1 INTRODUCTION

1.1 PROJECT BACKGROUND

Great Bear Resources Ltd. a wholly owned subsidiary of Kinross Gold Corporation, is proposing to develop a gold mine (the Great Bear Project or Project) at the Great Bear Property (Property). The Property is located approximately 25 kilometres (km) southeast of the Municipality of Red Lake (Figure 1-1) in northwestern Ontario. The Project involves extracting and processing ore from two open pits and an underground mine. The main components of the Project shown on Figure 1-2 include:

- Underground mine
- LP Central pit
- West Viggo pit / West Viggo management facility (VMF)
- East Viggo pit / East VMF
- Tailings management facility (TMF)
- TMF pond
- Mine water pond (MWP)
- AEX mine water pond
- AEX effluent treatment plant (ETP)
- AEX treated water pond (TWP)
- Holding pond
- Collection water pond (CWP)
- Main collection channel
- Dixie Creek flood protection berm
- Mine rock stockpile (MRS)
- Overburden stockpiles
- Ore stockpiles
- Process plant
- Other buildings and supporting infrastructure
- Water management and treatment facilities
- Sand and gravel (borrow) and quarry operations
- Explosives storage facility.

Construction of the mine site and associated infrastructure is expected to take approximately three years. Underground and open pit mining are expected to occur concurrently, with operation of the LP Central pit for up to about 9years, followed by underground mining only for an additional 17 years, for a total operations period of approximately 26 years. This will be followed by a closure phase, comprised of a three year active closure period when most of the decommissioning and reclamation is completed, and a passive closure period until the mine workings are filled and site waters are acceptable for passive release to the environment, and a final close out period of about six months when residual infrastructure is removed.

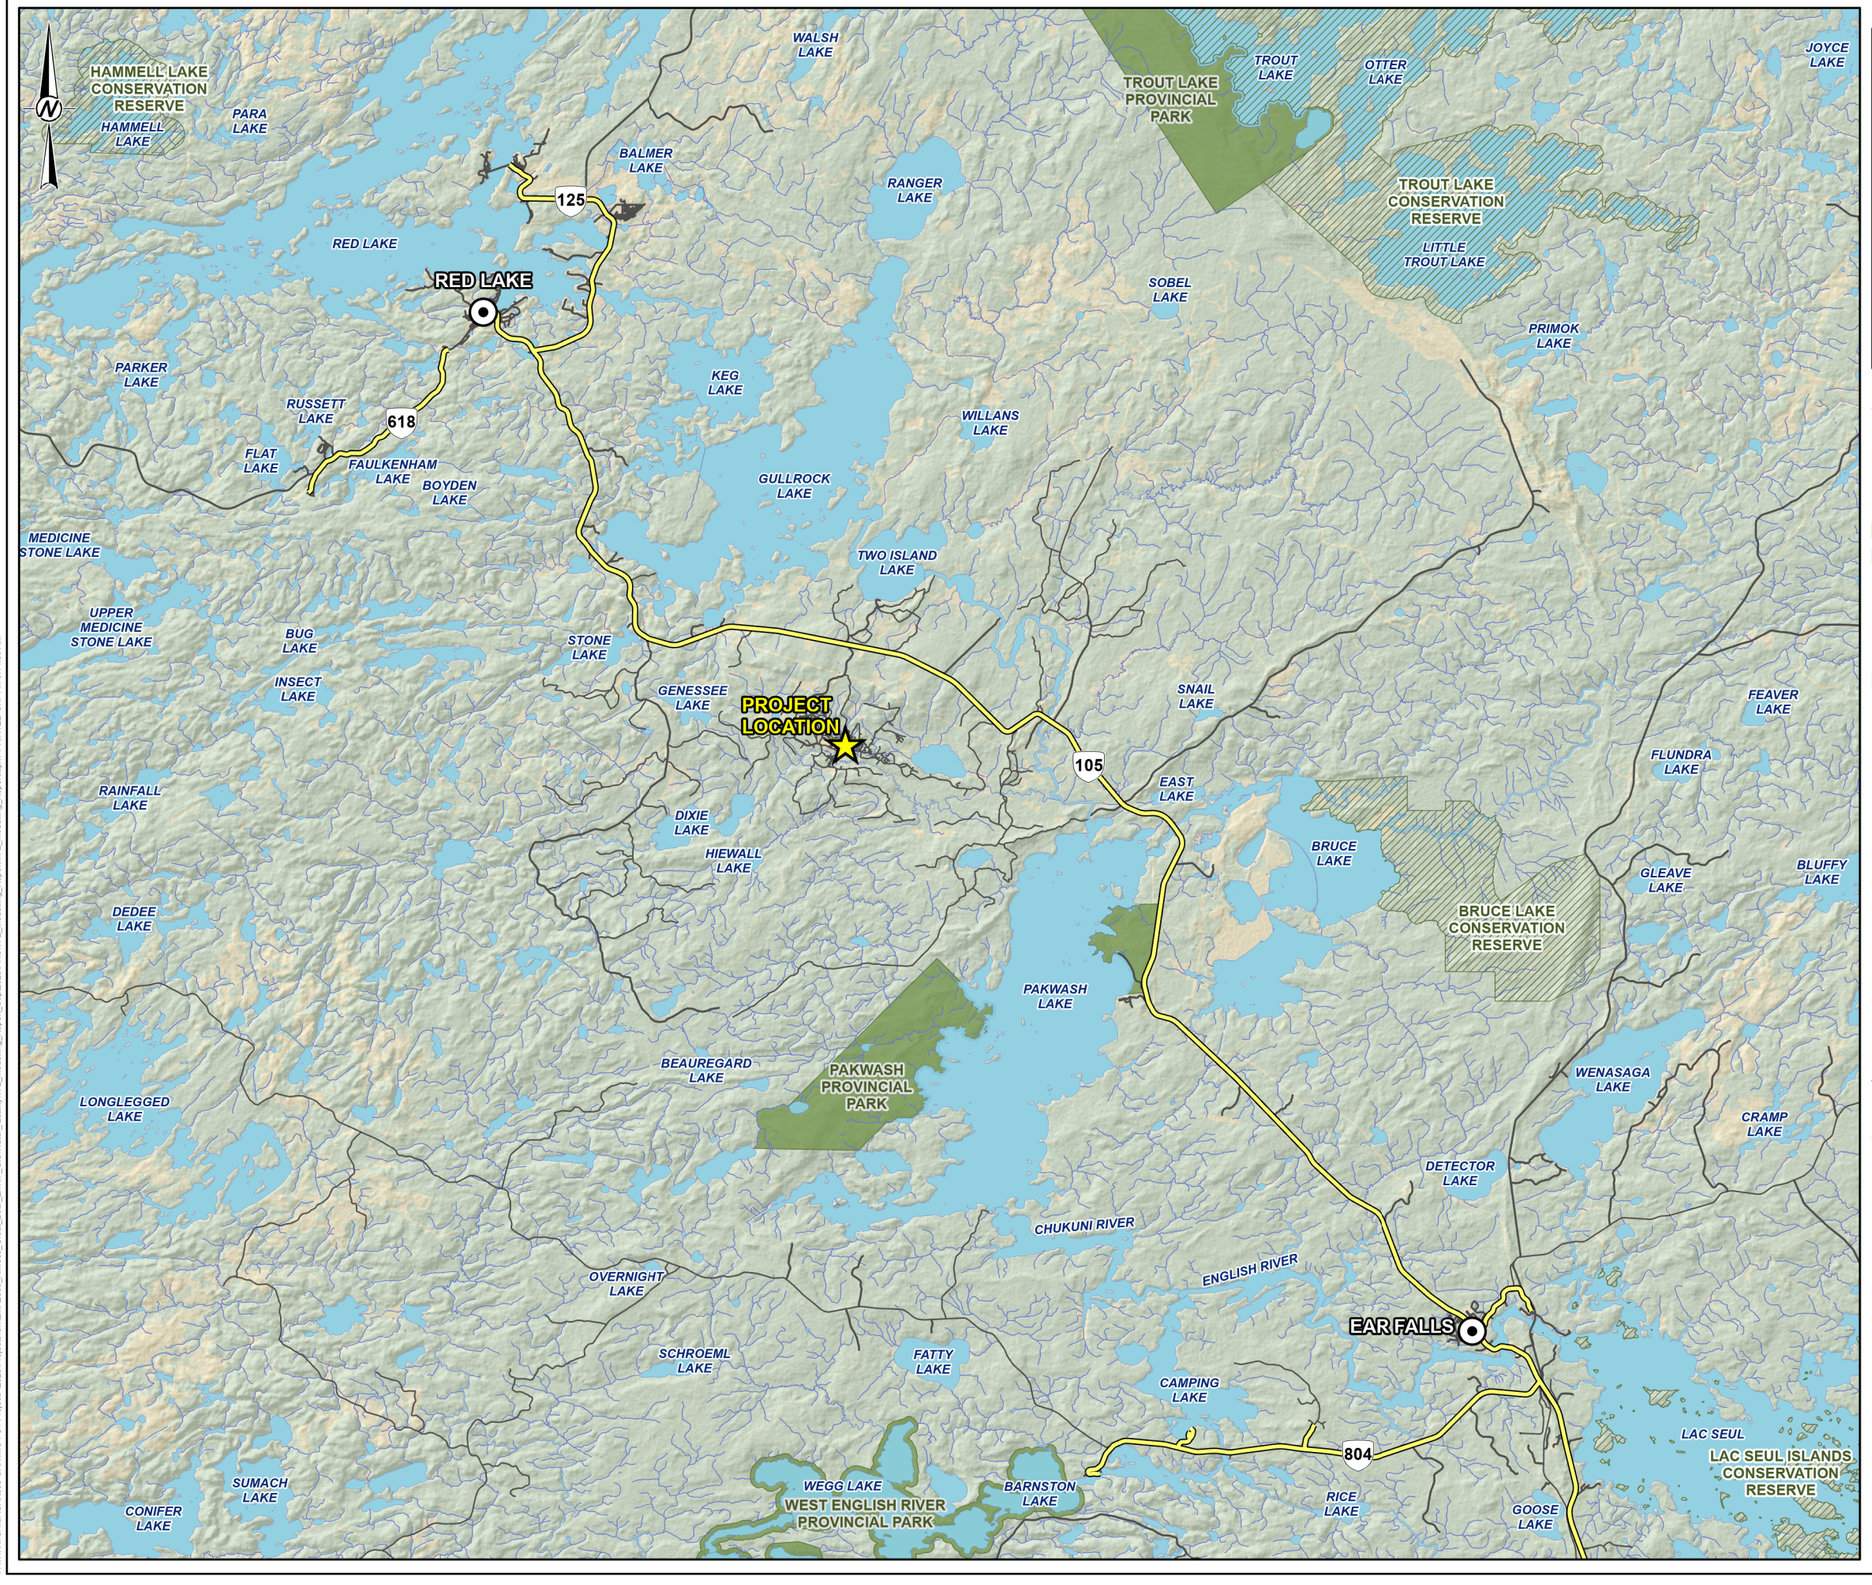
1.2 OBJECTIVE

This *Receiver Water Quality Modelling Report* has been prepared by WSP Canada Inc. (WSP) to summarize the findings of the receiver water quality modelling. The scope of work includes:

- Identifying the key pathways of interaction through which the Project may affect surface water quality of area watercourses and waterbodies
- Simulating potential changes in surface water quality, using appropriate modelling methods and robust data sources
- Provide the basis of the surface water quality effects assessment.

The receiver water quality model utilizes information from the Water Quality Baseline Report (WSP 2025a), Mine Site Water Quality Modelling Report (WSP 2025b), Mine Site Water Balance Report (WSP 2025c), Receiver Water Balance Report (WSP 2025d), Air Quality Modelling Report (WSP 2025e) and the Hydrogeological Modelling Report (WSP 2025f) completed by WSP.

1.3 ENVIRONMENTAL SETTING



The Project is primarily situated within the Dixie Creek watershed which feeds into the Chukuni River and eventually drains into Pakwash Lake. The proposed Project footprint (approximately 18 square kilometres; km^2) comprises of roughly 0.4% of the Chukuni River watershed (4,801 km^2), upstream of Pakwash Lake. Regional and local watershed areas and boundaries are presented in Figure 1-3 and Figure 1-4, respectively. At a regional scale, the Property is within the Red Lake mining district in northwestern Ontario, which has a long history of gold exploration and mining production. There are historical and currently operating mines in the region and within the Chukuni River watershed, including the Red Lake Mine.

Dixie Creek crosses the southern portion of the Property and flows into the Chukuni River to the east. The Dixie Creek watershed is comprised of tributaries and inland lakes which feed Dixie Creek generating a total watershed area of 365 km^2. The main source of flow through Dixie Creek is from Dixie Lake which has a watershed area of 187 km^2, including Genessee Lake. Genessee Lake is located west of the Project site, adjacent to location of the proposed TMF and drains south to Dixie Lake. The southern subwatershed drains into the main branch of Dixie Creek at Unnamed Watercourse 7, approximately 6 km upstream of the confluence with the Chukuni River. Unnamed Waterbody 6 is located east of the Project and drains to Dixie Creek approximately 2 km upstream of the confluence with the Chukuni River.

The Chukuni River is the proposed receiving environment for the Project. The Chukuni River is a large, regulated watercourse with flow controlled by the Snowshoe Rapids Dam, constructed in 1927 to raise upstream water levels for transporting equipment and goods to support gold mining operations in the Red Lake area before the construction of Highway 105. Today, the Snowshoe Rapids Dam is operated by the Ministry of Natural Resources with multiple objectives in mind, including flood protection, navigation, water supply and environmental considerations. Water levels and flows are managed according to a rule curve designed to balance these goals. The local catchment area of the Chukuni River, at the proposed discharge location, is approximately 4,415 km^2.

The confluence of the Chukuni River into Pakwash Lake is about 6 km downstream by river of the of the proposed discharge location. Pakwash Lake is a large lake, greater than 98 km^2, with a maximum measured depth of 17.4 metres (m) and average depth of about 6.8 m. A bathymetric map of Pakwash Lake is provided in Figure 1-5. Pakwash Lake has a watershed area of approximately 8,020 km^2 and receives flow from the Chukuni River, Trout Lake River, Lac Seul and Cedar River (Figure 1-3). The Chukuni River enters the shallow north basin of Pakwash Lake (less than 4 m deep), which transitions into a larger, deeper central basin. The south basin remains consistently deep (greater than 10 m) and discharges to the English River system via the Chukuni River. The outlet of Pakwash Lake is located approximately 26 km downstream of the proposed discharge point on the Chukuni River.

Baseline surface water quality results indicate that water quality of Dixie Creek, the Chukuni River, and Pakwash Lake is typical of proposed mining developments in northern Ontario, including circumneutral to slightly acidic pH, low concentrations of nitrogen species (ammonia, nitrate, nitrite), low concentrations of total dissolved solids and occasionally elevated concentrations of some metals. Sulphate concentrations were variable across the baseline study area and ranged from 0.15 to 25.0 milligrams per litre (mg/L), with a 2.2 mg/L average across all samples collected. In the Chukuni River, concentrations of most total and dissolved metals were low, except for total arsenic and total phosphorus, which were observed to be frequently greater than Water Quality Guidelines for the Protection of Aquatic Life (WQG PAL). Concentrations of most total and dissolved metals were low in Dixie Creek; however, total arsenic, total and dissolved aluminum, total iron and total phosphorus results were frequently greater than WQG PAL.

