the models used for predictions. Non-radiological indicator compounds were assessed against their respective criteria and averaging periods (e.g., SO_2 has criteria with 1-hour, 24-hour and annual averaging periods).

Prior to air dispersion modelling, 1-hour (hourly) emission rates were calculated for NOx, SO_2 and CO and 24-hour (daily) emission rates were calculated for SPM, PM_{10}, $PM_{2.5}$, NOx, SO_2 and CO. Hourly emission rates represent emissions averaged over a period of one hour while daily emission rates represent emissions averaged over a day, based on the activities operating schedule as described in Table 4. The 8-hour CO emission rate was conservatively assumed to equal its 1-hour emission rate. Annual emission rates were used following the completion of the modelling and were estimated using the Project's annual operating schedule.

The emission rates for GHG emissions are expressed in tonnes of carbon dioxide equivalent (CO_2eq) per year, as required under the assessment frameworks discussed in EIS Section 6.2.2.4.1 Methods.

4.1 Indicator Compounds – Emission Calculations

Non-radiological indicator compound emissions for particulates (SPM, PM_{10}, $PM_{2.5}$), NOx, SO_2 and CO were calculated for activities described in the Project description (Section 3.0) for the closure phase. These included the following:

- fugitive emissions from material handling activities related to demolition and grouting;
- vehicles exhaust from non-road equipment and on-road vehicles;
- fugitive dust from paved roads;
- emissions released from activities associated with the temporary batch mixing plant, including grout production, raw material handling and propane combustion; and
- products of combustion from emergency power generators.

The assessment follows scientifically accepted and well-documented calculation methods and emission factors, such as AP-42 from the US EPA.

4.1.1 Material Handling

Material handling activities associated with the demolition and grouting activities are expected to occur during two of the Project stages, including the grouting of below-grade structures and systems and removal of above-grade WR-1 structures and systems. These are characterized during the Project by the potential of fugitive dust during the grouting process and by the movement of material during demolition.

4.1.1.1 Grouting

The second stage of the Project, namely the grouting process, will involve the filling of below-grade areas with grout according to engineered fill schedule, which is proposed to involve multiple lifts of grouting pours. The grout-filling is expected to be completed through manually installed pipes (slick lines) within the building to direct grout where needed, eliminating the need to relocate lines and pumps during the grout pouring process and distributing the grout from the batch mixing plant directly to the WR-1. Material handling emissions from the grouting process were estimated based on the planned daily volume of grout to be used. These estimates are considered very conservative, as the process should have minimal lifts of materials, and therefore, limited exposure of material to the environment.

Predictive emission factors for particulate emissions were developed using equations from the US EPA document entitled *Compilation of Air Pollutant Emission Factors, AP-42, Fifth Edition, Volume I: Stationary Point and Area Sources* (AP-42) (US EPA 1995). Equations documented in AP-42 Section 13.2.4 – Aggregate Handling and Storage Piles (US EPA 2006). The following predictive emissions equation was used in determining the emission factors for material handling:

$$\text{Emission Factor } [\frac{\text{kg}}{\text{Mg}}] = \text{k} \times 0.0016 \times \frac{\left(\frac{\text{U}}{2.2}\right)^{1.3}}{\left(\frac{\text{M}}{2}\right)^{1.4}}$$

Where:

k = particle size multiplier for particle size range (Table 5)
U = mean wind speed (metres per second [m/s])
M = moisture content of material (percent [%])

Table 5: Particle Size Multiplier for Particle Size Range Used for Material Transfer Assumptions

SPM	PM_{10}	$PM_{2.5}$
0.74	0.35	0.053

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter

The following is a sample calculation for the SPM emission factor from the material handling of grout at the Project. A mean wind speed of 5.0 m/s calculated using the hourly wind speed data obtained from the ECCC meteorological station at Pinawa WNRE (2010 to 2015) was used for the calculation. This wind speed is the average daily mean wind speed. A moisture content of 11% for miscellaneous fill material was used, which was obtained from Table 13.2.4.1 of the US EPA AP-42.

$$\text{Emission Factor} = 0.74 \times 0.0016 \times \frac{\left(\frac{5.0}{2.2}\right)^{1.3}}{\left(\frac{11}{2}\right)^{1.4}}$$

$$\text{Emission Factor} = 3.19\text{E}-04 \frac{\text{kg}}{\text{Mg}}$$

The following is a sample calculation for the daily SPM emission rate under the maximum scenario for a grout movement rate of 42 tonnes/day.

$$\text{Emission Rate} = 3.19\text{E}-04 \frac{\text{kg}}{\text{Mg}} \times \frac{2168\ \text{Mg}}{\text{day}} \times \frac{1\ \text{day}}{24\ \text{hr}} \times \frac{1\ \text{hr}}{3{,}600\ \text{s}} \times \frac{1{,}000\ \text{g}}{1\ \text{kg}}$$

$$\text{ER} = 8.02\text{E}-03 \frac{\text{g}}{\text{s}}$$

The emission rates of PM_{10} and $PM_{2.5}$ were calculated as presented above with their corresponding calculated emission factors.

4.1.1.2 Demolition

The demolition activities as part of the third stage of the Project will involve the removal of the following components: main reactor hall, above-grade portion of the Primary Heat transport System, 50T reactor hall bridge crane and Ventilation Stack. Some of the removed components will be emplaced below-grade (i.e., Primary Heat transport System) while some will be hauled away for disposal. The third stage of the Project will involve the removal of hazardous waste, recycling of materials and disposal of asbestos at the WL landfill (it should be noted that some clean asbestos may be disposed of offsite). Demolition activities, as well as material removal, will be completed using non-road equipment. Emissions released from demolition activities are estimated based on the area of the proposed demolition.

Predictive emissions for particulate emissions were estimated using the demolition emission factors for PM_{10} obtained from the WRAP Air document titled WRAP Fugitive Dust Handbook, Chapter 3 - Construction and Demolition (Western Governors' Association 2006). The following equation was used to calculate particulate emissions from demolition:

$$\text{Emission Rate} \left[\frac{\text{g}}{\text{s}}\right] = \text{Emission Factor} \left[\frac{\text{ton}}{\text{acre} - \text{month}}\right] \text{x Area Demolished [acre] x Activity Period [month] x Conversion Factors}$$

The following is a sample calculation for the daily PM_{10} emission rate from the demolition activities under the maximum scenario:

$$\text{Emission Rate} = 0.42\frac{\text{ton}}{\text{acre} - \text{month}} \text{ x } 907{,}185\frac{\text{g}}{\text{ton}} \text{x } \frac{1 \text{ acre}}{0.004 \text{ km}^2} \text{ x } 0.0034 \text{ km}^2 \text{x } \frac{1 \text{ month}}{20 \text{ days}} \text{ x } \frac{1 \text{ day}}{24 \text{ hr}} \text{ x } \frac{1 \text{ hr}}{3{,}600 \text{ s}}$$

$$\text{Emission Rate} = 0.18 \frac{\text{g}}{\text{s}}$$

As the available emission factor is for PM_{10}, the emission factors for SPM and $PM_{2.5}$ were calculated using the particle size distribution for fugitive sources as per US EPA's AP-42 Chapter 13.2.4.

4.1.2 Non-Road Vehicles – Exhaust Emissions

Exhaust and Crankcase Emission Factors for Nonroad Compression-Ignition Engines in MOVES2014b (US EPA 2018); (Crank case document) were used to calculate the exhaust (tailpipe) emissions from on-site vehicles. A load factor of 1.0 was assumed for equipment that did not have an explicitly defined a load factor or a representative load factor to use in the pieces of equipment identified in the Crank case document. It was assumed that all on-site vehicles comply with Tier 4 emission standards.

The following predictive emissions equation was used to calculate the daily emission rates for on-site vehicles:

$$\text{Daily Emission Rate} = \text{Emission Factor}\left[\frac{\text{g}}{\text{hp} - \text{hr}}\right] \times \text{Engine Horsepower Rating[hp]} \times \text{Load Factor} \times \text{Numberof Units per Day} \times \text{Daily Operating Hours} \times \text{Conversion Factors}$$

The following is a sample calculation for the daily PM_{10} emissions for the tractors to be used for the Project:

$$\text{Daily Emission Rate} = 0.01 \frac{\text{g}}{\text{hp} - \text{hr}} \times 600 \text{ hp} \times 0.21 \times 2 \text{ Tractors} \times \frac{10 \text{ operating hr/day}}{24 \text{ hr/day}} \times \frac{1 \text{ hr}}{3{,}600 \text{ s}}$$

$$\text{Daily Emission Rate} = 2.92\text{E} - 04 \text{ g/s}$$

The emissions rates for PM_{10}, NOx and CO were calculated using the same equation. The emission rate for SPM was assumed to equal the emission rate of PM_{10}. The emission rate for $PM_{2.5}$ was calculated by multiplying the PM_{10} emission rate by 97%, as per the guidance document (US EPA 2018). The emission rate calculation for SO_2 included a conversion calculation for the emission factor prior to using the above equation. The emission rates for non-road equipment were calculated for all equipment associated with the Project based on the type and number of equipment present (e.g., dozers, excavators). Emission calculations for non-road equipment assume all equipment is operating at the same time and all are located at the Project.

4.1.3 On-Road Vehicles – Exhaust Emissions

Emission factors for the vehicle exhaust for on-road vehicles for the Project were obtained using the US EPA's mobile source emission factor model MOBILE6.2. The Canadian version of MOBILE6.2, which integrates the Canadian climate and fuel compositions emission model, was used for this assessment (MOBILE6.2C, Version 6.2.3).

The following inputs to MOBILE6.2C were created by following the Ministry of Transportation's Environmental Guide for Assessing and Mitigating the *Air Quality Impacts and Greenhouse Gas Emissions of Provincial Transportation Projects* (MTO 2012).

- The month of evaluation was July which is the preferred month by the MTO.
- The diurnal patterns in temperature were derived using the average ECCC meteorological station located on-site (Pinawa WNRE) hourly data from July 2013 (Refer to Appendix 6.2-1 – Baseline Air Quality and Meteorology for more details).
- The diurnal patterns in relative humidity the average ECCC meteorological station located on-site (Pinawa WNRE) hourly data from July 2013 (Refer to Appendix 6.2-1 – Baseline Air Quality and Meteorology for more details).
- The vehicle characteristics parameters including the vehicle miles travel (VMT) fraction, age distribution, annual mileage accumulation rates and diesel fractions for the 16 vehicle classes, were based on the default input data built into the MOBILE6.2C.
- The Canadian Sulfur in Diesel Fuel Regulation requires the diesel sulphur content of 15 parts per million (ppm), which was used.
- The emission reductions due to Inspection and Maintenance (I/M) Programs have not been considered as a conservative approach.
- Local was used as the road type and the speed of 20 kilometres per hour (km/hr) were used as the average speed on-site.
- Fuel composition and properties was representative of Manitoba.

The main inputs to the MOBILE 6.2C for this assessment are summarized in Table 6.

Table 6: MOBILE 6.2C Inputs

External Conditions	Input
Calendar year of evaluation	2019
Month	July
Altitude	Low, appropriate for use for the altitude of approximately 280 m at the WL Site.
Temperature	Average hourly temperature at the CNL on-site station
Humidity	Average hourly relative humidity at the CNL on-site station
Pressure	29.11 in Hg (Refer to Appendix 6.2-1 – Baseline Air Quality and Meteorology Appendix for more details)
Fuel Options	
RVP (PSI)	8.9 psi
Diesel sulphur content	15 ppm (Canadian legal requirement since 2010)[1]
Gasoline sulphur content	25 ppm
Air Toxics	
Gasoline aromatics (%)	28.4
Gasoline olefin (%)	10.3
Gasoline benzene (%)	0.8
Vapor percentage of gasoline at 200 F (%)	47.3
Vapor percentage of gasoline at 300 F (%)	83.3
Oxygenate volume% of Ethanol or Ethyl Alcohol (Ethanol)	10% volume and 20% market share
Vehicle Fleet Characteristic	
Distribution of Vehicle Registrations	default
Diesel fractions	default
Annual mileage accumulation rates	default
Vehicle Miles Travelled (VMT) fraction	default
Natural gas vehicles (NGVs) fraction	default
Alternate emission factors for NGVs	default

Fractions of Vehicle Miles Traveled (VMT)	default
VMT by facility, hour and speed	default
Starts per day	default
Distribution of vehicle starts during the day	default
Soak distribution	default
hot soak activity	default
Diurnal soak activity	default
Weekday trip length distribution	default
Weekend trip length distribution	default
Use weekend vehicle activity	default
Facility type	Local

[1] Federal Sulfur in Diesel Fuel Regulations and the Fuels Information Regulations.

The emission factors developed for the trucks are provided in Table 7. These emission factors were converted from VMT to vehicle kilometres travelled (VKT) and used for estimating emissions from on-road vehicles in both the construction and operations phases.

Table 7: Emission Factors for Fleet Trucks Calculated Using MOBILE6

Compound	Emission Factor (g/VKT)
SPM	4.46×10^{-2}
PM_{10}	4.46×10^{-2}
$PM_{2.5}$	2.65×10^{-2}
NO_X	1.23×10^{0}
SO_2	8.14×10^{-3}
CO	6.46×10^{-1}

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_X = oxides of nitrogen; SO_2 = sulphur dioxide; CO = carbon monoxide; g/VKT = grams per vehicle kilometres travelled.

