There are reasonable and probable grounds to conclude that the amount of mercury that will be released into the environment as a consequence of the logging plan constitutes an immediate, and long term, danger to the health of people in Grassy Narrows.

6. Efforts to Raise the Mercury Issue

Grassy Narrows has consistently objected to the planning process that MNR used for this logging plan and for Forest Management Plans generally. This process does not approach us within a government to government relationship with mutual respect. Instead, it treats us as a stakeholder, asking merely for our input that can be (and in our experience, has been) easily ignored. Only MNR or a proponent holds the pen. It does not provide adequate resources for First Nation community participation or the studies required to gather crucial environmental and traditional knowledge. It sets the wood supply as the highest objective, and compromises other objectives, those that are most important to Grassy Narrows to meet the wood supply targets.

However, when resources allow we have communicated our position, in a limited way, in the Forest Management Planning process for fear of being run over by it. We do so under duress and our limited input in no way indicates our agreement with the legitimacy of the process itself, or its outcomes.

When we do not participate, our absence is used as justification to ignore our concerns. When we do participate, our input is similarly ignored, and our presence is used to justify the process. After well over a decade of engagement we see little, if any, of our concerns reflected in the current logging plan.

Grassy Narrows has raised concerns about logging plans for our territory in the Whiskey Jack Forest through at least 3 cycles of the forest management planning process, with a written record dating back at least to 1997, and likely longer. Notably, this will be at least the 3rd request for an Individual Environmental Assessment of a logging plan from Grassy Narrows following those in 1999 and 2005. The first two requests were rejected, and so two early opportunities were neglected for the MOE and the EA process to catch the omission by the planning team of the logging-mercury problem after it was identified in the scientific literature.

Grassy Narrows has always asserted that the logging problem is connected to the mercury problem, and to the legacy of racism, residential schools, relocation, and hydro damming. We have also asserted our knowledge that everything in the environment is connected

and that the impacts of clearcutting will be felt throughout the ecosystem and eventually, in our bodies.

The scientific evidence on the impact of clearcutting on the mercury problem has come to our attention relatively recently, due to our lack of access to scientific resources. We have brought this information forward since 2010 (at least) with direct reference to the key scientific literature cited in this request. Our efforts have been heard and commented on publicly by Premier Wynne (then minister of Aboriginal Affairs), former Premier Dalton McGuinty, then-Minister of the Environment John Gerretsen, Minister of Natural Resources David Orazietti, MP Greg Rickford, then-federal Health Minister Leona Aglukkaq, among others. Our concerns about logging and mercury have also been widely reported in the news media both nationally, and locally. Therefore, our specific concerns about logging and mercury have been known by the planning team since the earliest stages of the development of the FMP, and even during the development of the Long Term Management Direction (LTMD).

A partial record of some of the instances where we have raised explicit concerns about the logging-mercury problem citing the scientific literature is recorded here:

a) Chief Fobister's letter to Premier Wynne, copied to the plan author, dated October 24, 2013.
b) Earthroots' comments sent to the plan author as submission re: EBR Registry Number 010-9240 – Forest Management Plan for the Whiskey Jack Forest for the 10-year period April 1, 2012 to March 31, 2022 – Review of Draft Forest Management Plan. No response received.
c) Approximately 2,000 submissions by members of the public to the plan author and the Premier before, during, and after the official public comment period for the logging plan. No response received.
d) Thursday August 22nd, public release of Joint letter (see next item). No response received.
e) Joint letter to Premier Wynne, copied to MNR District Manager and MNR Regional Director, June 25, 2013. No response received. Signatories represent over 1 million Ontario residents as members of: Amnesty International Canada, Canadian Friends Service Committee, Christian Peacemaker Teams – the Aboriginal Justice Team, Council of Canadians, Earthroots, Greenpeace Canada, KAIROS: Canadian Ecumenical Justice Initiatives, Ontario Federation of Labour, Ontario Secondary School Teachers' Federation, National Indigenous Anglican Bishop.
f) River Run 2012. A press conference, public speaking event, fish fry, march, and rally in Toronto. Then minister of Aboriginal Affairs Kathleen Wynne comments on the logging-mercury problem on CBC The Current and commits to renew relationship with Grassy Narrows to "get it right."

g) River Run 2010. A press conference, public speaking event, march and rally in Toronto. Then premier Dalton McGuinty tells the Toronto Star that he has "a heavy responsibility" to get to the bottom of the scientific reports on the mercury problem in Grassy Narrows.

A partial list of instances in which we have raised broad concerns about clearcutting, sustainability, and threats posed by logging to our way of life and health is included (and in most cases hyperlinked) below:

i) Letter from Chief Simon Fobister to MNR Minister Gravelle, and MNR Regional Director, re: LTMD – December 19, 2011.

ii) Grassy Narrows letters to Minister Jeffery about the LTMD – March 17, 2010, August 17, 2011, and October 31, 2011.

iii) Grassy Narrows letters to MNR Minister Cansfield about the contingency plan – October 27, 2008, and January 2009.

iv) Ontario Minister of Environment to Ontario Minister of Natural Resources re: decision to reject Grassy Narrows' request for an individual environmental assessment of the Whiskey Jack Forest Management Plan 2002-2023 – August 31, 2005

v) Grassy Narrows trappers letter to Ontario Ministry of Natural Resources unanimously stating their concerns on logging practices on Grassy Narrows' land – March 15, 2002

vi) Joseph B. Fobister to Ontario Ministry of Natural Resources re: concerns with the Whiskey Jack Forest Management Plan 2004-2025 – March 21, 2002

vii) Joseph B. Fobister to Ministry of Natural Resources re: Abitibi has made no efforts to discuss their plans with the First Nation – March 8, 2000

viii) Joseph B. Fobister to Minsitry of Natural Resources re: I ask that your government stop violating the Treaty rights of the Grassy Narrows First Nation – March 7, 2000

ix) Grassy Narrows First Nation Environmental Committee to Ontario Ministry of the Environment expressing concerns with clearcut logging on their traditional land – June 17, 1999

x) Ontario Ministry of the Environment to Ms. Roberta Keesick and Ms. Judy DaSilva re: rejection of requested individual environmental assessment on the Whiskey Jack Forest Management Plan. May 19, 1999.

xi) Letter from Chief William Fobister Sr. Grassy Narrows First Nation to Honorable Robert Nault Member of Parliament, Kenora-Rainy River. Re: lack of meaningful response to letter to Minister of Indian Affairs, Minister of Natural Resources, and Minister of Environment regarding concerns about logging on Grassy Narrows' land – April 15, 1999.

xii) Grassy Narrows First Nation Chief and Councillors to Minister of Natural Resources and Minister of the Environment – January 8, 1999.

xiii) Grassy Narrows First Nations Member, Chrissy Swain, letter to Abitibi, criticizing how their logging has impacted her life. Date unknown.

7. Measures in the Logging Plan to Deal with the Mercury Problem

The logging plan text does not contain the word 'mercury.' The supporting documents for the logging plan also do not contain the word 'mercury.' There is no discussion of the context of elevated mercury levels and human health impacts in the planning area. There is no discussion of the known impacts of clearcutting on water quality, fish, and on human health. There is no discussion of measures to prevent the release of mercury into the local water and food chain. There is no discussion of how measures will be adapted to the unique local context of elevated mercury levels and consequent human health impacts.

There is no evidence that mercury issues were identified, evaluated, and addressed anywhere in the FMP. Harvesting methods, volumes, Area of Concern prescriptions, and other operational prescriptions appear to be largely the same as those used in other parts of the boreal forest in Ontario (see later sections for a discussion on their content and shortcomings).

In particular, the approved logging plan allows for activities that are likely to raise mercury levels including the following:

- use of clearcutting (for 100% of harvesting)
- extraction of large volumes of wood
- road building and creation of machine tracks
- extensive use of heavy machinery
- logging in close proximity to the shoreline and shoreline wetlands
- logging in close proximity to wetlands
- logging in close proximity to fish spawning areas and wetlands which drain into fish spawning areas
- logging in close proximity to moose aquatic feeding areas
- heavy machine operation in close proximity to the shoreline and wetlands
- extensive cutting close to the English and Wabigoon Rivers and their catchments
- cutting in the catchments of lakes, rivers, and streams used for fishing and trapping, and bodies of water that flow into them
- extensive cutting close to the reserve

The *Crown Forest Sustainability Act* and the *Forest Management Planning Manual* also

do not contain the word ‘mercury.’

The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scale* (Stand and Site Guide) contains no measures specifically designed to avoid mercury impacts from logging. It only mentions mercury in relation to logging in the section titled “What to evaluate - identifying key uncertainties” (Section 7.2 p.165, 166) [see appendix I for a full excerpt of the relevant text]

Here it asks the question of whether or not current forest practices “retain sufficient residual forest within catchments to ensure that hydrological effects resulting from forest management operations: i) do not exceed those observed in naturally disturbed catchments and ii) do not exceed acceptable levels for specific parameters (e.g. methyl mercury)?”

The Stand and Site Guide goes on to name a few current studies on the impacts of harvesting on water quality, nutrients, and flow in streams. However, it concludes by noting that the MNR considers these studies to be inadequate because “their ability to assess effectiveness of direction relative to emulation of natural disturbances is limited and this question should be a high priority for consideration within MNR’s effectiveness monitoring program.”

Thus, the Stand and Site Guide acknowledges that the MNR does not know whether current logging practices will elevate methyl mercury levels.

8. Stand and Site Guide Rationale on Mercury

The *Stand and Site Guide Background and Rationale for Direction* document (the rationale) contains a general discussion of the mercury impacts associated with logging under the heading of “Mercury and catchment-scale effects.” (p. 21-25) [see appendix II for a full excerpt of the relevant text]

The rationale can be summarized in three key points:

1. Logging is essentially equivalent to fire so attempts to emulate fire will eliminate Hg impacts.
2. Existing measures in the Stand and Site Guide implement sufficient mitigation measures. No additional mercury specific measures are required.
3. The MNR will monitor to see later if 1 and 2 above are not true.

We will summarize at greater length below.

After a discussion of some mercury sources and methylation processes the rationale states:

> Studies in Finland have shown that forest management activities can lead to an increase in the concentration of total mercury and MeHg in groundwater and surface waters (Munthe et al. 2007a, Povari et al. 2003, Povari and Verta 2003). Recent research conducted in Quebec has shown that mercury levels in periphyton, plankton, and fish in lakes within watersheds that have been disturbed by forest management activities or fire (sic) are higher than in undisturbed lakes (Garcia and Carignan 1999, 2000, 2005; Desrosiers et al. 2006).
>
> These results have raised concerns over the impact of forest management activities on mercury levels in aquatic systems and the potential risk this may pose to wildlife and humans consuming fish.

A following section is titled "Implications for direction in this guide." The statements in this section are summarized here, and then discussed in further sections.

The general mitigation approach is based on the concept of natural disturbance emulation and is summarized in the first sentence. "Removal of trees from catchments by timber harvest or wildfire is associated with generally similar changes in the hydrology, chemistry, and biota of lakes and streams."

The rationale argues that the cumulative effect of logging operations "will result in a level of catchment-scale disturbance that is within the range of that associated with natural disturbances. Thus, there is no additional fine filter direction prescribed to mitigate the general catchment-scale effects of timber harvest."

This conclusion was reached by comparing the size and shape of planned logging footprints to the size and shape of the pre-suppression natural disturbance footprint.

The potential for difference between the impacts of fire and logging is dealt with by pointing to the high priority research question noted earlier in Section 7.2 of the Stand and Site Guide.

Next the rationale states:

> There is fairly compelling evidence that timber harvest (and wildfire) results in an increase in the movement of mercury from

> terrestrial to aquatic environments where it may be converted to MeHg. Associated with this, there is a growing concern about the associated potential risk to wildlife and human health.

The rationale goes on to argue that mercury is transported bound to particulate organic matter and may be methylated in 'hotspots.'

It then claims that while there are no specific measures for mercury in the Stand and Site Guide, existing measures regulating site disturbance, hydrological disturbance, sedimentation, and buffers are sufficient to mitigate mercury impacts.

It concludes with a section justifying the elimination of catchment level disturbance thresholds that were in previous guides.

9. Fundamental Problems with MNR Rationale

A. Natural Disturbance Emulation Not Appropriate for Mercury Safety

SUMMARY

The first pillar of the MNR rationale is that boreal logging is designed to emulate natural disturbance, and in particular forest fire. Since logging is designed to emulate fire, it is claimed that the impacts will be similar to those that occur naturally in this ecosystem, and therefore they are acceptable.

However, when it comes to mercury, this argument is not borne out by the scientific evidence.

Logging and forest fire have nearly opposite impacts on mercury. While large fires remove mercury to the atmosphere, logging mobilizes mercury into local water bodies and increases the bio-accumulation of mercury in the aquatic food chain. Natural disturbance emulation does not prevent mercury impacts.

EVIDENCE

Forest removal by fire and harvesting has different effects on the physical and chemical properties of watersheds and lakes [11,19]. (Carignan et al., 2000, and Bormann and Likens, 1979, as cited in Garcia and Carignan, 2005)

"Concentrations of DOC, and light extinction coefficient tended to be highest in the forest harvested lakes, whereas concentrations of chlorophyll a, SO^{2-}_4, total P, and total N generally were the highest in the fire-impacted group. (Garcia et al., 2007)

The different physical and chemical effects of fire and logging on lakes have different impacts on fish habitat and lead to different impacts on mercury levels in fish.

"Contrary to forest fires, clear-cut logging results in increased MeHg accumulation in aquatic organisms." (Garcia et al., 2007)

In summary, "fish from lakes with harvested catchments tended to show higher total mercury (Hg) levels relative to fire-impacted and undisturbed lakes. (Garcia and Carignan, 2000, 2005, as cited in Garcia et. al., 2007)

Two studies "compared effects of wildfire and clear-cut logging on MeHg in zooplankton and on total Hg in northern pike (*Esox lucius*), a top predatory fish [8.9]. Those results showed that high MeHg and total Hg were associated with clear-cut logging but not with wildfires." (Garcia and Carignan, 1999, 2000, as cited in Garcia and Carignan, 2005)

In a third study "Hg concentrations exceeded the advisory limit for human consumption (0.5 ug/g wet wt) from the World Health Organization in all top predatory species (northern pike, walleye, and burbot) found in cut and two partially burnt lakes." (Garcia and Carignan, 2005)

"This limit was surpassed in only 18% of piscivorous species populations found in reference lakes and in no species from completely burned lakes." (Garcia and Carignan, 2005)

A similar trend has been documented lower in the food chain in zooplankton. (Garcia and Carignan, 1999)

"High MeHg and total Hg were associated with clear-cut logging, but not with wildfires." (Garcia and Carignan, 1999, 2000, as cited in Garcia and Carignan, 2005)

While one study found that fish had elevated mercury levels in two lakes that experienced small fires, this finding is of limited relevance. The large majority of the area impacted by fire in Ontario in a natural fire regime is impacted by large fires, which have been found not to significantly raise mercury levels in fish compared to undisturbed reference lakes.

"Fires greater than 200 ha represent 97% of the area burned." (NOAA National Severe

Storms Laboratory, as cited in MNR FireSmart Questions and Facts – Fire Ecology Facts on www.mnr.gov.on.ca/en/Business accessed on January 8, 2014)

There are plausible theories that explain the observed difference in mercury impacts between logging and large forest fires. They include:

"In clear-cut areas, the organic soil is preserved, whereas intense fires tend to mineralize this layer. Therefore, higher DOC concentrations in cut lakes could explain the higher Hg levels observed in fish sampled in these lakes." (Garcia and Carignan, 2005)

"[D]uring high-intensity fires, most of the inorganic Hg pool in the soils could be reduced to Hg^0 and emitted to the atmosphere [7]." (Sigler et al. 2003, as cited in Garcia and Carignan, 2005)

"Alternatively, the high phytoplankton biomass observed in the studied burnt lakes (Planas et al., 2000) may have caused a biological dilution of the available Hg (Pickhard et al., 2002)." (Garcia et al., 2007)

The scientific evidence clearly shows that clearcutting and natural fire disturbance have dramatically different impacts on mercury in fish. Clearcutting increases mercury levels in fish, often above the level for safe human consumption.

On the other hand, 97% of the fire impacted landscape is subject to large fires which have been found not to increase mercury levels in fish significantly. In fact, intense fire may be a major pathway for mercury out of boreal watersheds and back into the atmosphere.

Current fire suppression has altered the fire interval from a historical range between 20 and 100 years to a current interval estimated at over 560 years. (MNR FireSmart Qustions and Facts- Fire Management Facts, www.mnr.gov.on.ca/en/Business/AFF accessed on January 8, 2014). Logging and fire suppression is planned for approximately 95% of the productive Crown forest in the Whiskey Jack.

The MNR may argue that while clear-cutting does not effectively emulate large natural fires when examining mercury impacts on fish, natural disturbance emulation remains the best approach due to its other claimed desirable benefits. The larger question of the ecological efficacy of natural disturbance emulation is beyond the scope of this request. The ECO calls natural disturbance emulation "a massive experiment on public lands." (Environmental Commissioner of Ontario. 2002)

Regardless of how this question is answered for other parts of the Province, in Grassy Narrows, where fish are known to currently have critical levels of mercury that are impacting human health, the mercury impacts of logging must take precedence over other perceived benefits/considerations.

CONCLUSION

Replacing fire with clear-cutting on the landscape will dramatically increase mercury levels in fish. It will also likely eliminate an important natural pathway for mercury out of the watershed.

B. Mitigation Science is Not Sufficiently Developed

SUMMARY

The second pillar of the MNR rationale is the claim that pre-existing measures, which were not designed with mercury issues in mind, happen to constitute effective mitigation measures. While there are no forestry regulations that explicitly deal with mercury, the MNR rationale claims that "there are many pieces of direction in the guide that will address these [mercury] concerns… Thus, there is no [measure] prescribed to mitigate the catchment-scale effects of timber harvest on mercury export."

EVIDENCE

Most fundamentally, this argument depends on the existence and implementation of proven mitigation measures to prevent mercury export and bioaccumulation. However, the science behind mercury mitigation is undeveloped. We know of no peer reviewed scientific journal articles that experimentally test and evaluate mitigation measures for mercury and logging.

There is one journal article exploring best practices. Due to the lack of studies on these processes in forest soils the article engages in a theoretical discussion based on findings from sediments and wetland soils. It notes that "[t]hese theoretical discussions, however, need to be verified by experiments both in the field and in the laboratory." (Bishop et al., 2009)

The article makes a number of other cautionary statements about mitigation measures:

"An understanding of the process controlling the output of Hg from catchments to surface waters, and subsequent bioaccumulation, is not sufficiently developed to confidently recommend ameliorative measures for forestry." (Bishop et al., 2009)

"[T]here is an urgent need to advance our understanding of the way in which forestry influences the cycling of Hg, and its bioaccumulation in aquatic ecosystems." (Bishop et al., 2009)

While there is clear experimental evidence that logging elevates mercury levels in fish above safe levels, there are no experimentally tested or proven mitigation methods. Therefore there is no experimental scientific evidence supporting the MNR claim that their mitigation measures will work.

To the contrary, studies in Quebec which identified the logging-mercury problem examined clear-cuts which included many of the measures that the MNR is currently claiming as mitigation measures. Those clear-cuts "were of the CPRS type (cut with protection of regeneration and soils). Cut block size generally ranged from 5 to 50 ha but occasionally reached 200 ha, with 20-m buffer strips fringing permanent streams, lakes and wetlands." (Garcia et al., 2007) This suggests that measures similar to those in the logging plan, which are intended to avoid site disturbance, hydrological disruption, and sedimentation are not sufficient to avoid mercury impacts.

While the existence of the mercury problem is relatively straightforward to identify, understanding the mechanisms that underlie it is a far more complex, and relatively unstudied, problem. Once the mechanisms are understood, developing and testing effective methods to mitigate against those impacts is a further complex problem that has received no published scientific experimental attention.

Given the multi-variate complexity of forest and aquatic ecosystems, and the added complexity of their interactions, our predictive capabilities in this system are currently limited to non-existent. The claim that current mitigation methods will work is an educated guess at best.

CONCLUSION

The MNR claims to be mitigating the dangerous bioaccumulation of mercury using measures for which there is no experimental evidence. This approach does not meet the standard that requires the Minister to be reasonably "satisfied that the plan provides for the sustainability of the Crown forest, having regard to the plant life, animal life, water, soil, air and social and economic values, including recreational values and heritage values, of the Crown forest. (CFSA 1994, c. 25, s. 9 (2))"

The question of whether the measures are consistent with the limited theoretical conjecture on mitigation best practices will be discussed later.

C. Log Now, Test Later Approach.

SUMMARY

The third pillar of the MNR rationale is that mercury export is specifically identified in Section 7.2 of the Stand and Site Guide as a priority for effectiveness monitoring. The MNR contends that if the current measures (natural disturbance emulation and mitigation through existing practices) do not work sufficiently, this will be determined by effectiveness monitoring.

DISCUSSION

There are a number of problems with this approach:

1. Mitigating a scientifically known problem with untested measures does not solve the problem with any reasonable degree of confidence (See section 9B above re: Mitigation Science is Not Sufficiently Developed). This is not an acceptable approach when dealing with a neurotoxin in an area with a history of contamination and ongoing human health impacts.
2. The planned mitigation measures do not comply with theoretical best practices, and there are clear deficiencies in the planned mitigation measures that indicate that they are unlikely to succeed. (see Section 9A above re: Natural Disturbance Emulation Not Appropriate for Mercury Safety and Sections 12, 13 below).
3. The MNR presents no details about the monitoring effort. When will it be done? Where will it be done? How will it be done? Who will do it? When will the results be peer reviewed and published? How will the results influence logging practices and how will this be determined? If the monitoring identifies that the current measures are insufficient, when will new measures come into effect?
4. The monitoring of mercury impacts was given a high priority by the MNR in the Stand and Site Guide in 2010. And yet there is no discussion of the preliminary results of this monitoring in the logging plan. It appears that this monitoring program has not informed the logging plan in any way. We ask for a report on the current status of this high priority monitoring program now, 3.5 years after the MNR identified it as a priority.
5. The mercury impacts of clearcutting need to be studied over time in order to be understood. The scientific process of study design, implementation, analysis, review, and reporting also takes time. It could easily take a number of years for monitoring to determine whether current mitigation measures are effective. Throughout that time more mercury will likely continue to be added into the food chain in Grassy Narrows through clearcutting. The health impacts of this neurotoxin are irreversible and can have life-long impacts on fetuses and children.
6. If monitoring reveals that current measures are insufficient, then new mitigation measures would presumably be introduced. Those mitigation measures may also be untested and unproven, but the MNR would identify monitoring of those measures as a high priority. Another long, but unspecified, amount of time may pass before it becomes apparent whether those measures are effective. Mercury could be added to

> the food chain by logging for another long period of time, and this could be repeated indefinitely through multiple iterations of the log now and test later rationale.

This approach is particularly unacceptable in the specific circumstances of Grassy Narrows and methyl mercury poisoning.

CONCLUSION

The MNR provides no scientific experimental evidence that their mercury mitigation measures are effective. Instead, they say that they will monitor to test this, while providing no details about this monitoring program. This "log now, test later" approach is likely to lead to increased bioaccumulation of mercury in Grassy Narrows' food chain with serious and long-lasting impacts (see section 11 below re: Duration and Intensity of Impacts).

10. Delay and Hardship

The MNR and the logging industry may argue that they cannot afford to wait for proven mitigation methods. The argument that honouring Grassy Narrows' human rights would cause the logging industry to suffer hardship has been used to trump Grassy Narrows' concerns repeatedly, including in the rejection of the 1999 request for IEA.

The long term trend of prioritizing industrial interests at the expense of Grassy Narrows has had devastating consequences. It has led to a compounding series of harmful actions imposed on Grassy Narrows including the damming of their river to supply power for the logging and mining industries, the dumping of 20,000 pounds of mercury into their river by a paper mill, and the clearcutting of their forests. The cumulative impact of these decisions has placed the health, culture, livelihood, and rights of Grassy Narrows in a degraded and precarious position where the impacts of further harm are likely to be magnified, intense, and long lasting.

Beyond this, we argue that all regional mills could have their real wood supply needs met without the use of wood from Grassy Narrows Territory. This has largely been the case since June 2008, so granting our request would preserve the *status quo*, not upset it.

Rainforest Action Network and the Wildlands League have prepared two reports that support our assertion on the existence of a long-term alternative wood supply by analyzing the MNR's own public wood supply data. The Kenora Daily Miner and News reported in 2008 that:

> [while] forest industry liaison for Thunder Bay Region, Pat Corbett, agreed with the general thrust of a report from environmentalists about area wood supplies, he didn't necessarily agree with their conclusions. "I've seen the RAN report," he said, of the Rainforest Action Network

> report that asserts there is enough wood to supply Kenora mills without infringing on the Grassy narrows traditional lands. “Essentially, the theme is correct. It’s just a matter of can Weyerhaeuser afford to transport the wood (to its iLevel plant in Kenora).”

The report only examined wood supplies that are within a hauling radius from Kenora that is similar to hauling distances from within the Whiskey Jack Forest. These hauling distances are significantly shorter than the distance from the Whiskey Jack Forest to Fort Frances, a hauling route that was previously in heavy use. Therefore, utilization of alternative supplies should result in only minor increases in hauling costs, if any, that are within the range commonly used in the region.

The impacts of incremental increases in hauling costs pale in comparison to the multi-generational impacts of mercury poisoning in Grassy Narrows. If the question of comparative impacts and alternative wood supply is taken up by the MOE we have further information to supply on this matter.

On the issue of delay the MNR and the logging industry are the authors of their own misfortune because they have chosen not to deal meaningfully with this problem for 17 years.

“The potential role that forest management has in the Hg problem throughout [the boreal] region was identified over a decade ago, particularly the need to define and evaluate the prospective management alternatives, such as riparian buffer zones, that might mitigate the enduring threat posed by Hg output from catchment soils to surface waters (11).” (Bishop et al., 1997 as cited in Bishop et al., 2006).

Given that the problem was identified, and published, in 1997, the MNR and the logging industry have had ample time to study the problem and to test mitigation measures experimentally. The Government of Ontario and the logging industry have ample resources at hand to support academic research on this question if they choose to.

Instead, discussion of mercury first appeared in forestry guidelines in Ontario in 2010, 13 years after the problem was identified. This discussion introduces no new measures to mitigate mercury impacts, but rather mandates the use of pre-existing forest practices. To make matters worse, the new guidelines are likely to be even less effective at mitigating mercury impacts than previous guidelines because they weaken protections by allowing logging to the shoreline and by removing catchment disturbance thresholds (see Sections 12A and 12B below). Given that the MNR's claimed mitigation practices were pre-existing, there is no reason that their efficacy could not have been tested previously.

In addition, Grassy Narrows has requested for many years that the government of Ontario fund the establishment of a permanent environmental health monitoring station in Grassy Narrows. This would have allowed Grassy Narrows to collaborate with academic experts

to engage in monitoring and study that could have shed light on these questions. However, those requests have never been answered.

Ontario, the MNR, and the logging industry chose not to monitor the impacts of logging practices on mercury for over a decade after the problem was identified. So they have only themselves to blame for the current lack of experimental evidence supporting their claim that Ontario's forest practices prevent mercury impacts. Grassy Narrows should not pay with their health for Ontario's failure to study solutions to this problem.

11. Duration and Intensity of Impacts

SUMMARY

If further clearcutting is allowed without proven mitigation measures, and methyl mercury levels in local fish are elevated as a result, the impacts would likely be grave and long lasting.

EVIDENCE

Clear-cutting has been found to increase MeHg bioaccumulation in boreal lakes by two- to four fold, and sometimes as much as eight fold. (Bishop et al., 2009)

Scientists estimate that as much as 37% of the Hg in fish across a managed forest landscape would result from the increased Hg outputs associated with felling and thinning. (Bishop et al., 2009)

The MNR claims that "the transitory effects of both fire and harvesting on water quality appear to have limited impact on fish assemblages (St. Onge and Magnan 2000; Steedman 2003; Tonn et al. 2003, 2004)." (Stand and Site Guide Rationale, p.104)

This conclusion appears to be false when it comes to mercury.

The impacts of clearcutting on mercury have been found to persist for at least five years, with no known end point.

"The Hg in fish higher in the food chain continued to increase several years after the harvest." (Garcia and Carignan, 2000, 2005, as cited in Bishop et al., 2009)

"The increased Hg loading effect has also been observed to persist up to at least 5y, and

there are no examples so far of the logging effect having dissipated." (Bishop et al., 2009)

For the purposes of extrapolation Bishop et al., 2009 estimate that logging impacts on mercury will last a decade.

It has been found that the effects of clearcutting alone are often sufficient to raise mercury levels in fish above the limit for safe human consumption. (see Section 2 above re: Logging Elevates Mercury Levels in Fish) It is also known that mercury levels in lakes and rivers in Grassy Narrows Territory are already at, or near the safety limit. (see Section 4 above re: Fish in Grassy Narrows Have Critical Levels of Mercury)

Therefore logging is likely to:

i) Further elevate the mercury level in fish in previously contaminated lakes.

ii) Prolong the length of time for which fish in previously contaminated lakes remain unsafe to eat.

iii) Elevate the mercury levels in fish in marginally safe lakes above the safety limit.

iv) Elevate mercury levels in fish in currently safe lakes above the safety limit.

Clearcutting leads to higher Dissolved Organic Carbon (DOC) compared to reference lakes and burned lakes. (Garcia and Carignan, 2005) In addition to acting as a vector of Hg from terrestrial to aquatic ecosystems (Kalbitz et al., 1998), DOC also:

a) stimulates bacterial methlyation of Hg; (Matilainen, 1995)

b) decreases MeHg photodegradation; and (Sellers et al.,1996)

c) possibly decreases the photoreduction of Hg (II) to Hg(0) in lakes. (Haines et al., 1994)

(all as cited in Garcia and Carignan, 2005)

Effects b) and c) are likely due to lower light penetration associated with higher DOC.

This means that clearcutting in Grassy Narrows' English-Wabigoon River watershed may have even greater impacts on fish mercury levels than in areas previously studied, which have no historical point source of contamination.

Approximately 20,000 lbs of mercury were dumped into the Wabigoon River by a paper mill at Dryden between 1962 and 1970. (Hutchison, 1977) This dumping occurred with the permission of the government of Ontario. No clean-up has been attempted. (Neff et al., 2012)

Sediment studies show that the English-Wabigoon river system continues to have mercury levels in sediment that exceed background levels, and in some locations, continue to increase. (Sellers, 2011) If logging exports DOC into these water bodies it will not only transport new mercury and methyl mercury into the water, it may also intensify the impact of pre-existing mercury contamination by increasing the rate at which it is methylated, decreasing the rate at which existing MeHg is photodegraded, and decreasing the rate at which existing Hg(II) it is photoreduced.

It is well known that people in Grassy Narrows continue to eat the fish in their territory, with a focus on walleye, as part of their subsistence, culture, and the exercise of their inherent, Aboriginal and Treaty rights. (Comments by Wynne on CBC radio 2012, Scars of Mercury movie, CBC The National 2010)

There is clinical evidence that Minamata Disesase is impacting people born long after the historic point source contamination was terminated. And there are indications that congenital Minamata Disease may continue to afflict children born in Grassy Narrows today. (Harada et al., 2005, 2011) (see Section 5 above re: Mercury Health Impacts in Grassy Narrows)

Therefore it is likely that mercury released, or methylated, through the impacts of clearcutting in Grassy Narrows will:

i) bio-accumulate in fish which are eaten by people in Grassy Narrows;

ii) intensify health impacts in people already suffering from mercury-related health problems in Grassy Narrows;

iii) contribute to causing new health impacts in currently health people in Grassy Narrows;

iv) contribute to causing congenital mercury poisoning in fetuses; and

v) reduce the number and/or proximity of lakes with safe fish which some Grassy Narrows people can access.

As previously discussed, methyl mercury is a potent neurotoxin, and may also impact the cardiovascular system, the immune system, the kidneys, (Environmental Commissioner, 2009) mental health, and other aspects of human health.

The human health impacts of mercury are mostly permanent, cumulative, and irreversible.

CONCLUSION

The impacts of releasing mercury into the environment in Grassy Narrows through clearcut logging are likely to last at least a decade in fish, and at least one human lifespan beyond that in people.

12. Changes to Guidelines Are Likely to Make Mercury Problem Worse.

A. Logging to the Shoreline

SUMMARY

Current Areas of Concern prescriptions for lakes are weaker than the previous prescriptions and allow logging to the shoreline. These Areas of Concern prescriptions are likely to allow impacts including transport of DOC, as well as increased wind exposure. These contribute to MeHg bioaccumulation.

EVIDENCE

Riparian buffers are one measure that is hypothesized to help mitigate mercury impacts. (Bishop et al, 2009)

Previously, Areas of Concern for lakes required that vegetation on shorelands be maintained, leading to no-cut reserves generally between 30m and 90m in width (and sometimes greater to reduce the risk of blowdown). (Timber Management Guide for the Protection of Fish Habitat (TMGPFH), 1988 P.10) These reserve widths were based on recommendations to prevent watercourses from input of sediment. (TMGPFH, 1988 P.10)

This Area of Concern design preceded identification of mercury problems and did not take into account a number of relevant factors that we now know are likely important for preventing unacceptable levels of mercury transport and methylation. These include:

i) The buffer widths are based on preventing the flow of sediment into watercourses. However, dissolved organic carbon (DOC) is a primary vector for mercury export and catalyst for methlyation due to clearcutting. DOC does not appear as particulate matter. It is generated through different processes, and travels differently. In particular DOC can be carried in sub-surface flows.

ii) The buffers are narrowest for low slopes, and widest for steep slopes. Mercury research would suggest the opposite. Mercury impacts are inversely correlated with catchment slope. (Desrosiers et al., 2006)

iii) There is no evidence that these buffer widths are sufficient for mitigating MeHg bioaccumulation.

Point ii) above is contrary to specific recommendations made in the scientific literature. Desrosiers et al., 2006 write:

> Before government permits are issued to forestry companies, authorities should seriously scrutinize the watershed morphometric characteristics, particularly its slope. Our study suggests that lakes within watersheds that have a mean slope under 7.0% are much more sensitive to logging, even if a small relative area of the watershed is cut."

Rather than updating these Areas of Concern prescriptions to reflect the current state of mercury science, the changes in the new Stand and Site Guide introduced in 2010 make them even weaker, and less likely to sufficiently mitigate mercury impacts. These counter-effective changes include:

i) allowing logging within shoreline Areas of Concern, including logging up to the shoreline. This approach is likely to increase both sediment and DOC flows. It is also likely to increase wind exposure which effects thermal stratification, dissolved oxygen concentrations, and ultimately fish habitat (Garcia et al., 2007);

ii) allowing road building and machine tracks within shoreline Areas of Concern. Machine tracks have been found to dramatically increase mercury export (Munthe et al., 2004);

iii) weak, aspirational conditions on identifying and protecting hydrological connections, including ephemeral streams, seeps, and springs (see Section 13 below re: Specific Deficiencies in MNR Mitigation Measures);

iv) weak conditions on protection for likely methylation hotspots including wetlands, and logging the entire shoreline of some woodland pools and ponds;

v) retention of the direct correlation between slope and Area of Concern width.

These changes are justified using the logic of natural disturbance emulation, which does not work for mercury mitigation (see Section 9A above re: Natural Disturbance Emulation Not Appropriate for Mercury Safety).

The changes are likely to make mercury impacts from logging more intense than under the previous guidelines.

"Forest removal, for example, may increase wind exposure, alter water clarity and decrease light penetration in lakes, therefore affecting thermal stratification, dissolved oxygen concentrations, and ultimately fish habitat." (Steedman & Kushneriuk, 2000; Scully, Leavitt, & Carpenter 2000, as cited in Garcia, Carignon, & Lean 2007)

It appears that the purpose of the Areas of Concern has been turned on its head. Instead of being designed to confidently protect water quality and fish habitat it is now designed to emulate natural disturbance on the false assumption that habitat protection will flow from this.

It appears that any references to the Areas of Concern in the mercury rationale are after the fact attempts to dress up measures that were developed without mercury mitigation in mind.

CONCLUSION

A number of important Areas of Concern prescriptions for water bodies are less likely to sufficiently mitigate mercury impacts on water quality and fish than previous prescriptions that were designed without any consideration for mercury.

B. Catchment Disturbance Thresholds Removed

SUMMARY

The *Forest Management Guide for the Protection of the Physical Environment* (OMNR 1997) included a general rule that no more than 50% of a second order watershed be harvested in a 10 year period. This direction was not included in the new Stand and Site Guide. The MNR rationale explains that it was dropped because it was deemed arbitrary, ineffective, unnecessary, and conflicting with principle of natural disturbance emulation.

EVIDENCE

Earthroots agrees that the 50% figure for catchment disturbance threshold is arbitrary, but we generally reach opposite conclusions from the MNR based on the scientific literature on MeHg bioaccumulation. We argue that the disturbance threshold likely needs to be made much stronger.

The MNR rationale notes that "changes in the communities of some biota, such as benthic invertebrates, have been detected in streams associated with <25% catchment disturbance (Martel et al., 2007, Kreutzweiser et al., 2008a)."

One study suggested that "lakes with watersheds that have mean slopes less than 7.0% are much more sensitive to logging, even if a small relative area of watershed is cut. For example, the MeHg concentration in periphyton of [lake] K3 increased 9.5- fold when only 26% of the watershed was logged." (Desrosiers et al., 2006)

Another study found "a significant correlation between MeHg in zooplankton and deforested catchment area (DEF) normalized to lake volume (VOL) in forest harvested lakes…" (Garcia et al., 2007)

The DEF:VOL ratio has been shown in turn to explain 86% of the variability of DOC in forest harvested lakes (Carignan et al., 2000)." (Garcia et al., 2007)

We briefly discuss each of the MNR's key points in the rationale below:

a) **MNR:** It is difficult to determine what the appropriate geographic response unit is.

Earthroots: For headwater lakes it is easy to determine the appropriate geographic response unit. Clearly, it is their catchment area.

For other bodies of water the answer to this question can be determined experimentally through the use of methods including isotope tracking and/or or pre and post-logging monitoring experiments.

b) **MNR:** Different catchments show hydrological responses at different levels of disturbance.

Earthroots: This may be true, but it does not justify the removal of any threshold whatsoever. The complexity of this question should give rise to caution, not the abandonment of the duty to sustainability.

The DEF:VOL ratio appears to be key to explaining the extent of mercury impacts in logged lakes (including DOC export and MeHg in zooplankton).

This implies that catchment disturbance level thresholds may be important to preventing mercury impacts.

There is also evidence that mean watershed slope plays an important role.

c) **MNR:** A hydrological response is not necessarily negative as the response (e.g., increased water yield) is often consistent with a naturally disturbed system.

Earthroots: As discussed earlier hydrological responses in logged catchments lead to mercury levels in fish above the limit for safe human consumption. This is clearly negative.

This is not consistent with natural disturbance due to fire (see section on Natural Disturbance).

d) **MNR:** Current logging guidelines are expected to produce a natural pattern of disturbance (and retention) at multiple scales.

Earthroots: Natural disturbance emulation is not a valid approach to mitigating MeHg bioaccumulation. (see Section 9A above re: Natural Disturbance Emulation Not Appropriate for Mercury Safety)

e) **MNR:** The 2nd order catchment rule has the potential to be contradictory to the CFSA's principle of emulating natural disturbances and landscape patterns.

Earthroots: The CFSA's primary principle is sustainability including regard to water quality and fish. Natural disturbance emulation is only valid insofar as it achieves sustainability.

CONCLUSION

The scientific literature supports the common sense inference that logging a larger portion of a catchment will have a larger impact on the mercury problem. The removal of this threshold is likely to lead to mercury impacts of a greater magnitude than before. Rather than removing the threshold, the threshold should be strengthened to a level that can be experimentally proven to prevent MeHg bioaccumulation with a high degree of confidence.

13. Specific Deficiencies in MNR Mitigation Measures

SUMMARY

The measures identified in the Stand and Site Guide Rationale for mercury mitigation are inadequate and do not even meet theoretical best practices. The Stand and Site Guide:

i) contains no measures designed to mitigate mercury impacts, it simply points to existing measures that were designed for other purposes;

ii) only points to measures that address a small subset of the mechanisms theorized to underlie the mercury problem;

iii) contains measures that are weak, open to wide discretion, and often lack numerical limits;

v) iv) offers no experimental evidence that these measures work for mercury (see section 9B above re: Mitigation Science Not Sufficiently Developed); and significantly weakens key measures from previous guides (see sections 12A and 12B above re: Logging to the Shoreline, and Catchment Disturbance Thresholds Removed, respectively).

DISCUSSION

The MNR rationale claims that no specific mercury related measures are needed because existing pieces of direction happen to deal with mercury concerns.

The Rationale section on "Implications for direction in this guide" identifies two potential mechanisms of the mercury problem:

a. Mercury export bound to particulate organic matter; and
b. the creation of methylation 'hotspots'.

However, these two potential mechanisms are only a small subset of the mechanisms that

mercury mitigation theory identifies. Notably, the mercury rationale "Implications for direction" makes no mention of the role of dissolved organic matter (DOM) and raised groundwater tables which are thought to be key to the transport and methylation of mercury after logging.

Bishop et al, 2009 summarize that "the key processes by which clear-cutting and thinning operations may enhance mobilization of Hg/MeHg and production of MeHg are:

i) raising the groundwater table to surface horizons with a high potential for MeHg production;
ii) increasing output of easily degradable plant debris;
iii) increasing DOM concentrations in soils and runoff;
iv) increasing inorganic sulfide concentrations in soils; and
v) changing the biogeochemical input lakes, which has complex limnological implications including changes in the biomagnification of Hg.

Next, the Rationale "Implications for direction" names broad sections of the Stand Site Guide that the MNR claims will mitigate the two mercury mechanisms that they list. Those measures are:

i) reduce the creation/mobilization and transport of particulate matter (S5.2, S4.1, S45.1;
ii) maintain hydrological function and connectivity (S5.2, S3.2, S4.1); and
iii) minimize disturbance of potential methylation 'hotspots' (S.32, S4.1).

However, these measures were not designed with mercury mitigation in mind. Most are based on previous measures that were developed to prevent sedimentation before the identification of the logging mercury problem. Where the measures have been updated they have generally been weakened in order to emulate natural disturbance (see sections 12A and 12B above re: Logging to the Shoreline, and Catchment Disturbance Thresholds Removed, respectively).

No experimental evidence is presented to support the assertion that these measures will effectively prevent mercury impacts.

While some of the measures partially address some activities that may contribute to the mercury problem (like soil rutting, compaction, hydrological disruption), they are often weak, not compulsory, lack quantitative measures, and leave large amounts of discretion in their application. When dealing with some practices that are likely to have significant impacts (eg. building roads through organic soils) the guide only requires that loggers

"explore alternative options" or "take reasonable precautions." These provide no assurance that mercury impacts will be avoided, even in activities that the MNR acknowledges are likely to contribute to the mercury problem.

A non-exhaustive list of problematic examples includes:

i) S5.1 Allows for road building in water bodies and in wetlands.

ii) S5.1 Provides direction for roads to "avoid recognizable ephemeral streams, springs, seeps, and other groundwater discharge areas" many of which are unmapped. However, the rationale acknowledges that "not all springs, seeps, etc. will be recognizable in all operating conditions (e.g. deep snow)." Further, logging greatly increases water fluxes and so areas that may not be recognizable as hydrologically important during low-flow operating periods may become important post-logging.

iii) S5.2 allows for up to 10% of a cutblock to be rutted by machines. Only ruts deeper than 30 cm and longer than 4 m are counted.

iv) S5.2 places no numerical limits on mineral soil exposure and erosion in cutblocks.

v) S4.1 allows logging to the shoreline of lakes.

vi) S4.1 allows for logging of the entire shoreline of some ponds.

vii) There are no thresholds for catchment level disturbance.

viii) The widths of buffers on water bodies are directly proportional to shoreline slope, while mercury impacts appear to be inversely proportional.

The Stand and Site guide acknowledges that these measures may not be sufficient in some circumstances and leaves room for the planning team to develop protective measures to deal specifically with local conditions.

For example:
"Roads may also have an effect on other values, features, or resources that may require the implementation of specific mitigation techniques not provided by this section of the guide… In some situations, appropriate mitigative measures may have to be developed by the planning team." (Stand and Site Guide Rationale section 5.1 p. 493)

However, the logging plan contains no discussion about whether additional mitigation measures are required for roads and machine tracks in the Whiskey Jack area due to the mercury problem and the known impacts of machine tracks on mercury export. It appears that no additional measures are included in the logging plan.

The Rationale also admits that the "choice of harvesting and logging system will affect the degree of risk of erosion. Generally speaking, clearcutting and full tree harvesting

present a greater risk than does partial harvest and cut-to-length logging... The removal of competing vegetation can also prolong the time period during which the site is at an elevated risk."

However, the logging plan makes exclusive use of the clearcutting harvest method and explores no silvicultural options other than clearcutting.

CONCLUSION

The mercury mitigation measures in the FMP, if any, appear to be based on those identified in the Stand and Site Guide Rationale's "Implications for this guide." Those measures are incomplete, weak, and unproven. They cannot be relied upon to prevent elevated mercury levels in fish with any reasonable degree of certainty.

14. Need for an Individual Environmental Assessment

Grassy Narrows and Earthroots submit that an IEA is necessary for a number of reasons. The *Environmental Assessment Act* has a broader mandate than the *Crown Forest Sustainability Act*.

The purpose of the *Environmental Assessment Act* is the betterment of the people of the whole or any part of Ontario by providing for the protection, conservation and wise management in Ontario of the environment. R.S.O. 1990, c. E.18, s. 2. Environment is defined broadly under the Act to include the natural environment, plant and animal life, as well as "human life". The *Crown Forest Sustainability Act* is principally focused on sustaining the Crown forests to meet social, economic and environmental needs of present and future generations. Its focus, and what it requires of forest management plans, is protection of "Crown forest health", not on preventing potential adverse human health impacts.

This request raises substantive evidence that the Whiskey Forest Management Plan 2012-2022 does not protect, conserve, and wisely manage the environment in that part of Ontario. Most gravely, the implementation of the plan is likely to have irreversible neurological impacts on people in Grassy Narrows by prolonging and deepening the mercury problem.

The original mercury tragedy in Grassy Narrows was one of the crises that gave rise to the *Environmental Assessment Act*. The local history of contamination, and its ongoing impacts, requires that the highest duty of care be exercised in decisions that may harm the health of the environment and the people in Grassy Narrows.

The oversight provided by an Individual Environmental Assessment (IEA) is necessary as part of the process of ensuring that mistakes of the past are not repeated at the expense of the environment and people in Grassy Narrows.

An IEA is also necessary because a number of conditions in the Declaration Order have not been complied with. These include:

a) Public consultation. (Dec. Order section 63, p.9)

This condition requires that the MNR respond to all public comments with an explanation of the results of consideration of the comments.

No response to Earthroots' comments has been received, and many of Grassy Narrows' comments have received no response. No response has been given to the nearly 2,000 members of the public who commented in opposition to the logging plan.

b) S18. Areas of Concern. (Declaration Order section 18, p. 20-22)

This condition requires that Areas of Concern be developed for values that may be impacted by forest management. Where standard Areas of Concern are not sufficient this condition provides for the development of new, science based, Areas of Concern to deal with local conditions.

The measures in the standard Areas of Concern are not sufficient to prevent the elevation of mercury levels in fish. The logging plan fails to develop new Areas of Concern that recognize the local context of the mercury problem.

The Areas of Concern prescriptions fail to protect the values of water quality, fish habitat, wildlife health, and fishing for recreation, subsistence, commerce, and the exercise of Aboriginal and Treaty rights.

c) Monitoring program

i) Provisions for monitoring operations shall be prepared and documented, and shall include specific provisions for monitoring operations in Areas of Concern. (Declaration order Section 31 a) i))

The plan contains no provisions for monitoring whether operations in Areas of Concern will elevate mercury levels in fish.

> ii) Scientific monitoring program to assess effectiveness of guides. Progress should be reported on in annual report. (Declaration Order section 31, p.31)

The most recent annual report that is publicly available is for 2009/2010. It makes no mention of the mercury problem.

> iii) Annual report should include summary of significant advances in scientific research

(Declaration Order, section 32 b) xi))

The most recent annual report that is publicly available is for 2009/2010. It makes no mention of the mercury problem.

> iv) State of the Forest report should include summary of significant advances in forest research, and a discussion of how the results are being incorporated into forest management. (Declaration Order section 33 b) ii))

The most recent State of the Forest report that is publicly available covers the period April 1, 2004 to March 31, 2009. The report, and its supporting documents, contains no instances of the word 'mercury'. Thus it fails to summarize and discuss the incorporation of significant advances in forest research on mercury including Garcia et al., 2007, Desrosiers et al., 2006, and Bishop et al., 2009.

The State of the Forest report section on Criterion 3 "Protecting and Conserving Ontario's Forest Soil and Water Resources" which includes "Guidelines for Protecting Water Quality" and "Guidelines for Protecting Fish Habitat" notes that:

> The data for most of the indicators were assessed as inadequate. Data quality limited the evaluation of many of the indicators, all of which are indirect or proxy indicators. Direct monitoring methods are too intensive and costly for operational-level monitoring. During the reporting period, no province-wide standards existed for evaluating soil and water conservation. Standards are now included in the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (2010). (State of Ontario's Forests, 2012, p. 54)

Since there are no provincial Annual Reports or State of the Forest reports since the new Stand and Site Guide was released in 2010, there appears to be no public discussion of new science, new monitoring efforts, or how their results are being incorporated into forest management since 2010. There appears to be no public information available on the monitoring outlined in section 7.2 of the Stand and Site Guide.

The logging plan itself also fails to discuss advances in mercury science, monitoring efforts, and how their results are being incorporated into the plan.

"MNR says that if monitoring or feedback from those using the Guide suggests that there are significant and unmanageable economic, ecological or social impacts, consideration will be given to a review and possible revision of the Guide before the normal five-year review." (Environmental Commissioner of Ontario, 2002)

However, feedback from Grassy Narrows and Earthroots suggesting that there are significant and unmanageable ecological and social impacts associated with the logging-mercury problem has not led to revision of the guide.

The spirit of the Declaration Order clearly requires that forest managers actively report on how they are making use of new scientific advances to ensure sustainability and environmental protection. The science on mercury impacts has not been meaningfully incorporated into the logging plan.

In summary, Grassy Narrows and Earthroots submit that the logging plan warrants a review under an Individual Environmental Assessment because:

- the outstanding mercury issues (i.e. impacts upon human and ecosystem health) have not been addressed adequately, or at all, under the *Crown Forest Sustainability Act*, or in the forest management planning process, to date;
- similarly, they will not be adequately addressed in any other current or future regulatory or approvals process regarding the logging activities in Whiskey Jack Forest (e.g., in the *Lakes and Rivers Improvement Act* regarding water-crossings);
- these public interest issues raise matters of profound importance both to Grassy Narrows First Nation, and to other stakeholders and the public at large;
- to effectively and thoroughly address these issues it is necessary, as a preliminary step, for the proponent of the logging plan to prepare an Individual Environmental Assessment that fully examines (with public input) all matters listed in section 6.1(2) of the *Environmental Assessment Act*, especially in relation to:
    - the alleged purpose of, or rationale for, allowing clearcutting/logging

activities to occur in Grassy Narrows Territory
- the alleged purpose of, or rationale for, allowing clearcutting/logging activities in close proximity to fish-bearing waterbodies within the Whiskey Jack Forest despite the risk of additional mercury contamination;
- alternative sources of wood for the real wood supply needs of local mills;
- alternatives to the proposed forestry activities and alternative methods of carrying out such activities;
- the environment affected, and the environmental effects (direct, indirect, and cumulative) of the logging activities;
- proven mitigation actions to prevent the risk of mercury contamination from logging activities; and
- systematic evaluation of the advantages and disadvantages of the proposed activities and the alternatives.

The precise nature and scope of the foregoing factors can be developed (with public input) in the Terms of Reference which precede the preparation of the Individual Environmental Assessment.

In summary, the potential mercury impacts are significant, adverse, long-lasting, and are unresolved to date in the forest management planning process. These impacts are best addressed through a process that includes, but is not necessarily limited to, a robust Individual Environmental Assessment.

15. Remedy Requested

Grassy Narrows and Earthroots are requesting the following:

- an order under section 16(1) of the *Environmental Assessment Act* from the Minister of the Environment requiring the proponent/MNR to comply with Part II of the *Environmental Assessment Act* (i.e. prepare and submit an Individual Environmental Assessment (IEA) of the logging plan for the Whiskey Jack Forest and not proceed to implement the logging plan until the IEA has been completed, and approval to proceed granted by the Minister, or the Environmental Review Tribunal);
- an order that forest management operations including harvest, tending, and new road building be suspended on the Whiskey Jack Forest until such time as:

    a. Experimentally proven measures are developed that prevent logging from elevating mercury; and

    b. the free, prior, and informed consent of the Grassy Narrows First

Nation is given; and

- participant funding is provided to Grassy Narrows and Earthroots so that they may participate meaningfully in the IEA process

The request for such an order is warranted under section 16(4) of the *Environmental Assessment Act* because (1) as noted above, the purpose of the *Environmental Assessment Act* is broader than that of the *Crown Forest Sustainability Act* under which the logging plan was prepared, (2) the logging plan differs from other undertakings in this class of undertakings covered by the class environmental assessment because of the mercury threats posed to the environment and human health in this geographic area that has long been susceptible to harm from this substance, (3) the significance of the factors that have been raised earlier in this document, and (4) the reasons that Grassy Narrows and Earthroots have provided in this request.

APPENDIX I – Stand and Site Guide Section 7.2

(Excerpted from MNR, 2010a, pp. 165-168)

7.2 What to Evaluate – Identifying Key Uncertainties

Many individual pieces of coarse and fine filter direction in this guide do not require rigorous testing because they are based on an extensive body of scientific evidence, or may already have been tested within the context of Ontario's forest management practices (see Background and Rationale for Direction).

Conversely, there are many pieces of direction in the guide for which there is uncertainty associated with the outcome of their application. Unfortunately, there are insufficient resources to address all of these uncertainties. Consequently, a list of ten key effectiveness monitoring questions was identified based on the degree of uncertainty, the potential impact of applying incorrect direction, and the interest expressed by stakeholders. Some of these questions are being addressed by ongoing research projects. Others are not and are high priorities for consideration within MNR's effectiveness monitoring program.

Direction contained within this guide for many species at risk is associated with a high degree of uncertainty. Direction with the highest degree of uncertainty tends to be associated with species with few known sites (e.g., flooded jellyskin habitat, wolverine dens). While further research on these species is desirable, specific questions have not been identified as a high priority for consideration within MNR's effectiveness monitoring program because too few sites are typically known to permit a scientifically rigorous evaluation.

Q1. Within the context provided by direction in the Landscape Guide, will the coarse filter direction in Section 3.2.2, in concert with the fine filter direction in Section 4, produce a pattern of harvested and residual forest at stand and multi-stand scales that supports wildlife communities similar to those found in habitats disturbed by natural events?

Direction in the Stand and Site Guide is intended to provide levels of residual forest cover similar to those prescribed by the *Forest Management Guide for Natural Disturbance Pattern Emulation (NDPEG)*. Direction in the *NDPEG* was based on the amount of residual forest observed in a sample of wildfires in Ontario. While additional study has been conducted by researchers at MNR's Ontario Forest Research Institute (OFRI) to document the amount and pattern of residual forest in wildfires, the response of wildlife communities to this direction has not been rigorously tested. Thus, this question should be a high priority for consideration within MNR's effectiveness monitoring program.

Evaluating the effectiveness of the Landscape Guide will involve comparison of wildlife communities across small landscapes (10,000-20,000 ha) arising from forest management operations following the guide and from natural disturbance (see MNR's *Effectiveness Monitoring of Forest Management Guidelines: Strategic Direction (In prep.)*). Analysis of these data at the stand and multi-stand scale will address this question.

Q2. Within the context provided by direction in the Landscape Guide, will the coarse filter direction in Section 3.2.2, in concert with the fine filter direction in Section 4, retain sufficient residual forest within catchments to ensure that hydrological effects resulting from forest management operations: i) do not exceed those observed in naturally disturbed catchments and ii) do not exceed acceptable levels for specific parameters (e.g., methyl mercury)?

A number of ongoing studies in Ontario are evaluating hydrological catchment-scale effects of forest management activities. For example,

o The Comparative Aquatic Effects Program at MNR's Centre for Northern Forest Ecosystem Research (CNFER) is evaluating the catchment-scale effects of harvesting on water quality in small streams in northwestern Ontario.

o The Forest Watershed and Riparian Disturbance Project, conducted by researchers at Lakehead University, is evaluating how watershed disturbance influences the movement of water and nutrients into forest streams in northwestern Ontario.

o The Scalable Indicators of Disturbance Project, conducted by researchers from the universities of Trent, Guelph, and Western Ontario, is attempting to predict the cumulative impacts of harvesting on streamflow across a range of spatial scales.

Models developed by these research projects may help define the appropriate scale to assess catchment-scale effects and the amount of residual forest required to maintain acceptable export levels of specific parameters such as methyl mercury. However, none of these studies includes naturally disturbed catchments as controls. Thus, their ability to assess effectiveness of direction relative to emulation of natural disturbances is limited and this question should be a high priority for consideration within MNR's effectiveness monitoring program.

Q3. Will the direction in Section 3.2.3 retain a sufficient number and variety of wildlife trees in harvested areas to support cavity-using wildlife communities similar to those found in habitats arising from natural events?

The literature suggests that differences in cavity-using wildlife communities (especially bird communities) is one of the major differences between recently harvested and naturally disturbed habitats. Direction on wildlife trees has been designed to better address the needs of cavity-using wildlife species in harvested forest (e.g., more emphasis on stubbing to create habitat for species such as the black-backed woodpecker) to minimize these differences, but is still largely based on previous direction (e.g., 25 trees/ha prescribed by the *NDPEG*) which, in some cases, does not have a strong scientific basis and has not been rigorously tested.

Ongoing research in the Great Lakes–St. Lawrence forest by MNR's Southern Science and Information Section (SSIS) is evaluating the relationship between abundance of various cavityusing birds and the density and characteristics of live cavity trees and dead standing trees in partial harvests. However, this question, as it pertains to application of the Stand and Site Guide in the boreal forest, should be a high priority for consideration within MNR's effectiveness monitoring program.

Q4. Will the direction for AOCs (around water features and other site-specific values), small residual patches, wildlife trees, and downed woody material in Section 3.2.3 maintain or produce sufficient downed woody material through time in habitat arising from harvesting to support DWMdependent wildlife communities and ecological processes (e.g., nutrient cycling) similar to those found in habitats arising from natural events?

Direction in the guide is a working hypothesis due to the limited scientific information available to define thresholds. Thus, this question should be a high priority for consideration within MNR's effectiveness monitoring program. However, analysis at the stand and multi-stand scales of data collected to evaluate the effectiveness of the Landscape Guide (see Q1 above) will address this question.

Q5. Will the fine filter direction for moose in Section 3.3.4 create habitat that sustains a higher

density of moose (or a higher harvest of moose) than that produced by general coarse filter direction in the Landscape and Stand and Site Guides?

Direction is based largely on preliminary results from the Moose Guidelines Effectiveness Monitoring Project conducted by MNR's CNFER. Habitat suitability and population dynamics models developed by this project will be valuable in predicting the effects of applying this direction. However, effectiveness can only be fully evaluated by comparing moose response (controlling for hunter harvest) inside and outside areas identified for application of this fine filter direction. Thus, this question should be a high priority for consideration within MNR's effectiveness monitoring program.

Q6. Will the forest management activities permitted within shoreline AOCs (Section 4.1.1 and 4.1.2) have undesirable effects (e.g., cause a HADD) on water quality or aquatic biota?

The available evidence suggests that forest management operations permitted within shoreline AOCs will not have adverse effects on water quality and aquatic biota if thoughtfully planned and carefully implemented (see Background and Rationale for Direction). Much of this evidence comes from research that has been conducted in Ontario (e.g., MNR Coldwater Lakes Study, CNFER – Forest Ecosystem Science Co-op Shoreline Forestry Study, Canadian Forest Service (CFS) Turkey Lakes Watershed Study). However, some components of the shoreline AOC direction are based largely on expert advice or inductive inference. Moreover, given public perception about harvesting adjacent to aquatic systems, further research on the effectiveness of this direction is warranted.

However, this question is a low priority for consideration within MNR's effectiveness monitoring program because a variety of studies investigating the effects of forest management activities on aquatic systems is currently ongoing in Ontario, and will ultimately address many of the uncertainties associated with direction in the guide. For example,

o The Comparative Aquatic Effects Program at MNR's CNFER is evaluating the effects of harvesting and the effectiveness of the *Timber Management Guidelines for the Protection of Fish Habitat* on water quality and aquatic biota in small streams in northwestern Ontario.

o The White River Riparian Harvesting Impacts Project conducted by the CFS is evaluating the effects of partial harvesting within AOCs adjacent to permanent streams on water quality and aquatic biota in northeastern Ontario.

o The Turkey Lakes Watershed Study led by the CFS is evaluating the effects of partial and clearcut harvesting on various aspects of water quality and aquatic biota in lakes and streams in the Great Lakes–St. Lawrence forest.

o The Esker Lakes Research Project conducted by researchers from the University of Guelph is evaluating the effectiveness of riparian buffers of various widths for the protection of water quality and aquatic biota in lakes in northeastern Ontario.

o A project conducted by MNR's OFRI is modelling the supply and recruitment of large downed wood in the littoral zone of lakes in the Great Lakes–St. Lawrence forest.

Q7. Will the forest management operations permitted within shoreline AOCs result in undesirable effects on hydrological linkages between upland forest and aquatic habitats?
Hydrological linkages between upland forest and aquatic habitats (e.g., springs, seeps, ephemeral streams) are considered to be important components of fish habitat. However,

relatively little is known about the effects of forest management activities within shoreline areas on hydrological linkages and direction is precautionary. Thus, additional research is warranted. This question is a low priority for consideration within MNR's effectiveness monitoring program because research is currently being conducted by the Comparative Aquatic Effects Program at MNR's CNFER to develop methods to predict and map hydrological linkages and evaluate the effects of forest management operations on associated brook trout habitat.

Q8. Will forest management operations permitted within shoreline AOCs (Sections 4.1.1 and 4.1.2) create a diversity of ages of shoreline forest that maintains a riparian wildlife community (including beavers) similar to that found in habitats arising from natural events?

Direction involving retention of shoreline forest in Section 4.1 is predicated on the assumption that creating a mix of age classes of shoreline forest will maintain a diverse riparian wildlife community (including keystone species such as beavers) that is similar to that found in habitats arising from natural events. While there is some empirical support for this assumption and some evidence that past practices may have been too conservative, and may have had a negative effect on some species requiring early to mid-successional shoreline forest (see Background and Rationale for Direction), the evidence in the literature is not conclusive and requires further research.

However, this question is a low priority for consideration within MNR's effectiveness monitoring program, because relevant research has been conducted as part of the White River Riparian Harvesting Impacts Project conducted by the CFS. Moreover, researchers at the University of Guelph have (in collaboration with MNR, Canadian Wildlife Service, and others) initiated a study to compare waterbird communities (and the supply of beaver habitat) in managed and naturally disturbed landscapes.

Q9. Will seasonal restrictions on forest management operations around occupied bird nests (Section 4.2.2) result in reproductive output comparable to nests in undisturbed situations?
Seasonal buffers for most species in Section 4.2.2 are based on a model relating body size to flushing distance (see Background and Rationale for Direction). Empirical evidence from other jurisdictions for a few species suggests that direction should be effective. However, the direction needs to be tested in Ontario, especially for those species for which the direction has changed substantially from previous guides (i.e., bald eagles, ospreys, great blue herons). Thus, this question should be a high priority for consideration within MNR's effectiveness monitoring program.

Q10. Will restrictions on rutting and skid trail coverage in Section 5.2.1 result in acceptable growth of residual trees (partial harvests) and regeneration success (all harvests)?

The Forest Engineering Research Institute of Canada, MNR's SSIS, and MNR's CNFER have conducted a number of studies in Ontario to document typical levels of site disturbance in the Great Lakes–St. Lawrence forest and boreal forest. Some of these studies have examined the link between site disturbance and silvicultural objectives on specific sites over relatively short time frames (site damage occurs when site disturbance affects silvicultural objectives).

Direction in Section 5.2 was based largely on expert opinion, as informed by results from these studies. There is an ongoing debate among stakeholders about the appropriateness of the thresholds identified in the guide. Thus, this question should be a high priority for consideration within MNR's effectiveness monitoring program.