2 WATER MANAGEMENT AND DISCHARGE

This section summarizes the water management and treatment components relevant to the receiving water quality model. It outlines how water will be managed and discharged during the various phases of the Project, providing context for the receiving water quality modelling approach, data inputs and results. Detailed description of the Project's water management system is provided in the Mine Site Water Balance Report (WSP 2025c). The information and associated water balance model predictions from that report have been directly incorporated into this receiving water quality model.

The Project's water management strategy incorporates best management practices, tailored to the specific requirements of each Project phase, to support effective collection, control and treatment of water. Both contact water, defined as water that interacts with Project infrastructure or activities, and non-contact water will be present. Contact water may contain elevated concentrations of metals, metalloids, and nutrients compared to WQG PAL and / or baseline water quality conditions, and such water must be appropriately collected, managed, and discharged, as applicable. Contact water qualities are predicted by the Mine Site Water Quality Model (WSP 2025b).

Overall water management engineering for the Project is based on the following approach:

- Reduce the generation of contact water by diverting non-contact water away from the site where feasible, and by collecting and transferring contact water to the integrated site water management system. This system will be established during the construction phase and maintained through the operations phase and will continue into the closure phase, as appropriate.
- Collection and transfer of contact water into the integrated site water management system, initiated during the construction phase and maintained through operations. The contact water management system is designed to collect, store, convey and treat contact water for an environmental design flood, defined as the 100-year return period event during the operations and closure phases.
- Management of contact water in facilities designed to be protective of the environment, using facilities constructed on low-permeability native materials or lined with commercial-grade liners to reduce seepage, as appropriate
- Recycling and re-use of contact water on the site, including for use in ore processing during commissioning and operations, and dust control during all Project phases
- Treatment of excess contact water to meet applicable regulatory discharge criteria, with treated effluent released to the Chukuni River. Treated effluent discharge will occur in adherence with anticipated provincial and federal regulatory requirements, including the Ministry of the Environment, Conservation and Parks (MECP) Policy B-1-5 and the Metal and Diamond Mining Effluent Regulations (MDMER).

The layout of the surface water management infrastructure is shown in Figure 1-2.

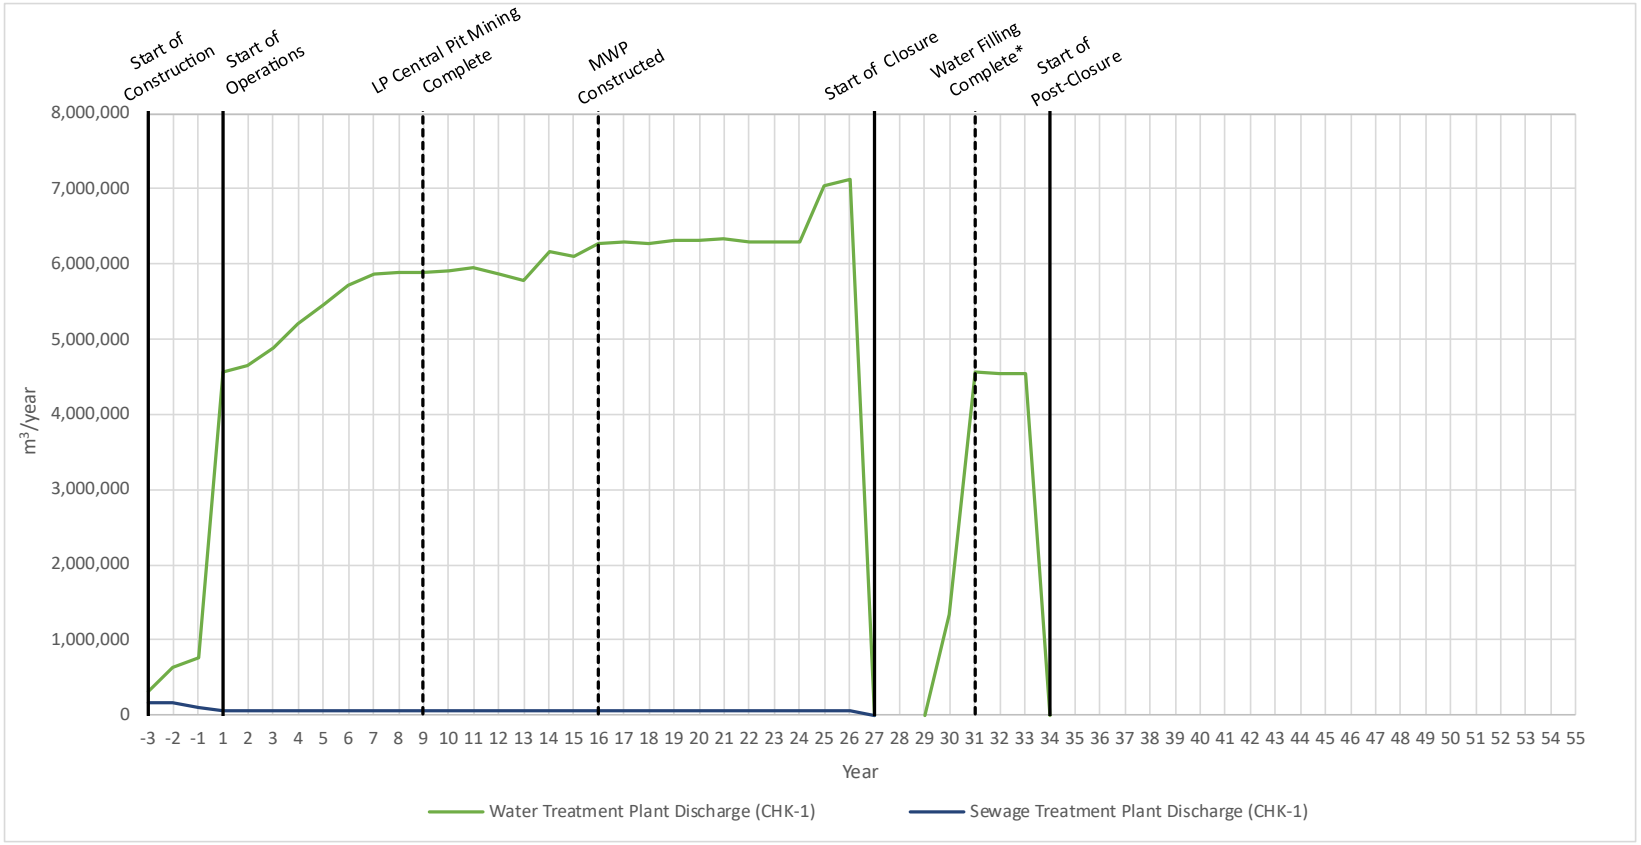
Discharge requirements are predicted to vary throughout the Project, as shown in Figure 2-1, which presents predicted effluent discharge rates for the average climate condition (WSP 2025c).

In construction, discharge of treated effluent to the Chukuni River (0.31 to 0.78 $Mm^{3/}$year)

In operations, average annual discharge to the environment ranges from 4.64 to 7.22 million cubic metres (Mm^3) , peaking in Year 26 (the last year in operations).

The Project will transition to the closure phase following the end of operations, when mining and process plant activities cease. The active closure period is expected to span approximately three years when the majority of site reclamation is completed. During this period, contact water from the site will be redirected to the LP Central pit to help expedite the filling of the pit with water. Freshwater will also be drawn from the Chukuni River via the treated effluent pipeline to fill the LP Central pit, VMF, and underground

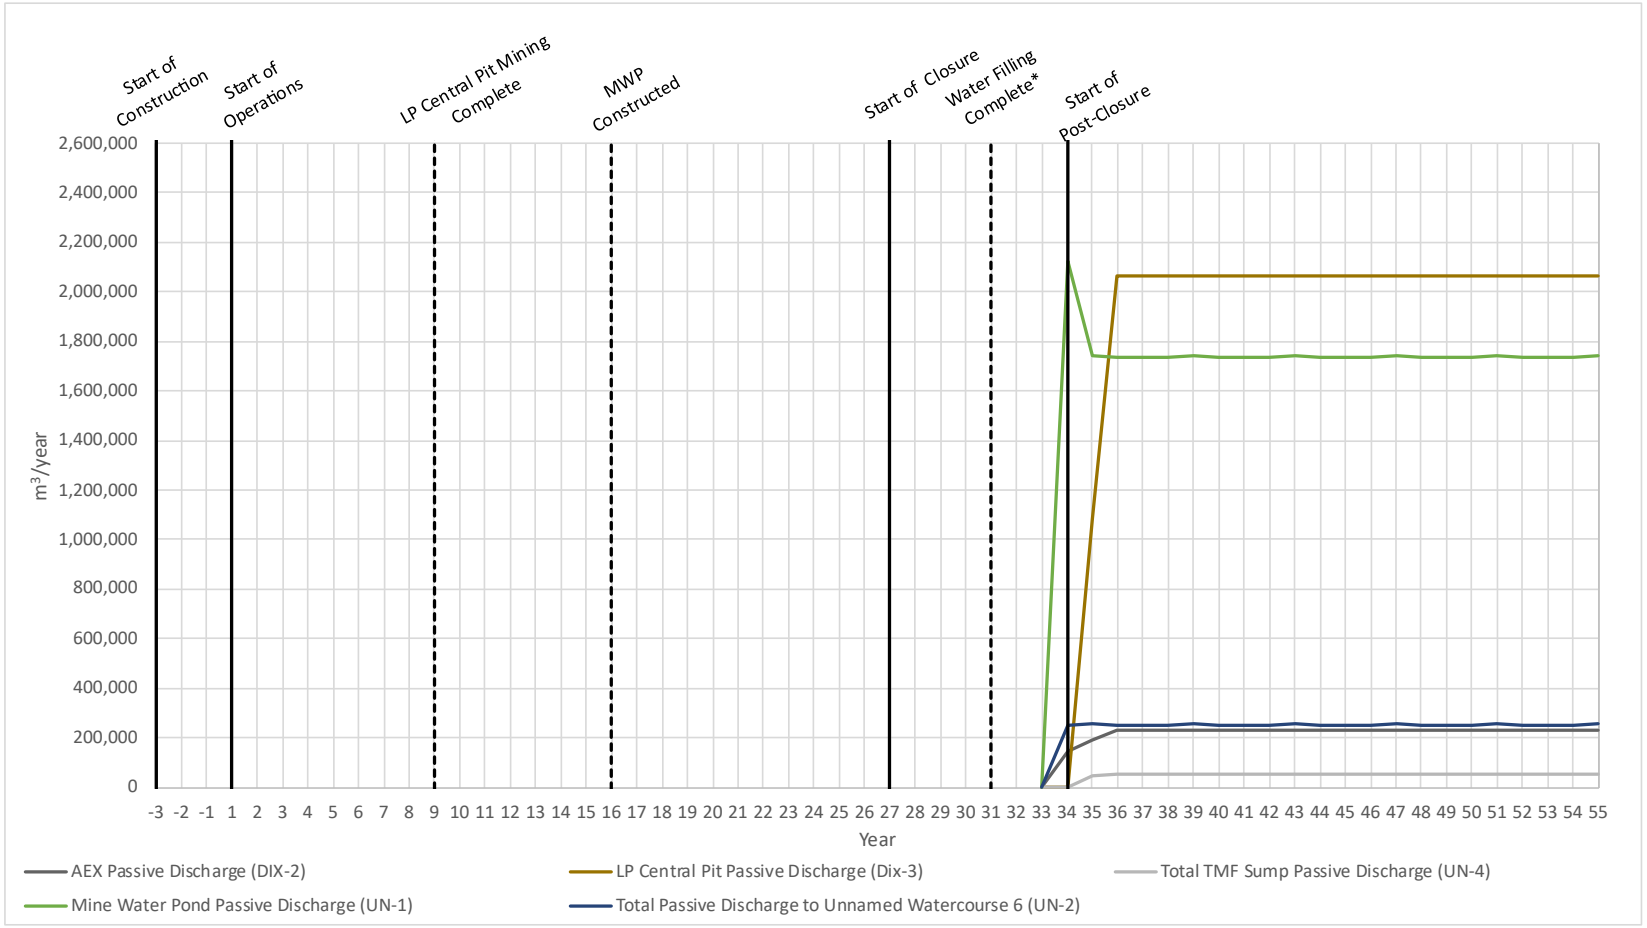
workings. No treated effluent will be discharged to the Chukuni River during this time. Filling of the LP Central pit, VMF and underground workings are anticipated to be complete by the end of Year 30 (Section 5.19.3.1).



Once the LP Central pit is filled to approximately 5 m below the future outflow elevation:

- If the water quality does not meet regulatory needs, the LP Central pit lake will be maintained at that level by pumping and treating water in the water treatment plant (WTP) for discharge to the Chukuni River.
- Once the water quality in the pit lake meets regulatory needs, the pit lake will be allowed to continue to fill and will periodically overflow through a spillway to a residual channel of Unnamed Watercourse 3 (which flows to Dixie Creek).

For modelling purposes, it has been assumed that contact water from the Project will require treatment and discharge to the Chukuni River for a period of at least three calendar years once filling of the LP Central pit, VMF and underground mine is complete (WSP 2025c). The actual duration will be determined based on water quality results at the time. A passive closure period was evaluated in the model to simulate site water quality following pit filling where the water quality is not yet suitable for passive discharge to the environment. During this passive closure period, treatment and discharge to the Chukuni River will resume, discharging up to 4.6 Mm^3 per year. The reduction in site discharge compared to the operations phase is driven by reduced runoff and groundwater inflows, due to site reclamation activities.



Once water quality objectives for the closure phase are achieved, the final closure period will be initiated. During the final closure period, the WTP and related infrastructure will be decommissioned, and the site will passively discharge to the environment. Predicted passive discharge rates for average climate conditions are presented in Figure 2-3. The MWP discharge to Unnamed Watercourse 1 peaks in the first year of passive closure (Year 34) as the TMF pond and MWP dams will be lowered, and excess water will be directed to the environment.

Additional discussion of water treatment is provided in Section 3.4.3.

Note:
"Water Filling" refers to the filling of the LP Central pit, VMF, and underground mine with water from the Project site and freshwater from Chukuni River.

Figure 2-1: Site Discharge – Average Climate Conditions

Note:
"Water Filling" refers to the filling of the LP Central pit, VMF, and underground mine with water from the Project site and freshwater from Chukuni River.

Figure 2-2: Passive Discharge – Average Climate Conditions

3 METHODOLOGY

3.1 INFORMATION SOURCES

This receiver water quality model has been developed using empirical data and predictive model results from the following technical reports, listed as follows:

Water Quality Baseline Report (WSP 2025a)	– Characterizes existing surface water quality conditions in the Project area. – Initial condition of the receiving environment is equivalent to median or average (Section 3.4.1) baseline concentration for water quality parameters (Appendix A).
Mine Site Water Quality Modelling Report (WSP 2025b)	– Provides water quality estimates for mine site features, including seepages and WTP influent qualities. The sewage treatment plant (STP) discharge constitutes less than 1 percent (%) of the combined WTP and STP total discharge flow to the environment; effluent quality is thus assumed equivalent to predicted WTP quality. – Modelled parameters are concentrations (mg/L).
Mine Site Water Balance Report (WSP 2025c)	– Predicts the quantity of treated effluent discharge to the receiving environment; estimates runoff from the various modelled land uses. – Modelled parameters are flows (cubic metres per second).
Receiver Water Balance Report (WSP 2025d)	– Predicts the changes in flows and flow regime in the receiving environment because of Project development, including changes in groundwater-surface water interactions as estimated by hydrogeological modelling (WSP 2024e). – Modelled parameters are flows (cubic metres per second).
Air Quality Modelling Report (WSP 2025e)	– Assesses the changes in air quality from emissions related to Project activities. – Modelled parameters used in this assessment are total dust deposition rates (grams per metre squared).