The following equation was used to calculate the vehicle kilometres travelled per day (VKT/day):

$$\text{Daily Vehicle Kilometers Travelled } \left[\frac{\text{VKT}}{\text{day}}\right] = \frac{\text{\# of Trucks}}{\text{day}} \times \text{Number of Passes per Road} \times \text{Road Length Travelled [km]}$$

The following is a sample calculation for daily vehicle kilometres travelled on one segment (P1) of the paved roads:

$$\text{Daily Vehicle Kilometers Travelled} = \frac{97 \text{ Trucks}}{\text{Day}} \times 2\frac{\text{passes}}{\text{road}} \times 3.7 \text{ km}$$

$$\text{Daily Vehicle Kilometers Travelled} = 718\frac{\text{VKT}}{\text{day}}$$

Each of the road segments P1 to P4 and were calculated using the equation above. The road segments are presented on Figure 1 Site Layout and Dispersion Modelling Plan, and the length of the segments were estimated based on the site imagery. The following predictive emissions equation was used to calculate the vehicles exhaust emission rates for on-site vehicles travelling on paved road P1:

$$\text{Emission Rate } \left[\frac{\text{g}}{\text{s}}\right] = \text{Emission Factor } \left[\frac{\text{g}}{\text{VKT}}\right] \times \text{Daily Vehicle Kilometer Travelled} \frac{\text{VKT}}{\text{day}} \times ConversionFactors$$

The following is a sample calculation for daily SPM emissions for on-site vehicles exhaust emissions on paved road segment P1.

$$\text{Emission Rate} = 4.46\text{E}-02\ \frac{\text{g}}{\text{VKT}} \times 718 \frac{\text{VKT}}{\text{day}} \times \frac{1\ \text{day}}{24\ \text{hr}} \times \frac{1\ \text{hr}}{3{,}600\ \text{s}}$$

$$\text{Emission Rate} = 3.70\text{E}-04 \frac{\text{g}}{\text{s}}$$

The PM_{10}, $PM_{2.5}$, SO_2, NOx and CO rates were calculated using the same equation.

4.1.4 On-Road Vehicles – Paved Road Dust

The US EPA AP-42 emission factors from Chapter 13.2.1 – Paved Roads (January 2011) were used to calculate the fugitive dust emissions from paved roadways. The following predictive emissions equation was used to calculate the fugitive dust emission factor for paved roads:

$$\text{Emission Factor } [\frac{\text{g}}{\text{VKT}}] = (\text{k}(\text{sL})^{0.91} \times (\text{W})^{1.02})$$

Where:

k = particle size multiplier for particle size range and units of interest (Table 8)
sL = road surface silt loading (grams per square metre [g/m^2]) assumed to be 12 (as per US EPA AP-42 Section 13.2.1-3, silt loading for concrete batching)
W = average weight (tons) of the vehicles travelling the road

Table 8: Particle Size Assumptions for Paved Road Dust

Size Range	SPM	PM_{10}	$PM_{2.5}$
k(g/VKT)	3.23	0.62	0.15

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; k(g/VKT) = the constant for the particle size multipliers used on the Road Dust emission calculations, in units of g/VKT (or grams per vehicle kilometre travelled).

The following is a sample calculation for SPM for the predictive emission factor for vehicles that will travel along paved segment 1 (P1) on the main site access. It was estimated that the fleet vehicles will have an average weight of 45.7 tons.

$$\text{Emission Factor} = (3.23\ \times (12)^{0.91} \times (45.7)^{1.02})$$

$$\text{Emission Factor} = 1{,}687.61 \frac{\text{g}}{\text{VKT}}$$

The emission rate of particulates was calculated according to the following equation.

$$\text{Daily Emission Rate } \left[\frac{\text{g}}{\text{s}}\right] = \text{Emission Factor } \left[\frac{\text{g}}{\text{VKT}}\right] \times \text{Daily Vehicle Kilometers Travelled } \left[\frac{\text{VKT}}{\text{day}}\right] \times (100\% - \text{Control Efficiency}) \times \text{Conversion Factors}$$

A control efficiency of 75% was selected to represent the implementation of limiting on-site vehicle speed to 15 mph. The following is a sample calculation for the SPM emission rate for vehicles travelling along the same paved road segment:

$$\text{Emission Rate} = 1{,}687.61\,\frac{\text{g}}{\text{VKT}} \times 718\,\frac{\text{VKT}}{\text{day}} \times (100\% - 75\%) \times \frac{1\text{ day}}{24\text{ hr}} \times \frac{1\text{ hr}}{3600\text{ s}}$$

$$\text{Emission Rate} = 3.51\text{ g/s}$$

The emission rates of PM_{10} and $PM_{2.5}$ were calculated as presented above.

4.1.5 Batch Mixing Plant

The temporary batch mixing plant is proposed to produce grout material for the filling of below-grade areas. The batch mixing plant will involve raw material handling activities, which will be sheltered, as well as supporting propane combustion activities to heat water required for grout production.

4.1.5.1 Grout Production

It is expected that the batch mixing plant will produce between 30 to 110 cubic metres (m³) of grout per hour. Production time is estimated to be eight to nine hours per day on a shift duration of 12 hours per day, five days per week. The maximum scenario is therefore considered to have a throughout of 990 m³/day and the average scenario is considered to have a throughput of 630 cubic metres per day (m³/day). Based on a material density of 2190 kilograms per cubic metre (kg/m³), these throughputs are 2168 tonne/day and 1150 tonne/day, respectively.

Emission factors for SPM and PM_{10} were obtained from US EPA AP-42 Chapter 11.12 – Concrete Batching, Table 1 (US EPA 2006). Controlled emission factors were used if available; if no controlled emission factors were available, a control efficiency was applied, if possible. The emission factor for $PM_{2.5}$ was calculated using the particle size distribution for fugitive sources as per US EPA AP-42 Chapter 13.2.4 (US EPA 2006).

The following equation was used to calculate the daily emission rates for particulates:

$$\text{Daily Emission Rate } \left[\frac{\text{g}}{\text{s}}\right] = \text{Emission Factor } \left[\frac{\text{kg}}{\text{Mg}}\right] \times \text{Daily Throughput } \left[\frac{\text{tonne}}{\text{day}}\right] \times \text{ Conversion Factors}$$

The following is a sample calculation for the maximum daily SPM emission rate for the aggregate transfer activity:

$$\text{Daily SPM Emission Rate} = 1.05\text{E}-03\,\frac{\text{kg}}{\text{Mg}} \times 294\,\frac{\text{tonne}}{\text{day}} \times \frac{1000\text{ g}}{1\text{ kg}} \times \frac{1\text{ day}}{24\text{ hr}} \times \frac{1\text{ hr}}{3{,}600\text{ s}}$$

4.1.5.2 Raw Material Handling

Although the calculation of emissions related to the production of grout includes fugitive emissions related to material transfer and truck loading, raw material handling was assessed to include all fugitive emissions related to the process. The amount of raw material required to produce the abovementioned daily throughput was estimated based results from the grout formulation package. The mean moisture content for the raw material was based on US EPA AP-42 Chapter 13.2.4 (Table 1; US EPA 2006). The raw material percent composition and mean moisture content is summarized in Table 9.

Table 9: Composition and Mean Moisture Content of Grout Raw Material

Component	Material Concentration (kg/m^3)(1)	Percent Composition(2)	Mean Moisture Content (%)	AP-42 Table 13.2.4-1 Material
Portland Cement Type I/II	89	4%	2.1	Various Limestone Products
Fly Ash Class F	297	13%	27	Fly Ash
Sand	1570	50%	7.4	Sand
Water	232	11%	—	—

1) Based on Table 1 – Use of Cementitious Materials for SRS reactor Facility In Situ Decommissioning (Langton et al. 2010) retrieved from http://www.iaea.org/inis/collection/NCLCollectionStore/_Public/44/122/44122428.pdf

2) Percent Composition was selected for structural fill grout PR-ZB-FF-8-D based on the following: grout mix PR-UZB-FF-8 is for underwater placements, the grout mix with higher percent compositions (PR-ZB-FF) does not include gravel and has a high water content (15%), and the selected grout mix has the highest percent composition of non-water components.

kg/m^3 = kilogram per cubic metre; % = percent; - = not applicable.

Although it is expected the Project will install a complete enclosure for the raw material handling, a three sided enclosure was assumed for conservatism. The daily amount of raw material handling was calculated by multiplying the maximum and average throughputs by the percent composition of the raw material.

Emissions from raw material handling were calculated with the same equation as described in Section 4.1.1. Similarly, a mean wind speed of 5.0 m/s was used in the calculation. The following is a sample equation for the emission factor and emission rate of SPM from the material handling of cement under the maximum scenario.

$$\text{Emission Factor} = 0.74 \times 0.0016 \times \frac{\left(\frac{5.0}{2.2}\right)^{1.3}}{\left(\frac{2.1}{2}\right)^{1.4}}$$

$$\text{Emission Factor} = 3.25\text{E}-03 \frac{\text{kg}}{\text{Mg}}$$

$$\text{Emission Rate} = 3.25\text{E}-03 \frac{\text{kg}}{\text{Mg}} \times 88.1 \frac{\text{Mg}}{\text{day}} \times \frac{1 \text{ day}}{24 \text{ hr}} \times \frac{1 \text{ hr}}{3{,}600 \text{ s}} \times \frac{1{,}000 \text{ g}}{1 \text{ kg}}$$

$$\text{ER} = 9.93\text{E}-04 \frac{\text{g}}{\text{s}}$$

4.1.5.3 Propane Combustion

The process of grout production in the batch mixing plant will require the heating of water using a propane-fired boiler. It is assumed there will be one boiler with a maximum thermal input of 1,500,000 British thermal unit per hour (Btu/hr). Based on the propane heat content of 91,500,000 Btu/10³ gal, this boiler is expected to require 16.4 gallons per hour (gal/hr) input of propane.

Emission factors were obtained from US EPA AP-42 Section 1.5 - Liquefied Petroleum Gas Combustion. The emission factor for propane is provided in lb/10³ gal. The calculated hourly emission rate is conservatively assumed to equal the daily emission rate.

The following is the equation and sample calculation for the emission rate of NO_x from propane combustion:

$$\text{Emission Rate } [\frac{\text{g}}{\text{s}}] = \text{Maximum Gas Input } \frac{\text{gal}}{\text{hr}} \times \text{ Emission Factor } \frac{\text{lb}}{10^3\text{gal}} \times \text{Conversion Factors}$$

$$\text{NOx Emission Rate } = 16.4\frac{\text{gal}}{\text{hr}} \times 13\frac{\text{lb}}{10^3\text{gal}} \times \frac{1\text{ hr}}{3600\text{ s}} \times \frac{454\text{ g}}{1\text{ lb}}$$

$$\text{Emission Rate } = 2.69\text{E} - 02\frac{\text{g}}{\text{s}}$$

4.1.6 Emergency Power Generators

The Project proposes four diesel-fired emergency power generators to be installed at the WL site for provision of power in the event of electrical power loss. Only the testing of the generators was included in this assessment. It is assumed that only one generator will be tested at a time, for one hour per month. The generators will have a rated capacity of 250 kilowatts (kW).

Crank case emission factors for non-road Engine Modelling (Compression Ignition) – US EPA 009d (July 2010); Crank case document) were used to calculate the exhaust (tailpipe) emissions of NOx and CO from the generators. The emission factor for SO_2 were obtained from US EPA AP-42 Chapter 3.3 – Gasoline and Diesel Industrial Engines (US EPA 1996). The emission factor is provided in pound per horsepower-hour (lb/hp-hr). This was converted to kilograms per kilowatt-hour (kg/kW-hr) by multiplying by 0.608 as per Note (a) in Table 3.3-1 of the US EPA Chapter 3.3. To assess the worst-case scenario for daily emissions, it was assumed there is one hour testing per day. Emissions were estimated for contaminants that have limits with averaging periods less than 1-hour (i.e., NOx, CO and SO_2). It was assumed that all generators comply with Tier 4 emission standards.

The following is the equation and sample calculation for the daily emission rate of NO_x from emergency power generators testing:

$$\text{Emission Rate } \left[\frac{\text{g}}{\text{s}}\right] = \text{Rated Capacity [kW]} \times \text{ Emission Factor } [\frac{\text{kg}}{\text{kW} - \text{hr}}] \times \text{Number of Generators} \times \text{Conversion Factors}$$

$$\text{NOx Emission Rate} = 250\text{ kW } \times 4.02^{-4}\ \frac{\text{kg}}{\text{kW} - \text{hr}} \times 4\text{ Generators} \times \frac{1\text{ hr testing}}{24\text{ hr per day}} \times \frac{1\text{ hr}}{3{,}600\text{ s}} \times \frac{1000\text{ g}}{1\text{ kg}}$$

$$\text{Emission Rate} = 0.00465 \frac{\text{g}}{\text{s}}$$

4.2 Greenhouse Gas – Emission Calculations

The GHG emissions, including CO_2, CH_4 and N_2O, were calculated for on-road and non-road equipment (mobile equipment) as well as stationary general combustion sources. Emissions for the Project stages were calculated using the equipment/vehicle information available for the closure phase. The assessment generally followed the calculation methods in the ECCC GHG Emissions Reporting Program, as well as other guidance was used as deemed appropriate.

4.2.1 On-Road and Non-Road Equipment (Mobile Equipment)

The GHG emissions from mobile equipment from the Project were calculated based on fuel consumption and fuel-specific emission factors as presented in Table A6-11 in Part 2 of ECCC's National Inventory Report 1990-2013 for calculating CO_2, CH_4 and N_2O emissions (ECCC 2015a). The method to calculate GHG emissions from mobile equipment is based on equipment rating, load factor and the default fuel specific emission factor (grams per litre [g/L]).

The equations below present the methods for calculating CO_2, CH_4 and N_2O emissions from mobile equipment:

$$\text{Emissions}\left[\frac{\text{tonnes}}{\text{yr}}\right] = \text{BSFC}_{\text{i,k}}\left[\frac{\text{lb}}{\text{hp}-\text{hr}}\right] \times \text{h}_{\text{pi,k}}\,[\text{hp}] \times \text{h}_{\text{i,k}}\left[\frac{\text{hr}}{\text{yr}}\right] \times \text{LF}_{\text{i,k}} \times \text{Daily \# of Units} \div \text{Diesel Density}\left[\frac{\text{kg}}{\text{L}}\right] \times \text{EF}_{\text{i,CO2}}\left[\frac{\text{g}}{\text{L}}\right] \times \text{Conversion Factors}$$

Where:

$h_{i,k}$ = total annual hours of operation for the mobile equipment sources
$h_{pi,k}$ = rated equipment horsepower for mobile equipment
$LF_{i,k}$ = load factor for mobile equipment, between 0 and 1
$BSFC_{i,k}$ = brake-specific fuel consumption for mobile equipment
EF = fuel-specific default emission factor

It was assumed that all mobile equipment is fueled by diesel. The annual fuel consumption for each vehicle type was calculated based on an assumed vehicle horsepower, brake specific fuel consumption and load factors from the Crank case document (US EPA 2018).