APPENDIX II – Stand and Site Guide Rationale

(Excerpted from MNR, 2010b, 23-25).

Mercury and catchment-scale effects
Mercury is a natural element occurring in air, water, soil, and biota in the boreal forest. Mercury, which exists in several inorganic or elemental forms and as organic methylmercury (MeHg), alternates between forms and cycles among different components of the ecosystem as part of a complex biogeochemical process. Natural levels of mercury are spatially variable depending ongeology, soil, and forest characteristics. However, the global atmospheric pool of mercury has increased 2 to 5 fold over pre-industrial times (Lindberg et al. 2007). Mercury derived fromindustrial activity, primarily the burning of fossil fuels, may increase mercury levels in the immediate area of such activities, but increased mercury levels in remote areas, such as the Arctic, indicate the importance of the global atmospheric mercury pool as a source of contamination. Although mercury emissions in North America and Europe have been dramatically reduced in the last few decades, the global atmospheric pool of mercury has not decreased, partly due to increases in emissions from developing countries (Lindberg et al. 2007). Current estimates are that approximately half of the mercury deposition in the boreal forest comes from anthropogenic sources, although such estimates are highly uncertain (Grigal 2002, Lindberg et al. 2007).

In the boreal forest, existing mercury, and mercury deposited from the atmosphere, is primarily stored bound to humic particles in the upper few centimetres of the soil profile (Grigal 2002, Povari and Verta 2003). The soil mercury pool is relatively stable and experimental additions of mercury indicate that most newly deposited mercury is held in the soil (Hintelmann et al. 2002). Hintelmann et al. (2002) further suggest that their observations indicate that the primary source of mercury in aquatic systems away from point source discharges is direct deposition from the atmosphere with terrestrial runoff contributing relatively less mercury. However, disturbance to forest areas, including forest management activities (Povari et al. 2003) and natural disturbances including fire (Kelly et al. 2006), severe storm events (Munthe et al. 2007b), and drought (Grigal 2002), can result in the release of mercury from the soil pool and subsequent volatilization to the atmosphere or entrance into surface runoff or groundwater, bound to dissolved or particulate organic carbon (Grigal 2000). Waterborne mercury moving into aquatic systems may then be methylated, primarily by sulphur-reducing bacteria in low oxygen environments within wetlands and lake sediments (Morel et al. 1998). The capacity of aquatic systems to form MeHg depends on a number of factors, including the proportion of wetlands associated with lakes or streams (Grigal 2002). However, methylation in aquatic systems is the principal mechanism by which mercury is made available for incorporation and biomagnification in aquatic ecosystems.
There is a developed body of research on the process by which water impoundment releases mercury stored in the soil and may accelerate the production and bioaccumulation of MeHg in flooded areas, particularly those with high proportions of flooded organic material such as wetlands (Bodaly et al. 2004, Hall et al. 2005). There has been much less research on the impacts of other types of disturbance. Studies in Finland have shown that forest management activities can lead to an increase in the concentration of total mercury and MeHg in groundwater and surface waters (Munthe et al. 2007a, Povari et al. 2003, Povari and Verta 2003). Recent research conducted in Quebec has shown that mercury levels in periphyton, plankton, and fish in

lakes within watersheds that have been disturbed by forest management activities or fire are higher than in undisturbed lakes (Garcia and Carignan 1999, 2000, 2005; Desrosiers et al. 2006).

These results have raised concerns over the impact of forest management activities on mercury levels in aquatic systems and the potential risk this may pose to wildlife and humans consuming fish.

Implications for direction in this guide
Removal of trees from catchments by timber harvest or wildfire is associated with generally similar changes in the hydrology, chemistry, and biota of lakes and streams. Moreover, effects are generally transitory and most do not appear to translate to higher biotic levels (but see discussion on *Mercury and catchment-scale effects*).

It is anticipated that the cumulative effect of applying the coarse and fine filter direction in the Landscape Guide and Stand & Site Guide will result in a level of catchment-scale disturbance that is within the range of that associated with natural disturbances. Thus, there is no additional fine filter direction prescribed to mitigate the general catchment-scale effects of timber harvest. However, since the response of some variables may differ between harvested and burned catchments, catchment-scale effects are identified as one of the high priority questions for evaluation during effectiveness monitoring of the guide (see Section 7.0).

This conclusion was reached after undertaking a comparison of the extent of disturbance incatchments resulting from the actual harvest pattern from the previous 25 years of harvesting, the expected future harvest pattern directed by forest management guides, and the estimated pattern resulting from a natural disturbance regime. This comparison demonstrated that past and expected future harvests result in catchment level disturbance patterns within the range expected on a naturally disturbed landscape.

There is fairly compelling evidence that timber harvest (and wildfire) results in an increase in the movement of mercury from terrestrial to aquatic environments where it may be converted to MeHg (see above). Associated with this, there is a growing concern about the associated potential risk to wildlife and human health. Kolka et al. (1999, 2001) suggest that most terrestrial mercury is transported bound to particulate organic matter and thus recommend management practices that limit site disturbance and particulate transport to aquatic features, such as use of buffer strips and erosion control devices. There is also growing evidence that specific locations within catchments may be ‘hotspots’ for mercury methylation (Branfireun and Roulet 2002, Mitchell et al. 2008). These sites may be associated with areas of flow accumulation that focus movements of water, mercury, and sulfates from surrounding uplands into areas of saturated soils (anoxic conditions), thus facilitating increased levels of methylation by sulfate-reducing bacteria. Operations that result in disturbance of these ‘hotspots’ or disrupt the hydrologic flow to them could potentially affect the rate of methylation or the subsequent transport of methylated mercury to aquatic features (Porvari et al. 2003, Munthe and Hultberg 2004).

While there is no direction explicitly labeled as ‘catchment-scale’ in the guide, there are many pieces of direction in the guide that will address these concerns. Section 5.2 provides general direction to minimize site disturbance within upland areas which will reduce the creation/mobilization of particulate matter as well as maintain hydrological function. Sections 4.1 and 5.1 provide comprehensive direction to minimize the subsequent risk of particulate matter transport to aquatic features. Sections 3.2 and 4.1 also provide direction to specifically minimize site disturbance, and preferentially retain residual forest, in areas that are hydrologically connected to aquatic features and that may be linked to or function as potential methylation ‘hotspots’ (i.e., ephemeral streams, springs, seeps, and other areas of groundwater discharge). Thus, there is no additional fine filter direction prescribed to mitigate the catchment-scale effects of timber harvest on mercury export. However, given the growing concern expressed by stakeholders, mercury export is specifically identified in Section 7.0 as a priority for effectiveness monitoring.

Previous direction
The *Forest Management Guide for the Protection of the Physical Environment* (OMNR 1997) included a rule of thumb that no more than 50% of a second order watershed be harvested in a 10 year period. Second order watersheds typically range from 10s to 100s of hectares but can be several thousand hectares with significant variation in average size between management units. This direction was considered for inclusion in the Stand and Site Guide but deemed ineffective, and more importantly unnecessary.

Second order watersheds are an arbitrary response unit for assessing catchment scale effects with limited scientific basis. By varying the definition of catchment/watershed, a single township could have anywhere from a few to dozens or even hundreds of catchments. Devito et al. (2005) argue that response units are not the same everywhere and there are many factors at many spatial scales that influence what an appropriate unit might be. There does not appear to be a defensible method of deriving an appropriate geographic response unit.

There is limited scientific basis for setting a threshold of percent disturbed in a geographic response unit. While 50% is a reasonable generalization of how much of a catchment can be disturbed before seeing a measurable hydrologic response, some studies show a response at levels as low as 15% while others show no response at 100% (e.g., Stednick 1996). Further, a hydrological response is not necessarily negative as the response (e.g., increased water yield) is often consistent with a naturally disturbed system.

In addition to being ineffective, the second order watershed direction is no longer necessary. Landscape level pattern direction, coupled with stand level retention requirements, is expected to produce a natural pattern of disturbance (and retention) at multiple scales. This level of sophistication in pattern direction did not exist at the time the *Forest Management Guide for the Protection of the Physical Environment* (OMNR 1997) was developed. The 2nd order watershed direction was originally included without the benefit of this context and is now considered unnecessary and further has the potential to be contradictory to the CFSA's principle of emulating natural disturbances and landscape patterns.

ATTACHMENT

The following map material was developed at the request of the Ministry of the Environment and Climate Change ("MOECC") in early February 2014 following the filing by Grassy Narrows and Earthroots of their bump-up request in January 2014. The MOECC request and the Grassy Narrows – Earthroots response resulted in the submission of three maps by the groups. The Ministry of Natural Resources and Forestry ("MNRF") reduced this material to a single composite map (the last page of this attachment) that was used to outline the geographic location of the affected areas of concern in the bump-up request. The MOECC request and responses have been included as part of this attachment to Exhibit "C".

Good Morning,

As David described, the map accurately depicts the area of concern.

Thank you.
JB

Subject: Re: Whiskey Jack Forest Management Plan request for IEA

Hi Devon,

This map appears to accurately depict the area affected by the IEA request (assuming that the bodies of water are included in the IEA area and that the eastern boundary is based on the Grassy Narrows traplines). This is without prejudice to a proper determination of the extent of Grassy Narrows Territory.

Thanks to you and the MNR for making this map.

Please go ahead with your review.

Take care,

David

Hello,

I have been in contact with the MNR in regards to the three maps you have provided which illustrates your understanding of Grassy Narrows Territory within the Whiskey Jack Forest. The MNR has overlaid the three maps into one map which is an approximation of the area you have outlined. Can you please confirm that the attached map is an accurate depiction of the area affected by the IEA request?

Due to the strict timelines of MNR's Forest Management Class Environmental Assessment, it is important that you provide a response for the above question as soon as possible so that we may move forward with our review. I look forward to hearing your reply.

Subject: Re: Whiskey Jack Forest Management Plan request for IEA

Hi Devon,

It is good to meet you. Thank you for your work reviewing our request.

Our request applies to Grassy Narrows Territory within the Whiskey Jack Forest. I do not know of any definitive map of this area. As part of the Iaccobucci Process, Ontario was to fund Grassy Narrows to complete a thorough land use and occupancy study which could have shed light on this question. However, funding was cut off before the completion of that study.

As a provisional measure you may consider the request to apply to the overlay sum of the following three mapped areas:
i) Grassy Narrows MNR trapline areas (first attachmet);
ii) MNR Grassy Narrows Study Area (second attachement);
iii) The area avoided during the creation of the recent Whiskey Jack Contingency Plan (orange, pink, and green areas on the third attachment).

This is without prejudice to any future determination that Grassy Narrows may make about the extent of their Territory.

I believe that the MNR has GIS shapefiles that should make this overlay to visualize.

The specific proposed forest management activities of concern are:
a) harvesting;
b) tending;
c) new road building; and
d) any other activities that may elevate mercury levels in water and fish.

I hope that this provides you with the information that you require.

The best way to contact Earthroots is by contacting me using this email address.

Joseph Fobister is the contact for Grassy Narrows and can be reached by email at jbfobister@gmail.com.

Please copy both Joseph, and me, on any communications regarding our joint request.

If you have any further questions, please do not hesitate to contact us.

Take care,

David Sone

Hello,

I am the Project Evaluator assigned to the Whiskey Jack Forest Management Plan's request for an Individual Environmental Assessment (IEA). In reviewing your joint request, it has come to my attention that your concerns to not outline a specific area within the Whiskey Jack Forest. IEA Requests must include a description of the specific proposed forest management activities of concern, and a description and/ or map that identifies the geographic location of the affected areas. Please provide a map(s) that identify the specific area of concern within the Whiskey Jack Forest that your request for an IEA is related to.

Due to the strict timelines of MNR's Forest Management Class Environmental Assessment, it is important that you provide the required documentation as soon as possible so that we may move forward with our review. Please inform me of the best methods of contacting your organization that will expedite the information gathering process. I look forward to hearing from you shortly.

Thanks,

Devon Wills

SUBJECT: EBR Registry Number 010-9240 – Forest Management Plan for the Whiskey Jack Forest for the 10-year period April 1, 2012 to March 31, 2022 – Review of Draft Forest Management Plan

Thank you for the comments provided by Earthroots in your letter dated October 31st, 2013 regarding the 2012-2022 Draft Whiskey Jack Forest Management Plan (FMP). This letter stated concern with three primary topics; Grassy Narrows First Nation consultation, the 2009 Whiskey Jack Independent Forest Audit (IFA), and the impact of harvesting on the land. All of these concerns will be discussed below.

The development of the 2012-2022 Whiskey Jack FMP has consciously worked to respect the on-going discussions between Grassy Narrows First Nation and the Ministry of Natural Resources (MNR) within the context of the Process Agreement and other efforts currently in progress. This has been accomplished through application of some fundamental principles that have been applied in the FMP.

a. The MNR has undertaken considerable effort to involve Grassy Narrows First Nation in the preparation of the 2012-2022 Whiskey Jack FMP. These efforts included written and direct invitations to join the planning team, phone calls and offers for information centres in the community to discuss proposed harvest areas. During development of the long-term management direction for the FMP, the objectives, strategies and targets for the FMP were developed by the planning team along with the Local Citizen Committee, and were broadly made available for review and input, including efforts by MNR to have open houses in the community of Grassy Narrows.

b. Planned harvest operations nearest to Grassy Narrows First Nation have been deferred to the 2nd phase of planning (2017-2022) to allow for ongoing discussions to continue with the community.

... 2

c. The FMP includes planned harvest opportunities closer to Grassy Narrows should the community, or a community member, wish to pursue forest harvesting as an economic development opportunity.

It is Grassy Narrows First Nation's right to object to the FMP process and choose not to participate. However, that position does not remove our responsibilities to the many other individuals and communities, including other First Nations that rely on the Whiskey Jack Forest, nor the responsibility to have an approved forest management operating plan.

The current legal framework outlining the Crown's duty to consult with Aboriginal peoples does not include the language of free, prior and informed consent. In most cases, Aboriginal peoples do not have a veto over proposed activities or developments. Consent may be required only in rare cases, where the Crown's action or decision will result in serious impacts on established rights.

To see how the recommendations from the 2009 Whiskey Jack Independent Forest Audit were addressed, please refer to the associated Action Plan and the Action Plan Status Report. These documents may be found on the following website: http://www.mnr.gov.on.ca/en/Business/Forests/1ColumnSubPage/STEL02_167055.html

In your letter, Earthroots lists a number of concerns with the Long Term Management Direction (LTMD) and the Draft FMP. Please see the list below for responses.

a. *Loss of the few remaining roadless areas in the forest through new road building;*

The Whiskey Jack Forest is a well accessed management unit with numbered highways, primary and branch forest access roads. These existing roads are essential for accessing the planned harvest area and minimizing the construction of new permanent road systems. Of the planned 55.9 km of primary and branch road construction in the FMP, approximately 39.4 km is actually reconstruction of previously abandoned roads. The remaining 16.5 km of planned new road construction are extensions of existing roads. Environmental guidelines are in place to maintain, construct and decommission these roads once they are no longer required.

b. *Logging targets what little mature forest that remains after decades of intensive logging, insect infestations, blow down and fire;*

The FMP was produced in accordance to the direction provided in *the Crown Forest Sustainability Act* (1994) and the subsequent four regulated manuals. In addition, this FMP was developed using the latest scientific information in the form of the science package for the draft *Forest Management Guide for Boreal Landscapes.*

The plan proposes to harvest up to 51,947 hectares over the 10 year period of the plan. These harvest areas were selected from a total of 196,425 hectares of eligible wood which does not include provincial parks, conservations reserves, and large landscape patches which have been set aside to satisfy wildlife habitat objectives.

c. *Near extirpation of caribou and now moose from the forest. The complete loss of winter caribou habitat and long term failure of to meet martin(sp.) core objectives;*

During this plan period (2012-2022), there is final harvesting planned to occur in 4 caribou "A" blocks. This small amount of planned harvesting is intended to reduce forest fragmentation and accounts for the short-term reduction in refuge and preferred winter habitat that is noted in the FMP. An increase in the refuge and preferred winter habitat is then projected from term 3 to term 6. This increase in habitat levels will achieve target levels within the 30-year target timeframe. Caribou habitat generally increases from the beginning of the plan to exceed the minimum desirable levels by term 6 and onwards. The caribou strategy for this plan was developed utilizing principles outlined in the Caribou Conservation Plan (2009).

The decline in moose populations in some parts of northwestern Ontario and in neighbouring Manitoba and Minnesota are due in part to a combination of environmental and biological factors that are not impacted by forest management activities. For example, warmer than average climatic conditions, expansion of deer populations, higher deer densities and associated parasite caused moose mortality. Moose have not been extirpated from the Whiskey Jack Forest. Moose still roam the Whiskey Jack Forest, though not in the numbers previously experienced.

Marten cores were developed to meet habitat requirements in the short, medium and long term ranges and to incorporate the best concentrations of suitable habitat, spatially distributed across the forest. The Whiskey Jack Forest has lots of conifer stands that meet the requirements of suitable habitat but they are not currently spatially concentrated enough to achieve the desirable level in the short term. The target level is expected to be achieved in 60-80 years based on the assessment of projected spatially suitable marten habitat.

d. *Extremely low levels of protected areas (approximately 4%);*

During the calculation of the sustainable harvest level, approximately 35% of the forested land base on the Whiskey Jack Forest was calculated to be unavailable. This area is located in parks, conservation reserves and areas of concern (e.g. eagles nests). This information can be found in the 2012-2022 FMP tables - Reconciliation of SFMM Initial Land Base to Tables FMP-1 and FMP-3.

e. *Return to extensive use of aerial spraying of herbicides in spite of scientific evidence on impacts to amphibians and biodiversity:*

Tending, as discussed in the 2012-2022 FMP, includes more methods than aerial application of herbicides. Tending also includes; manual cleaning with brush-saws, ground application of herbicide and pre-commercial thinning. All herbicides intended for use on the forest are legally licensed for use on forested lands by the federal government and their use in Ontario is regulated by the Ministry of the Environment Ontario.

The total amount of tending proposed in the 2012-2022 FMP is 8,065 hectares. When compared to the total amount of regeneration that is proposed (53,470 hectares), tending is planned to occur on only 15% of the harvested area.

f. *High volumes of wood for low job intensity products.*

Currently, there are only three relatively small forest companies seeking to harvest on the Whiskey Jack Forest. These three companies are all owned by Aboriginal people from neighbouring First Nations communities also located within the same forest. Harvesting is limited to areas away from those areas of greatest concern to Grassy Narrows First Nation. The FMP makes a sustainable level of wood fibre from the Whiskey Jack Forest available for harvest in order to provide social and economic benefits to the people of Ontario. The wood from the Whiskey Jack may be utilized to make products such as pulp, paper, dimensional lumber, utility poles and wooden utensils.

g. *Failure to account in any way for the scientifically established impact of clearcutting on mercury levels in the piscivorous fish in local lakes and rivers already known to contain dangerous levels of mercury;*

MNR has determined that there is a sufficient legal, regulatory and policy framework, including guidelines, to ensure that current information and knowledge about mercury dynamics in the Boreal Forest is considered in land-use and resource management decisions. Further, as part of its adaptive management framework MNR is currently reviewing, updating and developing new policies and monitoring protocols for forest management activities and waterpower projects based on current, scientifically sound information on the environmental impacts of these activities. To support the implementation of these policies and protocols, MNR is actively involved in research that seeks to improve the understanding of the dynamics of mercury in the Boreal forest and directly contribute to the development of land-use practices which minimize the risk of altering these dynamics.

h. *Prioritizing logging over all other landuse and values.*

Ontario's Crown forests are managed to meet the social, economic and environmental needs of a broad range of users of present and future generations. The Forest Management Plan is prepared by a diverse group of individuals who include, but are not limited to, trappers, cottagers, aboriginal peoples, anglers, hunters, naturalists, mining, forest industry and government. The inclusion of such a variety of interest groups is vital in the development of the desired future forest and benefits to be derived from a Forest Management Plan.

If you wish to discuss any of these concerns further or if you require clarification on any matter I would be pleased to meet with you.

Sincerely,

Deb Weedon

RE: MNR RESPONSE TO MOE REQUEST FOR INFORMATION FOR THE 2012 TO 2022 FOREST MANAGEMENT PLAN FOR THE WHISKEY JACK FOREST

Dear Agatha:

The Ministry of Natural Resources (MNR) has received your request to provide information in relation to issues identified in the Individual Environmental Assessment (IEA) request on the 2012-2022 Forest Management Plan (FMP) for the Whiskey Jack Forest.

MNR has completed the response to the Ministry of the Environment (MOE) request and is pleased to provide it to you at this time. I have attached the response, containing the information requested.

If you have any questions regarding this response, please feel free to contact the MNR District Contact, Kurt Pochailo at (807) 468-2597 or kurt.pochailo@ontario.ca.

Sincerely,

Deb Weedon

MNR Response to 2012-2022 Whiskey Jack FMP IEA Request

Introduction

The Director, Environmental Approvals Branch (EAB), Ministry of the Environment (MOE), has requested MNR provide specific documentation for consideration in its review of a joint request for an Individual Environmental Assessment on the 2012-2022 Whiskey Jack Forest Management Plan (FMP). This joint request was submitted by former Chief Simon Fobister, previous Chief of Grassy Narrows First Nation (GNFN), on behalf of Grassy Narrows First Nation, and Amber Ellis, Earthroots Executive Director, on behalf of Earthroots.

Documentation requested by MOE includes:

1. A detailed description of the involvement of the IEA requesters in the planning process;
2. A detailed description, with supporting documentation, of how the issues raised in the IEA requests;
    a. Were addressed in the planning process;
    b. Will be addressed in the implementation of forest operations and/or through additional commitments; and
3. A summary of Aboriginal involvement in the preparation of the FMP.

Potential mercury contamination appears to be the focus of the IEA requester's issues with the FMP. As this issue was raised late in the FMP process by the requesters, there is very little documentation of the issue in the FMP process as is explained in the following responses to MOE's questions. As a result, MNR has included an additional component in this response from MNR's forest science experts that should help MOE understand how MNR has been and will continue to investigate mercury issues through science and whether MNR is providing current science perspectives in the guides used to support the development of FMPs.

Further, MNR has a long standing relationship with Grassy Narrows First Nation and has been in ongoing discussions /negotiations on many topics, including forest management topics, for many years. MNR has included a brief summary of those topics and discussions to illustrate to MOE that MNR is making every attempt to address the first nation's interests and concerns.

Response to MOE's Questions

The MNR's response is structured to follow the information requested and is linked to the stages of consultation associated with the preparation of a FMP. For each stage of consultation, the response provides a brief overview of the requester's involvement in the planning process (Tables 1 and 2), and how the issues raised in the IEA request were addressed in the planning process

1. **A detailed description of the involvement of the IEA requestors in the planning process.**

Public consultation for the 2012-2022 Whiskey Jack FMP (Phase I) was developed in accordance with the requirements outlined in the 2009 Forest Management Planning Manual (FMPM).

The MNR's response is structured to follow the information requested and is linked to the following five stages of consultation for the development of the FMP; recognizing the preparation of the 2012-2022 Whiskey Jack FMP was interrupted by the preparation of a two year Contingency Plan (CP). The 2012-2014 CP was initiated during the planning process mainly to provide additional time to work with GNFN. The CP encompassed the first two years of operations developed for the 2012-2022 FMP. The endorsed CP Proposal can be found in Appendix A.

The resulting consultation stages for the 2012-2022 Whiskey Jack FMP are outlined as follows and include the stages of consultation for the preparation of the CP:

- Phase I: Stage One – Invitation to Participate
- Phase I: Stage Two – Review of Proposed Long-Term Management Direction

- Contingency Plan – Information Centre: Review of Proposed Operations
- Contingency Plan – Inspection of MNR-approved Contingency Plan

- Phase I: Stage Three – Information Centre: Review of Proposed Operations
- Phase I: Stage Four – Information Centre: Review of Draft Forest Management Plan
- Phase I: Stage Five – Inspection of MNR-approved Forest Management Plan

Prior to the commencement of the formal public consultation process for the preparation of the 2012-202 Whiskey Jack FMP, the Kenora District Manager, in accordance with

Part A, Section 4.4 of the FMPM, invited GNFN to discuss the development of a consultation approach for forest management planning with the community (i.e., customized consultation approach). GNFN indicated verbally to the Kenora District Manager that they did not want to discuss the preparation of the 2012-2022 Whiskey Jack FMP.

GNFN and Earthroots representatives received written notices for all stages of the consultation process in the preparation of the 2012-2014 CP and the 2012-2022 FMP, as required by the FMPM. In addition, at each stage of consultation, direct written notices were provided to some members of GNFN (e.g., trappers), public notices were placed in local newspapers, and an Information Notice was placed on the Environmental Registry website. Tables 1 and 2 provide a brief overview of the requester's involvement in the planning process for the 2012-2014 CP and the 2012-2022 FMP. The correspondence identified in Tables 1 and 2 can be found in Appendix A.

Table 1: Timeline and Correspondence Summary of Grassy Narrows First Nation in the FMP Process.

Date (dd/mm/yy)	Stage of Consultation and Contact
Stage One: Invitation to Participate	
20-Apr-09	Letter to Chief (6 months prior to Invitation to Participate) notifying of 2012-2022 FMP planning starting in November 2009.
3-Feb-10	Notification letter sent regarding the commencement of forest management planning process on the Whiskey Jack Forest (WJF)
2-Feb-10	Media Notice 2012-2022 FMP - Kenora Daily Miner
3-Feb-10	Media Notice 2012-2022 FMP - Red Lake Northern Sun News
6-Feb-10	Media Notice 2012-2022 FMP - Lake of the Woods Enterprise
10-Feb-10	Media Notice 2012-2022 FMP - Dryden Observer
18-Feb-10	Media Notice 2012-2022 FMP - Wawatay News
Stage Two: Long Term Management Direction	
14-Dec-11	Notification letter to review and comment on LTMD for the 2012-2022 FMP for the WJF
14-Dec-11	Media Notice 2012-2022 FMP - Kenora Daily Miner
17-Dec-11	Media Notice 2012-2022 FMP - Lake of the Woods Enterprise
19-Dec-11	Requested maps of LTMD were picked up by consultant and GNFN band member.
21-Dec-11	Media Notice 2012-2022 FMP - Dryden Observer
22-Dec-11	Media Notice 2012-2022 FMP - Wawatay News
2012-2014 Contingency Plan Development	

31-May-12	Registered letter sent to the Chief to bring GNFN up to date on the preparation of the 2012-2022 Whiskey Jack FMP. Notification of planning for Contingency Plan.
31-May-12	Media Notice 2012-2014 CP – Draft Plan Review – Kenora Lake of the Woods Enterprise
31-May-12	Media Notice 2012-2014 CP – Draft Plan Review – Wawatay News
1-Jun-12	Media Notice 2012-2014 CP – Draft Plan Review – Daily Miner
6-Jun-12	Media Notice 2012-2014 CP – Draft Plan Review – Northern Sun News
6-Jun-12	Media Notice 2012-2014 CP – Draft Plan Review – Dryden Observer
13-Jun-12	GNFN letter about the 2012-2022 FMP, presented at the CP planning team meeting on June 14th.
18-Jun-12	2012-2014 CP – Information Centre - Kenora
19-Jun-12	2012-2014 CP – Information Centre – Sioux Narrows
20-Jun-12	2012-2014 CP – Information Centre – Red Lake
21-Jun-12	2012-2014 CP – Information Centre – Ear Falls
30-Jul-12	Emails between District Manager and GNFN representative regarding planning of Aug 3rd meeting with GNFN.
3-Aug-12	Meeting with GNFN to discuss Whiskey Jack CP – GNFN would not discuss CP and left meeting – notes attached.
30-Aug-12	Letter to GNFN thanking them for their letter of June 13/2012 submitted to the planning team. This letter was in response to the 2012-2014 Draft CP.
18-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Daily Miner
19-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Northern Sun News
19-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Dryden Observer
20-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Kenora Lake of the Woods Enterprise
20-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Wawatay News
25-Sep-12	Letter to Chief – Invitation to inspect Approved CP
Stage Three: Review of Proposed Operations	
31-Jan-13	Registered letter to GNFN providing notification of upcoming Public Information Centres – offer in letter to have an information centre held at the community. No response received.
28-Jan-13	Media Notice 2012-2022 FMP Stage 3 - Lake of the Woods Enterprise
29-Jan-13	Media Notice 2012-2022 FMP Stage 3 - Kenora Daily Miner
2-Feb-13	Media Notice 2012-2022 FMP Stage 3 - Dryden Observer
2-Feb-13	Media Notice 2012-2022 FMP Stage 3 - Red Lake Northern Sun News
14-Feb-13	Media notice 2012-2022 FMP Stage 3 - Wawatay News
26-Feb-13	Letter sent to GNFN Chief reminding them of the upcoming Information Centres.
4-Mar-13	Information Centre 2012-2022 FMP Stage 3 - Kenora

5-Mar-13	Information Centre 2012-2022 FMP Stage 3 - Sioux Narrows
6-Mar-13	Information Centre 2012-2022 FMP Stage 3 - Red Lake
7-Mar-13	Information Centre 2012-2022 FMP Stage 3 - Ear Falls
3-Apr-13	Letter sent to GNFN Chief with CD containing maps and information on Stage 3 – Proposed Operations. Letter extended offer to hold an Information Centre in the community.
Stage Four: Review of Draft Plan	
30-Jul-13	Letter sent to GNFN inviting them to the upcoming Information Centres and provided a copy of GNFN Report on the Protection of Identified Aboriginal Values for review and comment. No comments were received from GNFN.
1-Aug-13	Media Notice 2012-2022 FMP Stage 4 - Lake of the Woods Enterprise
1-Aug-13	Media notice 2012-2022 FMP Stage 4 - Wawatay News
2-Aug-13	Media Notice 2012-2022 FMP Stage 4 - Kenora Daily Miner
7-Aug-13	Media Notice 2012-2022 FMP Stage 4 - Red Lake Northern Sun News
7-Aug-13	Media Notice 2012-2022 FMP Stage 4 - Dryden Observer
3-Sep-13	Information Centre 2012-2022 FMP Stage 4 - Sioux Narrows
4-Sep-13	Information Centre 2012-2022 FMP Stage 4 - Red Lake
5-Sep-13	Information Centre 2012-2022 FMP Stage 4 - Ear Falls
6-Sep-13	Information Centre 2012-2022 FMP Stage 4 - Kenora
24-Oct-13	Premier received letter regarding Draft Plan from GNFN
28-Oct-13	Received comments from GNFN on Draft Plan - Sent to Regional Director
Stage 5: Inspection of MNR Approved Plan	
19-Dec-13	Media notice 2012-2022 FMP Stage 5 - Wawatay News
	Notification of MNR-approved FMP and 30 day Plan Inspection period
23-Dec-13	Media Notice 2012-2022 FMP Stage 5 - Kenora Daily Miner
24-Dec-13	Media Notice 2012-2022 FMP Stage 5 - Dryden Observer
25-Dec-13	Media Notice 2012-2022 FMP Stage 5 - Red Lake Northern Sun News
27-Dec-13	Media Notice 2012-2022 FMP Stage 5 - Lake of the Woods Enterprise

Table 2: Timeline and Correspondence Summary of Earthroots in the FMP Process.

Date	Stage of Consultation and Contact
Stage One: Invitation to Participate	
No correspondence received	
Stage Two: Long Term Management Direction	
22-Mar-12	Email from Earthroots requesting GIS files and past harvest information for the Whiskey Jack Forest
05-Apr-12	MNR responded to March 22, 2012 email requesting information – provided a list of requested materials and inquired if this would fulfill the requestors needs

05-Apr-12	Earthroots requested additional planning information in subsequent email
10-Apr-12	MNR response to April 5, 2012 email from Earthroots and directed them to the information requested.
2012-2014 Contingency Plan Development	
21-Jun-12	Received email from Earthroots requesting a specific individual is added to the Whiskey Jack Forest mailing list as well as a map and digital information of the plan.
Stage Three: Review of Proposed Operations	
No correspondence received	
Stage Four: Review of Draft Plan	
31-Oct-13	Received Earthroots comments on the 2012-2022 Whiskey Jack Draft FMP
1-Nov-13	Received email from Earthroots requesting data for the Draft Plan and the LTMD
05-Nov-13	Received email posing question regarding the Planned Wood Utilization by Mill (FMP-15) table from the Draft FMP
05-Nov-13	Email sent to Earthroots responding to request for large amounts of information on the 2012 Draft FMP
06-Nov-13	MNR responded to Earthroots November 5, 2013 request for digital information on the 2012-2022 FMP
26-Nov-13	Email from Earthroots regarding public input received during draft plan review and other questions related to planning
23-Dec-13	Responded to Earthroots email of November 26, 2013 providing all of the requested information.

2. **A detailed description, with supporting documentation, of how the issues raised in the IEA request:**
    a. **were addressed in the planning process; and**
    b. **will be addressed in the implementation of forest operations and/or through additional commitments.**

MOE determined that the following issues raised in the IEA request would be reviewed:

Issue 1 Harvest – Application of the clear cut silvicultural system on the area affected by the IEA request will disturb the soil causing naturally occurring mercury to become in flux and travel through the water system collecting in catchment areas already stressed with mercury, further exaggerating the existing mercury contamination issue in local waterways which may potentially affect human and ecosystem health and adversely impact Aboriginal and Treaty rights.

Issue 2 Harvest – MNR doesn't have the science and information base to support the development of prescriptions to mitigate the effect of mercury on terrestrial or aquatic ecosystems.

Issue 3 Harvest – FMP contains no requirements for ongoing monitoring of mercury levels in the area affected by the IEA request to determine if in fact approved forest operations once implemented would (further) elevate mercury levels in catchment areas.

Issue 4 Access – The construction of forest access roads on area affected by the IEA request will disturb the soil causing naturally occurring mercury to become in flux and travel through the water system collecting in downstream areas already stressed with mercury, further exaggerating the existing mercury contamination issue.

Issue 5 Consultation – MNR did not respond to comments submitted by the requestors on the mercury issue during the preparation of the FMP and the requestors have raised concerns about the failure to discharge the duty to consult in the development of this forest management plan.

Issues 1 to 4 deal with content of the FMP versus issue 5 which deals with the forest management planning process requirements. Therefore, issues 1 to 4 will be dealt with together and issue 5 will be dealt with separately.

Issues 1 to 4

During stages 1 through 3 of the planning process, issues 1 through 4 were not raised by the requesters. During Stage 4, the impact of clearcutting on mercury levels in piscivorous fish in local lakes and rivers was brought forward as one of a number of issues Earthroots had with the FMP. There was no corresponding mention of this issue in the response MNR received on the Draft FMP from GNFN. MNR responded to the issue brought forward by Earthroots indicating that MNR complied with the legislative, regulatory and policy requirements, including the approved forest management guides, which mitigate potential adverse effects on the environment. Through the implementation of the FMP, including the application of Area of Concern prescriptions, silvicultural ground rules, and best management practices for road construction activities, MNR will be further mitigating potential adverse effects on the environment. MNR has made no further commitments in the FMP to address the issues raised by the requesters.

Issue 5

In regards to the claim that MNR did not discharge its duty to consult during the development of the forest management plan, MNR followed the public and Aboriginal

consultation requirements outlined in the Forest EA approval and the FMPM as outlined below.

Aboriginal consultation for the 20012-2014 Whiskey Jack CP and the 2012-2022 Whiskey Jack FMP (Phase I) was undertaken in accordance with the requirements outlined in the 2009 Forest Management Planning Manual (FMPM):

1. Prior to the commencement of the formal public consultation process for the preparation of the 2012-202 Whiskey Jack FMP, the Kenora District Manager, in accordance with Part A, Section 4.4 of the FMPM, invited GNFN to discuss the development of a consultation approach for forest management planning with the community (i.e., customized consultation approach). GNFN declined the opportunity to develop a customized consultation approach.
2. The Kenora District Manager offered GNFN an opportunity to have a community representative sit on the FMP planning team and Local Citizens Committee (LCC). GNFN did not take the opportunity to become a member of the planning team or the LCC.
3. At each stage in the development of the CP and FMP notification letters were sent to GNFN to invite participation in the FMP process.
4. During the preparation of the 2012-2014 CP and the 2012-2022 FMP:
    a. the Kenora District Manager sought the involvement of GNFN to review and update the existing Aboriginal Background Information Report (ABIR), including the Aboriginal values maps; and
    b. The planning team produced a Report on Protection of Identified Aboriginal Values during the planning of operations as per the requirements of Part A, Section 4.6 of the FMPM

MNR responded to all comments submitted to the planning team during the preparation of the 2012-2014 CP and the 2012-2022 FMP in accordance with the requirements of the FMPM (Part A, Section 3.3.2.3). MNR did not receive any correspondence from GNFN, throughout the planning process, that there was a concern with the impact of clearcutting on mercury levels in piscivorous fish in local lakes and rivers. MNR did receive correspondence from Earthroots during Stage 4 of the planning process (i.e., Draft Plan Review) that they were concerned with, amongst many other concerns, with the impact of clearcutting on mercury levels in piscivorous fish in local lakes and rivers (Appendix A). MNR responded to these concern identified by Earthroots, indicating that MNR applied the direction in the approved forest management guides to mitigate potential adverse effects of forest management activities on the environment. (Appendix A).

In regards to the claim that MNR did not discharge its duty to consult during the development of these forest management plans, MNR followed the public and Aboriginal consultation requirements outlined in the Forest EA approval and the FMPM. Further, MNR has made substantial efforts to consult with GNFN on the specifics of the development of the 2012-2022 Whiskey Jack FMP and previous FMP plans (e.g., 2009 CP, 2012 CP). These efforts have been substantially rejected by GNFN. The duty to consult requirement is mandated under the Constitution Act, 1982 and as directed by case law, principally decisions rendered by the Supreme Court of Canada. It is also taken from this case law that First Nations cannot thwart the Crown's efforts to consult, such as refusing to participate in real and sincere efforts to consult. In regards to GNFN's assertion that "MNR did not discharge its duty to consult", with respect, the Ministry of the Environment has not been mandated to make a determination as to whether the MNR has met the burden of the Government's duty to consult.

In conclusion, the 2012-2014 CP and the 2012-2022 FMP for the Whiskey Jack Forest were prepared in accordance with the requirements of the FMPM.

3. Provide the web link to where a summary of Aboriginal involvement in the preparation of the FMP can be found.

The 2012-2022 Whiskey Jack FMP can be found on the Electronic FMP site at the following link:

http://www.efmp.lrc.gov.on.ca/eFMP/home.do

The summary of Aboriginal involvement has been retained at the Kenora District MNR office and its location is identified in Appendix C of the Supplementary Documentation. A copy of the summary can be found in the attachments to this letter.

Summary

GNFN, is the appropriate silvicultural system for the boreal forest, and ecosystem dominated by forest disturbance (eg. wildfire) and the planned harvest levels are in support of balanced objectives.

The issue of methylmercury was raised by GNFN for the first and only time, prior to the IEA request, in an October 24th, 2013 letter to the Premier, coincident with the Stage 4 – Review of Draft Plan. Earthroots also identified methylmercury as a potential issue for the first time in a letter dated October 31st, 2013 during Stage 4 – Review of Draft Plan.

The planning process contemplated the issue of methylmercury through the application of the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* 2010 (SSG). The accompanying Background and Rationale document for the SSG clearly acknowledges the potential for forest management activities to mobilize mercury, it provides a comprehensive summary of available scientific literature on the topic, provides a clear rationale for guide direction and acknowledges the uncertainty associated with this direction. There are no claims that SSG direction and application of the SSG will mitigate or eliminate Hg mobilization.

The summary of Aboriginal involvement identifies how MNR followed the requirements identified within the FMPM pertaining to Aboriginal consultation.

In addition to the information requested by MOE, MNR has provided some additional information with regard to the additional efforts to work with GNFN on many aspects of forestry and forest management planning on the Whiskey Jack Forest.

MNR Science Review

As part of MNR's review of the IEA request submitted by Grassy Narrows First Nation and Earthroots, MNR sought input from MNR forest scientists. They reviewed the submission, and in particular the many scientific references throughout, to ensure they were valid and pertinent to the discussion. Subsequently, MNR's forest scientists prepared the following response to the IEA requester's submission.

Introduction:

The IEA requestors contend that the Whiskey Jack forest management plan "fails to adequately deal with the impacts of logging on mercury levels in boreal water and fish" and that the plan will "harm water quality, fish habitat, wildlife and the health of people who eat the fish". To support their concern the requestors present as evidence a number of research studies that have shown that forest disturbance (both forest management and fire) result in changes to mercury dynamics within watersheds which may increase the movement of terrestrial bound mercury into aquatic systems and may be associated with higher levels of mercury in aquatic organisms.

The requestors also argue that the forest management guidelines, provided in the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (the Stand and Site Guide or SSG), do not adequately address the issue of forest management impacts on mercury dynamics.

The IEA request is presented in 15 sections which address various related concerns. In the MNR science team's attempt to evaluate the scientific basis of the request and provide comments on current forest management policies and guidelines related to the issue, we have divided the sections into 4 general themes and we will address the scientific evidence and the interpretation of this evidence that is presented in themes A and B:

A) Concerns arising from research on mercury and forest management

1. Clearcutting Impacts Water Quality Through Mercury Contamination
2. Clearcutting Elevates Mercury Levels in Fish
3. Elevated Mercury Levels Impact Wildlife
11. Duration and Intensity of Impacts

B) Concerns associated with forest management policy (SSG)

7. Measures in the Logging Plan to Deal with the Mercury Problem
8. Stand and Site Guide Rationale on Mercury
   - (i) Natural Disturbance Emulation Not Appropriate for Mercury Safety
   - (ii) Mitigation Science is Not Sufficiently Developed
   - (iii) Log Now, Test Later Approach.
12. Changes to Guidelines Are Likely to Make Mercury Problem Worse
   - (i) A. Logging to the Shoreline
   - (ii) Catchment Disturbance Thresholds Removed
13. Specific Deficiencies in MNR Mitigation Measures

C) Concerns arising from historical contamination

4. Fish in Grassy Narrows Have Critical Levels of Mercury
5. Mercury Impacts Human Health in Grassy Narrows

D) Concerns arising from the planning process (not directly linked to science/research)

6. Efforts to Raise the Mercury Issue
10. Delay and Hardship
14. Need for an Individual Environmental Assessment
15. Remedy Requested

A) Concerns arising from research on mercury and forest management

Mercury is a natural element that occurs in air, water, soil and biota in the boreal forest. Mercury, which exists in several inorganic, or elemental, forms (Hg) and as organic methylmercury (MeHg), alternates between forms and cycles among different components of the ecosystem as part of a complex biogeochemical process. Natural levels of mercury are spatially variable depending on geology, soil and forest characteristics; however, the global atmospheric pool of mercury has increased two to five fold over pre-industrial times (Linberg *et al.* 2007). There is clear evidence from a number of studies that forest management is one of a large number of factors that influence mercury dynamics within watersheds. In sections 1, 2, 3 and 11 the IEA requestors provide quotations from some of these studies to support their conclusions regarding the risk of mercury increases associated with forest management. The following is a review of these sections:

1. Clearcutting Impacts Water Quality Through Mercury Contamination

The requestors contend that forest management activities will result in an increase in Hg and MeHg in waterbodies in the area. As evidence to support this conclusion they present results from several studies conducted in Quebec, Sweden and Finland, much of which is summarized in a review paper by Bishop et al (2009).

MNR review:

- Increased mobilization of mercury within watersheds following forest disturbance has been documented in several studies done in Canada, Sweden and Finland.
- Disturbance impacts include increases in the concentration of Hg and MeHg in surface runoff (increased concentration) and increases in runoff, thereby increasing the movement of Hg even without concentration changes (transport or flux).
- Changes in Hg dynamics are highly variable among watersheds depending on a large number of factors, including watershed characteristics and the extent of disturbance. For example, Bishop et al (2009) show post-harvest Hg concentration response ranging from a 4 fold increase in a Finnish study to no increase found in a study done in Northwestern Ontario.
- Very little work is available which directly compares Hg mobilization between harvested and burned watersheds. Studies done in Quebec measured increases in dissolved organic carbon (DOC), to which Hg is bound in surface water runoff, following harvest under some conditions (large disturbance area within the watershed and a large watershed to lake area ratio) but not consistently (Carignan et al 2000).
- No research has been conducted to test the effectiveness of specific forest management planning or operational measures at mitigating increases in Hg

mobilization. Bishop et al (2009) provide some recommended practices which are similar to direction provided in the SSG (see discussion in theme B below).

Conclusion: There is strong evidence, based on a number of studies, that the rate of movement of Hg and MeHg from terrestrial to aquatic areas will increase following forest disturbance. There is not sufficient evidence to conclude that the magnitude of Hg response to forest management disturbance differs significantly from natural disturbance events in all cases; however, the mechanism of response is likely different. There is also no research available which tests the effectiveness of guidelines to mitigate changes in watershed Hg dynamics arising from forest disturbance.

2. Clearcutting Elevates Mercury Levels in Fish

The IEA requestors state that forest management activities in the Whiskey Jack forest will increase Hg inputs into aquatic systems which will harmfully alter fish habitat and result in an increase in MeHg levels in fish and other aquatic organisms. As evidence they present a number of quotes from Bishop et al (2009) as well as from Garcia and Carignan (2005). It should be noted that the Bishop et al (2009) paper is a review of previous research and all information presented on fish Hg levels come from a study by Garcia and Carignan (2000, 2005) so the evidence comes from a single study.

MNR review

- Fish in disturbed watersheds (cut and burned) had higher mercury levels than fish in undisturbed reference lakes
- Fish mercury levels were highly variable and were strongly positively correlated with fish size (fig 1) and fish trophic position (fig 4) (Garcia and Carignan 2005)
- Based on fig 4 (Garcia and Carignan 2005) more than 3 times more variability in fish mercury is associated with trophic position than with watershed disturbance and there is very little difference between fish mercury levels in cut and burned lakes when trophic position is controlled for.
- ‘The highest Hg concentrations were observed in fish from two partially burnt lakes’ (pg 690, Garcia and Carignan 2005). It appears that fire intensity (proportion of the watershed burned and the amount of organic layer burned) has a substantial impact on mercury dynamics in the watershed and the potential response of aquatic organisms.
- Through elevating DOC export from soils, an enhanced vector of Hg export to aquatic ecosystems occurs.

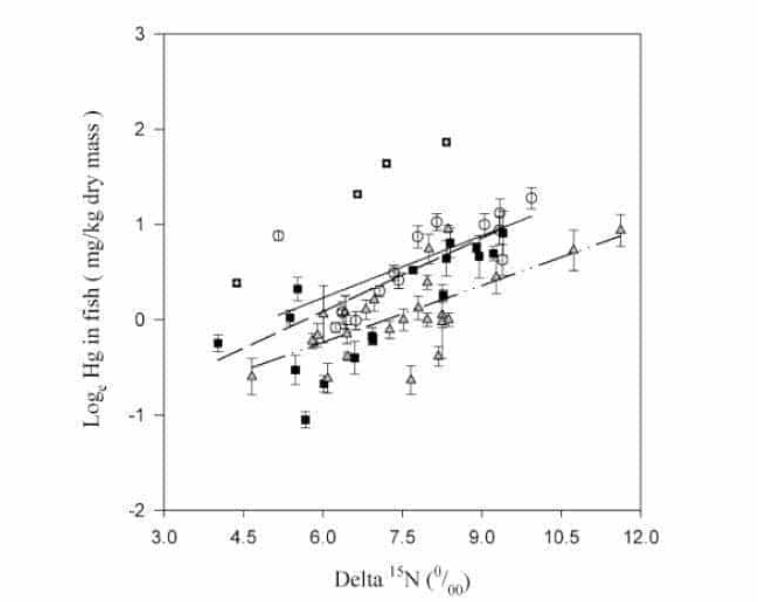

Fig. 4. Relationships between mercury (Hg) concentrations and fish $\delta^{15}N$ for reference lakes (triangles and dash-dot-dot line), and for lakes with cut (open circles and solid line) and burnt catchments (black and dotted squares for completely and partially burnt catchments, respectively, and dashed lines). Points represent fish of a standardized length from 62 populations. The $\delta^{15}N$ values are corrected for baseline variations. Error bars correspond to standard deviation.

From: Garcia and Carignan 2005

Conclusion: The comprehensive study of Quebec lakes provides evidence that fish in disturbed watersheds tend to have higher Hg concentrations than those in undisturbed watersheds. The study does not provide strong evidence that fish Hg concentrations consistently differ between burned and harvested watersheds. When trophic position is included in the analysis, fish Hg levels in harvested watersheds fall within the broader range of fish Hg levels in burned watersheds (fig 4, Garcia and Carignan 2005). This single study, despite being a very comprehensive, does not provide sufficient information to understand all the factors that influence fish Hg levels or how these factors may interact. Given the complexity of how disturbance impacts Hg dynamics and how aquatic systems may respond, it is unlikely that identical results would be seen in other regions of the boreal zone.

3. Elevated Mercury Levels Impact Wildlife

The IEA requestors express a concern that the mercury levels in a number of wildlife species, presumably those that consume fish, may increase if fish mercury levels increase. They provide evidence, primarily citing Environment Canada websites, which explains that mercury contamination can have negative impacts on the growth, development, behaviour and reproduction of wildlife species.

MNR review

- There is strong evidence that high body burdens of mercury may have toxic effects on certain wildlife species and lead to a number of health issues.
- Elemental mercury (Hg) in water and plants is not toxic to animals and is not stored in animal tissue; however, methylmercury (MeHg) is toxic and is stored and bioaccumulated in muscle and fat tissue. The main source of MeHg for terrestrial animals is the consumption of fish.
- We are unaware of any studies that directly examine the relationship between forest disturbance and wildlife Hg levels.

Conclusion: While it may be reasonable to assume that increases in fish Hg levels could lead to Hg increases in piscivorous wildlife species, the relationship between forest disturbance and fish Hg is not well understood (see section 2) and the further connection to wildlife is likely very complex and associated with a large number of interacting factors.

11. Duration and Intensity of Impacts

The requesters state on page 24 that “if further clearcutting is allowed without proven mitigation measures, and methyl mercury levels in local fish are elevated as a result, the impacts would likely be grave and long lasting.” They further contend that “the impacts of releasing mercury into the environment in Grassy Narrows through clearcut logging are likely to last at least a decade in fish, and at least one human lifespan beyond that in people”. They base their conclusions on data from studies conducted in (1) Ontario, Québec, Finland, and Sweden, much of which are summarized in studies by Bishop et al. (2009) and Garcia and Carignan (2005).

MNR review:

- The proponents state that “clearcutting has been found to increase MeHg bioaccumulation in boreal lakes by two to four fold, and sometimes as much as eight fold (Bishop et al., 2009)” (Page, 24). The further state that “As much as 37% of Hg in fish across a managed landscape would result from the increased Hg outputs associated with felling and thinning”. Bishop et al. (2009) actually calculated that forest harvesting may contribute 9 to 23% of MeHg fluxes from the soil following harvesting. They also made the point that many uncertainties existed in the calculations (e.g., small number of samples and a large range of impacts across studies).

- Few studies have been published regarding the effects of clearcut harvesting on fish MeHg concentrations. Those studies suggest that although MeHg concentrations in fish may increase following clearcut operations, it is generally limited to cases when soils are disturbed, and not to the harvesting of trees. This

was alluded to by Bishop et al. (2009), as well as reported in findings and discussions of other studies (Povari et al., 2003, Sørensen et al., 2009, Eklöf et al., 2012, 2013). Soil disturbance contributes to elevated fish concentrations in upland catchments via particulate matter (organic and mineral) transport from forest soils to streams and lakes. Whereas, soil disturbance of lowland (e.g., wetlands and riparian zones) catchments increase MeHg runoff to streams and lakes via enhanced dissolved organic carbon (DOC) transport. Therefore, no evidence exists contrary to the protection of soils from disturbance as described in the Stand and Site Guide as a mitigation measure minimizing forest harvesting operation effects on fish MeHg concentrations.

- The requesters further contend on pages 24 – 25 that “impacts of clearcutting on mercury have been found to persist for at least five years, with no known endpoint” and “the increased in Hg loading effect has also been observed to persist up to at least 5 years, and there are no examples so far of the logging effect having dissipated (Bishop et al., 2009)”. In fact, Skyllberg et al. (2009) assessed stream MeHg concentration in Sweden by comparing 47 clearcut stands dominated by Norway spruce to 10 mature Norway spruce-dominated stands. They showed stream MeHg concentrations were elevated in stands 0 to 4 years after harvested, but no differences occurred in MeHg concentration in streams 4 to 10 years after harvested. Skyllberg et al. (2009) suggested these results were attributed to increased organic matter added by logging residue stimulating Hg methylating bacteria in the soil, and by 4 to 10 years, this effect dissipated.

- The Hg in fish higher in the food chain continued to increase several years after harvest (Garcia and Carignan 2000, 2005, as cited in Bishop et al., 2009 (Page 24).
  See response to section 2 for discussion of fish Hg response.

- The requesters contend on pages 25 – 26 that logging is likely to (1) further elevate mercury in fish in previously contaminated lakes due to increasing methylation rates of newly added mercury and stored mercury in lake sediments, (2) prolong the length of time for which fish in previously contaminated lakes remain unsafe to eat, (3) elevate mercury levels in fish in marginally safe lakes above safety limit, and (4) elevate mercury levels in fish in currently safe lakes above the safety limit.

trends in mercury in walleye, northern pike, and lake-whitefish in 4 lakes along a chain of lakes occurring from closest to furthest locations from a paper mill source (approximately 10 tonnes Hg input between 1962 and 1970); Clay, Ball, Separation, and Tetu Lakes, respectively. Neff et al. (2012) found that for all lakes and fish species, mercury declined by 35 to 94% through time, although walleye and northern pike mercury concentrations were above (Clay Lake) or near (Ball and Separation Lakes) the human consumption guideline of 0.5 µg g-1 of fish tissue. Additionally, the authors summarized mercury concentrations of walleye (45 cm length) and northern pike (50 cm length) based on 143 and 123 locations in northwestern Ontario. Neff et al., (2012) reported median values near the 0.5 µg g-1 guideline for walleye (25th – 75th percentiles = 0.38 and 0.75 µg g-1, respectively) and median of 0.38 (25th – 75th percentiles = 0.25 and 0.60 µg g-1, respectively) for northern pike.

Most rapid declines in fish mercury concentrations occurred between 1970 and 1985; however declines slowed from the late 1980s to 2010. Contributions to the slower declines are many and include (1) the lakes approaching baseline values prior to mercury contamination, (2) climate change enhancement of (a) area burned and severity of soil organic matter and mercury combustion or (b) extended drought followed by intense precipitation events, (3) catchment cover types and the wetland-to-lake ratio, and (4) connectivity of wetlands, streams, rivers, and lakes in a drainage basin.

- The proponents also suggest on pages 25 – 26 that “clearcutting leads to higher DOC compared to reference lakes and burned lakes (Garcia and Carignan, 2005), stimulating bacterial methylation, decreasing photo-oxidation of MeHg to Hg^{2+}, and possibly decreasing photo-reduction of Hg^{2+} to gaseous mercury. Those processes were suggested to elevate mercury levels in fish.

  Research has shown in the temperate and boreal regions of North America (Couture et al., 2012) and Europe (Laudon et al., 2013) that climate change is the primary cause of elevated DOC concentrations in lakes. Moreover, although studies (e.g., Haines et al., 1994; Sellers et al., 1996) suggest elevated DOC concentrations may inhibit photo-oxidation of MeHg and reduction of Hg^{2+} to gaseous mercury these results are far from universal. For example, although DOC is an important transport vector for Hg^{2+} and MeHg, this DOC is highly recalcitrant (e.g., low bacterial degradability). Whereas bacterial methylation is dependent upon the presence of easily degradable DOC concentrations (as well as electron acceptors such as sulphate); thus increasing DOC-Hg transport from soil to lakes does not necessarily translate into greater rates of mercury-methylation.

Conclusion: For forest harvesting to further exacerbate walleye and northern pike mercury concentrations in lakes situated in the English-Wabigoon River System, any mercury input to upstream catchments will need to traverse a myriad of interconnected

wetlands, streams, and lakes within the river system. However, we are aware of no published studies addressing potentially elevated long-range mercury transport in large drainage basins. In terms of MeHg (and assuming it is elevated in headwater catchments), some of it would be removed from the water column of lakes through (1) MeHg photo-oxidation to Hg^{2+} and its subsequent reduction to gaseous mercury and loss to the atmosphere or (2) settling of DOC- and particulate matter-bonded mercury from the water column to the sediments as water moves downstream. While much variation occurs in the photo-oxidation rates of MeHg to Hg^{2+} and its reduction to gaseous mercury, the current scientific evidence indicates that protecting soils from disturbance during harvesting operations as spelled out in the Stand and Site Guide will minimize total and methyl mercury loading from soils to streams and lakes in a catchment. Furthermore, it can be reasonably argued that any MeHg-containing water resulting from harvesting in headwater catchments will be diluted prior to reaching the English and Wabigoon Rivers and their connected lakes, thereby contributing little to mercury concentrations in the river system's lakes.

B) Concerns associated with forest management policy (SSG)

Direction in the SSG was based on a thorough review of existing literature, and discussions with and review by ecological researchers, practitioners, policy makers, stakeholders, and members of the public to ensure that direction would be effective in meeting ecological objectives, while also being feasible to implement and socially palatable. *'In all cases, the direction in the Stand and Site Guide represents a series of predictions or hypotheses. Those with a high degree of uncertainty have been identified as a high priority for testing through an effectiveness monitoring program (see Section 7). The results of this monitoring program, along with other sources of information, will be used during periodic reviews of the Stand and Site Guide to help determine when the guide needs to be revised'* (SSG section 1.3.5, pg 5). The SSG therefore represents a summary of the best available direction to meet MNR's objectives and legislative requirements for sustainable forest management and incorporates an adaptive management approach to evaluate and improve direction in areas of uncertainty.

Section 1.3 of the SSG summarizes the guide's approach to conserving forest biodiversity using guidance characterized as coarse and fine filters. This direction is based on the principles of the *Crown Forest Sustainability Act, 1994* (CFSA) which a key piece of legislation regulating forest management. Specifically the CFSA states:

> *The long term health and vigor of Crown forests should be provided for by using forest practices that, within the limits of silvicultural requirements, emulate natural disturbances and landscape patterns* [coarse filter] *while minimizing adverse effects on plant life, animal life, water, soil, air and social and economic values, including recreational values and heritage values* [fine filters] (CFSA s. 2(3)2).

The coarse filter approach to the emulation of natural disturbance and landscape patterns is intended to maintain the natural diversity of forest condition and ecological processes in order to conserve forest biodiversity and is a legal requirement under the CFSA. The coarse filter is not intended as a specific mitigation measure but rather an approach to maintain the state of all elements of the forest ecosystem within a natural range. Fine filter direction is included when there is evidence that additional mitigation measures will improve the protection of specific values.

During the development of the SSG, MNR did an extensive review of the body of scientific literature examining the relationship between forest disturbance and mercury dynamics. A summary of this review and the resulting decision on guide direction are provided in the SSG Background and Rationale document (pg 23-25) which is included as an appendix in the IEA request. The key points from the review were:

- The potential for forest management activities to result in mobilization of terrestrial mercury into aquatic systems is well documented and a serious concern.
- The nature and magnitude of changes in mercury dynamics within a watershed following disturbance are complex and related to a number of interacting factors including area disturbed, changes to hydrology, the amount and type of wetland in the area and soil disturbance.
- There is limited information on the potential for fish Hg levels to be influenced by harvest disturbance but the best available evidence shows that fish in lakes with disturbed watersheds had higher mercury levels than those in undisturbed watersheds and that the range of Hg levels in fish in harvested watersheds was within the range of those in burned watersheds (Garcia and Carignan 2000, 2005).
- There is a high degree of uncertainty regarding Hg response to forest management and the issue should be a high priority area for guide effectiveness monitoring.

Because there are no studies which identify or evaluate mitigation measures to minimize mercury mobilization following disturbance there are no mitigation measures specific to mercury in the SSG. The guide does provide direction to minimize site disturbance, sediment transport and hydrologic disruption (listed on pg 24 of the SSG Background and Rationale) all of which may be associated with increased mercury mobilization. In a review paper published following the release of the SSG, Bishop et al (2009) conclude that “An understanding of the processes controlling the output of Hg from catchments to surface waters, and subsequent bioaccumulation, is not sufficiently developed to confidently recommend ameliorative measures for forestry” (pg 378). They do offer some suggested practices, which include minimizing site disturbance and hydrological disruption and protecting wetlands. Direction in the SSG is entirely consistent with the recommendations of Bishop et al (2009).

The IEA request raises a few specific concerns about the SSG which suggest that they have misinterpreted the direction in the guide:

- In section 8 the requestors interpret the SSG rationale on mercury as stating "1. Logging is essentially equivalent to fire so attempts to emulate fire will eliminate Hg impacts". The SSG does not suggest that emulation of natural disturbance patterns will eliminate Hg impacts. The emulation of natural disturbance patterns within watersheds is expected to result in watershed scale hydrologic changes that are within the range that would occur as a result of natural disturbance processes. The SSG provides additional direction to minimize site disturbance associated with harvest and road construction, particularly in areas that are expected to have higher soil moisture levels. The SSG acknowledges that Hg dynamics will likely change within the watershed as a result of any type of forest disturbance and that further research and monitoring is required to refine direction in the guide.

- In section 9 the requestors state that "logging and forest fire have nearly opposite impacts on mercury" (pg. 16). This statement is demonstrably false as all the literature they cite as evidence shows that Hg is mobilized and/or bioaccumulated following both fire and harvest disturbance. The mechanism and magnitude of Hg response almost certainly differs between burned and harvested watersheds but all of the studies cited found some level of Hg response following disturbance by fire. Fire intensity is likely an important factor that influences Hg response with high intensity fires volatilizing Hg bound in the organic soil layer and low intensity fires leaving this layer undisturbed and Hg subsequently being mobilized as water tables rise and surface runoff increases. In their study of fish Hg levels, Garcia and Carignan (2000, 2005) found the highest Hg levels in fish from watersheds impacted by low intensity fires and lower Hg levels in fish from watersheds with high intensity fires. Fish Hg levels in harvested watersheds fell within this range (Garcia and Carignan, 2000, 2005). (Note that the requestors appear to use fire size and fire intensity interchangeably when in fact these measure different things)

Conclusion: The Stand and Site Guide and accompanying Background and Rationale document clearly acknowledge the potential for forest management activities to mobilize mercury, provide a comprehensive summary of available scientific literature on the topic, provide a clear rationale for guide direction and acknowledge the uncertainty associated with this direction. There are no claims that SSG direction will mitigate or eliminate Hg mobilization.

Outline of recently completed, ongoing, and proposed MNR research activities addressing identified science gaps with respect to total and methyl-mercury dynamics in forested watersheds.

As noted in section B (Concerns associated with forest management policy – SSG) of MNR's response to the current IEA request, and highlighted in the SSG Background and Rationale document there remains a high degree of uncertainty regarding Hg response to forest management activities. As such, MNR views this as a high priority area for guide effectiveness monitoring and research. It is anticipated that results from MNR's ongoing research efforts will be a valuable source of new scientific knowledge that will be used during the required periodic reviews of the SSG as part of the adaptive management approach to evaluate and improve direction in the guide with respect to minimizing the adverse effects of Hg mobilization and subsequent bioaccumulation.

As has been clearly highlighted in MNR's response to the IEA request of the Whiskey Jack FMP, total and methyl mercury export from terrestrial to aquatic ecosystems, and their accumulation through trophic levels in the latter are controlled by a myriad of interacting processes, including disturbance type and intensity, inherent site conditions, atmospheric mercury deposition, and climate change. These interacting factors contribute further to the high variability in mercury dynamics within forested watersheds. As such, MNR is supporting a number of research projects that are well-positioned to address critical science gaps associated with terrestrial and aquatic mercury dynamics, many of which have been part of multi-institutional (provincial ministries, federal , and academic) partnerships. The summary below provides brief overviews of research projects that are: (1) examining patterns in fish mercury bioaccumulation, (2) evaluating the levels of mercury runoff from forest and wetland soils to aquatic systems, (3) mercury research conducted by other provincial and federal agencies, some of which include MNR as partners, and (4) a proposed synthesis of land use effects (e.g., mining, hydroelectric, and forest management activites) on watershed Hg cycling and export..

1. **Fish mercury bioaccumulation**
   A. MNR research lead: Dr. Tom Johnston, Research Scientist, Aquatic Research and Monitoring Section
      1) Ongoing efforts to update fish mercury information, both in the near north and far north, to improve consumption guidelines and assist with community-based land-use planning.
      2) Determine temporal changes in fish mercury bioaccumulation, 1970s to present. These efforts are largely focused in the near north but does include some work in the far north as well. This project was the basis for Rex Tang's MSc thesis and has already been published (Tang et al. 2013. Sci. Tot. Environ.). Additional work is targeting additional lakes to provide

better geographic coverage for the analysis, and considering to repeat the analysis over shorter (more recent) timeframes.