3.2 MODEL OVERVIEW

This receiver water quality model was developed using mass-balance calculations in GoldSim to simulate the transport and concentration of chemical species over the life of the Project. Model predictions were generated over a timeseries of consecutive monthly timesteps, aligned to the water balance (WSP 2025c,d) for all Project phases (Figure 3-1). In addition, long-term equilibrium conditions representing post-closure steady-state were modelled.

In this receiver water quality model, the Project interacts with the surface water environment through six general pathways, based on information sources identified in Section 3.1:

- Diverted non-contact water
- Water taking
- Fugitive seepage from Project components
- Treated effluent discharge to the receiving environment (the Chukuni River)
- Passive discharge from reclaimed Project catchment areas
- Fugitive dust deposition.

To characterize the potential influence of these Project-related interactions on existing surface water quality, model predictions were generated at strategically selected locations, referred to as nodes (Figure 3-2). These nodes represent locations where the Project is expected to interact with the surface water receiving environment, as identified through the information sources outlined in Section 3.1. This node based approach is an industry standard practice and provides a structured framework for evaluating potential water quality changes.

Additional details regarding model configuration, data inputs and assumptions are provided in the following sections.

3.3 MODEL CONFIGURATION

3.3.1 MODEL NODES

A total of 20 modelling nodes were identified within the Dixie Creek, Chukuni River and Pakwash Lake watersheds. The modelling nodes are described in Table 3-1 and presented in Figure 3-2.

Modelling nodes were named and organized as follows:

- Nodes with the DIX prefix are located on Dixie Creek, from the Dixie Lake outlet (DIX-1) to the Tote Road bridge crossing (DIX-5), approximately 3.6 km upstream from the Dixie Creek confluence with the Chukuni River.
- Nodes with the UN prefix are located on unnamed waterbodies or watercourses, within and adjacent to the Project footprint.
- Nodes with the GEN prefix are located within Genessee Lake area; GEN-L is the most upstream modelling node which ultimately reports to Dixie Creek via Dixie Lake.
- Nodes with the CHK prefix are located on the Chukuni River, both upstream and downstream of the Dixie Creek confluence.
- Nodes with the PAK prefix are located within Pakwash Lake. PAK-OUT is the most downstream modelling node, located at the outlet of Pakwash Lake, approximately 26 km downstream of the proposed discharge point on the Chukuni River.

3.3.2 MODELLED PHASES

The following Project phases were evaluated in this receiver water quality model:

- Construction phase (Year -3 to Year -1)
- Operations phase (Year 1 to Year 26)
- Closure phase (including active closure and passive closure periods; Year 27 to Year 33)
- After the completion of the closure phase, a final closure period period will occur starting in Year 34.

Figure 3-1 shows the approximate timeline of the Project phases, highlighting key events within each phase that influence onsite water management and interactions with the receiving environment. Detailed discussion of mine site material and water management is provided in the Mine Site Water Quality Modelling Report (WSP 2025b) and the Mine Site Water Balance (WSP 2025c). Project activities in each Project phase are summarized in this section to provide context for the modelling approach and results documented herein.

Throughout the construction, operations, and closure phases, excess water at the Project site will be collected, treated, and discharged via a pipeline to the Chukuni River on a year-round basis immediately upstream of node CHK-1 (Figure 3-2). This includes treated effluent discharge from the WTP, membrane filtration and the STP, as applicable.

The construction phase occurs from Year -3 to Year -1. During construction, non-contact water will be diverted to minimize water entering the Project site. Runoff from areas disturbed by construction will be managed locally, avoiding watercourses, and tested for total suspended solids (TSS) and nitrogen species from explosives use, prior to discharge to its existing (pre-development) watersheds. Runoff from areas that may contain potentially deleterious material will be collected and treated by the Advanced Exploration Program (AEX) effluent treatment plant or WTP prior to discharge or stored for process plant commissioning and start-up.

The operations phase corresponds to Year 1 through Year 26. During this time, water from the entire Project site and process plant is actively managed. In the first 15 years, contact water from the Project's watershed is directed to the TMF pond, the AEX mine water pond, and the VMF. From there, collected contact water is conveyed to the WTP, except for excess water from the TMF and TMF pond, which is routed for membrane filtration treatment. Treated effluent from both treatment streams is conveyed to the AEX treated water pond prior to discharge to the receiving environment. Starting in Year 16, the MWP will be constructed to support ongoing site water management. This addition is necessary due to the anticipated reduction in available water storage capacity within the east VMF. Excess water collected in the MWP will be pumped to the AEX mine water pond for treatment and subsequent discharge.

Modelling for the closure phase included an active closure period and passive closure period. Post-closure was also modelled. The closure phase is assumed to be initiated immediately after the end of operations (Figure 3-1). The Project will enter the active closure period once the operations phase has ended, and mining and process plant operations have ceased; it is assumed the active closure phase will occur over three years (Year 27 to 29). During this time, fresh water will be drawn from the Chukuni River through the treated effluent pipeline, to actively fill the LP Central pit, the VMF and the underground workings with water. There are no treated effluent discharges to the Chukuni river during this time; all pit filling is completed by the end of Year 30.

During the closure phase, in order to evaluate potential effects in a scenario where site water quality is not yet suitable for passive discharge to the environment immediately following pit filling, it has been assumed that passive closure (considered as a water management sub-phase) will extend approximately three calendar years after the LP Central pit and VMF have been filled. During this time, the water management strategy will remain the same, but it is assumed that water from the LP Central pit lake and Viggo pit lake will require treatment and discharge to the Chukuni River (CHK-1).

Once water quality objectives for the closure phase are achieved, the WTP and related infrastructure will be decommissioned, and the site will passively discharge to the environment. In the model, these

conditions are represented by predictions for long-term steady state flows and geochemical loadings. The expected passive discharge locations to the environment are provided in Figure 2-2. Predicted passive discharge rates for average climate conditions are presented in Figure 2-3. Geochemical loadings (source terms) integrated into this receiving environment model are discussed in Section 3.4.2.

3.3.3 MODELLED PARAMETERS AND WATER QUALITY GUIDELINES

Modelled parameters include:

- Parameters with Provincial Water Quality Objectives (PWQO) and interim PWQO (iPWQO) for the protection of aquatic life (Table 3-3)
- Nutrients and anions, including nitrate, nitrate, ammonia, chloride and sulphate
- Parameters identified within the Mine Rehabilitation Code of Ontario (O. Reg 35/24): cyanide, ammonia, sulphate, aluminum, arsenic, cadmium, calcium, copper, iron, lead, mercury, molybdenum, nickel and zinc
- Parameters with effluent criteria as per the federal MDMER: arsenic, copper, cyanide, lead, nickel, zinc and un-ionized ammonia
- Parameters of interest identified as an outcome of consultation and engagement including sulphate and mercury.

Modelled parameters do not include TSS. The industry-standard water quality models used cannot accurately represent or predict TSS levels due to the complexity of TSS sources and transport mechanisms, that make it difficult to establish consistent relationships between model input parameters and TSS levels. In Ontario, mining operations must adhere to stringent regulatory requirements and environmental standards governing water quality, including TSS levels. Comprehensive water management mitigation strategies for TSS have been integrated into the Project's design, providing proactive measures to safeguard water quality and minimize the potential for environmental effects.

Although pH and radium-226 are listed under the MDMER, these parameters were not included in the predictive modelling due to:

- Known methodological limitations: pH cannot be reliably estimated using a mass balance approach, as it is a dynamic parameter influenced by complex geochemical interactions rather than additive concentration inputs. Estimated pH for contact water qualities are provided in the Mine Site Water Quality Modelling Report (WSP 2025b).
- A geochemical source term for radium-226 was not available, there is no anticipated loading source for radium, precluding its inclusion in this receiving environment model.

All effluent discharged from the Project will comply with anticipated regulatory requirements; for pH this corresponds to pH range of 6.5 to 8.5 for treated effluent discharge, during all periods of discharge. This required pH range has been incorporated into water treatment design criteria and engineering (Section 3.4.3, Appendix C). Furthermore, baseline monitoring data for both pH and radium-226 are available and will be used to support follow-up monitoring and address anticipated compliance verification throughout the Project lifecycle.

To support the Impact Statement, model results were compared to a consistent set of WQG PAL as per WSP's most recent experiences and the latest guidance from the MECP. The WQG PAL used are listed in Table 3-3. WQG PAL are based on rigorous peer-reviewed study to specifically safeguard the most sensitive life stages of aquatic species for periods of indefinite exposure. For parameters with PWQO and iPWQO, recent MECP guidance has recommended the utilization of the most up-to-date and scientifically defensible WQG PAL sourced from either the PWQO / iPWQO, Canadian Council of Ministers of the Environment Water Quality Guidelines, Federal Environmental Quality Guidelines, or as available guidelines from other provinces, as appropriate. This approach aligns with the evolving regulatory landscape and reflects the commitment to adhere to the most up-to-date standards in safeguarding aquatic ecosystems.

To support the receiver water quality assessment, model results are also compared to baseline water quality concentrations. A threshold of 20% relative percent difference (RPD) is used to identify changes in water quality predicted by the mass balance as measurably different from baseline concentrations (i.e. a likely observable change). A calculated RPD represents a straightforward and interpretable metric for interpreting predicted concentrations relative to baseline values, allowing for focussed discussion on predicted incremental increases in water quality concentrations, as applicable. The use of RPD as a screening tool here is particularly appropriate in the context of this conservative mass balance model, which does not account for natural attenuation processes such as degradation or attenuation; i.e., by design, the modelling approach herein assumes that all mass introduced into the system remains in the system. This assumption will result in higher predicted concentrations than would likely occur under real-world conditions for many parameters. As such, a calculated RPD serves as a useful screening tool for flagging potential changes and identifying the key incremental changes relative to existing conditions. The selected 20% threshold corresponds to general analytical resolution capabilities of water quality lab tests and considers that a calculated RPD of 20 to 25% are generally used in quality assurance and quality control protocols of environmental monitoring programs to define data as measurably different (BC MOE 2013 and CCME 2016). The RPD is calculated here as:

$$\text{RPD} = \frac{(\text{predicted concentration} - \text{baseline concentration})}{((\text{predicted concentration} + \text{baseline concentration}) * 0.5)}$$

While RPD is a useful screening tool for identifying key parameters, it should always be interpreted in conjunction with absolute concentrations. This is particularly important at low concentrations, where an RPD threshold of 20%, although helpful for guiding discussion, corresponds to a very small magnitude of change.

3.4 DATA INPUTS AND SOURCE TERMS

3.4.1 GENERAL DATA INPUTS AND ASSUMPTIONS

Water quality model results are dependent on several inputs, including meteorological conditions, baseline surface water quality conditions, outcomes of geochemical test work, and operational schedule and mine development planning. Where uncertainty exists, professional knowledge and experience was used to develop a conservative approach, or a sensitivity analysis was completed (Section 3.5).

The general model assumptions included:

- Predictive modelling is conducted on a monthly time-step as a continuous timeseries, from mine Year 1 through Year 55.
- Existing conditions of Project area watercourses and waterbodies, including the Chukuni River (the receiving environment) are equivalent to monthly median (or average) baseline concentrations, where the number of samples available for each month were greater than three. In cases where only one or two baseline data samples were available for that month (e.g., winter months when monitoring locations could not be safely accessed during the baseline sampling program), source term inputs for unnamed watercourses were instead developed as seasonal inputs (i.e. quarterly grouping: November to January, February to April, May to July, August to October). For unnamed waterbodies, if less than three datapoints per month were available, source terms were developed for under ice versus. open water seasons (November to April and May to October). Model source terms for existing conditions are provided in Appendix A.
- For existing conditions source terms, half the reported method detection limit (MDL) was used for source terms if a result was below the MDL, as applicable. This approach is consistent with available guidance documents regarding environmental data handling (EPA 1990, EPA 1991, Environment Canada 2012). This substitution assumes that all values between zero and the MDL could be present and that the average value of non-detects could be as high as half the MDL. Adherence to available guidance documentation in this regard follows regulatory standards while promoting consistency in

data interpretation and reporting across various stages of the Project life cycle and between provincial and federal jurisdictions relevant to the Project.

- Project operational and engineering components turn on and off instantaneously.
- Treated effluent discharge occurs immediately upstream of node CHK-1 (Figure 1-2) at the required discharge rates predicted by the mine site water balance (WSP 2025c).
- Mixing of Project-related discharges such as seepage and treated effluent discharge with the receiving environment does not consider attenuation and it is assumed to be instantaneous and complete.
- Precipitation and evaporation are assumed to be neutral inputs and outputs with no associated geochemical loads.
- Along fugitive seepage pathways from Project components to Dixie Creek, Unnamed Waterbody 6, Unnamed Watercourse 1, Unnamed Watercourse 2, Unnamed Watercourse 5, and Dixie Creek, water quality parameters behave conservatively and are not reduced by mechanisms such as secondary mineral formation, dilution by regional groundwater, attenuation through sorption processes, or biogeochemical reactions such as assimilation or biodegradation.
- Along the treated effluent discharge flow pathway, water quality parameters behave conservatively and are not reduced by mechanisms such as secondary mineral formation, attenuation through sorption processes, or biogeochemical reactions such as assimilation or biodegradation.

3.4.2 GEOCHEMICAL SOURCE TERM INPUTS

The Mine Site Water Quality Modelling Report (WSP 2025b) incorporates the results of geochemical baseline characterization programs conducted to support the Impact Statement and estimates the quality of contact waters to be managed on site. This section summarizes key inputs and model results from that report, that have been used in this receiver water quality model.

The approach and testing methods used in the geochemical characterization studies were based on the requirements described under the *Ontario Mining Act*; namely guidance found within the reference document Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND 2009), which represents best practice and industry-standard approaches and methodologies for metal leaching and acid rock drainage (ML/ARD) sampling and characterization in Canada.

The overall goal of the ML/ARD program is to generate the data needed to inform mine planning and management decisions related to mined materials, including overburden, mine rock, and ore-grade materials, as well as exposed mine surfaces and other geologic materials such as tailings and backfill. The overall objectives of the ML/ARD characterization program included:

- Obtaining samples that accurately represented the geochemical variation of mine rock and ore-grade materials in the region of the proposed development
- Characterizing the ML/ARD potential of tailings and paste backfill to be produced by the Project
- Evaluating the geochemical characteristics of overburden that will be relocated as part of Project development.

Various types of mine materials will be managed at the Project, including non-potentially acid generating / non-metal leaching (NPAG / NML) mine rock, non-acidic potentially acid generating (PAG) mine rock, acidic PAG mine rock, non-potentially acid generating / metal leaching (NPAG / ML) mine rock, NPAG desulphurized tailings, and PAG concentrate tailings. PAG and NPAG / ML mine rock will be placed in the MRS or rehandled as underground backfill. The MRS will be covered with a revegetated low permeability compacted clay cover, prior to acidification of the PAG rock, to limit the interaction of surface water and oxygen with these materials and consequently reduce mass loadings from the mine rock. NPAG / NML mine rock will be stockpiled at the MRS and used for construction activities at the Project. Any NPAG / NML rock remaining at the MRS at closure will be covered and revegetated. NPAG desulphurized tailings will be stored in the TMF and ultimately covered with a revegetated soil cover. PAG concentrate tailings

will be placed sub-aqueously in the east VMF and isolated from atmospheric oxygen. The submerged PAG concentrate tailings will be covered in a blanket of NPAG tailings prior to closure and accelerated filling of the VMF with water. Tailings (prior to flotation) along with membrane filtration reject solution (previously stored in the west VMF) will also be used to generate paste tailings that will be used underground as backfill. The specific geochemical characteristics of these mine materials were considered in detail for contact water quality predictions as described in the Mine Site Water Quality Report (WSP 2025b).