The following is a sample calculation for the emission rate of CO_2 from the non-road tractors:

$$\text{Emissions}_{\text{CO2}} = 0.367\frac{\text{lb}}{\text{hp}-\text{hr}} \times 600\ \text{hp} \times 10\frac{\text{hr}}{\text{day}} \times 250\frac{\text{days}}{\text{yr}} \times 0.21 \times 2\ \text{units} \times \frac{1\ \text{L}}{0.845\ \text{kg}} \times 2690\frac{\text{g}}{\text{L}} \times \frac{0.454\ \text{kg}}{1\ \text{lb}} \times \frac{1\ \text{tonne}}{1{,}000{,}000\ \text{g}}$$

$$\text{Emissions}_{\text{CO2}} = 334\frac{\text{tonne}}{\text{yr}}$$

4.2.2 General Stationary Combustion

Stationary combustion sources for the Project includes propane combustion for the hot water boiler as part of the batch mixing plant, propane combustion for the heating of the building once it is disconnected from the grid, as well as diesel combustion by the emergency power generators. For the purposes of this assessment, ECCC's Technical Guidance on Reporting GHG Emissions (2015b) was used to calculate emissions of CO_2, CH_4 and N_2O.

4.2.2.1 Propane Combustion

ECCC's Technical Guidance on Reporting GHG Emissions (ECCC 2015b) references Volume 2, Chapter 2 of the 2006 IPCC Guidelines (IPCC 2006), which presents energy-based emission factors for liquefied petroleum gas (in kilograms per terajoule [kg/TJ]). The equation below presents the methods for calculating CO_2, CH_4 and N_2O emissions from general stationary combustion:

$$\text{Emissions}\left[\frac{\text{tonnes}}{\text{yr}}\right] = \text{MaximumThermal heat Inpupt}\left[\frac{\text{GJ}}{\text{hr}}\right] \times \text{Daily Operating Hours [hr]} \times \text{EmissionFactor}\left[\frac{\text{kg}}{\text{TJ}}\right] \times \text{Conversion Factors}$$

Maximum Thermal Heat Input for the propane-fired boiler was estimated based on the assumed boiler rating of 1,500,000 Btu/hr. The following is a sample calculation for the emission rate of CO_2 from the combustion of propane as part of the batch mixing plant:

$$\text{Emissions}_{CO_2} = 1.58\frac{\text{GJ}}{\text{hr}} \times 9\frac{\text{hr}}{\text{day}} \times 109\frac{\text{days}}{\text{yr}} \times 63{,}100\ \frac{\text{kg}}{\text{TJ}} \times \frac{1\ \text{tonne}}{1{,}000\ \text{kg}} \times \frac{1\ \text{TJ}}{1{,}000\ \text{GJ}}$$

$$\text{Emissions}_{CO_2} = 97.6\ \frac{\text{tonnes}\ CO_2}{\text{yr}}$$

Maximum Thermal Heat Input for the building heat supplied via propane was estimated based on the combined kW rating of the individual units, converted to GJ and assumed to operate over an eight month heating period. The following is a sample calculation for the emission rate of CO_2 from the combustion of propane to provide building heat:

$$\text{Emissions}_{CO_2} = 24{,}261.12\frac{\text{GJ}}{\text{yr}} \times 63{,}100\ \frac{\text{kg}}{\text{TJ}} \times \frac{1\ \text{tonne}}{1{,}000\ \text{kg}} \times \frac{1\ \text{TJ}}{1{,}000\ \text{GJ}}$$

$$\text{Emissions}_{CO_2} = 1{,}530.9\ \frac{\text{tonnes}\ CO_2}{\text{yr}}$$

4.2.2.2 Diesel Combustion

Emission factors for CO_2, CH_4 and N_2O were obtained from Table 20-2 of ON.20 (General Stationary Combustion) of the Ontario Guideline for Greenhouse Gas Emissions Reporting (as set out under Ontario Regulation 452/09 under the *Environmental Protection Act;* MOECC 2015). Emissions of GHGs from the diesel generators were conservatively calculated using the number of hours that the generators will operate, the horsepower of each generator and emission factors for diesel provided in Table 20-2 of ON.20 (General Stationary Combustion). The following describes the equation used to calculate the GHG emissions from the diesel generators.

$$\text{Emission}\left[\frac{\text{tonne}}{\text{yr}}\right] = \text{Emission Factor}\left[\frac{\text{g}}{\text{GJ}}\right] \times \text{Rated Capacity [hp]} \times \text{Number of Generators} \times \text{Hours of Operation [hr]} \times \text{Conversion Factors}$$

The following is a sample calculation for the emission rate of CO_2 from the combustion of diesel:

$$\text{Emissions}_{CO_2} = 69{,}530\,\frac{\text{g}}{\text{GJ}} \times 250\ \text{kW} \times \frac{1.341\ \text{hp}}{1\ \text{kW}} \times 0.00268\,\frac{\text{GJ}}{\text{hp}-\text{hr}} \times 4\ \text{Generators} \times \frac{1\ \text{hr}}{1\ \text{month}} \times \frac{12\ \text{months}}{1\ \text{year}} \times \frac{1\ \text{tonne}}{1{,}000{,}000\ \text{g}}$$

$$\text{Emissions}_{CO_2} = 3.00\,\frac{\text{tonne}}{\text{yr}}$$

4.2.3 Global Warming Potentials

Emissions from CO_2, CH_4 and N_2O were converted to CO_2e. The GHG emissions are expressed as tonnes of equivalent CO_2, by multiplying the annual emissions of each GHG by its 100-year global warming potential (GWP). The GWP of each gas represents the gas's ability to trap heat in the atmosphere in comparison to CO_2. The federal GWPs that are used to calculate the GHG emissions from the Project are listed in Table 10 (ECCC 2015b). Federal GWPs were used to compare against the Canada-wide GHG emissions.

Table 10: Federal Global Warming Potentials

GHG Compound	GHGRP GWP
CO_2	1
CH_4	25
N_2O	298

Note: GHG = greenhouse gas; CO_2 = carbon dioxide; CH_4 = methane; N_2O = nitrous oxide; GHGRP GWP = Greenhouse Gas Reporting Program global warming potential.

5.0 EMISSION RATES

This section outlines the emission rates to be used in the Air Quality Assessment (in g/s) and GHG Assessment (in tonne CO2e/year), which were calculated for the Application Case as described in Section 4.0.

5.1 Air Quality Assessment

Table 11 and Table 12 summarize the maximum and average scenario daily emission rates, respectively, for each activity at the Project. Tables 13 and 14 summarize the maximum and average scenario percentages, respectively, that each source contributes to the overall emissions from the Project stages during the closure phase based on the daily emission rates.

Table 11: Maximum Scenario Summary of Daily Emissions Rates During the Closure Phase

Project Stage	Duration	Project Component		Emission Source Type	Daily Emission Rates (g/s)					
					SPM	PM_{10}	$PM_{2.5}$	NO_x	SO_2	CO
1 Preparation for In Situ Disposal	2022 - 2025	1.1	Create pathways between rooms	Non-road Equipment Exhaust	2.92E-04	2.92E-04	2.83E-04	8.75E-03	1.46E-04	7.58E-02
		1.2	Batch mixing plant (temporary)	Process	7.62E-02	2.62E-02	5.46E-03	—	—	—
				Non-road Equipment Exhaust	1.74E-04	1.74E-04	1.68E-04	2.42E-02	4.82E-05	3.21E-02
				Raw Material Handling	4.09E-03	1.93E-03	2.93E-04	—	—	—
				Road Exhaust	3.70E-04	3.70E-04	2.20E-04	1.02E-02	6.76E-05	5.37E-03
				Paved Roads	3.51E+00	6.73E-01	1.63E-01	—	—	—

Miscellaneous		Emergency Power Generators		Combustion	—	—	—	3%	74%	4%

1) For the emissions estimate, it was assumed that clean asbestos would be disposed of at the WL Landfill; however, some clean asbestos may be disposed of offsite.

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_X = oxides of nitrogen; SO_2 = sulphur dioxide; CO = carbon monoxide; < = less than; % = percent; — = not applicable.

For simplicity, emission rates may also be summarized based on the type of source considered in the Air Quality Assessment, specifically road (including dust from paved roads, exhaust emissions from paved roads) and non-road emissions (including exhaust emissions from non-road equipment, batch mixing plant, in situ disposal and demolition and emergency power generators). These emissions for the Maximum Scenario are summarized in Table 15.

Table 15: Summary of Maximum Scenario Project Emissions for Road and Non-Road Emissions

Contaminant	CAS No.	Averaging Period (hours)	Maximum Scenario Emission Rate (g/s)
Roads Emissions			
SPM	N/A-1	24-hour	3.671
PM_{10}	N/A-2	24-hour	0.705
$PM_{2.5}$	N/A-3	24-hour	0.171
NO_x	10102-44-0	1-hour	0.026
NO_x	10102-44-0	24-hour	0.011
CO	630-08-0	1-hour	0.013
CO	630-08-0	8-hour	0.013
SO_2	7446-09-5	1-hour	0.00017
SO_2	7446-09-5	24-hour	0.00007
Non-Roads Emissions			
SPM	N/A-1	24-hour	0.346
PM_{10}	N/A-2	24-hour	0.289
$PM_{2.5}$	N/A-3	24-hour	0.096
NO_x	10102-44-0	1-hour	8.239
NO_x	10102-44-0	24-hour	1.475
CO	630-08-0	1-hour	2.150

SO_2	7446-09-5	24-hour	0.020

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_X = oxides of nitrogen; SO_2 = sulphur dioxide; CO = carbon monoxide; g/s = grams per second.

Following dispersion modelling, annual emission rates were calculated to account for the annual days of operations since the Project will not operate every day of the year.

5.2 Greenhouse Gas Assessment

The GHG emissions were estimated for the project phases including emissions from mobile and stationary fuel combustion sources. Table 16 presents the Application Case annual emissions from the Project. Tonnes of CO_2e were calculated using the federal GWPs.

Table 16: Summary of GHG Emission Rates

Source	Annual Emissions (tonnes CO_2e)			Total Annual Emissions (tonnes CO_2eq)
	CO_2	CH_4	N_2O	
	124-38-9	74-82-8	10024-97-2	
Mobile Equipment (Road & Non-Road)	11,886	17	693	12,595
Propane Combustion	1,629	0.65	0.77	1,630
Emergency Power Generators	3	0.004	0.13	3
Total	**13,517**	**17**	**694**	**14,228**

CO_2 = carbon dioxide; CH_4 = methane; N_2O = nitrous oxide; CO_2eq = carbon dioxide equivalent.

6.0 CONSERVATISM IN EMISSION CALCULATIONS

Table 17 outlines the areas where conservatism was assumed in the emission rate calculations for air quality and GHG emissions, which results in an assessment that is not likely to under-predict the emissions associated with the Project.

Table 17: Areas of Conservatism in the Emission Rate Calculations

Project Activity	Conservatism
Non-road Equipment	It is conservatively assumed that all non-road equipment is operating simultaneously during the daily operating hours for Project Stages 1 to 3 and for the entire duration. In reality, it is unlikely that all equipment would operate simultaneously and that the same type of equipment will operate simultaneously for different components of these phases (e.g., it is assumed that two small wheel loaders are operated during both Stages 2 and 3).
Propane combustion	Based on assumed maximum equipment firing rate.
Fugitive Dust from Paved Roads	Roadway segments at the Project were assessed based on the type of roadway and anticipated traffic. Emission estimation equations from Chapters 13.2.1 of the AP-42 Emission Factor (US EPA 2011) were used for fugitive road dust from paved roads. These emission estimates are conservative and will overestimate emissions from facility roadways for the following reasons. ■ The US EPA AP-42 equations were developed from measured emissions from public roadways and as a result will tend to over-estimate low speed vehicle traffic from construction and industrial sites. ■ All roadways at the Project were modelled assuming simultaneous and continuous use; however, it is unlikely that this situation will occur in reality. ■ As the dust best management practices are revised through continuous improvements, the emissions from the on-site roadways are likely to decrease. ■ Seasonal variability for fugitive dust emissions was not considered in the assessment.

1.0 INTRODUCTION

This Appendix was prepared to support the Environmental Impact Statement (EIS) for the Canadian Nuclear Laboratories (CNL) In Situ Decommissioning of WR-1 at the Whiteshell Laboratories Site (the Project). This Appendix describes the dispersion model and modelling approach used to conduct the non-radiological air dispersion modelling as part of the effects assessment. More specifically, this Appendix documents the methods, inputs and assumptions that were used to prepare and complete the dispersion modelling to predict ground-level concentrations of non-radiological indicator compounds resulting from the Project.

The modelling approach described within this Appendix follows generally accepted practices for conducting environmental assessments and modelling guidance. It should be noted that the Manitoba Sustainable Development (now Manitoba Environment, Climate and Parks), Climate Change and Air Quality Branch, has limited dispersion modelling guidance included in the *Draft Guidelines for Air Dispersion Modelling in Manitoba* from the Manitoba Conservation (2006) – Air Quality Section. Therefore, the Draft Guidelines and the following guidance documents were followed as appropriate: the Ontario Ministry of the Environment and Climate Change (MOECC) document titled *Air Dispersion Modelling Guideline for Ontario* (2017), the Saskatchewan Ministry of the Environment (MOE) document titled *Saskatchewan Air Quality Modelling Guideline* (2012) and in the National Stone, Sand and Gravel Association (NSSGA) document titled *Modeling Fugitive Dust Sources* (2004). The air dispersion modelling for the Project included the following approach:

AERMOD dispersion modelling for emissions sources and paved roads.

2.0 AIR DISPERSION MODELLING

2.1 Dispersion Modelling

The likely environmental effects for the air quality indicators were evaluated with the aid of the AERMOD dispersion model (version 22112) developed by the United States Environmental Protection Agency (U.S. EPA).

The selection of the AERMOD model was based on the following capabilities:

- has a technical basis that is scientifically sound and is in keeping with the current understanding of dispersion in the atmosphere;
- applies formulations that are clearly delineated and are subjected to rigorous independent scrutiny;
- makes predictions that are consistent with observations;
- is recognized by federal and provincial regulators, including Manitoba, as one suitable for use;
- evaluates the source configurations and indicator compounds associated with the Project;
- the terrain surrounding the Project is relatively simple and can be addressed by the terrain features of the model;
- allows for the use of localised meteorological data;
- incorporates building downwash effects; and
- long-range transport of compounds is not anticipated.