3) Assess the relative importance of food web position and growth rate in shaping interspecific variability in piscivore mercury concentrations. This project is targeting lakes that have co-habiting populations of lake trout, burbot, walleye, and northern pike. This will allow us to control, to some extent, the between-lake variability when making interspecific comparisons.
4) Determine the spatial variation in fish mercury concentrations from headwaters to James Bay in the Attawapiskat River drainage basin (Lescord PhD project, started 2013). This project is restricted to the far north and looks at mercury dynamics following a river continuum framework. The PhD candiate will compare how mercury moves through the food web at various points along the continuum from the headwater lakes of the shield, to the main stem river of the lowlands.
5) Determine the roles of physical-chemical limnology and food web structure in shaping fish mercury patterns in lakes across a climatic gradient (Sumner MSc project, started 2013). The MSc student will examine lakes across the near north and far north, comparing the role of climate (inferred from latitude or GDD) with the role of other factors. She may include some landscape factors (e.g., area or vegetation cover of drainage basin) in the analysis.

B. MNR research lead: Dr. Rob Mackereth, Research Scientist, Centre for Northern Forest Ecosystem Research
   1) Ongoing monitoring of mercury in small stream biota to evaluate the association between the rate of bioaccumulation and biomagnification of mercury and stream characteristics, including catchment disturbance. Sampling of periphyton, benthic invertebrates and fish have been conducted in watersheds having different forest management histories. Results to date show that mercury is present in all stream biota and tends to be higher in small streams compared to large. We have found no differences in fish mercury levels based on forest management activities in the watershed. Fish and invertebrate mercury concentrations tend to be associated with local conditions including pH, conductivity, stream gradient and temperature. Future work will focus on measuring fish and invertebrate mercury levels in streams within burned watersheds.

2. Mercury runoff from forest and wetland soils to aquatic systems

A. MNR research lead: Dr. Rob Mackereth, Research Scientist, Centre for Northern Forest Ecosystem Research
   1) The Escape Lake experimental watershed study was initiated to evaluate the impacts of forest management activity on the hydrologic connectivity between terrestrial and aquatic habitats and to observe the catchment scale hydrologic (groundwater levels, surface water flow, water chemistry)

and soil chemistry response. Beginning in March 2003, the watershed was surveyed (high resolution DEM, vegetation plots, soil pits) instrumented (wells and pizometers in wetland and along 3 experimental and 1 reference hillslope transect, resin bag transects) and monitored for 1.5 years. Experimental clearcut harvesting was carried out in June 2004, and included harvesting merchantable trees within the prescribed 30m buffer. Water quality constituents examined include major cations (Ca^{2+}, Mg^{2+}, K^{+}, Na^{+}) and anions (SO_4^{2-}, Cl^{-}), nutrients (NO^{3-}, NH^{4+}, TN, ortho-P, TP), TSS, turbidity, DOC, SRSI and metals (Al, Fe, Mn, Cu, Cd, Pb, Zn, Ni and MeHg and THg). Mercury concentration in ground and surface waters did not increase; however, following harvest, catchment water yield approximately doubled relative to pre-h
Hg flux.

2) The associations between watershed and lake scale characteristics with THg in piscivorous fish were examined as part of an MSc research project (Victoria Danco). ArcGIS was used to delineate the waterbody catchment area and extract waterbody catchment characteristics for 243 of northern Ontario's lakes. Walleye (*Sander vitreus,* n= 121 lakes), lake trout (*Salvelinus namaycush,* n= 60 lakes), brook trout (*Salvelinus fontinalis*, n= 18 lakes), northern pike (*Esox lucius,* n =107 lakes), smallmouth bass (*Micropterus dolomieu*, n = 37 lakes), and burbot (*Lota lota,* n= 4 lakes) populations were standardized to the mean length of the populations by using power-series regressions. Multivariate analysis (non-metric multidimensional scaling) and univariate analysis were used to determine the associations between total mercury concentrations in fish and watershed scale and lake scale variables. Watershed and lake chemistry characteristics poorly described the variability in THg concentrations. Forest harvesting and natural disturbance were not associated with fish mercury concentrations.

B. MNR research lead: Dr. Jim McLaughlin, Research Scientist, Forest Research and Monitoring Section

1) Climate change effects on total and methyl mercury runoff from peatlands. Intact peat monoliths were collected in 2012 from peatland located near White River and transported to the University of Western Ontario BIOTON, where we are exposing the cores to varying atmospheric-CO_2 concentrations, air temperature, and water table levels in a replicated experiment. Preliminary results point to low water table followed by rewetting of the peat through precipitation significantly elevated MeHg in runoff water compared to other treatments. Our PhD student (Catherine Dielman, started in 2013) is currently testing the relationships among climate change, plant vegetation, peat decomposition, Hg release, and its transport in conjunction with DOC flux.
2) On April 4 2014, the NSERC-Research Tools and Infrastructure funding program awarded us (University of Western Ontario, lead institute) a grant

to establish a field-based experimental system for the evaluation of the effects of elevated temperature and elevated atmospheric carbon dioxide (CO_2) on total and methyl mercury runoff peatlands.

3) Establishing baseline conditions for Far North peat total mercury storage. This project is ongoing, where peat samples are collected and analyzed for total mercury concentration, bulk density, and peat depth to mineral sediment recorded. The data will then be used to scale peat mercury levels to peatland area of the Far North.
4) Establishing baseline conditions for forest soil mercury storage. This project is also currently ongoing, where organic (e.g., forest floor) and mineral soil samples collected at selected locations are analyzed for total mercury and bulk density, and soil horizon thickness. These will then be used to scale total mercury levels by forest cover types in the Far North and Managed forest.

3. Other provincial and federal mercury research and monitoring studies

A. Ontario Ministry of the Environment
   1) Monitoring Results for Mercury in Ontario's Water in the Great Lakes, northern Ontario lakes, and the English-Wabigoon River System.
   2) Ontario Ministry of Environment commitment to fund the Experimental Lakes Area (ELA), which is one of the world's premier watershed-based studies on forest, wetland, and aquatic mercury cycling and transport research in the boreal forest. Past research has involved the Department of Fisheries and Oceans.

B. Canadian Network for Aquatic Ecosystem Services
   1) This national research network supported by NSERC's Strategic Network Grants program, which encourages large-scale, multidisciplinary, collaborative research projects that could improve Canada's economy, society and environment within the next decade. The network is a consortium of approximately 30 researchers from 11 universities, government, and industrial partners. The Attawapiskat River Basin is one of the intensive study locations.
   2) Provincial (MOE and MNR) and federal (Department of Fisheries and Oceans and Canadian Forest Service) are network partners, whose research and monitoring staff are working with Ontario universities (University of Western Ontario, University of Toronto, and Laurentian University), and those across Canada, to establish baseline conditions of aquatic mercury levels and understanding mercury transport (and methylation) mechanisms from terrestrial to aquatic ecosystems.

C. Environment Canada
   1) Canadian Environmental Sustainability Indicators tracks the emissions of mercury to the air. The data used to calculate these indicators are taken from the Air Pollutant Emission Summaries and Trends and the National

Pollutant Release Inventory (NPRI), Canada's legislated, publicly accessible inventory of pollutant releases. National and regional emissions of mercury are provided, with emissions broken down by source.

4. Synthesis of land use (e.g., mining, hydroelectric, forest harvesting and regeneration) effects on watershed total and methyl mercury cycling and export

A. Draft outline for synthesis
   1. Mercury atmospheric deposition amounts and trends.
   2. Forest and peatland mercury cycling and runoff to aquatic ecosystems.
   3. Mercury methylation and demethylation processes.
   4. Mercury turnover rates in litter and soil.
   5. Watershed hydrology and mercury fluxes.
   6. Aquatic mercury cycling and fluxes.
   7. Land use activities (e.g., forest harvesting, hydroelectric, mining activities) and their cumulative effects on aquatic mercury levels.

It is anticipated that this synthesis effort will be a key science product that will help guide the development of future research efforts to continue targeting important science/knowledge gaps with respect to Hg dynamics and response to land use activities.

Additional Forestry Discussions with Grassy Narrows First Nation

It is very important to note, that in addition to the consultation requirements addressed during the preparation of the 2012-2014 Whiskey Jack CP, and the 2012-2022 Whiskey Jack FMP, MNR has been actively involved in improving the relationship with GNFN for many years. Various representatives of MNR including the local District Manager, Regional Director and Assistant Deputy Minister's, have engaged in direct face-to-face efforts to hear and understand Grassy Narrows's community leadership and its members' views on forestry. Preparation of the 2009-2019 ten (10) year Forest Management Plan was delayed numerous times using interim FMPs called contingency plans (CP). These plans, the 2009-2012 CP and the 2012-2014 CP, were used to demonstrate MNR's commitment to the relationship by enabling ongoing discussions with GNFN. The result was that the development of a full and complete forest management plan, as per the Crown Forest Sustainability Act, was delayed for 5 years.

The following is a brief summary of the additional discussions undertaken by MNR with GNFN that are outside of the forest management planning process, that demonstrate MNR's ongoing commitment to build a sound relationship with GNFN:

- Grassy Narrows First Nation (GNFN), MNR, Abitibi and Indian and Northern Affairs Canada (INAC) have been in forestry discussions, individually or as a group, at various times, since at least 2004. In March 2004, focused discussions were initiated in response to road blockades organized by members of GNFN and their sympathizers. These discussions sought to understand and respond to GNFN grievances around forestry activities on the Whiskey Jack Forest.
- MNR, Abitibi and INAC indicated throughout the talks that they were prepared to discuss GNFN grievances on a practical basis, i.e., measures to address concerns

about how forestry was conducted, not rewriting the provincial forestry legislation or considering assertions for jurisdictional control of the GNFN traditional lands. The parties met on numerous occasions throughout 2004 and 2005 and exchanged a series of Interim Measures documents including a final joint offer that responded substantively to GNFN demands for enhanced consultation and involvement in forest management planning and increased economic benefits from forestry activities.

- The Interim Measures included annual funding for three years for capacity, infrastructure and community support as well as economic benefits in the form of preferential contracting and employment and annual wood allocation valued at approximately $2.5 million. Grassy Narrows First Nation has not responded or accepted these interim measures to date.
- Grassy Narrows has repeatedly rejected recent offers and has indicated that all future land use activities on their "homeland" will be directed by a culturally and ecosystem-based plan to be prepared independently by GNFN.
- GNFN has indicated that they will no longer react to "clearcut plans" of others nor are they able to remove existing blockades, release downed wood behind the blockades or enter into any agreement that would guarantee no further disruption of forestry operations.
- In 2008 Grassy Narrows First Nation and MNR signed a Memorandum of Understanding, which is referred to as the “Process Agreement”, to explore numerous aspects of forestry in the Whiskey Jack Forest as part of a multi-year process. The Honorable Justice Frank Iacobucci mediated the discussions between GNFN and MNR that led to the development and signing of the Process Agreement.
- During that time Grassy Narrows has received significant provincial funding and has worked with MNR on various working groups on matters related to forestry practices (i.e. new area of concern prescriptions, harvest block design, harvesting systems, etc.) and traditional values and use studies. These forestry practices were to be tested in the 115,000 hectare Pilot Project Area that was identified and agreed to by GNFN as part of the Process Agreement.Between 2009 and 2014 MNR deferred the completion of a new forest management plan to allow for Grassy Narrows to apply these practices; unfortunately little progress has been made during that time.
- This Process Agreement was twice mediated by the Honorable Justice Frank Iacobucci without resolving the lack of commitment by GNFN to achieving the practical measures identified in the agreement (e.g., traditional use study, forest management prescriptions to protect identified aboriginal values, etc.) or those identified in the mediated settlements (e.g., concurrent limited harvesting and concurrent forest management planning).

- In 2012, MNR initiated detailed discussions with Grassy Narrows on the basis of their potential involvement in establishing a new forest tenure arrangement for the Whiskey Jack Forest.

- In 2013, MNR begun discussions with nine First Nation communities, including Grassy Narrows First Nation, to explore transition to an enhanced sustainable forest licence (ESFL) for the Whiskey Jack Forest and give First Nations communities a greater say in the resource management.
- Since 2004, Kenora District MNR staff have engaged the communities leadership, Chief and Council, on matters relating to economic development opportunities for the community and the opportunities to be afforded to the community by participating in the forest economy (e.g., tree planting, brush saw tending contracts, slash pile burning, etc.) and forest management planning.
- Since 2004 the issue of mercury or methyl mercury release through forest practises was not brought up as an issue critical to the community, until the IEA Request was filed by GNFN/ Earthroots.

- TBA - Ochiichagwe'babigo'inning First Nation (Dalles)

Communications

Invitation to Participate
Letters were sent on February 2, 2010 from the District Manager to the current Chief of each First Nations Community in both the Whiskey Jack and the Kenora Forest Management Units as an Invitation to Participate in the 2012-2022 Plans. The letter mentions the possibility of combining forest units as well as the need for an Aboriginal Task Team.

Only one response was received through the Minister's Office. A response from the Ministers Office was sent out June 22, 2010

LTMD
Registered Letter was sent to communities and Metis Council on December 14, 2011 inviting review and comment on the Long Term Management Direction for the Whiskey Jack Forest. One community requested an open house in early 2012.

(See Contingency Plan Consultation for communications during hiatus)

Stage 3
Letters were sent January 14, 2013 from the District Manager to the Chiefs of each First Nation Community identified above, to inform that Planning is starting for the WJ FMP 2012-2022. Please advise if Chief and Council would like a session brought to their community.

On January 31, 2013, a follow-up letter was sent from the District Manager to Chiefs within the WJF and the Metis Council announcing the MNR et al intentions to hold public information centres on the progress to date in the preparation of the FMP for the WJF.

Draft Plan
On July 30, 2013, a detailed information package and letter was sent to Chiefs within the WJF and to the Kenora Metis Council regarding the upcoming information centres for the Draft Plan. This letter invited the communities to Information Centres for the 2012-2022 Whiskey Jack Forest Draft Management Plan to be held September 3 to 6th in Kenora, Sioux Narrows, Red Lake and Ear Falls. The option to have an information centre at individual communities was presented.

Final Plan
On December 23, 2013 letters were sent from the District Manager to the Chiefs of each First Nation Community identified above, to invite them to inspect the Approved 2012-2022 Whiskey Jack FMP. The Final Plan was available for inspection between December 23rd, 2013 and January 22nd, 2014.

RE: Reply of Grassy Narrows and Earthroots to Ministry of Natural Resources' Response to Request for an Individual Environmental Assessment on Whiskey Jack Forest Management Plan 2012-2022

Dear Mr. Wills,

This letter and the attached document are the reply to the Ministry of Natural Resources (MNR) response to the request of Grassy Narrows and Earthroots for an Individual Environmental Assessment (IEA) of the Whiskey Jack Forest Management Plan (FMP).

We expected the MNR to argue that their mitigation measures will work, that mercury will not be released by logging, and that human and environmental health will not be harmed by the implementation of the Whiskey Jack FMP 2012-2022. They did not.

The MNR's overall argument appears to be about process, not outcome. They claim they have followed the letter of the law on forest management planning (regardless of whether the FMP will lead to the release of mercury).

This reply responds to MNR's characterization of the science and of the input from Earthroots and Grassy Narrows, points out relevant scientific issues that they have ignored, and argues (along with the original IEA request) that they have not met the specific requirements of the their own Stand and Site Guide (SSG) and FMP Manual (FMPM) (see section on Page by Page Comments below for a partial list).

More fundamentally, this matter is about protecting the health of people in Grassy Narrows and the health of the environment.

The FMP activities are likely to release mercury into the environment causing harm to human and environmental health. The MNR does not deny this. Therefore, the FMP is flawed, should not be implemented, and should be subjected to an IEA.

If the Crown Forest Sustainability Act (CFSA), FMPM and SSG can be complied with while causing harm to human health and the environment, then they are flawed.
The MNR does not challenge our assertion that the FMP will cause harm through the release of mercury into the environment. Rather the MNR seems to be arguing that they don't have a duty to prevent harm because they have followed the SSG requirements (i.e. that there are no proven measures to mitigate the harm, and that the harm is within the range of that caused by fire).

It is not acceptable for the MNR to knowingly cause harm simply because they don't know how to mitigate it, and because acts of god also cause harm.

The damming of Grassy Narrows' river, the dumping of 9,000 kg of mercury by a Dryden mill into the river, and now clearcutting, have had severe and compounding impacts on Grassy Narrows' health and way of life. Each of these successive actions "followed the rules" at the time but did not apply the precautionary principle, and did not have Grassy Narrows' free, prior, and informed consent. All of these past activities are now known to be harmful.

In this case, there is already sufficient scientific evidence to know that clearcutting will likely cause harm through the release of mercury. There is also sufficient discretion and existing legislation for the MOE to act now to prevent this avoidable harm.

There is one proven measure to prevent this harm – don't permit logging in Grassy Narrows Territory until there are proven ways to avoid harm, and until Grassy Narrows has given their free, prior, and informed consent.

Will Ontario start on a new path towards respect, healing, and reconciliation with Grassy Narrows by requiring an IEA of this logging plan? Or will Ontario repeat the mistakes of the past at the expense of another generation of Grassy Narrows' children?

Thank you for considering our request and for taking these comments (see following document) into consideration.

If you have any questions, or would like elaboration on any points, please do not hesitate to contact us.

Sincerely,

Amber Ellis

C.	**Page by Page Comments (responding to Appendix 6)**	**9**
D.	**Conclusions**	**21**

A. MNR APPARENT ARGUMENT

The MNR's overall argument appears to be that it concedes that:

I. "The potential for forest management activities to result in mobilization of terrestrial mercury into aquatic systems is well documented and a serious concern." (p.19 ph3)
II. "There are no claims that SSG direction and application of the SSG will mitigate or eliminate Hg mobilization." (p. 10 ph 3) "MNR has made no further commitments in the FMP to address the issues raised by the requesters. (p.7)

But we have complied with the law because the law requires us only to comply with the SSG and FMPM. The CFSA (s. 2(3)2) requires us to apply coarse filters (natural disturbance emulation) and fine filters (specific mitigation measures), and this is implemented through the SSG.

1. **Mercury release from logging is allowed by the coarse filter requirements**

   "The coarse filter is not intended as a specific mitigation measure but rather an approach to maintain the state of all elements of the forest ecosystem within a natural range." (p.19 1st ph)

   "The range of Hg levels in fish in harvested watersheds was within the range of those in burned watersheds (Garcia and Carignan 2000, 2005)." (MNR p. 19)

   "There is not sufficient evidence to conclude that the magnitude of Hg response to forest management disturbance differs significantly from natural disturbance events in all cases; however, the mechanism of response is likely different." (p. 13 2nd ph)

   Therefore, the legal requirements of the coarse filter have been met.

2. **Specific mitigation measures for mercury are not required**

   "Fine filter direction is included in the SSG when there is evidence that additional mitigation measures will improve the protection of specific values." (p.19 first ph)

   "No research has been conducted to test the effectiveness of specific forest management planning or operational measures at mitigating increases in Hg mobilization." (p.12 last ph)

   "Because there are no studies which identify or evaluate mitigation measures to minimize mercury mobilization following disturbance there are not mitigation measures specific to mercury in the SSG. (p.19 last ph)

   Therefore the legal requirements of the fine filter direction are met.

3. **We are studying the problem.**

"Those [SSG directions] with a high degree of uncertainty have been identified as a high priority for testing through an effectiveness monitoring program (see Section 7). The results of this monitoring program, along with other sources of information, will be used during periodic reviews of the Stand and Site Guide to help determine when the guide needs to be revised." (p. 5, SSG)

The measures in the SSG for mercury are highly uncertain and so we have identified them as a high priority for monitoring and study. We are supporting a number of studies on mercury.

Therefore the legal requirement to have up to date science, use adaptive management, and monitor are met.

4. **The complaints about mercury came late in the process**

Earthroots and Grassy Narrows raised the mercury issue late in the process so it was not given special consideration in the FMP. We followed the letter of the planning process.

B. GENERAL COMMENTS (corresponding to points above)

I., II., These statements alone should be sufficient to justify an Individual Environmental Assessment (IEA). The MNR does not state a position on whether or not an IEA should be required. But given the nature of their other comments we assume that they oppose an IEA.

1. **MNR Position**: The mercury impacts of logging are within the range of those from fire. The coarse filter is intended to "maintain the state of all elements of the forest ecosystem within a natural range." (p.19)

GRASSY NARROW/EARTHROOTS Reply:

a. Act of god vs. act of man:

-Fires create environmental conditions (including heat, smoke, and lack of oxygen) that kill people and wildlife, destroy property, and cause other harm. That does not mean that it is acceptable for logging to do so;

-If lightening starts a fire it is an act of god; If a person starts a fire it is a crime (arson). Both fires may have the exact same impacts, but one is illegal and the other is not;

-Un-preventable acts of god are not sufficient bounds for the impacts of planned and deliberate human activities;

-Analogy: Earthquakes are natural and can destroy entire cities. Therefore, it is allowable for blasting to destroy a city.

b. MNR ignores the fact that most area burned by fires in the boreal forest is burned by intense fires:

-Garcia and Carignan indicate that intense fires do not significantly raise mercury levels in fish (logging did);

-Intense fires may form a pathway for mercury out of the total forest mercury pool (terrestrial + aquatic) (logging does not);

-"Most area burned in N American boreal forests is by high intensity crown fires, and this is likely to continue in the future" (de Groot et al., 2003, p.363);

-Therefore, the total mercury pool in a logging dominated landscape may be higher than a fire dominated landscape. (i.e. not within the natural range for the landscape);

-The total aquatic mercury pool in a logging dominated landscape may also be higher than in a fire dominated landscape;

-When looking at the statistical trend line (rather than the data points) Fig. 4 of Garcia and Carignan shows that logging generally led to higher levels of mercury in fish than fire did.

2. **MNR Position:** There has been no testing of mitigation measures. Proven mitigation measures do not exist, so we don't need to mitigate.

GRASSY NARROW/EARTHROOTS Reply:

a. Lack of proven mitigation does not justify authorizing activities that release poisons that are harmful to humans and the environment;

b. There is one proven mitigation measure – not logging until mitigation measures (e.g. selective logging with large buffers) are tested and proven;

c. The MNR ignores the fact that the Quebec study conducted by Garcia and Carignan tested logging using the Clearcut with Protection for Regeneration and Soils method. This method includes mitigation measures that are generally equivalent to, or stronger than, those in the SSG (buffers, relatively small clearcuts, limiting soil disturbance, and hydrological disruption). So the Quebec study is a de-facto test of those mitigation methods. Those clearcuts raised mercury levels above safety limits in all cut lakes in that study. So there is evidence that the non-mercury specific mitigation measures in the SSG do not work for mercury;

d. The MNR does not account for the fact that scarification and thinning may release and methylate mercury as well as harvesting in some circumstances through possible mechanisms including soil disturbance, increased availability of fresh and decaying

e. The SSG claims that "Where information was incomplete and/or ambiguous, a conservative approach was taken through judicious application of the precautionary principle." (SSG p. 5) The SSG and FMP do not use a precautionary approach for mercury:

In the MNR response they quote the final paragraph of SSG section 1.3.5, page 5 but notably omit the first sentence that states:

"This could be considered as following the precautionary principle. In all cases, the direction in the Stand and Site Guide represents a series of predictions or hypotheses. Those with a high degree of uncertainty have been identified as a high priority for testing through an effectiveness monitoring program (see Section 7). The results of this monitoring program, along with other sources of information, will be used during periodic reviews of the Stand and Site Guide to help determine when the guide needs to be revised."

The MNR is not following a precautionary approach. What MNR has provided is proof that mercury will likely be released and that it has no mitigation answer. The MNR also has little or no baseline information for mercury levels in many Grassy Narrows lakes, no program to monitor the impacts of logging on mercury levels in Grassy Narrows Territory, and no program anywhere to directly test and evaluate the mercury impacts of various logging methods and mitigation measures.

f. The SSG measures are not "entirely consistent with the recommendations of Bishop et al. 2009." They are also not consistent with recommendations made by others. This is discussed in our original IEA request and below in the section titled Page by Page Comments.

3. **MNR Position:** We are supporting science that will inform an adaptive management approach to update the SSG during the required periodic review (referring to studies being undertaken or supervised by MNR)(referred to below as "MNR study" or "MNR studies").

GRASSY NARROW/EARTHROOTS Reply:

a. None of the MNR studies monitor the impacts of logging on mercury in the IEA area;

b. None of the MNR studies look at systems with known historic mercury point source contamination;

c. None of the MNR studies directly test mitigation measures in the SSG;

d. None of the MNR studies directly test alternative mitigation measures to those in the SSG;

e. One MNR study looks at logging impacts on small streams but no peer reviewed articles are provided. Streams have substantially different dynamics compared to lakes including dramatically lower water residence time;

f. Another MNR study (MSc project) looks at mercury levels in fish in lakes and considers, but does not seem to have been designed to test, logging impacts. No peer reviewed articles for this MNR study are provided so data, methodology, and results cannot be examined or relied on;

g. None of the MNR studies appear to use the solid, peer reviewed methodologies used by Garcia and Carignan, or by Desrosiers;

h. The MNR does not state when they will conduct the next periodic review of the SSG, nor when the findings of the review will be implemented;

i. The MNR does not state how the unique issues related to the IEA area will be examined at that time (i.e. considerations arising from the history of mercury pollution and mercury health impacts in Grassy Narrows);

j. The MNR makes no mention of whether special mitigation measures, monitoring, or caution is required for mercury releases in Grassy Narrows Territory relative to the rest of the Province;

k. With no monitoring of logging impacts on mercury in the IEA area, and no testing of SSG mercury mitigation measures, how will the SSG be improved at the next review in a way that protects Grassy Narrows? And what will happen to the health of the people of Grassy Narrows in the interim?

4. **MNR Position:** Earthroots and Grassy Narrows raised the mercury issue late in the process.

GRASSY NARROW/EARTHROOTS Reply:

a. It is the proponent's (MNR's) and the reviewer's (MOE's) responsibility to ensure that the FMP is sustainable, and does not harm ecosystem and human health. It is not the responsibility of Grassy Narrows or Earthroots;

b. Grassy Narrows and Earthroots have very limited resources available to them and will not benefit from the implementation of the FMP. The proponent has relatively extensive resources and will receive stumpage fees and taxes. The burden is, and should be, on the proponent to identify potential harms, and propose robust measures to prevent harm;

c. The MNR vetoed Grassy Narrows' chosen forest ecology advisor in the Iaccobucci process (Herb Hammond), did not fund the completion of Grassy's environmental study, and did not grant Grassy Narrows' request for participant funding for the FMP process;

d. If Grassy Narrows and Earthroots made no comments at all, it would still not be acceptable to poison people and the environment;

e.

clearcutting that are inclusive of all its negative impacts, including mercury;

f. Grassy Narrows has raised the mercury logging issue, and cited Carignan, as early as 2003 (Toronto Star, 07/28/2003) and repeatedly since June 2012. (see partial list in our request);

g. The MNR states in their April 7, 2014 letter to Earthroots that "Consent may be required only in rare cases, where the Crown's action or decision will result in serious impacts on established rights." Grassy Narrows and Earthroots say this appears to be such a case;

h. Grassy Narrows did submit lengthy letters explaining their concerns about the forest management planning process (see the correspondence from Grassy Narrows in the MNR response);

i. The Whiskey Jack Forest Independent Audit 2004-2009 Final Report (IFA) wrote that "There are fundamental differences in the viewpoints between GNFN and MNR regarding forest management principles and practices. It is the audit team's opinion that these differences cannot be resolved without the Province setting aside many of the requirements to manage the Whiskey Jack Forest under the CFSA and the FMPM, and relinquishing significant authority to the First Nation to manage portions of the Whiskey Jack Forest according to the desires of the GNFN community. The audit team further believes that the forest management planning process did not anticipate, nor was it designed to resolve the type of dispute currently being experienced on the Whiskey Jack Forest." (p.7)

j. The independent forestry experts who prepared the IFA substantiate Grassy Narrows' concerns that the forest management planning process is not fit for the circumstances;

k. In spite of Grassy Narrows' objections, and despite the above statement in the IFA, the MNR used the standard process to prepare the FMP. It is no surprise that this process has led to dispute again.

l. This is at least the third forest management planning process in which Grassy Narrows has participated without any satisfaction that their interests and concerns are being meaningfully integrated into the final plan.

In summary, it is not sufficient to follow the process, the outcomes must be good.

The outcome of this FMP process is likely harm to human health and the environment through mercury contamination. That is not acceptable.

It is also important to note that the MNR also makes some claims that their mitigation measures are consistent with current science. This is of limited relevance since they acknowledge that none of the measures are tested, and the MNR makes no claims that they will work. But it is discussed in our initial request and touched on below.

Finally, Grassy Narrows and Earthroots also note that the MOE questions to the MNR have a number

of deficiencies. Most importantly, they limit the mechanisms of mercury flux from logging to soil disturbance when there are many other likely mechanisms. Some of these other mechanisms are discussed below.

C. PAGE BY PAGE COMMENTS

(page heading references **in boldface** are to MNR Response Appendix 6)

Page 1

MNR response statement, p. 1: "As this issue was raised late in the FMP process by the requesters, there is very little documentation of the issue in the FMP process as is explained in the following responses to MOE's questions."

Grassy Narrows/Earthroots reply: The proponent (MNR) is responsible for ensuring that FMPs are sustainable, and the MOE is responsible for providing oversight to ensure that the health of the environment, including people, is protected, regardless of whether stakeholders raise specific concerns. The unique mercury issue in the planning area was known to the MNR and should have been considered.

The issue was actually raised far earlier, and as early as 2003 (see reply to point 4 above) (see also reply to MNR, pages 2-5, below).

Pages 2-5

MNR response statement, pp. 2-5 is to the effect that Grassy Narrows and Earthroots were given lots of opportunities by MNR to participate in the FMP process in accordance with the requirements of the FMPM to raise their concerns but largely chose not to participate.

Grassy Narrows/Earthroots reply: We recommend that MOE read Grassy Narrows' extensive correspondence to MNR explaining their concerns with the FMP process, requesting participant funding, objecting to clearcutting, etc. There are legitimate reasons why Grassy participated in a limited way in the FMP process. These are discussed more fully in reply to MNR comments at page 9 of the MNR response document, set out below.

- Many communications are left out of the tables including the joint letter by Earthroots and others to the Premier (cc'd to MNR Minister) June 25, 2013 (raises mercury–logging issue, no response), Grassy Narrows River Run press releases and many prominent news articles June 2012 (directly raise mercury-logging issue, response from Wynne on CBC), Grassy Narrows letter rejecting LTMD, Grassy Narrows briefing note to MNR Minister in late 2013.

-MNR refused to fund completion of Grassy Narrows' environmental information gathering see letters), and vetoed Grassy Narrows' choice of ecologist (Herb Hammond).

-Grassy Narrows very publicly raised the mercury logging issue, and cited Carignan, as early as 2003 (Toronto Star)

Page 6

We note that the MNR Response from the District Manager to the Oct. 31, 2013 comments of Earthroots on the Draft FMP has been left off the list. We note that it was sent on April 7, 2014, long after the final plan was released (Dec. 23, 2013) and after our IEA request was submitted. As a result, we were not able to include any concerns with this document's statements in our IEA request. The District Manager does not respond to our concerns about mercury beyond a boilerplate statement that the relevant laws, policies, and procedures are being followed.

We note further that with respect to the MOE determined issues, there is a concern with how the first issue has been characterized by MOE:

"Issue 1 Harvest – Application of the clear cut silvicultural system on the area affected by the IEA request will disturb the soil causing naturally occurring mercury to become in flux and travel through the water system…"

Grassy Narrows and Earthroots say that:

-the concern is with both increased mercury flux, and increased methylation and bioaccumulation;

-It is understandable that the MOE focuses on soil disturbance since our response to the concurrence request focused on that.

-As describe in our IEA request, soil disturbance is only one mechanism causing mercury flux and methylation. Other likely mechanisms include raised water levels (due to reduced evapotranspiration), increase in fresh decaying organic matter, increased organic sulfide concentrations in soils, increasing dissolved organic matter, changing biogeochemical inputs, changes in water temperature and cycling. (Bishop et al., 2009);

-in general, the mechanisms are poorly understood and relatively unstudied, but the outcome is clear (mercury flux and bioaccumulation). Therefore, we would focus the issue on the outcome, not the mechanism.

-mercury in flux due to logging includes both naturally occurring mercury and a substantial proportion of mercury atmospherically deposited from anthropogenic sources (e.g. coal power plants, incinerators).

-mercury will impact areas already stressed with mercury, as well as areas currently not stressed. Both are of concern.

-Issue 1 could be more accurately summarized as "Issue 1 Harvest – Application of the clear cut silvicultural system on the area affected by the IEA request will cause mercury to become in flux, and will cause mercury to be methylated, further exaggerating the existing mercury contamination issues in local waterways which is likely to affect human and ecosystem health and adversely impact Aboriginal and Treaty rights."

Page 7

With respect to the second issue listed by MOE: "Issue 2 Harvest – MNR doesn't have the science and information base to support the development of prescriptions to mitigate the effect of mercury on terrestrial or aquatic ecosystems", Grassy Narrows and Earthroots note that:

-this statement seems to be uncontested by the MNR;

-the core issue is not about supporting development of prescriptions in the future;

-the core issue is that current prescriptions are not scientifically tested and found to be effective;

-in fact, there are indications that current prescriptions are not effective (as demonstrated in the Garcia and Carignan studies)

With respect to the fourth issue listed by MOE: "Issue 4 Access – The construction of forest access roads on area affected by the IEA request will disturb the soil causing naturally occurring mercury to become in flux and travel through the water system collecting in downstream areas already stressed with mercury, further exaggerating the existing mercury contamination issue", Grassy Narrows and Earthroots note that:

-mercury released by road building will impact areas already stressed with mercury, as well as areas not currently stressed (those upstream from the English-Wabigoon River). Both are of concern; and

-the activity of construction of forest access roads also likely has more mechanisms for mercury release and methylation than soil disturbance (e.g. disrupting water flow)

MNR response statement: "During stages 1 through 3 of the planning process, issues 1 through 4 were not raised by the requesters. During Stage 4, the impact of clearcutting on mercury levels in piscivorous fish in local lakes and rivers was brought forward as one of a number of issues Earthroots had with the FMP. There was no corresponding mention of this issue in the response MNR received on the Draft FMP from GNFN. MNR responded to the issue brought forward by Earthroots indicating that MNR complied with the legislative, regulatory and policy requirements, including the approved forest management guides, which mitigate potential adverse effects on the environment."

(and repeated similar comments throughout the response including p.8 last paragraph, p.10 paragraph 2)

Grassy Narrows/Earthroots reply:

-see comments on pp. 1-5 in Page by Page Comments and on point 4 in General Comments;

-Grassy Narrows did raise the mercury-logging issue clearly in Chief Simon Fobister's Oct. 24, 2013 open letter to Premier Wynne that also ran in the Toronto Star on Nov. 3, 2013. "New clearcut logging will bring even more mercury into our river and our food chain, further prolonging and exacerbating this avoidable tragedy";

-Grassy Narrows' repeated statements generally opposing the practice of clearcutting over many years (including their comments on the draft FMP) are overarching and stand against all the negative impacts of clearcutting including issues 1 through 4. It is not Grassy Narrows' responsibility to be experts on the specific ecological and chemical impacts of clearcutting;

-MNR did not respond to Earthroots' comments on mercury until long after the FMP was made final, and made no changes to the plan as a result of the comments;

-Earthroots and Grassy Narrows raised this issue many times in the past through letters to Premier, Minister, press releases, media articles, website etc (see above).

Page 9

MNR response statement: "In conclusion, the 2012-2014 CP and the 2012-2022 FMP for the Whiskey Jack Forest were prepared in accordance with the requirements of the FMPM".

Under the "Summary" heading on page 9 MNR states further that: "The above documentation requested by MOE shows how MNR followed the *Forest Management Planning Manual* – 2009 (FMPM) and engaged GNFN and Earthroots throughout the planning process. GNFN chose to remain on the periphery of forest management planning for the Whiskey Jack Forest by not participating on the planning team and rejecting offers to hold information centres at the community or engaging in face-to-face discussions. GNFN provided comments through the submission of letters at various stages throughout the planning process, and MNR responded to the concerns identified…"

Grassy Narrows/Earthroots reply:

-The core issue is about outcomes not process. Will the application of the FMP harm the environment and human health? Likely it will;

- But even at a process level, the MNR response lacks merit because: (1) there are legitimate reasons why Grassy Narrows only participated in a limited way in MNR's FMP planning process: (a) Grassy Narrows was – and still is – in litigation with MNR over the legal authority of MNR to issue forest licences allowing clear-cutting in the territory of Grassy Narrows, and would not have wanted to prejudice its legal position in that litigation by participating in, and possibly being seen to legitimize, the very process it was objecting to; (b) Grassy Narrows was simultaneously involved in the Iaccobucci negotiation process, which was designed to resolve the overarching conflict between MNR and Grassy Narrows regarding forest management activities on Grassy Narrows' territory, and which Grassy Narrows hoped would also address the issue of clear-cutting; and (c) MNR refused to fund the environmental information-gathering proposed by Grassy Narrows and vetoed its choice of ecologist – Herb Hammond – who would have raised the mercury issue, and (d) Grassy Narrows and the IFA auditors both believe that the planning process is not designed to resolve the issues at hand; and (e) Previous iterations of the planning process have not brought any satisfaction and have not dealt with the mercury logging issue; and (f) Grassy Narrows has few resources available to engage in the FMP process and to obtain technical support and advice for this process. The MNR did not grant Grassy Narrows' request for participant funding; and (2) many early communications to the government and to the media on the mercury issue (e.g. as early as 2003) are left out of the

Page 10

MNR response statement: "The issue of methylmercury was raised by GNFN for the first and only time, prior to the IEA request, in an October 24th, 2013 letter to the Premier, coincident with the Stage 4 – Review of Draft Plan. Earthroots also identified methylmercury as a potential issue for the first time in a letter dated October 31st, 2013 during Stage 4 – Review of Draft Plan."

GRASSY NARROWS/EARTHROOTS reply:

-The MNR statement ignores the methylmercury logging issue being raised by Grassy including in 2003 in the Toronto Star, in 2012 in the River Run events and associated news, in parliament (by the NDP), and in 2013 in the joint letter copied to the Minister.

-see earlier comments respecting p. 7 of MNR response, pp. 1-5, and point 4 under General Comments of this Grassy Narrows/Earthroots reply.

Page 12

MNR response statement: "For example, Bishop et al (2009) show post-harvest Hg concentration response ranging from a 4 fold increase in a Finnish study to no increase found in a study done in Northwestern Ontario."

GRASSY NARROWS/EARTHROOTS reply:

-This MNR statement is accurate, but potentially misleading. The Northwestern Ontario study found a doubling of mercury flux/export (there was no significant increase in concentration, but a doubling of flow). Export = flow x concentration. The total amount of mercury exported is the important measure here (along with the proportion of methyl mercury).

Page 13

The MNR review and conclusions in point 2 contains many flaws.

Most importantly, it fails to note the important difference that the study found between partially burnt lakes (n=2) and completely burnt lakes (n=7).

MNR response statement: "Fish in disturbed watersheds (cut and burned) had higher mercury levels than fish in undisturbed reference lakes".

Study Authors: "No significant augmentation of Hg levels was observed in fish from lakes with completely burned catchments compared to those from reference lakes." (Garcia and Carignan, 2005, p.690 Discussion, paragraph 1)

Fish mercury levels were significantly augmented in clearcut lakes and in two partially burnt lakes.

MNR response statement: "When trophic position is included in the analysis, fish Hg levels in harvested watersheds fall within the broader range of fish Hg levels in burned watersheds (fig 4, Garcia and Carignan 2005)."

Grassy Narrows/Earthroots reply:

-the MNR is focusing on the scatter of the individual data points;

-when looking at the statistical trend line (far more meaningful) we see that the trend line for logging is higher than that for fire for nearly the entire range of trophic levels, and never below;

The MNR review does not discuss Garcia and Carignan, 1999, 2000: "Those results showed that high MeHg [in zooplankton] and total Hg [in northern pike] were associated with clear-cut logging but not with wildfires" (Garcia and Carignan 1999, 2000 as cited in Garcia and Carignan 2005).

The MNR review also does not consider Garcia, Carignan and Lean, 2007 which looks at zooplankton, a key part of the food chain for fish: "MeHg concentrations observed in mid-summer zooplankton from forest harvested lakes were significantly higher than in reference and fire-impacted lakes" (Garcia, Carignan and Lean, 2007).

-Later on p.17 the MNR attempts to cast doubt on Garcia and Carignan's 2005 discussion of DOC's key role in the mercury cycle. As we have said before, the mechanisms are relatively poorly understood and unstudied. There appear to be studies with different results with respect to the mechanisms of mercury flux and methylation. These studies may be conflicting, or may reflect a different relative importance of various mechanisms under different circumstances (eg. different slopes, moisture levels, wetland prevalence, soil types, temperatures, etc.). The Garcia and Carignan study provides compelling evidence that DOC plays an important role under some common circumstances that appear similar to those in Grassy Narrows.

But the MNR ignore the fact that Garcia and Carignan 2005 also discuss the effect of variables other than DOC that are not discussed by MNR in their response: "Variations in other environmental variables related watershed disturbances could effect Hg concentrations in fish from cut and burnt lakes. For example, the increase in nutrient loading (total P and total N) following fire resulted in significantly higher algal biomass in burnt lakes compared to that in reference lakes [27]. High phytoplankton biomass may cause a biological dilution of the available Hg pool, thereby reducing Hg concentrations in organism, including those occupying higher tropic levels [28]. Alternatively, lower light penetration may account for the lower algal biomass in cut lakes as compared with burnt lakes [27]".

The literature also includes discussion of other mechanisms including sulfides, thiols, etc.

Page 15

MNR response statement: "Bishop et al. (2009) actually calculated that forest harvesting may contribute 9 to 23% of MeHg fluxes from the soil following harvesting".

Study Authors: "If there is thinning during the forest rotation that has a similar impact, then … the extra Hg burden in fish will be 17-37%." (Bishop et al., 2009)

Thinning is a common practice in Ontario and is part of the planned activities in the FMP.

"Clear-cutting and Thinning: Both activities reduce the number of trees and thus the evapotranspiration. This means that the water table will move closer to the soil surface (38, 39). Large supplies of fresh carbon from logging slash and decaying roots are also present, and organic rich surface soil horizons (such as…) will be water saturated more frequently. This will result in the mobilization of DOM…[N.B. we did not copy the detailed discussion of other mechanisms here]..

Thus, clear-cutting and thinning generally promote Hgtot and MeHg mobilization and transport from soils to surface waters…" (Bishop et al., 2009)

MNR response statement: "Those studies suggest that although MeHg concentrations in fish may increase following clearcut operations, it is generally limited to cases when soils are disturbed, and not to the harvesting of trees."

Grassy Narrows/Earthroots reply: Bishop 2009 lists a number of mechanisms for mercury export and increased methylation that are not related to soil disturbance (see above, including elevated ground water levels, large supplies of fresh carbon from logging slash and decaying roots, changes in other chemical and physical variables, etc.).

Page 16

MNR response statement: "no evidence exists contrary to the protection of soils from disturbance as described in the Stand and Site Guide as a mitigation measure minimizing forest harvesting operation effects on fish MeHg concentrations."

Grassy Narrows/Earthroots reply:

-more importantly, no evidence exists in favour of this assertion;

-evidence does exist to the contrary and it is ignored by the MNR in both their response and their Stand and Site Guide Rationale.

In the key Quebec study by Garcia and Carignan they say:

"Clearcuts were of the CPRS type (cut with protection of regeneration and soils). Cut block size generally ranged from 5 to 50 ha but occasionally reached 200 ha, with 20-m buffer strips fringing permanent streams, lakes, and wetlands" (Garcia, Carignan, and Lean, 2007);

CPRS type clearcuts generally include measures to protect soils from disturbance that are equal to, or greater than, those in the SSG. (e.g. no-cut riparian buffers of 20m vs. 3m, much smaller clearcuts in study area than in the FMP, protection for young trees in CPRS cut blocks vs. no protection for young trees in the FMP, similar or greater measures to reduce soil and hydrological disruption from machine operation, road building, etc.). And yet these clearcuts were found to raise mercury levels in fish above safe levels for human consumption in all clearcut watersheds.

-The site preparation practice of scarification is common, and planned in the Whiskey Jack FMP, and entails extreme soil disturbance. This negates the soil protection measures used during harvest;

-The soil protection measures in the FMP are actually not very restrictive. The definition of rutting includes only severe disturbance, and rutting is allowed to cover a substantial portion of the area (see discussion in original IEA request). There is no indication that the thresholds for soil disturbance by the SSG are effective at preventing mercury impacts.

Page 16, paragraph 2

MNR claims that Skyllberg et al. 2009 found an end to the effect of logging on MeHg in streams after 4 years.

There are a number of issues here:

1. A number of other studies did not find an end after 5 years: "The increased loading effect has also been observed to persist up to at least 5 y[ears] and there are no examples so far of the logging effect having dissipated" (Bishop et al., 2009). (N.B. Skyllberg is a co-author on Bishop et al., 2009. The Skyllberg et al., 2009 paper was accepted one month before Bishop et al., 2009 was published);

2. The Skyllberg study is on streams, not on lakes. Streams have a much shorter water residence time than lakes so would be expected to have a shorter-lived effect from any contaminant;

3. The study looks at mercury in water, not in fish, which are likely to have a longer-lived effect from mercury exposure;

4. Skyllberg et al., actually found that "the 4-10 year-old clear-cuts showed intermediate concentrations [between reference and 0-4 yr old clear-cuts] with non-significant differences as compared to references." The fact that the difference (intermediate elevated levels) was not statistically significant at 4-10 years may reflect a physical reality in the studies streams, or may be an artifact of the level of statistical power provided by the study design;

5. The Skyllberg study looked at stands where "No site had any significant contribution from wetlands." Wetlands are thought to play an important role in the mercury cycle, and are generally present in Grassy Narrows Territory.

Page 16, last paragraph

MNR response statement: "Skyllberg et al. (2009) reported that 17% of MeHg in streams came from methylation of stored mercury, while 73% arose from methylation of newly added mercury from logging debris and that TOC (total organic carbon in non-filtered water samples) and its structure did not differ between streams draining clearcut and mature forest catchments."

The MNR attempts to say that this refutes our point that the amount of methyl mercury in Grassy Narrows lakes is likely to rise as a result of logging.

Grassy Narrows/Earthroots reply: This summary does not refute our point. It talks about proportion, not rate or magnitude. So it says nothing about whether or not logging increases methylation rates of new and stored mercury. For example, methyl mercury from stored mercury could stay at 17% of total methyl mercury while the rate of methylation for both sources of mercury doubled;

- It is a stream study, not a lake study, and a water study, not a fish study;

-Various studies seem to find conflicting results on the importance of various mechanisms. This shows that the mechanisms and relevant variables are not fully understood.

Page 17

-It is not clear what the MNR is trying to establish with their characterization of Neff et.al.

"Concentrations in the English-Wabigoon fish are elevated, and may still present a potential health risk to humans consuming fish from this system" (Neff et al., 2012);

-MNR seems to claim that Neff et al., found walleye and pike mercury levels to be within within the 25th-75th percentile range.

Neff et al. actually say that mercury levels for all three fish species were above the 75th percentile for all three lakes studied in Grassy Territory (Clay, Ball, Separation) for all sizes except WE60cm

"It appears, then, that potential factors such as the introduction of invasive species, changes to fish condition and climate change do not individually provide adequate explanations for the patterns in mercury decline observed in this system. It is possible that instead, dynamics in mercury concentrations are more related to changes in rates of methylation and demethylation" (Neff et al., 2012).

.

"data from the most recent decade indicate that mercury concentrations in sport fish may still pose a risk to human consumers" (Neff et al., 2012).

The causes of slowed decline in Neff et al., are hypothetical, with no evidence or testing in this system. Logging is conspicuously absent in the discussion by Neff et al. 2012. It is also worth noting that Neff et al., look at only 4 lakes. One lake is outside of Grassy Narrows Territory (Tetu), and another (Ball Lake North Basin) is upstream from the confluence with the Wabigoon River and therefore relatively un-influenced by the Dryden dumping (see Sellers' work). A third of the four lakes (Separation) is near the most distant point on the English River in Grassy Narrows Territory from the point source contamination in Dryden, and therefore likely less impacted than other parts of the Territory.

Equally, if not more importantly, Neff may be authority for the proposition that in an already mercury-contaminated ecosystem, such as the English-Wabigoon, MNR has an obligation to understand, address, and prevent the cumulative impact of introducing new sources of mercury into the system.

MNR response statement: "climate change is the primary cause of elevated DOC concentrations in lakes."

Grassy Narrows/Earthroots reply:

-this is beside the point. Garcia and Carignan looked at logged and unlogged lakes that are subject to the same climate. They wrote that "the positive correlations between Hg in fish and the extent of the catchment area logged when normalized to lake area or volume seem to reflect the influence of organic matter in Hg loading to lakes. Indeed, these two impact rations showed significant correlations with DOC in the cut group" (Garcia and Carignan, 2005).

The deforested catchment area short form is DEF. "DEF:VOL ratio has been shown in turn to explain up to 86% of the of the variability of DOC in forest harvested lakes" (Carignan et al., 2000).

The current SSG has removed the limits on the portion of a catchment that can be harvested that were present in earlier guides.

Pages 17-18 (conclusion)

MNR response statement: Mercury inputted into upstream catchments will mostly be photo oxidated, reduced to gaseous mercury, settled, and diluted before reaching the English-Wabigoon River.

Grassy Narrows/Earthroots reply:

-there is extensive logging planned directly adjacent to the English-Wabigoon River System. Water flows from those cutblocks directly to the English Wabigoon River system, not through a circuitous route;

-headwater lakes are also of concern, not just those on the English Wabigoon River system. People eat the fish in those lakes, and so do wildlife.

Page 18

MNR response statement: "the current scientific evidence indicates that protecting soils from disturbance during harvesting operations as spelled out in the Stand and Site Guide will minimize total and methyl mercury loading from soils to streams and lakes in a catchment".

Grassy Narrows/Earthroots reply:

-as discussed earlier, the Quebec study looked at clearcuts with similar or greater protection for soil during harvesting and found significantly elevated mercury in fish;

-scarification post-harvest, and thinning may contribute to mercury release in some circumstances, even if soil was protected during harvest; and

-the MNR response itself says that there is no evidence on the effectiveness of mitigation efforts.

Page 19

MNR response statement: "Fine filter direction is included when there is evidence that additional mitigation measures will improve the protection of specific values."

MNR response statement: "Because there are no studies which identify or evaluate mitigation measures to minimize mercury mobilization following disturbance there are no mitigation measures specific to mercury in the SSG."

Grassy Narrows/Earthroots reply:

-This is unacceptable. Where there is a possible harm to health of the environment and humans it must be prevented. Not having evidence of how to mitigate the harm is not justification for allowing the harm to occur.

"the range of Hg levels in fish in harvested watersheds was within the range of those in burned watersheds (Garcia and Carignan 2000, 2005)."

-also "within the range" of the impacts of natural disturbance are:
- death to humans and wildlife (including endangered species);
- destruction of human property including homes, fish and hunt camps, etc.
- killing of millions of ha. of forest due to pine beetle kill

-that does not mean that human activities should be allowed to do these things. There is a difference between an act of god that is unpreventable, and an act of human which is planned and deliberate. There is also a difference between a natural disturbance process with which the ecosystem has evolved for millenia, and a human process that includes heavy machinery, herbicides, and other forces new to the ecosystem;

-as long as MNR views clear-cutting as the only acceptable harvesting method in the Whiskey Jack it will be incapable of conceiving of, let alone executing, effective mitigation measures. The FMP mentions that there are other harvest method alternatives, such as shelterwood and selective cutting, but MNR only proposes clear-cutting for all 50,000 plus hectares of the Whiskey Jack proposed for harvesting in the period 2012-2022. That too is something the IEA could look at.

Page 19, last paragraph

MNR response statement: "They do offer some suggested practices, which include minimizing site disturbance and hydrological disruption and protecting wetlands. Direction in the SSG is entirely consistent with the recommendations of Bishop et al (2009)."

Grassy Narrows/Earthroots reply:

The direction in the SSG is often not consistent with Bishop recommendations.
Bishop recommendations that are not in the SSG include:

-minimizing disturbance in riparian zones (SSG: no-cut zones of only 3 m on lakes. Cutting the entire shoreline of some woodland pools allowed);

-avoid creation of large clear-felled areas in connection with moist areas (MNR plans clearcuts an order of magnitude larger than those studied by Carignan, allows the entire shoreline of some woodland pools to be logged);

-avoid clear-felling in moist areas (exclusive use of clearcutting);

- that mercury impacts were greater in watersheds with lesser slopes. The SSG directs buffers to be directly proportional to slope.

-etc. (see IEA request)

Page 20

MNR response statement: "all the literature they cite as evidence shows that Hg is mobilized and/or

bioaccumulated following both fire and harvest disturbance."

Grassy Narrows/Earthroots reply:

-in our IEA request we quote directly from the authors of the peer reviewed studies in the IEA request;

-in general, Garcia and Carignan found that completely burned watersheds (7) did not show a statistically significant rise in mercury bioaccumulation following fire. Two (2) partially burned watersheds did.

MNR response statement: "(Note that the requestors appear to use fire size and fire intensity interchangeably when in fact these measure different things)"

Grassy Narrows/Earthroots reply:

We follow the convention of the paper authors (Garcia and Carignan) who usually refer to the size of the fire as a portion of watershed area burned (partially vs. completely burned, or % of catchment). They don't give much information on fire intensity but it does appear that the partial fires were also less intense (see statement in their 2007 paper).

We agree that intensity of the fire is likely important (and severity probably even more important)

The general point holds:

"Most area burned in N American boreal forests is by high intensity crown fires, and this is likely to continue in the future." (de Groot et al., 2003, p.363)

Article: Simulating the effects of future fire regimes on western Canadian boreal forests
de Groot, W.J.1*; Bothwell, P.M.1; Carlsson, D.H.1 & Logan, K.A.2 Journal of Vegetation Science 14: 355-364, 2003 © IAVS; Opulus Press Uppsala.

"As a result of climate change in the Canadian boreal forest region, a general increase in fire intensity, fire severity (depth of burn) and fire season length (Flannigan & Van Wagner 1991; Wotton & Flannigan 1993; Stocks et al. 1998; Flannigan et al. 2001) is expected." (in de Groot et al., 2003)

A more complete summary would be:
1. Low intensity fires appear to bioaccumulate mercury.
2. High intensity fires were not found to bioaccumulate mercury (not statistically significant).
3. High intensity fires may form a pathway for mercury out of the watershed.
4. Most area burned by fires in the N American boreal forest is by high intensity fires.
5. Climate change is likely to increase the intensity and severity of fire in the Canadian boreal forest.

	Low intensity fire	**Clearcut Logging**	**High intensity fire**
Bioaccumulates mercury?	Yes.	Yes.	No
Path for mercury into atmosphere?	No/small.	No.	Yes. (likely)
% of productive forest landscape impacted over 100 years	Low (natural and managed)	Most (managed)	Most (natural)
Will increase due to climate change?	No	No	Yes.

Most area burned by fires in the boreal forest experience intesne fires that have mercury impacts that are very different from logging.

Page 21

-Only 2 MNR studies look at fish and logging. One is in streams, not lakes. Neither has published in peer reviewed scientific journals so they cannot be assessed or relied upon;

-None are in the IEA area;

-None study or monitor impacts of mercury from logging planned in the IEA area;

-None test mitigation measures and alternatives;

-

D. CONCLUSIONS

For all the above reasons, and those in the IEA request, Grassy Narrows and Earthroots say that MNR has provided no justifiable reason why MOE should not order that an IEA be performed on the Whiskey Jack FMP.

Devon Wills
Project Evaluator
Ministry of the Environment
Environmental Assessment Services
2 St. Clair Avenue West
Toronto, Ontario, M4V 1L5

Dear Mr. Wills,

Re: Supplementary Submissions on the Grassy Narrows/Earthroots Request for an Individual Environmental Assessment (IEA) on the Whiskey Jack Forest Management Plan for 2012-2022

These are supplementary submissions to our request with Grassy Narrows First Nation for an IEA on the Whiskey Jack Forest Management Plan (FMP) for the period 2012-2022.

The submissions are prompted by our recent receipt of a document from the MNR through a Freedom of Information and Protection of Privacy Act request. (attached)

The document is listed as an "Excerpt from Stand and Site Guide Comments Wildlife and Fisheries Forum" in the index of records (attached), and it is undated.

We infer that this was a forum held by the MNR to receive comments on the Stand and Site Guide (SSG), presumably while it was in draft form.

In the document Mark Sobchuk and Evan Armstrong make a number of relevant comments.

Both Mr. Sobchuk and Mr. Armstrong appear to have been MNR employees at the time that the SSG was approved. Neither appear to be employed by the MNR today, based on a search of the Government of Ontario online staff directory.

Sobchuk, MNR, NWR is credited in the SSG on page 173 for:

"Significant contributions to the writing of individual sections of the guide"

He appears to have been a senior fisheries biologist for the MNR.

Evan Armstrong appears to have been an MNR Area Biologist and was listed in media reports as recently as 2013 as a contact for the MNR in the Geraldton Area, Nipigon District on fisheries and aquatic issues. (http://www.thetimesstar.ca/broad-scale-monitoring-of-kenogamisis-lake/)

In the comments they say that "The reduction in protection for river, stream, pond and lake shorelines [in the SSG] needs to be reconsidered" for three reasons:

1. Climate change has not been considered.
2. Mercury is finding its way into water courses from cutovers even with the current reserves/AOCs in place. This is likely to be exacerbated if complete removal of shoreline vegetation is permitted.
3. The task team that "developed the latest recommendations for protecting aquatic habitat didn't propose clear cutting entire shorelines so why are we. This task team included some very knowledgeable folks including some of our research scientists".

Mr. Sobchuk and Mr. Armstrong also noted that: "The public and especially First Nations are very sensitive of mercury entering our water systems and they are not going to like the idea that it might be increased".

These observations from MNR staff involved in the drafting of the SSG corroborate a number of the points Earthroots and Grassy Narrows First Nation raised in our IEA request including:

a. That riparian reserves/AOCs prior to the new SSG were not sufficient to prevent mercury export into local water bodies after clearcutting.
b. That the new SSG weakened existing riparian protections (ie. reserves and AOCs).
c. That the amount of mercury entering water bodies is likely to increase as a result of the changes contained in the new SSG.
d. That the SSG is not consistent with the limited current science on preventing mercury releases from clearcuts.

The attached material also reveals that the MNR may not have followed the advice of its own fisheries and aquatic habitat experts in developing the SSG as it relates to key concerns respecting the mercury issue.

We trust that you will take this information into account in considering our request for an IEA of the Whiskey Jack FMP 2012-2022.

Sincerely,

Amber Ellis
Earthroots

75	Mark Sobchuk;Evan Armstrong	MS	4.1	30		**Section 4.1 Aquatic & wetland Habitats.** The reduction in protection for river, stream, pond and lake shorelines needs to be reconsidered for 3 reasons. 1/ climate change and its affects have not been considered and we are being asked to consider climate change in our decision making; 2/ a recent paper by Dr. R. Mackereth indicates that mercury is finding its way into water courses from cutovers even with the current reserves/AOC`s in place. This is likely to be exascerbated if complete removal of shoreline vegetation is permitted. The public and especially First Nations are very sensitve ot mercury entering our water systems and they are not going to like the idea that it might be increased!; and 3 the task team that developed the latest recommendations for protecting aquatic habitat didn`t propose clear cutting entire shorelines so why are we. This task team included some very knowledgeable folks including some of our research scientists.	Maintaining Suitability of Aquatic and Wetland Habitats and Shoreline Forest

Re: Third Supplementary Submission on the Grassy Narrows/Earthroots Request for an Individual Environmental Assessment (IEA) on the Whiskey Jack Forest Management Plan for 2012-2022

Dear Mr. Wills,

These are supplementary submissions to our request for an IEA on the Whiskey Jack Forest Management Plan (FMP) for the period 2012-2022.

The submissions are prompted by: (1) our attention to a report that was previously not available to the general public regarding human health impacts of mercury on members of the Grassy Narrows community (attached); and (2) various documents, including letters, media coverage, and related materials that underscore what is said in the report and express concerns by members of the Grassy Narrows community about future further exposure to mercury as a result of clear-cutting proposed under the Whiskey Jack FMP. We regard this information as important to your consideration of our request for an IEA of the Whiskey Jack FMP and would ask that the Ministry of the Environment (MOE) consider this material in conjunction with the material that we have previously submitted to your office on this matter.

MERCURY DISABILITY BOARD REPORT

The first document is a review paper commissioned by the Mercury Disability Board. It consists of two main sections, one summarizing new developments in the scientific understanding of the human health impacts of mercury since the 1980's, and the second offering domestic expert opinions on work of Dr. Harada and his team in Grassy Narrows up to their paper released in English in 2010 (N.B. Harada's team has released at least two papers on Grassy Narrows since that time, one in 2011 (referenced in our original request), and another in 2014 (Takaoka et al.)).

Mercury Disability Board, *Literature Review: The Impact of Mercury on Human Health*, prepared by Donna Mergler and Laurie Chan (Kenora, Ont.: MDB, September 2010) .

a. A Review of Current Understanding of Mercury Poisoning - September 21, 2009

b. Opinions on Dr. Masazumi Harada's studies in Ontario based on articles provided by the Mercury Disability Board - October 29, 2009 and updated September 15, 2010.

The report was prepared by Donna Mergler and Laurie Chan, two Canadian academics who are often employed for government work as experts on the impacts of toxics in the environment on human health.

Please consider the full contents of these reports, and in particular, the following points excerpted directly from the reports (headings added):

People in Grassy Narrows were poisoned by mercury

- There is no doubt that there was high mercury exposure in these two communities in the late sixties and early seventies (Part b, p.7).
- There is no doubt that at these levels of exposure many persons were suffering from mercury-related neurologic disorders (Part b, p.7).

People are still sick, and some still have high exposure to mercury

- Dr. Harada's follow-up study indicates that there is probably still a problem due to previous mercury exposure (Part b, p. 7).
- Some individuals may still have high exposure [25 ppm and 60.3 ppm observed in Grassy Narrows and White Dog] (Part b, p. 7).

Health care and support for mercury survivors is substandard

- We also want to highlight the urgent need to improve the general health of these two communities as the health status of the participants was clearly poor (Part b, p.8)
- It is paramount that members of the two communities are receiving the necessary medical care and support. In contrast, residents in Minamata, Japan enjoy superb health care from neurologists and therapists even [if] they had not been classified as victims of Minamata Disease (Part b, p.8).

Government monitoring of health has been inadequate

- There should have been extensive examinations and follow-up of these communities from [the 1970's] forward, and assistance with respect to health and nutrition" (Part b, p.7). "
- Many of the health complaints from the affected population have not been properly diagnosed and documented. (Part a, p.27)
- Dr. Harada's follow-up study shows the "need for a comprehensive epidemiologic study that would include all of the known outcomes of mercury exposure (including cardiovascular disease) and take into account co-morbidity from other diseases, such as diabetes and/or alcohol and test for possible interactions" (Part b, p.8).

Mercury survivors are being denied compensation

- Among the 60 participants diagnosed with Minamata Disease [by Dr. Harada], 21 were acknowledged and 39 were not acknowledged by the [Mercury Disability Board] (Part b, p. 6).

- The approach used by the Mercury Disability Board to assess whether or not an applicant has signs or symptoms consistent with mercury poisoning was designed based on the state of science and knowledge of the impact of mercury on human health in the 1980s (Expert Report Intent, p.1).

- The Japanese government is revising their definition of Minamata Disease victims to be more inclusive and a new round of compensation is expected to release in 2011."(Part b, p.7)

Dr. Harada and his team's work is important

- "[Dr. Harada and his team] have made significant contributions to the understanding of the long-term effects of mercury contamination and the health of residents in the two communities" (Part b, pp. 7-8).

Mercury impacts foetuses and children at much lower levels than others. Some effects are permanent.

- Today there is a wide consensus that even at low levels of mercury, mercury can affect children's intellectual and motor development, which is not immediately obvious in children examined individually, but can be observed in population studies (Part a, p. 19).

- The evidence for mercury developmental neurotoxicity continues to accumulate (Part a, p.15).