The Mine Site Water Quality Modelling Report (WSP 2025b) is a mass balance water quality model structured as a monthly water balance with associated baseline water quality inputs and geochemical source terms to estimate contact water quality (e.g., interacting with mine rock, tailings, and underground) as well as evaluate the transfer of water volumes and mass loads through the mine site to the WTP. The model outputs were used to generate source terms (input values) for this receiving water quality model and are provided in Appendix B for ease of reference. The model results for contact water quality from the mine site water quality model are:

- Operations Phase: estimates include the influent to the WTP (AEX pond), the influent to the membrane filtration treatment plant (TMF pond), fugitive seepage from the TMF and mine water pond (MWP) and contact water from the VMF.
- Active closure period: estimates include fugitive seepage from the TMF and MWP, TMF pond water and fugitive seepage, VMF pond water and fugitive seepage, and the overall site contact water pumped to the LP Central pit as part of accelerated filling (via the AEX pond).
- Passive closure period: estimates include fugitive seepage from the TMF and MWP, VMF pond water and fugitive seepage, along with key inflows to the WTP including contact water from the TMF pond, MWP, and AEX catchment. The overall influent to the WTP (AEX pond) is provided along with the pit lake water quality at the passive closure water level of 343 metres above sea level (masl).
- Post-closure: estimates include long-term steady state water quality conditions for fugitive seepage from the TMF, Viggo pit lake water and fugitive seepage, and contact water from the closure covers and other rehabilitated areas including the former AEX catchment and MWP catchment. LP Central pit lake water quality is presented for two milestones including when the pit lake initially reaches its long-term elevation (348 masl) and long-term steady state conditions.

Pit lake modelling for the LP Central pit to predict quality of surface water from the pit lake overflowing to Dixie Creek in post-closure was also incorporated into this receiving water quality model. Simulations were conducted using GoldSim, applying a mass balance framework, and supplemented with geochemical modelling in PHREEQC (WSP 2025b). With accelerated filling of the LP Central pit with water, the pit lake reaches a water level of 343 masl after approximately four years (WSP 2025a). This operating water level is maintained during passive closure to provide storage capacity to manage design events and is 5 m below the long-term closure water level for the pit lake. The long-term maximum water level in post-closure is 348 masl, such that excess water is passively discharged to Dixie Creek during post-closure.

3.4.3 WATER TREATMENT AND DISCHARGE

The Project incorporate strategies for managing water to provide environmental protection and maintain regulatory compliance. Measures to be implemented related to water treatment and discharge include the following:

- Onsite contact water ponds will serve as the primary mechanism for TSS removal, functioning as settling ponds that allow particulates to settle out of the water column before further treatment or discharge.
- The WTP will be a centralized facility located close to the process plant and infrastructure area. The WTP will be designed to produce water that is suitable for re-use or discharge to the environment in accordance with applicable regulatory requirements, including the MDMER and the anticipated effluent concentrations required by the MECP to protect the receiving water and aquatic resources.

Best available technologies that are economically achievable are being considered for the WTP to meet the protection requirements of local Indigenous Nations. The primary WTP design is expected to include the following sequential treatment steps:

  - Collection and preliminary treatment (neutralization and softening) through chemical and reagent addition, and aeration in reaction mixing tank(s) to facilitate metals removal from the contact water
  - Flocculant addition to bind solids into larger, heavier flocs to settle out and create a precipitate sludge and produce a clarified solution
  - Filtration to remove additional solids.

- Excess contact water from the TMF will undergo enhanced treatment using membrane filtration technology to reduce sulphate concentrations in treated effluent discharged to the Chukuni River. Membrane filtration uses a semi-permeable membrane to separate components of a liquid based on their size and properties. The contact water to be treated is passed through the membrane by differential pressure to produce clear water and a reject solution. This treatment chain, with the membrane filtration step, has been designed to remove 95 to 98% of incoming sulphate concentrations (Appendix C). Excess treated water will be discharged to the Chukuni River in accordance with applicable regulatory requirements.
- Tailings thickener underflow will be pumped to two parallel, cyanide destruction tanks for additional retention and treatment. Cyanide destruction is expected to use the SO2/air process with sodium metabisulphite used as the source of SO2. The target concentration of total cyanide in the tailings after the cyanide destruction circuit in the process plant will be compliant with the International Cyanide Management Code (ICMI 2021) which sets a limit that is protective of wildlife and birds. The residual cyanide concentrations will naturally degrade when exposed to sunlight within the TMF and east VMF. This reduces cyanide concentrations in the contact water, fugitive groundwater seepage from the TMF, and in treated effluent discharged to the Chukuni River.
- Following cyanide destruction, the majority of detoxified tailings will be pumped to a desulphurization flotation circuit to generate a larger volume of desulphurized tailings that are NPAG for placement in the TMF, and a lower volume of sulphide-containing concentrate tailings for management in the east VMF. This reduces sulphur, sulphate, and metal concentrations in the TMF contact water, fugitive groundwater seepage from the TMF, and in treated effluent discharged to the Chukuni River.
- Treated effluent will be discharged in the Chukuni River, at a location where sufficient flow exists to minimize the potential for erosion and promote rapid mixing.

In this receiving water quality model, treated effluent quality was modelled by applying the anticipated treatment efficiencies from Hatch (Appendix C), expressed as percentage mass removal, from the water treatment design described above, in combination with influent quality predictions derived from the mine site water quality model (WSP 2025b). These treatment efficiencies were incorporated into the receiving water quality model to simulate monthly effluent discharge quality to the Chukuni River. Corresponding model results are presented in Section 4.

Influent chemistry to the WTP reflects mine contact water collected via the AEX mine water pond, receiving inputs from the VMF, MWP, and underground dewatering sources. The influent to the membrane filtration system is equivalent to TMF water quality, with contingency provisions for excess water from the VMF, as appropriate (Figure 3-4).

The Chukuni River is the proposed receiving environment for the Project and will receive treated effluent discharge during construction, operations and active closure phases, as required. Discharge will occur immediately upstream of node CHK-1 (Figure 3-2). Water treatment engineering for this stage of the Project was completed by Hatch Engineering (2025a,b) and is presented in this section. A schematic of the proposed water treatment processes is provided in Figure 3-3

Final effluent quality will meet environmental discharge standards in accordance with applicable regulatory requirements, including the federal MDMER and provincial effluent limits established by the MECP to protect receiving waters and aquatic ecosystems. Water treatment engineering will be further

developed and refined during the provincial approvals process, consistent with Ontario's regulatory framework for proposed mining projects.

Hydrodynamic mixing analyses were also completed to estimate the maximum extent of the discharge plume within the Chukuni River; this is further discussed in Section 4.2.1.

3.4.4 FUGITIVE GROUNDWATER SEEPAGE

The Project may influence local groundwater quality because of fugitive groundwater seepage from Project facilities. Changes to local groundwater quality could affect the quality of groundwater discharging to surface water features.

A hydrogeological model was developed for all Project phases, including existing conditions, and used to estimate the effects of the Project on local groundwater and / or surface water conditions (WSP 2025f). A seepage collection system will be in place for the Project. Thus, seepage to the environment considered in this model is described as fugitive groundwater seepage. The greatest seepage source to the model nodes is the TMF, which is estimated to contribute approximately 507.5 cubic metres per day of seepage to node UN-1 during post-closure (the seepage from the TMF at post-closure replaces the natural groundwater flow to UN-1, indicating a loss in fresh groundwater at this node). Seepage contributions to each node, during each Project phase, are provided in the Hydrogeological Modelling Report (WSP 2025f).

It has been assumed to be conservative, that the predicted quality of fugitive groundwater seepage from Project components is representative of the groundwater contributing to surface water features (i.e., is not diluted by or mixed with baseline groundwater). As per the receiving environment water balance model (WSP 2025d), for conservative modeling purposes, when the groundwater losses are predicted to be greater than the surface inflows (prior to the addition of seepage) at a given node, the seepage flow will be routed to the next downstream node. This is to maintain mass balance and seepage loading within the model. This only occurs at the small watersheds with groundwater losses (UN-1 and UN-2) during the low flow months.

3.4.5 DUST DEPOSITION

Suspended particulate matter, primarily composed of fugitive dust, is generated through various activities at mine sites, such as crushing, screening, road traffic, and material handling. WSP has conducted quantitative predictive air quality and dispersion modelling using AERMOD (version 22112), the United States Environmental Protection Agency's regulatory air dispersion model currently adopted in Ontario (WSP 2025e), Air quality model result outputs were incorporated into this water quality model to conservatively account for potential loadings from dust deposition during construction and operations. The generation of dust will be minimal and localized during active closure activities and return to baseline conditions post-closure (WSP 2025e). Additional details regarding air quality model data inputs, assumptions, and results are provided in WSP 2025e.

Dust input was included in the model as the amount of dust falling on a waterbody or watercourse upstream of the modelling node, within the air quality regional study area (WSP 2025e). Dust deposition model results for representative points for major waterbodies and watercourses around the Project were used to determine the dust input. For larger waterbodies and watercourses, where dust deposition rates vary with distance from the Project, a series of points were averaged and one value was assigned to the waterbody, or in the case of Dixie Creek, all points between each receiver water quality node were averaged to capture different Project activities. For example, dust input to DIX-4 was added to the length of Dixie Creek from DIX-3 to DIX-4. For smaller waterbodies and watercourses, such as Unnamed Waterbody 2, the closest modelled point was selected, with preference given to points closer to the Project.

Metal loading rates from dust deposition were estimated by multiplying the measured dust deposition rate at each point (in grams per square metre) by the total surface area of the upstream waterbody or watercourse for each node. This calculation provided an estimate of the total dust deposited on surface

water upstream of each receiver node. These values were then combined with whole-rock metal geochemical test results for mine rock to determine the associated metal loadings. For the mass balance, it was assumed that 80% of the metal content in whole-rock contributes to surface water quality via deposited dust. This assumption is highly conservative. Air quality modelling indicates that fugitive dust emissions are primarily generated by haul roads and vehicle traffic rather than rock piles. Similarly, metals associated with dust were estimated using whole-rock results, even though metals in whole-rock are partly bound within the crystalline structure of the parent material. Complete release of these bound metals under local surface water conditions is unlikely as metals remain would not readily solubilized or picked up in a surface water total metals scan. Additionally, a fraction of dust particles will settle in the water column, while some remain suspended. Consequently, the assumption that 80% of the metal content will contribute to loading is considered highly conservative. GoldSim model inputs for chemical species loadings from dust per node for construction and operations are provided in Appendix B.

3.5 MODEL CASES

To characterize the effects of the Project on receiver water quality, a base case scenario (i.e., a conservative expected case) was defined with respect to predicted Project loadings, treated effluent discharge rates, and changes in surface-groundwater interactions. Conceptually, the base case represents the most likely set of conditions based on current Project design, operational assumptions, and environmental conditions. Key inputs and assumptions defining the Base Case include:

- Initial baseline concentration: the water quality model assumes a median (or average, see Section 3.4.1) baseline concentration for water quality parameters to represent initial conditions.
- Conservative predicted geochemical loadings: the mine site water quality model uses the expected metal release rates for mine rock and tailings based on currently available kinetic testing results and geochemical information for the Project (WSP 2025b).
- Water balance model results for average conditions: the construction, operations and closure phases were modelled under average annual climatic conditions. Monthly snowfall distribution (percent of precipitation that falls as snow), and runoff coefficients were based on Climate Normals and calibrated to observed runoff at a representative nearby streamflow gauge (WSP 2024d).
- Expected groundwater changes: the interaction between groundwater and surface water was assessed in the model by analyzing water budgets at surface water features determined through hydrogeological modelling (WSP 2024e). These modelled water budget changes provide a measure of potential changes in groundwater contribution (or losses) to surface water or baseflow of the receiving environment and the associated water balance.
- Expected seepage rates: seepage rates from Project components to receiving waters were modelled for operations and closure; seepages from Project components are not expected in construction (i.e., advance of mine operation and tailings production).

In addition to the base case, sensitivity analyses were completed to support the receiver water quality assessment. The sensitivity analysis is a key component of water quality modelling and an industry-standard practice used to evaluate the robustness of model predictions. By systematically varying key input parameters, the analyses identify which variables most influence model outcomes, confirm that the model responds appropriately to changes in system conditions, and confirm that mitigation and management measures have been appropriately defined.

Sensitivity analyses also help characterize and define the range of plausible future scenarios, including extreme hydrologic conditions (e.g., wet and dry years), potential climate change influences, and variations in baseline water quality assumptions. Evaluating these scenarios provides a more complete understanding of the potential range of water quality outcomes, supports assessment of the resilience of proposed water management strategies, and enhances confidence in the predictive reliability of the model. Sensitivity analyses completed include:

- Extreme dry case, to evaluate changes to water quality under drought conditions by evaluating water quality changes under 1:100 dry year climate / flow conditions. All other data inputs and assumptions are the same as the base case.
- Extreme wet case, to evaluate changes to water quality under heavy rainfall conditions by evaluating water quality changes under 1:100 wet year climate / flow conditions. All other data inputs and assumptions are the same as the base case.
- Climate change case, to evaluate changes to water quality under potential climate change conditions. This includes average climate conditions for construction and operations and conditions with the influence of climate change for closure and post-closure. All other data inputs and assumptions are the same as the base case.
- Upper baseline case, to evaluate changes to water quality assuming a consistently reduced assimilation capacity of the receiving water environment, for all modelled parameters. All other data inputs and assumptions are the same as the base case.

3.6 MASS BALANCE CALCULATION

This receiver water quality model was developed using a mass-balance in GoldSim to simulate the volume and flow of water, and the concentrations and transport of chemical species, over the life of the Project. The model accounts for flows and chemical loadings entering and leaving Project components, such as the WTP, as well as chemical loadings entering the surface water receiving environment.

The generalized mass balance equations applied in the model are:

$$C_{A+B\,i} = \frac{(C_{A\,i} \times Q_A + C_{B\,i} \times Q_B)}{(Q_A + Q_B)} \qquad \text{[Equation 1]}$$

Where:

C_{Ai} and C_{Bi} are the concentrations of chemical species *i* in waters A and B, respectively.

Q_A and Q_B are the flow rates or volumes of water in waters A and B, respectively.

$C_{A+B\,i}$ is the concentration of chemical species i in the mixed body of waters A and B.

$$\sum (\text{Mass Loading In})_i - \sum(\text{Mass Loading out})_i = \Delta C_i \times V \qquad \text{[Equation 2]}$$

ΔC_i is the change in concentration of chemical species *i* in a body of water; V is the volume of the body of water.

$\sum(\text{Mass Loading In})_i$ and $\sum(\text{Mass Loading out})_i$ are the sum of masses of chemical species *i* added to, and removed from, the body of water, respectively.

A summarized example mass balance calculation used in the model for sulphate at node CHK-2 during operations is presented below. An example calculation for the entire discharge flow path, is presented in Appendix D.