More specifically, AERMOD is recognized by federal regulators as one of the regulatory default dispersion models and is suitable to model construction activities, waste disposal operations, and fugitives.

AERMOD consists of the model and two pre-processors; the AERMET meteorological pre-processor and the AERMAP terrain pre-processor (Figure 1). The following approved dispersion model and pre-processors were used in the assessment:

- AERMOD dispersion model (v. 22112); and
- AERMAP surface pre-processor (v. 18081).

AERMET was used by Lakes Environmental Software to prepare a 5-year meteorological dataset for the Project site.

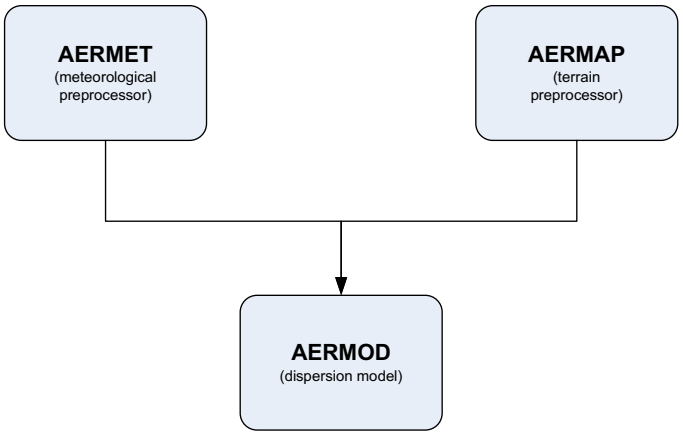

Figure 1: AERMOD Model System

2.1.1 Model Development

The AERMOD dispersion modelling system was developed by the U.S. EPA as a replacement to the long-standing Industrial Source Complex (ISC) model, as the model recommended by the U.S. EPA for regulatory applications in the United States. The model is generally based on Gaussian plume dispersion theory (U.S. EPA 2004), but also incorporates a series of specific algorithms to reflect current understanding of dispersion theory (U.S. EPA 2004). The selected model is recommended by Manitoba Conservation (2006) as a refined model and is an approved regulatory dispersion model in several Canadian provinces including Ontario (MOECC 2017) and Saskatchewan (MOE 2012), which border Manitoba; therefore, the AERMOD model is considered a suitable model for the Project.

2.1.2 Model Calibration and Validation

Regulatory dispersion models do not readily lend themselves to modification to incorporate site-specific characteristics in the equations themselves. However, the model does require site-specific meteorological data to operate. Digital terrain data for the site and surrounding area are also required inputs to the AERMAP pre-processor and used to characterize how the local topography could affect the dispersion of air contaminants. Part of the rigorous process used by the U.S. EPA prior to adopting AERMOD as a regulatory model

(U.S. EPA 2004) was a significant peer review process to confirm that the model could accurately predict ground-level concentrations when compared to monitoring data (U.S. EPA 2003, 2004).

2.1.3 Model Uncertainty and Sensitivity

Dispersion models employ assumptions that simplify the random processes associated with atmospheric motions and turbulence. While this simplification limits the model's ability to replicate individual events, the strength of the model lies in the ability to predict overall values for a given set of meteorological conditions. The process undertaken by the U.S. EPA ensured that the model predictions can be relied on as reasonable estimate of the likely concentrations. AERMOD is based on known theory and proven to reliably produce repeatable results. To limit the uncertainty associated with emissions input to the model, conservative assumptions were made where practical. Finally, five years of meteorological data are used as an input to the model to ensure the full range of possible meteorological conditions is evaluated.

2.2 Dispersion Modelling Inputs

To predict ambient air concentrations with the aid of AERMOD, a series of inputs are required that parameterize the sources of emissions as well as their transport. These inputs can be grouped into categories:

- Dispersion meteorological data;
- Terrain and receptors;
- Building downwash; and
- Emissions and source configurations.

2.2.1 Dispersion Meteorological Data

The Manitoba Sustainable Development (now Manitoba Environment, Climate and Parks), Climate Change and Air Quality Branch, as well as other agencies, recommends that five years of hourly data be used in the model to cover a wide range of potential meteorological conditions (Manitoba Conservation 2006). A localized pre-processed meteorological dataset for the Project, created with the aid of AERMET, was purchased directly from Lakes Environmental Software on November 28, 2023. The dataset covers the period of January 2018 to December 2022.

The meteorological input files used by the AERMOD dispersion model are generated using the AERMET pre-processor, which is designed to be run in three stages:

1) Extracts the data and assesses data quality.
2) Merges the available data for 24-hour periods and writes these data to an intermediate file.
3) Reads the merged data file and develops the necessary boundary layer parameters for dispersion calculations by AERMOD.

The AERMET pre-processor produces two meteorological data files. The first file contains boundary layer scaling parameters (e.g., surface friction velocity, mixing height, and Monin-Obukhov length) as well as wind speeds, wind directions and temperature at a reference-height (i.e., 10 m). The second file contains one or more levels (a profile) of winds, temperature, and the standard deviation of the fluctuating components of the wind. These files are used as inputs to AERMOD.

2.2.2 Terrain and Modelling Receptors

Terrain elevations have the potential to influence air quality and odour concentrations at individual receptors, therefore surrounding terrain data is required when using regulatory dispersion models in both simple and complex terrain situations (U.S. EPA 2004). Digital terrain data is used in the AERMAP pre-processor to determine the base elevations of receptors, sources and buildings. AERMAP then searches the terrain height and location that has the greatest influence on dispersion for each receptor (U.S. EPA 2004). This is referred to as the hill height scale. The base elevation and hill height scale produced by AERMAP are directly inserted into the AERMOD input file.

2.2.2.1 Digital Terrain Data

The terrain information required by the AERMOD dispersion model was generated by the AERMAP pre-processor. An AERMAP file was developed based on Digital Elevation Model (DEM) data for the Project study area obtained from Geobase section 052i04/05 and 062i01/08. The terrain in the study area is open with flat topography; elevations range from approximately 250 to 305 metres above sea level. The Digital Elevation Model (DEM) files used in the modelling for the Project are as follows:

- 052I04_0100_demw.dem;
- 052I05_0100_demw.dem;
- 062i01_0100_demw.dem; and
- 062i08_0100_demw.dem.

2.2.2.2 Modelling Domain

The modelling domain was set to be 24 kilometres (km) by 24 km in size to encompass the site, local, regional study areas for the Project (Property Boundary, LSA, and RSA, see Figure 2 – Modelling Domain and Receptors). This domain is large enough to capture the potential air quality effects of the Project on the surrounding area.

2.2.2.3 Model Receptors

Air quality concentrations were predicted at selected groups of receptors which include receptors along the property boundary, receptors along the LSA, and a grid of receptors covering the entire RSA. Receptor locations are specified in terms of X, Y and Z coordinates. A total of 1,490 receptors were placed along the property boundary at intervals of 20 m and 68 receptors were placed along the LSA, spaced approximately 470 m apart. A uniform cartesian grid of receptors within the boundary of the RSA was used that produced 728 receptors at intervals of approximately 500m within the RSA. All receptors are assumed to be ground-level receptors (i.e., Z = 0 m). This positioning allows for more receptors closer to the emission sources. All receptors within the property boundary were removed for the air quality assessment. The air quality receptor grid is illustrated on Figure 2.

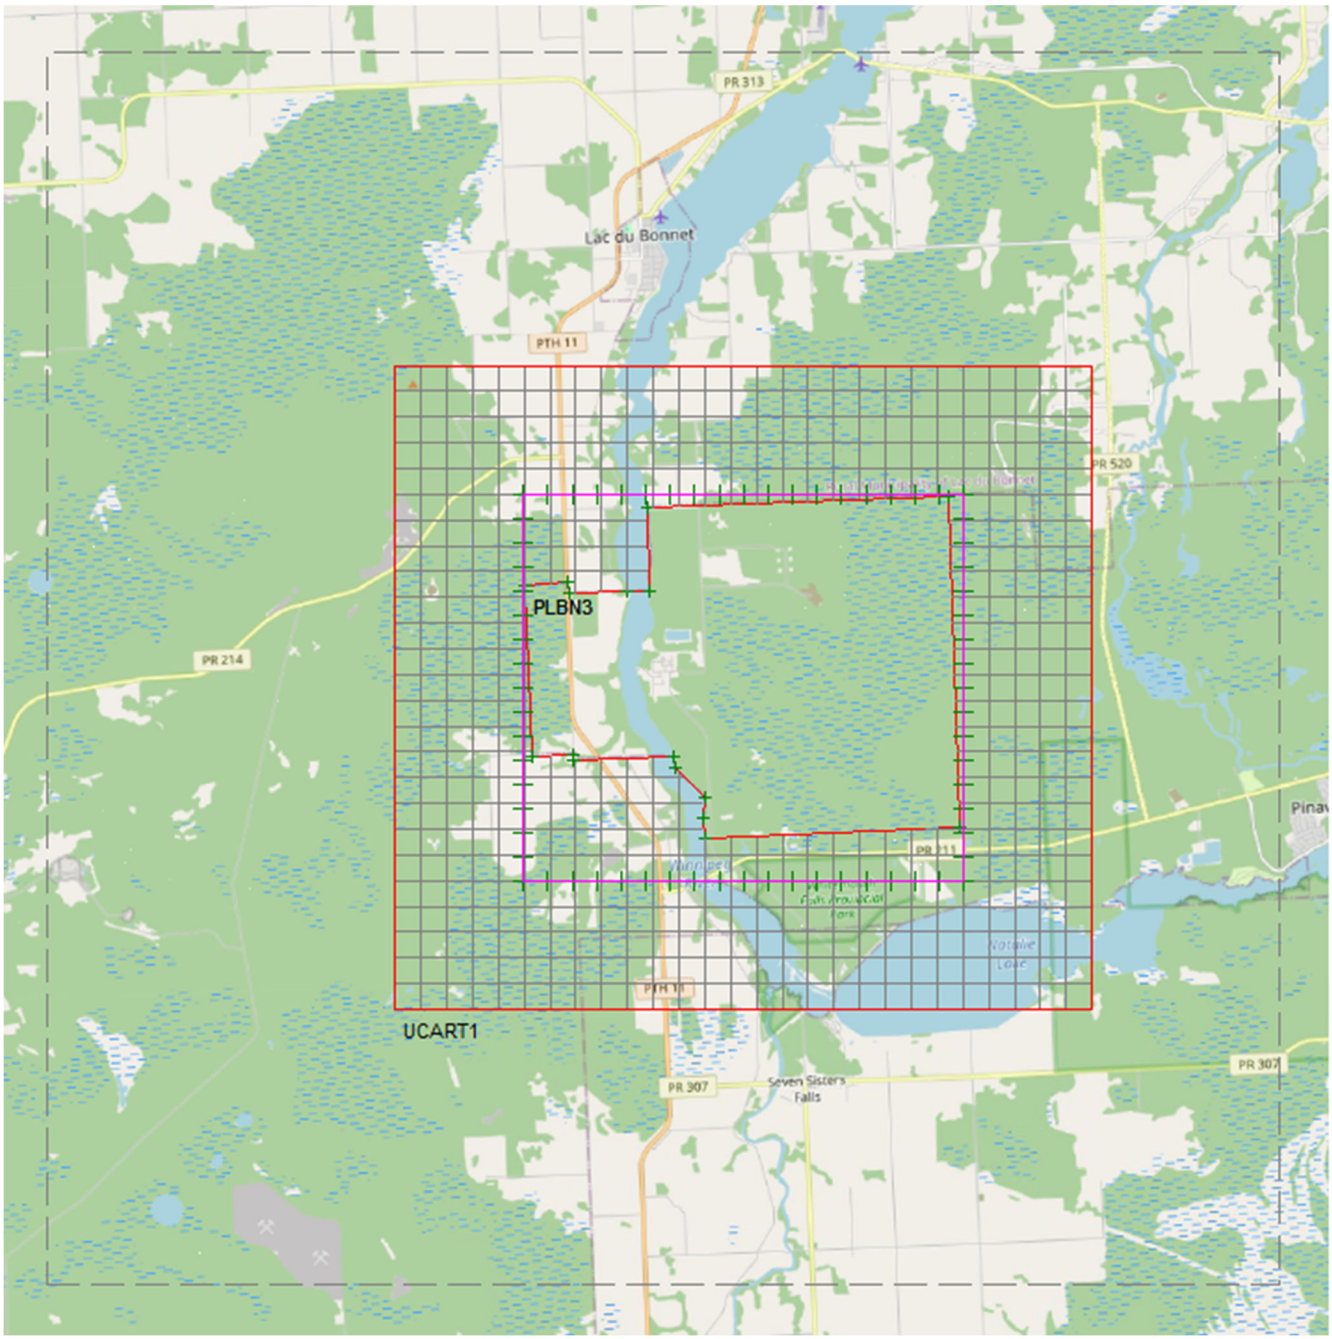

Figure 2: Modelling Domain and Receptors

2.2.3 Building Downwash

For this assessment, the effects of building downwash were not included given the low level fugitive nature of the sources, they are not expected to be subject to downwash effects from nearby buildings.

2.2.4 Emissions and Source Configurations

Air emission rates were estimated for the Project sources for which a measurable change from existing conditions is anticipated and may occur. These emission rates were then used as inputs for the dispersion modelling that provided estimates of maximum ground-level concentrations resulting from the Project emissions. Appendix 6.2-2 provides a detailed description of the methods, inputs, and assumptions used to estimate emission rates.

2.2.4.1 Volume Sources

The model source types used in this assessment were volume sources. Figure 3—Site Layout and Dispersion Modelling Plan illustrates the model source locations used in this assessment for the Project. Volume sources are used to model releases from a variety of industrial sources that cannot be classified as a point or area source. All sources were modelled as volume sources for this assessment.

Volume sources are square and are determined by calculating the shortest side length of the area which the source's dimensions result in. The volume source parameters developed for the dispersion model were based on the source dimensions and the calculation of the shortest side length, following guidance in *Modelling Fugitive Dust Sources* (NSSGA 2004). The volume source parameters are summarized in Table 1.