- Even a short-term impairment in this cascade [of Central Nervous System development] may cause irreversible neurotoxicity if the tissue cannot compensate for the damage (Part a, p.7).

- The effects on brain function associated with prenatal methylmercury exposure therefore appear to be multi-focal and permanent (Part a, p.14).

- At the sub-clinical and population level, several studies in different parts of the world, have reported poorer neurologic status and slower development in newborns, infants and/or children exposed in utero MeHg and/or during early childhood (xxi,xxxii,xxxiii,xxxiv,xxxv,xxxvi,xxxvii,xxxviii,xxxix,xl,xli,xlii), although some studies did not observe effects (xliii,xliv,xlv). In children, MeHg exposure has been associated with lower performance on tests of language, attention, memory, and/or visuo-spatial and/or motor functions (Part a, p.8)

- Findings suggest that factors often associated with a poorer home environment, such as poorer nutrition and less parental stimulation, may increase vulnerability to toxics (Lxxvi, lxxxvii) (Part a, p.17).

Mercury impacts people at levels far below those previously considered safe

- Recent studies conducted among Minamata residents who suggested that the lowest-observed-effect level for clinical effects is likely to be considerably lower [than 50 ug/g in hair, 200 ug/L in blood] (Part a, p.7).

- These suggest the possibility of clinical effects, perhaps in a sensitive sub-set of the general population, at levels of exposure considerably below those previously associated with clinical effects in poisoning episodes (Part a, p.7).

- Studies of persons from a nearby polluted area, who had been exposed to lower doses of mercury over a twenty year period, still suffered from distal paresthesia of the extremities and lips 30 years after cessation of exposure (part a, p.20).

- This result suggests that neurologic signs, especially perioral sensory loss, was found among residents with hair mercury content below 50 ug/g after exposure was ceased for 11 years. Ninomiya et al reported that sensory loss remained even 30 years after the cessation of methylmercury exposure (Part a, p.10).

- The loss of color vision and contrast sensitivity has been demonstrated in [Amazonian fish-eating] populations, at methyl mercury levels of contamination below 50 ug/g of total hair Hg, which was traditionally considered the threshold for clinical effect (Part a, p.13).

- A Canadian study of fish eaters with levels of blood Hg <20/ug/L, showed a negative association between Hg and monoamine oxidase activities in platelets. Experimental studies have shown that Hg exposure disrupts the function and transmission of the monoaminergic nervous system, inhibiting the enzyme activities of monoamine oxidase (MAO, EC 1.4.3.4)lxi. Biochemical changes may constitute a sensitive, although non-specific, early indication of Hg-induced alterations to the nervous system, but more work is needed in this area (Part a, p.10).

- Current estimates of risk based on MeHg exposure alone could underestimate the population risk. Additional research is clearly needed to address these questions (Part a, p. 26).

- There is a clear need for more studies on the effects of mercury with age (Part a, p.24).

- While exposures throughout the world are lower than those producing the historical epidemics of MeHg poisoning, there is growing evidence that for many populations, exposures are sufficient to alter normal functioning of several systems and constitutes an important public health problem (Part a, p.7).

Mercury has health impacts beyond the classic neurological symptoms including direct and secondary psychological impacts

1. Risk of acute myocardial infarction can double with mercury exposure. (paraphrase)

2. Dietary mercury exposure at levels found relatively commonly in western populations can result a significantly elevated risk of AMI [acute myocardial infarction] (Part a, p.22).

3. This result suggests that exposure to Hg can cause varying degrees of permanent neuropsychological disability (Part a, p.11)

4. These findings suggest that sensory symptoms resulting from Hg exposure could be determined even in the presence of neurological or neurologically related diseases." p.12

The MDB review paper also summarizes the key findings of a report titled "Final Report of the Anishinabek knowledge Component National First Nations Environmental Contaminants Program (NFNECP) Health Canada 2008-2009." The authors wrote:

> The key findings are:
>
> a) The perceived risk of mercury pollution is still high. Scientists and health professionals have not been able to communicate the level of certainty in different findings and recommendations. People are confused with the scientific findings and public health messages and think that scientific information is not reliable.
>
> b) There is a high level of mistrust for the scientific communities and the government. The risk communications including dietary advice have not been effective. The advices were either issued by the government or by scientists in different reports. The scientific studies and public health advice have been perceived to be out of context and did not take into account of the Indigenous perspectives. There is no long-term knowledge base available locally for such information.
>
> c) The overall impact of mercury pollution has been more than just the health effects of mercury poisoning. Many other determinants of health including disruptions of culture, rapid change of diet, decline in jobs and income etc. have not been properly addressed and are clearly still having an impact on the overall health status of the people.

This information, together with that supplied in our earlier submissions, support a number of important points including:

1. **Women and children are disproportionately impacted by mercury contamination for reasons including:**

   -fetuses and children suffer permanent impacts at low mercury levels, and at lower levels than other populations

   -women do a disproportionate amount of childcare and informal health care and therefore the unpaid burden of caring for sick family members and impacted children disproportionately falls on them

-women, on average, earn less than men for equivalent work, and therefore are more likely to be unable to afford diets other than the traditional fish diet . This is especially true for single mothers.

-women are chronically under-represented on Grassy Narrows Chief and Council

-Anishinaabe women are traditionally responsible for protecting the water and therefore the social, psychological, spiritual, and physical burden of dealing with water contamination falls disproportionately on them

-women are disproportionately impacted by sexual assault and domestic violence. The secondary impacts of mercury including unemployment, poverty, despair, violence, substance abuse, and social conflict are associated with increased rates of sexual assault and domestic violence.

-women and children are already disadvantaged relative to other members of society

2. **Mercury has both direct physical, and psychological health impacts, as well as secondary health impacts** due to social disruption arising from unemployment, poverty, loss of culture, changing diet, loss of autonomy, and despair. This too has impacts on the physical and psychological health of people in Grassy Narrows. Anthropologists (including Shkylnik) have documented greatly increased rates of violence, sexual assault, substance abuse, injury, and death coinciding with the compounding impacts of relocation and mercury on Grassy Narrows.

3. **The government and scientists have not succeeded in effectively communicating information about risks and benefits of fish consumption to people in Grassy Narrows.** Grassy Narrows people are not generally aware of the comparative mercury levels of various bodies of water, nor of the differences in mercury levels between fish species and fish sizes. Government fish consumption advisories are not well communicated to Grassy Narrows people, and are not well known or understood.

CONCERNS EXPRESSED BY GRASSY NARROWS COMMUNITY ON MERCURY EXPOSURE FROM CLEAR-CUTTING

The types of findings raised in the MDB report are underscored in the concerns expressed by the Grassy Narrows community to the government for years about the potential for further mercury exposure from proposed clear-cutting of the Whiskey Jack. The following excerpts from various documents are arranged chronologically for MOE's consideration in conjunction with, and as part of, our bump-up request:

Jan. 8, 1999	Grassy Narrows Chief Bill Fobister and Councillors write to MNR Minister John Snobelen expressing "grave concerns with the 1999-2004 Forest Management Plan for the Whiskey Jack Forest, and lack of response to the concerns, by both the Ministry of Natural Resources, and Abitibi Consolidated Corporation"…"We are a community increasingly surrounded by huge clearcut areas of former forest....We intend to pursue our right to use the Grassy Narrows Traditional Land Use Area to sustain our culture and our ties to the land…Our community has already lived through the devastating effects of more than one environmental disaster (mercury pollution, and hydro-electric flooding). We don't intend to sit back and let it happen to our people again".[1]
May 19, 1999	MOE Minister Norman Sterling writes to Grassy Narrows' members Judy Da Silva and Roberta Keesick, copying MNR Minister Snobelen, informing them that their request for an IEA of the 1999-2019 Whiskey Jack Forest Management Plan is not warranted. The letter states that "it is unlikely that an individual EA, under the EAA, would bring to light any adverse environmental effects previously unanticipated by the planning team during the development of the forest management plan. Therefore, an individual EA is not required".[2]
July 28, 2003	Thirty years after a Japanese researcher identified Canada's biggest case of mercury poisoning, he has returned to discover that the problem is far from resolved and may be getting worse. Masazumi Harada's new research raises troubling fresh questions about the sources and effects of mercury contamination present in water and fish in many parts of the country. The results of Harada's study are particularly sobering for aboriginal people who depend on a diet rich in fresh fish. It had been expected that the health of First Nations people on the Grassy Narrows and White Dog reserves near Kenora would improve after a mill stopped dumping mercury in the English and Wabigoon river systems in 1970. But when Harada returned to the area last fall, he found evidence of continuing, pervasive health problems consistent with Minamata disease, a neurological disorder caused by mercury. The results of Harada's study have not been published but were summarized by Steve Fobister Sr., deputy chief of …Grassy Narrows, who has seen them. Of approximately 60 First Nations people who were examined at the Grassy Narrows and White Dog reserves last fall, 70 per cent showed symptoms of neurological disorder, said Fobister. Symptoms included blurred vision, slurred speech, twitching, numbness, shaking, and poor muscle co-ordination. The symptoms of eight people who were part of the study in the 1970s had become more severe.

[2] < http://freegrassy.net/wp-content/uploads/2010/03/Copy_of_Letter19May99_CAMinEnvr_2Keesick_Dasilva.pdf >.

Fobister says that he himself has serious neurological disease. “I can hardly tie my shoes any more”, he said in an interview. Even children in the community are showing serious problems, including seizures, he said. Fobister blames clear-cut logging in the area for the continuing high levels of mercury contamination – a theory for which there is some scientific support, although debate continues. A University of Montreal researcher reported in 2001 that mercury levels were up to 100 per cent higher in heavily logged watersheds than in lakes where there was no logging nearby. The theory is airborne mercury from sources such as coal-fired power plants and incinerators tends to be held in the soil and foliage of an intact forest, but runs into waterways in areas that have been clear-cut. Health Canada is funding a new study of neurological disease in the Grassy Narrows area in the light of the recent research developments. “It is alarming to see there are so many people still suffering neurological symptoms in this community after 30 years”, said Laurie Chan of McGill University, who is leading the study.[3]

Sept. 4, 2004 — Aboriginal leaders in northwestern Ontario call for a public inquiry after an international health expert says people living in the area are still showing effects of mercury poisoning. Dr. Masazumi Harada, a world-renowned neurologist, says that the conditions of people exposed to mercury three decades ago have stayed the same or worsened.[4]

Feb. 2006 — A Grassy Narrows letter to logging companies states that decades of unsustainable logging have poisoned waters with mercury and other toxins, interfered with economic opportunities and nearly eliminated the ability to practice an aboriginal way of life. Spokesman Joseph Fobister says: “We have participated fully in planning for many years, and our concerns are never properly considered,” he said. “We are never treated as equal partners in the process. What's worse, our attendance at the information sessions and open houses is misconstrued as participation or approval”.[5]

Apr. 5, 2010 — CBC reports on continuing impacts of mercury in Grassy Narrows, including impacts on children. [This is a 5-page transcript – the following excerpts cover just the statements of three people interviewed – Sherry Fobister, a Grassy Narrows resident, Bill Fobister, former Chief of Grassy Narrows, and Steve Fobister, Grassy Narrows Chief in 1983]. “Sherry Fobister: ‘I feel angry knowing that something that happened in the ‘60s, you know…Like, how it affected my

family….' . Bill Fobister: 'During the '60s, we were in full bloom, fishing, guiding, everything, that we did and we thought everything was okay. But not until we're seeing some of our fish acting weird and dying off, that's when …there is something wrong.' Bill Fobister: 'My symptoms is my numbness and loss of sensation and my vision. My speech is kind of getting pretty sloppy. My taste, I lost my taste. I lost my smell. I can't smell any more.' Steve Fobister: 'I don't think, you know, it's right to say, look, you know, you don't have to go trapping. You can live on welfare….My whole nervous system is out of whack, you know, I can't barely walk and, you know, I have to hold my jaw to talk because my muscles are practically gone…[As a fishing guide, he] had [to eat what he caught even after the mercury was discovered] We had to do this in order to appease our guests that the fish was ok. The tourist camp owners encouraged us to do it…[Dr. Harada, during his return to Grassy Narrows in March 2010, said to Steve Fobister] 'You know you have some kind of a metal poisoning' And the closest definition to [Harada's] examination…it's got to be mercury'…'I only have one granddaughter. She's the one who kind of possesses violent seizures.' Sherry Fobister: '[Ms Fobister ate fish when she was pregnant]…it's [eating fish] a part of life, you know…I love eating fish. It's a delicacy…it's part of our lifestyle. I don't know, I still eat it to this day. [no one told her not to eat fish when she was pregnant].[6]

Apr.7, 2010 — Grassy Narrows' members and supporters protest in Toronto at the provincial legislature calling for justice for mercury survivors and an end to clearcutting. A Grassy Narrows' press release quotes a Grassy Narrows mother: "When I was pregnant I couldn't afford to buy food at the store, so I ate what my grandfather brought home – mostly fish," explained Sherry Fobister, a young Grassy Narrows mother. "Now both my children are sick with strange illnesses, just like their cousins. I myself have tremors and numbness, but I don't qualify for compensation. Sometimes I can't afford to bring my kids to Winnipeg for treatment. I want everyone in Grassy Narrows tested." "As Chief in the 1970's, when the government first negotiated with us, I said that Grassy Narrows requires the control over our land and resources for our people to recover from the devastating impacts of mercury pollution on our health, our culture, and our economy. This is still true," said Grassy Narrows Chief Simon Fobister.[7]

2010 — Toronto Star reports that "Premier Dalton McGuinty responded to the chief's concerns by saying the province has a 'heavy responsibility' to study Harada's findings, because they conflict with what the federal government claims – that

[7] < http://freegrassy.net/wp-content/uploads/2010/01/River_Run_Press_Release_April_71.pdf >.

	mercury poisoning at Grassy Narrows is under control. 'It seems we have conflicting data and information,' McGuinty told reporters in Peterborough where he was visiting a health clinic. 'We have a report, apparently, which says we have a continuing problem and this contrasts with the federal government which is saying, 'Well, things are under control'." The Toronto Star reports further that: "While the federal and provincial governments say contamination is no longer a problem, Harada's research indicates the possibility of congenital Minamata disease is high," said Ontario Regional Chief Angus Toulouse. Children are being born with neurological symptoms, mental deficiency and cerebral palsy, he said".[8]
July 20, 2010	The Assembly of First Nations passes a resolution calling for a public inquiry into mercury contamination at Grassy Narrows. They also call for an end to logging in the community's traditional territory, as well as permanent monitoring of the long-term effects on residents. The resolution supports Grassy Narrows' demand to "restore Grassy Narrows' control over Grassy Narrows Territory, including putting a stop to clear-cut logging, as this contributes to the leaching of mercury into waterways".[9]
2010	Grassroots Grassy Narrows members and supporters release a public fact sheet on mercury and Dr. Harada's findings.[10]
June 2012	Grassy Narrows' leadership, members, and supporters hold a week of events in Toronto called River Run 2012 to call for justice on mercury issues and an end to clear-cutting. Aboriginal Affairs Minister Wynne says that there is a committee of ADMs from various ministries seeking to deal with the mercury issue. Wynne commits to visiting Grassy Narrows and does so later in the summer. She commits to try to repair the relationship with Grassy Narrows and "getting this right".[11]
June 4, 2012	The Canadian Press reports that Chief Simon Fobister stated: "While our people suffer, Ontario has made plans to continue the destruction of our culture,

livelihood, and health through another decade of logging in our forest against our will".[12]

June 6, 2012 — A Toronto Star Editorial writes that: "the compensation package set up in the 1980s is so inadequate that it now doesn't cover most of those with symptoms of mercury poisoning".[13]

June 7, 2012 — Aboriginal Affairs Minister Wynne answers question about logging and mercury link on CBC's "The Current": "We do believe that there is still contamination... nobody should be eating contaminated fish..."

Q. Tremonti: "They are also calling for an end to logging in the area because they talk about the cutting and the mercury contamination that comes from the soil once the trees are gone, are you about to look into that?"

A. Wynne: "I think that is part of the broad conversation. I am not going to make any commitments on logging or the economic future in terms of that industry, but I think its part of the mix, part of what we need to talk about....There is the adding of mercury as part of that industry, but there is also the cleanup.....What I haven't have heard is a clear kind of plan for how we would do the cleanup. If there were a way to do the cleanup then maybe the conversation about logging would be different".[14]

Minister Wynne also notes that the "fish for food" program is not widely used No applications for fish are made from 2006 to April 2012.[15]

N.B. Grassy Narrows people note that the frozen fish lack cultural compatibility and the social and cultural benefits of fishing, undermine self sufficiency, are inappropriate fish species, are not fresh, and are freezer burned.

June 11, 2012 — The people of Grassy Narrows believe that large-scale clear-cut logging, which has been linked to increased mercury run-off into rivers and streams, is a key factor in the persistent contamination of their territory.[16]

[15] *Ibid.*

June 25, 2013	In June, a wide range of human rights, faith, labour, and environmental organizations with over one million members in Ontario write to the Premier urging her to call an end to unwanted logging permits on Grassy Narrows' lands as a good faith demonstration of the province's commitment to a forest management approach that respects Aboriginal rights. The letter states in part that: "…large-scale clear cut logging has not only destroyed trap lines and wiped out areas that provided berries and plant medicines, and driven off essential game species, it has almost certainly also contributed to new mercury leaching into their rivers and streams".[17]
Oct. 24, 2013	Letter from Grassy Narrows' Chief Simon Fobister to Ontario Premier Kathleen Wynne objecting to the logging plan and noting past and future concerns respecting mercury poisoning: "You are fully aware that our community continues to struggle with the devastating health impacts from 9,000 kg of mercury that was dumped into our river system in the 1960s with the permission of the government of Ontario. Three generations of our people bear the burden of this degenerative neurological poison. New clearcut logging will bring even more mercury into our river and our food chain, further prolonging and exacerbating this avoidable tragedy. We condemn such processes and plans".[18]
Oct. 30, 2013	Chief Fobister speaks on CBC "As it Happens" objecting to the proposed FMP: "The clearcuts contribute to leaching of mercury into the watershed…there are bacteria that will turn that mercury into methyl mercury. We already have 12 tonnes of methyl mercury in the river sediment…and there has not even been any cleanup by Ontario".[19]
Nov. 7, 2013	Grassy Narrows' media release regarding logging plan asks whether government of Ontario "will…force logging on our community against our will, knowing that logging would release more mercury into our food chain".[20]

[20] Media Release "Minister Makes False Statement on Logging in Grassy Narrows", November 7, 2013.

Dec. 23, 2013	Media release from Grassy Narrows reports on Ontario government approval of the logging plan, which the release says will harm a community already struggling with the long-term health impacts of mercury poisoning. The media release notes that clear-cut logging approved under the plan, in which some cuts will be nearly the size of pre-amalgamation Toronto, will elevate mercury levels in fish, deepening the tragedy caused when 20,000 pounds of mercury were dumped into the river system in the 1960s by a paper mill upstream from Grassy Narrows.[21]
Feb. 3, 2014	Letter from Grassy Narrows' Chief Simon Fobister to Ontario Minister of Natural Resources David Orazietti and Ontario Minister of Aboriginal Affairs David Zimmer restating opposition to logging plan for a variety of reasons including that the "plan is likely to prolong and deepen the tragedy of mercury poisoning in our community" which is "unacceptable".[22]
Feb. 3, 2014	CBC external link report states that "People in Grassy Narrows have been poisoned by mercury for over 40 years. 20,000 pounds of mercury was dumped into the Wabigoon River-English River system by an upstream paper mill, Dryden Chemicals Inc., which had permission from the province to freely dispose of chemicals between 1962 to 1970. People in Grassy Narrows have developed neurological Minamata disease from eating contaminated fish. The disease can cause blurred vision, tremors, lack of motor control, seizures, and children born with cerebral palsy, according to [an unnamed] report. The community is especially concerned that when logging starts, the mercury levels will rise." [A photo of fish frying in a pan accompanying the CBC report contains a caption that reads in part:] "Fish is a staple diet for anishinaabe people. Grassy Narrows people have eaten and still eat fish contaminated with mercury as not everyone can afford food not caught nearby".[23]
Mar. 28, 2014	Kenora news report indicates that MNR Minister David Orazietti is defending the province's new 10-year FMP for the Whiskey Jack Forest which is set to come into force on April 1, 2014. A Grassy Narrows activist, Judy Da Silva, an architect of her community's decade-long blockade against forestry operations, said the forest cannot support more logging industry. She pointed to, among other things, the on-going effects of mercury poisoning. Orazietti said that since 2009 0.075 per cent of the Whiskey Jack's forested areas has been logged each

[21] Grassy Narrows First Nation, Media Release, "Wynne ruins Xmas in Grassy Narrows, logging plan approved" (23 December 2013).
[22] Letter from Chief Simon Fobister, Asubpeeschoseewagong Netum Anishinabek, Grassy Narrows, Ontario to the Hon. David Orazietti, Ontario Minister of Natural Resources and the Hon. David Zimmer, Ontario Minister of Aboriginal Affairs, February 3, 2014.
[23] Crystal Greene, CBC News, "Grassy Narrows First Nation on alert for logging" (Thunder Bay: CBC, February 3, 2014).

year, and under the FMP that would be increased to 0.1 per cent for the year 2014-2015. But he said no trees would be touched during that time within 60 kilometers of Grassy Narrows. Da Silva said "We've already had 9,000 kilograms of mercury spilled in the forest and there is research showing that the logging industry helps contribute to the build-up of mercury. If this is going to continue on, then we are going to have a bleak future in this forest", said Da Silva.[24]

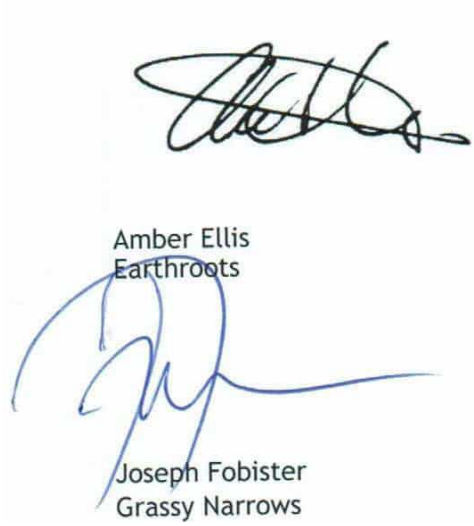
CLOSURE

Finally, please also take into account the recent media reports on this issue during the week of July 28 to August 1 2014 (http://freegrassy.net/news-reports-about-river-run-2014/), including the statements made by Minister Zimmer at his press conference with Steve Fobister Sr. on Tuesday July 29, 2014 and by Premier Wynne on CBC on Wednesday July 30th. In particular:

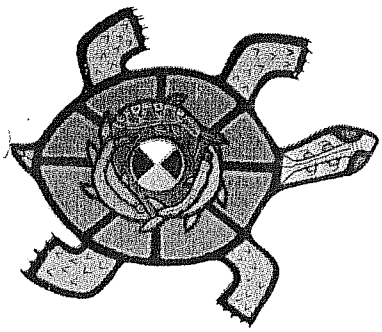
Ontario Premier Kathleen Wynne: "There is no doubt in my mind that there are disabilities that have come about because of the pollution of the water." *July 30, 2014*

We trust that you will take this information into account in considering our request for an IEA of the Whiskey Jack FMP 2012-2022.

Sincerely,



[24] Alan S. Hale, "Orazietti defends Whiskey Jack forestry plan as its implementation looms", Kenora Daily Miner and News (Mar. 28, 2014).



MERCURY
DISABILITY BOARD

Literature Review:

The Impact of Mercury on Human Health

2010

Mercury Disability Board
Literature Review: The Impact of Mercury on Human Health

INTENT

The approach used by the Mercury Disability Board to assess whether or not an applicant has signs or symptoms consistent with mercury poisoning was designed based on the state of science and knowledge of the impact of mercury on human health in the 1980s. In 2009 the Board commissioned a review of the literature to determine if there is new knowledge that might in some way inform the Board's work. Proposals were sought from senior scientists who have published in this field in the scholarly literature. Drs. Laurie Chan and Donna Mergler were engaged in July, 2009 to complete the work, as follows.

The intent of this project was to address the literature since 1985 on mercury contamination in human populations in order for the Board to review its current procedures and tools:

a) The effects of mercury contamination on human health (including the fetus) particularly:
- *the effect of human physiology over the life course including short and long term effects;*
- *disability related to mercury;*
- *mental health or behavioural effects of mercury including psychosis;*
- *any evidence that mercury accelerates the development of chronic diseases related to the thyroid gland, arthritis, diabetes and the nervous system.*

b) Any evidence of an interactive effect of mercury and other contaminants on human health.

c) Methods of measuring past or present mercury exposure in humans.

d) Independent review of literature produced by Dr. Masuzumi Harada.

e) Opinions on environmental contamination reporting in the area.

OUTCOMES

The following reports as provided by Laurie Chan, Ph.D. and Donna Mergler, Ph.D. and bound together in this package are:

A Review of Current Understanding of Mercury Poisoning - September 21, 2009
This provides a review and presentation of literature on mercury exposure and effects in humans building on earlier literature, other reviews and more recent literature (since 1985) highlighting current understanding in the field.

Opinions on Dr. Masazumi Harada's studies in Ontario based on articles provided by the Mercury Disability Board – October 29, 2009 and updated September 15, 2010
This provides a review and opinions on the following articles regarding Dr. Masazumi Harada's studies in Ontario:

1. Harada, M.; Fujino, T.; Akagi, T.; Nighigaki, S. Epidemiological and Clinical Study and Historical Background of Mercury Pollution on Indian Reservations in Northwestern Ontario, Canada. Bull. Inst. Constit. Med. 26 (3-4). 15 pgs. 1975.

A Review of Current Understanding of Mercury Poisoning

Prepared by Laurie Chan, Ph.D. and Donna Mergler, Ph.D.

September 21, 2009

Introduction

This paper is commissioned by the Mercury Disability Board (MDB) to review literature on the impact of mercury on human health. The paper is not intended to be a comprehensive review and presentation of all the literature on mercury (Hg) exposure and effects in humans, but builds on earlier literature, other reviews, and more recent literature (since 1985) in highlighting current understanding in the field and addresses issues raised by the MDB.

There has been an increasing interest and growing knowledge on Hg toxicity in recent years primarily because of the concern of chronic exposure via fish consumption. A number of critical reviews of the toxicology of Hg and its health effects have been published [i,ii]. Several governments, international agencies, and other organizations have compiled extensive information on the sources, environmental fate and transport, potential health effects, exposure estimates, and potential risks of elemental mercury, inorganic mercury and methylmercury (MeHg). Several useful resources are listed below with their full citations appearing in the reference list at the end of this document.

- Elemental Mercury and Inorganic Mercury Compounds: Human Health Aspects (WHO, 2003)[iii]
- Toxicological Profile for Mercury (Update) (US ATSDR, 1999)[12]
- Toxicological Effects of Methylmercury (NRC, 2000)[119]
- Mercury - Environmental Health Criteria Documents (WHO, 1990)[128]
- Mercury – Guidance for identifying populations at risk from mercury exposure (UNEP/WHO, 2008)[iv]

Humans are exposed to different forms of mercury (Hg), and potential health risks from forms other than MeHg can occur, including mercury vapor from dental amalgams as well as from occupational exposures (e.g. dental offices, chlor-alkali plants, fluorescent lamp factories, mercury mining) and from artesanal and small-scale gold and silver mining operations[v,vi,vii,viii,ix]. The main focus of this paper will be on MeHg as most of the current advance in understanding is on the toxicity of this form of Hg and as it is the form that is found in fish, its toxicity has wider human health implications.

1. The effects of mercury contamination on human health

All humans are exposed to low levels of mercury. Almost all people have at least trace amounts of mercury in their tissues (i.e. MeHg in their hair). Generally, these low exposures are not likely to cause adverse health effects. However, Hg can cause significant effects on human health if exposure levels exceed established safe levels.

The factors that determine the occurrence of adverse health effects and how severe the health effects include:

- chemical form of mercury;
- dose;
- age of the person exposed (developing systems are susceptible);
- duration of exposure;
- route of exposure (inhalation, ingestion or dermal contact); and,
- dietary patterns of fish and seafood consumption.

The primary targets for toxicity of Hg and Hg compounds are the nervous system, the kidneys and the cardiovascular system. It is generally accepted that developing organ systems (such as the fetal nervous system) are the most sensitive to toxic effects of Hg. Fetal brain MeHg levels are higher than in maternal blood [x], and the developing central

nervous system of the fetus is currently regarded as the system of highest concern as it demonstrates the greatest sensitivity[xi]. It should be noted, however, that in humans the nervous system continues to develop through adolescence.

Other systems that may be affected include the respiratory, gastrointestinal, hematologic, immune, and reproductive systems. The health effects caused by elevated exposures to elemental Hg, inorganic Hg compounds, and organic Hg compounds such as MeHg differ [xii].

1.1 Effect on human physiology over the life course including short- and long-term effects

1.1.1 Overview of toxic effects of different forms of mercury

The ingestion of liquid metallic mercury or "quicksilver" does not appear to be toxic in itself. Health hazards from quicksilver are due to its potential to release of mercury vapor. Inhaled mercury vapor can also cause damage to the central nervous system due to its ability to cross the blood–brain barrier[1]. The high mobility of inhaled mercury vapor in the body is assumed to be due to its physical properties as an uncharged, monatomic gas that can readily diffuse through the lipid monolayers of the cell membrane. The mechanisms of transport of mercurous and mercuric cations are not well understood. Neurological and behavioral disorders in humans have been observed following inhalation of Hg vapor. Symptoms include tremors, initially affecting the hands and sometimes spreading to other parts of the body; emotional lability (often referred to as "erethism" and characterized by irritability, excitation, excessive shyness, confidence loss, and nervousness); insomnia; neuromuscular changes (such as weakness, muscle atrophy, or muscle twitching); headaches; polyneuropathy (such as paresthesia, stocking-glove sensory loss, hyperactive tendon reflexes, slowed sensory and motor nerve conduction velocities); and memory loss and performance deficits in tests of cognitive function. At higher concentrations, adverse kidney and thyroid effects, pulmonary dysfunction, changes in vision and deafness may also be observed [xiii,xiv,xv]. Short-term exposure to high concentrations of Hg vapor damages the lining of the mouth, irritates

lungs, cause tightness of chest, coughing, nausea, vomiting, diarrhea, and increased blood pressure[11]. Dental amalgam releases mercury vapor that can be inhaled and presumably behaves toxicologically like mercury vapor inhaled from external sources such as in occupational exposures. However, other than rare cases of contact allergy, no convincing evidence is yet forthcoming that dental amalgam can cause adverse health effects[1].

Mercurous mercury, in the form of mercurous chloride or calomel, has a long history of medicinal uses, especially as a laxative and in infant teething powders. Both mercurous and mercuric compounds are believed to be the causal agents in the childhood disease of acrodynia or "pink disease." Symptoms include profuse sweating, and swollen red feet and hands, which were cold, clammy, desquamating, and painfully sensitive to touch. Sometimes there was a rash on body, legs, and arms. There was progressive weight loss, marked weakness, and apathy. Insomnia and photophobia were also distressing attributes of the disease [xvi].

The mercuric cation, Hg2+, is believed to be the proximate toxic agent for all these inorganic forms of mercury. All species of inorganic mercury have the capacity to elicit idiosyncratic reactions. Such reactions require exposure to mercury, but the prevalence and severity do not appear to be dose related. The nephrotic syndrome and acrodynia are examples[1]. Mercuric mercury is known to exit liver cells into bile as a complex with reduced glutathione. Mercuric mercury has a limited capacity to cross the blood–brain and placental barriers but is accumulated by the kidneys. The most sensitive adverse effect observed following exposure to Hg2+ is the formation of autoimmune glomerulonephritis (inflammation of kidney). Accidental ingestion of mercuric chloride by children resulted in cardiac effects (increased heart rate and blood pressure)[11,12]. Accidental drinking or ingestion of inorganic Hg can cause damage to the digestive tract and kidney. In addition, dermal exposures to ionic mercury can lead to adverse effects to the skin [11].

1.1.2 Toxic Effects of organic mercury on infants and adults

The methyl- and ethylmercury compounds have similar chemical properties and are often referred to as the "short-chain alkyl mercurials." The primary target is the central nervous system. The ethyl compounds differ from their methyl relatives in that they are converted more rapidly to inorganic mercury in the body and produce kidney damage, whereas methylmercury appears to exclusively damage the central nervous system, at least in primates. The intact organomercurial cation is believed to be the proximate toxic agent responsible for damage to the central nervous system, and the mercuric cation released from ethylmercury plays this role in kidney damage. The high mobility of methylmercury in the body is due to the formation of a complex with the amino acid cysteine. The structure of this complex resembles that of a large neutral amino acid, methionine, and thereby gains entry into cells on the large neutral amino acid carrier. Methylmercury exits from cells as a complex with reduced glutathione on the membrane carrier for this peptide. Much more toxicological information is available for methylmercury than for ethylmercury. However, there has been concern about ethylmercury toxicity among children from Thimerosal. Thimerosal is used as a preservative in vaccines (such as DTP, hepatitis B, and Hib), to protect against bacterial contamination; this preservative contains nearly 50 % ethylmercury. Once in the body, thimerosal is transformed into organic (ethyl) mercury. Canada has decreased or eliminated the use of thimerosal from many vaccines[xvii]. However, thimerosal still exists in some vaccines used. Therefore, when assessing exposures to mercury for a population or subpopulation, this possible source of exposure should be considered. The Global Advisory Committee on Vaccine Safety of WHO concluded that there is currently no evidence of mercury toxicity in infants, children, or adults exposed to thimerosal in vaccines and advised continued use of thiomersal-containing vaccines was recommended[xviii].

Other organomercurials include phenylmercury and methoxyethylmercury compounds. This group of mercurials is rapidly converted to inorganic mercury so that their toxic effects are similar to those of mercuric mercury compounds. In general, however, they are more efficiently absorbed into the body than inorganic mercury. Toxic effects of on the nervous system are due to damage to discrete anatomical regions in the brain with sensory and motor coordination functions[xix]. The outcome is usually irreversible as

neuronal cells are destroyed. There is also evidence of peripheral neuropathy that may account for the signs of sensory loss in the extremities[xx]. The appearance of signs and symptoms of poisoning can be preceded by a latent period after exposure has ceased. This latent period can amount to weeks or even months or years. Weiss et al presented three examples of delay (latency) in the appearance of signs and symptoms of poisoning after exposure to methylmercury[xxi]. First, a case was presented of a 150-day delay period before the clinical manifestations of brain damage after a single brief (<1 day) exposure to dimethylmercury. The second example was taken from the Iraq outbreak of methylmercury poisoning in which the victims consumed contaminated bread for several weeks without any ill effects. Indeed, signs of poisoning did not appear until weeks or months after exposure stopped. The last example was drawn from observations on nonhuman primates and from the sequelae of the Minamata, Japan, outbreak in which low chronic doses of methylmercury may not have produced observable behavioral effects for periods of time measured in years.

The toxic effects of methylmercury differ between adult and prenatal exposures. They differ both in terms of the type of damage to the brain and in terms of the lowest toxic doses. They are therefore treated separately here. Distinction between acute and chronic toxicity of methylmercury is not really meaningful. A single dose can elicit the same syndrome of clinical methylmercury poisoning as chronic exposure.

Clinical manifestations of exposure to methylmercury

In 1958, McAlpine and Araki[xxii] linked the unusual neurological disease that had been associated with fish consumption from Minamata Bay to MeHg exposure. This historic recognition of the brain and nervous system as the primary target organ for MeHg poisoning, resulting in marked distal sensory disturbances, constriction of visual fields, ataxia, dysarthria, auditory disturbances and tremor, remains unchanged[xxiii,xxiv]. Based on analysis of the studies of human poisoning, the WHO estimated that 5% of MeHg-exposed adults would experience neurologic effects with a blood Hg level of 200 μg/L

(corresponding to a hair level of approximately 50 μg/g). This estimate has, however, been called into question by a re-analysis of the these studies by Kosastsky and Foran[xxv] and the recent studies conducted among Minamata residents (see Section 1.2 below for detailed discussion) who suggested that the lowest-observed-effect level for clinical effects is likely to be considerably lower. Indeed, anecdotal and case reports of diffuse and subjective neurologic symptoms in adults and older children with moderately elevated MeHg exposures continue to appear[xxvi]. In many cases, cessation or significant curtailing of fish consumption results in improvement of symptoms in conjunction with reduction in biomarker concentrations. These suggest the possibility of clinical effects, perhaps in a sensitive sub-set of the general population, at levels of exposure considerably below those previously associated with clinical effects in poisoning episodes. Currently, there is no formal case description or diagnostic criteria for such effects.

While exposures throughout the world are lower than those producing the historical epidemics of MeHg poisoning, there is growing evidence that for many populations, exposures are sufficient to alter normal functioning of several systems and constitutes an important public health problem.

Effects in neonates, infants and children

Central Nervous System development encompasses a tightly regulated temporal and spatial sequence of events (proliferation, migration, synaptogenesis, selective programmed cell death, myelination). Even a short-term impairment in this cascade may cause irreversible neurotoxicity if the tissue cannot compensate for the damage. The routes of exposure to toxicants during development are rather unique (e.g., transplacental in fetus, *via* breast milk in nursing infants, hand-to-mouth in early childhood) and have no parallel among adults. Moreover, on a body-weight basis children eat and drink more than average adults, and thus they are potentially more heavily exposed to food contaminants than grown-up individuals[xxvii].

The poisoning in Minamata brought attention to the risk from fetal exposure. Exposed to MeHg through the placenta of the exposed mother, infants showed severe cerebral palsy-like symptoms, even when their mothers had mild or no manifestation of the poisoning[xxviii]. Mental retardation, cerebellar ataxia, primitive reflexes, disarthria and hyperkinesias were observed. These symptoms described over 25 years ago[xxix], continue as the clinical hallmark of congenital methylmercury poisoning. Reconstruction of maternal or fetal doses resulting in these symptoms is difficult due to lack of concurrent sampling. An estimate of the mean maternal hair concentration resulting in such symptoms of 41μg/g ppm was proposed[xxx], however, large uncertainty surrounds this estimate. Health effects observed with poisonings should not be confused with the more subtle population effects observed at lower levels of exposure.

At the sub-clinical and population level, several studies in different parts of the world, have reported poorer neurologic status and slower development in newborns, infants and/or children exposed *in utero* MeHg and/or during early childhood[xxxi,xxxii,xxxiii,xxxiv,xxxv,xxxvi,xxxvii,xxxviii,xxxix,xl,xli,xlii], although some studies did not observe effects[xliii,xliv,xlv]. In children, MeHg exposure has been associated with lower performance on tests of language, attention, memory, and/or visuo-spatial and/or motor functions. Detailed review of the recent cohort studies showing evidence of Hg effects on neurodevelopment will be presented in Section 1.3.1.

Effects in adults

Much of the effects of MeHg have been learned from the poisoning cases in Minamata, Japan which is now know as Minamata Disease (MD). MD was first discovered in 1956 around Minamata Bay, Kumamoto Prefecture (KP), Japan. A second epidemic in Japan occurred in 1965 along the Agano River, Niigata Prefecture (NP). The severe contamination by methylmercury continued until 1968, when the plant finally stopped discharging its wastewater into Minamata Bay. According to Japanese government

figures, 2,955 people contracted Minamata disease, and 1,784 people have since died[xlvi]. MD patients showed neurologic signs including sensory loss, ataxia, constriction of visual field, dysarthria, and hearing difficulties. It was recently reported that large amounts of methylmercury were generated by the chemical processes of the Chisso acetaldehyde plant and later dumped directly into Minamata Bay[xlvii]. This has significant implications that MD was likely caused by consumption of MeHg directly released in the environment and accumulated in fish instead of from inorganic Hg methylated and bioaccumulated in the environment[l]. Eto[xlviii] reported that in the cases found in KP, at autopsy, the most conspicuous destructive lesion in the cerebrum was found in the anterior portions of the calcarine cortex. Less severe but similar lesions were found in the post-central, pre-central and temporal transverse cortices. Secondary degeneration from primary lesions was seen in cases with long survival. In the cerebellum, pathological changes occurred deep in the hemisphere. The granule cell population was more affected, compared with Purkinje cells. Among peripheral nerves, sensory nerves were more affected than motor nerves. More recently, Eto et al[xlix] reevaluated 30 autopsy cases related to MD in Niigata Prefecture (NP) and found that the pathological findings leading to the diagnosis of MD in the NP cases were essentially the same as those in KP, including the peripheral nerve lesions. In the most severely affected case of MD in NP, formation of multiple vacuoles of various sizes was observed in the cerebellar cortex, which was never encountered in the KP cases.

The current WHO threshold for adult exposure (hair level: 50 μg/g) was based on evidence from NP, which included only acute and severe cases. Many residents in the area and researchers have questioned the possibility of more subtle effects at lower exposure levels. A recent case control study published in 2009 identified 120 residents from exposed areas who had mercury in hair data measured in 1960 and neurological outcomes measured in 1971, compared to a control of 730 residents from an unexposed area[l]. They found that hair mercury levels were associated with perioral sensory loss in a dose-response relationship. The adjusted prevalence odds ratios and 95% confidence intervals for perioral sensory loss, compared with the lowest exposure category (0–10 μg/g), were 4.5 (0.5–44), 9.1 (1.0–83), and 10 (0.9–110), for the dose categories >10 to

20, >20 to 50, and >50 μg/g, respectively. The prevalence of all neurologic signs was higher in the exposure area than in the control area. This result suggests that neurologic signs, especially perioral sensory loss, was found among residents with hair mercury content below 50 μg/g after exposure was ceased for 11 years. Ninomiya et al reported that sensory loss remained even 30 years after the cessation of methylmercury exposure[li,lii]. The study also reported a weak trend for other neurological symptoms such as bilateral sensory disturbance, ataxia, and dysarthria suggesting that some neurologic functions may have improved due to central nervous system plasticity[liii].

Other than the major accidents and industrial release, few studies have addressed the neurotoxic effects of Hg exposure in adults. Mercury related deficits in motor, psychomotor, visual and/or cognitive functions have been reported for different populations within the Brazilian Amazon[liv,lv,lvi,lvii] and for tuna consumers from the Mediterranean[lviii]. A recent study of older adults (50-70 years old) in the United States, with low blood Hg levels, (mean = 2.1 μg/L), however, showed inconsistent evidence of effect across neurobehavioral tests[lix]. A Canadian study of fish eaters with levels of blood Hg <20μg/L, showed a negative association between Hg and monoamine oxidase activities in platelets[lx]. Experimental studies have shown that Hg exposure disrupts the function and transmission of the monoaminergic nervous system, inhibiting the enzyme activities of monoamine oxidase (MAO, EC 1.4.3.4)[lxi]. Biochemical changes may constitute a sensitive, although non-specific, early indication of Hg-induced alterations to the nervous system, but more work is needed in this area.

Studies of associations between nervous system outcomes and MeHg exposure in adult populations in which frequent and lifetime fish consumption is a cultural norm, generally cannot distinguish between effects due to adult exposure and permanent developmental effects due to gestational and early childhood exposures.

1.2 Disability related to Hg

Classical mercury poisoning is characterized by a triad of signs, namely tremors, erethism and gingivitis. Mercurial erethism, which is characterized by behavioral and personality changes such as extreme shyness, excitability, loss of memory, and insomnia are also observed[lxii]. Recently, the effects of mercury exposure at levels around 0.05 mg/m3 or lower have been of concern and may include minor renal tubular damage, increased complaints of tiredness, memory disturbance and other symptoms, subclinical finger tremor, abnormal EEG by computerized analysis and impaired performance in neurobehavioral or neuropsychological tests. Abnormal gait, dysarthria, ataxia, deafness and constriction of the visual field are typical of the symptoms of methylmercury poisoning observed in Minamata and Iraqi outbreaks, as well as in occupational methylmercury poisoning cases. Disability caused by Hg exposure can be demonstrated from reports for observed effects among patients suffering from occupational exposure. For example, Powell[lxiii] reported neurobehavioural symptoms of mercury poisoning, in a group of Zulu chemical workers (n = 16), employed by a mercury processing plant, exposed to neurotoxic levels of mercury, 5 years after exposure. A group-control design was adopted, where the exposed group was matched for age, sex, race, occupational and educational background. Both groups were administered a specially selected battery of psychometric tests to measure neuropsychological functioning. The exposed group had significantly impaired short term verbal and spatial memory, impaired sustained and divided attention, and impaired motor speed. They also suffered from elevated clinical levels of psychiatric symptomatology, including anxiety, depression and phobic avoidance, and neurological symptoms of tremor, weakness in the limbs, and excessive sweating. This results suggest that exposure to Hg can cause varying degrees of permanent neuropsychological disability.

Paresthesias

Paresthesias are the first symptom that people report following toxic doses of methylmercury. Takaoka et al[lxiv] conducted a psychophysical study of tactile sensation to evaluate the somatosensory abilities of subjects living in a methylmercury-polluted area

around Minamata City, Japan. Acuity of fine-surface-texture discrimination was disturbed not only in subjects with clinical complaints of hand numbness, but also in subjects without hand numbness who lived in the district where methylmercury exposure occurred. In a more recent study, Takaoka et al[76] studied 197 residents from the Minamata area who had a history of fish consumption. They divided the exposed subjects into non-complicated (E) and complicated (E+N) groups based on the absence or presence of other neurological or neurologically related disorders and compared them to residents in control area (C) after matching for age and sex. They quantitatively measured four somatosensory modalities (minimal tactile sense by Semmes-Weinstein monofilaments, vibration sense, position sense, and two-point discrimination) and did psychophysical tests of fine-surface-texture discrimination. Subjective complaints were higher in groups E and E+N than C. Over 90% of E+N and E subjects displayed a sensory disturbance on conventional neurological examination. The prevalence of these neurological findings was significantly higher in exposed subjects than controls. All sensory modalities were impaired in the E and E+N groups. All four quantitatively measured sensory modalities were correlated. The prevalence of complaints, neurological findings, and sensory impairment was similar or a little worse in group E+N than in group E. These findings suggest that sensory symptoms resulting from Hg exposure could be determined even in the presence of neurological or neurologically related diseases.

Ataxia

Takaoka et al studied 197 residents from the Minamata area who had a history of fish consumption during the polluted period and found that about 50% had upper and lower extremity ataxia and about 70% had truncal ataxia[lxv].

Vision

Impairment of visual functions has been studied in patients exposed to mercury. These studies have been shown partial loss of color vision in workers exposed to several

solvents and to metallic mercury[lxvi,lxvii,lxviii]. Amazon gold miners exposed to mercury vapor were found to show visual dysfunction[lxix]. Color vision and contrast sensitivity (CS) impairment were also found in fish-eating Amazonian populations where Hg exposure is today among the highest in the world due to deforestation and gold-mining activities[lxx]. The loss of color vision and CS has been demonstrated in these populations, at methyl mercury levels of contamination below 50 μg/g of total hair Hg, which was traditionally considered the threshold for clinical effect[65,66,78] . In the Minamata study, 28% of the study group reported visual constriction[74]. The measurement of CS in 7-yr old children with prenatal exposure to methylmercury did not show impairment in their CS[lxxi].

Activities of Daily Living

Reports of ill health increased sharply following the 2004 Supreme Court ruling instructing the Japanese government to pay damages to MD patients. Over 13,000 residents came forward to be examined for MD[74]. Ushijima et al examined the distribution of disability in activities of daily living (ADL), and the association between MD status in terms of compensation system and ADL disability among the general population of previously methylmercury-polluted areas[lxxii]. They collected data by two-stage stratified sampling of residents 40–79 years old in 172 postal-code on the endemic area of MD. Questionnaires were distributed to eligible subjects (n = 2100) and collected at a later visit or by mail. Information on demographic factors, basic ADL (BADL), and instrumental ADL (IADL) was obtained using questionnaires. Logistic regression analysis were used to assess the relationship between MD status in terms of compensation system and ADL disability. They classified the 1422 residents who completed the questionnaire in accordance with their MD status in terms of compensation system: *Early* (those who received MD compensation before the Supreme Court decision), *Recent* (those who applied for compensation after the Supreme Court decision), *Not Yet* (those who have not yet applied for compensation, but have health-related anxieties about MD effects), and *Normal* (those who have not applied for compensation, and do not have health-related anxieties about MD effects). Adjusting for

confounding factors, MD status was significantly associated with the disability grades of BADL and IADL with an increasing trend in the order of *Normal*, *Not Yet*, *Recent*, and *Early*. The odds ratios (95% CI) based on *Normal* were 2.08 (1.08–4.01), 3.87 (2.14–7.01), and 4.50 (2.66–7.61) for BADL and 2.41 (1.62–3.61), 3.20 (2.12–4.85) and 3.68 (2.52–5.38) in *Not Yet*, *Recent*, and *Early* for IADL, respectively. The authors concluded that *Early*, *Recent*, and *Not Yet* had lower ADL grades than *Normal*. Moreover, the population with a low ADL grade and health-related anxieties had increased throughout the previously methylmercury-polluted areas.

Learning and Development

Human neurodevelopmental consequences of exposure to methyl-mercury (MeHg) from eating fish remain a question of public health concern. The current knowledge is based on the findings of a number of on-going cohort studies. A cohort of 1022 consecutive singleton births was generated during 1987–1988 in the Faroe Islands, where increased methylmercury exposure occurs from traditional seafood diets that include pilot whale meat[lxxiii]. The prenatal exposure level was determined from mercury analyses of cord blood, cord tissue, and maternal hair. At age 14 years, 878 of 1010 living cohort members underwent detailed neurobehavioral examination. Indicators of prenatal methylmercury exposure were significantly associated with deficits in finger tapping speed, reaction time on a continued performance task, and cued naming. These findings are similar to those obtained at age 7 years. An analysis of the test score difference between results at 7 and 14 years suggested that mercury-associated deficits had not changed between the two examinations. In structural equation model analyses, the neuropsychological tests were separated into five groups; methylmercury exposure was significantly associated with deficits in motor, attention, and verbal tests. These findings are supported by independent assessment of neurophysiological outcomes[lxxiv]. The effects on brain function associated with prenatal methylmercury exposure therefore appear to be multi-focal and permanent.

Axelrad et al[lxxv] estimated a dose-response relationship between maternal mercury body burden and subsequent childhood decrements in intelligence quotient (IQ), using a

Bayesian hierarchical model to integrate data from three epidemiologic studies conducted in the Faroe Islands, New Zealand, and the Seychelles Islands. They found a central estimate of -0.18 IQ points (95% confidence interval, -0.378 to -0.009) for each part per million increase of maternal hair mercury. IQ is a useful end point for estimating neurodevelopmental effects, but may not fully represent cognitive deficits associated with mercury exposure, and does not represent deficits related to attention and motor skills. Nevertheless, the integrated IQ coefficient provides a more robust description of the dose-response relationship for prenatal mercury exposure and cognitive functioning than results of any single study.

1.3 Mental health or behavioural effects of mercury including psychosis

1.3.1. Effects of mercury on children's neurodevelopment

As discussed in Section 1.1.2, infants are at the most susceptible life stage for mercury toxicity. Much effort has been devoted to identify the subtle effects on neurodevelopment due to fetal and childhood low dose chronic exposure. The evidence for mercury developmental neurotoxicity continues to accumulate. Most published information comes from the two major child cohort studies carried out in the Faroe Islands, where mercury exposure is from the consumption of marine fish and pilot whale, and in the Seychelles, where marine fish is the source of exposure.

Several hundred children have now been followed from birth to 14 years of age in the Faroes and 9 years of age in the Seychelles. For many years the results coming from these two studies were contradictory. The study in the Faroes has showed effects of mercury on children's neurobehavioral performance and electrophysiological measures, while up until recently, the study in the Seychelles has not shown associations between mercury exposure and neurobehavioral outcomes.

In the Faroe Islands, where there were relatively high levels of mercury exposure, evidenced by median umbilical cord blood levels of 24μg/L, a cohort of over 1000 newborns were initially enrolled in a study in 1987-88 and most or selected groups have

been periodically tested from birth to 14 years of age. Although in the initial cohort, no effects were observed on developmental milestones in the first year[lxxvi], a later study of 182 Faroese newborns, born in 1994-95, showed lowered neurologic optimality scores associated with increased cord blood mercury[lxxvii] and mercury-related decreased height and weight at 18 months and a lesser relation at 42 months[lxxviii]. When examined at the age of 7 years, the 1987-88 cohort presented neuropsychological dysfunctions which increased with prenatal mercury exposure; the most pronounced were in the domains of language, attention, and memory, and to a lesser extent in visuo-spatial and motor functions. These associations remained after adjustment for covariates and after exclusion of children with maternal hair mercury concentrations above 10 micrograms[33]. Electrophysiological studies of a subgroup of these children showed mercury-related delayed latencies for Auditory Brain Stem Evoked Potentials[lxxix]; similar results had previously been reported for 7 year olds from Madeira, Portugal[lxxx]. At 14 years old, over 80% of the Faroes children were again tested. Indicators of prenatal methylmercury exposure were significantly associated with deficits in finger tapping speed, reaction time on a continued performance task, and cued naming. Mercury-associated deficits did not change between the two examinations; methylmercury exposure was significantly associated with deficits in motor, attention, and verbal tests. The results for electrophysiological measures showed similar delays to those observed at 7 years[lxxxi].

On the other hand, until recently, the birth cohort studies carried out in the Seychelles, consistently have shown no association between prenatal mercury exposure and neuro-outcomes (for review see: Davidson et al, 2006[lxxxii]). A total of 779 newborns, exposed to mercury through maternal fish consumption, were enrolled in this study in 1989-90. Prenatal exposure was measured in maternal hair and recent postnatal exposure in the child's hair. The cohort was examined six times over 11 years using extensive developmental test batteries and only one adverse association was observed at 9 years on a test of fine dexterity, speed and coordination[lxxxiii], while at 66 months, prenatal mercury was associated with improved performance on a language scale, but this was not observed at older ages. Further analyses of the data from the fine dexterity test suggest that the relation between prenatal exposure and this motor performance may be non-

linear, with no effect until exposures were relatively high (maternal hair mercury above 10-12 μg/g)[lxxxiv]. The authors suggest that there may be delayed toxicity and continue to follow-up these children. Further analyses of the 9-year old data[lxxxv] showed that motor proficiency and activity level improved significantly with increasing mercury for 53% of the children who had an average home environment. However, motor proficiency significantly decreased with increasing prenatal exposure in 7% of the children whose home environment was below average. This analysis suggests that effects may be non-homogeneous. This may be similar to what has been shown for lead exposure, where children with lower socio-economic status present deficits in intellectual functioning at lower exposures than children from families with medium or high economic status. These findings suggest that factors often associated with a poorer home environment, such as poorer nutrition and less parental stimulation, may increase vulnerability to toxics[lxxxvi, lxxxvii].

Because of the importance of the nutritional input from fish consumption, in 2001, the researchers in the Seychelles study initiated another birth cohort study, where they examined the maternal nutritional status by measuring a series of indicators including the omega-3 fatty acid, docosahexaenoic acid (DHA)[lxxxviii,lxxxix]. Mothers were enrolled at 14-24 weeks of pregnancy and evaluations took place at 5, 9, 25 and 30 months of age. A total of 229 children completed the 30-month examination. Results from this study showed that when examined separately from nutritional intake, there was, as in previous studies, no relation between mercury exposure and children's performance on the Bayley Scales of Infant Development. However, when both mercury and nutritional intake were taken into account in the analyses, mercury was significantly and negatively related to the Psychomotor Development Index.

More recent cohort studies have similar findings. The risks from mercury exposure and the benefits from fish consumption on infant development were likewise examined in the United States[xc] for 135 mother-infant pairs. The investigators assessed maternal fish intake during pregnancy and maternal hair mercury at delivery with respect to a visual recognition memory test given at 6 months of age. Higher fish intake was associated with

higher infant cognition, but an increase in mercury was associated with lower cognition. In another study[xci], this research group examined 3 year olds who had been enrolled in a birth cohort study of 341 mother-child pairs in Massachusetts. Children's performance was assessed on a picture vocabulary test and a test of a wide range of visual motor abilities. For both these tests, higher fish intake during pregnancy was associated with better child cognitive test performance, and higher mercury levels with poorer test scores. It should be noted that mercury exposure in these groups was particularly low.

While most of the studies on children have examined fetal exposure, the Seychelles study recently published their results with respect to post-natal exposure[xcii]. Although there were some relations between mercury exposure and neurobehavioral performance, the authors conclude that the results were not consistent. In the Amazon region, where freshwater fish are a dietary mainstay, there have been two studies of children. In French Guiana, 156 indigenous children living downstream of gold mines were examined[xciii]. The authors report a dose-dependent association between maternal hair mercury level and increased deep tendon reflexes, poorer coordination of the legs, and decreased performance on a test of visuo-spatial organization. In a region of the Brazilian Amazon, where mercury contamination of the aquatic food chain is from deforestation and subsequent soil erosion, Grandjean and his coworkers[xciv] reported poorer performances on tests of motor function, attention, and visuo-spatial associated with mother's hair-mercury concentrations at the time of testing.

Electrophysiological measures made on 102 Inuit children, with exposure to both Hg and PCBs showed changes in visual evoked potentials; the association with blood mercury levels at the time of testing was much stronger than with fetal exposure measured in cord blood[xcv].

In summary, our knowledge on the developmental effects of mercury following fetal exposure has increased substantially since the tragedy of Minamata where mothers with high mercury exposure gave birth to children with a debilitating, progressive neurological disorder, Fetal Minamata Syndrome, although they themselves were asymptomatic.

Today there is a wide consensus that at even at low levels of mercury, mercury can affect children's intellectual and motor development, which is not immediately obvious in children examined individually, but can be observed in population studies. This is important for society because the reduction of an average of 5 points of the IQ scale means that there are twice as many children with learning difficulties and half as many children "high performers"[xcvi]. Recent studies also reveal that there are nutritional elements in some fish that can offset the effects of mercury, notably omega-3 fatty acids and possibly other nutrients. Current studies are focusing on these factors.

1.3.2 Effects of mercury exposure on the adult nervous system

Neurological effects caused by high dose of Hg occupational exposure were discussed in Section 1.2. There are very few reports on chronic effects of exposure to Hg vapor. Heyer et al[xcvii] reported low dose exposure to elemental mercury among 230 female dental assistants associated with increased self-reported neurological symptoms and mood. The brain-derived neurotrophic factor (BDNF) polymorphism was also associated with increased symptom and mood scores. Moreover, the combined effects of Hg exposure and BDNF polymorphism were additive. No association was found among the 193 male dentists in the same study. More recently[xcviii], the same group reported no association between Hg exposure and symptoms among 183 male dentists and 213 female dental assistants in a follow up study.

Similarly, relatively few studies have been carried out on the neurotoxic effects of low level exposure to methylmercury in adults. As indicated above, the adult victims of mercury poisoning in Minamata and Iraq suffered from a severe neurological disorder with marked distal sensory disturbances, constriction of visual fields, ataxia (loss of coordination), dysarthria (motor speech disturbance), auditory disturbances, and tremor [xcix]. More recently, studies were carried out of persons over 40 who had lived in the mercury-polluted areas surrounding the city of Minamata[c]. Annual medical examinations, performed on about 1,500 persons, showed no difference in the prevalence of disease between those from the polluted area and those from other areas, although those from the

polluted area had more complaints of poor health. Persons with a history of compensated Minamata Disease scored significantly lower on a scale of activities of daily life[ci]. Other studies of persons from a nearby polluted area, who had been exposed to lower doses of mercury over a twenty year period, still suffered from distal paresthesia of the extremities and lips 30 years after cessation of exposure[cii].

The effects of mercury on nervous system function have been examined in fish-eaters in different parts of the world. In the Brazilian Amazon, studies have shown motor, visual and cognitive deficits associated with increasing mercury exposure in communities who consume fresh-water fish almost daily[52,54,55]. A follow-up study was undertaken in the Brazilian Amazon subsequent to a campaign to encourage persons to eat more fish that didn't eat other fish. The findings showed that over a 5-year period, persons continued to eat the same amount of fish, but preferentially consumed non-predators. Their hair mercury concentrations diminished by almost 40% and re-testing of motor and visual functions showed that the former significantly improved while the latter continued to deteriorate in relation to previous exposures (article in preparation). In this same region of the Brazilian Amazon, we recently completed a major study of 450 persons in the Brazilian Amazon that confirms a negative effect of mercury exposure on motor and visual functions (articles in preparation), but selenium (which is high in this region primarily due to the consumption of Brazil nuts[ciii] seems to offset some of the meurbehavioral effects of mercury, notably for motor functions (Lemire et al. article in preparation). In Italy, Carta et al.[120] examined 22 fishers who habitually eat tuna and noted loss of cognitive and motor functions associated with increasing blood organic mercury.

In an urban adult population, a cross-sectional study found no effects between mercury levels in blood on neurobehavioural tests in 474 randomly selected participants in the Baltimore Memory Study, a longitudinal study of cognitive decline involving 1140 Baltimore residents aged 50 to 70 years[civ]. The median blood mercury level was very low at 2.1 microg/L (range, 0-16 microg/L).

1.3.4. Fish consumption, mercury and mental health

To date there is no evidence that Hg exposure from fish consumption directly affects children's mood and behavior. In a recent Korean study of ADHD in relation to blood lead and mercury, Ha and coworkers[cv] reported a positive association between attention deficit and hyperactivity disorders ADHD and blood lead, despite the fact that lead levels were very low, but no relation with blood mercury concentrations. Although there does not seem to be a direct effect of Hg on mood and behavior, the loss of cognitive and motor skills affects children's coping and learning skills for adulthood.

It has been suggested that omega-3 fatty acids and fish consumption may be protective for depression in adults and children[cvi,cvii], however results are inconsistent and few studies consider Hg exposure that may come from fish consumption. In a study of neuropsychiatric symptoms in Quebec fresh-water fish eaters, Philibert et al[cviii] reported a positive association between hair Hg concentrations and symptoms. In men, there was a positive association between omega-3 fatty acids and neuropsychiatric symptoms, particularly on the scales of depression and interpersonal sensitivity; further analyses showed that this relation was strongest among those with higher alcohol intake, suggesting that there may be an interaction between omega-3 and alcohol. On the other hand, in women, there was no association between omega-3 fatty acids and neuropsychiatric symptoms, but there was a positive between hair mercury and scores on the scales for obsessive compulsiveness, interpersonal sensitivity, depression, anxiety, and psychotism, as well as the General Stress Index. Gender differences with respect to omega-3 fatty acids have also been reported by others; one population-based study reports a protective effect of omega-3 fatty acids on depression was observed for men, but not for women[106].

1.4 Evidence that mercury accelerates the development of chronic diseases

1.4.1 Cardiovascular disease

There is growing evidence that fish consumption is protective for cardiovascular disease[cix]. However, mercury exposure may offset some of the benefits. The evidence for causal association of mercury with cardiovascular events has been reviewed by Chan and Egeland[cx] and by Stern[cxi]. The strongest evidence is for acute myocardial infarction (AMI) in adult men. A cohort of men from eastern Finland [cxii,cxiii,cxiv] and a case-control study of men with a first diagnosed myocardial infarction from a European and Israeli multicenter study[cxv] found significant associations between biomarkers of MeHg exposure and acute myocardial infarction (AMI). The relative risk and odds ratios for AMI from these studies showed a doubling in the upper range of exposures and suggest that dietary mercury exposure at levels found relatively commonly in western populations can result in a significantly elevated risk of AMI. In the study by Guallar et al [102], both the positive effects of DHA and the negative effects of mercury were evident.

Other studies have not observed a relation between bioindicators of mercury and coronary heart disease. In a prospective Swedish study of 1462 women, who were 38 to 60 years of age at baseline examination (1968–1969), baseline total serum Hg concentrations were not related to an increased risk of MI, stroke, and many other outcomes within a 20-year follow-up period[cxvi]. In another Swedish study[cxvii], where a new cases of myocardial infarction among persons participating in a very large cohort study, both fatty acids and mercury (measured in erythrocytes) were associated with a lower incidence of myocardial infarction. In this study, men and women were not studied separately and there were many more men (n = 60), compared to women (n = 16). The authors suggest that both of these are indicators of fish consumption; the average mercury concentrations in this cohort were very low. In a cohort of U.S. professionals, no association was observed between mercury exposure and coronary heart disease[cxviii]. It should be noted that in that study, dentists accounted for 63% of controls and had Hg exposure more than twice that of the other groups in the cohort. Presumably, the dentists' exposures were influenced by occupational exposure to elemental mercury from amalgams. A mortality study of Finnish fishermen and their wives showed that they had a reduced rate for many causes, including ischaemic heart diseases[cxix].