Using the mass balance equations above and the input values in Table 3-6 for sulphate at CHK-2 in January, the final mixed chemistry is mass-balanced as follows:

$$\text{Mixed Chemistry at CHK-2} = \frac{\text{Total Load in CHK-2}}{\text{Total Flow at CHK-2}}$$

$$= \frac{\text{Upstream CHK-1 Load + Upstream DIX-5 Load + Dust Load to CHK-2 + Freshwater Load to CHK-2}}{\text{Upstream Flow from CHK-1 + Upstream Flow from DIX-5 + Freshwater Flow at CHK-2}}$$

$$= \frac{\text{(CHK-1 Flow x CHK-1 Chem) + (DIX-5 Flow x DIX-5 Chem) + CHK-2 Dust Load + (CHK-2 Flow x CHK-2 Chem)}}{\text{Upstream Flow from CHK-1 + Upstream Flow from DIX-5 + Freshwater Flow at CHK-2}}$$

$$= \frac{(17{,}583\ \text{L/s} \times 6.62\text{mg/L}) + (1{,}216\ \text{L/s} \times 2.4\ \text{mg/L}) + 0.05\ \text{mg/s} + (42\ \text{L/s} \times 4.2\ \text{mg/L})}{17{,}583\ \text{L/s} + 1{,}216\ \text{L/s} + 42\ \text{L/s}}$$

$$= 6.3\ \text{mg/L}$$

A comparison of mass balance Excel calculations compared to GoldSim modelled results are presented in Table 3-7.

Table 3-1: Receiver Water Quality Model Nodes

Waterbody	Node ID	Summary Description
Chukuni River	CHK-1	Chukuni River, Project effluent discharge location. Corresponds to surface water quality station CR-FDP.
	CHK-2	Downstream of Project effluent discharge location and confluence with Dixie Creek. Corresponds to surface water quality station CR-DS.
Dixie Creek	DIX-1	Outlet of Dixie Lake to Dixie Creek. Corresponds to surface water quality station DC-US.
	DIX-2	Dixie Creek after confluence with Unnamed Watercourse 1. Corresponds to surface water quality station SW-03.
	DIX-3	Dixie Creek, south of the LP Central pit. Corresponds to surface water quality station SW-08.
	DIX-4	Dixie Creek after confluence with Unnamed Watercourse 7.
	DIX-5	Dixie Creek after confluence with Unnamed Watercourse 6. Corresponds to surface water quality station SW-15.
Genessee Lake	GEN-1	Outlet of Genessee Lake to Unnamed Watercourse 11.
	GEN-L	Genessee Lake. Corresponds to surface water quality station SW-GL.
Pakwash Lake	PAK-IN	Inlet to Pakwash Lake from the Chukuni River. Corresponds to surface water quality station PL-01.
	PAK-IN-2	Upstream node on Pakwash Lake that is not directly influenced by Project activities. Represents flows and water quality from the Trout Lake watershed into Pakwash Lake and corresponds to surface water quality station PL-02
	PAK-L	Pakwash Lake. Corresponds to surface water quality station PL-03.
	PAK-OUT	Outlet of Pakwash Lake. Corresponds to surface water quality station PL-05
Small unnamed waterbodies and watercourses	UN-1	Unnamed Watercourse 1. Outlet of Unnamed Waterbodies 1 and 2 to Dixie Creek. Corresponds to surface water quality station SW-01.
	UN-2	Inlet to Unnamed Waterbody 6 from various unnamed watercourses. Corresponds to surface water quality station SW-12b.
	UN-3	Outlet of Unnamed Waterbody 6 to Unnamed Watercourse 6.
	UN-L6	Unnamed Waterbody 6. Corresponds to surface water quality station SW-14.
	UN-4	Unnamed Watercourse 8. Corresponds to surface water quality station SW-GL-02.
	UN-5	Unnamed Watercourse 11. Corresponds to surface water quality station GL-TRIB.
	UN-6	Unnamed Watercourse 10. Corresponds to surface water quality station SW-18.

Table 3-2: Modelled Water Quality Parameters

Total Metals

Notes:

1 *Ontario Provincial Water Quality Objectives (PWQO) and interim PWQO (iPWQO).*
2 *Canadian Council of Ministers of the Environment (CCME) water quality guidelines for the protection of aquatic life (long-term exposure).*
3 *Federal Environmental Quality Guidelines (FEQG); these are issued to support federal environmental quality monitoring and risk assessment for parameters for which CCME guidelines do not yet exist or are not reasonably expected to be updated in the near future.*
4 *British Columbia long-term exposure guidelines, freshwater (BC WQG).*
5 *Saskatchewan Environmental Quality Guidelines (SEQG).*
6 *BC WQG are accessed here in the absence of available suitable Ontario or Federal guidelines (sulphate).*
7 *Existing arsenic concentrations in the Chukuni River (the receiving environment) are greater than available water quality guidelines; the most appropriate environmental benchmark is the baseline condition (75th percentile arsenic = 0.0096 mg/L).*
8 *There is no guideline for concentrations of total chromium; it is most common to adopt the PWQO and CCME guidelines for hexavalent (0.001 mg/L) or trivalent (0.0089 mg/L) chromium, dependent on-site conditions and in consultation with regulators.*
9 *BC WQG are accessed here as the CCME guideline is an alert concentration and only applicable to sensitive lacustrine environments (selenium).*

December	23,139	6.2	23,140	6.2

Notes:
Years indicated on the timeline represent the first day of the year, therefore the operations phase extends Years 1 to 26.
1 Filling of the VMF, LP Central pit and underground mine with site contact water and freshwater from the Chukuni River is expected to take approximately four years under average climate conditions, with the closure water management strategy described in Section 2.2.3.
2 Post-closure will begin once site contact water no longer requires water treatment. For the purposes of this model, it is assumed to commence three calendar years (January to December) after water filling has completed. For example, if the LP Central pit is anticipated to fill in August Year 30, post closure will begin Year 34.

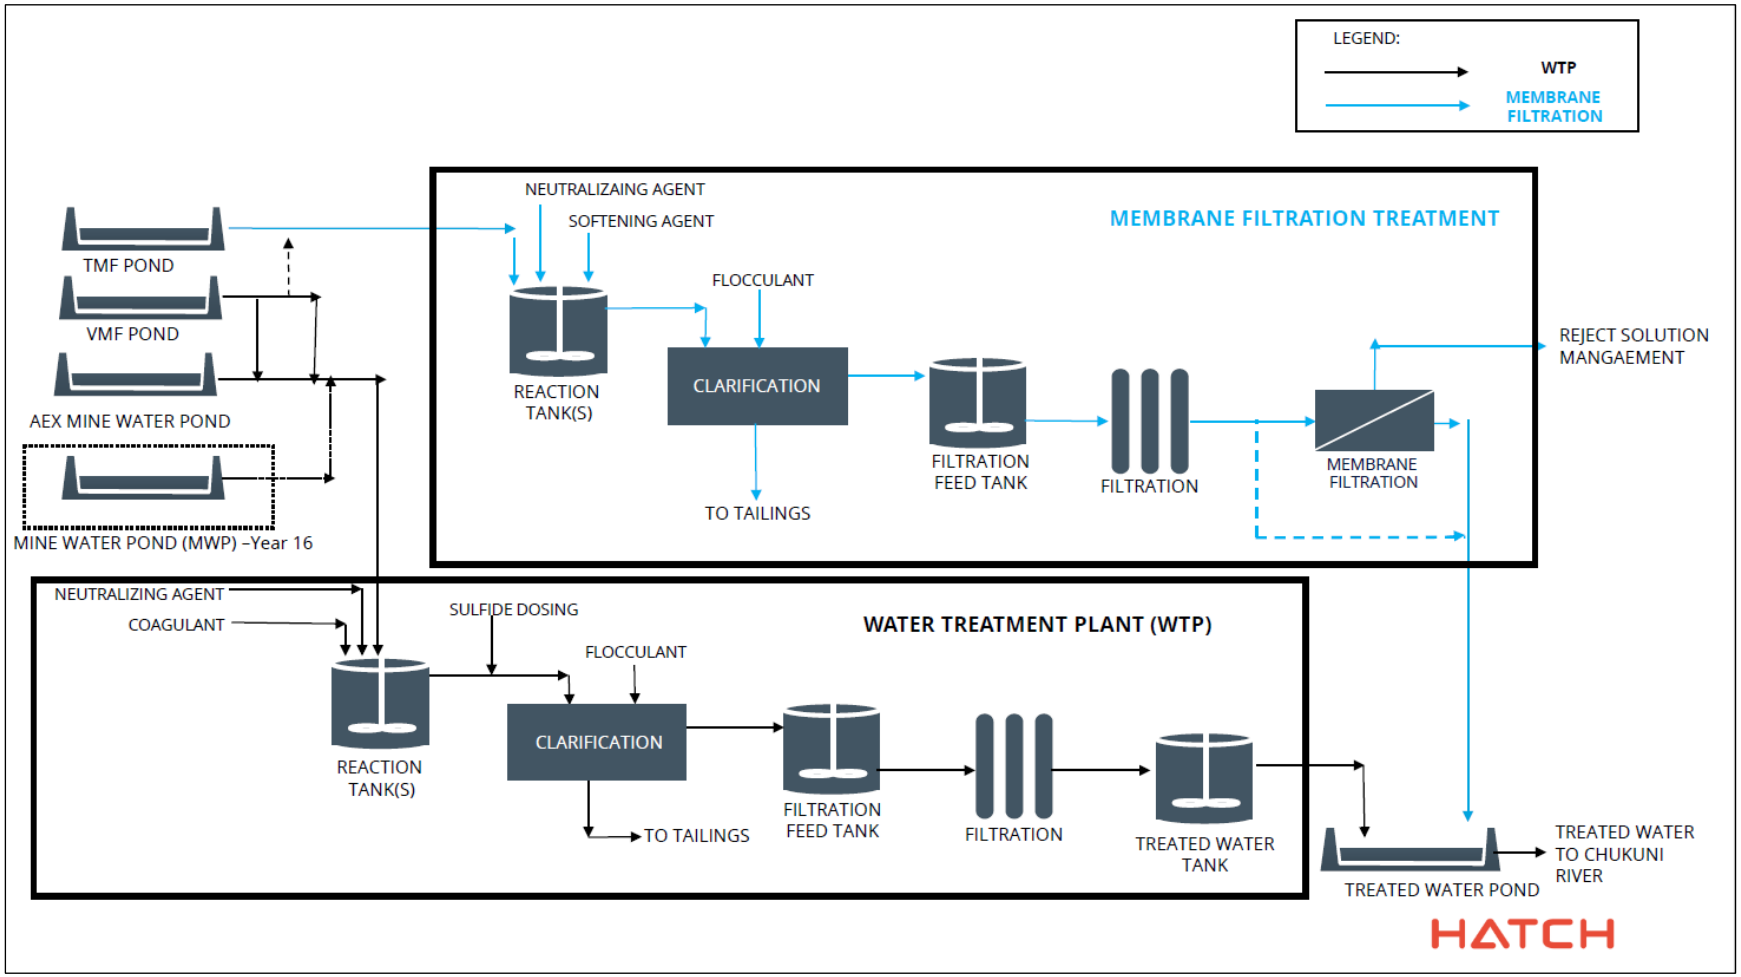

Figure 3-3: Water Treatment, Block Flow Diagram

4 RESULTS, TREATED EFFLUENT DISCHARGE

The Chukuni River is the proposed receiving environment for the Project and will receive treated effluent discharge during the construction, operations, and active closure phases, as required.

The following technical studies were undertaken to estimate treated effluent discharge requirements and treated effluent quality (Section 3):

- Estimated required discharge volumes and rates to the Chukuni River (Table 4-1)
- Hydrodynamic mixing analyses to estimate the maximum extent of the discharge plume within the Chukuni River (Table 4-2)
- Predicted treated effluent quality, based on currently available water treatment engineering Table 4-3, Table 4-4).

The corresponding results of these studies are presented in the following sections.

4.1 REQUIRED DISCHARGE RATES

Mine site water balance modelling results (WSP 2025c) indicate that treated effluent discharge requirements will vary seasonally and throughout the mine life; base case discharge rates predicted by the mine site water balance model are provided in Table 4-1. Key water balance results are:

- Average annual discharge to the environment from the WTP, STP and membrane filtration ranges from 4.64 to 7.22 Mm^3 during the operations phase
- Under average climate conditions (base case), the maximum required discharge rate is approximately 1,300 cubic metres per hour (m^3/h)
- The design discharge rate for peak conditions is 1,330 m^3/h
- The highest required discharge rates are associated with the final years of operations (Years 25 and 26), with the highest discharge occurring in May and June.

As the Chukuni River is a high flow system; treated effluent discharge is predicted to constitute a small fraction of the total flow at CHK-1. For example, the 1,330 m^3/h design discharge rate for peak conditions represents approximately:

- 1.2% of the Chukuni River annual average flow (108,000 m^3/h)
- 2.6% of the Chukuni River minimum monthly flow (March, 51,898 m^3/h).

Sensitivity analyses were also completed to establish a range of potential treated effluent discharge rates to the Chukuni River, including 1:100 wet and 1:100 dry year cases (WSP 2025c).

Results from the 1:100 wet year simulation indicate that discharge requirements increase to 8.80 Mm^3 per year in the operations phase, where an additional 2.53 Mm^3 of surface water is stored onsite following the 1:100 wet year, to be discharged over the next calendar year.

Results from the 1:100 dry year simulation indicate that annual discharge to the environment is reduced to 0.06 Mm^3 in the first year of the operations phase.

A sensitivity analysis was also conducted in accordance with MECP Policy B-1-5, which provides guidance on characterizing the theoretical maximum mixing zone under a worst-case discharge scenario. This scenario assumes that the maximum required discharge rate occurs during the 7Q20 low-flow condition, defined as the lowest seven-day average river flow expected once every 20 years. In this scenario, the 1,330 m^3/h design discharge rate represents approximately 20.5% of the 7Q20 low flow

condition. It is highly unlikely that the peak discharge rate of 1,330 m^3/h, which is intended for wet conditions and contingency planning, would coincide with an extreme drought event.

4.2 EFFLUENT QUALITY

Treated effluent quality was simulated on a monthly timestep using expected treatment efficiencies from the water treatment processes outlined in Section 3.4.3, together with influent quality predictions from the mine site water quality model (WSP 2025e). A summary of the predicted treated effluent discharge quality is presented in Table 4-4, with the complete time series covering all discharge months over the life of mine provided in Appendix C.

The conceptual diffuser design and water treatment process is expected to meet the design criteria for achieving adequate assimilation within the mixing zone such that WQG PAL are achieved by the end of the mixing zone under a range of operational conditions; this was modelled here via hydrodynamic mixing analyses and is detailed in the following section.

4.2.1 CORMIX MODELLING

A hydrodynamic mixing analysis was undertaken to assess the maximum spatial extent of the treated effluent discharge plume within the Chukuni River (i.e., mixing zone size). This evaluation was completed using the Cornell Mixing Zone Expert System (CORMIX), Version 12.0. CORMIX is a United States Environmental Protection Agency-approved mixing zone hydrodynamic model, widely used for the mixing analysis and outfall design of urban and industrial point source discharges into receiving waterbodies. CORMIX predicts mixing behavior and plume geometry based on ambient conditions and discharge characteristics. It incorporates the configuration of the effluent discharge and provides a high resolution of effluent mixing behavior for the near-field region, where source properties dominate the mixing process. Additional details regarding CORMIX model software capabilities are available in Doneker and Jirka (2007).

A series of modelling scenarios were developed to characterize the spatial extent of the mixing zone and to evaluate the influence of key parameters, such as effluent discharge rate, diffuser configuration, and receiving water flow conditions on mixing zone size. The CORMIX model was configured using the following key inputs and assumptions:

- Effluent was assumed to be discharged via a multiport diffuser that extends the width of the river, and the effluent pipeline to the diffuser is located on the west bank of the Chukuni River (Figure 4-1).
- The diffuser consists of three ports, each with a diameter of 20.3 centimetres.
- Ports are oriented in the downstream direction (parallel to current flow), angled 30 degrees above horizontal and positioned 0.5 m above the channel bottom.
- Ports are evenly spaced across the river (approximately 19.1 m) based on the simplified cross section shown in Figure 4-1.
- The modelled discharge rate corresponds to the peak design flow of 1,330 m^3/h, resulting in an effluent discharge velocity of 3.8 m/s with the proposed multiport diffuser.
- Receiving water conditions were modelled under a theoretical worst-case scenario, assuming the peak discharge occurs during a low 7Q20 low flow condition (6,480 m^3/h); this corresponds to MECP Policy B-1-5 (MECP 1994).
- Receiving water conditions were modelled under a conservative expected case scenario, assuming peak discharge occurs during average flow conditions, with Chukuni River flow rate of 108,000 m^3/h.