Table 1: Summary of Project Volume Source Parameters

Source Description (ID)	Volume Height [m]	Release Height [m]	Length of Side [m]	Initial Lateral Dimension [m]	Initial Vertical Dimension [m]	Source Coordinate X [m]	Source Coordinate Y [m]
Non-Road Vehicles - Exhaust Emissions (NONROAD)	1.5	1.5	300	69.8	0.35	709929	5562648
Batch Mixing Plant - Grout Production (RMX)	3	3	4	0.93	1.40	709946	5562623
Batch Mixing Plant - Material Handling (RMX_MH)	6.5	1.09	3	0.70	3.02	709952	5562693
Batch Mixing Plant - Propane Combustion (PROPANE)	3	3	5	1.16	1.40	709963	5562623
Demolition and Material Handling (WR-1)	17.8	8.9	25	5.81	8.28	709885	5562663
Emergency Power Generators (DG)	2	2	4	0.93	0.93	709792	5562600

m = metre.

Manitoba Conservation does not specify a source type to use for modelling paved roads, however, the Ontario MOECC has suggested that roads should be modelled as a series of individual volume sources creating a line that follows the road (MOECC 2017). The roads in the assessment were modelled using this volume source approach. The roads were divided into contiguous volume sources with a release height of 2.975 m which is calculated in AERMOD from the assumed height of the haul truck of 3.5m (NSSGA 2004). The roads at CNL are all paved and are 6 m wide. The emission rate for the entire road segment was divided amongst the total volume sources for the entire segment. There are three paved road segments considered in the assessment, accounting for the activities requiring truck hauling. The volume source parameters for roads are summarized in Table 2.

Table 2: Summary of Project Line Volume Source Parameters

Source Description (ID)	Vehicle Height [m]	Road/Vehicle Width [m]	Plume Height [m]	Release Height [m]	Plume Width [m]	Initial Lateral Dimension [m]	Initial Vertical Dimension [m]	Number of Volume Sources Comprising Segment
Paved Road (P1)	3.5	6	5.95	2.98	12	5.58	2.77	314
Paved Road (P2_P3)	3.5	6	5.95	2.98	12	5.58	2.77	262
Paved Road (P4)	3.5	6	5.95	2.98	12	5.58	2.77	374

1) Release Height = WR-1 Height ÷ 2.
2) Initial Lateral Dimension = Shortest Side Length ÷ 4.3.
3) Initial Vertical Dimension = WR-1 Height ÷ 2.15.

2.2.4.2 Model Options

Table 3 presents the modelling parameters used in the dispersion modelling assessment.

Table 3: Options Used in the AERMOD Model

Modelling Parameter	Description	Used in the Assessment?
DFAULT	Specifies that regulatory default options will be used.	Yes
CONC	Specifies that concentration values will be calculated.	Yes
AVERTIME	Time averaging periods calculated.	1-hr, 8-hr, 24-hr, Annual
1-Hour NO2 NAAQS	Based on multi-year average of ranked maximum daily values. Requires 98th Percentile (8th Highest) Daily Maximum.	Yes, for NO_2
1-Hour SO2 NAAQS	Based on multi-year average of ranked maximum daily values. Requires 99th Percentile (4th Highest) Daily Maximum.	Yes, for SO_2
24-Hour PM-2.5 NAAQS	Based on multi-year average of ranked maximum daily values.	Yes, for $PM_{2.5}$

2.3 AERMOD Dispersion Modelling Results

Individual model runs were conducted for each indicator compound and the maximum concentrations for all indicator compounds at all averaging periods were at receptors along the CNL property boundary. Further, three individual model runs each were conducted for NO_2, SO_2, and $PM_{2.5}$ to obtain results over a three-year period within the five-year meteorological data set that align with the statistical form of Canadian Ambient Air Quality Standards (CAAQS). The modelling options in AERMOD that were selected for these model runs are presented in Table 4 below.

Table 4: Summary of Special Modelling Options for Comparison to CAAQS

Contaminant	AERMOD Modelling Option	Met Data Years per Model Run	AERMOD Description	CAAQS Statistical Form
$PM_{2.5}$	24-Hour PM-2.5 NAAQS	2018-2020 2019-2021 2020-2022	Based on multi-year average of ranked maximum daily values	24-hour Averaging Time: The 3-year average of the annual 98th percentile of the daily 24-hour average concentrations Annual Averaging Time: The 3-year average of the annual average of the daily 24-hour average concentrations
NOx	1-Hour NO2 NAAQS	2018-2020 2019-2021 2020-2022	Based on multi-year average of ranked maximum daily values. Requires 98th Percentile (8th Highest) Daily Maximum.	1-hour Averaging Time: The 3-year average of the 98th percentile of the daily maximum 1-hour average concentrations
SO_2	1-Hour SO2 NAAQS	2018-2020 2019-2021 2020-2022	Based on multi-year average of ranked maximum daily values. Requires 99th Percentile (4th Highest) Daily Maximum.	1-hour Averaging Time: The 3-year average of the 99th percentile of the SO_2 daily maximum 1-hour average concentrations

The results of each dispersion modelling run using the full five-year Met Data Set are presented in Table 5 and the results of each dispersion modelling run using three-year Met Data Sets to align with the CAAQS are presented in Table 6.

Table 5: Summary of AERMOD Predicted Maximum Concentrations at the CNL Property Boundary Using Met Data Set 2018-2022.

Contaminant	Averaging Period	AERMOD Output ($\mu g/m^3$)
SPM	24-hour	158
	Annual	13.5
PM_{10}	24-hour	30.6
NOx	24-hour	3.54
	Annual	0.153
SO_2	24-hour	0.437
	Annual	0.015
CO	1-hour	465
	8-hour	171

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_X = nitrogen oxides; SO_2 = sulphur dioxide; CO = carbon monoxide; $\mu g/m^3$ = micrograms per cubic metre.

Table 4: Summary of AERMOD Predicted Maximum Concentrations at the CNL Property Boundary Using Three-Year Met Data Sets to Align with CAAQS

Contaminant	Averaging Period	MET Data Set Years	AERMOD Output ($\mu g/m^3$)
$PM_{2.5}$	24-hour	2018-2020	2.71
		2019-2021	**2.78**

	Annual	2018-2020	**0.633**
		2019-2021	0.633
		2020-2022	0.619
NOx	1-hour	2018-2020	**28.3**
		2019-2021	24.5
		2020-2022	24.4
SO_2	1-hour	2018-2020	**8.71**
		2019-2021	7.73
		2020-2022	8.50

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_X = nitrogen oxides; SO_2 = sulphur dioxide; CO = carbon monoxide; $\mu g/m^3$ = micrograms per cubic metre.
BOLD – Results in bold indicate values used in the assessment

2.4 Post-Processing

Most air quality concentration results are output directly from the model; however, there are certain parameters that require post-processing, including conversion of NO_2 using existing regional ozone concentrations. These post-processing methods are described in the following sections.

2.4.1 Conversions of NOx to NO_2

Emissions of oxides of nitrogen (NO_X) were used as inputs to the AERMOD model. Ambient predictions of nitrogen dioxide (NO_2), one of the criteria air contaminants, can be calculated from modelled NO_X values using the Ozone Limiting Method (OLM). The OLM consists of comparing the maximum modelled NOx concentration to the background ozone (O_3) concentration to assess the limiting factor to NO_2 (Cole and Summerhays 1979). The following equations present the method:

If background $[O_3] > 0.90\ [NO_x]$, total conversion: $[NO_2] = [NO_x]$

If background $[O_3] < 0.90\ [NO_x]$, NO_2 is limited by O_3: $[NO_2] = [O_3] + 0.10\ [NO_x]$

For the air quality assessment, the 1-hour, 24-hour and annual NO_2 concentrations were calculated assuming total conversion of NOx since background ozone values at these averaging periods were above 0.90 [NOx].

Table 7 provides a summary of the NO_2 calculation for the three averaging periods under the Maximum Scenario. The maximum O_3 background concentration from the five assessed stations was conservatively used for comparison.

Additional information on the background air quality assessment is presented in Appendix 6.2-1.

Table 7: Summary of Maximum Scenario NOx Conversion to NO_2

Averaging Period	O_3 Background Concentration (µg/m³)	NOx Estimated Concentration (µg/m³)	0.9 (NOx)	Required Approach	NO_2 Estimated Concentration (µg/m³)
1-hour	82.42	28.28	25.46	Full Conversion	28.28
24-hour	80.38	3.54	3.19	Full Conversion	3.54
Annual	58.13	0.153	0.138	Full Conversion	0.153

O_3 = ozone; NO_X = nitrogen oxides; NO_2 = nitrogen dioxide.

2.5 Application Case Dispersion Modelling Results

The dispersion modelling results for the Application Case (Maximum Scenario) may be summarized based on the type of source considered in the Air Quality Assessment, specifically road (including dust from paved roads, exhaust emissions from paved roads) and non-road emissions (including exhaust emissions from non-road equipment, batch mixing plant or other similar equipment, in situ disposal and demolition and emergency power generators). Emission rates (in g/s) for all sources assessed as part of the Application Case are presented in Appendix 6.2-2.

Maximum concentrations for the Application Case Maximum Scenario are summarized in Table 8 according to indicator compound and averaging period.

Table 8: Summary of Application Case Maximum Scenario Project Dispersion Modelling Results

Contaminant	CAS No.	Averaging Period (hours)	Maximum Scenario Emission Rate (g/s)	Maximum Predicted Concentration (µg/m³)
SPM	N/A-1	24-hour	3.95	158
SPM	N/A-1	Annual	3.95	13.5
PM_{10}	N/A-2	24-hour	0.926	30.6
$PM_{2.5}$	N/A-3	24-hour	0.201	2.78
$PM_{2.5}$	N/A-3	Annual	0.201	0.633
NO_2	10102-44-0	1-hour	0.484	28.3
NO_2	10102-44-0	24-hour	0.209	3.54
NO_2	10102-44-0	Annual	0.0209	0.153
CO	630-08-0	1-hour	3.34	465
CO	630-08-0	8-hour	3.34	0171
SO_2	7446-09-5	1-hour	0.0957	8.71
SO_2	7446-09-5	24-hour	0.0200	0.437
SO_2	7446-09-5	Annual	0.0200	0.0150

SPM = suspended particulate matter; PM_{10} = particles nominally smaller than 10 µm in diameter; $PM_{2.5}$ = particles nominally smaller than 2.5 µm in diameter; NO_X = nitrogen oxides; SO_2 = sulphur dioxide; CO = carbon monoxide; g/s = grams per second; $\mu g/m^3$ = micrograms per cubic metre.

2.6 Conservatism in Modelling and Post-Processing Approaches

Table 9 outlines the areas where conservatism was assumed in the modelling approach, which results in an assessment that is not likely to under-predict the air quality associated with the Project.

Table 9: Areas of Conservatism in the Modelling Approach

Area	Conservatism
The Project's Application Case (i.e., project phases 1 to 3) were assumed to occur simultaneously	The modelling assessment includes all operations occurring simultaneously and continuous over the entire modelling period.
Project activities were modelled as volume sources.	Modelling the emissions as a volume source is conservative since this model source type does not take advantage of favourable dispersion characteristics such as plume buoyancy and initial exit velocity of emissions for sources with stacks or exhausts (e.g., propane-fired boiler, batch mixing plant or other similar equipment). Further, the dispersion modelling source dimensions selected for the volume source result in a dispersion modelling source which is smaller than the corresponding real-life source. This is conservative since estimated emissions occur over a smaller area, and thus, are more concentrated (and therefore less dispersed) at the point of release.
Fugitive Dust Modelling	The parameters that were required for fugitive dust modelling from paved roads include the locations of the roadway segments, base elevations, effective heights of the emissions, and the initial plume size in the lateral and vertical directions. It is recognized that this modelling approach will result in higher predicted concentrations close to the roadways than actual values for the following reason: ■ When the roads are wet or snow-covered, the emissions will be reduced or eliminated. AERMOD has the capacity to have a variable emission rate that could account for actual meteorological emissions; however variable emission rates were not used in this assessment for conservatism. Despite the limitations of the emission rate estimates and dispersion modelling, these are the best estimates available.

It is assumed that the conservative emission rates, when combined with the conservative operating conditions and conservative dispersion modelling assumptions and post-processing assumptions description herein, are not likely to under predict the modelled concentrations at each of the identified receptors.