The conflicting findings may indicate that high mercury intake may have an effect on cardiovascular health but that the consequences of exposure may vary among populations owing to various modifying factors.[97]

Other cardiovascular endpoints have likewise been examined with respect to mercury exposure, these include hypertension and R-R variability (a measure of function of the autonomic nervous system that innervates the heart). Sorensen et al.[cxx] found an association between gestational exposure to mercury and increased systolic and diastolic blood pressure in the Faroese children at 7 years old and. This association was strongest for those children with decreased birth weight. However, the association did not persist when the cohort was re-examined at 14 years old[cxxi]. Studies of mercury exposure in adults have reported inconsistent associations between blood or hair Hg and blood pressure[cxxii,cxxiii], while a recent study in non-indigenous communities in the Brazilian Amazon indicates a positive relation between hair Hg and blood pressure[cxxiv]. In a recent study of 42 Faroese whaling men, mercury exposure was associated with blood pressure and carotid intima-media thickness[cxxv].

Decreased heart rate variability was observed in the Faroes children's cohort, and appears to result from gestational exposure to MeHg [107]. This effect persisted through 14 years of age. The health significance of this finding, however, is unclear. Decreased heart rate variability is observed in adults following myocardial infarction and is predictive of sudden cardiac death, but there does not appear to be evidence suggesting that decreased heart rate variability, in isolation, in children is either *per se* adverse, or predicative of an adverse outcome.

1.4.2 Other conditions and/or illnesses

There is no evidence of elevated diabetes associated with Hg exposure, although there is a growing literature on increased risk for diabetes in relation to organochlorine pollutants such as PCBs and DDT[cxxvi]. In a recent study that we carried out in collaboration with a Candian First Nation community and Health Canada, we observed an increased risk for

diabetes with certain PCB congeners and DDE (a metabolite of DDT). Consumption of trout and white, but not walleye and pike, were protective for diabetes (submitted for publication).

Animal studies have shown that mercury exposure can affect thyroid function[cxxvii]. In humans, few studies have examined this relation. In a study that we carried out with fresh-water fish-eaters from Quebec, we observed an increase in serum thyroid stimulating hormone (TSH) with hair and blood Hg concentrations in men, but not in women[cxxviii]. The long-term consequences of these changes are not known.

In a recent study of fish-eaters in the Brazilian Amazon, we observed a cataractogenic effect of mercury exposure (Lemire et al, submitted). The prevalence of age-related cataracts increased with increasing mercury exposure. This relation was not present for those with elevated plasma selenium, suggesting that selenium can offset this effect of mercury.

Like for diabetes, no evidence has been found for an association between mercury exposure and arthritis.

There is a clear need for more studies on the effects of mercury with age. In non-human primate studies, visual deficits, that had not been present in the monkeys when they were young, developed with age, in relation to prenatal exposure to Hg[cxxix,cxxx].

2. **Any evidence of an interactive effect of mercury and other contaminants on human health**

Fish tend to accumulate halogenated organics including PCBs, dioxins and related compounds. The neurodevelopmental effects of PCBs and, to a lesser extent, dioxins, share some similarities to those observed for MeHg[cxxxi]. This can potentially present difficulties in determining causality and in constructing MeHg-specific dose-response relationships. Because MeHg tends to associate more with proteins than fats, fish species

with elevated levels of MeHg are not necessarily those with elevated levels of the lipophilic halogenated organics. Thus, for fish consumption where both exposures occur, the influence of the individual contaminants can potentially be separated by statistical techniques if a variety of fish species is consumed and sufficiently precise exposure metrics are collected. In the Faroe Islands studies, both MeHg and PCBs appear to jointly affect some developmental endpoints. However, while MeHg appeared to enhance the PCB-attributable effects, the PCBs appeared to make a relatively minor contribution to the MeHg-specific effects[cxxxii,cxxxiii]. Contradictory findings were observed in a study of cognitive development associated with exposures to MeHg and PCBs in the Lake Oswego area of New York State.[cxxxiv]. In that study, elevated PCB exposure appeared to potentiate MeHg effects. However, both MeHg and PCB levels were considerably lower than in the Faroes study, and no PCB-MeHg association was observed on follow-up testing of the cohort. As yet, the limited epidemiological and experimental data do not support that developmental PCB co-exposure markedly exacerbates MeHg toxicity. In some cases, a competitive rather than synergistic action of PCBs was demonstrated on endpoints related to MeHg neurotoxicity[cxxxv]. The latter finding cannot be considered a neuroprotective action of PCBs. The final outcome may be masked by neuronal compensation or plasticity in young individuals, but may be uncovered with age[cxxxvi]. Humans are exposed to complex mixtures of contaminants through food. This implies that pollutants other than the PCBs may concur to toxicity. PCBs themselves do not behave as a single chemical entity. Distinct congeners possess different intrinsic toxicity and neurotoxic potential. This should be kept in mind when analyzing the biomarkers data of PCB exposure. Indeed, the scant knowledge in this field calls for additional human and animal studies that address these unresolved issues, as well as other metal contaminants that may also be present in fish[cxxxvii].

Elemental Hg continues to be used in dental amalgam for the treatment of dental carries. In populations with significant amalgam use, elemental Hg may account for a proportion of total Hg exposure comparable to or greater than MeHg [cxxxviii]. It is known that elemental Hg vapor can cross the placenta and accumulate in fetal tissue[cxxxix,cxl,cxli] and animal data suggests that elemental Hg has the potential to cause adverse neurologic

developmental effects[cxlii]. Both elemental Hg and MeHg are metabolized in the brain to the inorganic mercuric form[92]. It is not known whether the ultimate neurodevelopmental toxicant of MeHg is MeHg itself, the inorganic mercuric ion, free radicals generated in the conversion to the inorganic species, or some combination of these. If the inorganic form is the ultimate toxicant of MeHg in the developing brain, or if MeHg and inorganic Hg share common neurodevelopmental toxic mechanisms, then current estimates of risk based on MeHg exposure alone could underestimate the population risk. Additional research is clearly needed to address these questions.

3. Methods of measuring past or present mercury exposure in humans.

Hair and blood Hg concentrations are both accepted as valid biomarkers of MeHg exposure, although each provides a somewhat different reflection of exposure[cxliii]. Blood gives an estimate of exposure over the most recent one to two half-lives with the half-life of MeHg in blood being 50-70 days, while hair reflects the average exposure over the growth period of the segment[cxliv]. Hair Hg is predominantly MeHg with MeHg constituting from 80% to 90-98% of hair total Hg [cxlv]. For populations with regular and frequent fish consumption, hair total Hg and blood MeHg are consistently correlated[cxlvi]. Generally, hair is 250 to 300 times more concentrated in mercury than is blood[cxlvii]. However, in populations and individuals with infrequent fish consumption, or where bolus doses of MeHg occur, there can be considerable inter- and intraindividual variability in the relationship between hair and blood Hg levels resulting from temporal differences in the retention of Hg by each biomarker[128,cxlviii]. Segmental analyses of hair Hg can provide a chronology of exposure over time[101,102]. However, information on short term peaks in exposure is not well represented by such analyses[97]. Another consideration is that the growth rate of hair, generally estimated at 1 cm per month, can have both inter- and intra-individual variability[119]. Recent advances in a single hair strand analysis[cxlix], including measurement of Hg at micron resolution using laser ablation[cl] should yield more information on the relationship between Hg uptake and Hg deposition in hair.

Hg levels in toe and fingernails have also been used as biomarkers of Hg exposure, mostly in major studies of the cardiovascular effect of MeHg[cli,clii], but to what extent these reflect organic or inorganic Hg exposures remains to be clarified[cliii]. A recent study of women, with no history of occupational exposure to Hg, showed similar correlations between Hg intake through fish consumption and both toenail and hair Hg concentrations, however only total Hg was assessed[cliv]. In this study, hair, toenail and urinary total Hg were highly correlated. Urinary Hg levels largely reflect exposure to inorganic Hg[100] and are not considered useful bioindicators of MeHg exposure. There are, however, several recent reports of positive correlations between fish consumption and urinary Hg[clv,clvi,clvii] authors of these studies propose that demethylation may account, at least partially, for this observation. The relation of fish consumption and inorganic Hg in different biological tissues, and its consequence for human health still need to be elucidated.

Health effects from low to moderate levels of MeHg exposure have been reported in a variety of systems and domains. Each of these effects may depend on different aspects of exposure (e.g. fish-eating patterns, time of exposure (first, second or third trimester, childhood, adulthood)). Therefore, the different reflections of exposure provided by hair and blood Hg concentrations may provide different information about dose-response for different exposure populations and different exposure scenarios. Few studies have investigated side-by-side dose-response relationships for both biomarkers. In the study in the Faroe Islands, maternal hair and fetal cord blood predicted similar, but not identical patterns of effect across various measures of neurologic performance.[119]

5. Concluding Remarks

Many of the high dose exposure occurred decades ago. It is increasingly difficult to re-establish the dose-response relationship among the exposed population. Moreover, many of the health complains from the affected population have not been properly diagnosed and documented. It is important to have data from comprehensive health surveys in

affected areas to have a better understanding of the health effects. Meanwhile, the issue of mercury poisoning is a global concern. Burning of fossil fuel is the main source of Hg pollution in the atmosphere[clviii] and recent modeling study showed that Hg deposition in the Pacific Ocean would double relative to circa 1995 by 2050[clix]. Fish is an invaluable resources in many countries and about 20% of the world's population derives one-fifth of its animal protein from fish[clx] and it is an important component of traditional food among Aboriginal Peoples in Canada[clxi]. It is our hope that the recent increase of scientific research can generate results that can be used effectively in promoting healthy diet and good health.

7. "Long-term study on the effects of mercury contamination on two indigenous communities in Canada (1975-2004)" by Masazumi Harada et al. Translation by Tadashi Orui, proofread by Thor Aitkenhead.

The seven documents contain information on 3 studies conducted by a team of Japanese researchers led by Dr. M. Harada:

1. Results of neurological examinations conducted on 89 inhabitants of Grassy Narrows and White Dog in March and August of 1975 and 71 hair samples were collected for mercury analysis.
2. Results of neurological examinations conducted on 57 inhabitants of Grassy Narrows in August/September 2002 and 47 hair samples were collected for mercury analysis.
3. Results of clinical examinations including tests on sensation, fingertip movement and sociological research conducted on 87 residents from Grassy Narrows and 69 residents from White Dog.

Dr. M. Harada has 29 publications on mercury poisoning as cited in PubMed with the first one published in 1964. His team of researchers are affiliated with departments of Neuropsychiatry, Psychology and Environmental Medicine at various institutions in Japan. Most of them are from Kumamoto, the Prefecture where Minamata disease occurred. The authors have clinical experience on diagnosing neurological symptoms associated with mercury exposure and recently published (2008-2010) 5 papers on observations from follow up studies on Minamata residences in the journal Epidemiology, Environmental Research and Science of the Total Environment. However, only 1 of the 7 documents supplied reporting results from the studies in Canada was published in an international journal, Bulletin of Environmental Contamination and Toxicology which has a very low impact factor of 0.609 (2008).

Harada et al, 1977. Mercury contamination in human hair at Indian reserves in Canada; Kuamoto Med. J. 30:57-64

This article reports some of the aspects of the study that was performed in 1975. A total of 89 persons from the Grassy Narrows and White Dog Reserves were examined for signs and symptoms of Minamata Disease and 71 hair samples were analysed for mercury.

The presentation of the results for hair sampling would not be accepted by today's standards, but the information presented was important. They show that hair mercury concentrations were high and related to fish consumption patterns based on answers from an interview question of the participants "do eat fish during summer" versus "not eating fish since 1970". Sequential hair mercury analyses revealed that in summer when fish consumption increased, there was a parallel increase in hair mercury.

Among the group that continued to eat fish following 1970: 23/71 (32.4%) had levels above 30 ppm, 20/71 (28.1%) had concentrations above 20 ppm (one assumes between 20 and 29 ppm), and one person had a maximum hair mercury level of 80.3 ppm. For those who had not continued to eat fish since 1970, levels were considerably lower and from Figure 2, one can see that most were below 10 ppm, although at times, this level was exceeded.

The authors indicate that no one presented all of the classical signs and symptoms of Minamata Disease, determined through examination of the Minamata victims, although many persons presented one or more classical signs of the disease. Since this was a clinical study and not an epidemiologic study, the authors based their diagnosis on the combination of clinical signs such as visual field constriction and 'glove an stocking' type sensory disturbance and high mercury levels. In addition, the authors describe what they refer to as a 'correlation' between characteristic signs of Minamata Disease and exposure; indeed there were more persons with

more and more severe signs and symptoms with higher levels of mercury, better confirming a possible causal relation. Results presented in Figure 3 of this paper is the only evidence available showing there is a relationship between body burden of mercury and neurological symptoms among inhabitants in the two First Nation communities. Although there is no true statistical analysis, the results are compelling.

Harada et al, 1976. Epidemiological and clinical study and historical background of mercury pollution on Indian Reservations in Northwestern Ontario, Canada. Bul. Inst. Constitut. Med. 26: 169-184.

In this article, the authors indicate that the situation is more serious than they previously believed. One learns in this article that of the 89 persons reported on above, 33 reported that they had reduced or stopped eating fish, while 14 replied that they continue to eat "just as much as before". They also indicated in this article that bread was being baked with fish roe and concentrations of 0.41 ppm were measured in bread, which was consumed more regularly than fish.

They report on the mercury concentrations in fish, indicating that they were very high and many largely surpassed government agency recommended levels. They also briefly describe the study that was preformed by Takeuchi on a cat from White Dog, where damage, characteristic of methylmercury poisoning, was observed primarily in the brain and to a lesser extent in the peripheral nerves. These results were consistent with studies that had been previously carried out by Health Canada with cats that had eaten fish from Clay Lake. They present a table that show similar concentrations of mercury in the various organs of the cat from White Dog to the cats from Minamata.

With respect to human exposure, they indicate that the Environmental Services Branch (of Health Canada?) had reported in 1970 maximum exposure concentrations of 198 ppm from White Dog and 95.7 ppm from Grassy Narrows. It is not clear how all of the numbers from the 1970 measurements fit together, except to say that exposure was very high. They indicate that in 1975, they measured hair samples (see above) and reproduce a table from the Environmental Health Services Branch that show declining concentrations. We do not know from this table whether it was the same people that were sampled over time and at what time of year the sampling was done since the Harada et al study had shown important seasonal variations, with the highest levels in the summer.

In this article they provide more detailed information on the 89 persons that were examined using the "same methods that were applied in our mass examination for Minamata Disease in Japan". Here we learn that that the age of those examined ranged from 6 – 84 years. It should be noted that sick persons, who were unable to work, were excluded from this study which only included persons who were healthy enough to work. Many worked as guides, but some had sought other work.

They present the results of the neurological signs and symptoms that are characteristic of Minamata Disease, indicating that these were immediately recognized. They describe the details of the results of the neurologic examination, with emphasis on constricted visual fields, eye movement disturbances, sensory disturbances (including 'glove and stocking' paresthesia),

tremor, changes in reflexes and other motor dysfunctions. They conclude that although they observed a fair number of signs of Minamata poisoning, these are mild cases and many may have been caused by other factors. For sensory deficits, they did however report a dose-effect relation (see above).

This was not an epidemiologic study, but a clinical study and no causal relation was established. No data are presented with respect to age, and we have no information in this article whether the persons who presented neurological signs of dysfunction were young or old. Nor do we have any information on other factors, such as diabetes that may affect certain neurological functions. There is also no mentioning of how the participants of the study was chosen and it is not possible to deduce the level of representativeness of the observations to other inhabitants in the 2 First Nation communities.

Harada, S. Harada Report, translated, titled : " Minamata Disease Report – an investigation into Mercury Contamination in the Indian Reserves – A Clinical Study" with advisory note re the translation, 1975 from the Ministry of Health, Ontario.

This translated article appears to be an earlier draft manuscript for the publications discussed above. Many of the tables and figures are the same. However, it provided some raw data such as observations on constriction of visual field of an individual participant and the clinical history of two participants who had 44 ppm and 33 ppm mercury in hair. Both of them worked as fishing guide. One participant showed symptoms of abnormal movement of the eyeball, adiadochokinesis, sensory disturbances in upper lip and the end of limbs, and weakening of muscular strength and the other showed symptoms of audio disturbances, subtle trembling, adiadochokinesis, sensory disturbances in the end of limbs.

Harada et al, 2005. Follow-up study of mercury pollution in indigenous tribe reservations in the province of Ontario, Canada 1975 – 2002. Bull. Environmental Contamination and Toxicology 74. 689-697.

In 2002, Dr. Harada's group went back to Grassy Narrows and examined 57 people, using the same neurological protocol as previously and as was used for Minamata patients in Japan. They also measured visual fields using Förester's perimetry.

Statistical analyses were minimal; they did not report any paired statistics, comparing those who had been examined twice or any multiple regressions that would take into account age or other factors.

No information is provided on the bases for recruitment.

They provide tables of symptoms and signs, and on the basis of clinical criteria for Minamata Disease, they classified the persons examined into 4 categories: those with Minamata Disease (11 persons); those with Minamata Disease with complications (12 persons); those with Light Minamata Disease (22 persons) and others (12 persons). Those with Minamata Disease were the older than those with milder forms, and the group 'others' included 8 children. They seem to indicate there were statistically more men than women in the more severe categories.

They indicate that the rate for Minamata Disease was 78.9%, but we have no idea what is the denominator. It may be 78.9% of this group of persons, most of whom had multiple subjective symptoms. Because there is no mention whether the samples were randomly selected, the results provide no information on whether the same percentage can be applied to other inhabitants in Grassy Narrows. In the discussion, the authors mention compensation and indicate that 21 of he persons examined here had received compensation, 20 were denied and a decision is pending for 3, while 13 did not file claims. Was this the basis for inclusion in the study? The compensation decisions appear to be related to age. The question of foetal mercury poisoning is not discussed.

The authors note that 43.2% of the 44 persons from Grassy Narrows that had been evaluated in 1975, had died, but do not provide any information on those that had been retested.

Harada, M,; Fujino, T.; Oorui, T.; Nakati, S.; Ohno, H.; Clincial Follow up Research of Mercury Intoxication in a Reserve (1975 – 2002) (Literal summary translation) Sources Unknown.

This unpublished report provided many of the critical information missing in the previous article. The same two doctors conducted the examination in both the 1975 and 2002 studies. Nine persons participated in both studies. Hair mercury concentration results presented in Chart 1 show that their mercury body burden has significantly decreased. All nine of them had hair mercury concentration higher than 6 ppm and the maximum concentration was 44.2 ppm in 1975. In 2002, 8 of them were below 6 ppm and only one individual had higher mercury concentration at 18.1 ppm (the same person had 13.1-36.3 ppm in 1975). However, the authors concluded that the nine people only showed mild symptoms in 1975 but seven of the nine people had progressed from mild symptoms to typical or typical with complications in 2002 even though their hair mercury body burden had decreased.

The average of all 47 hair samples collected was quite low at 2.11 ppm (minimum: 0.11 ppm and maximum 18.1 ppm). Based on the results of the repeated participants, the authors predicted that the other examinees in the mild Minamata Disease group will likely progress to Minamata Disease in the future. Without information on the age of the participants, it is not possible to comment on whether this prediction is valid.

"Long-term study on the effects of mercury contamination on two indigenous communities in Canada (1975-2004)" Masazumi Harada, Masanori Hanada, Takashi Miyakita, Tadashi Fujino, Kazuhito Tsuruta, Akira Fukuhara, Tadashi Orui, Shigeharu Nakachi, Chihito Araki, Masami Tajiri, Itsuka Nagano. Translation by Tadashi Orui, proofread by Thor Aitkenhead.

This is a translation of a review paper (source is unknown). It summarized the findings of Dr. Harada's research on the two communities since 1975 including results of the study conducted in 2004 which has not been reported before.

The authors classified participants as having Minamata Disease if they showed more than one symptom, such as sensory disturbances (specifically the loss of sensation in the extremities), ataxia, disturbed ocular movement, imbalance, concentric construction of the visual field (tunnel

vision) and speech impairment. However, in cases when the participants were showing only sensory disturbances, they also classified them as Minamata Disease as long as there was no other disease causing the symptom. If the participants had another disease and also showed symptoms of Minamata Disease (but were not explained by that other disease), they classified the case as Minamata Disease with complications. If Minamata Disease symptoms were observed in case when the participants also reported other complications or were suffering from unstable mental state, or symptoms were inconsistent, they classified them as possible Minamata Disease. If symptoms, caused by another disease, were observed or no symptoms stated above were observed, they either classified them as another disease or normal.

Using the criteria above, they reported 60 cases of Minamata Disease (34.2% of total participants, excluding people 10 years old and younger), 54 cases (30.8%) of Minamata disease with complications and 25 cases (14.2%) of possible Minamata Disease for a total of 139 cases (79.4%). The rest were other diseases or normal.

They also reported 7 cases of cerebral palsy, 7 cases of intellectual developmental delay among toddlers and children. The authors did not specify how they defined the age of children but they reported 12 participants between 1 to 10 years old and 12 participants between 11 to 20 years old. However, they did not relate the cases to mercury poisoning.

The authors also compared their diagnoses with the decisions made by the Mercury Disability Board (MDB). Among the 60 participants diagnosed with Minamata Disease, 21were acknowledged and 39 were not acknowledged by the MDB. Among the 54 participants diagnosed as Minamata disease with complications, 27 were acknowledged and 27 were not by the MDB. In total, the MDB acknowledged 38.1% of the people we diagnosed with Minamata Disease, Minamata Disease with complications and possible Minamata Disease. Among the 75 participants not acknowledged by the MDB, 28 were diagnosed to have Minamata disease, 21 were diagnosed to have Minamata disease with complications and 11 were diagnosed to have possible Minamata disease by the authors, with a total of 60 (80.0%). Most of them had mild Minamata disease with sensory disturbances or sensory disturbances and impaired hearing, or mental symptoms. It is clear that the criteria used by the MDB were relatively more stringent.

The most valuable information reported was the observations of the 27 individuals who participated in both studies in 1975 and the follow up study in 2004. Most of them had moderate elevated level of mercury exposure with hair concentrations ranging between 10 to 20 ppm and the highest at 44.2 ppm in 1975. However, the authors did not report the hair concentrations of these individuals in 2004 but we presumed they were lower as the mean of all the participants were 2.3 ppm with the maximum at 25 ppm. Comparing the symptoms of the 27 residents between 1975 and 2002-04, 2 cases of sensory disturbances (the loss of sensation in extremities and around the mouth) and 6 cases of only sensory disturbances (the loss of sensation in extremities) in 1975 increased to 6 cases and 13 cases respectively in 2002-04. Seven of them also indicated the loss of sensation in whole body (2 cases duplicated with the loss of sensation in extremities). Three of them did not have sensory disturbances. Those with ataxia increased from 2 to 16 cases, concentric constriction of the visual field increased from 3 to 4 cases, speech impairment increased from 3 to 8 cases, imbalance increased from 2 to 7 cases, tremor increased from 5 to 10 cases, walking difficulties increased from 0 to 6 cases and stroke (cerebral

infraction) increased from 0 to 4 cases. According to their diagnosis, 13 of them had Minamata Disease, 11 had Minamata Disease with complications for a total 24 (88.8%). For comparison, the MDB acknowledged 21 applicants (77.7%) out of 27 participants and is providing them a pension. The authors acknowledged the possible effects of aging and complications but the progression of Minamata Disease-like symptoms were evident.

Conclusions:

There is no doubt that there was high mercury exposure in these two communities in the late sixties and early seventies. Although not as high as those that had been observed in Minamata, the concentrations are certainly considerably higher than those reported in the many studies that have conducted since that time, and in which neurological and/or cardiovascular effects have been reported in adults and children.

There is no doubt that at these levels of exposure many persons were suffering from mercury-related neurologic disorders. Following the results of exposure and effects in 1975, as well as earlier mercury in blood monitoring study conducted by Health Canada since 1970, there should have been extensive examinations and follow-up of these communities from that time forward, and assistance with respect to health and nutrition.

Dr. Harada's follow-up study indicates that there is probably still a problem due to previous mercury exposure. This is consistent with findings from animal studies, where effects, which were absent when the animals were young, became evident as they aged[i,ii]. Similar latency period between exposure and neurological symptoms was also observed in humans (see Weiss et al. 2002) for review[iii]. Their study focussed only on neurological clinical outcomes when the scientific literature shows that neurobehavioral performance and cardiovascular functions can be affected through *in utero* and post-natal exposure.

The discrepancies between Dr. Harada's assessment and the MDB are due to different criteria used for evaluations. Similar discrepancies between Dr. Harada's team and the Japanese government are reported in Japan. However, the Japanese government is revising their definition of Minamata Disease victims to be more inclusive and a new round of compensation is expected to release in 2011 (Dr. Hikaru Kobayashi, Vice-Minister of the Environment Ministry of the Environment in Japan, personal communication, April 2010).

Even though the general populations in the two communities have almost background levels of mercury exposure as indicated by the hair mercury concentration. Some individuals may still have high exposure as shown by Dr. Harada's latest report that the maximum was 25 ppm. One of us (Chan) conducted a study with the two communities in 2003 and found similar low level of mercury in hair samples as reported by Dr. Harada in Grassy Narrows. However, higher levels (maximum at 60.3 ppm) were found in some individuals in White Dog suggesting that the problem of mercury exposure still persists in White Dog. Unfortunately, as stated in the latest report from Dr. Harada: "there is hardly a report with data of both hair mercury levels and clinical examinations, together, on each examinee, even in Canada".

We acknowledge Dr. Harada and his team for their effort that spans three decades of research. They have made significant contributions to the understanding of long-term effects of

mercury contamination and the health of the residents in the two communities. However, Dr. Harada's follow-up clinical evaluation should be seen as a preliminary study showing the need for a comprehensive epidemiologic study that would include all of the known outcomes of mercury exposure (including cardiovascular disease) and could take into account co-morbidity from other diseases, such as diabetes and /or alcohol and test for possible interactions. Such a study should also take into account the presence of other contaminants. For this study it would be most useful to have all of the results of hair and blood sampling by Health Canada, Dr. Chan and Dr. Harada, as well as the results of the neurological examinations that were done by Dr. Harada.

We also want to highlight the urgent need to improve the general health of the two communities as the health status of the participants was clearly poor. The rate of residents reporting neurological symptoms was very high for such as small population. There were many other reported diseases including 49 cases (28.0%) of high blood pressure, 42 cases (24.0%) of diabetes, 19 cases (10.8%) of heart disease, 13 cases (7.4%) of stroke, 7 cases (4%) of thyroid problems, 5 cases (2.8%) of Kennedy-Alter-Sung Syndrome (genetic diagnosis). In addition to those, dystrophy, an impaired spinal column in the cervical vertebrae, wounds such as broken bones, cancer, tuberculosis, sniffing, liver disease, kidney disease, Buerger's disease and sarcoidosis were seen. It is paramount that members of the two communities are receiving the necessary medical care and support. In contrast, residents in Minamata, Japan enjoy superb health care from neurologists and therapists even they had not officially been classified as victims of Minamata Disease.

Literature Review regarding the Impact of Mercury on Human Health

Summary of a text produced by Drs. Laurie Chan and Donna Mergler for the Mercury Disability Board

presented by
Donna Mergler PhD
Professor Emerita
University of Quebec at Montreal

Cinbiose – Centre d'etude des interactions biologiques entre la santé et l'environnement

PAHO-WHO Collaborating Center for the Prevention of Work and Environment related Illness

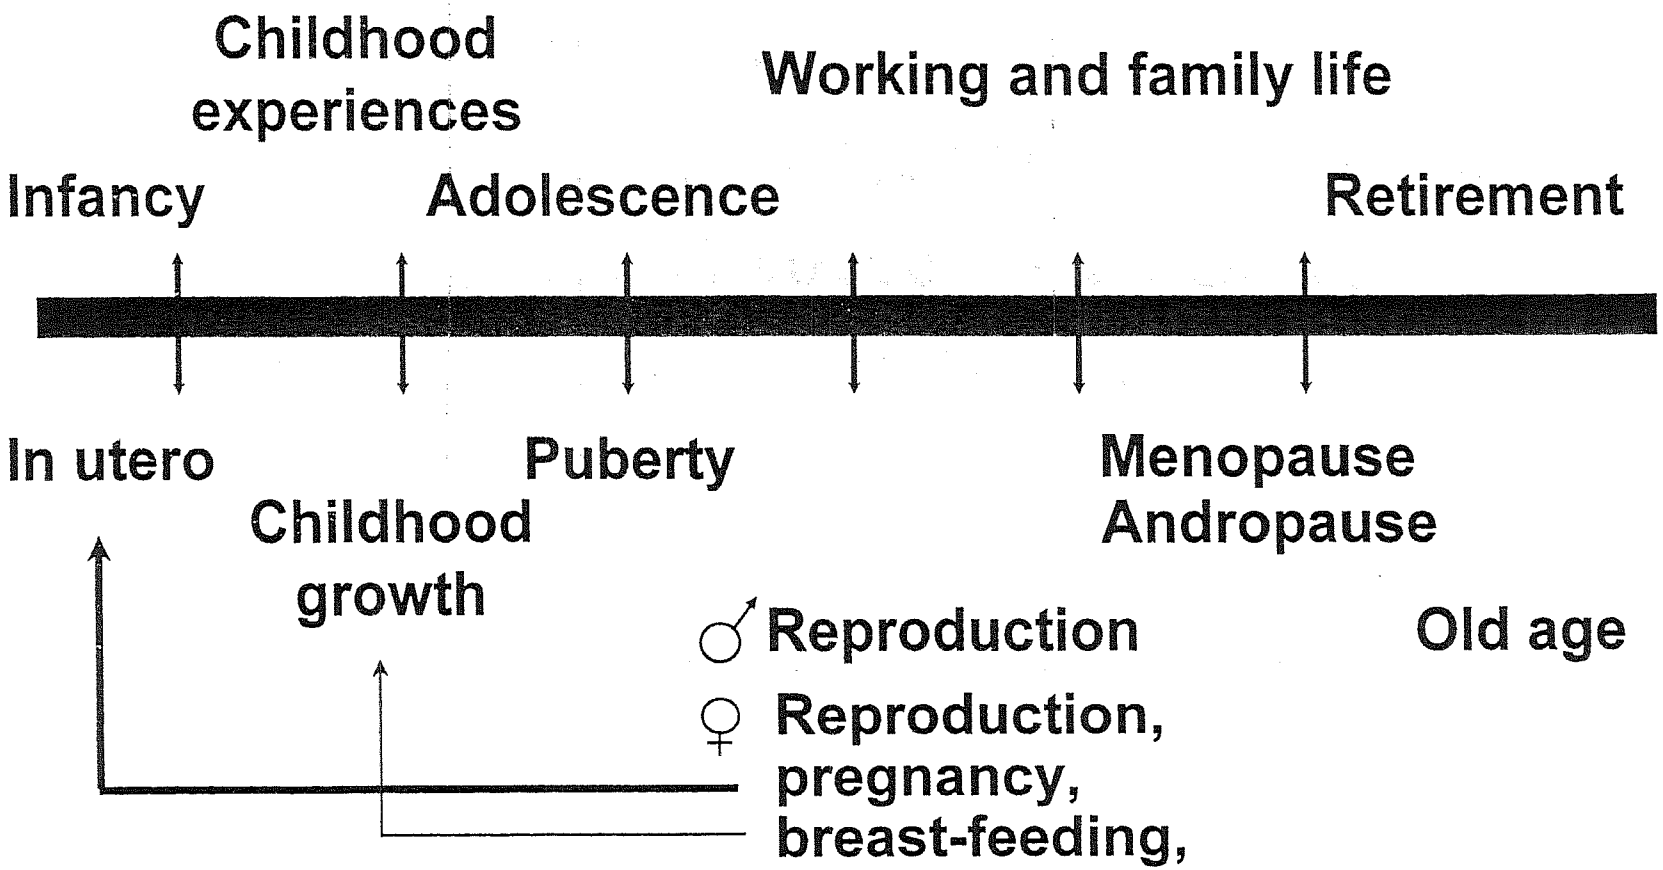
PAHO/WHO

Mandate

1. The effects of mercury contamination on human health, including the fetus particularly:
    - 1.1 Effect on human physiology over the life course including short- and long-term effects;
    - 1.2 Disability related to mercury;
    - 1.3 Mental health or behavioural effects of mercury including psychosis;
    - 1.4 Any evidence that mercury accelerates the development of chronic diseases related to the thyroid gland, arthritis, diabetes and the nervous system.
2. Any evidence of an interactive effect of mercury and other contaminants on human health.
3. Methods of measuring past or present mercury exposure in humans.
4. A review of Dr. Harada's work

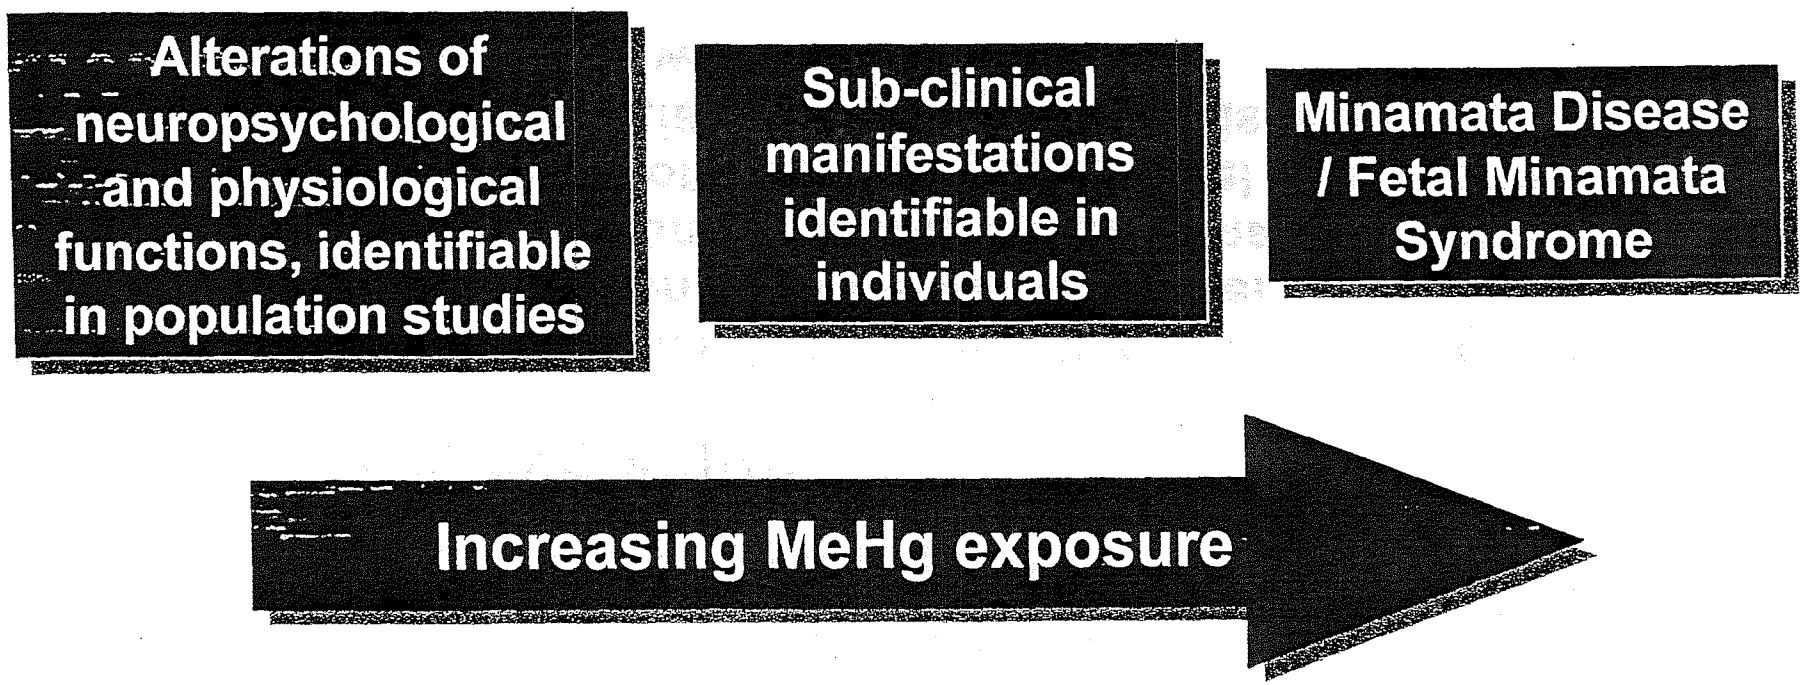
The Board intends to use the literature review to inform a process regarding the value of the current tools used in assessing eligibility for funding

Social and biological life span



Sinbiose
Centre d'étude des interactions biologiques entre la santé et l'environnement

A continuum of severity of effects with increasing exposure



Effects on human physiology throughout the lifespan

- *In utero* exposure:
  - **In Minamata, infants exposed to mercury through the mothers' placenta showed severe cerebral palsy-like symptoms, even when their mothers had mild or no manifestation of the poisoning: mental retardation, cerebellar ataxia, primitive reflexes, disarthria and hyperkinesias were observed.**
  - **At the sub-clinical and population level, several studies in different parts of the world, have reported poorer neurologic status and slower development in newborns, infants and/or children exposed *in utero* MeHg and/or during early childhood.**
  - **Some studies have shown both positive effects of fish consumption and negative effects of mercury**

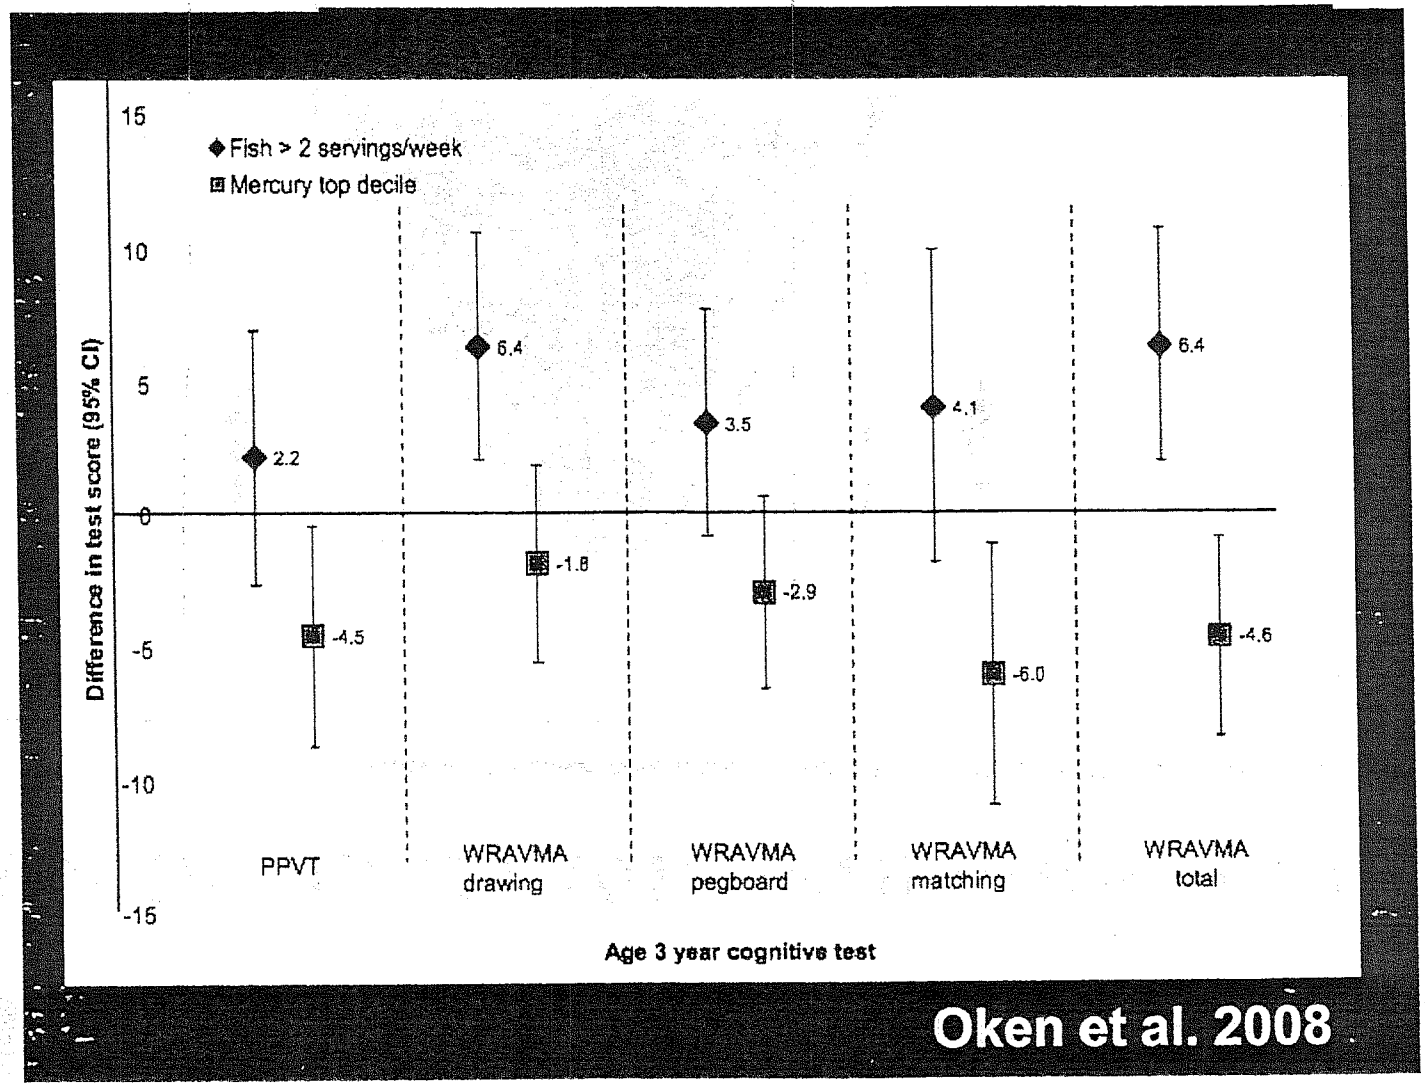
Opposing effects of Hg and fish consumption on neurobehavioral performance in 3 year olds

N = 341 mother/child pairs (Massachusetts)

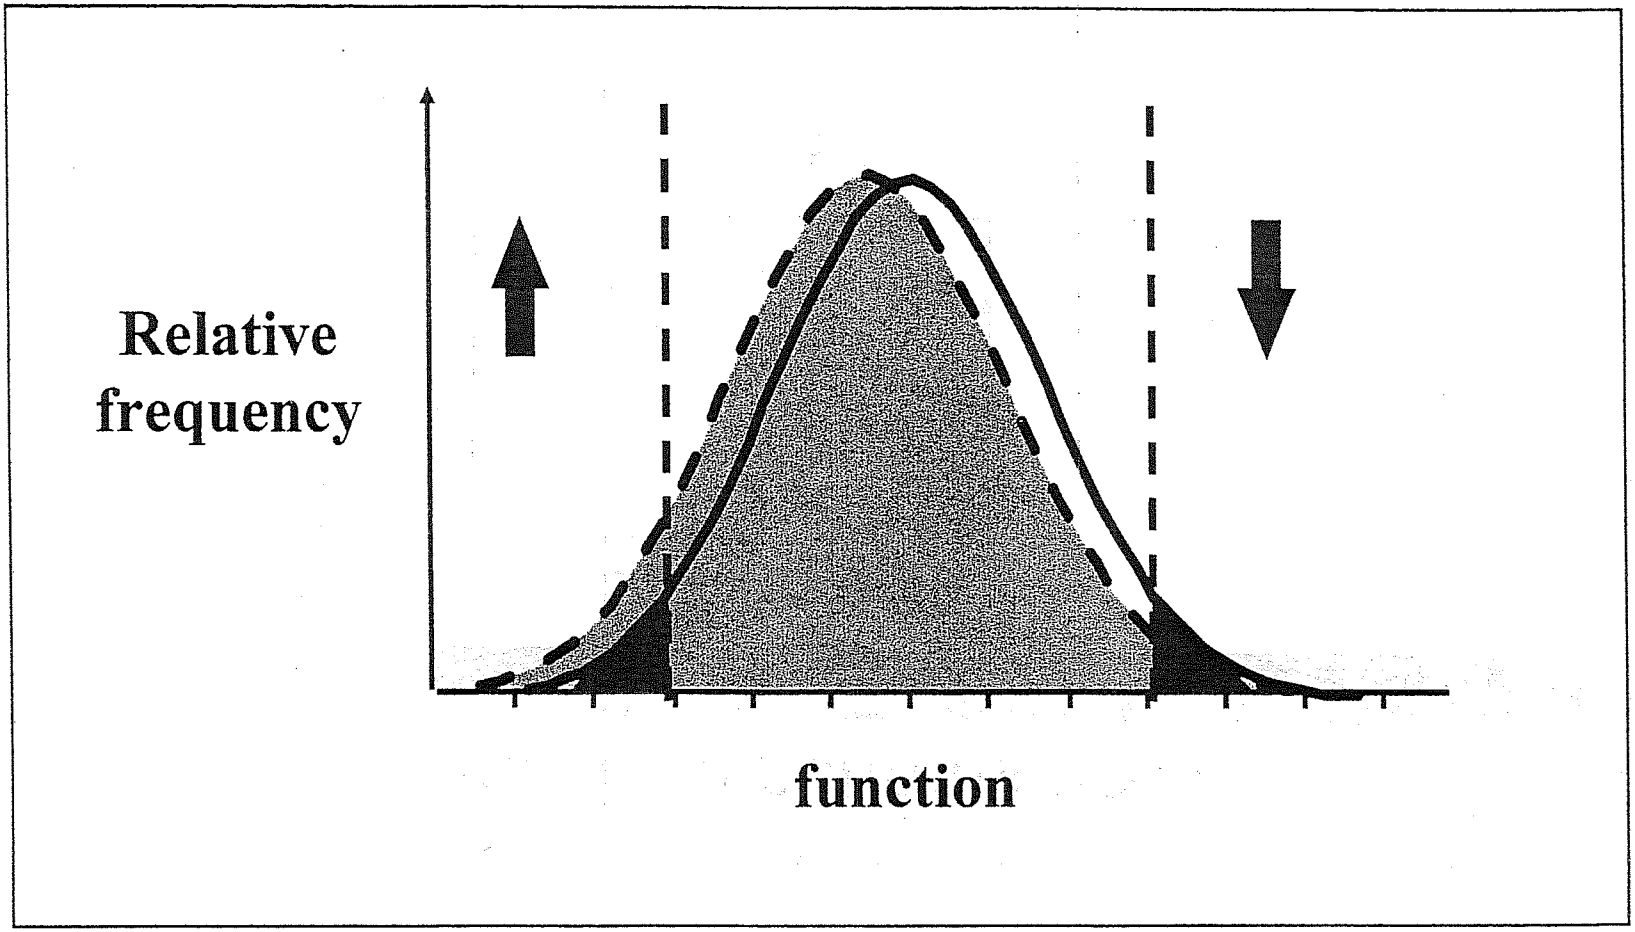
Mean maternal total fish intake :1.5 ± 1.4 servings/week

40 (12%) mothers consumed >2 servings/week

Mean maternal hair mercury level: 3.8 ng/g. Top decile >1.2µg/g



Why subtle alterations are important



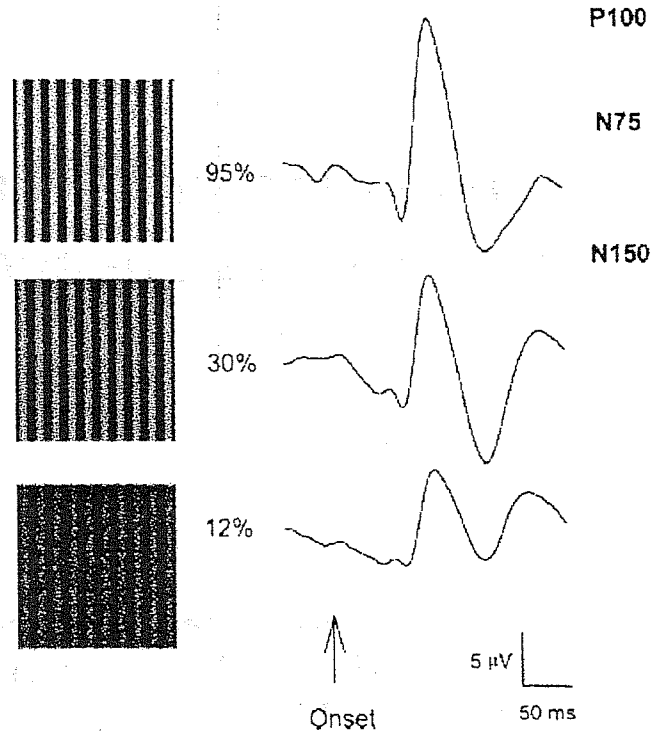
(adapted from Rice, 1998)

Effects on human physiology throughout the lifespan

- **Childhood exposure**
  - **Studies of children exposed to mercury through fish-consumption have shown cognitive and motor deficits.**
  - **Electrophysiological studies of children exposed in relation to mercury have shown changes in evoked potentials**

A study with Inuit children reported Hg-induced electrophysiological changes

- In Canadian Inuit children, prenatal and current Hg exposure were associated with changes in latencies for Visual Evoked Potentials



(St-Amour et al, 2006)

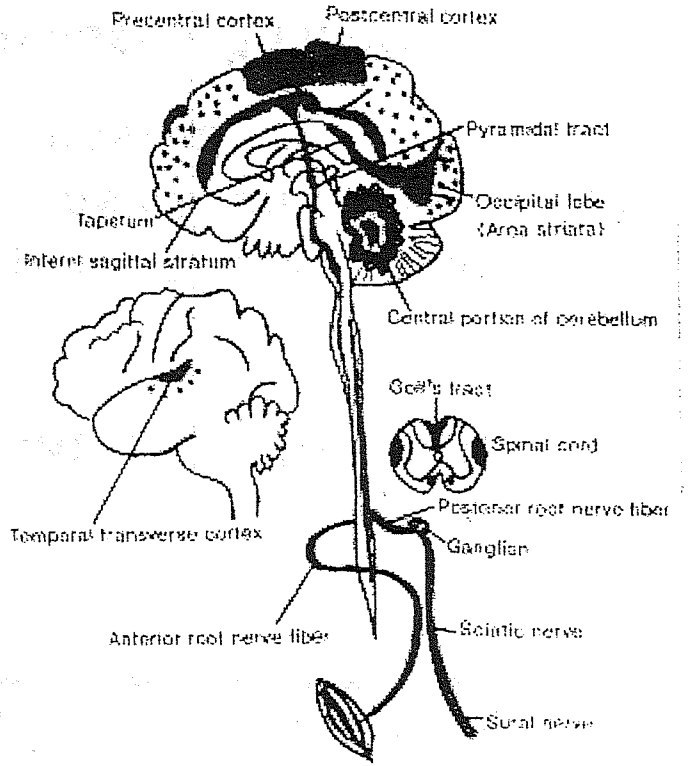
Effects on human physiology throughout the lifespan

- **Reversibility**
  - **In our studies with fish-eaters in the Brazilian Amazon:**
    - **Following reduction of exposure, motor functions improved but visual functions continued to decline in relation to past mercury exposure;**
    - **Age-related cataracts increased with mercury exposure**

Effects on human physiology throughout the lifespan

- Adult exposure
  - MD at very high exposures
  - Lower exposures have been associated with motor, cognitive and visual deficits
  - Inconsistent results at very low exposures



Red: primary lesions
Blue : secondary lesions
(from the Minamata Institute)

Effects on human physiology throughout the lifespan

- Aging and past mercury exposure
  - Studies carried out of persons over 40 who had lived in the mercury-polluted areas surrounding the city of Minamata. Annual medical examinations, performed on about 1,500 persons, showed no difference in the prevalence of disease between those from the polluted area and those from other areas, although those from the polluted area had more complaints of poor health.
  - Persons with a history of compensated Minamata Disease scored significantly lower on a scale of activities of daily life.
  - Other studies of persons from a nearby polluted area, who had been exposed to lower doses of mercury over a twenty year period, still suffered from distal paresthesia of the extremities and lips 30 years after cessation of exposure.

Cardiovascular system in adults

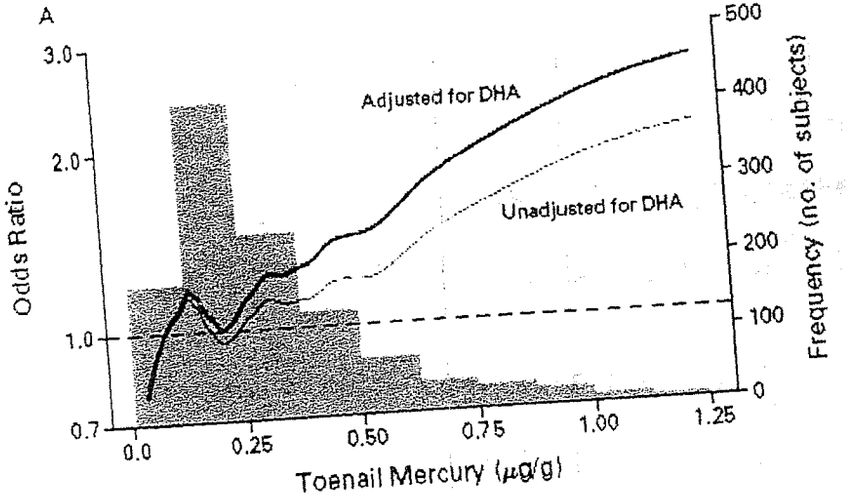
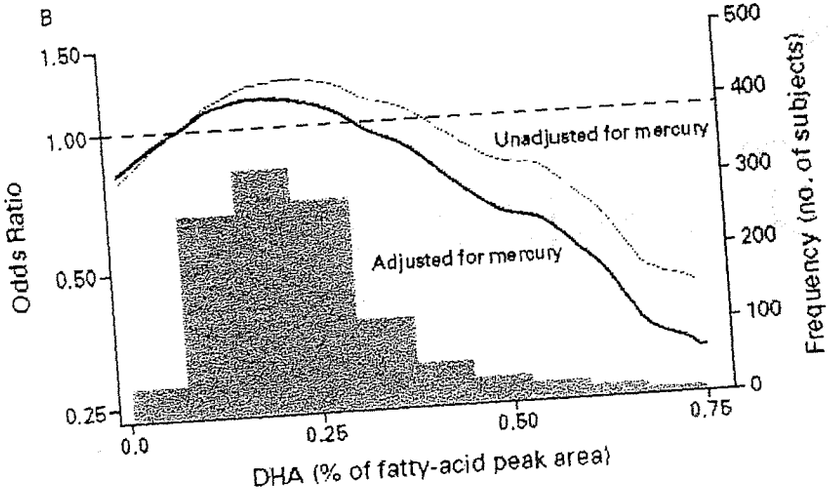
The Panel on Health Risks and Toxicological Effects of Methylmercury:
Donna Mergler, Henry A. Anderson, Laurie Hing Man Chan, Kathryn R. Mahaffey, Michael Murray, Mineshi Sakamoto and Alan H. Stern

Methylmercury Exposure and Health Effects in Humans: A Worldwide Concern





Case control study of 684 men with a first diagnosis of myocardial infarction and 724 controls

(Guallar et al, 2002)

Cardiovascular function

- Blood Hg was associated with changes in heart rate variability (HRV) and increased systolic pressure in Canadian Inuit men and women (Valera et al, 2008)
- In Faroese whalers, Hg exposure was associated with increased blood pressure and common carotid intima-media thickness, but HRV was equivocal (Choi et al, 2009)

Systolic Blood Pressure in a Canadian Inuit Population (n =731)

	Beta estimate	p
Blood Hg (log)	+1.27	0.05
Serum %EPA	- 1.75	0.05
Blood Se	- 2.80	0.03
Blood Hg (log)	+2.14	0.0004

- EPA and Hg did NOT modify the relation between blood Hg and blood pressure (interaction term not significant)
- Not adjusting for these elements could underestimate effect size

Valera et al . 2009

Study of Dr. Harada's team

- Returned to the population-based study of 1971.
- Compared hypertension in exposed group from Minamata (n= 833) with control group (n=755) for the exposed group in relation to hair mercury from 1960
- Prevalence Odd's ratios for the Minamata population compared to controls :
  - Past history of hypertension: 1.6 [95%CI:1.2–2.1]
  - Measured hypertension: 1.4 [95% CI: 1.1–1.9],
- The authors conclude a causal relation

(Yorifuji et al, 2010)

Other physiological effects

- There is some evidence for effects of mercury on thyroid hormones, but more research needs to be done before this is confirmed
- There is some evidence for effects of mercury on mood states, but more research needs to be done before this is confirmed
- Although some studies suggest that mercury and other pollutants (such as PCBs) may act through different pathways, PCBs have also been shown to be neurotoxic and there is growing evidence linking PCBs with a higher prevalence of Type 2 Diabetes

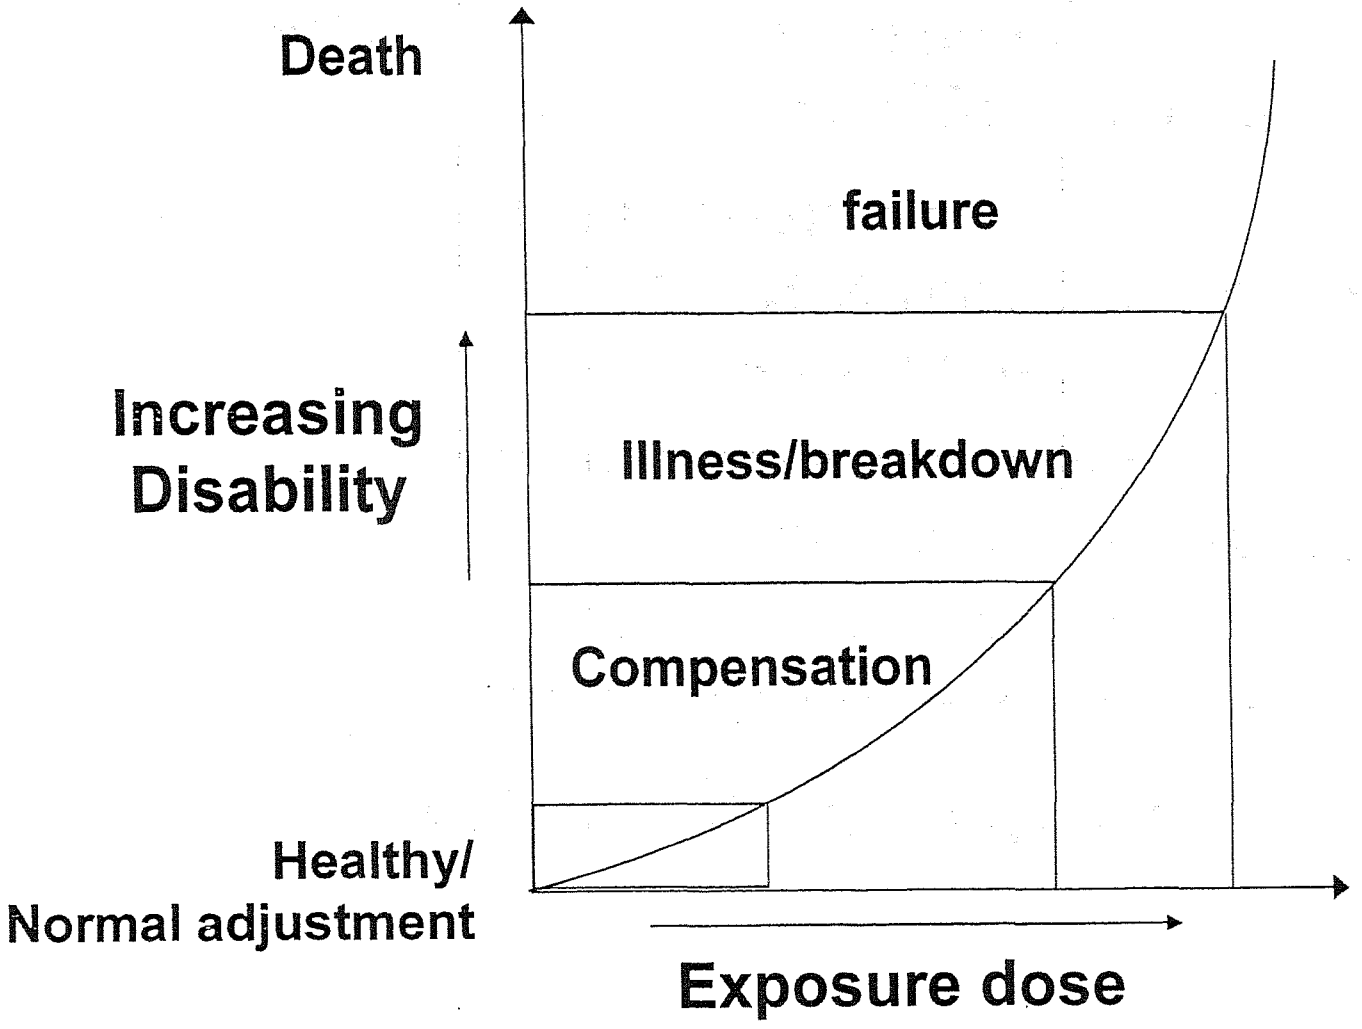
Exposure & Disability



(Hatch, 1962)

Minamata Disease (MD)

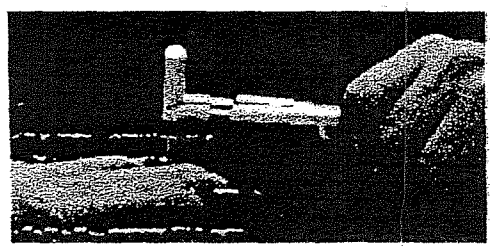
- Sentinal neurologic signs of MD
  - distal sensory disturbances (glove & stocking)
  - constriction of visual fields
  - ataxia (loss of coordination)
  - dysarthria (motor speech disturbance)
  - auditory disturbances
  - tremor

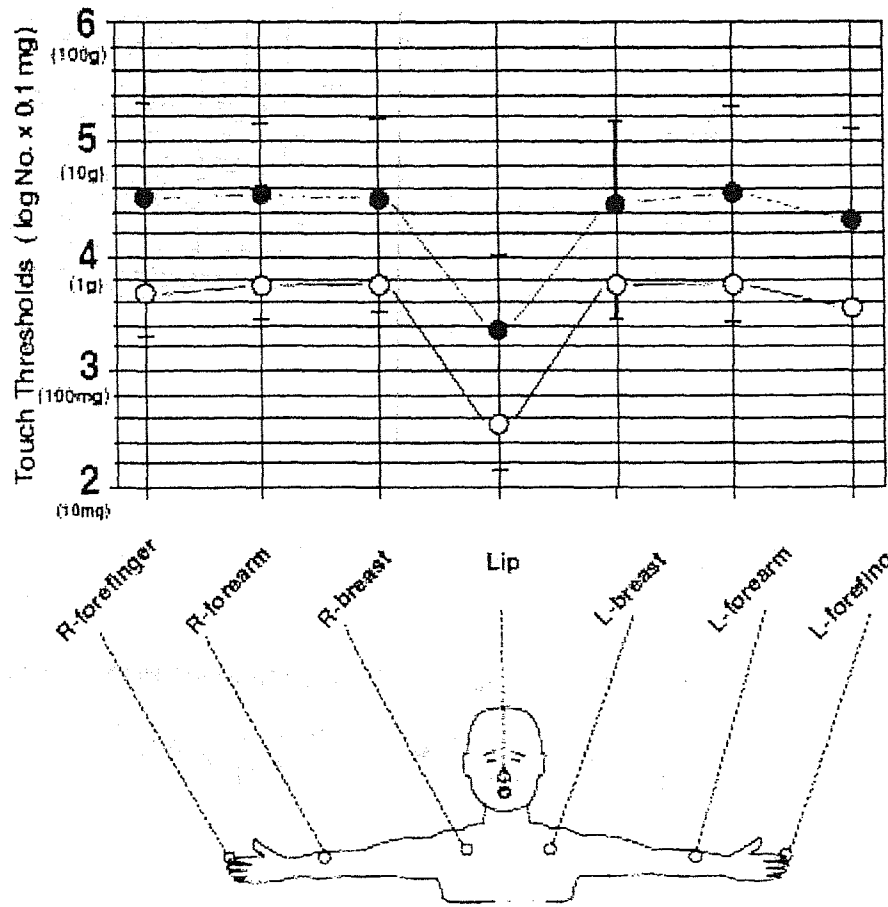
Sensory Testing

- The Minamata Disease diagnosis includes glove and stocking sensory loss, which reflects damage to the peripheral sensory nerves
- In 2001, Uchino et al, wrote about the 2 different theories on MD sensory loss:
  - *"..it is derived from lesions in the peripheral nerves based on clinical observation that most patients present so-called "glove and stocking" like sensory disturbances based on clinical observations"*
  - *"..sensory disturbances are caused by lesions in the sensory cortex based on pathological and electrophysiological findings"*