Table 4-2 summarizes key model inputs and assumptions used for the CORMIX model. CORMIX model results are presented in Table 4-3, Figure 4-2 and Figure 4-3.

For the theoretical worst-case scenario during the 7Q20 low flow condition, CORMIX modelling results indicate the effluent strength decreases from 100% at the discharge point to approximately 2.1% at 300 m

downstream (Table 4-3, Figure 4-2). Furthermore, under the 7Q20 low flow conditions, the model predicts that the effluent plume becomes fully hydrodynamically mixed both vertically and laterally with the ambient water at approximately 350 m downstream of the proposed discharge point. At this location, the plume is distributed across the modelled channel width of 76.5 m (Figure 4-2). It is likely that complete mixing is expected to occur near the downstream distance where CORMIX predicts the effluent dilution to reach the theoretical maximum dilution factor (i.e., less than 10 m downstream). These various estimates arise from the complex hydrodynamic mixing processes simulated by CORMIX, which go beyond the assumptions used in simple flow-based dilution calculations. Key contributing factors include:

- Jet entrainment effects: The discharge jet actively entrains ambient water as it propagates downstream, enhancing local dilution beyond what is predicted by simple flow ratios.
- Momentum and buoyancy-driven mixing: High-velocity or buoyant jet can penetrate and mix more effectively with ambient flows, resulting in greater dilution within the near-field mixing zone.
- Model assumptions: CORMIX operates under idealized conditions, such as steady-state flow and uniform ambient velocity, which differ from the assumptions used in calculating the theoretical dilution factor.
- Local versus complete mixing: The theoretical maximum dilution factor assumes complete and instantaneous mixing across the entire cross-section of the receiving waterbody. In contrast, CORMIX simulates realistic near-field mixing, where localized dilution can greater than the theoretical maximum due to dynamic jet behaviour and entrainment.

Under average river flow conditions, the effluent strength decreases to approximately 2% at approximately 20 m downstream (Figure 4-3). All parameters are less than WQG PAL by this 2% isocline.

Sensitivity analyses were completed in CORMIX relative to the two cases discussed above to assess the influence of key discharge and ambient parameters on the downstream distance required to achieve targeted mixing.

The sensitivity cases focused on variables that, based on WSP's experience, are most likely to affect mixing dynamics and the extent of the mixing zone. These parameters included variation in diffuser configuration (number of ports), effluent discharge velocity (port diameter), channel geometry (including ice-cover), and effluent flow rates.

Key findings from the sensitivity analysis are summarized below:

- Diffuser configuration: Changes to the port diameter (ranging from 15 to 40 centimetres) and the number of ports (six and ten) resulted in minor differences to the predicted dilution under 7Q20 low-flow conditions. However, these variations did not significantly affect the overall mixing performance and do not warrant alterations to the diffuser design.
- Winter ice cover: Increasing the ice thickness to 1 m (representing winter conditions) resulted in enhanced lateral mixing, with the effluent predicted to be fully mixed laterally within 100 m downstream.
- Effluent flow rates: Sensitivity runs using an effluent flow rate of 1000 m^3/h showed a slight increase in predicted dilutions compared with effluent flow rate of 1330 m^3/h under 7Q20 the low-flow condition. However, the differences were not substantial enough to warrant alterations to the diffuser design.

In summary, maximum monthly predicted concentrations and peak design flow rates were used to inform mixing modelling. The modelling results indicate that WQG PAL are achieved at the end of the mixing zone in the Chukuni River, by the 3% isocline. This is approximately 10 m downstream of the discharge point under average flow conditions, and approximately 300 m downstream under 7Q20 low flow conditions (Figure 4-3 and Figure 4-2 respectively).

Note:

Units are m^3/h

Table 4-2: Summary of Key CORMIX Model Inputs

Category	Parameters	7Q20 Low Flow Conditions	Average River Flow Conditions
Effluent	Flow (m^3/h)	1,330	1,330
	Flow (m^3/s)	0.369	0.369
	Density (kg/m^3)	1,000.71	1,002.00
Ambient	Ambient Flow (m^3/s)	1.80	30.0
	Predicted Depth (m)	3.51	3.64
	Top Width (m)	76.5	76.5
	Density (kg/m^3)	998.83	1000.02
Outfall	Number of Ports	3	3
	Port Diameter (m)	0.203	0.203
	Length (m)	38.25	38.25
	Start from Bank (m)	19.13	19.13
	End From Bank (m)	57.38	57.38
	Vertical Angle (degrees)	30.0	30.0
	Height off Bottom (m)	0.50	0.50

Notes:
kg/m^3: kilograms per square metre
m^3/s: cubic metres per second
Densities of effluent and ambient flows were derived from water temperature and total dissolved solids concentrations.
Diffuser configurations were assumed to promote the effluent mixing and maintain a discharge velocity of below 4 m/s to prevent erosion and scour of the channel bed.

Table 4-3: CORMIX Model Results, Effluent Strength

Distance Downstream of Discharge Point (m)	Predicted Effluent Strength (%)	
	Theoretical Worst Case	Conservative Expected Case
0	100	100
10	5.4	2.7
25	3.9	1.9
50	3.5	1.8
100	3.0	1.7
150	2.7	1.6
300	2.1	1.5

Note:
Italic values under the theoretical worst case are above the theoretical maximum dilution factor derived from the ratio for ambient and effluent flow rates.

Table 4-4: Summary of Treated Effluent Discharge Quality (Annual Average)

Mine Year	Chloride	Ammonia (as N)	Nitrate (as N)	Phosphorus	Sulfate	Cyanide, WAD	Aluminum	Antimony	Arsenic	Cadmium	Cobalt	Copper	Iron	Lead	Mercury	Moly.	Nickel	Selenium	Tungsten	Vanadium	Zinc

5 RESULTS, BASE CASE

As discussed in Section 3.5, to support the receiver water quality assessment, a base case scenario (i.e., a conservative expected case) was defined with respect to predicted Project loadings, treated effluent discharge rates and changes in surface - groundwater interactions. Conceptually, the base case represents the most likely set of conditions based on current Project design, operational assumptions and environmental conditions.

Receiver water quality model results for the base case for all modelled parameters across all model timesteps are presented in Appendix E and Appendix G, with corresponding time series graphs provided in Appendix F.

Key model results (operations and ost-closure) presented in the following sections by waterbody, with results presented in tables Table 5-1 through Table 5-14. Operations phase predictions correspond to the greatest predicted change in surface water quality relative to baseline conditions of all Project phases. Post-closure represents long-term equilibrium conditions (i.e., is the longest time period). Receiver water quality model results for the base case for all modelled parameters across all model timesteps are presented in Appendix E and Appendix G.

Unless explicitly stated otherwise, all results discussed in the following sections represent total concentrations.

5.1 DIXIE CREEK

Dixie Creek crosses the southern portion of the Project footprint and flows into the Chukuni River to the east (Figure 3-2). The Project is predicted to interact with Dixie Creek via the following pathways:

- Fugitive seepage from Project components.
- Dust deposition as a result of Project activities, such as construction and open pit mining.
- In post-closure, drainage from the closed and reclaimed Project footprint as well as from the LP central pit.

Changes to Dixie Creek water quality were quantitatively assessed at the following nodes, listed as follows from upstream to downstream (Figure 3-2):

- DIX-2: downstream of the outlet of Dixie Lake, downstream of the confluence with Unnamed Watercourse 1; corresponds to baseline water quality station SW-03
- DIX-3: downstream of the LP Central pit; corresponds to baseline water quality station SW-08
- DIX-4: downstream of the confluence with Unnamed Watercourse 7; downstream of baseline water quality station SW-10
- DIX-5: downstream of the confluence with Unnamed Watercourse; corresponds to baseline water quality station SW-15.

Summary statistics for Dixie Creek for key Project phases (operations and post-closure) are presented in Table 5-1 through Table 5-8. Supporting timeseries graphs and tabulated results are presented in Appendices F and G, respectively. Operations phase predictions correspond to the greatest predicted change in surface water quality relative to baseline conditions of all Project phases. Post-closure represents long-term equilibrium conditions (i.e., is the longest time period).

Water quality predictions for Dixie Creek were informed by the predicted pathways of interaction with the Project as well as upstream modelling results for Dixie Lake and Genessee Lake (Section 5.5). Dixie Creek predictions, in turn, informed the downstream water quality predictions for the Chukuni River (Section 5.2).

Modelling results indicate that predicted concentrations of all modelled parameters in Dixie Creek remain well below the identified WQG PAL across all timesteps and Project phases. As discussed in Section 3.4.1, these results were generated using a conservative mass balance approach, which does not account for degradation, assimilation, or natural attenuation processes along Dixie Creek, which would serve to further reduce predicted concentrations of some parameters in Dixie Creek.

In construction, there are no predicted changes to water quality relative to baseline conditions for Dixie Creek (all nodes: DIX-2, DIX-3, DIX-4 and DIX-5). The interaction of Dixie Creek with the Project during the construction phase is limited to fugitive dust deposition from Project activities, as predicted by the air quality model (Section 3.4.5). There is no surface water discharge or fugitive groundwater seepage from the Project to Dixie Creek as predicted by water balance modelling.

During the operations and active closure phases, several water quality parameters in Dixie Creek are predicted by the mass balance model to increase relative to baseline conditions; however, predicted concentrations remain well below WQG PAL. The greatest relative increases are predicted for node DIX-2 in operations. Parameters with a RPD of at least 20%, ranked from highest to lowest RPD, are: sulphate, ammonia-N, lead, tungsten and cadmium. The highest relative change to baseline concentrations occur in low flow winter months (December, January, February and March). DIX-2 is predicted to receive fugitive groundwater seepage from the TMF, TMF pond, and once it is constructed in Year 16, the MWP. In the winter, DIX-2 has also been conservatively modelled in the receiving water balance and hydrogeological model (WSP 2025d,f) to receive additional bypass seepage from the TMF and TMF pond, due to assumed frozen conditions upstream at UN-1; fugitive seepage reports to UN-1 in the rest of the year.

These predicted concentrations at DIX-2 decline progressively downstream to DIX-5, located upstream of the Chukuni River confluence, where only sulphate maintains RPD values above 20%. This predicted decrease in concentration reflects the influence of dilution along the creek, an outcome of the conservative nature of the model. Note, while RPD is a useful screening tool for identifying key parameters, it should be interpreted alongside absolute concentrations. In this case, the predicted increases are minor in magnitude. For example, baseline sulphate concentrations at DIX-5 range from approximately 1.0 to 1.2 mg/L and are projected to increase to between 1.5 and 2.2 mg/L during the operations phase (Table 5-1, Appendix F).

In post-closure (long-term equilibrium), after the MWP and TMF ponds will be breached, resulting in the cessation of seepage from these sources. Seepage from the closed TMF will continue to influence water quality at DIX-2 and the LP Central pit lake will passively discharge to DIX-3. Model results indicate that the largest changes relative to baseline conditions occur immediately downstream of influences from the LP Central pit lake overflow, specifically at node DIX-3. At this node, several parameters are predicted by the mass balance to increase relative to baseline; however concentrations are well below WQG PAL. Parameters with a RPD of at least 20%, ranked from highest to lowest RPD, are: sulphate, tungsten, cadmium, molybdenum, selenium, zinc, mercury, cobalt, uranium and chloride (Table 5-4). These incremental increases diminish downstream as flow progresses toward DIX-5 such that sulphate, cadmium, molybdenum, antimony, tungsten and zinc have RPD greater than 20%. These predicted increases in actual concentrations are low in magnitude. For example, baseline sulphate concentrations at DIX-5 are approximately 1.0 to 1.2 mg/L, and increase to increase to between 1.8 to 2.7 mg/L in post-closure (Table 5-4, Appendix F). Importantly, these changes to water quality of Dixie Creek relative to baseline conditions are well below the WQG PAL, indicating that water quality remains protective of aquatic life and downstream uses, even under conservative mass balance modelling assumptions.

5.2 CHUKUNI RIVER

The Chukuni River is the proposed receiving environment for the Project and will receive treated effluent discharge during the construction, operations and active closure phases, as required. As discussed in Section 4, results from hydrodynamic modelling indicate that the maximum extent of the mixing zone ranges from approximately 10 to 300 m, and at which point effluent is 2 to 3% of flow and WQG PAL are achieved. This section presents results of the mass balance model for the Chukuni River for modelled parameters.

The Project is predicted to interact with the Chukuni River via the following pathways:

- Discharge of treated effluent to the Chukuni River occurs at rates of 0.31 to 0.78 Mm^3/year in construction and 4.64 to 7.22 Mm^3/year in operations
- Changes in upstream water quality, near the Project site (Dixie Creek, Section 5.1)
- Dust deposition as a result of Project activities, such as construction and open pit mining.

Changes to receiver water quality were quantitatively assessed at the following modelling nodes in the Chukuni River (Figure 3-2):

- CHK-1: At the end of the mixing zone of treated effluent discharge, corresponds to baseline water quality station CR-FDP
- CHK-2: Downstream of Project effluent discharge location (CHK-1) and the confluence with Dixie Creek; corresponds to baseline water quality station CR-DS.

Summary statistics for the Chukuni River for key Project phases (operations and post-closure) are presented in Table 5-10 through Table 5-12. Operations phase predictions correspond to the greatest predicted change in surface water quality relative to baseline conditions of all Project phases. Post-closure represents long-term equilibrium conditions (i.e., is the longest time period). Supporting timeseries graphs and tabulated results are presented in Appendices F and G, respectively. Chukuni River predictions informed the downstream water quality predictions for Pakwash Lake (Section 5.3).

Modelling results indicate that predicted concentrations of all modelled parameters in the Chukuni River remain well below the identified WQG PAL across all timesteps and Project phases or, in the case of existing concentrations greater than WQG PAL (arsenic, phosphorus), remain equivalent to baseline quality (Table 5-9 to Table 5-12). As discussed in Section 3.4.1, these results were generated using a conservative mass balance approach, which does not account for degradation, assimilation or natural attenuation processes, which would serve to further reduce predicted concentrations of some parameters in the Chukuni River.

During the periods of treated effluent discharge, several water quality parameters at CHK-1 are predicted by the mass balance model to increase relative to baseline conditions; however, predicted concentrations remain well below WQG PAL. Parameters with a RPD of at least 20% , ranked from highest to lowest RPD, are: nitrate-N, ammonia-N, tungsten, thallium, cadmium, molybdenum, sulphate, nitrite-N, beryllium and cobalt. Generally, the highest concentrations are associated with the end of the operations phase (maximum loadings from maximum build out), and active closure (when the underground is acidic). As discussed in Section 5.1, while RPD is a useful screening tool for identifying key parameters, it should be interpreted alongside absolute concentrations. In this case, the predicted increases are low in magnitude. For example, 95th percentile baseline nitrate-N concentrations at CHK-1 are approximately 0.13 mg/L and are projected to increase to 0.28 mg/L during the operations phase (Table 5-12, Appendix F). This is well below the WQG PAL for nitrate-N of 3.0 mg/L.