EIS FOR THE IN SITU DECOMMISSIONING OF WR-1 AT THE WL SITE
APPENDIX 6.6-1: VALUED COMPONENT SELECTION AND SPECIES AT RISK SCREENING TABLE
REVISION 5

Scientific Name	Common Name	Confirmed at WL	Included as VC?	Justification for Inclusion/Exclusion	COSEWIC[a]	SARA[b]	ESEA[c]	G-Rank[d]	S-Rank[d]
Mammals									
Myotis lucifugus	Little Brown Myotis	Yes (Acoustic recording in 2015 in the LSA, an individual with an injured wing observed on pallet on north side of B412 – unverified species identification on visual observation)	Yes	Species may roost in buildings in LSA and decommissioning of buildings may result in roost loss. Also may be affected by noise if roosting in surrounding forested area in RSA	END	END	END	G3G4	S2N, S5B
Myotis septentrionalis	Northern Myotis	Yes (Acoustic recording in 2015 in the LSA)	Yes	Species unlikely to roost in buildings; may be affected by noise if roosting in surrounding forested area in RSA	END	END	END	G2G3	S3S4N, S4B
Reptiles									
Chelydra serpentina	Snapping Turtle	Yes (4 individuals recorded in 2014 and 2016 crossing road near lagoon, by east gate to the WMA (on east side of east gate at road crossing), and on Ara Mooradian Way (Plant Road), individuals were recorded in 2021 on the east side of Plant Road and on the far west side of the lagoon	Yes	Species has been recorded in the RSA at road crossings and populations are susceptible to increases in adult mortality, particularly due to vehicle collisions	SC	SC	-	G5	S3
Birds									
Cardellina canadensis	Canada Warbler	Yes (Acoustic recordings in 2018 at station 3 and in 2019 at stations 1 and 5, most likely originating from RSA outside of LSA)	No	Acoustic recordings can be detected from locations up to 2 km away from recording device. Suitable breeding habitat for this species likely present in the RSA, but unlikely in the LSA. Canada warbler breeding habitat is moist, mixed coniferous and deciduous forests with a well-developed understory near streams, swamps or bogs. The LSA contains manicured turf grass and scattered trees. Golden-winged warbler breeding and foraging habitat consists of early successional habitat at the interface of forest and open habitat (i.e., edge habitat). Golden--winged warbler was originally selected as the suitable VC species because it was determined to have a higher likelihood of occurrence, given the presence of mapped critical habitat in the region and the existing habitat conditions at WL. It serves as an appropriate surrogate for potential indirect effects of noise on Canada warbler as the potential effects on Golden-winged warbler would be predicted to be greater, based on the closer proximity of edge habitat than forests with well-developed understories to the LSA.	SC	THR[e]	THR	G5	S3B
Chaetura pelagica	Chimney Swift	No	No	Species has not been recorded in the RSA	THR	THR	THR	G4G5	S2B
Chordeiles minor	Common Nighthawk	No	No	Species has not been recorded in the RSA	SC	SC	THR	G5	S2S3B
Contopus cooperi	Olive-sided Flycatcher	Yes (Acoustic recordings in 2019 at stations 5 and 6, most likely originating from RSA outside of LSA)	No	Acoustic recordings can be detected from locations up to 2 km away from recording device. Suitable breeding habitat for this species likely present in the RSA, but unlikely in the LSA. Olive-sided flycatcher breeding habitat consists of natural openings in coniferous or mixed forests, including bogs, burns, riparian zones, and cutover areas. They are also found in semi-open forest stands and early successional forest when tall snags and residual live trees are present. In the boreal forest it is often associated with muskeg, bogs, fens and swamps dominated by spruce and tamarack. Open areas with tall trees or snags for perching are used for foraging (COSEWIC 2018). Nests are usually built on horizontal branches of conifers (Peck and James 1987). The LSA contains manicured turf grass and scattered trees. Golden-winged warbler breeding and foraging habitat consists of early successional habitat at the interface of forest and open habitat (i.e., edge habitat). Golden-winged warbler was originally selected as the suitable VC species because it was determined to have a higher likelihood of occurrence, given the presence of mapped critical habitat in the region and the existing habitat conditions at WL.	SC	SC	THR	G4	S2S3B
Contopus virens	Eastern Wood-pewee	No	No	Species has not been recorded in the RSA and suitable habitat is not likely present in the LSA	SC	SC	-	G5	S3B
Cygnus buccinator	Trumpeter Swan	Yes (pair observed in 2015 in secondary cell of sewage lagoon)	No	Suitable breeding habitat is not likely present in the LSA	-	-	END	G4	S2B
Dolichonyx oryzivorus	Bobolink	No	No	Species has not been recorded in the RSA and suitable habitat is not likely present in the LSA	SC	THR[e]	-	G5	S3S4B

Scientific Name	Common Name	Confirmed at WL	Included as VC?	Justification for Inclusion/Exclusion	COSEWIC[a]	SARA[b]	ESEA[c]	G-Rank[d]	S-Rank[d]
Birds (cont'd)									
Hirundo rustica	Barn Swallow	Yes (2016 - breeding pair found with active nest in marine container west of B411 and one observed perching on north fence of WMA; 2015 – 13 nests observed on buildings within the main campus; 2018 – multiple individuals observed nesting at CRA marine container, two individuals observed sitting on south end Quonset, nesting pairs observed on marine containers WCF-C1 and WCF-C8, at least two individuals observed nesting/feeding young on a vent on the north side of B412; in 2021 an individual was found deceased inside B300)	Yes	Species nests in buildings and structures in the LSA. Culverts, as well as buildings and other infrastructure present in the LSA and RSA provide suitable nesting habitat; decommissioning of buildings may result in nest losses.	SC	THR[e]	-	G5	S4B
Falco peregrinus anatum/tundrius	Peregrine Falcon	Yes (Observed in flight over Plant Road in 2018)	No	Although one Peregrine falcon has been observed in flight in the RSA, it has not previously been observed nesting on buildings in the LSA. Species breeding range extends across North America in scattered populations. Suitable breeding habitat includes cliffs along rivers or ocean coasts and anthropogenic structures such as buildings or towers. Pre-demolition surveys to determine the presence of barn swallow nests on the exterior of the WR-1 building will also determine the presence of Peregrine falcon nests (with appropriate mitigation applied to protect the species if confirmed to be nesting). Barn swallow serves as an appropriate surrogate for potential effects of building demolition on Peregrine falcon because the potential effects on barn swallow are predicted to be greater, based on the numerous LSA observation records to-date including confirmed nesting activity on buildings in the LSA.	NAR	NAR	END	G4	S2BS3M
Ixobrychus exilis	Least Bittern	No	No	Species has not been recorded in the RSA and suitable habitat is not likely present in the LSA	THR	THR	END	G4G5	S2S3B
Lanius ludovicianus excubitorides	Loggerhead Shrike (Prairie subspecies)	Yes (individual observed in a tree by B401 in 2014)	No	Subspecies has been assigned based on updated taxonomy and range information. Although this species was recorded in the LSA in 2014, there is little suitable habitat present in the LSA and there is a low probability that this species will breed in the LSA.	THR	THR	END	G4T4	S1B
Melanerpes erythrocephalus	Red-Headed Woodpecker	Yes (individual observed having a dust bath on east shoulder of Ara Mooradian Way (Plant Road) just outside of parking lot in 2014	No	Although this species was recorded in the RSA in 2014, there is little suitable habitat present in the LSA and there is a low probability that this species will breed in the LSA.	END	END	THR	G5	S3B
Riparia riparia	Bank Swallow	No	No	Species has not been recorded in the RSA and suitable habitat is not likely present in the LSA.	THR	THR	-	G5	S4B
Vermivora chrysoptera	Golden-winged Warbler	No	Yes	Species has not been recorded in the LSA or RSA; however, suitable breeding habitat is present in the RSA. Golden-winged warbler breeds in regenerating scrub habitat with dense ground cover and a patchwork of shrubs, usually surrounded by forest. Their preferred habitat is characteristic of a successional landscape associated with natural or anthropogenic disturbance such as rights-of-way, and field edges or openings resulting from logging or burning. Golden-winged warbler nests are built on the ground at the base of a shrub or leafy plant, often at the shaded edge of the forest or at the edge of a forest opening (Confer et al. 2011). Chosen as a VC to represent avian species potentially affected by noise in surrounding habitat in the RSA, and because the RSA is located within a 10x10 km standardized UTM grid square identified as containing critical habitat in the Recovery Strategy (ECCC 2016).	THR	THR	THR	G4	S2S3B

Invertebrates									
Danaus plexippus	Monarch	No	No	Species has not been recorded in the RSA and suitable breeding habitat (i.e., obligate larval host plant milkweed) is not likely present in the LSA.	END	END	-	G4	S3S4B

Notes:

a) COSEWIC END = Endangered; THR = Threatened; SC = Special Concern; NAR = Not at Risk.

b) Federal *Species at Risk Act* (SARA), 2002. Schedule 1 (Last amended 03 February 2023); Part 1 (Extirpated - EXP), Part 2 (Endangered - END), Part 3 (Threatened – THR), Part 4 (Special Concern – SC).

c) Manitoba *Endangered Species and Ecosystems Act* (ESEA) (2015) (C.C.S.M. c. E111 Current as of July 14, 2023); END = Endangered; THR = Threatened; SC = Special Concern; NAR = Not at Risk.

d) Global Ranks (G-Rank) and Provincial Ranks (S-Rank) are rarity or conservation status ranks assigned to species or ecological communities by NatureServe and Manitoba Conservation Data Centre, respectively, and are current as of July 2023. These ranks are not legal designations. Rank definitions: G1 or S1 (Critically Imperilled); G2 or S2 (Imperilled); G3 or S3 (Vulnerable); G4 or S4 (Apparently Secure); G5 or S5 (Secure); G#G# or S#S# (Range Rank); GNR or SNR (Not Ranked); GU or SU (Unrankable – Data Deficient); GX or SX (Presumed Extinct or Extirpated); GH or SH (Possibly Extinct or Extirpated – Historical); SNA (Not Applicable). Qualifiers: B = Breeding; N = Non-breeding; M = Migrant; ? = Inexact or uncertain numeric rank.

e) Currently under consideration for status change

WL = Whiteshell Laboratories; EIS = Environmental Impact Statement; VC = Valued Component; - = not listed/no status; COSEWIC = Committee on the Status of Endangered Wildlife in Canada.

1. INTRODUCTION

1.1 Background

Decommissioning of Whiteshell Laboratories is being completed in two phases. Phase 1 activities for the WR-1 reactor included removal of the organic coolant, heavy water moderator, irradiated fuel, and some decontamination and dismantling activities and are complete. CNL has now proposed In Situ Decommissioning (ISD) as the strategy for the Phase 2 decommissioning of the WR-1 Reactor. This is a change to the original Phase 2 strategy of dismantlement and removal [1] and requires an EA under the Canadian Environmental Assessment Act, 2012. To support the EA, an Environmental Impacts Statement (EIS) is being developed, which includes a section on accidents and malfunctions.

1.2 Objective

The objective of this hazard identification report is to identify potential hazards and associated malfunctions and accidents which could arise during the Phase 2 decommissioning activities of WR-1, causing harm to people or the environment. The findings from this report support development of the *Accidents and Malfunctions* section of the EIS for the in-situ decommissioning of WR-1.

1.3 Scope

This hazard identification assesses Phase 2 activities, which encompass all remaining activities to place the WR-1 in a final decommissioned state. The Phase 2 activities include:

- Emplacement of radiological wastes from the above grade structure into the below grade structure.
- Crawlspace remediation into below grade structure.
- Establishment of a supply of mixed grout.
- Grouting of WR-1 reactor system components where void spaces cannot be effectively filled during final grouting.
- Grouting of WR-1 below grade building structure/systems including all remaining penetrations and void spaces.
- Installation of an engineered cover and environmental controls.

Potential radiological and non-radiological hazards associated with accidents and malfunctions are to be identified for the WR-1 ISD activities of Phase 2. The associated consequence and likelihood are also to be estimated for each hazard, as well as any mitigating factors.

Hazards which result in consequences only over long timeframes (i.e., after the engineered cover is complete and the WR-1 site closed) will be identified as part of the Decommissioning Safety Analysis Report and are not in the scope of this assessment.

2. METHODOLOGY

This hazard ID report was developed through the following activities:

- Document reviews
- What-If workshop

Document Reviews

Numerous documents from CNL and other sources were reviewed to identify the activities which will be carried out for decommissioning and to determine the types of hazards present. This review was also used to develop a checklist to guide the What-If Workshop.

What-If Workshop

This hazard identification was executed as a structured *What-If* workshop, which is a *What-If* workshop guided by a checklist. In this case, the checklist (shown in Appendix A) was populated with a set of hazards relevant to the decommissioning activities, identified from various sources. Team brainstorming of potential malfunctions and accidents was not constrained by the checklist and participants were encouraged to present all ideas which may result in the identification of hazards associated with malfunctions or accidents. An initial estimate of the consequence, likelihood, and mitigating factors was also attempted for each hazard or *What-If* question posed by the team. Likelihoods were roughly estimated based on the frequency indices shown in Table 1.

Table 1: Frequency Indices

Index	Events/Year
Occasional	$3x10^{-2}$ to $3x10^{-1}$
Rare	10^{-4} to $3x10^{-2}$
Extremely Rare	10^{-6} to 10^{-4}

The process is organized according to the Phase 2 Decommissioning Work Packages identified in [1]. These include the following:

1. Building Systems
2. Prepare Reactor Systems
3. Grout Installation
4. Building Demolition and Site Remediation

What-If tables (see Appendix B) were used to record results of the workshop discussions. A separate table was used for each Decommissioning Work Package.

3. RESULTS

3.1 Type of Hazards

The literature review identified the following radiological and non-radiological high level hazards.

3.1.1 Radiological Hazards

Radiological hazards associated with WR-1 decommissioning include potential exposure to beta, gamma, and alpha-emitting radionuclides produced during the operational period of WR-1. These consist primarily of the following:

1. Fission products
2. Activation products
3. Tritium
4. Corrosion products

Fission products are normally contained within the fuel, although fuel defects or failures result in the release of fission products in small quantities, which are then circulated throughout the reactor core and heat transport system during the operational life of the reactor.

Activation products are produced by irradiation of neutron absorbing materials, which become radioactive.

Tritium is produced when heavy water captures neutrons.

Corrosion products are small, mobile activation products, produced when small debris from corrosion is transported through the core (e.g., in the moderator or coolant) and are irradiated.

3.1.2 Non-Radiological Hazards

Non-radiological hazards present during the ISD of WR-1 include conventional construction and demolition hazards, chemical hazards, biological hazards, fire hazards, and hazards from external events.

Conventional industrial hazards associated with the decommissioning activities include working at heights, in confined spaces, and with energized systems, hoisting and rigging, grouting, and falling objects. Dismantling and demolition of B100, will involve the use of cranes and movement of heavy loads.

Hazardous materials that are present include asbestos, lead, PCBs, mercury, mould, and various chemicals.

Potential external events include fires, floods, aircraft strikes, earthquakes, extreme weather events (e.g., tornadoes, heavy precipitation).

3.2 Potential Accident Scenarios

The main results from the What-If workshop discussions are recorded directly in the What-If tables in Appendix B. These results include the What-If questions, consequences, likelihood, and mitigating factors.