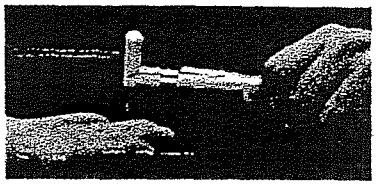
Sensory testing

Touch threshold

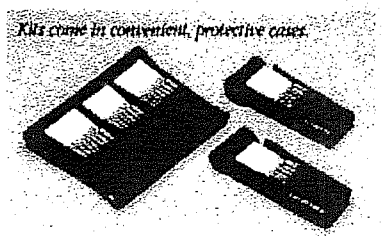




(Ninomiya et al, 2005)



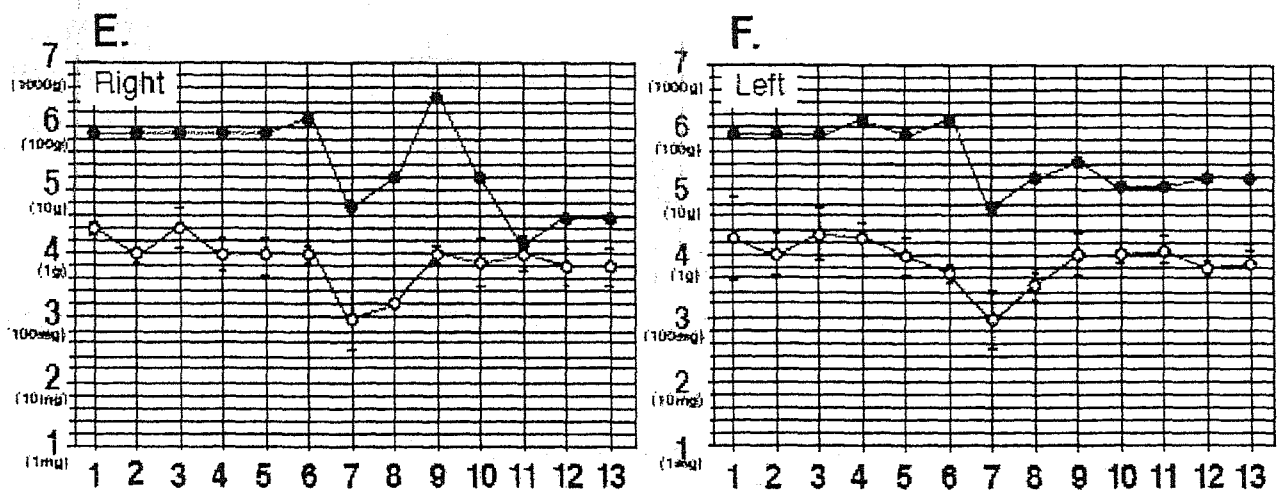
Sensory testing



Touch threshold : Minamata patient

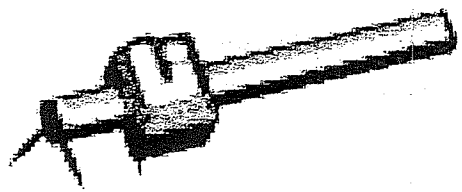
Case 3

Control group
(n= 53)

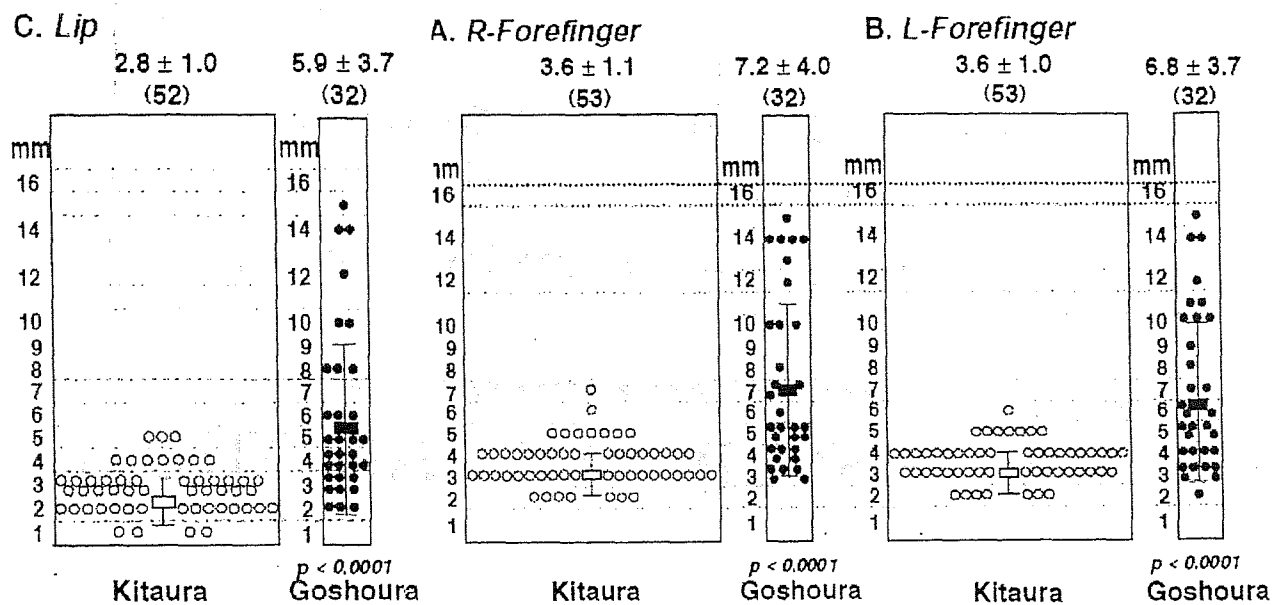


(Ninomiya et al, 2005)

Sensory testing



Two-point discrimination



(Ninomiya et al, 2005)

A recent study on sensory loss

- 197 residents from Minamata with a history of fish consumption during the period of high pollution, compared to 214 controls from non-polluted area.
- Persons from Minamata:
  - Most had never applied for certification for MD
  - Divided into 2 groups:
    - E+N : exposed with complications: diabetes mellitus; cervical spondylosis; lumbar radiculopathy; carpal tunnel disturbance; cerebrovascular disease; and other
    - E: exposed with no complications

(Takaoka et al, 2008)

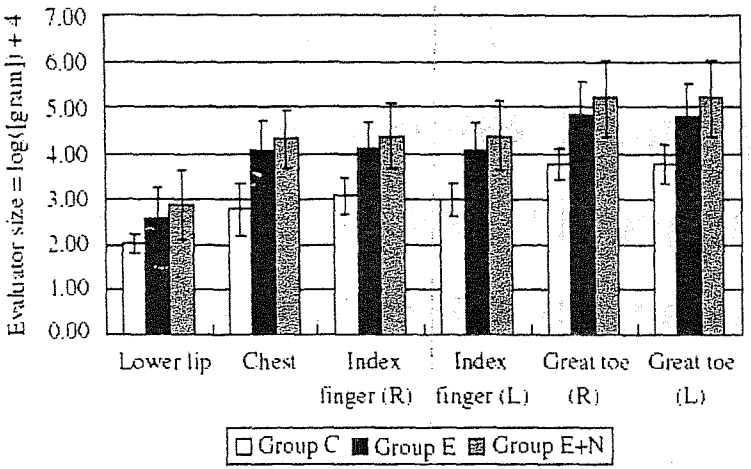
A recent study on sensory loss

- Neurologic examination, questionnaire and 4 quantitative tests of sensory function:
  - Touch (minimal tactile sense)
  - Two-point discrimination
  - Vibration sense (tuning fork)
  - Position sense

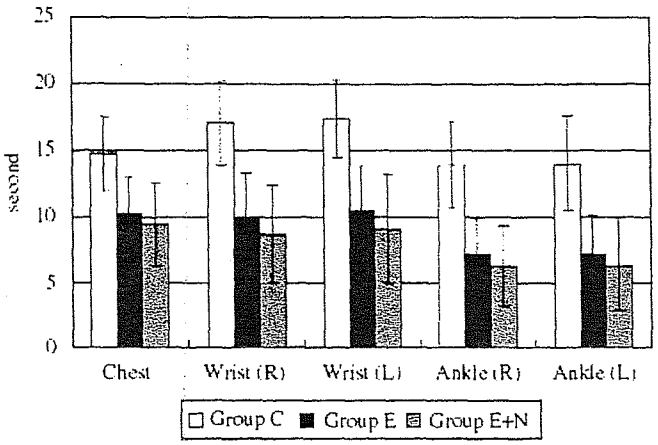
(Takaoka et al, 2008)

Results of sensory loss

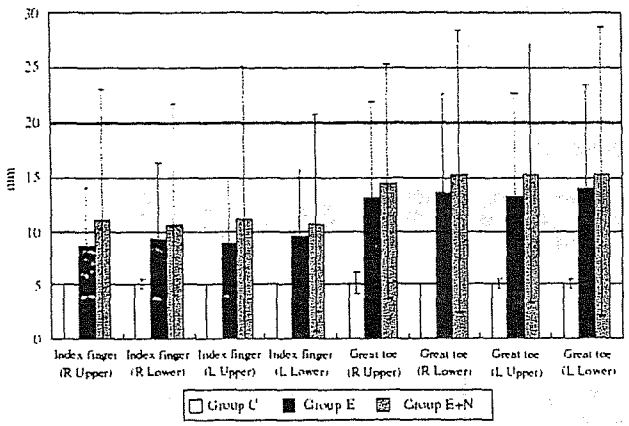
Touch



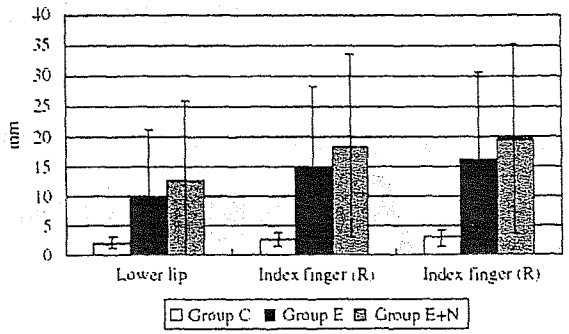
Vibration



Position sense



2-point discrimination



(Takaoka et al, 2008)

A recent study on sensory loss

- Findings:
  - Differences between Controls and Exposed without (E) and with complications (E+N) on all tests
  - No differences between E and E+N on all tests
  - No differences between E and E+N on the large majority of reported MD symptoms
  - Sensory and motor nerve conduction velocities of the right median nerve were similar in group E and controls
  - Sensory nerve conduction velocity was correlated with discrimination of fine-surface-texture, but not with other sensory modalities

(Takaoka et al, 2008)

A recent study on sensory loss

- **Conclusions :**

  "Residents of Goshoura and MD patients have not been aware of the sensory disturbances in their whole body. Thus, it is speculated that paresthesia at the distal parts of the extremities is a subjective complaint of MeHg poisoning patients. The crude clinical tests using a painting brush and pinprick are effective in evaluating gross sensory response. However, they are not quantifiable and their reproducibility is poor. On the other hand, the examinations of threshold of touch and two-point discrimination are semiquantitative, and more reproducible and reliable than the crude clinical tests. Consequently, it could be stated that the quantifiable sensory examinations are more suited to detect the somatosensory disorders caused by damage to the cerebral cortex."

  (Takaoka et al, 2008)

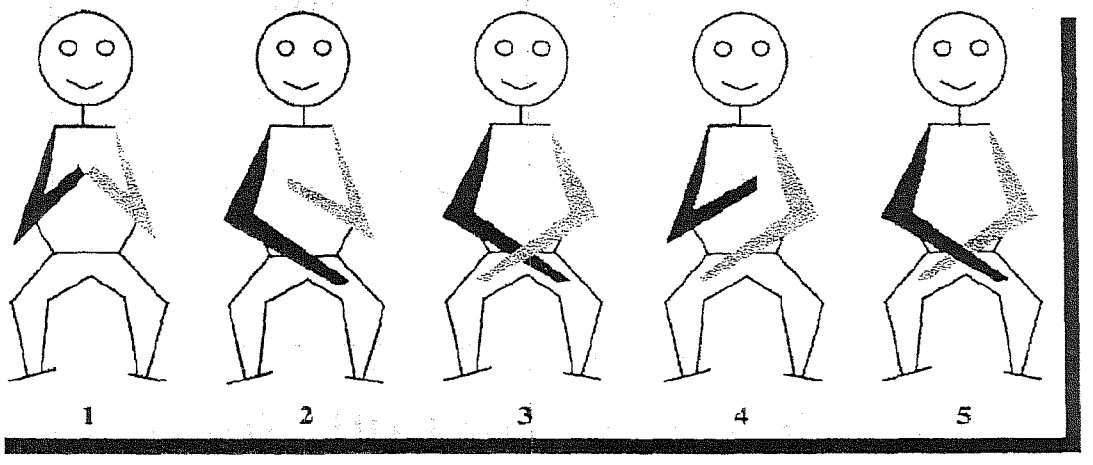
Visual functions

- Different types of visual deficits have been shown with mercury exposure :
  - restricted visual fields,
  - near visual contrast sensitivity loss,
  - color vision loss
  - changes in visual evoked potentials.
- In a recent study in the Amazon, we showed that the prevalence of age-related cataracts increased with mercury exposure

Motor testing

- In the early nineties, Dr. Fernando Branches, the Brazilian physician who first identified neurologic abnormalities in persons exposed to mercury vapours from gold mining activities and in fish-eaters exposed to methylmercury, was invited to Minamata where he learned to apply the neurologic examination for MD.
- His examinations of Brazilian fish-eaters with high mercury exposure showed some abnormalities, but not classical or chronic MD.
- He devised a new motor test that has proven to be very sensitive to methylmercuy exposure.

Branches Alternate Movement Task



- For Amazonian fish-eaters with hair mercury greater than 10µg/g the Odds Ratio for disorganized movements is: 1.88 [CI : 1.22-2.92]
- For those who can do the movement, the number of movements in 30 seconds decreases significantly with increasing hair mercury

Neurobehavioral Testing

- Neurobehaviorat tests which provide quantitative measures of cognitive, sensory and motor functions and emotional state have been used since the 1980's to describe acute and chronic effects of exposure to toxic substances on the nervous system.
- Clinically, they provide a complement to the neurologic examination.
- For mercury exposure, they have been extensively used to show deficits in children subsequent *in utero* exposure; in adults they likewise show mercury-related deficits, but there are fewer studies.

Dr. Harada's studies

- Dr. Harada did pioneering work in Japan, demonstrating neurologic damage of Minamata Disease
- In a recent report, he stated: *"During the early stages of the MD crisis in Minamata, patients, who were diagnosed with MD, seemed to be typical and severe cases of the Hunter-Russell syndrome, including sensory disturbance, concentric constriction of the visual field, ataxia, speech impairment and impaired hearing. However, through more study, it became clear that such severe cases were rather exceptional and many more mild cases were progressing to chronic Minamata Disease. I observed that the symptoms of Minamata Disease became more chronic and atypical in the 1970s. Also I have been proving that sensory disturbances, specifically stronger loss of sensation in the extremities, were seen among patients of methylmercury poisoning at a very high rate, through clinical examinations on family members of patients with sever and typical symptoms or mothers of congenital Minamata Disease patients"*

Dr. Harada's studies

- In the '70s, he showed that persons in Grassy Narrows and White Dog manifested similar signs and symptoms to MD and there appeared to be a dose-relation with mercury exposure
- In 2002 and 2004, he and his team went back. In total they examined 156 people from Grassy Narrows and White Dog.
  - Age ranged from 1-90 years
  - No information was provided on how persons were recruited

Dr. Harada's studies

- Diagnostic criteria:
  - MD: more than one symptom of: sensory disturbances,ataxia, disturbed ocular movement, imbalance, concentric construction of the visual field and speech impairment.
  - In cases where examinees were showing only sensory disturbances, we acknowledged MD as long as there was no other disease causing the symptom.
  - If an examinee had another disease and still showed symptoms of MD that were not explained by that other disease, we defined the case as MD with complications.

Dr. Harada's studies

- **Findings:**
  - 60 cases of MD (34.2% of total examinees, excluding people 10 years old and younger);
  - 54 cases (30.8%) of MD with complications;
  - 25 cases (14.2%) of possible MD for a total of 139 cases (79.4%).
- **They conclude :**
  - It is very high rate of neurological symptoms for a sample of a population, even though examinees came because of other health issues. It is as high as contaminated areas in Minamata. We cannot help but recognize the effects of methylmercury from the symptoms we have seen.

Our conclusions

- Dr Harada and his group did not evaluate the prevalence of MD in this population, but reported on the percentage of MD signs and symptoms within the group that they examined.
- We consider that Dr. Harada's follow-up clinical evaluation should be seen as a preliminary study showing the need for a comprehensive epidemiologic study that would include all of the known outcomes of mercury exposure and could take into account co-morbidity from other diseases, such as diabetes and /or alcohol and test for possible interactions. Such a study should also take into account the presence of other contaminants. For this study it would be most useful to have all of the results of hair and blood sampling by Health Canada, Dr. Chan and Dr. Harada, as well as the results of the neurological examinations that were done by Dr. Harada.

Opinions on environmental contaminants studies in Ontario based on reports provided by the Mercury Disability Board.

Prepared by Laurie Chan, Ph.D.
May 16, 2010

We have received the following 6 reports from the Mercury Disability Board for review.

1. Asubpeechoseewagong Netum Anisinaabek and Wabauskang First Nation Contaminants Project, 2004-2005 (Summary) submitted in May 31, 2005

2. Mercury in the sediment and crayfish of lakes supporting Grassy Narrows and Wabauskang First Nations, Ontario submitted in May, 2005

3. Wild Meat Contaminants Study Year 3: Heavy Metals June 2005.

4. Wild Meat Contaminants Study Year 3: Organochlorines December 2005.

5. Report on the Indigenous Knowledge Workshop Asubpeechoseewagong Nwtum Anishinaabek and Wabauskang First Nation 2005.

6. Final Report of the Anishinabek knowledge Component National First Nations Envrionmental Contaminants Program (NFNECP) Health Canada 2008-2009

1. Asubpeechoseewagong Netum Anisinaabek and Wabauskang First Nation Contaminants Project, 2004-2005 (Summary) submitted in May 31, 2005

2. Mercury in the sediment and crayfish of lakes supporting Grassy Narrows and Wabauskang First Nations, Ontario submitted in May, 2005

These two reports documented results from the same study. Sediment and crayfish samples were collected from 16 sites around the territory of the Asubpeechoseewagong Netum Anisinaabek and Wabauskang First Nations in 2005 and measured for Hg. The results provide insights on whether the chemical pollution in Dryden in the 1960s and 1970s is still having an impact on the English-Wabigoon River system.

The key findings are:

a) Sediment in water bodies that are closed to Dryden like Clay Lake and Ball Lake were still highly contaminated with Hg even though the levels had decreased compared to the 1970s.
b) The decreasing trend will continue as evidenced by the sediment core data.
c) The Hg in the sediment is bioavailable as evidenced by the elevated levels of Hg in crayfish collected in Ball Lake.
d) Sediments and crayfish collected from Grassy Narrow Lakes showed higher levels of Hg but the evidence is less convincing and no statistical tests were performed.
e) Sediment in Wabauskang Lake had background level of Hg.

Significance:

People should be advised not to consume fish collected from Clay Lake and Ball Lake as there are still residual effects of Hg pollution. Lakes around Grassy Narrows may still be affected and monitoring of Hg in fish should be continued.

3. Wild Meat Contaminants Study Year 3: Heavy Metals June 2005.

4. Wild Meat Contaminants Study Year 3: Organochlorines December 2005.

These two reports documented results of heavy metals including arsenic, cadmium, lead and mercury, and organochlorines including dioxins and furans, PCBs, chlorobenzens, hexachlorohexanes, chlordanes and DDTs in 159 wild meat (fish, mammals, and birds) collected by local hunters in 2005. Results help to identify potential chemical hazard as a result of consuming these food items.

The key findings are:

a) All metal and organochlorine concentrations in the wild meat samples were low or comparable to the concentrations found in like samples in Canada.
b) Concentrations of mercury and organochlorines were found in animals a higher trophic level such as otter, walleye, pike etc. as these contaminants are known to bioaccumulate and biomagnify along the food chain.
c) Migratory waterfowls had higher levels of organochlorines as they might have exposed to organochlorines in more polluted areas elsewhere.
d) One otter sample had higher level of mercury from unknown reason. One possible reason is age as mercury is known to accumulate in older animals but age was not determined.

Significance:

Results of this study show that there is no evidence of local pollution. The presence of the contaminants is likely due to either long-range transport or natural sources. There is no particular health concern from the consumption of these food items.

From the public health point of view, there is little value reporting whether Hg is detectable in certain food or comparing the Hg level to the guideline level used for regulation of commercial fisheries (i.e. 0.2 ug/g). The results can even evoke fear of the presence of contaminants in the local food supply. It will be more useful to combine the contaminant concentration data with food use data (in terms of gram per day intake) to estimate daily dose of contaminants. Such food frequency data are available at least for the fish species from an earlier study. See
Chan et al. (2005) "Our waters, our fish, our people" Mercury contamination in fish resources of two Treaty #3 communities.

5. Report on the Indigenous Knowledge Workshop Asubpeechoseewagong Nwtum Anishinaabek and Wabauskang First Nation 2005.

6. Final Report of the Anishinabek knowledge Component National First Nations Envrionmental Contaminants Program (NFNECP) Health Canada 2008-2009

These two reports presented results of two Elders meetings conducted in 2004-5 and 2008-9 on Anishinabek knowledge and perspectives on environmental contaminants. It is important the elders who are the local knowledge holders identify and report what are the main health issues in the communities. The information is also very useful in evaluating the effectiveness of the research activities and public health program as well as using the lessons learned to plan for future programs.

The key findings are:

a) The perceived risk of mercury pollution is still high. Scientists and health professionals have not been able to communicate the level of certainty in different findings and recommendations. People are confused with the scientific findings and public health messages and think that scientific information is not reliable.

b) There is a high level of mistrust for the scientific communities and the government. The risk communications including dietary advice have not been effective. The advices were either issued by the government or by scientists in different reports. The scientific studies and public health advice have been perceived to be out of context and did not take into account of the Indigenous perspectives. There is no long-term knowledge base available locally for such information.

c) The overall impact of mercury pollution has been more than just the health effects of mercury poisoning. Many other determinants of health including disruptions of culture, rapid change of diet, decline in jobs and income etc. have not been properly addressed and are clearly still having an impact on the overall health status of the people.

Significance:

Future studies should ensure local participation/leadership and capacity building. Risk communications need to be done on an ongoing basis with trained local personnel taking the lead. Proper dietary advice should be provided by individuals who have the authority and are trusted by the communities.

Re: Fourth Supplementary Submission on the Grassy Narrows/Earthroots Request for an Individual Environmental Assessment (IEA) on the Whiskey Jack Forest Management Plan for 2012-2022

Dear Mr. Wills,

These are further supplementary submissions to our request for an IEA on the Whiskey Jack Forest Management Plan (FMP) for the period 2012-2022.

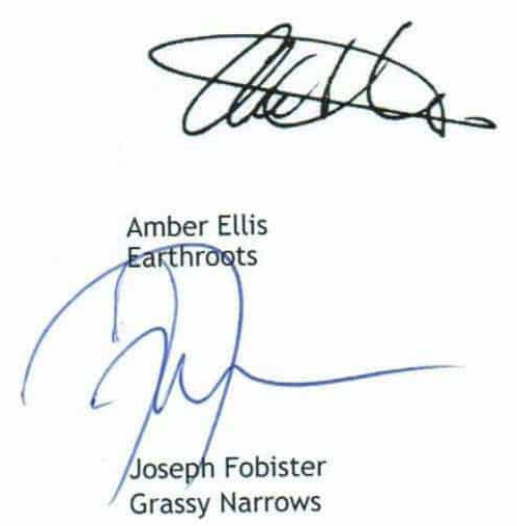
The submissions are prompted by: (1) our recent receipt of a number of government reports previously not in our possession regarding the Grassy Narrows mercury issue and the MNR monitoring program; and (2) various documents, including scientific journals articles and related materials that are relevant to the issues at hand.

The documents include information about:

1. Adequacy of the guide monitoring program
2. Psychological impacts of mercury on Grassy Narrows
3. Differences between logging and fire
4. Ontario Guide to Eating Sport Fish is not appropriate for Grassy Narrows
5. Sport Fish guide does not sufficiently protect fetuses
6. Fishing in Grassy Narrows culture
7. Mercury in Grassy Narrows blood

We regard this information as important to your consideration of our request for an IEA of the Whiskey Jack FMP and would ask that the Ministry of the Environment (MOE) consider this material in conjunction with the material that we have previously submitted to your office on this matter.

Sincerely,



1. ADEQUACY OF GUIDE EFFECTIVENESS MONITORING PROGRAM

SUMMARY: In 2010 the new Stand and Site Guide (SSG) identified as a key uncertainty and monitoring priority the question of whether implementation of the Landscape Guide and Stand and Site Guide will ensure that effects on aquatic ecosystems resulting from forest management activities: i) do not exceed those observed in naturally disturbed catchments and ii) do not exceed acceptable levels for specific parameters (e.g., methylmercury).

Two MNR publications about the monitoring program from 2011 reported that:

a. It was agreed among MNR scientists that current research and monitoring work is not sufficient to address aquatic ecosystem processes uncertainties.

b. Most projects are focused on specific research questions as opposed to monitoring the effectiveness of management actions at mitigating impacts. The projects that do exist are looking at the old rules, not the new rules contained in the Guide.

c. Only through implementation on the ground and through measurement and comparison of expected results versus observed results can the effectiveness of policy options be rigorously evaluated.

d. Information on the effectiveness of guide direction or adaptive modification of guidance should not be expected for several years after guide implementation.

e. Cumulative effects of various projects, other industries, and forestry practices on mercury had not yet been studied, but this is identified as a "next step."

f. Directed new funding from MNR is required to fund the core effectiveness monitories data collection activities.

RELEVANT EXCERPTS:

"Rob Mackereth's work in the Mackenzie watershed ecosystem and Dave Kreutzweiser's work in the White River area are the main contributors to the Aquatic Ecosystem Processes question. The White River study is examining catchment and stream characteristics, aquatic invertebrate communities, and community function (organic matter breakdown) across catchments that are fire-disturbed (about 12 years ago), logging-disturbed (about 5-15 years ago), and not recently disturbed (about 60+ year old stands). The shortcoming of this project is that it is does not directly address the effectiveness of the new guide because the logging was conducted under the old guide. As a result, it was agreed that current work is not sufficient to address Aquatic Ecosystem Processes uncertainties; with monitoring gaps being insufficient fire treatments in their study design and little understanding of the impact of temporal scale disturbances. (Debruyne and Remple, MNR 2011, p.3)

"NEXT STEPS: Find out resulting cumulative effects from various projects, other industries, and forestry practices." (Debruyne and Remple, MNR 2011, p.6)

"A number of ongoing research projects are addressing issues of uncertainty around catchment scale disturbance impacts (Table 2). Most projects are focused on research into harvest impacts on stream and lake systems and focus on biological, chemical and hydrologic responses. Most projects are focused on specific research questions as opposed to monitoring the effectiveness of management actions at mitigating impacts." (Debruyne and Remple, 2011, p.14)

"Effectiveness Monitoring of Guide direction to mitigate hydrologic impacts:
Although a number of past and ongoing research programs may contribute to an effectiveness monitoring program, it was agreed that current work is not sufficient to address Aquatic Ecosystem Processes uncertainties. A comprehensive monitoring program, conducted across a broad spatial and temporal scale is required to evaluate guide effectiveness. The proposed program will incorporate indicators developed by previous studies to characterize stream ecosystems, including aquatic habitat, biota, hydrology water quality and riparian condition. The monitoring program should be long-term and cover all ecosite types within the area of the undertaking. The proposed program will utilize a standardized site survey to collect information and an ongoing research program to analyze survey data and continue to develop, refine and validate indicators." (Debruyne and Remple, 2011, p.15)

"Although the development of a monitoring program to evaluate the effectiveness of guide direction at mitigating catchment scale hydrologic impacts is underway, implementing the program is a long term undertaking. The actual monitoring work cannot begin until forest management activities incorporate the direction of the new guides (2012?) and will take time to refine and evaluate. Information on the effectiveness of guide direction or adaptive modification of guidance should not be expected for several years after guide implementation." (Debruyne and Remple, 2011, p.16)

"Only through implementation on the ground and through measurement and comparison of expected results versus observed results can the effectiveness of policy options be rigorously evaluated." (Remple et al., 2011, p.1)

"There are two situations when direction given in the Guides is not based on the natural disturbance paradigm: when no natural analog exists (eg. soil rutting or specific mercury levels), and when employing the natural disturbance paradigm might result in an effect that society does not condone (eg. violates Migratory Bird Convention Action or Fisheries Act) or does not meet its goals (eg. conservation of species at risk or species of economic or recreational value)." (Remple et al., 2011, p.4)

"Directed new funding from MNR is required to fund the core effectiveness monitoring data collection activities." (Remple et al., 2011, p.9)

2. PSYCHOLOGICAL HEALTH IMPACTS OF MERCURY

A report by the Ministry of Environment in 1986 identified the following facts:

i) The threat of mercury poisoning in Grassy Narrows has serious psychological impacts including fear, anxiety, and mental trauma.

ii) The physical, mental health, and economic impacts of mercury in the English-Wabigoon River have been felt disproportionately by people at Grassy Narrows (and other First Nations people) who practice a traditional Anishinaabe way of life that includes fishing.

iii) A reduction in mercury contamination in fish could lead to a reduced physical and psychological health risk among the Native people at the White Dog and Grassy Narrows Bands.

iv) Health and Welfare Canada recommends that mercury concentrations in fish should be 0.2 ppm or lower before the people at Grassy Narrows and Whitedog communities can safely eat fish.

v) Mercury levels would have to be below 0.5 ppm before the commercial fishery could be revived.

A report by Peter Usher had further relevant findings.

RELEVANT EXCERPTS:

"Of 105 individuals in Ontario who have (blood mercury) levels greater than 100 ppb, 98 (93%) were from the two communities of Whitedog (Islington) and Grassy Narrows, with 39 individuals (37%) from Whitedog and 59 individuals (56%) from Grassy Narrows. (Health and Welfare Canada, December 1979: 71)." (Donnan, MOE 1986, p.28)

"People who live in the Grassy Narrows and Whitedog Indian Settlements have ingested enough mercury contamination to suffer possible health effects (Health and Welfare Canada, December 1979). Health and Welfare Canada (December 1979: 60) recommends that mercury concentrations in fish should be 0.2 ppm or lower before the people at Grassy Narrows and Whitedog communities can safely eat unlimited quantities of fish." (Donnan, MOE 1986, p.28)

"High blood mercury levels contribute to anxiety and possibly to specific illnesses or symptoms which these people have exhibited." (Donnan, MOE 1986, p.28)

"Because sport fishing has remained open after the commercial fishery was banned, some people on the settlements may have been confused about government warnings and continued to eat contaminated fish from the system." (Donnan, MOE 1986, p.28)

"Physical and mental health effects such as anxiety due to mercury contamination in the Wabigoon-English River System have been borne almost entirely by the Native people of the Grassy Narrows and Whitedog Bands." (Donnan, MOE 1986, p.28)

"For Grassy Narrows in particular, the mercury pollution has probably been the most devastating set-back." (Donnan, MOE 1986, p.30)

"Discovery of mercury in fish and in the Native people had several profound adverse consequences… the fear and anxiety from knowing they were contaminated was debilitating to many. The threat of mercury poisoning clearly affected the mental health of these people even if the medical evidence of any effects on their physical health was inconclusive." (Donnan, MOE 1986, p.31)

"The closure of the commercial fishery was a particularly serious blow. It denied the Indians a source of income, an important source of food, economic self sufficiency, a vigorous and healthful occupation and a feeling of self reliance and well-being." (Donnan, MOE 1986, p.31)

"A reduction in mercury contamination in fish could lead to a reduced health risk among the Native people at the White Dog and Grassy Narrows Bands because these people have the most opportunity and inclination to eat fish from contaminated water bodies. Any benefit in terms of reduced health risk to sport fishermen is judged to be slight because anglers eat comparatively little fish and because the sport fish eating guidelines are available. Other non-Native consumers of fish are not at risk because commercial fishing of contaminated fish is banned and the federal fish testing program is intended to prevent contaminated products from reaching consumers." (Donnan, MOE 1986, p.31)

"Potential Benefit Categories: Reduced Physical and Mental Health Risks." (Donnan, MOE 1986, p.33)

"Health and Welfare Canada (1979: 60) recommends that mercury concentrations in fish should be 0.2 ppm or lower before the people at Grassy Narrows and Whitedog can safely eat them." (Donnan, MOE 1986, p.43)

"[A] reduction in fish mercury levels could help to reduce anxiety and mental trauma experienced by these people." (Donnan, MOE 1986, p.44)

"a. reduced physical and mental health risks to the Native people of the Grassy Narrows and Whitedog Reserves;" (Donnan, MOE 1986, p.57)

"We have also concluded that the loss of the fishery played a major part in the disruption of the family as a producing economic unit, and in the consequent ramifications of that for the socio-economic structure. It is these social changes, as well as the loss of income (cash and domestic) and employment, which have led in turn to disproportionately high rates of violent death, suicide attempts, child neglect, emotional distress and crime on both reserves." (Usher 1979, p.368)

"Mercury pollution stands out as a the major event in the history of the two reserves, which eliminated a central economic activity and a major source of income, and endangered health and aroused anxiety in regard to same. " (Usher 1979, p.368)

3. DIFFERENCES BETWEEN LOGGING AND FIRE ON MERCURY

SUMMARY: The MNR claims (in the SSG and in their response to our IEA request) that the impacts of logging emulate the natural disturbance of fire. However, statements from the MNR monitoring scientists and from the peer reviewed scientific literature about mercury contradict this. This issue is discussed in our earlier submissions, but the following additional sources of information are relevant in substantiating our arguments.

RELEVANT EXCERPTS:

"Studies of logging and fire impacts in forest catchments have demonstrated that logging disturbance is not the same as fire disturbance in the short-term (several years at least). " (Debruyne and Remple, MNR 2011, p.16)

“We have a poor understanding of the temporal scale of disturbance impacts on aquatic systems: how long do they take to manifest and how long until recovery?” (Debruyne and Semple, MNR 2011, p.16)

“Recent studies from Canada’s Boreal Shield reported higher MeHg concentrations in zooplankton and fish from lakes with logged watersheds than in undisturbed watersheds (Garcia and Carignan 1999, 2000). The same studies reported no influence of forest fire on MeHg concentrations in aquatic biota. These findings have important implications for the natural disturbance paradigm of forest management, which proposes that timber harvesting can emulate the ecological impacts of natural disturbances such as forest fire (see Seymour et al. 2002).” (Allan et al. 2005)

“Two years after fire, MeHg concentrations in five of six aquatic taxa were similar in burned and reference lakes.” (Allan et al. 2005)

“Three months after fire, biota MeHg concentrations had decreased by 32%–50.” (Allan et al. 2005)

We note that the only paper which reports an overall significant increase in fish mercury levels after fire (Kelly et al. 2006) was done in a different ecosystem (Rocky Mountains), looked at a different fish species (primarily rainbow trout), and only looked at one lake.

“Our research has documented an increased flux of mercury, both elemental and the biologically active methy-mercury, in streams following harvesting.” (Mackereth, MNR 2007)

“Small streams are particularly vulnerable to forest management [partly because of] the large number that are unmapped.” (Mackereth, MNR 2007)

We discuss Garcia and Carignan's findings in our earlier submissions. They found that large/intense fires do not significantly elevate mercury levels in fish.

Large fires are more likely to be intense because fire intensity is a factor contributing to fire growth and also because the conditions that give rise to large fires (eg. drought, lots of fuel), also tend to give rise to intense fires.

Here is further evidence that nearly all the area burned in the boreal is burned by large fires.

"The results from the Red Lake District also indicate that 5.33 percent of fires larger than 1000ha in size are responsible for 96.42 percent of the total area burned from 1976 to 1993. This result is consistent with reports by Stocks (1991) that the 2 or 3 percent of fires that grow larger than 200 ha are responsible for about 98% of the total burned area in Canada. The Red Lake results are also compatible with a theoretical investigation by Strauss et al. (1989)." (Li, NRC 2000, p. 123)

"[A]lthough large fires occur infrequently, they account for most of the disturbance caused by fires. (Turner and Romme 1994, Armstrong 1999, Johnson et al. 1999, Li 2000, Perera and Baldwin 2000)" (OMNR 2001, p.19)

"Eco-region 4S had the most severe fire regime (highest burn rates, largest fire sizes)" (Perera, Cui, 2010, p.1334)

Therefore, the impacts of small fires are not very relevant in seeking to emulate mercury impacts from natural disturbance in the boreal since small fires impact a very small portion of the boreal landscape.

4. MOE SPORT FISHING GUIDES NOT APPROPRIATE FOR FIRST NATIONS

SUMMARY: We have stated earlier that the MOE Guide to Eating Ontario Sport Fish is not appropriate for Grassy Narrows and does not protect Grassy Narrows people from impacts on their health, psychology, culture, and livelihood. The reasons for this include the following:

a) Many Grassy Narrows people are not aware of, do not trust, or do not have access to the guide (see earlier comments and references to report by Simpson summarized by Mergler and Chan).
b) The information in the guide is not culturally appropriate and many people in Grassy Narrows do not understand the information (Simpson).
c) Many people in Grassy Narrows lack the resources (including time, money, equipment, and knowledge) needed to follow the guide. For example fishing on lakes other than those next to the community requires a truck and trailer to move your boat and considerable time, and strength to do so. Fishing for other species requires knowledge of their specific habitat, behavioural patterns, appropriate equipment, timing, and location for catching them, etc.
d) First Nations people have fish consumption patterns that are different from sports fishers.
e) First Nations people have an inherent and Treaty right to fish. Walleye is the preferred and customary fish species for eating in Grassy Narrows.
f) People in Grassy Narrows have cultural rules (eg. Family use areas), and externally imposed rules (eg. Commercial fishing licences, registered trapline areas) that restrict their use to certain areas and prevent them from fishing wherever they choose.
g) The sport fishing guide is not created with cumulative impacts in mind. It assumes that no other sources of mercury are ingested when in fact Grassy Narrows people ingest mercury from a number of sources (eg. ducks, otters, wild rice, store-bought fish, dental fillings, etc.).
h) Many Grassy Narrows people already suffer from mercury poisoning. The sport fishing guide does not consider that people already suffering from mercury poisoning may be more vulnerable to cumulative impacts of additional mercury than people without previous elevated exposure.
i) The sport fishing guide is based on exposure guidelines that are considerably less protective than those used in the US by the Environmental Protection Agency and those recommended by Canadian mercury experts.

RELEVANT EXERPTS:

"The MOE recognizes that fish consumption patterns in First Nations communities would be different than those published in the guide to Eating Ontario Sport Fish." (MOE 2012, p.3)

"A reduction in mercury contamination in fish could lead to a reduced health risk among the Native people at the White Dog and Grassy Narrows Bands because these people have the most opportunity

and inclination to eat fish from contaminated water bodies. Any benefit in terms of reduced health risk to sport fishermen is judged to be slight because anglers eat comparatively little fish and because the sport fish eating guidelines are available. Other non-Native consumers of fish are not at risk because commercial fishing of contaminated fish is banned and the federal fish testing program is intended to prevent contaminated products from reaching consumers." (Donnan, MOE 1986, p.31)

"Because carnivorous fish are the most desirable sport and commercial species, walleyes and northern pike are used as the primary indication species for monitoring mercury levels." (Donnan, MOE 1986, p.16)

"[C]ontaminated fish has certainly not been eliminated from the diet of people of Whitedog and Grassy Narrows, despite the many warnings against consuming fish from the river system." (Usher 1979, p.300)

"A review of reserve residents' perceptions of the problem reveals reasons for this:

1. Fish are part of the Ojibwa heritage, and like other country food, have meaning beyond simply eating. This meaning lies in the skills, knowledge and labour of obtaining food, as well as the social links which are perpetuated by sharing it. Fish are the end product of a way of life.

2. Fish have always been a large part of the diet, and most people, young and old, have a strong preference for fish, particularly walleye, which being a predatory fish, has relatively high mercury levels.

3. Fish is easier to get than big game, or even small game. It can be obtained in good quantity with little effort on short trips. As people increasingly take up full time wage employment, fish becomes the country food resource most easily available to them.

4. Groceries are expensive, but fish is free for the taking, and plentiful.

5. Fish are more nutritious and satisfying than store-bought food. While most public health authorities have stressed the hazards of eating contaminated fish, it is evident that, given the alternatives available to the people, there are also nutritional hazards from not eating fish.

6. Although imported, frozen fish are currently provided under the alternative food programme, many people do not like the taste and cooking qualities of this fish. Nor are the desired species always available, although it is understood that MNR has made some effort to obtain the preferred varieties through the Freshwater Fish Marketing Board. It is not always possible to obtain walleye containing less than 0.2 ppm of mercury, which is the recommended maximum for those already at risk.

7. Some reserve residents do not believe that the fish are really dangerous. Some never believed the "mercury scare," since neither the appearance, taste or observable health and behaviour of fish are affected by mercury contamination. Others, who avoided fish in their diet for a number of years are beginning to think the problem is over. There has been no sudden, horrendous outbreak of Minimata disease, and despite fears and suspicions, nothing has been proved

conclusively one way or another. In any event sport fishermen seem to be getting away with eating fish, and with the apparent blessing of the government.

8. There has, not surprisingly, been a sense of beleagerment among Indian commercial fisherment in the region, due to the provincial government's avowed preference for the sports fishery. Consequently, some reserve residents have viewed the 'mercury scare' as merely a hoax, perpetrated by the government to shut down both their commercial and domestic fishery, and given the fish resource entirely over to the tourist camp operators."
(Usher 1979, p.301-303)

"It would appear that cultural inclinations, economic imperatives, nutritional needs, conflicts in government information and policies toward the problem, and a general mistrust of government intentions, especially with respect to traditional Indian resources, conspire against the elimination of contaminated fish in the diet. The situation is alarmingly similar to that described by Feit and La Rusic (in Berkes et al, 1972: 180-187) in the James Bay area of Quebec, and by Usher (1977b) at Cedar Rapids, Quebec, where local fish supplies have been contaminated by mercury." (Usher 1979, p.303)

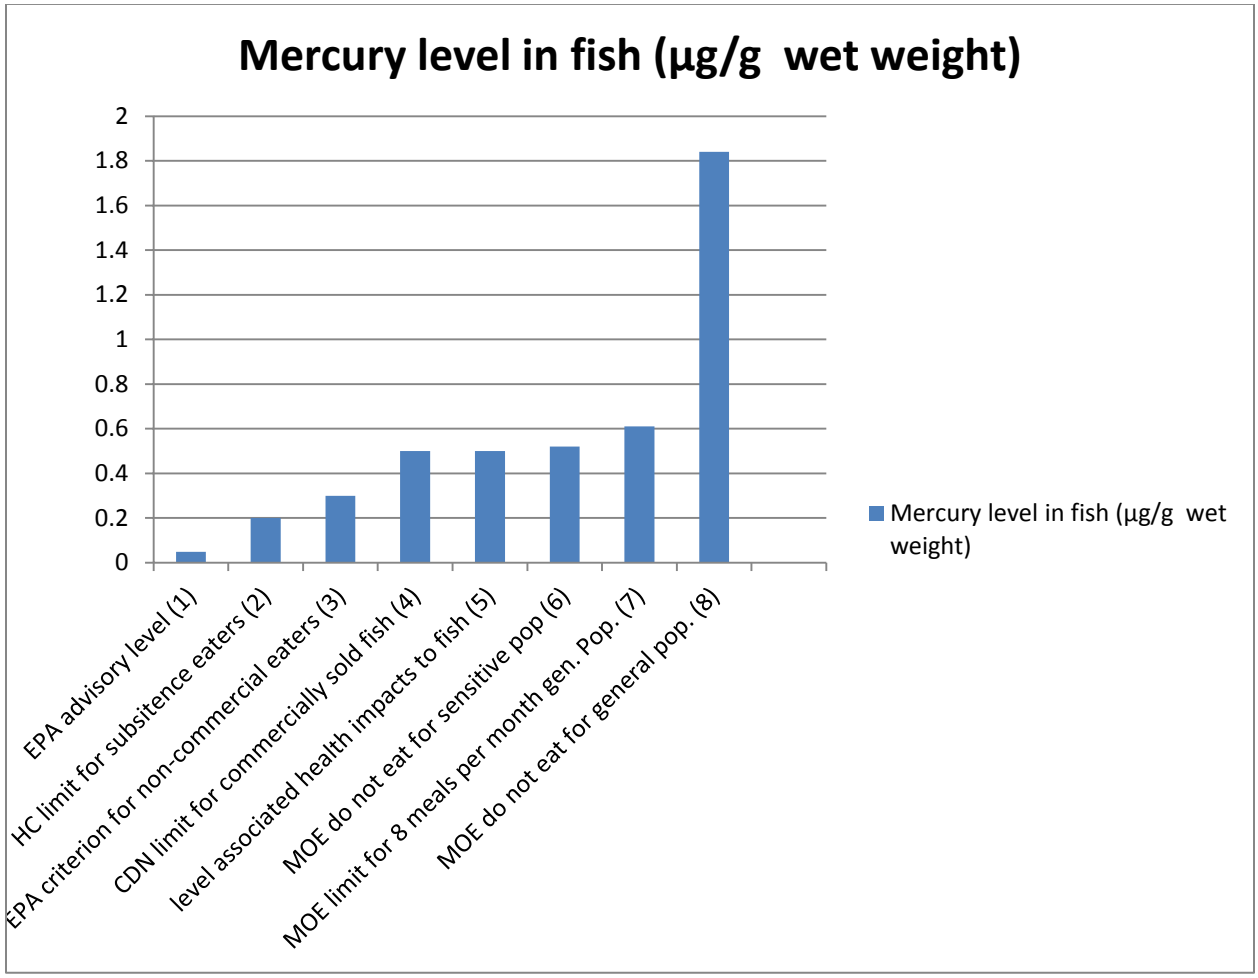
"We believe, however, that although there may have been a very marked decline in fish eating in the early and mid-1970's, consumption of contaminated fish is now on the rise on both reserves. To the degree that commercial fishing and guiding are re-established on the Winnipeg, English or Wabigoon Rivers, historic fish use patterns will probably reassert themselves, and people will retain increasing quantities of fish for domestic consumption as byproducts of these activities.

Consequently, even if there has been no adverse effect on health to date from eating contaminated fish (and this has by no means been proven), the possibility exists that body loadings of mercury in the reserve populations will gradually increase in the future. If that is the case, the medical problem at Grassy Narrows and Whitedog, is far from over. It may be just beginning." (Usher 1979, p.303.304)

"It follows, in our opinion, that the prevention of future medical and nutritional problems will not be achieved by education and information campaigns, or alternative food programmes, unless the fundamental difficulties of the two reserves are also dealt with, and the people no longer have grounds for the fears and suspicions enumerated above." (Usher 1979, p.304)

"Health and Welfare Canada (1979: 60) recommends that mercury concentrations in fish should be 0.2 ppm or lower before the people at Grassy Narrows and Whitedog can safely eat them." (Donnan, MOE 1986, p.43) The MOE sport fish guide does not list a fish as "do not eat" for the general population until its mercury levels are more than nine times that level - above 1.84 ppm (parts per million or micrograms per gram). Even when a fish is listed as "do not eat" there is no requirement that a physical sign be posted at access points to that body of water (or in Grassy Narrows itself) to alert users of that fish. In order to access the information in the guide fishers would need to know about the guide, obtain a current copy, or have internet access, be fluent in English and scientifically literate (eg. Chart reading).

COMPARATIVE MERCURY ADVISORY LEVELS:



(1) 0.049 µg/g - consumption advisory trigger set by the US Environmental Protection Agency (Holloman and Newman 2012)

(2) 0.2 µg/g wet weight - "Health and Welfare Canada (1979: 60) recommends that mercury concentrations in fish should be 0.2 ppm or lower before the people at Grassy Narrows and Whitedog can safely eat them." (Donnan, MOE 1986, p.43)

(3) 0.3 µg/g wet weight - the US Environmental Protection Agency tissue residue criterion for methylmercury (established to protect the health of persons who eat non-commercial fish) (Holloman and Newman 2012)

(4) 0.5 µg/g wet weight – limit above which it is illegal to possess fish for commercial sale in Canada

(5) 0.5 µg/g wet weight - estimated threshold level associated with altered biochemical processes, damage to cells and tissues, and reduced reproduction in fish. (Holloman and Newman, 2012)

(6) 0.52 µg/g – Level above which `do not eat` is recommended in MOE sport fish guide for sensitive population

(7) 0.61 µg/g - MOE sport fishing guidelines maximum level at which 8 meals per month are recommended for the general population

(8) 1.84 µg/g – Level above which `do not eat` is recommended in the MOE sport fish guide for general population

5. The Guide is Not Restrictive Enough to Protect Fetuses

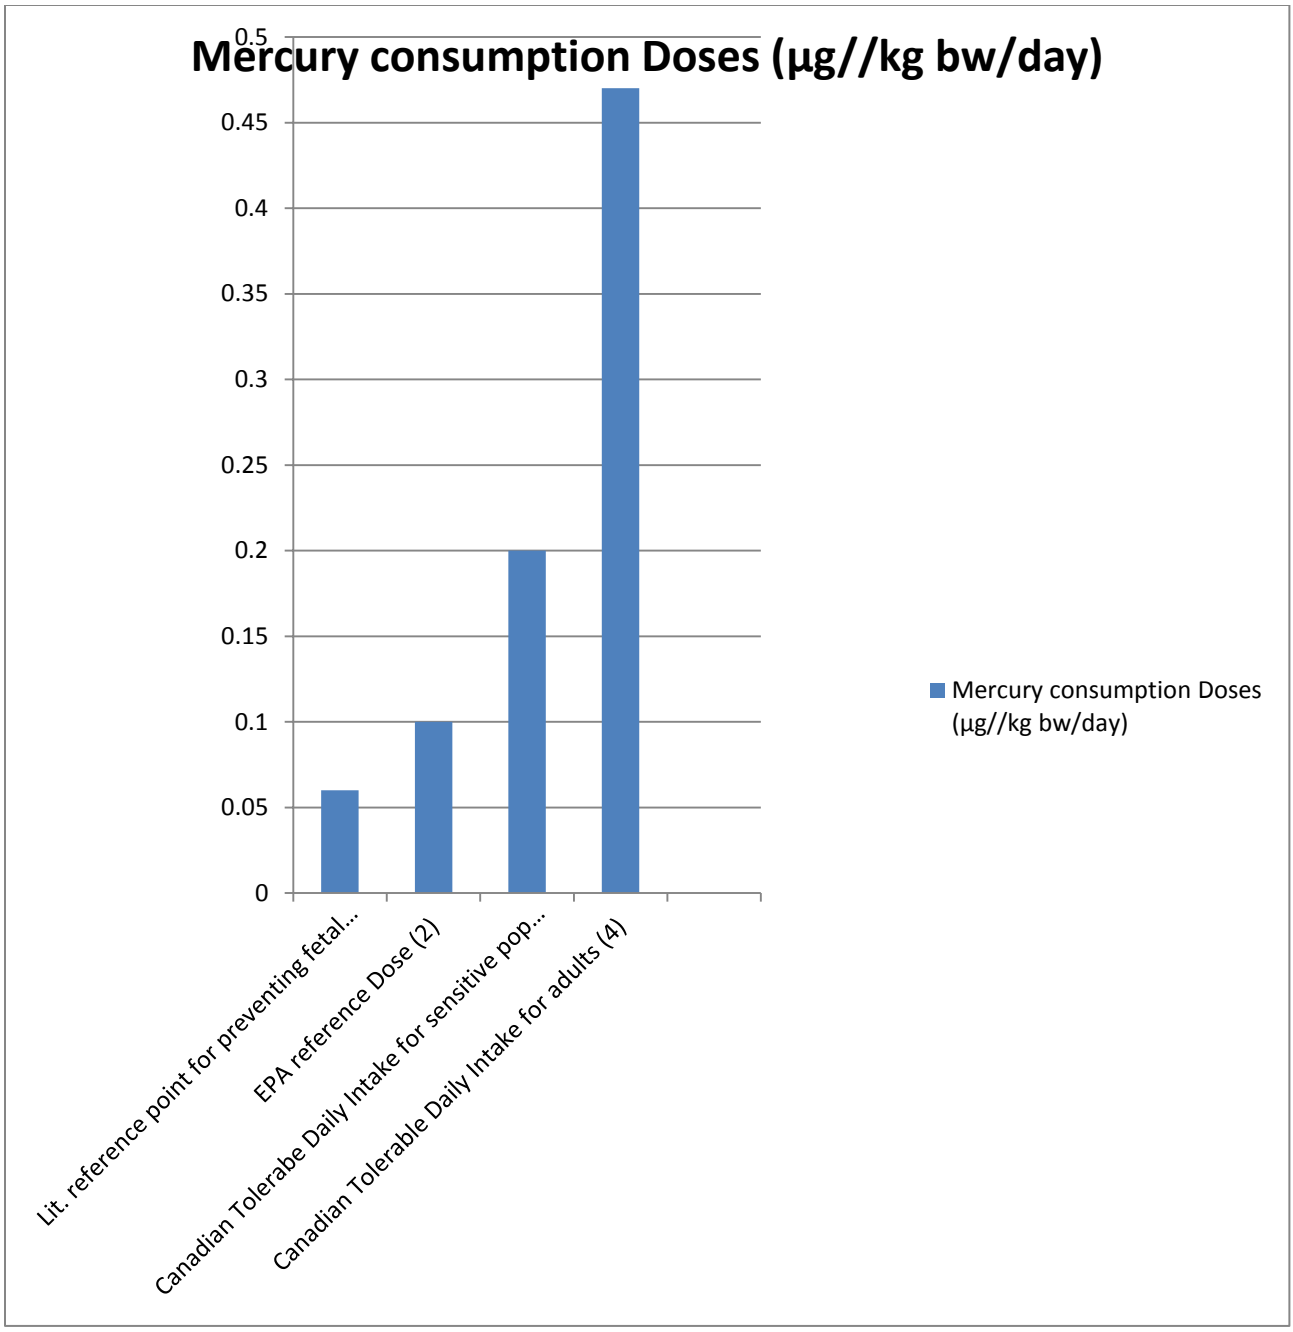
SUMMARY:

-The tolerable daily dose of mercury for pregnant women used by the Guide is double that used by the US EPA to protect against "chronic and developmental mercury toxicity."

-The scientific literature recommends that the allowed dose should be 70% lower than the US EPA reference dose to account for the bio-concentration of mercury across the placenta. That is one third of the dose used for the MOE guide.

-5% of fetuses have mercury blood levels more than three times that found in their mothers blood.

"The fish consumption advice issued by Toronto Public Health 32,42-44 (summarized in a patient handout available from CFPlus*) deserves highlighting for 2 reasons. First, the risk calculations are based on the US EPA RfD, 27 33 a more conservative measure than Health Canada's provisional tolerable daily intake. We consider this caution appropriate in a country with diverse population groups, many of which consume large amounts of fish for cultural reasons." (Ablesohn et al., 2011)



(2) To protect humans against chronic and developmental mercury toxicity, US EPA developed an oral reference does (RfD) of 0.10 ug/kg bw/day, an estimate of a daily oral exposure that is likely to be without an appreciable risk of adverse health effects over a lifetime. (US EPA, 2001a, 2001b) (cited in Holloman and Newman, 2012)

(1) Mergler et al., 2007 point out that in the risk assessment upon which the US EPA's RfD (corresponding to 5.8 µg/L in blood) is based, the US National Research Council used cord blood mercury

measures and did not account for the bioconcentration of methylmercury across the placenta when determining a maternal reference blood mercury level. (Mergler et al., 2007) Mahaffey and colleagues suggest, therefore, that maternal blood mercury levels exceeding the range of values from 3.5 µg/L (15 nmol/L) to 5.8 µg/L (29 nmol/L) should be the reference point for preventing fetal neurotoxicity. (Mahaffey et al., 2008) (cited in http://www.cfp.ca/content/57/1/) Consequently we have divided the EPA reference dose by 1.7 – the average concentration factor suggested by Mergler et al. 2007.

(3) Canadian tolerable daily intake for pregnant women and children (0.20 µg /kg bw/day)

(4) Canadian tolerable daily intake (0.47 µg /kg bw/day) for adults. (Abdelouahab et al. 2008)

"Although maternal and cord blood Hg concentration is highly correlated, cord blood MeHg is consistently higher than the corresponding maternal concentration, with an average ratio of about 1.7 (24, 61, 73, 74). Consequently, biomonitoring adult women's blood MeHg as a surrogate for potential fetal exposure, the corresponding fetal level will be, on average, 70% higher than maternal blood and up to three times higher at the 95th percentile. The maternal body burden of MeHg tends to decrease during gestation consistent with hemodilution and a transfer of a portion of the maternal body burden to the fetus (24)." (Mergler et al., 2007)

Example:

1.0 µg/g mercury is common in 50 cm walleye in the English River near Grassy Narrows

One 250g walleye fillet at 1.0 µg/g gives 250 µg mercury

For a 50 kg woman that is 5 µg mercury per kg body weight in one day

This is 5x the daily intake that has been documented to produce adverse health effects

At CDN limit level of 0.2 µg/kg bw/day that is 25 days worth of doses in one meal

At US EPA limit level of 0.1 µg/kg bw/day that is 50 days worth of doses

At lit level of 0.06 µg/kg bw/day that is approx. 80 days worth of doses

6. FISHING IN GRASSY NARROWS

"Subsistence fishing has long been an important component of the Native peoples lifestyle in this region. Many Native people fished commercially and, prior to an awareness of the mercury pollution, caught fish for home or subsistence consumption." (Donnan MOE 1986, p. 22)

"As indicated in the Ideas program, the Native people regard commercial fishing as a component of their traditional way of life." (Donnan MOE, 1986, p. 47)

"Food or subsistence fishing is another important component of the Indian lifestyle. However, this practice has been severely curtailed as a result of the mercury contamination. According to the recommendations of Health and Welfare Canada, the people on Grassy Narrows and Whitedog could enjoy unrestricted consumption of fish only if the mercury concentrations were reduced to 0.2 ppm." (Donnan MOE, 1986, p.47)

"For Native people, food fishing is part of their culture and has helped to strengthen their social fabric." (Donnan MOE, 1986, p.48)

"Commercial and food fishing are important components of the Indian lifestyle. Mercury contamination and the subsequent loss of these activities coupled with relocation, flooding of wild rice and fishing areas and the lack of clear hunting , trapping, fishing, and forestry rights have all but eliminated opportunities for the Whitedog and Grassy Narrows bands to be self sufficient." (Donnan MOE, 1986, p.51)

"This report has shown that the fishery, and particularly its commercial and domestic aspects, was the keystone of the traditional mode of production at Whitedog and Grasssy Narrows, at the time that mercury pollution was discovered in 1970. Far from being a dying activity the fishery had assumed a growing economic, social and cultural role on the two reserves. It was the single greatest source of food, employment and income. The fishery was the chief means by which children were socialized into the traditional mode of production, and by which traditional socio-economic bonds and obligations were fulfilled. (Usher 1979, p.364)

"[t]he loss of the fishery due to mercury contamination must be viewed as a most serious event in the history of the two reserves; the one which does indeed make their experience unique." (Usher 1979, p.365)

"It is commonly thought that the traditional economy is slowly dying throughout the North, and therefore blows to it are not a serious matter in the long run. We have shown that this is rarely the case…" (Usher 1979, p.366)

"We have shown that the loss of the fishery meant much more to the reserves than the loss of commercial fishing income alone, or even the decline in guiding income. The decline of the domestic fishery, coupled with the decrease in hunting opportunities (because, without the fishery, hunting was no longer as economic), led to an enormous decline in country food production." (Usher 1979, p.367)

"[C]ontaminated fish consumption has not been eliminated, and is in our opinion likely to rise in the coming years. The quality of food that has replaced the traditional harvest of meat and fish is of much poorer nutritional quality." (Usher 1979, p.368)

"We have also concluded that the loss of the fishery played a major part in the disruption of the family as a producing economic unit, and in the consequent ramifications of that for the socio-economic structure. It is these social changes, as well as the loss of income (cash and domestic) and employment, which have led in turn to disproportionately high rates of violent death, suicide attempts, child neglect, emotional distress and crime on both reserves." (Usher 1979, p.368)

"Mercury pollution stands out as a the major event in the history of the two reserves, which eliminated a central economic activity and a major source of income, and endangered health and aroused anxiety in regard to same. " (Usher 1979, p.368)

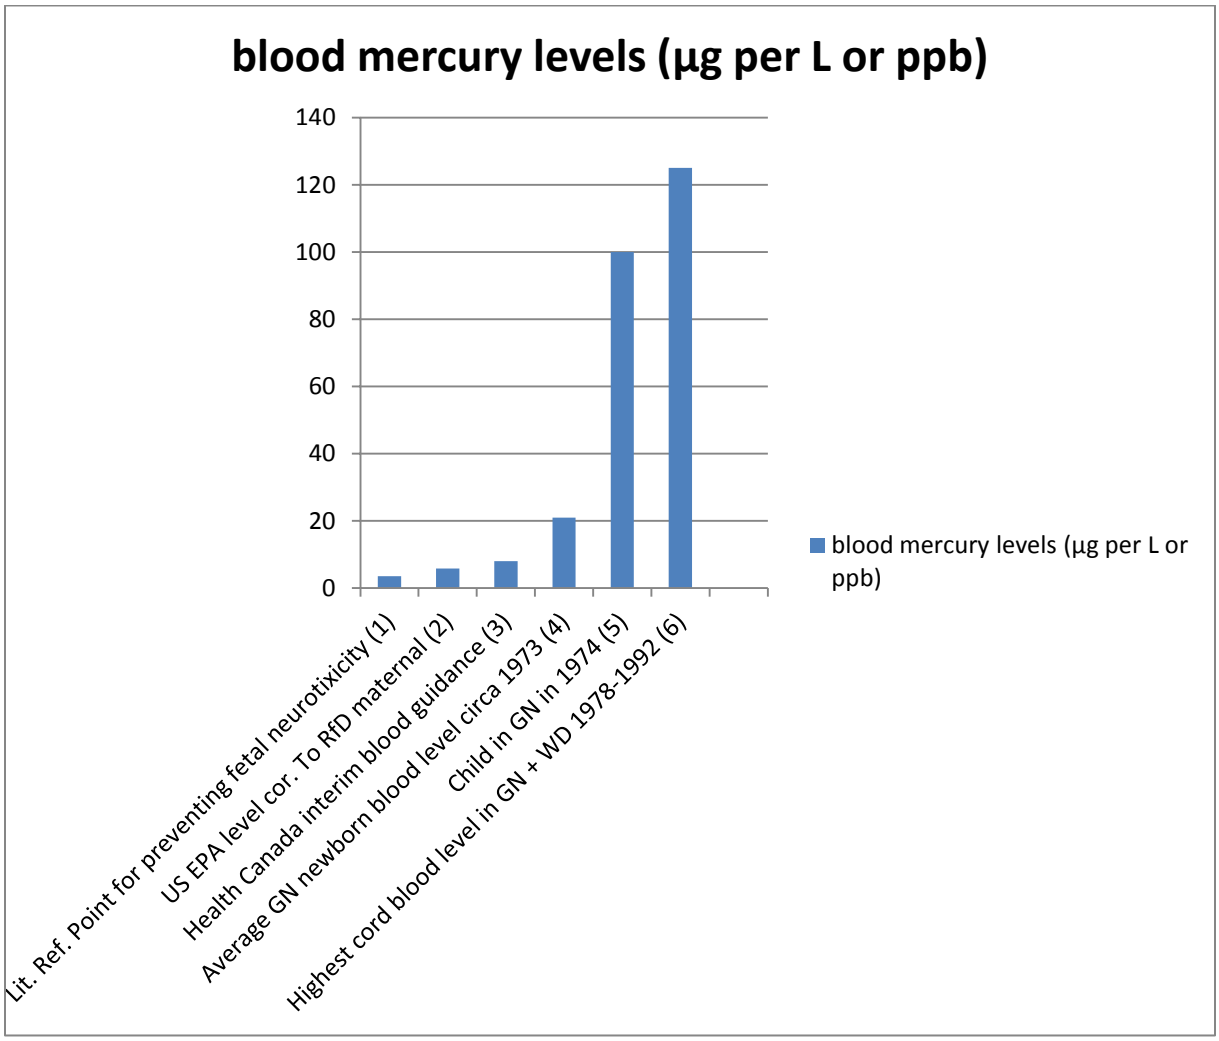
"If these processes [erosion of Indian peoples' use and enjoyment of their traditional resource base, and declining Indian control over reserve life] are not reversed, then in our view, whatever other remedial measures are taken on either reserve will not be of much long term significance. This argues for, among other things, economic reconstruction which incorporates a reliance on the traditional resource base to a large degree, rather than replacing it with industrial wage labour." (Usher 1979, p.369,370)

"The view that somehow northern Indians should be expected to survive economically on their own reserve lands, and that any special access to off-reserve lands and resources is a privilege, to be withdrawn whenever it is no longer convenient to the dominant society, is guaranteed to create social and economic misery on the reserves, ultimately at not small cost to non-native society." (Usher 1979, p.370)

"Troubled and unhappy and demoralized as many individuals may be, they are evidently resolved to build a future with the economic and cultural resources they had in the past, could have in the present, and – they insist – should have in the future. "(Usher 1979, p.363)

7. MERCURY LEVELS IN GRASSY NARROWS BLOOD

a. Mothers, umbilical cords, new borns, children.