During the periods of treated effluent discharge, several water quality parameters at CHK-2 are predicted by the mass balance model to increase relative to baseline conditions; however, predicted concentrations remain well below WQG PAL. As discussed above, CHK-2 is influenced by predicted quality of Dixie Creek and treated effluent discharge at CHK-1. Parameters with a RPD of at least 20%, ranked from highest to lowest RPD, are: nitrate-N, ammonia-N, tungsten, thallium, cadmium, sulphate, molybdenum, and nitrite-N. The predicted relative increases are low in magnitude. For example, baseline sulphate concentrations at CHK-2 range from approximately 5.3 to 5.8 mg/L and are projected to increase to between 6.6 and 8.0 mg/L during the operations phase, with peak values anticipated in the first half of operations, declining in later years (Table 5-12, Appendix F).

In post-closure (long-term equilibrium), there are no predicted changes relative to baseline conditions for either CHK-1 or CHK-2 (Table 5-10, Table 5-12). There are no Project interactions with CHK-1; water quality of CHK-2 reflects upstream influences from Dixie Creek, including passive discharges from the LP Central pit lake.

5.3 PAKWASH LAKE

The Chukuni River flows into the shallow northern basin of Pakwash Lake, approximately 6 km downstream from the discharge point. The outlet of Pakwash Lake is about 26 km downstream of the discharge point. During Project development, the Project interacts with Pakwash Lake via the following general pathways:

- Project loadings at upstream watercourses (Dixie Creek and Chukuni River)
- Dust deposition as a result of Project activities such as construction and open pit mining.

Changes to Pakwash Lake water quality were quantitatively assessed at the following modelling nodes in Pakwash Lake (Figure 3-2):

- PAK-IN: inlet to Pakwash Lake directly downstream of confluence with the Chukuni River; corresponds to baseline water quality station PL-01
- PAK-L: downstream of PAK-IN, corresponds to baseline water quality station PL-03
- PAK-OUT: the outlet of Pakwash Lake; corresponds to baseline water quality station PL-05
- PAK-IN-2: an upstream node on Pakwash Lake that is not directly influenced by Project activities; represents flows and water quality from the Trout Lake watershed into Pakwash Lake and corresponds to baseline water quality station PL-02.

Summary statistics for Pakwash Lake outlet for key Project phases (operations and post-closure) are presented in Table 5-13 and Table 5-14. Model results for all timesteps for all nodes are presented in supporting timeseries graphs and tabulated results are presented in Appendices F and G, respectively.

Modelling results indicate that predicted concentrations of all modelled parameters in Pakwash Lake remain well below the identified WQG PAL across all timesteps and Project phases (Table 5-13 and Table 5-14). As discussed in Section 3.4.1, these results were generated using a conservative mass balance approach, which does not account for degradation, assimilation, or natural attenuation processes, which would serve to further reduce predicted concentrations of some parameters in Pakwash Lake.

During the operations phase, some water quality parameters are predicted by the mass balance to increase relative to baseline conditions, with the greatest increases observed directly downstream of inflows from the Chukuni River (node, PAK-IN); however, predicted concentrations remain well below the WQG PAL. The calculated RPD values greater than 20% as predicted by the mass balance were observed for (ranked from highest to lowest): nitrate-N, ammonia-N, tungsten, thallium, cadmium, sulphate, molybdenum and nitrite-N at PAK-IN.

At node PAK-OUT, the calculated RPD values greater than 20% as predicted by the mass balance were observed for: nitrate-N, ammonia-N, tungsten, thallium, nitrite-N, cadmium and sulphate; however, predicted concentrations remain well below WQG PAL. Note, while RPD is a useful screening tool for identifying key parameters, it should be interpreted alongside absolute concentrations. In this case, the predicted increases are minor in magnitude. For example, baseline sulphate concentrations at PAK-OUT range from approximately 3.8 to 4.2 mg/L and are projected to increase to between 4.9 and 5.4 mg/L during the operations phase.

There are no parameters different from baseline for Pakwash Lake during construction, active closure and post-closure (long-term equilibrium).

5.4 OTHER WATERCOURSES

5.4.1 SMALL UNNAMED WATERBODIES AND WATERCOURSES

There are several small watercourses and waterbodies within the Property boundary (Figure 1-4, Figure 3-2). The main small watercourses and waterbodies in the area around the planned development, that are part of the modelling domain, include:

- Unnamed Watercourse 1
- Unnamed Watercourse 2
- Unnamed Watercourse 3
- Unnamed Watercourse 4
- Unnamed Watercourse 6
- Unnamed Waterbody 1
- Unnamed Waterbody 6.

These are minor watercourses and waterbodies in terms of size and flow. For example, the largest, Unnamed Watercourse 3, has an estimated catchment area of about 9.4 km², representing less than 5% of the Dixie Creek watershed.

There will be no direct discharge of water into the unnamed waterbodies and watercourses. These features are all located upstream of the treated effluent discharge point into the Chukuni River, as well as upstream of any LP Central pit lake overflows to Dixie Creek in post closure. During Project development, the Project is predicted to interact with these small unnamed waterbodies and watercourses via the following general pathways:

- Fugitive groundwater seepage from Project components
- Dust deposition as a result of Project activities such as construction and open pit mining
- Flow reductions associated with Project development in upstream watershed, and baseflow reductions associated with mine dewatering activities
- In post-closure, drainage from the closed and reclaimed Project footprint.

Changes to receiver water quality were quantitatively assessed at the following modelling nodes in small unnamed waterbodies and watercourses (Figure 3-2):

- UN-1: Unnamed Watercourse 1. Outlet of Unnamed Waterbodies 1 and 2 to Dixie Creek (DIX-2); corresponds to baseline water quality station SW-01
- UN-2: Inlet to Unnamed Waterbody 6 (UN-L6) from various unnamed watercourses; corresponds to baseline water quality station SW 12b
- UN-3: Outlet of Unnamed Waterbody 6 (UN-L6) to Unnamed Watercourse 6, downstream of baseline station baseline water quality station SW 12b
- UN-L6: Unnamed Waterbody 6, corresponds to baseline water quality station SW-14
- UN-4: Unnamed Watercourse 8, corresponds to baseline water quality station SW-GL02
- UN-5: Unnamed Watercourse 11 inlet to Dixie Lake, corresponds to baseline water quality station GL-TRIB
- UN-6: Unnamed Watercourse 10, corresponds to baseline water quality station SW-18.

Base case model results are provided in Appendix E and Appendix G. The following are they key results:

- Predicted concentrations of all modelled parameters are below WQG PAL across all timesteps and Project phases for all unnamed watercourses and waterbodies, with the exception of Unnamed Watercourse 1, which is targeted by the Fish Habitat Offset and Compensation Plan. At UN-1, the greatest increase in concentrations are predicted for cobalt and phosphorus, which are consistently greater than guidelines in operations. In post-closure, there are no concentrations predicted greater than WQG PAL in Unnamed Watercourse 1.
- There are no changes relative to baseline conditions for UN-2 and UN-6 for all Project phases and post-closure.
- Several water quality parameters are projected to increase compared to baseline conditions during operations at UN-3, UN-L6, UN-4, UN-5, and UN-6; however, all predicted concentrations remain well below the WQG PAL. In general, the greatest changes relative to baseline at these nodes were predicted for: ammonia-N, antimony, cadmium, cobalt, lead, phosphorus, and sulphate; although this varies by node.

The receiver water quality model results for all above-identified unnamed waterbodies and watercourses informed downstream conditions in the Chukuni River (Section 5.2), and Dixie Creek (Section 5.1), providing a comprehensive understanding of potential effects throughout the watershed.

5.4.2 GENESEE LAKE AND DIXIE LAKE

There will be no direct discharge of water into Genessee Lake and Dixie Lake and these features are located upstream of the treated effluent discharge point into the Chukuni River, as well as upstream of any pit lake overflows to Dixie Creek in post-closure. Genessee Lake and Dixie Lake were included in this receiving environment model as:

- During Project development, it was conservatively assumed that Genessee Lake and Dixie Lake will have dust deposition as a result of Project activities such as construction and open pit mining.
- There are Project loadings (small amount of seepage, as discussed in Section 3.4.4 and Section 5.4) predicted to occur at upstream Unnamed Watercourse 11 (UN-5), which reports to Dixie Lake near the Dixie Lake outlet.
- The water quality data from upstream waterbodies informed downstream conditions in the Chukuni River (Section 5.2), and Dixie Creek (Section 5.1), ensuring a comprehensive understanding of potential effects throughout the watershed.

Base case model results are provided in Appendix E and Appendix G.

Water quality modelling shows that all predicted concentrations for Genessee Lake and Dixie Lake the are well below the identified WQG PAL across all time periods and phases of the Project and there are no measurable changes relative to baseline conditions.

Table 5-1: Base Case Operations Water Quality, Dixie Creek (DIX-2)

Notes:
- no value available.
All units mg/L.
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life.
WQG PAL: Water Quality Guidelines for the Projection of Aquatic Life.
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines.
BC WQG: British Columbia Water Quality Guidelines (fresh water, long-term exposure).
SEQG: Saskatchewan Environmental Quality Guidelines.
1 Where applicable, receiving environment guidelines are here calculated using 25th percentile hardness and pH of baseline monitoring station to be conservative (Table 3-4).
2 Guideline corresponds to Cr(III).
3 The PWQO is for free cyanide.

Table 5-4: Base Case Long-term Equilibrium Water Quality, Dixie Creek (DIX-3)

Notes:
- no value available.
All units mg/L.
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life.
WQG PAL: Water Quality Guidelines for the Projection of Aquatic Life.
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines.
BC WQG: British Columbia Water Quality Guidelines (fresh water, long-term exposure).
SEQG: Saskatchewan Environmental Quality Guidelines.
1 Where applicable, receiving environment guidelines are here calculated using 25th percentile hardness and pH of baseline monitoring station to be conservative (Table 3-4).
2 Guideline corresponds to Cr(III).
3 The PWQO is for free cyanide.

Notes:
- no value available.
All units mg/L.
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life.
WQG PAL: Water Quality Guidelines for the Projection of Aquatic Life.
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines.
BC WQG: British Columbia Water Quality Guidelines (fresh water, long-term exposure).
SEQG: Saskatchewan Environmental Quality Guidelines.
1 Where applicable, receiving environment guidelines are here calculated using 25th percentile hardness and pH of baseline monitoring station to be conservative (Table 3-4).
2 Guideline corresponds to Cr(III).
3 The PWQO is for free cyanide.

6 RESULTS, SENSITIVITY ANALYSES

This section presents the results of sensitivity analyses completed relative to the base case (expected case).

As discussed in Section 3.5, the sensitivity analyses undertaken to support the receiver water quality assessment were designed to evaluate a range of plausible future scenarios, including extreme hydrologic conditions (such as extended wet or dry years), potential climate change influences, and variations in baseline water quality inputs. These scenarios provide valuable insight into how the receiving environment may respond under conditions that differ from the expected case.

Evaluating water quality predictions across these sensitivity scenarios enables a more comprehensive understanding of the range of potential of water quality outcomes and supports the evaluation of the robustness and adaptability of the proposed water management strategies.

As described above in Section 4.1, one key variable informing sensitivity cases is changes in required discharge volumes, related to changing inputs in climatic conditions. Specifically, sensitivity analyses were also completed to establish a range of potential treated effluent discharge rates to the Chukuni River, including 1:100 wet and 1:100 dry year cases (WSP 2025c). Results from the 1:100 wet year simulation indicate that discharge requirements increase to 8.80 Mm^3 per year in the operations phase, where an additional 2.53 Mm^3 of surface water is stored onsite following the 1:100 wet year, to be discharged over the next calendar year. Results from the 1:100 dry year simulation indicate that annual discharge to the environment is reduced to 0.06 Mm^3 in the first year of the operations phase.

A summary comparison of sensitivity case results relative to base case is presented in Table 6-1. Receiver water quality model results for the sensitivity cases at key nodes are presented in Appendix H. Results for all modelled nodes show that, while some absolute concentration values change relative to base case under these different assumptions, no predicted concentrations are greater than identified WQG PAL. These results reinforce the effectiveness of the Project's mitigation measures and confirm that the water management system for this stage in the Project is adequate.

Table 6-1: Summary Comparison of Base Case vs. Sensitivity Cases, PAK-OUT Operations Phase

Parameter	Model Baseline Water Quality		Base Case		Extreme Dry		Extreme Wet		Elevated Baseline		Climate Change

Notes:
- no value available.
All units mg/L.
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (Table 3-4).

7 SUMMARY

This Receiver Water Quality Modelling Report:

- Identified the key pathways of interaction through which the Project may affect surface water quality of area watercourses and waterbodies
- Simulated changes in surface water quality, using appropriate modelling methods and robust data sources
- Provides the basis of the surface water quality effects assessment.

The overall Project footprint is approximately 8 km², representing approximately 0.4% of the Chukuni River watershed. The Project has a comprehensive water management strategy including:

- Non-contact water is diverted away from the site.
- Contact water is collected, treated, and reused or discharged.
- Treated effluent will be released to the Chukuni River and will adhere to MDMER and anticipated provincial approval standards.
- Post-closure involves passive discharge once water quality objectives are met.

The Chukuni River, a large high flow system, is the receiving waterbody for treated effluent during construction and operations and for a short period in closure. Treated effluent discharge is predicted to constitute a small fraction of the total flow at the discharge point (node CHK-1). For example, the 1,330 m^3/h design discharge rate for peak conditions represents approximately:

- 1.2% of the Chukuni River annual average flow (108,000 m^3/h)
- 2.6% of the Chukuni River minimum monthly flow (March, 51,898 m^3/h)

Using GoldSim, the mass-balance model simulates monthly water quality changes over for construction, operations and closure phases of the Project. Key model results are:

- Predicted concentrations of all parameters remain below WQG PAL, or consistent with baseline levels for parameters already greater than guidelines (arsenic, phosphorus)
- Conservative assumptions (e.g., no natural attenuation) were used
- A small mixing zone is predicted within the Chukuni River downstream of treated effluent discharges. Under average flow conditions, the mixing zone extends approximately 10 m from the discharge point (Figure 7.7-8). The size of the mixing zone is consistent with the requirements of Policy B-1-5 and has been assessed to ensure that it does not adversely affect existing water users. Water quality modelling indicates that there is no acute lethality within the mixing zone and that all discharges to the Chukuni River will comply with applicable regulatory requirements.
- Sensitivity analyses assessed changes in water quality under extreme hydrologic conditions (e.g., 1:100 wet and dry years), potential climate change impacts, and variations in baseline assumptions. While predicted values for water quality parameters varied by scenario relative to the base case, no additional effects were identified beyond those already captured in the conservative base case.