APPENDIX A. WHAT-IF CHECKLIST/GUIDANCE SHEET

Table 2: What-If Guidance Sheet

Work Package	Item #	Hazards	Source
1. Building Systems Air gap building services, Remove Auxiliary Equipment, Remediate Crawlspace, Remove Building Support Systems	1	No unique hazards expected	WR-1 DDP [2]
	2	Some work will be in confined space – safety issues to consider	
	3	Some work will be in contaminated areas (e.g., crawlspace remediation).	
	4	Accidental cutting of contaminated piping	NUREG 0586 [3]
	5	Heavy equipment operation	IAEA, Decommissioning of Underground SSCs [4]
	6	Lifting and rigging	
2. Prepare Reactor Systems Prepare Heat Transport System, Reactor Vessel, Heavy Water & Helium Systems, Secondary Cooling and Auxiliary Systems and Active Ventilation Systems to receive grout; Remove, package and ship Fuel Transfer and Fuel Channel Flasks to CRL for long term management	7	Tritium removal procedures will need to be implemented to ensure worker safety.	WR-1 DDP [2]
	8	Radioactive water, organic coolant, particles and sludge may be present in some equipment.	
	9	Impact on ventilation patterns when active ventilation systems are shutdown, removed or if an opening needs to be cut.	
	10	High radiation fields exist in the reactor vault, upper and lower access rooms.	
	11	Damaged asbestos may be present on piping or tanks that require penetration or other preparatory work.	
	12	The need to remove some shielding to allow vessel preparation/grouting – use of temporary shielding to ensure worker safety.	
3. Grout Installation	13	Airborne particulate from grout constituents may be hazardous to respiratory health and precautions will	WR-1 DDP [2]

Work Package	Item #	Hazards	Source
Apply grout to selected areas, in and around special materials; Flood grouting of below grade structure		be taken to minimize dust generation and limit or prevent inhalation using respirators as appropriate.	
	14	Heavy truck traffic may occur at times during delivery of grout materials.	
	15	Impact on ventilation patterns when ventilation pathways are filled with grout.	
	16	Structural reinforcements may be necessary to ensure grout pressure does not compromise the structure and blow outs do not occur.	
	17	Deflagration/explosion: Aluminum scrap and metal alloys corrode when exposed to high pH (e.g., grout used at SRNL was 12+), producing hydrogen gas.	SRNL R-Reactor ISD [5]
	18	Structural failure: An unknown void space was discovered at the SRNL R-Reactor when a 3D CAD model was created.	[6]
4. Building Demolition and Site Remediation Demolition of B100 control room and office complex, reactor hall and ventilation stack; Installation of engineered cover; Site remediation and final grading	19	Work execution from heights – multiple floors above and below grade.	WR-1 DDP [2]
	20	Methods to backfill individual rooms in the lower levels need to be evaluated.	
	21	Radiological clearance needs to be completed well below ground prior to backfilling the excavation.	
	22	Heavy equipment operation	IAEA, Decommissioning of Underground SSCs [4]
	23	Lifting and rigging	
	24	Noise	
	25	Falling objects	
	26	Eye hazards	
	27	Explosion during demolition	WL CSR Vol. 1 [1]
	28	Weather event during dismantling activities.	DOE, Draft EIS [7]
General	29	Vehicle accident	DGR Malfunctions,

Work Package	Item #	Hazards	Source
			Accidents, Malevolent Acts [8]
	30	Fire: • At facility or involving equipment • During vehicle accident • During cutting	DGR Malfunctions, Accidents, Malevolent Acts [8]
	31	Electrical accidents • Misuse or poor maintenance of electrical equipment • Damage to electrical equipment • Access to live electrical equipment • Severe weather conditions, such as lightning	DGR Malfunctions, Accidents, Malevolent Acts [8]
	32	Spill of fuel, chemicals, lubricants and oils	DGR Malfunctions, Accidents, Malevolent Acts [8]
	33	Occupational accidents • Falls of workers • Injury during cutting • Injury during material handling • Heat exhaustion/stroke • Frostbite • Accidents related to moving/rotating machinery or other equipment • Machinery-related accidents during operation of drill, dozer or other equipment • Injury due to falling objects	DGR Malfunctions, Accidents, Malevolent Acts [8]
	34	Entrapment	

APPENDIX B. WHAT-IF WORKSHOP

Table 3: Workshop Form - 1 Building Systems

What-If	Potential Consequence	Likelihood	Mitigating Factors
1-1 What if the contamination levels of crawl spaces are higher than expected or take greater effort to remediate.	Higher worker exposure.	Rare	Previous characterization. RP surveys, PPE&C, contingency planning.
1-2 What if contaminated soil has spread (cross-contamination)	May require more cleanup/decontamination or higher worker exposures.	Occasional	Work planning to minimize potential spread of contamination. RP surveys, PPE&C.
1-3 What if there is more friable or loose asbestos in the soil or crawl spaces	Worker exposure to asbestos.	Occasional	Previous characterization. PPE&C
1-4 What if there is contamination released during cutting of tubing/conduit during air gapping. (e.g., cross contamination from other systems)	Potential spill or leak and higher worker exposure to radioactivity.	Occasional	Use of remote cutting techniques, PPE&C, radiation surveys, RP protection
1-5 What if there are some systems that are missed for isolation and air gapping (it's a large building)?	Electrical shocks, high pressure relief, industrial hazards, fire hazard, explosion hazard, etc.	Rare	Field verification, verification of design and design changes. Fire Protection, Emergency Preparedness plans.
1-6 What if the required systems (e.g., low level liquid waste collection, ventilation) are inadvertently isolated?	Loss of a safety-significant system. Higher radiological hazards. Potential loss of confinement and release of contamination (airborne and waterborne) to the environment. Potential worker injury.	Rare	Fail-safe modes of systems, backup power supplies. Detailed work plans. Verification of tie-ins.
1-7 What if failure of some remaining	Hazards may exist due to repair or maintenance being	Rare	Risks can be mitigated through careful assessment and work

What-If	Potential Consequence	Likelihood	Mitigating Factors
systems (e.g., low level liquid waste system) requires repair or more services than currently available to the building?	performed under conditions with limited building services.		planning for repair or remediation efforts.
1-8 What if organic coolant contains higher than expected levels of contaminated debris?	Higher exposure from coolant contaminated with radioactive debris.	Rare	RP surveys, PPE&C, potentially visible color change in coolant.

Table 4: Workshop Form - 2 Prepare Reactor Systems

What-If	Potential Consequence	Likelihood	Mitigating Factors
2-1 What if heavy equipment from the PHT or AVS is dropped or impacts the structure?	Structure could be damaged. Clean up for repair requires workers to spend more time in reactor incurring various hazards (e.g., industrial, radiological). Potential for airborne releases.	Rare	Procedural adherence. Verification of equipment. Personnel training, confinement by ventilation, emergency procedures.
2-2 What if negative pressure is not maintained in the reactor building?	Increased spread of airborne contamination, exposure to workers, and potential release to environment.	Occasional	Continuous air monitoring, PPE&C, work planning.
2-3 What if high levels of contamination exist in systems/components being prepared?	Potential for leaks and spills, worker exposure.	Occasional	Radiation Protection surveys, work permit, Personal Protective Equipment & Clothing (PPE&C), remote technology (e.g., automated guillotine cutters), temporary shielding, ventilation enclosure, conservative decision-making, work planning.
2-4 What if cutting or perforating causes	Potential for explosion.	Rare	Removal of combustibles. Use of cold cutting techniques, remote

What-If	Potential Consequence	Likelihood	Mitigating Factors
heating and pressurization of a sealed component during preparation?			technology. Fire protection. Emergency preparedness.
2-5 What if the systems state is unknown or different from expected? (more contamination than expected, or different in nature)	Various types of hazards (e.g., asbestos). The component may not be safe to prepare.	Occasional	Work planning, PPE&C, automated guillotine cutters.
2-6 What if there is an accident or incident resulting in a worker spending prolonged time in the reactor?	Higher worker exposure.	Rare	RP program, work plans, pre-job briefs, contingency plans, safety culture.
2-7 What if there is an accident during removal handling of heavy equipment (during hoisting, transferring)?	Heavy lifting, hoisting, transferring, transportation.	Rare	OSH procedures, PPE&C. Emergency procedures for rescue.
2-8 What if there is extreme weather during grouting (e.g., extreme cold)	See What-If **4-2.**		

Table 5: Workshop Form - 3 Grout Installation

What-If	Potential Consequence	Likelihood	Mitigating Factors
3-1 Can additional tritium be released during this phase (e.g., wet decontamination by, cutting of the ventilation system)?	Higher potential exposure to tritium.	Occasional	PPE&C, work plans, permit, decontamination techniques that do not create liquid waste. Temporary ventilation system during grouting.
3-2 What if there are unknown voids?	Structural integrity, chemical reactions? Higher likelihood of cracks near voids and potential release pathways.	Rare	Careful grout planning, sequencing. Use of visual tools (e.g., 3 D model, graphical method of display, video cameras during grouting).
3-3 What if there are reactions with metals, gases, or other materials (e.g., what if the grout is the wrong specification)?	Potential hydrogen explosion. Grout may not fill voids adequately. May affect post-closure environmental effects.	Rare	Design of grout plan. Knowledgeable grout specialist. Quality Control and Surveillance during grouting. Testing to determine performance of grout with HB-40.
3-4 What if it's not practical to reach certain areas with the grout (e.g., piping)?	Greater worker exposure to hazards such as radiation, confined spaces. Higher likelihood of void spaces.	Occasional	Identification of alternative methods for grouting difficult areas.
3-5 What if the contamination levels of crawl spaces are higher than expected or take greater effort to remediate.	Higher worker exposure.	Rare	Previous characterization.
3-6 What if heavy objects are dropped on the curing grout during this phase?	Potential damage to grout.	Rare /Occasional	Procedural adherence
3-7 What if the grout does not cure as expected to meet end-state objectives (e.g., thermal expansion during curing).	Failure modes of grout may be different or more likely.	Rare	Field testing of grout (including testing with HB-40) before ISD grouting. Grouting plan, and adherence to plan. Quality control

What-If	Potential Consequence	Likelihood	Mitigating Factors
			and surveillance in phases throughout grouting. Limit the grout lift volumes to prevent damage to the curing grout.
3-8 What if contaminated air is displaced by grout?	Spread of airborne contamination.	Rare	Provisions for controlling spread of contamination can be made (e.g., placement of filtered vents), temporary ventilation system during grouting.

Table 6: Workshop Form - 4 Building Demolition and Site Remediation

What-If	Potential Consequence	Likelihood	Mitigating Factors
4-1 What if heavy objects are dropped onto the grouted monolith?	Potential for generation of airborne contamination. Damage or breaks to contaminated systems or components below.	Rare	Ventilation system can confine airborne releases. Emergency and clean up procedures.
4-2 What if the grout behaves unexpectedly due to the organic coolant?	Failure modes of grout may be different or more likely. Migration of contaminants may be more likely.	Unknown	Study of HB-40.

Table 7: Workshop Form – 5 External Events

What-If	Potential Consequence	Likelihood	Mitigating Factors
5-1 What if there is extreme cold weather.	Electronic equipment, filters, respirators may not function, resulting in potential for dose.	Occasional	Work planning, contingency planning, stop work. Heat building.
5-2 What if fire fighting is necessary (also applies to internal fires)?	Large spread of contamination and release to environment. Higher worker doses during	Rare	Fire protection, PPE&C

What-If	Potential Consequence	Likelihood	Mitigating Factors
	cleanup/decontamination of reactor hall outside of ISD envelope. Higher worker doses due to contamination spread during reactor systems preparation (if not complete).		
5-3 What if there is an earthquake during ISD activities?	Worker hazards include falling objects, falling workers, potential collapse. Some spread of contamination is expected. Grout performance may be compromised if during or after grout installation (see What-If **4-2**).	Extremely Rare	WR-1 design basis. Grout design.
5-4 What if there is a flood during ISD activities?	Flooded areas could result in spread of contamination and greater worker doses. Electrical hazards.	Rare	[1] shows extremely low risk from flooding.
5-5 What if there are high winds or a tornado during ISD activities?	Most severe result is collapse of reactor hall, which could also cause a fire. This could result in spread of contamination and higher worker doses due to extensive clean-up activities.	Rare	Stop work during extreme weather events. WR-1 design basis.

1. OVERVIEW

Decommissioning of Whiteshell Laboratories is being completed in two phases. Phase 1activities for the WR-1 reactor, which included removal of the organic coolant, heavy water moderator, irradiated fuel, and some decontamination and dismantling activities, were assessed in a 2002 Environmental Assessment and are complete. Canadian Nuclear Laboratories (CNL) has now proposed In-Situ Decommissioning (ISD) as the strategy for the Phase 2 decommissioning of the WR-1 Reactor. This is a change to the original Phase 2 strategy of dismantlement and removal [1] and is therefore expected to require an Environmental Assessment under the Canadian Environmental Assessment Act, 2012. To support the Environmental Assessment, an Environmental Impacts Statement (EIS) is being prepared, which includes a section on accidents and malfunctions. This report contains a description of the potential accidents and malfunctions identified for the WR-1 ISD activities.

1.1 Objective

The objective of this accidents and malfunctions report is to identify credible accidents and malfunctions which could arise during the WR-1 ISD activities, causing potential harm to people or the environment. Potential effects from the accidents and malfunctions, as well as factors which may mitigate the effects are also identified. Results presented in Section 5 of this report are recommended for inclusion in the *Accidents and Malfunctions* section of the EIS for In-Situ Decommissioning of WR-1.

1.2 Scope

The accidents and malfunctions assessed in this report apply to the Phase 2 decommissioning, which encompasses all remaining activities to place the WR-1 in a final decommissioned state. Phase 2 decommissioning of WR-1 is described in [2] will consist of the following generic steps:

- Isolation of building from site infrastructure.
- Preparation of reactor systems and materials to permit encapsulation with grout.
- Encapsulation of reactor systems and below grade structure with grout.
- Demolition of non-reactor systems and structures and installation of an engineered cap.
- Institution of ongoing environmental monitoring program and return to AECL control.

Hazards which result in consequences only over long time-frames (i.e., after the engineered cover is complete and the WR-1 site closed) are outside of the scope of this report and will be assessed in the Decommissioning Safety Analysis Report. Some accidents and malfunctions with potential long-term consequences and mitigation factors were identified in this report, but the consequences have not been assessed and further analysis is required to determine the effects.

3. METHODOLOGY

The accidents and malfunctions were identified through the following hazard assessment activities:

- Review of CNL documentation related to WR-1.
- Review of EIS accidents and malfunctions reports for other similar facilities.
- OPEX reviews.
- Structured *What-If* workshop and report based on five work packages identified for WR-1 ISD.

The identified accidents and malfunctions were assessed for potential consequences and likelihood of occurrence. Events which were evaluated to have very low likelihoods and/or consequences or were clearly bounded by other scenarios of similar nature were screened out and not considered further. Accident and malfunction scenarios screened in were then further developed and mitigation factors were considered.