(1) Maternal blood mercury levels exceeding the range of values from 3.5 µg/L (15 nmol/L) to 5.8 µg/L (29 nmol/L) should be the reference point for preventing fetal neurotoxicity (Mahaffey et al. 2008)

(2) The US Environmental Protection Agency (US EPA) set the reference dose (RfD) at 0.1 µg/kg daily, equivalent to a maternal blood mercury level of 5.8 µg/L (29 nmol/L). (NRC 2000, US EPA 2001)

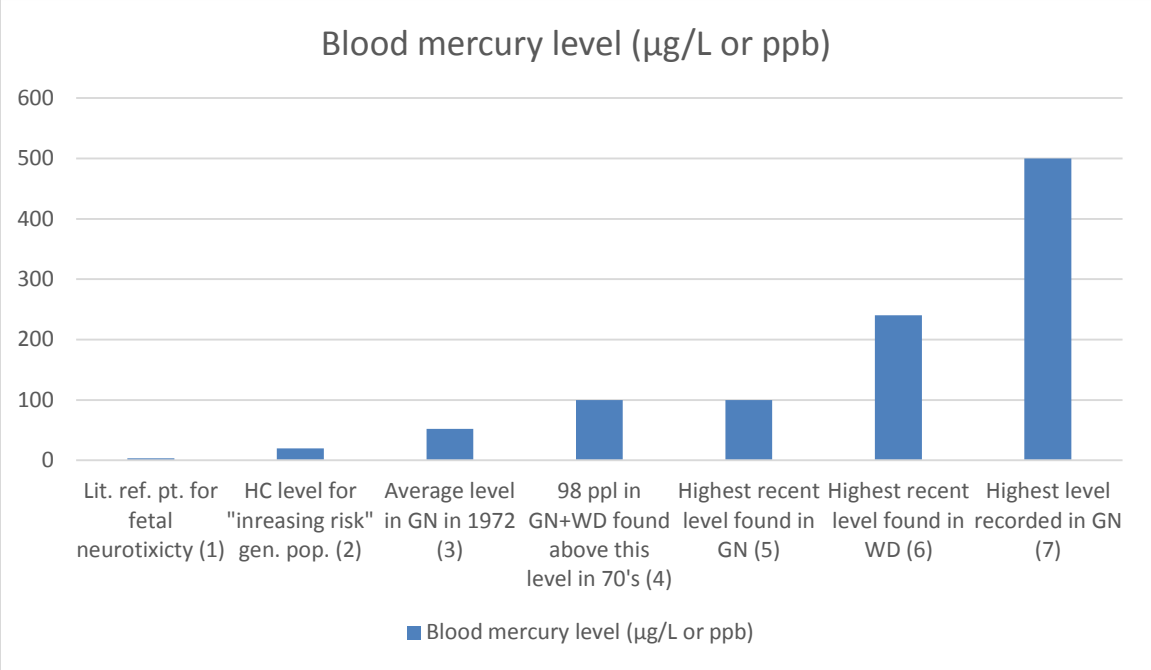
(3) Health Canada has recently developed a provisional interim blood guidance value of 8 µg/L based on the existing provisional tolerable daily intake of 0.2 µg/kg daily for children, pregnant women, and women of childbearing age. (Legrand et al., 2010)

(4) 21 ppm Average GN newborn mercury blood level circa 1973. (Miyamoto, 1980)

(5) 100 ppb – a child in Grassy Narrows was found with blood level higher than 100 ppb in 1974 (Miyamoto, 1980)

(6) Highest cord blood level found in Grassy 1978–1992 was approx. 125 ppb. (Health Canada Medical Services Branch database)

b. Unspecified age and gender.



(1) 3.5 ug/L in blood is the level at which a mother's blood could put her fetus at risk (Mahaffey)
(2) 20 ug/L is the level at which Health Canada considers people exposed to "increasing risk"
(3) 52 ppb average blood level in Grassy in 1972 (Miyamoto, 1980)
(4) 98 ppl in GN +WD were found by Health Canada to have blood levels above 100 in the 70's (Donnan MOE, 1986)
(5) 25 ppm in hair (Mergler and Chan, 2010) corresponds to 100 ppb in blood
(6) 60.3 ppm in hair (Mergler and Chan 2010) corresponds to 241 ppb in blood
(7) 500 ppb highest blood level recorded in GN (Miyamoto 1980, p.11, citing Clarkson)

N.B. Maternal blood level above 100 ppb corresponds to average cord blood levels on average above 170 ppb.
N.B.B. Maternal blood level above 100 ppb corresponds to cord blood level of 300 ppb at 95th percentile.

CHIEF ROGER FOBISTER, SENIOR
on their own behalf and on behalf of all other members of
GRASSY NARROWS FIRST NATION

Applicants

-and-

MINISTER OF NATURAL RESOURCES AND FORESTRY (ONTARIO)
and MINISTER OF THE ENVIRONMENT AND CLIMATE CHANGE (ONTARIO),
and THE ATTORNEY GENERAL OF ONTARIO

Respondents

AFFIDAVIT OF ROGER FOBISTER, SENIOR

I, ROGER FOBISTER, SENIOR, of Grassy Narrows, in the District of Kenora, AFFIRM AND SAY AS FOLLOWS:

1. I am one of the applicants in the within application for judicial review, and as such have knowledge of the matters hereinafter deposed to.

2. I am a member of the Grassy Narrows First Nation (hereinafter "Grassy Narrows"). I have been its elected Chief since April 2014.

3. I live on the Grassy Narrows Reserve. I fish in, and eat fish that I catch from, lakes, streams, and waters that form part of the watershed of the English-Wabigoon river system. This system runs through the Whiskey Jack Forest. Both the river system and this forest I have been taught by elders in my community are part of our traditional territory.

4. The members of Grassy Narrows continue to practice our traditional activities in our traditional territory today, just as I was taught and believe to be true our ancestors did in the past. We have used, and continue to use, all lakes and rivers in our traditional territory for fishing, trapping, hunting, gathering, travel and other traditional pursuits, which are central to our culture, our sustenance, and our economy.

APRIL 2014 MNRF RESPONSE TO BUMP-UP REQUEST

5. As mentioned and referred to in the affidavit of Amber Ellis and David Sone, of Earthroots, in April 2014, the Ministry of Natural Resources and Forestry ("MNRF") filed with the Ministry of the Environment and Climate Change ("MOECC") a response to the January 2014 bump-up request submitted by Grassy Narrows and Earthroots. Our request sought the preparation of an Individual Environmental Assessment ("IEA") that would examine the potential mercury impacts to the English-Wabigoon watershed, its fish, and our people, from clearcut logging authorized under a Forest Management Plan for the Whiskey Jack Forest ("Plan") approved by MNRF in December 2013. In its

response to the bump-up request, MNRF raised a number of issues specific to Grassy Narrows.

6. In its April 2014 response, a copy of which is attached as Exhibit "E" to the affidavit of Amber Ellis and David Sone, MNRF stated that (1) Grassy Narrows did not participate in the public participation process MNRF had established for considering the Plan, and (2) Grassy Narrows only raised the issue of mercury impacts from clearcut logging late in that process.

MAY 2014 REPLY TO APRIL 2014 MNRF RESPONSE TO BUMP-UP REQUEST

7. As mentioned and referred to in the affidavit of Amber Ellis and David Sone, in May 2014, Grassy Narrows and Earthroots filed with MOECC a reply to the MNRF response of April 2014. In our reply to the MNRF response that Grassy Narrows failed to participate during the Plan development process where our mercury concerns could have been addressed, we noted that (1) we have very limited resources available to us to participate in the process and will not benefit from implementation of the Plan, whereas MNRF has relatively extensive resources available to it and will receive stumpage fees and taxes from logging allowed under the Plan, (2) MNRF did not grant the request of Grassy Narrows for participant funding so that we could retain technical assistance to help us in any involvement in the Plan development process, and (3) MNRF refused to fund completion of environmental information-gathering proposed by Grassy Narrows and vetoed funding our choice of ecologist who would have raised the mercury issue. These events during the MNRF development of the Plan occurred during the tenure of

my immediate predecessor as Chief, Simon Fobister. A copy of the reply transmittal letter I sent with Amber Ellis is attached as Exhibit “A” to my affidavit. A copy of the full reply is attached as Exhibit “F” to the affidavit of Amber Ellis and David Sone.

8. In our reply to the MNRF response that Grassy Narrows only raised the issue of mercury impacts from clearcut logging late in the Plan development process, we noted that (1) many of our early communications to the government and to the media on the mercury issue going back to the early 2000s were left out of the tables that accompany the MNRF response to MOECC on our bump-up request, and (2) even if Grassy Narrows had made no comments to the government on the issue, which was not the case, it would still be incumbent on MNRF to ensure there would be no new mercury impacts to fish and to our people arising from clearcut logging authorized under the Plan.

SUBSEQUENT SUPPLEMENTARY SUBMISSIONS IN SUPPORT OF JANUARY 2014 BUMP-UP REQUEST

9. In July 2014, Earthroots filed supplementary submissions on our behalf with MOECC in support of our bump-up request for an IEA, based on information Earthroots received around that time from MNRF arising from a request the group made under the *Freedom of Information and Protection of Privacy Act*. The affidavit of Amber Ellis and David Sone filed in connection with this judicial review application summarizes and attaches that submission. I was aware of this submission at the time, and authorized Joseph Fobister, a member of Grassy Narrows who has assisted me on the bump-up issue, to approve its filing with the MOECC.

10. Subsequent to our filing the July 2014 supplementary submission, Grassy Narrows and Earthroots filed supplementary submissions in September and November 2014 with MOECC in support of our initial January 2014 bump-up request. I authorized Joseph Fobister to approve and sign each of these submissions on behalf of Grassy Narrows. These submissions are mentioned and referred to further in the affidavits of Amber Ellis and David Sone, and Joseph Fobister, respectively.

DECISION REFUSING TO GRANT BUMP-UP REQUEST

11. Despite our submissions and material filed, our bump-up request was refused by, or under the authority of, the Respondent Minister of the Environment in December 2014. In doing so, the refusal decision specifically relied on the mitigation measures MNRF had, in its April 2014 response to our bump-up request, disclaimed the effectiveness of in controlling mercury. The refusal decision simply imposed requirements for monitoring such measures during clearcut logging activity authorized under the Plan. The monitoring measures imposed were those already found in the MNRF guidance document, or that might be imposed through it in the future. A copy of the decision document addressed to Simon Fobister, my predecessor as Chief, is attached as Exhibit “B” to my affidavit.

POST-MOECC DECISION EVENTS

12. In late December 2014, Grassy Narrows issued a media release expressing our concern at, and disappointment with, the decision refusing to grant our bump-up request. A copy of the media release is attached as Exhibit “C” to my affidavit.

13. Also in January 2015, as set out in the affidavit of David Sone of Earthroots, he indicates that following a review of MOECC files he obtained a July 2014 MNRF document purporting to respond to our May 2014 reply submissions. Neither I, nor any other member of Grassy Narrows involved in the bump-up request, was aware of, or had ever seen, this July 2014 document before Mr. Sone brought it to our attention in January 2015. A copy of the July 2014 MNRF response document is attached as Exhibit “M” to Mr. Sone’s affidavit.

GRASSY NARROWS BAND COUNCIL RESOLUTION

14. On or about February 20, 2015, the Band Council of Grassy Narrows passed a resolution authorizing initiation of the within application for judicial review. A copy of the resolution is attached as Exhibit “D” to my affidavit.

EVENTS POST COUNCIL RESOLUTION

15. On or about July 31, 2015, Joseph F. Castrilli and Richard D. Lindgren, counsel for Grassy Narrows, sent letters to the Respondent Ministers requesting rescission of both the Plan and the refusal to grant our bump-up request, as well as reconsideration of our request to grant a bump-up and authorize the undertaking of an IEA on the mercury impacts of the Plan. I am advised by counsel, and I verily believe, that the Ministers have either declined to do so or not responded. Copies of counsel’s letters are attached as Exhibits “E” and “F” to my affidavit.

SUMMARY

16. In summary, at all material times I, my predecessors as Chief, and the members of Grassy Narrows, have feared, and expressed opposition to, the potential impacts that clearcut logging authorized under the Plan will have by releasing mercury to our river system, contaminating the fish we, as a people, consume from these waters, and harming our health and well-being. I have read sections 7 and 15(1) of the *Canadian Charter of Rights and Freedoms* and I believe that approving the Plan and not granting our bump-up request violates our legal rights under section 7 and our equality rights under section 15(1).

17. The history of past industrial discharges of mercury to our river system and the resulting, and on-going, health impacts to my people heighten my fear that clearcut logging will trigger new, or intensify existing, mercury-related health problems in the Grassy Narrows community. Our community is particularly vulnerable to these impacts because we are already dealing with past mercury exposure that has impacted our health and our culture and that has brought our community to the breaking point. Despite our expressions of concern over many years and the many government documents and peer-reviewed scientific studies we have pointed to regarding the impacts of mercury on our health, traditional lifestyle, and culture, the Respondents have approved the Plan and refused to examine under an IEA the potential for serious risk of harm and discrimination, implementation of the Plan will unleash in our community. My community and I are deeply concerned, fearful, disturbed, vexed, and anxious about the increase in mercury levels in our fish that is likely to occur if the Plan is implemented.

18. I affirm this affidavit in support of the within application for judicial review, and for no other or improper purpose.

AFFIRMED before me in the District of Kenora, in the Province of Ontario, this 26th day of August, 2015.

A Commissioner, etc.

RE: Reply of Grassy Narrows and Earthroots to Ministry of Natural Resources' Response to Request for an Individual Environmental Assessment on Whiskey Jack Forest Management Plan 2012-2022

Dear Mr. Wills,

This letter and the attached document are the reply to the Ministry of Natural Resources (MNR) response to the request of Grassy Narrows and Earthroots for an Individual Environmental Assessment (IEA) of the Whiskey Jack Forest Management Plan (FMP).

We expected the MNR to argue that their mitigation measures will work, that mercury will not be released by logging, and that human and environmental health will not be harmed by the implementation of the Whiskey Jack FMP 2012-2022. They did not.

The MNR's overall argument appears to be about process, not outcome. They claim they have followed the letter of the law on forest management planning (regardless of whether the FMP will lead to the release of mercury).

This reply responds to MNR's characterization of the science and of the input from Earthroots and Grassy Narrows, points out relevant scientific issues that they have ignored, and argues (along with the original IEA request) that they have not met the specific requirements of the their own Stand and Site Guide (SSG) and FMP Manual (FMPM) (see section on Page by Page Comments below for a partial list).

More fundamentally, this matter is about protecting the health of people in Grassy Narrows and the health of the environment.

The FMP activities are likely to release mercury into the environment causing harm to human and environmental health. The MNR does not deny this. Therefore, the FMP is flawed, should not be implemented, and should be subjected to an IEA.

If the Crown Forest Sustainability Act (CFSA), FMPM and SSG can be complied with while causing harm to human health and the environment, then they are flawed.
The MNR does not challenge our assertion that the FMP will cause harm through the release of mercury into the environment. Rather the MNR seems to be arguing that they don't have a duty to prevent harm because they have followed the SSG requirements (i.e. that there are no proven measures to mitigate the harm, and that the harm is within the range of that caused by fire).

It is not acceptable for the MNR to knowingly cause harm simply because they don't know how to mitigate it, and because acts of god also cause harm.

The damming of Grassy Narrows' river, the dumping of 9,000 kg of mercury by a Dryden mill into the river, and now clearcutting, have had severe and compounding impacts on Grassy Narrows' health and way of life. Each of these successive actions "followed the rules" at the time but did not apply the precautionary principle, and did not have Grassy Narrows' free, prior, and informed consent. All of these past activities are now known to be harmful.

In this case, there is already sufficient scientific evidence to know that clearcutting will likely cause harm through the release of mercury. There is also sufficient discretion and existing legislation for the MOE to act now to prevent this avoidable harm.

There is one proven measure to prevent this harm – don't permit logging in Grassy Narrows Territory until there are proven ways to avoid harm, and until Grassy Narrows has given their free, prior, and informed consent.

Will Ontario start on a new path towards respect, healing, and reconciliation with Grassy Narrows by requiring an IEA of this logging plan? Or will Ontario repeat the mistakes of the past at the expense of another generation of Grassy Narrows' children?

Thank you for considering our request and for taking these comments (see following document) into consideration.

If you have any questions, or would like elaboration on any points, please do not hesitate to contact us.

Sincerely,

Amber Ellis

A COMMISSIONER FOR TAKING AFFIDAVITS
ERICA STAHL

DEC 22 2014

Mr. Simon Fobister
Grassy Narrows Chief
Grassy Narrows Ontario
P0X 1B0

Dear Mr. Fobister:

Thank you for your interest in the Ministry of Natural Resources and Forestry's (MNRF) proposed Whiskey Jack 2012-2022 Forest Management Plan (Whiskey Jack FMP).

On January 22, 2014, I received your request that MNRF be required to prepare an individual environmental assessment (IEA) for the Whiskey Jack FMP. I am taking this opportunity to inform you that I have decided that an IEA is not required.

Despite my not requiring an IEA be prepared, I understand that concerns were raised in the IEA request with respect to mercury. Therefore, I am imposing conditions on the Whiskey Jack FMP. These conditions will ensure that further monitoring is undertaken and compliance with the most current requirements of the Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (Stand and Site Guide) are assumed by the MNRF.

In making my decision, I have given careful consideration to Whiskey Jack FMP documentation, the provisions of Declaration Order MNR-71, referred to as MNRF's Class Environmental Assessment Approval for Forest Management on Crown Lands in Ontario (Class EA), and the issues/concerns raised in your IEA request. Your concerns together with the reasons for my decision are set out in the attached table.

The Class EA is a process by which MNRF prepares Forest Management Plans (FMPs), including evaluating alternatives, assessing environmental effects, developing mitigation measures, and consulting with the public, without having to obtain approval from me and Cabinet for each individual FMP.

The Class EA has itself been subject to review and approval under the *Environmental Assessment Act* (EAA), which determined, in part, that the application of the Class EA

process would enable proponents to meet the intent and purpose of the EAA. MNRF has demonstrated that it has planned and developed the Whiskey Jack FMP in accordance with the provisions of the Class EA. I am satisfied, therefore, that the purpose of the EAA, "the betterment of the people of the whole or any part of Ontario by providing for the protection, conservation and wise management in Ontario of the environment", has been met for the Whiskey Jack FMP.

The issues/concerns you raised were extensively reviewed. I am satisfied that the issues/concerns have been addressed by the work done to date by MNRF, or will be addressed in future work that is required to be carried out.

With this decision having been made, MNRF can now proceed with the FMP activities set out in the Whiskey Jack FMP, subject to any other permits or approvals required. MNRF must implement the activities in the manner in which they are set out in the Whiskey Jack FMP, and inclusive of all commitments made during the review of the IEA request, mitigation measures, and environmental and other provisions therein.

Again, I would like to thank you for participating in the Class EA process and for bringing your concerns to my attention.

Sincerely,

Agatha Garcia-Wright
Director
Environmental Approvals Branch

c: Mr. Allan Willcocks, Regional Director, Northwest Region, MNR
Mr. Kurt Pochailo, Management Forester, MNR
Mr. Paul Glassford, MNR Senior Advisor, Forest Class EA – Sault Ste. Marie
Mr. John Sullivan, MNR Forest EA Implementation Coordinator
EA File No. 02-07 Whiskey Jack FMP 2012-2022

Whiskey Jack Forest 2012-2022 Forest Management Plan

Ministry's Review of Issues Raised by Grassy Narrows First Nation:

Issues	Response
Clearcut logging and the construction of access roads will disturb the soil causing mercury to travel through the water system, amplifying existing contamination.	The MNRF uses the Stand and Site Guide to develop forest management plans. The Stand and Site Guide provides direction to minimize site disturbance, sediment transport and hydrologic disruption in forest management plans. These reduce the potential for existing mercury mobilization as a result of forest disturbances. The MNRF has informed the Ministry of the Environment and Climate Change (MOECC) that mobilization of mercury following forest disturbance may not be any different than that experienced during natural disturbances. The Whiskey Jack FMP will also mitigate potential adverse effects on the environment including the application of Area of Concern prescriptions, silvicultural ground rules, and best management practices for road construction activities. The MNRF is currently undertaking research to gain further understanding of the potential connection between forestry operations and mercury. This will help inform the development of guidance material used for forest management planning. The MOECC is placing a condition requiring the MNRF to implement forest management planning activities in accordance with the Whiskey Jack FMP and the Stand and Site Guide to ensure that monitoring of the environment, which includes mercury, is undertaken. In addition, a condition requiring the MNRF to follow the most current version of the Stand and Site Guide will be imposed by the MOECC to ensure that the best available guidance is being used for the development of forest management planning. A final condition will be imposed requiring the MNRF to report to the Director, Environmental Approvals Branch, what changes have been made to the Whiskey Jack FMP as a result of any updates to the Stand and Site Guide. I am satisfied that the Stand and Site Guide, used to prepare the Whiskey Jack FMP, provides a methodology to minimize potential mercury contamination in waterways following disturbances such as road construction and clearcut logging.
An increase in mercury will harm fish and terrestrial animals that eat fish, including humans, for a long time period.	The MNRF has followed scientific studies which show that increases in methylmercury concentrations in fish following clearcut operations are generally limited to cases when soils are disturbed. As mentioned above, the Stand and Site Guide provides a methodology for minimizing soil disturbance, such as operating on frozen ground. As the Whiskey Jack FMP has been developed under the provisions of the Stand and Site Guide, the MNRF will minimize soil disturbance, thus minimizing potential mercury movement and contamination in fish and

Issues	Response
	terrestrial animals. The implementation of mitigation measures that the MNRF will be using for the WJFMU, such as emulating natural disturbance patterns, harvesting only in winter on shallow soil sites and reinforcing slopes and bank, will reduce the risk of mercury contamination in animals. I am satisfied that mercury movement and potential mercury contamination in animals will be mitigated using methodologies from the Stand and Site Guide which were incorporated into the Whiskey Jack FMP.
Clearcut logging leads to an increase in mercury, whereas forest fires remove mercury.	The MNRF informed the MOECC that fire intensity is an important factor that influences mercury response. High intensity fires volatilize mercury in the organic soil layer whereas low intensity fires leave this layer undisturbed, with mercury subsequently being mobilized as water tables rise and surface runoff increases. The MNRF has stated that studies conducted by various research groups have found that the highest mercury levels in fish are from watersheds impacted by low intensity fires and lower mercury levels are in fish from watersheds with high intensity fires. The MNRF has indicated that for the 10-year planned renewal and tending operations in the WJFMU, which consists of 745,548 ha of productive forest, prescribed burns will occur during site preparation over an area of 1,069 ha. The MNRF is also planning to undertake natural regeneration which will include clearcut silvicultural system over an area of 25,631 ha. Artificial regeneration will be applied over an area of 27,839 ha and will include planting and seeding. The MNRF claims that harvesting in the WJFMU should emulate natural disturbances (i.e. forest fires). The MNRF also claims that increases in mercury due to clearcut operations would be no different than those experienced for natural occurrences. The requester is suggesting that the production of methylmercury is greater with clearcut operations versus natural forest fires. The Stand and Site Guide acknowledges that mercury dynamics will likely change within the watershed as a result of any type of forest disturbance. MNRF has concluded that the mechanism and magnitude of mercury response differs between burned and harvested watersheds but that some level of mercury response is also found following disturbance by fire. As noted previously, potential mercury movement and contamination is associated with the disruption of soils. To reduce the disruption of soils and the level of mercury movement, the MNRF will implement mitigation measures, such as emulating natural disturbance patterns, harvesting only in winter on shallow soil sites and reinforcing slopes and bank, in the WJFMU.

Issues	Response
	I am satisfied that a combination of forest disturbances will be used during the management of the Whiskey Jack FMP and will include prescribed burns.
The MNRF does not have the science and information to develop prescriptions to mitigate the effect of mercury on terrestrial or aquatic ecosystems.	The Declaration Order stipulates that MNRF shall maintain a program of scientific studies to assess the effectiveness of forest management guides. Results from these studies are used to assist MNRF in the review and revision of forest management guides. The MNRF is currently supporting research projects that are examining patterns in fish mercury bioaccumulation, evaluating the levels of mercury runoff from forest and wetland soils to aquatic systems, and examining the synthesis of land use effects (e.g., mining, hydroelectric, and forest management activities) on watershed mercury cycling and export. The MNRF states that results from its ongoing research will be used during the required periodic reviews of the Stand and Site Guide. Periodic reviews of the Stand and Site Guide are required as part of the adaptive management approach in order to evaluate and improve direction in the guide with respect to minimizing the potential adverse effects of mercury mobilization and subsequent bioaccumulation. The Stand and Site Guide includes a series of predictions or hypotheses. Those with a high degree of uncertainty have been identified as a high priority for testing through an effectiveness monitoring program. The results of the monitoring program, along with other sources of information, are used during periodic reviews of the Stand and Site Guide to ensure the most up to date information is being used when developing forest management plans. The MNRF Stand and Site Guide Background and Rationale for Direction document outlines a mercury response to forest management activities but also identifies mercury export as a priority for effectiveness monitoring. The MOECC is imposing a condition requiring MNRF to conduct monitoring in the Whiskey Jack FMP in accordance with the most current version of the Stand and Site Guide. This will help to ensure that the best available guidance is being used and current research methods to minimize the adverse effects of mercury mobilization and subsequent bioaccumulation are implemented. I am satisfied that the MNRF has prepared the Whiskey Jack FMP in accordance with its Stand and Site Guide and will be subject to any updates based on new research.

Issues	Response
The Whiskey Jack FMP does not contain requirements for ongoing monitoring of mercury levels to determine if approved forest operations will elevate mercury levels.	The MNRF's Declaration Order and the Forest Management Planning Manual contain planning requirements for the monitoring of forest management activities in a forest management plan. The requirements include providing a description of the monitoring of forest operations, with specific provisions for Areas of Concern, to ensure operations are in compliance with the forest management plan. The prevention, minimization and mitigation of the effects of forest management on the environment are addressed through the application of the appropriate guides required by Condition 38 of Declaration Order MNR-71. The development, review and revision of these guides is also mandated by this same condition of the Declaration Order, and directs the MNRF to assess the effectiveness of guides through appropriate scientific research projects and does not implicate ongoing monitoring in the context of individual forest management plans. Concerns such as those identified by the requesters are addressed during the periodic review, and potential revision, of the guides. The Stand and Site Guide acknowledges that mercury dynamics will likely change within the watershed as a result of any type of forest disturbance and that further research and monitoring is required to refine direction in the guide. The MNRF is currently considering the issue of the effects of mercury in the review of the Stand and Site Guide which is scheduled for review in the fall of 2014, with a completion date of December 31, 2015. The MOECC has also established in the Declaration Order a requirement for the formulation and implementation of a Provincial Forest Technical Committee, whose role will be to ensure that Guides are kept current with respect to scientific knowledge and management practices. The committee acts as a review board for proposed changes to existing guides and recommending priorities for new or existing guides. The MOECC is imposing a condition requiring MNRF to conduct monitoring in the Whiskey Jack FMP in accordance with the most current version of the Stand and Site Guide. This will help to ensure that the best available guidance is being used and current research methods to minimize the adverse effects of mercury mobilization are implemented. I am satisfied that the MNRF is considering the effects of mercury in the review of the Stand and Site Guide.
The MNRF did not respond to comments	The MNRF did not receive correspondence during the planning process from the Grassy Narrows First Nation regarding mercury concerns. Concerns regarding honouring the Process Agreement made between

Issues	Response
submitted by you on the mercury issue during the preparation of the Forest Management Plan.	Grassy Narrows First Nation and MNRF, amalgamating the Whiskey Jack and Kenora forests, and being kept informed during the Whiskey Jack FMP planning process were raised by Grassy Narrows First Nation in 2010. The issue of methylmercury was raised by Grassy Narrows First Nation for the first time, prior to the IEA request, in an October 24th, 2013 letter to the Premier, coinciding with Stage 4 of the forest management planning process (review of the Draft Whiskey Jack FMP). The Premier's office responded to Grassy Narrows First Nation on February 11, 2014 and stated that Ontario wanted to continue to work together. The MNRF also received a letter from Grassy Narrows First Nation on October 28, 2013; however, there was no mention of mercury. On April 17, 2014 the MNRF responded to the concerns raised in Grassy Narrows First Nation's October 28, 2013 letter. Earthroots submitted correspondence to the MNRF on October 31, 2013 stating that it was concerned with the impact of clearcutting on mercury levels in fish in local lakes and rivers. The MNRF responded to the concerns identified by Earthroots in a letter dated April 7, 2014, indicating that MNRF applied the direction in the approved Stand and Site Guide to mitigate potential adverse effects of forest management activities on the environment. A more detailed account of the consultation conducted between Grassy Narrows First Nation and the MNRF can be found in the section below. I am satisfied that the MNRF responded to comments submitted by the requesters during the preparation of the Whiskey Jack FMP.
Concerns about the failure to discharge the duty to consult in the development of the Whiskey Jack FMP.	The MNRF informed the MOECC that it followed the public and Aboriginal consultation requirements outlined in the Declaration Order and the 2009 Forest Management Planning Manual for the Whiskey Jack FMP (Phase I). At each stage in the development of the Contingency Plan and Forest Management Plan notification letters were sent to Grassy Narrows First Nation to invite participation in the Forest Management Plan process. Prior to the commencement of the formal public consultation process for the preparation of the Whiskey Jack FMP the MNRF consulted with the Grassy Narrows First Nation. In a letter dated April 20, 2009 the MNRF invited six Aboriginal communities, including Grassy Narrows First Nation, to discuss the development of a customized consultation approach for forest management planning in advance of the formal public consultation. Also in this correspondence, the MNRF offered the Aboriginal communities an opportunity to have a community

Issues	Response
	representative sit on the Forest Management Plan Planning Team and Local Citizens Committee. All of the Aboriginal communities declined the opportunity to develop a customized consultation approach and did not provide representation to the Local Citizens Committee. All of the Aboriginal communities, except for Grassy Narrows First Nation, did provide representatives for the Planning Team. The Invitation to Participate, dated February 3, 2010, was sent by MNRF to the six Aboriginal communities. Grassy Narrows First Nation responded to the invitation on March 17, 2010 in which they outlined their concerns with moving forward with the planning of the Whiskey Jack FMP without a Process Agreement in place. The MNRF responded to Grassy Narrows First Nation's letter on June 22, 2010 and stated that MNRF wanted to work together with Grassy Narrows First Nation. No other formal response was provided by the other five Aboriginal communities; however, representatives from all five communities began attending the Planning Team meetings. A letter was sent on December 14, 2011 inviting the six Aboriginal communities to review and comment on the Long Term Management Direction for the Whiskey Jack FMP. Grassy Narrows First Nation submitted a letter to the MNRF on June 13, 2012 requesting information and providing an overview of their concerns. The MNRF responded on July 6, 2012. The other five Aboriginal communities participated in meetings with the MNRF and continued to participate on the Planning Team. On January 14, 2013 the MNRF sent letters to each of the six Aboriginal communities asking if they would like an information session provided to their communities. On January 31, 2013 the MNRF sent a follow-up letter to the six Aboriginal communities announcing the MNRF's intention to hold public information centres. On April 3, 2013 the MNRF sent another letter to Grassy Narrows First Nation asking if the community would like an information session to be held. The MNRF did not receive a response from Grassy Narrows First Nation.Specific Aboriginal communities, Whitefish Bay First Nation, Wabauskang First Nation and Dalles First Nation, accepted the MNRF's offer of information sessions. An invitation to review the Draft Plan for the Whiskey Jack FMP was sent to the six Aboriginal Communities on July 30, 2013. Grassy Narrows First Nation sent a letter to the Premier of Ontario dated October 24, 2013 outlining their concerns with the undertaking and highlighting mercury concerns. The Premier's office responded on February 11, 2014 and stated that Ontario wanted to continue to work together. A letter was also submitted by Grassy Narrows First Nation

Issues	Response
	to the MNRF on October 28, 2013 and was responded to by the MNRF on April 17, 2014. Whitefish Bay First Nation was the only other Aboriginal community to respond to the MNRF's invitation to review the Draft Plan; however, due to circumstances within the community a meeting was never held. On December 23, 2013 the MNRF invited the six Aboriginal communities to inspect the final Whiskey Jack FMP. Grassy Narrows First Nation submitted an IEA request and no response was received by the MNRF from the other communities. I am satisfied that the duty to consult has been met.

RELEASE Monday Dec. 29, 2014

ON says 'no' to environmental assessment of clearcut mercury impacts in Grassy Narrows

Science indicates that clearcuts will deepen the tragedy of mercury poisoning

Grassy Narrows – On the night before Christmas Grassy Narrows First Nation received notice that Ontario is rejecting the community's request for an Individual Environmental Assessment of the mercury impacts from the controversial final plan for clearcut logging on their homeland. Grassy Narrows is concerned that the planned clearcut logging will harm the health of their families by raising mercury poison levels in local fish – a traditional staple.

Ontario's logging plan makes no mention of mercury, and contains no special measures to account for the fact that Grassy Narrows' homeland is the site of Canada's most infamous case of mercury poisoning arising from 9,000 kg of mercury that was dumped into their river by a paper mill upstream in the 1960's. Scientific studies indicate that clearcut logging in the boreal forest can raise mercury in fish to unsafe levels.

"Ontario has ignored our voices and is planning to force more devastating clearcuts on our people without even applying their own Individual Environmental Assessment process," said Joseph Fobister, a Grassy Narrows land-user and businessman. "It makes me sad that our people will become even sicker if the government allows the logging industry to poison the fish that we eat."

"I am disheartened by this hurtful decision," said Chief Roger Fobister Sr. of Grassy Narrows. "It seems that our health and our culture do not matter to the government as they attempt to force their clearcut plans on us. The only honourable way forward here is to work together to gain our agreement before our land and water are used."

Grassy Narrows' request was an important test of Ontario's environmental laws. People with concerns can request an Individual Environmental Assessment (IEA) of a logging plan if they believe that environmental and human health are not being protected. However, such requests are rarely, if ever, granted since the current regulatory regime was established in 1994. The Timber Class Environmental Assessment for all logging which was approved in 1994 did not consider the mercury impacts from logging as they were not known until 1997.

"This is a glaring failure to use our environmental laws to ensure that the health of people and our environment are safe from the harmful impacts of industrial clearcut logging," explained Amber Ellis, Executive Director of Earthroots, which supported Grassy Narrows in their request. "It is hard to imagine a situation that requires an Individual Environmental Assessment more than the mercury issue in Grassy Narrows. What use is an Individual Environmental Assessment process when every request is rejected?"

The Ontario Ministry of Natural Resources and Forestry (MNRF) writes that "[t]he potential for forest management activities to result in mobilization of terrestrial mercury into aquatic systems is well documented and a serious concern." MNRF also admits that "[T]here are not mitigation measures specific to mercury in the [logging rules]," and "[t]here are no claims that the [logging rules] direction and application of the [logging rules] will mitigate or eliminate Hg mobilization."

And yet the Ontario Ministry of Environment and Climate Change has given the green light to the MNRF to authorize clearcut logging in one of the most mercury impacted parts of the planet, against the loud objections of Grassy Narrows where many families already suffer the debilitating symptoms of mercury poisoning.

BACKGROUND

Kathleen Wynne visited Grassy Narrows in the summer of 2012 as Minister of Aboriginal Affairs and promised to rebuild Ontario's relationship with Grassy Narrows. Instead, on December 23rd, 2013 the Wynne government approved unilateral plans for another decade of clearcut logging in Grassy Narrows Territory against the will of the community and without consent. Grassy Narrows' request for an Individual Environmental Assessment provided an opportunity for the Wynne Government to use their secure majority to ensure that logging does not deepen the mercury problem in Grassy Narrows.

The Whiskey Jack Forest Management Plan includes dozens of large clearcuts on Grassy Narrows Territory, one alone nearly the size of pre-amalgamation Toronto (79 sq km vs. 97 sq km). This logging will further erode the Aboriginal and Treaty Rights of Grassy Narrows which depends on the forest to sustain their families and to practice their culture through fishing, hunting, trapping, medicine harvesting, ceremony and healing for all generations.

The unilateral plan makes exclusive use of clearcut logging, a practice which has been scientifically reported to raise mercury levels in fish to dangerous levels. The most extensive study found that 100% of walleye and pike in studied clearcut boreal lakes in Quebec had mercury levels above the World Health Organization limit for safe human consumption, compared to only 18% in unlogged lakes (Gracia and Carignan 2005).

The Supreme Court of Canada ruled on July 11th, 2014 that Ontario must respect Grassy Narrows' Treaty rights when authorizing logging on their land, and has a duty to protect a meaningful ability for Grassy Narrows people to practice their right to fish and hunt.

The new logging plan was scheduled to take effect on April 1st, 2014 but then MNRF Minister Orazietti, promised that no logging would occur within 60km of Grassy Narrows until April 1st, 2015.

Ontario's rejection of Grassy Narrows' request for Individual Environmental Assessment gives the green light for clearcut logging to proceed over the long-standing objections of the people of Grassy Narrows.

QUICK FACTS

"There is clear indication that forest harvesting leads to increases in Hg_{tot} and MeHg loading, as well as increased bioaccumulation in downstream aquatic biota." (Bishop et al. 2009 review paper)

"The potential for forest management activities to result in mobilization of terrestrial mercury into aquatic systems is well documented and a serious concern." (MNRF response to IEA request p.19 ph3)

"There are no claims that the [logging rules] direction and application of the [logging rules] will mitigate or eliminate Hg mobilization." (MNRF response to IEA request p.10 ph3)

"Because there are no studies which identify or evaluate mitigation measures to minimize mercury mobilization following disturbance there are not mitigation measures specific to mercury in the [logging rules]." (MNRF response to IEA request p.19 last ph)

"MNR has made no further commitments in the [logging plan] to address issues raised by the requesters." (MNRF response to EA request p.7)

The logging rules to deal with mercury impacts have "a high degree of uncertainty" and have been identified as a "high priority for testing through an effectiveness monitoring program." (MNRF Guide for Conserving Biodiversity at the Stand and Site Scale)

A 2011 MNRF review of the effectiveness monitoring program found that "it was agreed that current work is not sufficient to address Aquatic Ecosystem Processes uncertainties" including mercury impacts.

BAND COUNCIL RESOLUTION

Chronological No. 3681

File Reference No.

This is Exhibit P referred to in the affidavit of ROGER FORSTER SR.

Affirmed sworn before me, this 26th day of AUGUST 2015

A COMMISSIONER FOR TAKING AFFIDAVITS

ERICA STAHL

The Council of the: GRASSY NARROWS FIRST NATION		Capital Account
Date of duly convened meeting: D M Y 20/02/2015	PROVINCE ONTARIO	Revenue Account $

DO HEREBY RESOLVE:

February 20, 2015

Resolution to begin litigation on mercury impacts of logging

Whereas:

- Our traditional homeland has been heavily impacted by mercury pollution in our waterways, including large volumes of mercury that were emitted from the Dryden paper mill in the 1950s-60s, and this mercury pollution has had a devastating impact on our fish, our environment, our health, our economy, our culture, our way of life, and other aspects of our rights and interests;
- We have learned about scientific research showing that logging, particularly clearcut logging in the boreal forest, increases the release of mercury into waterways;
- The Government of Ontario's Ministry of Natural Resources nevertheless approved a Forest Management Plan for the Whiskey Jack Forest in December 2013 that provides for large amounts of clearcut logging in our traditional homeland;
- We therefore submitted a "bump-up" request that asked the Government of Ontario's Ministry of Environment to conduct an individual environmental assessment of that Forest Management Plan to examine the impacts of mercury;
- That request was rejected in December 2014;
- The Canadian Environmental Law Association has offered to work with us on a legal challenge to these decisions of the Government of Ontario;

Now therefore we resolve that:

1. We retain Joseph F. Castrilli and Richard D. Lindgren, lawyers at the Canadian Environmental Law Association (the CELA lawyers) for the purpose of beginning an application for judicial review in the Ontario Divisional Court of:
   a. the decision of the Ontario Ministry of Natural Resources to approve the 2012-2022 Forest Management Plan for the Whiskey Jack Forest under the *Crown Forest Sustainability Act* (Ontario), and
   b. the decision of the Ontario Ministry of Environment to reject our request for an individual environmental assessment, also known as a "bump-up", under the *Environmental Assessment Act* (Ontario).

The Honourable Bill Mauro
Minister of Natural Resources and Forestry
99 Wellesley Street West
Room 6630, 6th Floor, Whitney Block
Toronto, Ontario M7A 1W3

Dear Minister Mauro:

RE: Ministry of Natural Resources and Forestry ("MNRF") - Whiskey Jack Forest Management Plan – 2012-2022 ("WJFMP")

We are the solicitors for Grassy Narrows First Nation and four individuals ("Grassy Narrows") concerning the above matter.

We have been instructed to request that you exercise your authority under s. 9 of the *Crown Forest Sustainability Act, 1994*, S.O. 1994, c. 25 ("*CFSA*"), and (1) rescind, or order the rescission of, the approval of the WJFMP issued under your authority in December 2013 under the *CFSA*, and (2) substitute an order that MNRF not operate, or allow third parties to operate, under the authority of the WJFMP until such time as MNRF has complied with Part II of the *Environmental Assessment Act*, R.S.O. 1990, c. E.18 ("*EAA*"), and prepared an indvidual environmental assessment ("IEA") examining the potential for clear-cut logging authorized under the WJFMP to release mercury to the environment, elevate mercury levels in water and fish, and produce adverse effects on the health of people who eat the fish.

If our office has not received a copy of your (1) rescission order, and (2) substitution order by Tuesday, August 11, 2015, we have been instructed by Grassy Narrows to initiate proceedings in this matter, which proceedings may be broader in the scope of relief sought than the request contained in this letter.

Yours truly,

MINISTER OF NATURAL RESOURCES AND FORESTRY (ONTARIO)
and MINISTER OF THE ENVIRONMENT AND CLIMATE CHANGE (ONTARIO),
and THE ATTORNEY GENERAL OF ONTARIO

Respondents

AFFIDAVIT OF JOSEPH FOBISTER

I, JOSEPH FOBISTER, of Grassy Narrows, in the District of Kenora, AFFIRM AND SAY AS FOLLOWS:

1. I am a Band member of the Grassy Narrows First Nation ("Grassy Narrows"), and I have acted as advisor to former Chief Simon Fobister on logging issues, and negotiator for Grassy Narrows on logging issues between 2007 and 2014. I have continued to work with

current Chief Roger Fobister, Senior on the bump-up request referred to below and matters arising from that issue. As such I have knowledge of the matters hereinafter deposed to.

2. I live on property located on the Grassy Narrows Reserve. I fish in the English-Wabigoon river system and its watershed and I eat the fish that I catch from these waters. I mostly eat walleye, and to a lesser extent I eat pike, and lake trout, as did my father and most people in the Grassy Narrows community, as these are our traditionally preferred fish species. The river system runs through the Whiskey Jack Forest most of which, I have learned through elders in our community, we regard as our traditional territory, or homeland.

FIPPA REQUEST

3. As mentioned and referred to in the affidavit of Simon Fobister, Grassy Narrows and Earthroots filed a January 2014 bump-up request with the Ministry of the Environment and Climate Change ("MOECC") asking that the 2012-2022 Whiskey Jack Forest Management Plan ("Plan"), which had been approved by the Ministry of Natural Resources and Forestry ("MNRF") in December 2013, be subjected to an Individual Environmental Assessment ("IEA"). The purpose of the bump-up request was to examine the potential impacts on the environment and human health at Grassy Narrows from the release of mercury to the English-Wabigoon river system watershed caused by clearcut logging allowed under the Plan.

4. In conjunction with the bump-up request, and in an attempt to learn the extent to which existing or potential mercury impacts had been considered by MNRF before it made its December 2013 decision to approve the Plan, in late January 2014, I filed on behalf of Grassy Narrows a request for information with the MNRF under the *Freedom of Information and Protection of Privacy Act* ("*FIPPA*"). The purpose of the *FIPPA* request was to seek all records as defined under *FIPPA* that related to mercury contamination, or potential mercury contamination, or mercury in so far as such information related to the Plan and for the period 1997 to 2014. A copy of my *FIPPA* request is attached as Exhibit "A" to my affidavit.

5. In March 2014, I received correspondence from Laura Lee May, an MNRF Information Coordinator, who indicated that records responsive to my request would be captured within the records of those requested by another requester. A copy of the correspondence from Ms May is attached as Exhibit "B" to my affidavit.

6. In July 2014, I exchanged email correspondence with Bernadette O'Neill, a *FIPPA* Senior Analyst with MNRF in which I indicated that I only wished to receive records responsive to my request that were not provided to Earthroots, the source of the other request. As noted in the affidavit of David Sone in connection with the within application for judicial review, he also had made, in January 2014, a similar, but more specific, request of MNRF under *FIPPA*. Ms O'Neill advised me in her July email that there were no additional records responsive to just my request as all of the responsive records were

considered responsive to both requests. A copy of this exchange of email correspondence is attached as Exhibit “C” to my affidavit.

7. Because it would have duplicated information that Earthroots was receiving, or in the process of receiving, from MNRF, as well as needlessly expensive, I did not further pursue the Grassy Narrows *FIPPA* request but was content to wait for the results of the Earthroots *FIPPA* request in furtherance of receiving information we were both seeking in support of the January 2014 bump-up request about the extent to which mercury had been considered prior to the MNRF decision to approve the Plan.

SUPPLEMENTARY SUBMISSIONS FILED WITH MOECC

8. As mentioned and referred to in the affidavit of Chief Roger Fobister, Senior in the within application for judicial review, Grassy Narrows and Earthroots filed supplementary submissions in September and November 2014 with the Ministry of the Environment and Climate Change (“MOECC”). Earthroots also filed a July 2014 supplementary submission by itself, but also on behalf of Grassy Narrows, which is attached to the affidavit of Amber Ellis and David Sone, and that addresses information received as a result of *FIPPA* requests filed by Earthroots. These supplementary submissions were all in support of the January 2014 bump-up request.

9. In this regard, Chief Fobister authorized me to approve the filing of all three of the supplementary submissions, and to sign the September and Novermber submissions in his stead, on behalf of Grassy Narrows. As a result, I am familiar with all three of these

submissions, but particularly the September and November submissions as they relate to matters directly impacting the people of Grassy Narrows from a lay perspective. On scientific and technical issues generally, Earthroots took the lead as co-authors of the submissions.

SEPTEMBER 2014 SUPPLEMENTARY SUBMISSIONS

10. In September 2014, Grassy Narrows and Earthroots filed with MOECC supplementary submissions in support of the bump-up request. These supplementary submissions are attached as Exhibit “H” to the affidavit of Amber Ellis and David Sone of Earthroots. As can be seen from the September 2014 submissions, a significant portion of the document was devoted to summarizing expressions of concern and fears of future harm by members of the Grassy Narrows community communicated to the media and the Ontario government during the 15-year period from early 1999 to March 2014 on the issue of clearcut logging generally, and mercury releases anticipated from clearcut logging, including that to be authorized under the Plan. These are fears I share given my long experience living in the Grassy Narrows community.

11. The September 2014 submissions also reported numerous neurological ailments members of the Grassy Narrows community are experiencing that they fear are caused by their exposure to mercury because they have eaten fish caught in our waters that were contaminated by past industrial discharges of mercury to the river system and its watershed.

NOVEMBER 2014 SUPPLEMENTARY SUBMISSIONS

12. In November 2014, Grassy Narrows and Earthroots filed further supplementary submissions with MOECC in support of the January 2014 bump-up request. A copy of these submissions is attached as Exhibit "I" to the affidavit of Amber Ellis and David Sone. These submissions note, based largely on government documents or scientific studies, that subsistence fishing, an important component of the lifestyle and culture of the Grassy Narrows community and one that helps to strengthen our social fabric and traditions, has been severely damaged by mercury contamination. This is an observation I agree with from my first hand experience living in the Grassy Narrows community. I fear that clearcut logging would prolong and deepen the mercury problem throughout our traditional territory causing more damage to our health, culture, economy, and social fabric.

13. I affirm this affidavit in support of the within application for judicial review, and for no other or improper purpose.

AFFIRMED before me in the District of Kenora, in the Province of Ontario, this 26th day of August, 2015.

A Commissioner, etc.

Dear Ms. May:

Re: Request for Information under the Freedom of Information and Protection of Privacy Act

Please consider the following as a request for information under the *Freedom of Information and Protection of Privacy Act* (*FIPPA*):

We request all records as defined under *FIPPA* that relate to mercury contamination, the potential for mercury contamination or mercury in so far as information in these three areas relates to the forest management plan covering forest management activities for the Whiskey Jack Forest for the period 2012 – 2022.

We are requesting all records for the period covering January 1, 1997 to January 22, 2014.

Enclosed please find a cheque for the sum of $5.00 (five dollars) made payable to the Minister of Finance.

If you have any questions with respect to the above please do not hesitate to contact me at 807-407-2745 or via email at jbfobister@gmail.com.

Yours truly,

Joseph Fobister

A COMMISSIONER FOR TAKING AFFIDAVITS
ERICA STAHL

Mr. Joseph Fobister
General Delivery
Grassy Narrows, Ontario POX 1 BO

MNR Reference Number: A-2014-000231BMO

Dear Mr. Fobister:

I am responding to your February 11, 2014 request, made under the Freedom of Information and Protection of Privacy Act (the Act), for

> "All records that relate to mercury contamination, the potential for mercury contamination or mercury ins so far as information in these three areas relates to the forest management plan covering forest management activities for the Whiskey Jack Forest for the period 2012-2022.
>
> All records for the period covering January 1, 1997 to January 22, 2014."

The Ministry received a request for similar information (see wording below) and based on discussions with staff in the Kenora District Office and the Northwest Regional Office they believe that the records responsive to your request would be captured within the records of the earlier request.

Wordlg of earlier request:

> all records as defined under FIPPA in the possession, management or control of the MNR from January 1, 1997 to January 22, 2014 that address, identify or evaluate:
>
> (a) the potential for logging activities (particularly clear cutting) authorized under the Forest Management Plan for the Whiskey Jack Forest for the period 2012-2022 to cause, or materially contribute torthe release of mercury into local watercourses;

(b) the potential for logging-related mercury releases to form methyl mercury that may be ingested, up taken or bioaccumulate within fish, wildlife or humans in the vicinity of the Whiskey Jack Forest;
(c) the likelihood or significance of the effects of logging-related mercury releases, or subsequent methyl formation, *upon fish,* wildlife *or humans in the vicinity of the* Whiskey Jack Forest;
(d) the mitigation measures needed to prevent, reduce or minimize logging-related mercury releases, methyl mercury formation and the above-noted impacts on ecosystem and human health in the vicinity of the Whiskey Jack Forest;
(e) the detailed requirements of an environmental monitoring program capable of detecting and assessing the logging-related mercury releases, rnethyl mercury formation and the above-noted impacts on ecosystem and human health in the vicinity of the Whiskey Jack Forest; and
(f) the detailed requirements of contingency measures or corrective action that will be taken by MNR (or logging companies) if logging-related mercury releases result in methyl mercury formation and cause the above-noted impacts upon ecosystem or human health in the vicinity of the Whiskey Jack Forest."

The Ministry has issued an interim fee decision on the earlier request and is waiting to hear if the requester wishes to proceed, We are asking the requester to pay 50% of the estimated fee and have also informed the requester that the Ministry is taking an additional 30 days to process the request. If the other request proceeds and you are willing to wait, then you will only have to pay for the photocopies of the records, which at this time we anticipate there being approximately 30 pages ($6.00).

However, if the requester in the earlier request does not wish to proceed or you are unwilling to wait then you will be required to pay the fee deposit. The estimated fee for the records that may be released has been calculated as follows:

Search time (7.50 hours x $30.00 per hour)	$225.00
Record preparation (0.25 hour x $30.00 per hour)	$7.50
Photocopies (30 pages x $0.20 per page)	$6.00
Total	**$238.50**

The Act states that a government organization may require a requester to pay a deposit equal to 50 percent of the estimated fee. Your written acceptance of the fee and a deposit of $119.25, payable to the Minister of Finance, is required before we can fully process your request. Please remit payment to:

_._-_M irri+ *rrrFe** a roes _____Information
Management Section
Information, Privacy & Records Management Unit 300
Water Street, 3rd Floor North
Peterborough, ON K9J 8M5

Visa or Mastercard payments can be made by calling Leeanne Battah at 705-755-1653 and providing your account number and expiry date.

Please contact Bernadette O'Neill at (705) 755-1625 fo' disduss how you would like to proceed.

Sincerely,

L.L. May

Laura Lee May
Information, Privacy and Records Management Coordinator

Section 57 - Fees

1. A head shall require the person who makes a request for access to a record to pay fees in the amounts prescribed by the regulations for,
   (a) the costs of every hour of manual search required to locate a record;
   (b) the costs of preparing the record for disclosure;
   (c) computer and other costs incurred in locating, retrieving, processing and copying a record;
   (d) shipping costs; and
   (e) any other costs incurred in responding to a request for access to a record.

Estimate of costs

3. The head of an institution shall, before giving access to a record, give the person requesting access a reasonable estimate of any amount that will be required to be paid under this Act that is over $25.

Waiver of payment

4. A head shall waive the payment of all or any part of an amount required to be paid under subsection (1) if, in the head's opinion, it is fair and equitable to do so after considering,
   (a) the extent to which the actual cost of processing, collecting and copying the record varies from the amount of the payment required by subsection (1);
   (b) whether the payment will cause a financial hardship for the person requesting the record;
   (c) whether dissemination of the record will benefit public health or safety; and
   (d) any other matter prescribed in the regulations.

Review

5. A person who is required to pay a fee under subsection (1) may ask the Commissioner to review the amount of the fee or the head's decision not to waive the fee. R.S.O. 1990, c. F.31, s. 57(25).

Disposition of fees

6. The fees provided in this section shall be paid and distributed in the manner and at the times prescribed in the regulations.

O.-Rgg..46D-s 7

1. If a head gives a person an estimate of an amount payable under the Act and the estimate is $100 or more, the head may require the person to pay a deposit equal to 50 per cent of the estimate before the head takes any further steps to respond to the request.

2. A head shall refund any amount paid under subsection (1) that is subsequently waived.

This is Exhibit C referred to in the affidavit of JOSEPH FOBISTER
ES affirmed sworn before me, this 26th
day of AUGUST 2015.

AFFIDAVIT OF WILLIAM FOBISTER, SENIOR

I, WILLIAM FOBISTER, SENIOR, of Grassy Narrows, in the District of Kenora, AFFIRM AS FOLLOWS:

1. I am one of the applicants in the within application for judicial review, and as such have knowledge of the matters hereinafter deposed to.

2. I was a Councilor of the Grassy Narrows First Nation (hereinafter “Grassy Narrows”) Band Council from 1980 to 1992. I was the elected Chief of Grassy Narrows from 1992 to 2002. From 2003 until the present time, I have again been a Councilor of the Grassy Narrows Band Council.

3. I live on property located on the Grassy Narrows Reserve. Like many of our people, I fish various lakes, streams, and waters of the watershed that is part of the English-Wabigoon River System and I eat fish that I catch from these waterways. I have learned from elders in my community and I believe it to be true that this river system runs through our traditional territory, or homeland, in the Whiskey Jack Forest and that our people have always occupied and used it for traditional activities like hunting, trapping, fishing and harvesting of plants for food and medicine.

4. I was born on my family’s trapline in 1946. My father was a trapper and a small-scale commercial fisherman, and my siblings and I were raised in the Anishinaabe way. We grew up on a diet that consisted primarily of wild fish and game. I ate fish from the English-Wabigoon River System every day. While I loved it, we did not have other options: wild fish was the cheapest, most reliably available source of protein accessible to my family. We survived off of fishing growing up.

5. I left my traditional territory for four to five years (1954-1958) as a child to attend Residential School. Luckily, my father had already taught me how to fish and work the traplines. When I was thirteen years old I got my first job as a fishing guide in Grassy

Narrows. I worked as a guide through the late 1950s into the mid 1960s. When guiding, I ate fish multiple times a day. I also brought fish home to feed my family daily, including my wife when she was pregnant.

6. After I stopped working as a guide I continued to catch and eat fish from the English-Wabigoon River System multiple times a week. The government told us that the river was contaminated in 1970 after which my father had to shut down his commercial fishing operation. Wild fish remained an extremely important part of my diet, as it was cheap and accessible, and this is our traditional way of life as Anishinaabe people. I love my way of life.

7. To this day, I continue to catch and eat fish from the English-Wabigoon River System several times a week. I also catch and eat fish from lakes from our homeland upstream from the English-Wabigoon River System. Most of the fish that I eat is walleye, which is my favourite and traditional fish. It connects me to my family and my culture, and store-bought or frozen fish is not as good. Health Canada says that it is safe to eat whitefish and walleye from the English-Wabigoon River System if the walleye weighs less than one (1) pound. If I were to limit myself to walleye under one pound it would seriously limit my catch and make the effort of feeding my family with fish much greater as I would have to throw out much of my catch, as my net catches fish of all sizes.

8. I have been examined by the Mercury Disability Board and diagnosed with symptoms consistent with mercury poisoning. As a result of my exposure to mercury I have no

sense of taste, no sense of smell, tunnel vision, twitching and weakness in my legs, weakness and tingling in my hands, and intermittent tingling and cramps in my legs. I was found eligible for compenation by, and I receive $350.00 each month from, the Mercury Disability Board.

9. In April 2010, I was interviewed by the CBC regarding the effects I have experienced due to exposure to mercury. Exhibit “A” to my affidavit contains underlined excerpts of my comments to the CBC, which state: “During the ‘60s, we were in full bloom, fishing, guiding, everything, that we did and and we thought everything was okay. But not until we’re seeing some of our fish acting weird and dying off, that’s when…there is something wrong….My symptoms is my numbness and loss of sensation and my vision. My speech is kind of getting pretty sloppy. My taste, I lost my taste. I lost my smell. I can’t smell any more.” I have reviewed these excerpts and they are true and accurate. These excerpts were included in a larger document Grassy Narrows filed with the Ministry of the Environment in September, 2014 in an attempt to persuade the Ministry to examine through an individual environmental assessment the effects of mercury released by clearcut logging authorized by the Respondent Minister of Natural Resources for the Whisky Jack Forest (the “Plan”) for the period 2012 to 2022.

10. I have also been examined on several occasions by a team of doctors from Japan, lead by Dr. Masazumi Harada. Dr. Harada is now deceased but his diagnosis was, and that of his team remains, that I have mercury poisoning. Over time, my symptoms have gotten worse and I fear that my health will continue to deteriorate.

11. My wife was recently diagnosed with symptoms consistent with mercury poisoning, and two of my grandchildren have also been so diagnosed, by doctors in Canada. I tell my children and grandchildren not to eat too much fish. However, the other options are not good either. Moose and deer populations are declining in our traditional territory, and the shift from a purely traditional diet to one more reliant on Western foods is causing higher incidences of obesity and diabetes in our community. Store food is expensive and many of our people are poor. Also, the activity of catching, cleaning, and preparing fish, being out on the water, is healthy for our people, and an important part of our culture. When we stop fishing, it is sometimes replaced by idleness, which is not healthy.

12. I am extremely concerned about future mercury exposure. I do not believe that the discharges of mercury from the Dryden plant in the early 1960s have been cleaned up, and I am concerned that my family and I are being exposed to chronic, low-level doses of mercury from that source. I am even more concerned that additional mercury could be released from the forest floor as a result of clearcutting. I fear that my existing symptoms will get worse if I am exposed to yet more mercury. I fear for the health of my wife, children, and grandchildren. I cry when I think about my grandchildren and the suffering they have had to endure through no fault of their own.

13. Yet, despite my fears I will never give up eating fish from the English-Wabigoon River System. This land is who I am. Fishing is who I am. It connects me to my father and my

culture. Even if more mercury is allowed to enter the river system, I will not break my connection to my ancestors and my land. Grassy Narrows will never relocate.

14. I want my great-grandchildren and great-great-grandchildren to have a safe environment so they can grow up the way I grew up. I want them to be able to fish off the dock, and out on the trapline, and not worry about losing their sense of taste, experiencing seizures, or creeping weakness in their limbs. I am strongly opposed to the clearcut logging recently authorized by the Respondents under the Plan. I fear that it will release more mercury into the watershed, contaminate the fish we eat from those waters, and harm our health and well-being. I have read sections 7 and 15(1) of the *Canadian Charter of Rights and Freedoms*. I believe the decision of the Respondents to approve clearcut logging and not study its effects on the people of Grassy Narrows would be in violation of our legal and equality rights under those sections. We do not want clearcut logging on our territory, and the Respondents have failed to present an acceptable alternative.

15. I affirm this affidavit in support of the within application for judicial review, and for no other or improper purpose.

AFFIDAVIT OF SHERRY FOBISTER

I, SHERRY FOBISTER, of Grassy Narrows, in the District of Kenora, AFFIRM AND SAY AS FOLLOWS:

1. I am one of the applicants in the within application for judicial review, and as such have knowledge of the matters hereinafter deposed to.

2. I am a member of the Grassy Narrows First Nation ("Grassy Narrows") and I live on the Grassy Narrows Reserve. I eat fish caught in various bodies of water that form part of the watershed of the English-Wabigoon River System, which runs through our traditional territory, in the Whiskey Jack Forest. I learned about our traditional territory and the traditional activities, such as hunting, trapping, and fishing, that we continue to practice as did our ancestors, from elders in my community. They taught me these activities and how they are practiced throughout our traditional territory. Recently, I have learned that clearcut logging for this Forest was approved by the Respondents as part of a Forest Management Plan (the "Plan") for the period 2012 to 2022.

3. I was born in 1978 on the Grassy Narrows Reserve and have lived here my entire life, with the exception of the nine-year period 1992-2001 when I attended school during the week, first in Kenora, Ontario and later in Winnipeg, Manitoba, returning to the Reserve on weekends. Even while I was away at school, I continued to eat wild food from the English-Wabigoon area because my parents would send me food, including fish, from the region to supplement my diet.

4. I suffered from seizures as a child, and continued to suffer from them as a young adult. At the age of eighteen (18), I was diagnosed with a neurological condition by a doctor in Winnipeg.

5. I went on anti-seizure medications in order to control my seizures. I have not had a seizure for the last eight to ten (8-10) years.

6. After I moved back permanently to Grassy Narrows, I got a job at the Band Office, and now support my three children, ages fifteen (15), seven (7), and two (2). I also support my mother and my nephew. Both my eldest child and my nephew have been diagnosed with symptoms consistent with mercury poisoning and receive compensation from the Mercury Disability Board. I am currently getting my middle child tested by the Mercury Disability Board because he has the same or similar symptoms as my eldest child.

7. I follow the government's guidelines around fish consumption to minimize my family's exposure to mercury, but I am deeply concerned about further exposing myself and my family to the mercury that is already in the English-Wabigoon River System as a result of the past industrial discharge from the Dryden pulp and paper plant, as well as mercury that might come from clearcut logging allowed by the Plan.