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated using site-specific cofactors (pH, 25th percentile hardness to be conservative). In the absence of site-specific dissolved organic carbon, the lower limit was inputted.
Seepage quality was obtained from Table 5-7 (Operations), Table 5-12 (Active Closure), Table 5-19 (Passive Closure) and Table 5-22 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated using site-specific cofactors (pH, 25th percentile hardness to be conservative). In the absence of site-specific dissolved organic carbon, the lower limit was inputted.
Seepage quality was obtained from Table 5-7 (Operations), Table 5-12 (Active Closure), Table 5-19 (Passive Closure) and Table 5-22 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Table B-2: Geochemical Source Terms, Seepage, Tailings Management Facility Pond

Year	Chloride (mg/L)	Ammonia (as N; mg/L)	Nitrate (as N; mg/L)	Nitrite (as N; mg/L)	Phosphorus, Total (mg/L)	Sulphate (mg/L)	Cyanide, WAD (mg/L)	Aluminum (mg/L)	Antimony (mg/L)	Arsenic (mg/L)	Beryllium (mg/L)	Boron (mg/L)	Cadmium (mg/L)	Calcium (mg/L)	Chromium (mg/L)	Cobalt (mg/L)	Copper (mg/L)

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for baseline groundwater quality as presented in the Water Quality Baseline Report (Appendix K-1).
Seepage quality was obtained from Table 5-8 (Operations), Table 5-13 (Active Closure) and Table 5-16 (Passive Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for baseline groundwater quality as presented in the Water Quality Baseline Report (Appendix K-1).
Seepage quality was obtained from Table 5-9 (Operations), Table 5-14 (Active Closure) and Table 5-20 (Passive Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for baseline groundwater quality as presented in the Water Quality Baseline Report (Appendix K-1).
Seepage quality was obtained from Table 5-9 (Operations), Table 5-14 (Active Closure) and Table 5-20 (Passive Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for baseline groundwater quality as presented in the Water Quality Baseline Report (Appendix K-1).
Seepage quality was obtained from Table 5-11 (Active Closure), Table 5-18 (Passive Closure) and Table 5-23 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for baseline groundwater quality as presented in the Water Quality Baseline Report (Appendix K-1).
Seepage quality was obtained from Table 5-11 (Active Closure), Table 5-18 (Passive Closure) and Table 5-23 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Table B-5: Geochemical Source Terms, Passive Discharge, Mine Water Pond Watershed

Year	Chloride (mg/L)	Ammonia (as N; mg/L)	Nitrate (as N; mg/L)	Nitrite (as N; mg/L)	Phosphorus, Total (mg/L)	Sulphate (mg/L)	Cyanide, WAD (mg/L)	Aluminum (mg/L)	Antimony (mg/L)	Arsenic (mg/L)	Beryllium (mg/L)	Boron (mg/L)	Cadmium (mg/L)	Calcium (mg/L)	Chromium (mg/L)	Cobalt (mg/L)	Copper (mg/L)

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node UN-1.
Discharge quality was obtained from Table 5-21 (Post-Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Table B-5: Geochemical Source Terms, Passive Discharge, Mine Water Pond Watershed

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node UN-1.
Discharge quality was obtained from Table 5-21 (Post-Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Table B-6: Geochemical Source Terms, Passive Discharge, Viggo Pit Watershed

Year	Chloride (mg/L)	Ammonia (as N; mg/L)	Nitrate (as N; mg/L)	Nitrite (as N; mg/L)	Phosphorus, Total (mg/L)	Sulphate (mg/L)	Cyanide, WAD (mg/L)	Aluminum (mg/L)	Antimony (mg/L)	Arsenic (mg/L)	Beryllium (mg/L)	Boron (mg/L)	Cadmium (mg/L)	Calcium (mg/L)	Chromium (mg/L)	Cobalt (mg/L)	Copper (mg/L)

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node UN-2.
Discharge quality was obtained from Table 5-21 (Post-Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Table B-6: Geochemical Source Terms, Passive Discharge, Viggo Pit Watershed

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node UN-2.
Discharge quality was obtained from Table 5-21 (Post-Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node UN-2.
Discharge quality was obtained from Table 5-21 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node UN-2.
Discharge quality was obtained from Table 5-21 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Table B-8: Geochemical Source Terms, Passive Discharge, Advanced Exploration Program Pond Watershed

Year	Chloride (mg/L)	Ammonia (as N; mg/L)	Nitrate (as N; mg/L)	Nitrite (as N; mg/L)	Phosphorus, Total (mg/L)	Sulphate (mg/L)	Cyanide, WAD (mg/L)	Aluminum (mg/L)	Antimony (mg/L)	Arsenic (mg/L)	Beryllium (mg/L)	Boron (mg/L)	Cadmium (mg/L)	Calcium (mg/L)	Chromium (mg/L)	Cobalt (mg/L)	Copper (mg/L)

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node DIX-2.
Discharge quality was obtained from Table 5-21 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Table B-8: Geochemical Source Terms, Passive Discharge, Advanced Exploration Program Pond Watershed

Year	Iron (mg/L)	Lead (mg/L)	Magnesium (mg/L)	Manganese (mg/L)	Mercury (mg/L)	Molybdenum (mg/L)	Nickel (mg/L)	Potassium (mg/L)	Selenium (mg/L)	Silver (mg/L)	Thallium (mg/L)	Tungsten (mg/L)	Uranium (mg/L)	Vanadium (mg/L)	Zinc (mg/L)	Zirconium (mg/L)

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node DIX-2.
Discharge quality was obtained from Table 5-21 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node DIX-3.
Discharge quality was obtained from Table 5-24 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node DIX-3.
Discharge quality was obtained from Table 5-24 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node UN-4.
Discharge quality was obtained from Table 5-21 (Post Closure) and Table 5-22 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life (WQG PAL).
WQG PAL applied here were calculated for receiver water quality modelling node UN-4.
Discharge quality was obtained from Table 5-21 (Post Closure) and Table 5-22 (Post Closure) of the Mine Site Water Quality Estimate (WSP 2025b).

Notes:
- value not available

Values represent loading to modelling node from dustfall on upstream water surface area (19,535 m^2) within the air quality regional study area as described in the Air Quality Modelling Report (WSP 2025).

Appendix C
Water Treatment

Table C-1. Estimated Membrane Filtration Treated Water Quality, Great Bear Project (Hatch Engineering, 2025).

DRAFT

Projection Date:	May-25
Revision:	D
Revision Date:	2025-06-27
Membrane type:	High-pressure RO membranes
Temperature:	15 C

Note: The projection (Table 1 and 2) are estimates and do not reflect actual conditions. These values are subject to change depending on feed chemistry and temperature. Testwork and vendor input is required to verify the data.
Based on experience, a factor was applied to the Table 1 permeate concentrations to define a reasonable range. Brine concentrations (in Table 1) have been rounded and may not be perfectly balance; however, any mass / concentration not found in the permeate is certainly present in the brine.

Table 1: Permeate and brine concentrations based on WAVE model projection.

Notes:

1 The initial water quality used for projection is based on Conservative Case - Operations (Equilibrated) for TMF Seepage.

2 The sulphate concentration used in the projection corresponds to the May 2040 chemistry.

3 Temperature was not reported, and is the single most important parameter

a. Higher temperatures increase the rate of transmission of ions across the membrane and since the flux is kept same, the quality goes down. Projections were ran at 2C and 15C but have provided results for the higher temperature of 15C here, as the worst quality is expected at higher temperature.

4 Table 1 results are based on WAVE software RO projection modeling and are not guarantees. These results do not correspond to end of life membrane quality.

5 While NF membranes were initially considered, the results presented here focus on RO systems, in alignment with Kinross's expressed interest in pursuing an RO-based solution

6 Different recovery scenarios (70% and 90%) were evaluated based on Kinross's request. However, the results presented here focus on the 90% recovery scenario, as Kinross has indicated a preference to proceed with that target. It's worth noting that future changes in water quality may influence both the RO system design and the required pre-treatment approach.

7 Approximate flowrates: RO Feed flowrate = 370 m3/h, permeate flowrate = ~333 m3/h, brine flowrate = ~37 m3/h.

8 Feed flow to the RO does not constitute the feedwater to the ETP since there are losses for pre-treatment for sludge or UF. To be considered in the future designs.

9 Feed water quality is not complete (indicated by a dash "-") and vendors will be interested in parameters not listed in the table such as silica, Ba, Sr and other parameter, organics/TOC/BOC that could potentially lead to premature fouling.

10 The provided permeate and brine concentrations are preliminary and are expected to change with changes in feed chemistry over time.

11 Rejection of ions will decline as membrane age.

12 The projection does not predict cobalt cyanide concentrations.

13 Testwork and vendor input is required to verify the data.

14 The maximum monthly average effluent criteria is obtained from WSP and Kinross's file 'OMEMA2303_GBR_Preliminary Water Quality Update_10Jan2025'.

Table C-2. Estimated Water Treatment Plant Treated Water Quality, Great Bear Project (Hatch Engineering, 2025).

1:100 scenario		
Maximum of the average flow rates for year 2040		
UGM / AEX	152	m3/h
VMF	750	m3/h
MWP	0	m3/h
Year 2040 was chosen since the monthly SO4 analysis was performed on year 2040.		
Water quality informat	2038	worst case scenario

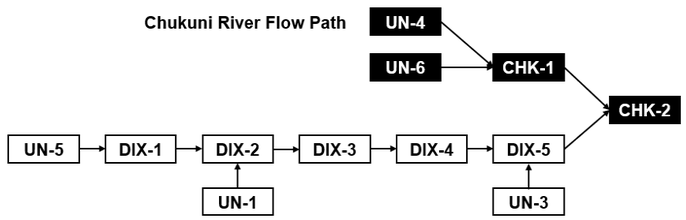
Notes

1. The maximum monthly average effluent criteria is obtained from WSP and Kinross's file 'OMEMA2303_GBR_Preliminary Water Quality Update_10Jan2025'.
2. The ETP feed chemistry is the blended chemistry reporting from MWP, AEX/UGM, and VMF.
3. The water quality used for AEX/UGM is based on Before Cover Placement - Conservative Case - Maximum monthly concentrations (Non-Equilibrated)
4. The water quality used for VMF is based on Before Cover Placement - Conservative Case - Maximum monthly concentrations (Non-Equilibrated)
5. The water quality used for MWP is based on Conservative Case - Operations (Equilibrated)
6. The TMF WTP feed chemistry is based on Conservative Case - Operations (Equilibrated) for TMF Seepage.
7. The TMF WTP feed sulphate concentration corresponds to the May 2040 chemistry.
8. The TMF WTP RO treatment is based on 90% recovery. Approximate flowrates: RO Feed flowrate = 370 m3/h, permeate flowrate = ~333 m3/h, brine flowrate = ~37 m3/h.
9. The provided treated water qualities are estimates based on experience and projection results (not guranteed).
10. The treated water quality will change with changes in feed chemistry.
11. Testwork and vendor input is required to verify the data.

Appendix D
Mass Balance Example



Summary of Mass Balance Calculations at CHK-2 (Breakdown of Chukuni River and Dixie Creek Flow Paths Below)

	CHK-2 Sulphate								
	Upstream Inputs				Mass and Flow Balance Calculations [1]			Predicted Flow and Chemistry	
	Upstream Input from CHK-1		Upstream Input from DIX-5		Sulphate Dust Load (mg/s)	Freshwater (Runoff Only) Input		Total Flow (L/s)	Mixed Sulphate (mg/L)
Month	Flow (L/s)	Sulphate (mg/L)	Flow (L/s)	Sulphate (mg/L)		Flow (L/s)	Sulphate (mg/L)		
January	17,583	6.6	1,216	2.2	0.051	42	4.2	18,841	6.3
February	14,828	6.9	1,055	2.3	0.047	36	4.7	15,919	6.6

1 Where applicable, receiving environment benchmarks are here calculated using 25th percentile hardness and pH of baseline monitoring station to be **conservative**
2 Guideline corresponds to Cr(III)
3 the PWQO is for free cyanide
All units mg/L.
- value not available
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life
WAD Cyanide: weak acid dissociable cyanide
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines
BC WQG: British Columbia Water Quality Guidelines
SEQG: Saskatchewan Environmental Quality Guidelines

Table E-2: Base Case Operations Water Quality, Chukuni River (CHK-2)

Parameter	Water Quality Guideline[1]	Source	Model Baseline Water Quality		Model Results, Median Monthly Water Quality During Operations												Predicted Overall Range

1 Where applicable, receiving environment benchmarks are here calculated using 25th percentile hardness and pH of baseline monitoring station to be **conservative**
2 Guideline corresponds to Cr(III)
3 the PWQO is for free cyanide
All units mg/L.
- value not available
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life
WAD Cyanide: weak acid dissociable cyanide
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines
BC WQG: British Columbia Water Quality Guidelines
SEQG: Saskatchewan Environmental Quality Guidelines

Table E-9: Base Case Operations Water Quality, Genessee Lake (GEN-L)

Parameter	Water Quality Guideline[1]	Source	Model Baseline Water Quality		Model Results, Median Monthly Water Quality During Operations												Predicted Overall Range	
					January	February	March	April	May	June	July	August	September	October	November	December

1 Where applicable, receiving environment benchmarks are here calculated using 25th percentile hardness and pH of baseline monitoring station to be **conservative**
2 Guideline corresponds to Cr(III)
3 the PWQO is for free cyanide
All units mg/L.
- value not available
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life
WAD Cyanide: weak acid dissociable cyanide
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines
BC WQG: British Columbia Water Quality Guidelines
SEQG: Saskatchewan Environmental Quality Guidelines

Table E-16: Base Case Operations Water Quality, Small Unnamed Waterbodies and Watercourses (UN-3)

Parameter	Water Quality Guideline[1]	Source	Model Baseline Water Quality		Model Results, Median Monthly Water Quality During Operations												Predicted Overall Range

1 Where applicable, receiving environment benchmarks are here calculated using 25th percentile hardness and pH of baseline monitoring station to be **conservative**
2 Guideline corresponds to Cr(III)
3 the PWQO is for free cyanide
All units mg/L.
- value not available
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life
WAD Cyanide: weak acid dissociable cyanide
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines
BC WQG: British Columbia Water Quality Guidelines
SEQG: Saskatchewan Environmental Quality Guidelines

Table E-22: Surface Water Quality Results, Base Case Long-term Equilibrium, Dixie Lake (DIX-1)

Parameter	Water Quality Guideline[1]	Source	Model Baseline Water Quality		Model Results, Median Monthly Water Quality, Long-term Equilibrium												Predicted Overall Range

1 Where applicable, receiving environment benchmarks are here calculated using 25th percentile hardness and pH of baseline monitoring station to be **conservative**
2 Guideline corresponds to Cr(III)
3 the PWQO is for free cyanide
All units mg/L.
- value not available
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life
WAD Cyanide: weak acid dissociable cyanide
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines
BC WQG: British Columbia Water Quality Guidelines
SEQG: Saskatchewan Environmental Quality Guidelines

1 Where applicable, receiving environment benchmarks are here calculated using 25th percentile hardness and pH of baseline monitoring station to be **conservative**
2 Guideline corresponds to Cr(III)
3 the PWQO is for free cyanide
All units mg/L.
- value not available
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life
WAD Cyanide: weak acid dissociable cyanide
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines
BC WQG: British Columbia Water Quality Guidelines
SEQG: Saskatchewan Environmental Quality Guidelines

1 Where applicable, receiving environment benchmarks are here calculated using 25th percentile hardness and pH of baseline monitoring station to be **conservative**
2 Guideline corresponds to Cr(III)
3 the PWQO is for free cyanide
All units mg/L.
- value not available
Grey highlighted values are greater than identified Water Quality Guidelines for the Projection of Aquatic Life
WAD Cyanide: weak acid dissociable cyanide
PWQO: Provincial Water Quality Objectives; iPWQO: interim PWQO.
CWQG: Corresponds to the most up-to date Canadian Council of Ministers of the Environment (CCME) of Federal Environmental Quality Guideline for the Protection of Aquatic Life.
FEQG: Federal Environmental Quality Guidelines
BC WQG: British Columbia Water Quality Guidelines
SEQG: Saskatchewan Environmental Quality Guidelines

Table E-37: Base Case Long-term Equilibrium Water Quality, Small Unnamed Waterbodies and Watercourses (UN-5)

Parameter	Water Quality Guideline[1]	Source	Model Baseline Water Quality		Model Results, Median Monthly Water Quality, Long-term Equilibrium												Predicted Overall Range