4. RESULTS

4.1 WR-1 In-Situ Decommissioning Hazards

The following hazards were identified to be present during the WR-1 decommissioning activities.

4.1.1 Radiological Hazards

Radiological hazards associated with WR-1 decommissioning include potential exposure to beta, gamma, and alpha-emitting radionuclides produced during the operational period of WR-1. These consist primarily of the following types of radiological hazards:

Fission products

Fission products are normally contained within the fuel, although fuel defects or failures result in the release of fission products in small quantities, which are then circulated throughout the reactor core and heat transport system, during the operational life of the reactor.

Activation products

Activation products are produced by irradiation of neutron absorbing materials, which become radioactive. They are most abundant in structures and components in or near the core of the reactor, such as the fuel channels.

Tritium

Tritium is produced when heavy water captures neutrons. Residual moderator left from draining WR-1 is expected to contain tritium.

Corrosion products

Corrosion Products are small, mobile activation products, produced when small debris from corrosion is transported through the core (e.g., in the moderator or coolant) and are irradiated.

4.1.2 Non-Radiological Hazards

Non-radiological hazards present during the ISD of WR-1 include conventional construction and demolition hazards, chemical hazards, biological hazards, fire hazards, etc.

Conventional industrial hazards associated with the decommissioning activities include working at heights, in confined spaces, and with energized systems, hoisting and rigging, grouting, and falling objects. Dismantling and demolition of B100 will involve the use of cranes and movement of heavy loads.

Hazardous materials present include asbestos, lead, polychlorinated biphenyl

compounds (PCBs), mercury, mould, and various chemicals.

4.1.3 External Events

External events may result in radiological and non-radiological consequences. Potential external events include fires, floods, aircraft strikes, earthquakes, extreme weather events (e.g., tornadoes, heavy precipitation).

4.2 Accidents and Malfunctions

The subsections which follow present the potential accidents and malfunctions recommended for inclusion in the WR-1 EIS.

4.2.1 Occupational Accidents

Potential worker accidents and injury may arise from conventional, industrial hazards, including working at heights, in confined spaces, and with energized systems, hoisting and rigging, and falling objects. Dismantling and demolition of B100, in particular, will involve extensive use of cranes and movement of heavy loads. Failure to isolate all energized systems (e.g., electrical, pressurized) from the building during the building isolation, either through improper isolation or accidental exclusion, may also pose a hazard to workers.

The level of risk posed by the ISD activities is comparable to many other industrial settings for these types of hazards and is acceptable with careful mitigation.

Effects

In addition to the potential injury or accident itself, incidents during decommissioning activities may result in increased exposures to the attendant hazards since the injured personnel may require assistance of rescuers or face delays before exiting to a safe location. In particular, accidents or injuries in confined spaces increase exposure of the worker and rescuers to confined space hazards, such as poor air quality, chemicals, and radiation. The hazard initiating the accident or injury may pose a particular threat to rescuers.

The use of saws, drills, and compressors can cause injury to the operator. Accidental non-isolation of an energized system could result in shocks to workers (e.g., electrical or physical). Workers will be at risk of falling or having objects fall on them.

Mitigation

Industrial hazards are identified and assessed through CNL's Occupational Safety and Health (OSH) Program. Work can be carefully implemented with CNL procedures for hoisting and lifting, working at heights, confined space entry, and working with energized systems. Workplace controls, and Personal Protective Equipment and Clothing (PPE&C), including hard hats, gloves, fall protection, and hearing protection, will mitigate these hazards to an acceptable level.

WL Fire fighters are trained in confined space rescue and there are emergency

procedures for dealing with injured workers.

4.2.2 Spills and Leaks

Spills and leaks of radioactive contamination are possible during all stages of ISD activities. During cutting and perforation of components and structures, unknown or greater than expected quantities of radioactive substances may be encountered. Accidental cuts or breaks of contaminated piping may also release radioactive substances. Leaks could also occur from equipment failure, such as the Low Level Waste Collection system.

Non-radiological hazardous materials in excess of the regulated exemption quantities in the above grade structure (as well as easily removed quantities in the ISD boundary) will be removed and disposed of off-site. Spills and leaks are possible during removal, handling, and transport of these materials, including friable asbestos, lead, PCBs, and chemicals of various degrees of toxicity.

Effects

Spills and leaks during worker activities could lead to external and internal exposures to workers. Volatile contaminants released to the atmosphere may be transported and deposited in a new location. Releases of liquid contaminants during transport to an appropriate disposal area may contaminate soil, groundwater, surface water, and air.

Mitigation

The effects of spills and leaks of radiological substances can be minimized by following procedures and practices of CNL's RP Program. Procedures developed under CNL's Environmental Protection Program, Waste Management Program, and OSH Program will aid in protecting workers and the environment from radiological and non-radiological hazards.

Adequate ventilation during decommissioning activities will minimize worker exposures to airborne contaminants, as well as filtration. The use of PPE&C (e.g., chemical resistant gloves, eye protection), routine inspections of equipment, spill trays, spill kits, and established emergency procedures can be used to manage these hazards and mitigate the effects of spills and leaks. Chemical protection suits and self-contained breathing apparatuses will protect workers who may be potentially exposed to more toxic chemicals, such as potassium hydroxide. Due to its slow biodegradation and low water solubility, hydrogenated terphenyl should be collected to a practical extent and disposed of appropriately.

4.2.3 Material Handling Accidents

Various ISD activities will involve lifting and moving of large, potentially contaminated materials. The heat exchangers from the Primary Heat Transport system will be placed inside the ISD envelope. Other items, such as fume hoods, will be removed from B100. Wastes collected during decommissioning activities may be placed in containers and moved. Demolition activities will require significant handling of heavy loads.

Effects

Drops of, or impacts from, large objects pose physical hazards for workers nearby, including explosions or fires. The dropped objects could also damage other equipment or structures, resulting in leaks and spills. Cleanup or remediation required following such an incident results in higher worker exposures. Dropping of contaminated rubble or concrete could cause fine, radioactive particles to be suspended in air, posing an internal exposure hazard. Drops and ruptures of waste containers, or contaminated equipment, such as fume hoods, could also spread contamination and cause it to become airborne.

Mitigation

Confinement from ventilation will curtail airborne releases. Accidents during demolition activities will not release contaminants from the ISD boundary because they will be immobilized in the grout. The use of stabilizing and immobilizing agents prior to demolition can reduce the spread of any remaining B100 contaminants. Implementation of CNL procedures, including hoisting and rigging, will reduce the likelihood of a material handling accident. Emergency Preparedness plans reduce the consequences of an accident if it occurs.

4.2.4 Offsite Transportation Accidents

Non-radiological hazardous wastes above exemption limits will be transported to an appropriate off-site waste facility. Off-site transportation of radiological materials is not anticipated during the ISD activities.

Effects

Transportation accidents involving vehicles carrying hazardous wastes may expose the driver or other members of the public, or release contaminants to the environment.

Mitigation

Low risk from transportation accidents can be maintained through proper packaging and handling of hazardous waste and the use of CNL's procedures on Management of Non-Radiological Hazardous Chemical Waste and WL Waste Materials Management. WL's Emergency Preparedness Program has emergency plans for off-site accidents. No quantities of radioactive materials are expected to be transferred off-site under the ISD strategy.

4.2.5 System and Equipment Failure

Equipment failure and malfunctions may result from improper operation or maintenance, loss of services, or extreme environmental conditions. Safety-significant systems and equipment, including alarm and monitoring systems (e.g., continuous air monitors), contamination collection and confinement (e.g., Low Level Liquid Waste Collection system, ventilation system, storage tanks), could potentially be affected.

Effects

Failures of systems or equipment could result in the accumulation or release of airborne

and liquid contaminants, as well as increased worker exposure. Failure of alarm and monitoring systems could put workers at higher risks of exposures or fail to provide notification of unsafe conditions. Worker injuries and accidents are also possible with failed equipment or systems.

Mitigation

Design of equipment with fail-safe modes, use of reliable power supplies, maintenance programs, and depth-in-defense minimize the likelihood or effects of failures. Use of PPE&C and adherence to OSH procedures, contingency planning, and safe back-out procedures provide protection to workers from system and equipment failure.

4.2.6 Fires and Explosions

Fires may result by ignition of combustible materials, equipment malfunction, electrical faults, or lightning strikes. A number of systems and components will require cutting or perforating during reactor systems preparation. The use of saws, cutting torches, and drills poses a risk of ignition of combustible material.

Cutting of sealed components, which may be specifically targeted so that grout will infiltrate them and minimize voids, may pose an explosion hazard if they contain combustibles.

During grouting, metals and alloys exposed to high pH (e.g., an improperly specified or mixed grout) produce hydrogen which could potentially reach an explosive concentration above the grout surface.

Effects

Small radioactive releases to the environment are possible during fires from the burning of contaminants. Waste generated from decontamination activities, such as wipes, protective clothing, and HEPA filters introduces combustible contaminated material, which could be released to the atmosphere during a fire.

Firefighting methods may spread contamination, primarily inside the ISD envelope, but also outside of the envelope (e.g., contamination spread in the 500 and 600 level from sections of the PHT and AVS). Since most of the reactor hall outside of the ISD will be removed, cross-contamination in these areas will burden the removal process with greater decontamination effort and higher dose rates.

Mitigation

There are limited quantities of combustibles in WR-1 and Whiteshell's Fire Protection would minimize the duration and consequences of a fire. Wastes from decontamination activities will be packaged and managed in compliance with WL materials management procedures to reduce the likelihood of ignition.

Fire hazards can be reduced through implementation of Whiteshell's Fire Protection Program, removal of combustibles, and preferential use of cold cutting equipment. CNL maintains an Emergency Preparedness Program which curtails consequences from fires and explosions.

The hazard to workers from explosions of sealed components can be mitigated by careful surveying prior to cutting, and through preferential use of remote cutting equipment.

This risk of hydrogen explosion is avoided through proper specification and formulation of the grout (i.e., appropriate pH).

Worker doses during cleanup following a fire can be kept to a safe level through radiation protection practices.

4.2.7 Non-Conformant Monolith

Non-Conformant Grout

Improper curing of grout may be possible if the grout design is incorrect, or if the grout preparation and lift sequencing is not performed according to specifications. This may also be caused by extreme weather (e.g., extreme temperatures) during curing.

Excessive Voids

Larger voids that remain in the monolith, either because they were not identified or were not practical to fill during preparation, are more prone to cracking during temperature induced expansion [3].

Effects

Effects of a non-conformant monolith include reduced isolation and reduced immobilization of contaminants. The formation of cracks near voids may provide a pathway for releases of contaminants to the environment and exposure to the public. Releases due to a non-conformant monolith are anticipated to occur at a slow rate and over the long term.

Mitigation

Grout performance can be maximized by careful design, formulation, and sequencing during installation. Field testing, including tests of the grout with the organic coolant, can increase the reliability of the grouting method. Use of an experienced grout supplier with an appropriate QA Program can ensure adequate grout performance. Quality Control and Quality Surveillance should be incorporated during all phases of grout design and installation. Field demonstration tests should be performed to provide a higher level of assurance of the grout performance. The use of visual tools (e.g., 3D model, graphical method of display, video cameras during grouting) can minimize the likelihood of significant, unanticipated voids.

4.2.8 External Events

Extreme Rainfall

Effects

Extreme rain could result in a significant increase in surface water run-off and accompanying soil. This may result in worker safety issues, such as slippery surfaces, reduced visibility, and increased electrical hazards. Surface water run-off could lead to spread of contaminants exposed to the water.

Mitigation

Suspension of decommissioning activities and securing and containment of potentially contaminated materials associated with the activities during extreme rainfall can reduce the risks from extreme rainfall to acceptable levels.

Earthquake

Effects

An earthquake during ISD activities could result in damage to containment systems, hazards to workers, and non-conformance of the monolith. Implementation of CNL's Emergency Preparedness Program plans will mitigate the consequences of a potential earthquake.

Mitigation

WR-1 and the grout formula have been will be designed to withstand extreme environmental events.

Floods and Extreme Rainfall

Effects

Flooding of the site due to a rise in the Winnipeg River is remote. A failure of the Seven Sisters hydroelectric dam, which is upstream of the WL site, is considered to bound potential rises in the river due to extreme rainfall. There has never been a failure of a hydroelectric dam in Canada. Flood levels of the river at the WL site following a failure of the Seven Sisters Dam were previously estimated to reach a peak at 7 m above normal water levels [1]. This is below the level of the reactor building and such an incident would not flood the WR-1 site. The risk from flooding is therefore insignificant. WR-1 is currently protected by the reactor building. The reactor building will not be demolished until the grout has cured and the contaminants are isolated and immobilized. At this point, extreme rainfall will have a negligible effect.

Mitigation

During extreme rainfall, activities will be suspended to prevent occupational accidents.

Tornado

The WR-1 reactor building is designed to withstand very high winds and decommissioning activities would be suspended during extreme weather events to protect workers. A tornado is not anticipated to have any measurable effect following closure of the WR-1 site.

Aircraft Crash

Following closure, an aircraft crash at the WR-1 location is not likely to have a significant effect. Damage may occur to the grout, potentially reducing the long-term performance.

Decommissioning activities are planned to be begin in 2019 with demolition of the reactor building complete by June 2022. The likelihood of an aircraft crash directly affecting the WR-1 site during this time-frame is remote.

5. CONCLUSION

A number of accidents and malfunctions were identified for Phase 2 decommissioning activities for the WR-1 reactor. These scenarios were identified through document review (WR-1 literature and international guidance and reports for similar activities), a What-If workshop, and OPEX reviews.

Radiological consequences of accidents and malfunctions during ISD activities are anticipated to be significantly smaller than those identified in [1], which assessed the Phase 1 decommissioning activities, as well as the original Phase 2 approach of complete dismantlement and removal of WR-1. The completion of Phase 1 activities removed the majority of radiological hazards through removal of the spent fuel, coolant, and moderator. Further, the significant reduction of activities which would be required for the complete dismantling and removal reduces the likelihood of accidents and malfunctions, and their accompanying radiological and non-radiological effects.

Accidents and malfunctions during ISD activities are anticipated to have local effects only.