8. In April 2010, I was interviewed by the CBC regarding the impacts I have experienced from mercury. Attached to my affidavit as Exhibit "A" are statements I made to the CBC at that time that state the following: "I feel angry knowing that something that happened in the '60s…Like, how it affected my family…" "[Ms Fobister ate fish when she was pregnant]…it's [eating fish] a part of life, you know…I love eating fish. It's a delicacy…it's part of our lifestyle. I don't know, I still eat it to this day. [no one told her not to eat fish when she was pregnant]." Exhibit "A" also contains other statements I made in April 2010 that appeared in a Grassy Narrows' press release, including: "When I was pregnant I couldn't afford to buy food at the store, so I ate what my grandfather

brought home – mostly fish….Now both my children are sick with strange illnesses, just like their cousins. I myself have tremors and numbness, but I don't qualify for compensation…" I have reviewed these statements and they are accurate and true. They were included in a larger document Grassy Narrows sent to the Ministry of the Environment in September, 2014 in an attempt to get the Ministry to examine the impacts of mercury from clearcut logging allowed by the Plan. A full copy of this document is attached as Exhibit "H" to the affidavit of Amber Ellis and David Sone in connection with this application for judicial review.

9. In my household we eat fish frequently. I support five (5) family-members, two of whom have serious disabilities, while earning a little over minimum wage, so I cannot afford to buy only store-bought meat. I supplement our diet with fish from the English-Wabigoon River System and, occasionally, wild game. In Grassy Narrows it is primarily women who are responsible for taking care of babies, children, and sick family members. The burden of caring for children and adults who are impacted by mercury falls mostly on women.

10. Given my family's current health problems resulting from mercury exposure, we avoid eating larger fish so as to minimize our mercury intake. Health Canada has told us that it is safe to eat fish that weigh less than one (1) pound. My family and I will continue to avoid eating the larger fish until Health Canada tells us that it is safe to eat them. I hope that happens as soon as possible. Elders in our community have taught me that eating fish is an important part of our culture, and safe fish is a healthy food good for children to eat.

11. It distresses me greatly to know that my daughter is suffering and may suffer for her whole life because of mercury. She deserves to live a good life and be happy. That the planned clearcut logging could make the mercury problem even worse, make my family even more ill, and deprive us and the whole Grassy Narrows community of our traditional diet of fish, scares and upsets me. I have read sections 7 and 15(1) of the *Canadian Charter of Rights and Freedoms* and I believe that approval and implementation of clearcut logging in our traditional territory violates my life, liberty, and personal security and that of my family by exposing us to more mercury and discriminates against us because we live on reserve and fish in our traditional territory.

12. It is an issue of cultural identity for me to be able to eat fish caught from our local waters. At Grassy Narrows, traditional feasts require the eating of traditional foods, such as fish we would catch, as well as wild game and wild rice. If the English-Wabigoon River System becomes further contaminated with mercury due to clearcut logging to the point that it is unsafe to eat the fish that are caught there, I will be forced to stop eating fish. Reducing the amount of fish that we can catch and eat would also deprive us of the many health benefits associated with eating fish, and the pride, happiness, peacefulness, healing, and self-sufficiency that comes from practising our fishing culture with our families. These are all things that improve my mental health and help to counter the feelings of depression, hopelessness, anxiety, and fear that I have experienced from living in a community suffering from mercury and having sick family members.

13. As a practical matter, I am uncertain that I could find other means of supplementing my family's food budget if we could not eat the fish we catch. My position would be untenable. My father is Steve Fobister. I hope that my children will be able to use his trapline as he has, including eating the fish from the many small lakes and streams in that area, including the lake that he calls Zagaatigooning-zaaga'iganish – Little Lake of the Dense Woods. I am concerned that this lake has extensive clearcut logging planned around it and I fear that such logging will contaminate fish in the lake with mercury.

14. I affirm this affidavit in support of the within application for judicial review, and for no other or improper purpose.

AFFIRMED before me in the District of Kenora, in the Province of Ontario, this 26th day of August, 2015.

(AMENDED) NOTICE OF APPLICATION TO DIVISIONAL COURT FOR JUDICIAL REVIEW

TO THE RESPONDENTS:

A LEGAL PROCEEDING HAS BEEN COMMENCED by the Applicants. The claim made by the Applicants appears on the following pages.

THIS APPLICATION for Judicial Review will come on for a hearing before the Divisional Court on a date to be fixed by the Registrar at the place of hearing requested by the Applicants. The Applicants request that this application be heard at Osgoode Hall, 130 Queen Street West, Toronto, Ontario, M5H 2N5.

IF YOU WISH TO OPPOSE THIS APPLICATION, to receive notice of any step in the application or to be served with any documents in the application, you or an Ontario lawyer acting for you must forthwith prepare a notice of appearance in Form 38A prescribed by the Rules of Civil Procedure, serve it on the Applicants' lawyer or, where

the Applicants do not have a lawyer, serve it on the Applicants, and file it, with proof of service, in the office of the Divisional Court, and you or your lawyer must appear at the hearing.

IF YOU WISH TO PRESENT AFFIDAVIT OR OTHER DOCUMENTARY EVIDENCE TO THE COURT OR TO EXAMINE OR CROSS-EXAMINE WITNESSES ON THE APPLICATION, YOU OR YOUR LAWYER MUST, IN ADDITION TO SERVING YOUR NOTICE OF APPEARANCE, SERVE A COPY OF THE EVIDENCE ON THE Applicants' lawyer or, where the Applicants do not have a lawyer, serve it on the Applicants, and file it, with proof of service, in the office of the Divisional Court within thirty days after service on you of the Applicants' application record, or not later than 2 p.m. on the day before the hearing, whichever is earlier.

IF YOU FAIL TO APPEAR AT THE HEARING, JUDGMENT MAY BE GIVEN IN YOUR ABSENCE AND WITHOUT FURTHER NOTICE TO YOU. IF YOU WISH TO DEFEND THIS PROCEEDING BUT ARE UNABLE TO PAY LEGAL FEES, LEGAL AID MAY BE AVAILABLE TO YOU BY CONTACTING A LOCAL LEGAL AID OFFICE.

Date: September 1, 2015

Lawyers for the Respondents

APPLICATION

This is an Application for judicial review of a provincial decision approving clearcut logging activities and refusing to order an individual environmental assessment ("IEA") regarding potential mercury contamination and adverse human health effects, arising from the approved activities.

The decision consists of two inter-related stages:

(1) a December 2013 decision by the Minister of Natural Resources and Forestry, or the Minister's designate (the "Natural Resources Minister"), approving a forest management plan ("Plan"), which allows clearcut logging of the Whiskey Jack Forest in northwestern Ontario under section 9 of the *Crown Forest Sustainability Act,* S.O. 1994, c. 25 ("*CFSA*"), and

(2) a December 2014 decision by the Minister of the Environment and Climate Change, or the Minister's designate (the "Environment Minister") refusing, under section 16 of the *Environmental Assessment Act,* R.S.O. 1990, c. E.18 ("*EAA*"), to grant a Part II order (or "bump-up") requested by the Applicants that would have allowed an IEA to be conducted on whether clearcut logging authorized under the Plan could:

(a) release mercury to the watersheds of and adjacent to the English-Wabigoon river system, which system runs through the

Whiskey Jack Forest most of which is part of the traditional territory of the Grassy Narrows First Nation ("Grassy Narrows"),

(b) contaminate fish therein, and

(c) increase the risk of harm to humans consuming the fish.

The Applicants challenge the approval of the Plan and the refusal of their request for a bump-up with respect thereto (collectively the "Decision") on the basis that the exercise of these statutory powers of decision infringe on the rights of their members (1) to life, liberty and security of the person as guaranteed by section 7 of the *Canadian Charter of Rights and Freedoms*, Part 1 of the *Constitution Act, 1982* being Schedule B to the *Canada Act 1982* (U.K.), c. 11 (the "*Charter*"), and (2) to equality under section 15(1) of the *Charter*.

The Applicants also challenge the Decision on other constitutional and administrative law grounds set out below.

1. The Applicants make application for:

Charter Remedies

(a) an order under section 24(1) of the *Charter* declaring that the Decision,

(i) infringes section 7 of the *Charter*, by depriving them of their life, liberty and security of the person in a manner not in accordance with the principles of fundamental justice;

(ii) infringes section 15(1) of the *Charter* by depriving them of their right to equality;

(b) an order under section 24(1) of the *Charter* setting aside the Decision;

(c) an order under section 24(1) of the *Charter* in the nature of mandamus directing the Environment Minister to authorize an IEA as requested by the Applicants;

(d) an interim and permanent order under section 24(1) of the *Charter* prohibiting the Natural Resources Minister from authorizing third parties, by licence or otherwise, from conducting clearcut logging in the Whiskey Jack Forest under authority of the Plan;

(e) an interim and permanent order under section 24(1) of the *Charter* enjoining third parties with a licence or other instrument from the Natural Resources Minister from conducting clearcut logging in the Whiskey Jack Forest under authority of the Plan;

Administrative Law Remedies

(f) an order declaring that:

(i) in failing to ensure that mercury releases would be prevented or mitigated, approval of the Plan by the Natural Resources Minister was without legal authority under the *CFSA* or, in the alternative, unreasonable; and

(ii) the refusal by the Environment Minister to grant a bump-up request so as to assess under an IEA potential environmental and

health impacts from mercury releases was without legal authority under the *EAA* or, in the alternative, unreasonable;

(g) an order quashing or setting aside:

(i) the Decision; and

(ii) any authorizations, licences, permits, or approvals by the Ministers, or their respective ministries, enabling implementation of the Plan to proceed, in whole or in part, before this Application has been heard and determined by this Honourable Court;

Remedies Based on the Federal Paramountcy Doctrine

(h) an order declaring that the Plan, by permitting release of mercury, a deleterious substance, into water frequented by fish, is contrary to, conflicts or is inconsistent with, section 36(3) of the federal *Fisheries Act*, R.S.C. 1985, c. F-14, and is thereby rendered inoperative to the extent of the conflict or inconsistency;

Costs

(i) an order requiring the Respondents to pay the Applicants costs of this Application if requested or, in the alternative, an order that all parties shall bear their own costs;

Other Relief

(j) such further or other relief as counsel may advise and this Honourable Court may permit.

Grounds for the Application

2. The Grounds for the application are:

The Parties

(a) The Applicants are:

(i) Chief Simon Fobister, ~~Senior,~~ the elected chief and a member of Grassy Narrows, and having the status of an "Indian" within the meaning of the *Indian Act*, R.S.C. 1985, c. I-5 ("*Indian Act*"), who is bringing this application on his own behalf and on behalf of all other members of Grassy Narrows;

(ii) Sherry Fobister, William Fobister, Senior, and ~~Simon~~ former Chief Roger Fobister, Senior each of whom is a member of Grassy Narrows, having the status of an "Indian" within the meaning of the *Indian Act*, who also bring this application on their own behalf and on behalf of all other members of Grassy Narrows; and

(iii) Grassy Narrows, a First Nation being among the Aboriginal peoples of Canada recognized under s. 35 of the *Constitution Act, 1982*, and having the status of a "band" within the meaning of the *Indian Act*. Members of Grassy Narrows live on and off the English River 21 Reserve (hereinafter the "Grassy Narrows Reserve"), a "reserve" within the meaning of the *Indian Act*. The members of Grassy Narrows, whose ancestors signed Treaty No. 3, are Anishinabe

(Ojibway) men, women, and children many of whom engage in the practice of traditional Anishinabe activities in their traditional territory, which are central to their identity, diet, culture, and economy, including by:

(A) fishing in the English-Wabigoon river system watershed, or adjacent watersheds, in the area that includes the Whiskey Jack Forest; and

(B) consuming fish caught from those waters.

(b) The Respondent Natural Resources Minister is responsible for the *CFSA*, Ontario's primary statute permitting logging of, and development and approval of forest management plans for, the Crown forests of Ontario.

(c) The Respondent Environment Minister is responsible for the *EAA*, Ontario's primary statute for examining the effects of undertakings, such as logging and related forest management activities on Crown lands in Ontario, on the natural environment, human life, and social, economic, and cultural conditions.

Overview

(d) The Applicants rely on fishing in the watershed of the English-Wabigoon river system as a significant part of their way of life, and on the consumption of area fish as a significant part of their diet. Existing

mercury pollution dating from the discharge of mercury by a Dryden, Ontario chlor-alkali plant into the same river system in the 1960s has had, and continues to have, a significant adverse impact, due to the consumption of mercury-contaminated fish, on the health and well-being of members of Grassy Narrows, including some of the individual Applicants who have been diagnosed with, or whose children have been diagnosed with, symptoms consistent with mercury poisoning. The Applicants fear that clearcut logging authorized under the Plan poses a serious risk of additional harm to the health and well-being of community members because it will trigger new releases of mercury to the watershed, increase the accumulation of mercury in the food chain, and prolong and exacerbate the existing mercury problem.

Historical Background: Industrial Discharges of Mercury in the English-Wabigoon River System

(e) Beginning in the 1960s, a chlor-alkali plant at Dryden, Ontario began discharging mercury into the English-Wabigoon river system, eventually discharging approximately 9,000 kilograms of mercury into the river system, which flows into and through the traditional lands and territory of the Applicants;

(f) Once in the water, the mercury was transformed by chemical-biological processes into methyl mercury, a nerve poison capable of bio-accumulating up the food chain, being ingested by fish, and adversely

impacting humans consuming methyl mercury-contaminated fish caught from waters in the aforementioned area;

(g) The consumption of methyl mercury-contaminated fish by members of Grassy Narrows resulted over the decades in serious, and well-documented, neurological harm and other adverse health impacts, many of which continue to afflict many members of Grassy Narrows to this day;

(h) Litigation by Grassy Narrows against the federal and Ontario governments, and the successor company to the original industrial discharger, resulted in a settlement in the 1980s and the payment of some compensation as well as the establishment of a mercury disability board to evaluate and compensate members of Grassy Narrows suffering on-going neurological harm and other adverse health impacts consistent with mercury poisoning arising from the industrial discharges of mercury into local bodies of water;

(i) The watershed of the English-Wabigoon river system where the industrial discharges of mercury took place encompasses most of the Whiskey Jack Forest;

(j) Fish within this watershed continue to have levels of mercury above, or near, the limit for safe human consumption;

(k) Grassy Narrows Reserve is located within the Whiskey Jack Forest itself.

The Whiskey Jack Forest Management Plan

(l) Starting in or about 2010 and continuing to late 2013, the Ministry of Natural Resources and Forestry ("MNRF") gave periodic public notice of its intention to develop a forest management plan that would authorize logging for the Whiskey Jack Forest, and sought from time to time public comment on various stages of what eventually became the approved Plan.

(m) Over this same 2010 to 2013 period, Grassy Narrows and other groups raised publicly through the media, and directly with the provincial government, their concern that the sole method of harvesting trees under the Plan, clearcut logging, would interfere with the rights of the members of Grassy Narrows and risked the release of new, or additional, sources of mercury into the region's watershed system, the potential for increased methyl mercury contamination of fish, and consequential harm, or further harm, to the health and well-being of members of Grassy Narrows consuming the fish.

(n) During the 2010 to 2013 period, and earlier, MNRF also was independently aware, through its own research and investigations, of the mercury problem arising from clearcut logging and the challenge of

preventing or mitigating it. Notwithstanding these concerns, the Natural Resources Minister approved the Plan in December 2013.

The Bump-up Request

(o) The notice of decision approving the Plan indicated that persons objecting to the decision could apply to the Ministry of the Environment and Climate Change ("MOECC") requesting a bump-up under the *EAA* that would, if approved, authorize an IEA to be performed before the Plan would be allowed to go into effect.

(p) Grassy Narrows, in conjunction with an environmental non-governmental organization not party to this application, filed such a request in January 2014 as well as supplementary submissions with supporting material in May, July, September, and November 2014.

(q) The initial request, the supplementary submissions of Grassy Narrows, and the response of MNRF demonstrated the need for an IEA, including:

(i) since the industrial discharges of mercury in the 1960s, clinical evaluations of members of Grassy Narrows show that many have suffered from, and continue to suffer from, a variety of neurological health problems attributable to eating methyl mercury contaminated fish caught in area waters;

(ii) peer-reviewed scientific studies show clearcut logging in boreal forests at latitudes similar to the Whiskey Jack Forest, leads to the presence, or increased presence, of methyl mercury in fish in watersheds where the logging takes place;

(iii) members of Grassy Narrows fear the health risks posed by eating mercury-contaminated fish but continue to do so for a variety of complex reasons, including because fishing and consumption of fish caught has always been part of their traditional way of life, diet, and culture, which they do not wish to lose, and because it is an affordable source of food in an impoverished community;

(iv) MNRF admitted that it makes no claims for the effectiveness of the only measures it proposes for the mitigation of mercury impacts to water from clearcut logging authorized under the Plan;

(v) MNRF personnel involved in preparation of, or comment with respect to, guidance materials for the Plan raised concerns that key measures proposed for use with the Plan would not be enforceable and would not adequately mitigate mercury releases to water and could, in fact, exacerbate them.

(r) Despite the above and related submissions and material filed by Grassy Narrows and admissions by MNRF, the Environment Minister, or his designate, refused the bump-up request of Grassy Narrows in December 2014, allowing implementation of the Plan to proceed. In doing so, the refusal decision specifically relied on the mitigation measures that MNRF disclaimed the effectiveness of in controlling mercury impacts, and simply imposed requirements for monitoring such measures during clearcut logging activity authorized under the Plan.

The Decision Violates the Section 7 *Charter* Rights of the Applicants

(s) Section 7 of the *Charter* declares that everyone has the right to life, liberty and security of the person and the right not to be deprived thereof except in accordance with the principles of fundamental justice.

Depriving Applicants of Right to Life, Liberty and Security of the Person

(t) The Decision violates the section 7 *Charter* rights of the Applicants by:

(i) Depriving them of their right to life guaranteed under section 7 by increasing their risk of death, illness or disease as a result of the approval and anticipated implementation of the Plan and corresponding refusal to examine beforehand, through an IEA, the potential impacts to them posed by consumption of mercury-contaminated fish arising from, or exacerbated by, clearcut logging authorized by the Plan in the Whiskey Jack Forest;

(ii) Depriving them of their right to liberty guaranteed under section 7 by undermining, or seriously compromising, their freedom to choose an environment in which to reside and in which to practice their traditional way of life, including fishing in their traditional territory, due to the serious risks they face, if they stay in the area, of neurological or other harm, or such further harm, as a result of eating fish caught in local waterways contaminated by methyl mercury caused by clearcut logging authorized by the Plan, and not studied beforehand, through an IEA;

(iii) Depriving them of their right to security of the person guaranteed under section 7 by:

(A) increasing the risk to their physical security by exposing them to health damage, or further health damage, including death or disability, due to approval and implementation of the Plan that will permit clearcut logging with known potential to release mercury into the watershed, contaminating fish, and leading to neurological and other harm to those consuming the fish, and not studying the issue beforehand through an IEA; and

(B) increasing the risk to their psychological security because the Decision constitutes serious state-imposed psychological stress arising from their fear that clearcut logging authorized by the Decision, which has been strongly linked in the scientific literature to runoff and bioaccumulation of mercury, will exacerbate the contamination of fish, as well as neurological and other health problems experienced by members of Grassy Narrows consuming the fish.

The Deprivations are not in Accordance with Principles of Fundamental Justice

(u) The Decision also constitutes a deprivation of the section 7 rights of the Applicants by not being in accordance with principles of fundamental justice.

Failure to Respect Sanctity of Human Life

(i) Given the history of mercury impacts on the members of Grassy Narrows, the Decision fails to respect the sanctity of human life, a substantive principle of fundamental justice, by risking further harm to human health and well-being, if not loss of human life, in the community from mercury exposure arising from approval and implementation of the Plan, which authorizes clearcut logging, and failing to examine the risks before hand through an IEA.

Denial of Procedural Protections

(ii) The Decision denies the Applicants procedural protections as it was made without their being able to appear before an independent body that could have considered these matters under three different statutes because:

(A) MNRF failed to promulgate a regulation setting out an appeal process for forest management plans as authorized under section 12 of the *CFSA*;

(B) MNRF and/or MOECC failed to classify by regulation forest management plans as instruments that are eligible for third party appeals under sections 38-48 of the *Environmental Bill of Rights, 1993*, S.O. 1993, c. 28 and O. Reg. 681/94 promulgated thereunder, which could have led to an independent public hearing with respect to the Plan;

(C) as a result of the Environment Minister refusing to grant the bump-up request, the Applicants were denied an opportunity:

(1) to obtain an IEA that could have provided in-depth study and consideration of the issue of mercury release to area waters and resulting health implications thereof, from the Plan's authorization of clearcut logging, matters of vital concern to their life, health, and well-being as consumers of fish from these waters; and

(2) to request an independent public hearing under sections 9.1-9.3 of the *EAA* with respect to the resulting IEA; and

(D) the substitution of a notice, comment, ~~and~~ consultation, and IEA request opportunity offered by MNRF/MOECC to Grassy Narrows was not adequate in the context of this case in comparison to a hearing before an independent body, particularly given the health threats posed by mercury to members of Grassy Narrows arising from clearcut logging authorized under the Plan, and the information known only to MNRF at the time respecting the limitations of its mercury mitigation measures. The MOECC, as the decision-maker in the IEA process, did not act in accordance with principles of fundamental justice in that it collaborated with MNRF, the Plan proponent, on

both MNRF's substantive submissions to, and on the ultimate decision of, MOECC, all without the knowledge of the Applicants.

Effects Grossly Disproportionate to Objectives

(iii) The effects of the Decision on the life, liberty, and security of the person of members of Grassy Narrows due to potential additional exposure to mercury and the failure to study same through an IEA before proceeding, are grossly disproportionate to the Decision's objectives of allowing the harvesting of trees in the Crown forest by clearcut logging.

Offends Basic Tenet of Legal System

(iv) The Decision also is not in accordance with principles of fundamental justice because it offends a basic tenet of the legal system by violating the equality rights of the Applicants under section 15(1) of the *Charter*, as set out below.

The Decision Violates the Section 15(1) *Charter* Rights of the Applicants

(v) Section 15(1) of the *Charter* declares that every individual is equal before and under the law and has the right to the equal protection and equal benefit of the law without discrimination and, in particular, without discrimination based on race, national or ethnic origin, colour, religion, sex, age or mental or physical disability.

(w) The Decision violates the section 15(1) *Charter* rights of the Applicants by: (1) creating a distinction based on grounds enumerated in, or analogous to, section 15(1); and (2) creating a disadvantage based on the distinction.

Creating a Distinction

(x) The Decision violates section 15(1) of the *Charter* by creating a distinction that:

(i) disproportionately burdens:

(A) members of Grassy Narrows who live within the watershed and who are identifiable by their Aboriginality, their place of residence, their historical and ongoing practice of traditional Aboriginal activities in their traditional territory, including fishing, all characteristics that are actually or constructively immutable, and which the government has no legitimate interest in expecting the people of Grassy Narrows to change in order to receive substantive equality under the law; and

(B) women of childbearing age in the community who must avoid consumption of methyl mercury-contaminated fish or risk exposing their unborn children to serious adverse health effects; and

(ii) ignores their pre-existing health disadvantage as a result of past consumption of methyl mercury-contaminated fish from local waters.

Creating a Disadvantage

(y) The Decision further violates section 15(1) of the *Charter* by creating a disadvantage on the basis of the above distinction that perpetuates the history of prejudice experienced by Aboriginal peoples in Canada in general, and the exposure to mercury suffered by members of Grassy Narrows in particular by authorizing, and refusing to examine beforehand through an IEA potential impacts to them posed by, clearcut logging that will trigger new releases of mercury into the local water system, thus effectively putting the members of Grassy Narrows in the position of either:

(i) giving up the fishing and other traditional activities in their traditional territory that are of significant importance to a band member's personal identity; or

(ii) further exposing themselves and their unborn children to harm due to consumption of fish contaminated by new releases of mercury to area waters.

The Decision is not justified by Section 1 of the *Charter*, or Disproportionately and Unreasonably Interferes with *Charter* Guarantees

(z) The violations of sections 7 and 15(1) of the *Charter* set out above do not constitute a reasonable limit demonstrably justified in a free and democratic society pursuant to section 1 of the *Charter*. The impugned Decision impairs the rights of the Applicants, does not advance a sufficiently important governmental objective and, in any event, fails to meet the proportionality requirements of section 1 of the *Charter*. Alternatively, the Decision, in seeking to meet statutory objectives, disproportionately and unreasonably interferes with protections guaranteed to the Applicants under sections 7 and 15(1) of the *Charter*.

The Decision Violates Administrative Law Principles

(aa) In making the Decision, the Ministers, or their designates, erred in law and/or acted beyond or without jurisdiction in that:

(i) there was no evidence that the mercury mitigation measures proposed pursuant to, or in conjunction with, the Plan would mitigate mercury impacts to the river system, avoid contamination of fish, or prevent serious risk of harm to members of Grassy Narrows consuming contaminated fish, and there was substantial evidence to the contrary;

(ii) the Natural Resources Minister failed to meet the purposes, duties, and conditions precedent imposed upon the Minister pursuant to

sections 1, 2, 9, and 68 of the *CFSA* and various manuals and guides promulgated thereunder, requiring the Minister to only approve a Plan that provides for the sustainability of the Crown forest ecosystem by meeting the social, economic, and environmental needs of present and future generations, as well as minimizing adverse effects to animal life and water;

(iii) the Environment Minister, in refusing to grant the bump-up request and order that an IEA be conducted and in allowing, without the knowledge of the Applicants, MOECC to collaborate with MNRF during the decision-making process with respect thereto, or failing to ensure such collaboration did not occur, acted unfairly or unreasonably, and failed to meet the purposes and duties imposed by sections 1, 2 and 16 of the *EAA* and declaration orders promulgated thereunder related specifically to forest management on Crown lands, to protect the environment, including human life;

(iv) relevant factors were not taken into account or, in the alternative, irrelevant factors were taken into account.

The Plan Conflicts, or is Inconsistent, with the Federal *Fisheries Act*

(bb) In authorizing the Plan under section 9 of the *CFSA*, which will allow clearcut logging operations causing or permitting the deposit of mercury, a

deleterious substance, into water frequented by fish, including the watersheds of and adjacent to, the English-Wabigoon river system, the Natural Resources Minister's decision conflicts or is inconsistent with the prohibition in section 36(3) of the *Fisheries Act* prohibiting such deposits and is thereby, pursuant to the federal paramountcy doctrine, inoperative to the extent of the conflict or inconsistency.

Constitutional and Statutory Provisions

(cc) *Canadian Charter of Rights and Freedoms*, Part 1 of the *Constitution Act, 1982* being Schedule B to the *Canada Act 1982* (U.K.), 1982, c. 11 (the "*Charter*"), sections 1, 7, 15(1), 24(1), 28;

(dd) *Constitution Act, 1982*, being Schedule B to the *Canada Act 1982* (U.K.), 1982, c. 11, section 35;

(ee) *Indian Act*, R.S.C. 1985, c. I-5;

(ff) *Crown Forest Sustainability Act*, S.O. 1994, c. 25;

(gg) *Environmental Assessment Act*, R.S.O. 1990, c. E.18;

(hh) *Environmental Bill of Rights, 1993*, S.O. 1993, c. 28 and O. Reg. 681/94;

(ii) *Fisheries Act*, R.S.C. 1985, c. F-14, section 36(3);

(jj) *Judicial Review Procedure Act*, R.S.O. 1990, c. J.1;

(kk) *Courts of Justice Act*, R.S.O. 1990, c. C.43;

(ll) *Rules of Civil Procedure*, R.R.O. 1990, Regulation 194.

(mm) Such further or other grounds as counsel may advise and this Honourable Court may permit.

Documentary Evidence

3. The following documentary evidence will be used at the hearing of the application:

(a) the record to be filed by the Respondent Ministers pursuant to section 10 of the *Judicial Review Procedure Act*, R.S.O. 1990, c. J.1;

Applicants' Application Record

(b) Affidavit of Simon Fobister, affirmed July 30, 2015;

(c) Affidavit of Amber Ellis and David Sone, sworn August 21, 2015;

(d) Affidavit of Chief Roger Fobister, Senior, affirmed August 26, 2015;

(e) Affidavit of Joseph Fobister, affirmed August 26, 2015;

(f) Affidavit of William Fobister, Senior, affirmed July 30, 2015;

(g) Affidavit of Sherry Fobister, affirmed August 26, 2015;

(h) Affidavit of David Sone, sworn August 21, 2015;

Applicants' Supplementary Application Record

(i) Affidavit of Dr. Richard Carignan, ~~to be~~ sworn February 18, 2016;

(j) Supplementary Affidavit of Dr. Richard Carignan, ~~to be~~ sworn February 18, 2016;

(k) Affidavit of Dr. Donna Mergler, ~~to be~~ sworn November 6, 2015;

(l) Affidavit of Dr. Anna Willow, ~~to be~~ sworn, February 18, 2016;

(m) Affidavit of Dr. Justin Podur, ~~to be~~ sworn, December 10, 2015;

AFFIDAVIT OF RICHARD CARIGNAN

I, RICHARD CARIGNAN, of the City of Montreal, in the Province of Quebec, MAKE OATH AND SAY AS FOLLOWS:

1. I am a professional limnologist and ecologist. I hold a doctorate in limnology from McGill University and a Bachelor of Science degree in ecology from the University of Quebec at Montreal. I am currently a professor in the Department of Biological Sciences at the Université de Montreal where I teach courses in such subjects as ecotoxicology,

limnology, advanced limnology, and research methods with respect to these areas. I am also a member of the Interuniversity Research Group on Limnology and the Aquatic Environment and I have been an associate editor of the Canadian Journal of Fisheries and Aquatic Sciences. I am qualified to research and analyze issues involving freshwater lakes and effects on fish in such lakes from the introduction of materials arising from human and natural activities. I have conducted field research projects at such lakes in the Boreal forest of Quebec studying the effects of clear-cut logging on mercury levels in fish. I have published on this subject in a variety of peer-reviewed scientific journals. In this regard, I have reviewed the Forest Management Plan approved by the Ontario Ministry of Natural Resources and Forestry in December 2013 that allows clear-cut logging for the portion of the northwestern Ontario Boreal Forest known as the Whiskey Jack Forest. I have also reviewed related documents, such as the Ministry's Stand and Site Guide, which addresses mercury mitigation measures in relation to logging activities. A copy of my curriculum vitae is attached to Exhibit "A", below.

2. In January 2015 I was asked by counsel for Grassy Narrows to answer certain questions in a report on the potential effects of the December 2013 Forest Management Plan on mercury contamination in fish. The questions and my answers to them appear as part of my February 2016 expert report attached as Exhibit "A" to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "B" to my Affidavit.

SWORN BEFORE ME in the City of Montreal, in the Province of Quebec, this ___ day of _____, 2016.

A Commissioner, etc.

Introduction

I am a professional limnologist and ecologist. I hold a doctorate in limnology from McGill University and a Bachelor of Science degree in ecology from the University of Quebec at Montreal. I am currently a professor at the Department of Biological Sciences at the Université de Montreal where I teach courses in such subjects as ecotoxicology, limnology, advanced limnology, and research methods with respect to these areas. I am also a member of the Interuniversity Research Group on Limnology and the Aquatic Environment and I have been an associate editor of the Canadian Journal of Fisheries and Aquatic Sciences. I am qualified to research and analyze issues involving freshwater lakes and effects on fish in such lakes from the introduction of materials arising from human and natural activities. I have conducted field research projects at such lakes in the Boreal forest of Quebec studying the effects of clear-cut logging on mercury levels in fish. I have published on this subject in a variety of peer-reviewed scientific journals. In this regard, I have reviewed the Forest Management Plan approved by the Ontario Ministry of Natural Resources and Forestry in December 2013 that allows clear-cut logging for the portion of the northwestern Ontario Boreal Forest known as the Whiskey Jack Forest. I have also reviewed related documents, such as the Ministry's Stand and Site Guide, which addresses mercury mitigation measures in relation to logging activities. My curriculum vitae appears in Appendix A of the Expert Report.

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association on behalf of Grassy Narrows First Nation to prepare an expert report that responds to several questions. I am solely responsible for the preparation of this report.

Questions

Question 1. What were the results of your studies on the effects of clear-cut logging? In particular:

1a. What effect, if any, did clear-cut logging have on mercury levels in piscivorous fish?

1b. What were the hypothesized mechanisms for mercury release and bioaccumulation?

1c. If effects were observed, what were their duration?

1d. What were your observations, if any, on the effect of fire on mercury levels in fish?

1e. If not covered by 1.d above, was there a difference between mercury impacts of clear-cutting and fire and, if so, what do you believe to be the reasons for the difference?

1f. What has research since your study generally found?

2. What effect, if any, could clear-cut logging planned under the FMP have on mercury levels in fish at Grassy Narrows? In particular:

2a. How do the watershed characteristics in the Whiskey Jack Forest (e.g. slope, soil types, forest type, geology, precipitation, percentage of wetlands, etc.) compare to those in your Québec study area and how likely are they to produce mercury effects after clear-cut logging?

2b. How likely is it, if at all, that the logging methods set out in the Plan could lead to mercury bio-accumulation?

2c. Please comment on the extent to which other FMP planned activities, such as scarification and thinning, could product mercury impacts?

2d. Please comment on the similarities and/or differences in the mitigation measures identified in the FMP (see Stand and Site Guide rationale) to those used in your Québec study site in terms of catchment disturbance thresholds, size of clear-cuts, nature of soil protections, size of riparian buffers, or other measures you wish to comment on, and what you would expect in terms of the ability of these respective measures to prevent, or not prevent, mercury impacts?

2e. Based on the landscape pattern map what, in your professional opinion, are the implications for mercury impacts, if any, of the proximity of currently planned cut-blocks to previous cut-blocks, or of the plan direction to create clear-cut areas as large as 7,900 ha?

2f. If not otherwise answered by you, what is your professional opinion on the effectiveness of the measures in the Stand and Site Guide, which the Stand and Site Guide Rationale suggests will control mercury impacts (e.g. measures to minimize soil compaction, measures to minimize hydrological disruption, riparian buffers, etc.)?

3. Please comment on whether clear-cut logging arising from the FMP is likely, or not likely, to compound the previous mercury problem at Grassy Narrows through cumulative effects, or otherwise. In particular:

3a. Does clear-cut logging proposed under the FMP risk, or not risk, increasing the release and bio-accumulation of mercury in bodies of water?

3b. Does clear-cut logging risk exacerbating, or not, pre-existing mercury conditions in the English-Wabigoon river system? In particular, (i) will it increase, or not, methylation of existing mercury in top layers of river sediment, (ii) will it decrease, or not, demethylation, (iii) will it decrease, or not, volatization, and (iv) will it increase, or not, supplies of fresh carbon and anoxic conditions?

3c. Please comment on whether headwater lakes upstream from the contaminated English-Wabigoon river system are likely, or not, to have elevated mercury levels in fish after clear-cut logging?

4. Please comment on whether selective logging would have greater, lesser, or no different impacts on the release of mercury than clear-cut logging? In particular:

4a. Would selective logging produce less, or more, hydrological impacts (e.g. raised water table, increased soil moisture, increased total flows) and soil impacts, than clear-cut logging?

4b. What are your views, if any, on the need for local experiments to confirm the effects of selective logging before allowing it as a substitute for clear-cut logging?

4c. What are your views, if any, on whether modified clear-cut logging methods such as measures to prevent soil damage, increased buffers, increased residuals, timing restrictions, measures to prevent hydrological disruption, etc., would prevent, or not prevent, mercury impacts to water/fish?

5. What is your general overall conclusion in light of your research on the capacity of clear-cut logging to increase mercury levels in fish in bodies of water in the Whiskey Jack Forest?

Organization of Expert Report

The Expert Report is organized to provide where appropriate both summary, followed by full, answers to the questions**.**

Overview

With an average concentration of about 0.05 ppm in crustal rocks, mercury (Hg) is a trace element which occupies the 66th rank in terms of abundance. Mercury occurs in nature as two oxidation states : Hg(0) and Hg(II). Elemental mercury [Hg(0)] is volatile and is the dominant form in the atmosphere, where its residence time exceeds one year. Because of its long atmospheric residence time, Hg (0) can circle the Earth many times before being eventually deposited as Hg(II) all over the globe. Natural sources of mercury to the atmosphere include evasion from oceans and other surface waters, rocks, top soils and vegetation, injection from volcanoes and other geothermal processes, and forest fires. Over the last centuries but especially since the mid 19th century, anthropogenic activities (coal burning, incineration, metal smelting and refining, artisanal gold mining, cement production and chloralkali plants) have become significant contributors to global mercury pollution. It is estimated that between 50% and 75% of the current global atmospheric Hg burden is contributed by anthropogenic sources. Mercury(II) naturally forms numerous inorganic and organic compounds including methyl mercury (MeHg or CH_3Hg^+), a potent neurotoxin which is bioamplified in food chains (Morel et al. 1998).

Summary and Full Answers to Questions

Question 1. What were the results of your studies on the effects of clear-cut logging? In particular:

1a. What effect, if any, did clear-cut logging have on mercury levels in piscivorous fish?

Summary Answer: Research conducted in the Quebec boreal forest strongly suggests that extensive clear-cut logging activities disrupt the natural cycling of mercury in watersheds and increase mercury levels in aquatic food webs. In cut lakes, mercury concentrations exceeded the advisory limit for human consumption (0.5 mg/g wet wt) from the World Health Organization in all top predatory species (northern pike, walleye and burbot).

Full Answer: In fish, total Hg is essentially present as MeHg. Between 1996 and 1998, total Hg levels were measured in northern pike (*Esox lucius*) found in 19 lakes with undisturbed (n=8), logged (n=4), or burned (n=7) catchments impacted in 1995 (Figure 1). The average Hg level in standard 560-mm northern pike, on a dry weight basis, was significantly higher in logged lakes (3.4 $mg \cdot g^{-1}$) than in reference lakes (1.9 $mg \cdot g^{-1}$). The average Hg concentration in burned lakes (3.0 $mg \cdot g^{-1}$) was intermediate, and did not differ significantly from those in logged and references lakes. The higher variability of Hg in pike from burned lakes in Figure 1 was attributed to the inclusion of one lake where low intensity fires cleared only 50% of the catchment.

Concentrations of Hg normalized to trophic position determined from isotopic composition yielded similar results. Mercury levels were above the World Health Organization safe consumption limit of 0.5 $mg \cdot g^{-1}$ or ppm (fresh weight) in all logged lakes. Mercury in northern pike was correlated with methyl mercury in zooplankton (+), total N (+), pH (–), alkalinity (–), sulfate (+), dissolved organic C loading (+), and light attenuation in lake water (+). Stepwise multiple regressions explained 79% of the variability in Hg in fish and included methyl mercury in zooplankton, pH, and sulfate as independent variables. Explained variability increased to 92% when a second-order lake with an exceptionally large drainage area was excluded. These results suggest that extensive clear-cut logging activities disrupt the natural cycling of Hg in watersheds and increase Hg levels in the aquatic biota.

Results pertaining to northern pike found in only 19 of the 38 lakes covered in the Carignan et al. studies were generalised to the entire fish communities present in all 38 lakes using stable isotopes to estimate trophic position and to correct for bioamplification effects (Garcia and Carignan 2005). Total mercury concentrations increased significantly with increasing fish trophic position (r^2 = 0.52, 0.49, and 0.30 for cut, reference and burnt lakes, respectively). Mercury concentrations in organisms at the base of the food chain in lakes with logged catchments were higher than that in reference lakes. In logged lakes, Hg concentrations in fish were significantly related to ratio of the clear-cut area to lake area (Figure 5). Applying Figure 5 to a 55 cm walleye having a 15N ratio of 7.9 per mil suggests that , on average, Hg concentration will increase from 0.24 mg/g to 0.51 mg/g (on a fresh weight basis) when the impact ratio (clear-cut:lake area) reaches 8. In other words, at a small impact ratio there is a small mercury increase, at a large impact ratio there is a large increase. The mercury increase is zero if the impact ratio is zero. The clear-cut area/lake area ratio was, in turn, significantly correlated with dissolved organic carbon (DOC). These findings suggest that differential loading of organic matter–bound Hg to lakes can affect Hg cycling. In addition, Hg concentrations exceeded the advisory limit for human consumption (0.5 mg/g wet wt) from the World Health Organization in all top predatory species (northern pike, walleye and burbot) found in cut and in two partially burnt lakes. None of the top predatory species exceeded 0.5 mg/g where fire had completely cleared the forest. Thus, high Hg concentrations in fish from harvested and partially burnt lakes may reflect increased exposure to Hg relative to undisturbed lakes.

The same region was revisited in 2000-2002 with the objective of evaluating the chemical and biological responses of lakes to clear-cut logging using a BACI (before/after control/impact) statistical approach. Water quality (DOC, TP and major ions), periphyton

biomass and Hg contamination were compared in 10 control and 8 lakes logged in 2001 and 2002 (Desrosiers et al. 2006). The BACI statistical analyses revealed a significant impact of logging on periphyton biomass (decrease; 0.6- to 1.5-fold) and MeHg accumulation (increase; 2- to 9.6-fold, Figure 2). Because periphyton is at the base of littoral food chains, the significant positive effect of logging on MeHg accumulation by periphyton strongly suggests that higher trophic levels (secondary consumers and fish) have been affected as well.

These Québec studies addressing directly the empirical links between watershed disturbances (fire or clear-cut logging), water quality and MeHg in the foodwebs of several lakes took advantage of the simultaneous occurrence of large fires and forest removal activities in the same region. For this reason, they have never been replicated elsewhere in the World. However, they have inspired several more studies reviewed in Bishop et al. (2009) and aimed at understanding the links between clear-cut logging and Hg mobilisation in aquatic systems. The studies reviewed in Bishop et al. (2009) generally supported our findings.

1b. What were the hypothesized mechanisms for mercury release and bioaccumulation?

Summary Answer: Dissolved organic matter is a known carrier of mercury to streams and lakes. Clear-cutting raises the water table of soils and increases the export of dissolved organic matter, mercury and methyl-mercury to lakes. Methyl-mercury is bioamplified along food webs resulting in human exposure through consumption of fish.

Full Answer: Mercury contamination of aquatic ecosystems and subsequent MeHg bioamplification are significant environmental problems of global extent which have been exacerbated by anthropogenic activities. A small fraction of mercury in natural waters is converted to MeHg by anoxic bacteria (Morel et al. 1998). Contrary to other Hg forms, MeHg can be accumulated and bioamplified along food webs resulting in human exposure through consumption of fish. Several environmental and biological factors can affect Hg methylation and accumulation in fish, including lake productivity, pH, alkalinity, sulfate and calcium concentrations, trophic position and age and growth (Hill et al. 1996; Hudson et al. 1994; Cabana et al. 1994; MacCrimmon et al. 1983). Humic matter, in particular, has been inferred as an important vector of Hg(II) from topsoils to lakes and streams (Kalbitz and Wennrich 1998; Kolka et al. 1999), and this may explain observed relationships between water color or dissolved organic carbon (DOC) and MeHg concentration in aquatic biota; furthermore, because colored DOC decreases light penetration and decreases MeHg photodegradation in surface waters (Sellers et al. 1996; O'Driscoll et al. 2006), under equal MeHg loading, the biota of colored lakes is expected to be more contaminated than that of clear lakes.

Forest removal by fire or logging increases soil temperature, runoff and DOC export to lakes (Hobbie and Likens 1973; Lamontagne et al. 2000; many others). Removal of the forest canopy by clear-cut logging or fire significantly reduces evapo-transpiration and normally causes a transient (years to decades) rise of the water table and an increase in runoff, thereby increasing the export of dissolved and particulate substances from catchments to the receiving waters. The impacts of forest removal by fire or logging on aquatic systems differ markedly, however. In the Carignan et al. studies, dissolved organic carbon (DOC) was up to threefold higher in cut lakes than in reference and burnt lakes (Figure 3). Compared with reference lakes, cut and burnt lakes had higher (two- to three-fold) concentrations of total phosphorus (TP) total organic nitrogen (TON, twofold), and K^+, Cl^-, and Ca^{2+} (up to sixfold). Nitrate and sulfate (SO_4^{2-}) concentrations were up to 60- and 6-fold higher, respectively, in burnt lakes than in reference and cut lakes. In most cases, impacts were directly proportional to the area harvested or burnt

divided by the lake's volume or area. The simple impact-intensity models generated from these observations correctly predicted the changes observed in three reference lakes harvested during the study. Collectively, these observations strongly indicate that clear-cut logging activities based on natural disturbance models do not mimic the chemical impacts of wildfire on streams and lakes. Logging mobilizes Hg from watersheds to lakes and streams with the amount of mobilization proportional to the clear-cut :lake area ratio whereas fire volatilizes Hg to the atmosphere (Woodruff and Cannon 2010).

Because clear-cutting significantly increases DOC export to lakes relative to wildfire, it was hypothesised that the supply of DOC-bound Hg to lakes and to their food webs would also increase. After clear-cutting and fires, the water table rises, the upper organic layer of the soil becomes waterlogged and more exposed to erosion, and the transfer of particulate matter and DOC to aquatic systems typically increases (Hobbie and Likens 1973). Since Hg^{++} strongly binds to the thiol (or sulfhydryl) groups of DOC in forest soils, its transfer to streams and lakes should also increase. Furthermore, the production of MeHg in the waterlogged sub-oxic or anoxic organic A_0 horizon of clear-cut soils is expected to increase. During high-intensity fires, however, most of the organic matter in the forest floor is mineralized and most of the liberated inorganic elements are leached to ground and surface waters (Bormann and Likens 1979) although some volatile elements, including Hg, are lost to the atmosphere (Sigler et al. 2003).

Analyses of MeHg in zooplankton collected in the same lakes (Garcia and Carignan 1999; Figure 4) confirmed that MeHg concentrations were significantly higher ($P < 0.01$) in zooplankton collected in lakes with recently logged catchments (135 ng·g dry weight^{-1}) than in lakes with recently burned (97 ng·g dry weight^{-1}) or undisturbed catchments (112 ng·g dry weight^{-1}). Methyl-mercury levels in zooplankton collected in burned and reference lakes were not significantly different. The increased contamination of zooplankton signifies that other components of the littoral and pelagic foodwebs, including pike and walleye will be contaminated as well. In these lakes, four variables (dissolved organic carbon, pH, dissolved oxygen, and immature zooplankton biomass) explained 43% of the variability in MeHg levels in bulk zooplankton. The presence of DOC in this statistical model supported the importance of catchment processes in the transfer of humic matter bound Hg to aquatic food webs.

1c. If effects were observed, what were their duration?

Summary Answer: After clear-cutting, the concentration of dissolved organic carbon (a known vector for mercury) in receiving lakes decreased at a rate of 10-15% per year. Methyl-mercury in short-lived organisms have likely followed similar trends. However, because Hg is bioamplified in food chains, the duration of excess Hg contamination is expected to last much longer in longer-lived top predators such as pike and walleye.

Full Answer: Some of the observed chemical effects occurred on different time scales (Figure 3). Mobile ions released by fire (K^+, Cl^-, SO_4^{2-}, NO_3^-) or harvesting (K^+, Cl^-) were rapidly flushed out of the catchment (50% decrease in 3 years) while other constituents (TP, TON, DOC, Ca^{2+}, Mg^{2+}) showed little change or were still increasing after three years. In particular, DOC concentrations in harvested lakes significantly decreased, but only at a rate of about 10-15% per year during the three years following impact. Because the transfer of Hg and DOC from catchments to lakes is expected to co-vary, Hg loading and MeHg contamination of short-lived organisms (phytoplankton, zooplankton and benthos) have likely followed trends similar to that of DOC. Mercury contamination in longer-lived top predators such as pike and walleye has only been followed for three years following clear-cut logging. However, because Hg is bioamplified

in food chains, the duration of excess Hg contamination is expected to last longer in longer-lived top predators. Bishop et al. (2009) estimated a 10 year duration for the increased Hg loading effect following a clear-cut. Because walleye can live up to 20-25 years in these lakes, increased Hg contamination may persist for more than 20 years.

1d. What were your observations, if any, on the effect of fire on mercury levels in fish?

Summary Answer: The average Hg concentration in northern pike collected in burnt lakes was similar to that of reference lakes and significantly lower than observed in clear-cut lakes when one lake with a partially and less severely burned watershed was removed from the dataset.

Full Answer: The impacts of forest removal by fire or logging on the chemical composition of aquatic systems differ markedly. As stated above (1b), DOC, a recognised Hg carrier, was up to threefold higher in cut lakes than in reference and burnt lakes (Figure 3). Compared with reference lakes, cut and burnt lakes had higher (two- to three-fold) concentrations of total phosphorus (TP) total organic nitrogen (TON, twofold), and K^+, Cl^-, and Ca^{2+} (up to sixfold). Nitrate and sulfate (SO_4^{2-}) concentrations were up to 60- and 6-fold higher, respectively, in burnt lakes than in reference and cut lakes. The average Hg concentration in northern pike collected in burnt lakes was similar to that of reference lakes and significantly lower than observed in clear-cut lakes when one lake with a partially (50.1%) and less severely burned watershed was removed from the dataset of Figure 1. The same effect of partial burns on high Hg levels in fish was observed when all species were considered and when Hg levels were normalized for trophic position (Garcia and Carignan 2005); Hg concentrations in fish from two partially burnt lakes were the highest observed. In these two lakes, substantial patches of crown fires and intact forest were left in the catchment compared to other burnt lakes, where fire was more severe and cleared the entire catchment area.

1e. If not covered by 1.d above, was there a difference between mercury impacts of clear-cutting and fire and, if so, what do you believe to be the reasons for the difference?

Summary Answer: Hot wildfires not only clear the forest, but also consume part of the forest floor (LFH horizon) where a large part of a watershed's mercury burden is stored. Being a volatile element, mercury stored in soils is expected to be at least partially lost to the atmosphere during fire.

Full Answer: Hot wildfires not only clear the forest, but also consume part of the forest floor (LFH horizon) where a large part of a watershed's Hg burden is stored. Being a volatile element, Hg stored in soils is expected to be at least partially lost to the atmosphere during fire (Sigler et al. 2003; Woodruff et al. 2010). This explains why DOC (a Hg carrier) export from burnt watersheds were considerably and significantly less than that observed in clear-cut watersheds. Furthermore, the large nutrient pulse which follows fire (Figure 3) normally stimulates primary production and causes a Hg decrease by biodilution at the base of the foodweb which propagates to higher trophic levels.

1f. What has research since your study generally found?

Summary Answer: Studies conducted elsewhere confirmed that logging operations generally increase mercury loading to streams and lakes.

Full Answer: Other studies of forestry effects have considered the concentrations and fluxes of Total Hg and/or MeHg in runoff. Porvari et al. (2003) showed in Finland that harvesting of a 7 ha stand increased Hg fluxes by a factor of four and MeHg by a factor of six. The increased fluxes resulted from both a doubling in runoff and concentration increases. It was difficult, however, to distinguish the effect of the harvest itself from the subsequent site preparation. Recent, unpublished data show that the harvest effect on this site has persisted for over 5 years (Porvari, pers. comm.). In a before/after study of clear-cutting impacts in a Thunder Bay (Ontario) watershed, Allan et al. (2009) reported that although no statistically significant changes occurred in post logging Hg concentrations, the export of MeHg and total Hg respectively increased by 81% and 116% after 22 months due to increased water yield. Such increased Hg loading from clear-cuts will increase in-lake Hg concentrations. Allan et al. (2009) further concluded that the increased Hg transport to aquatic systems was expected to persist for at least a decade.

2. What effect, if any, could clear-cut logging planned under the FMP have on mercury levels in fish at Grassy Narrows? In particular:

2a. How do the watershed characteristics in the Whiskey Jack Forest (e.g. slope, soil types, forest type, geology, precipitation, percentage of wetlands, etc.) compare to those in your Québec study area and how likely are they to produce mercury effects after clear-cut logging?

Summary Answer: In the Whiskey Jack Forest, there is a clear risk of increased mercury contamination following clear-cut logging. However, because of hydrologic and climatic differences between the Whiskey Jack Forest and other sites where research has taken place, a site-specific impact study would be necessary to confirm effects observed elsewhere.

Full Answer: The geomorphology and pedology of the Whiskey Jack Forest and of the Québec study site bear many resemblances. On both terrains, the moderate bedrock relief of only 50–70 m has been smoothed by a thin mantle of glacial till and sediment deposited in numerous glacial lakes covering ≈ 10-20% of the landscape. The Lake Wabigoon Ecoregion is comprised mainly of gneissic, granitic, and metavolcanic Precambrian bedrock (William et al. 2009) and has a similar geology to that of the Québec study site. Substantial areas, are characterised by bedrock exposures with limited (less than 2 m) unconsolidated matter. In Western Ontario, dystric brunisols dominate upland materials associated with thin moraine and glaciofluvial deposits while more eluviated ferro-humic podzols are encountered in the more humid Québec site.

According to the 2012-2022 Whiskey Jack Forest FMP, the most important forest units are: jack pine (24%), black or white spruce (17%), mixed hardwoods (14%), mixed conifers (12% and poplar (12%). With the exception of a larger prevalence of jack pine at the Whiskey Jack Forest, these percentages are similar to what is observed at the Québec study site (Carignan et al. 2000).

With a mean annual precipitation ranging between 565 and 724 mm (William et al. 2009), the climate of the Whiskey Jack Forest is relatively dry compared to that of the Québec study site, which annually receives ≈1000 mm of precipitation. The Whiskey Jack Forest is significantly influenced by the adjacent prairie climate, and seasonal weather patterns can include substantial periods of summer drought. The dryer climate results in a much lower mean

annual runoff (≈ 200 mm/y) than at the Québec study site (≈ 500 mm/y) and a less pronounced spring runoff (http://atlas.nrcan.gc.ca/site/english/maps/water.html).

As explained in Section 1, much of the excess Hg export and contamination associated with clear-cutting at the Québec site is thought to occur through increased DOC-Hg export following the rise of the water table due to reduced evapo-transpiration and possibly through increased MeHg production in waterlogged, sub-oxic and warm clear-cut soils. In other words, in clear-cut watersheds, the top of the summertime water table often intersects the warm organic LFH top layer at the Québec site, which favours Hg export to streams and lakes. Since annual runoff in the Whiskey Jack Forest is substantially lower than at the Québec site, waterlogged conditions are not expected to be as frequent, and Hg transfer to lakes and streams at the Whiskey Jack Forest should be lower than in Québec if other conditions (slope, thickness of unconsolidated deposits, catchment size) are equal. On the other hand, if similar forest biomasses are felled at both sites, the rise of the water table following clear-cut should be similar. Therefore, the formation of waterlogged sub-oxic soil zones where Hg methylation can occur on gently sloping terrain and near lakeshores and streams is also likely in the Whiskey Jack Forest.

Furthermore, because runoff is much lower in Northern Ontario than it is in central Québec, important in-lake properties such as water residence time, light penetration, DOC and Hg concentrations and dynamics likely differ between the two regions. For these reasons, my general conclusion is that there is a clear risk of increased Hg contamination, but that a site-specific impact study will definitely be necessary in the Whiskey Jack Forest.

2b. How likely is it, if at all, that the logging methods set out in the Plan could lead to mercury bio-accumulation?

Summary Answer: If the Québec results are applied to the Whiskey Jack Forest, mercury contamination problems due to planned clear-cut logging and excessive cut-block size are expected in several lakes. Note, however, that hydrology differs and food web structure may differ in both regions; for this reason, a site-specific impact study is recommended for the Whiskey Jack Forest.

Full Answer: The Québec studies reveal that large impacts of clear-cuts on lake chemistry are observed when the clear-cut:watershed area ratio exceeds about 0.2 (Carignan et al. 2000). Furthermore, significant impacts of clear-cuts on Hg levels normalised to trophic level in lake biota are observed in 1st order lakes when the clear-cut:lake area ratio exceeds about 2 (Garcia and Carignan 2005, Figure 5). However, these results only quantify the relationship between Hg levels in food webs and clear-cut logging in Québec; they cannot be directly applied to the prediction of Hg levels in walleye from the Whiskey Jack Forest because hydrology differs, because food web structure may differ and because such predictions are based on a knowledge of the trophic position of walleye in each lake of interest.

Nevertheless, in order to compare the importance of clear-cuts in the Whiskey Jack Forest to those of the Québec site, the Ontario Flow Assessment Tool (www.giscoeapp.lrc.gov.on.ca/web/mnr/wrip/ofat/Viewer/viewer.html) was used to delineate watersheds of 48 randomly selected lakes of varying sizes (0.1 – 43.4 km^2). These watersheds were then intersected with the cutblocks defined in the December 2013 Ontario Ministry of Natural Resources approved Whiskey Jack Forest Management Plan where the “HARVCAT” categories “REGULAR1” and “REGULAR2” were summed to estimate the size of the projected cutblocks for the entire duration of the 2012-2022 forest management plan.

The results (Table 1) indicate that if the Québec-specific impact indicators (water chemistry, Hg in fish) are applied to the Whiskey Jack Forest, Hg contamination problems due to planned clear-cuts and excessive cut-block size are expected in several lakes (highlighted in blue in Table 1). Furthermore, as revealed by a GIS analysis of previous clear-cuts in the Whiskey Jack Forest by Stephen Kilburn (2015), some of these lakes have already been impacted by clear-cuts performed in past decades. Note, however, that all the impacted lakes in our sample are rather small (0.11 – 1.78 km^2).

2c. Please comment on the extent to which other FMP planned activities, such as scarification and thinning, could product mercury impacts?

Summary Answer: Large effects of scarification and thinning compared to those of clear-cuts are not anticipated.

Full Answer: Insufficient scientific information exists on the effect of the various site-specific scarification procedures on Hg export to lakes and streams. However, large effects compared to those arising from the hydrological perturbations of the Hg cycle following large clear-cuts are not anticipated. The impact of thinning should be less pronounced than that of clear-cut logging because thinning leaves a substantial proportion of the forest cover unperturbed and does not affect evapo-transpiration and the hydrological balance as much as clear-cut logging does.

2d. Please comment on the similarities and/or differences in the mitigation measures identified in the FMP (see Stand and Site Guide rationale) to those used in your Québec study site in terms of catchment disturbance thresholds, size of clear-cuts, nature of soil protections, size of riparian buffers, or other measures you wish to comment on, and what you would expect in terms of the ability of these respective measures to prevent, or not prevent, mercury impacts?

Summary Answer: In my opinion, and as recognised in the Ontario Stand and Site Guide, the effects of harvesting and wildfire on water quality appear to be influenced by the relative extent of catchment disturbance, and not by shoreline buffers or other mitigation measures.

Full Answer: Although cut-block sizes are roughly comparable in Ontario and Québec, riparian buffers widths around stream and lakes differ considerably. In the publicly owned forest of Québec, buffers around streams and lakes are limited to 20 m beginning at the riparian-forest ecotone, and are often wind-blown after a few years. Québec regulations allow the removal of commercial stems within the 20-m buffer as long as the slope does not exceed 40% and as long as a minimum stem density of 500/ha is maintained for stems exceeding 10 cm.[1]

The Ontario Stand and Site Guide norms for conserving biodiversity at the stand and site scales are more complex[2]. Based on terrain slope, Ontario 'buffers/AOC' range from 30-90m on lakes and streams, but clear-cutting is allowed within the buffers to within 3m from the edge of woody vegetation, and within that 3m selective logging is allowed to remove approximately.

2 Ontario Ministry of Natural Resources, 2010. Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales – Background and Rationale for Direction.

50% of the cover. Other directive measures regarding rutting and soil compaction within AOC's are stated. However, in my opinion and as recognised in the Ontario Stand and Site Guide, the effects of harvesting and wildfire on water quality appear to be influenced by the extent of catchment disturbance, and not by shoreline buffers. Our studies in Québec indicate that it is the cut-block size relative the watershed and lake size that determine the severity of impacts by Hg contamination. In their present forms, the SSG rationales of both Ontario and Québec do not contain any directives regarding maximum catchment disturbance in relation to watershed or lake size.

2e. Based on the landscape pattern map what, in your professional opinion, are the implications for mercury impacts, if any, of the proximity of currently planned cut-blocks to previous cut-blocks, or of the plan direction to create clear-cut areas as large as 7,900 ha?

Summary Answer: It is not the absolute size of the cut-blocks that matters, but rather the relative size of all clear-cut areas within a watershed. In this regard, excessive mercury contamination may occur in many small lakes of the Whiskey Jack Forest.

Full Answer: The maximum size of the cut-blocks listed in the December 2013 Ontario Ministry of Natural Resources approved Whiskey Jack Forest Management Plan (Tables: FMP 12 Planned Clear-cuts > 260 Ha) is 7 905 ha. Most joined cut-blocks of this management plan are smaller than 300 ha. As noted above, according to our Québec observations, it is not the absolute size of the cut-blocks that matter, but rather the relative size of all clear-cut areas within a watershed. In this regard, Table 1 shows that excessive Hg contamination may occur in many small lakes of the Whiskey Jack Forest.

2f. If not otherwise answered by you, what is your professional opinion on the effectiveness of the measures in the Stand and Site Guide, which the Stand and Site Guide Rationale suggests will control mercury impacts (e.g. measures to minimize soil compaction, measures to minimize hydrological disruption, riparian buffers, etc.)?

Summary Answer: Excess mercury contamination likely arises from a general rise of the water table and flooding of organic soil layers following the reduction of forest transpiration after clear-cuts. Such catchment-level disturbances are ignored in the Ontario SSG.

Full Answer: Although the general forest management practises presented in the Stand and Site Guide appear generally more respectful of the environment than current practises observed in Québec, they do not include any specific measures to limit Hg bioaccumulation in the aquatic biota. As explained above (2b, 2d), excess Hg contamination likely arises from a general rise of the water table and flooding of organic soil layers following the reduction of forest transpiration after clear-cuts. Such catchment-level disturbances are ignored in the Ontario SSG. There is currently no experimental evidence showing that quantitative thresholds on the amount or depth of rutting or other alterations of the micro-scale hydrological connectivity will prevent mercury impacts. In my opinion, such thresholds will not lessen Hg-related problems in the receiving lakes and streams.

3. Please comment on whether clear-cut logging arising from the FMP is likely, or not likely, to compound the previous mercury problem at Grassy Narrows through cumulative effects, or otherwise. In particular:

3a. Does clear-cut logging proposed under the FMP risk, or not risk, increasing the release and bio-accumulation of mercury in bodies of water?

Summary Answer: The Whiskey Jack FMP is likely to increase Hg bioaccumulation in fish caught in some small lakes where the size of cut-blocks is large relative to watershed area or lake area.

Full Answer: The Whiskey Jack FMP is likely to increase Hg bioaccumulation in fish caught in some small lakes (Table 1) draining watersheds where the size of cut-blocks is large relative to watershed area or lake area. However, because of the very different hydrological context between Québec and the Whiskey Jack Forest, a site-specific study would be necessary to ascertain the effects of current clear-cut logging practises on Hg contamination in fish.

3b. Does clear-cut logging risk exacerbating, or not, pre-existing mercury conditions in the English-Wabigoon river system? In particular, (i) will it increase, or not, methylation of existing mercury in top layers of river sediment, (ii) will it decrease, or not, demethylation, (iii) will it decrease, or not, volatization, and (iv) will it increase, or not, supplies of fresh carbon and anoxic conditions?

Summary Answer: The impact of the Whiskey Jack FMP alone on the Hg cycle of the English-Wabigoon river system is most likely negligible. However, if the annual forest removal rate (about 0,7% per year or 7% per decade) of the Whiskey Jack FMP is extrapolated to the entire English-Wabigoon watershed, current forestry practises in Ontario may increase Hg contamination in a detectable manner.

Full Answer: The watershed of the English-Wabigoon river system is very large (48 700 km^2 at the outlet of Separation lake) relative to the total area of all cut-blocks (≈440 km^2) planned within the Grassy Narrows First Nation territory (≈6 800 km^2) under the Whiskey Jack FMP. Therefore, the impact of the Whiskey Jack FMP alone on the Hg cycle of the English-Wabigoon river system is most likely negligible. Nevertheless, if the annual forest removal rate (about 0,7% per year or 7% per decade) of the Whiskey Jack FMP is extrapolated to the entire English-Wabigoon watershed, current forestry practises in Ontario may increase Hg contamination in a detectable manner. For example, after reviewing several studies conducted in Canada, Finland, the United-Sates and Sweden, Bishop et al. (2009) estimated that under a 1% annual forest removal rate scenario, Hg concentration in fish would increase by 10% to30%. Changes anticipated in smaller watersheds and upstream lakes will likely propagate to larger river systems such as the English-Wabigoon where previous Hg contaminations problems are well documented.

3c. Please comment on whether headwater lakes upstream from the contaminated English-Wabigoon river system are likely, or not, to have elevated mercury levels in fish after clear-cut logging?

Please see 2a and 2b.

4. Please comment on whether selective logging would have greater, lesser, or no different impacts on the release of mercury than clear-cut logging? In particular:

4a. Would selective logging produce less, or more, hydrological impacts (e.g. raised water table, increased soil moisture, increased total flows) and soil impacts, than clear-cut logging?

Full Answer: Compared to clear-cut logging, selective logging in cut-blocks of identical sizes than those of the Whiskey Jack FMP would likely reduce hydrological flow and reduce Hg export to the aquatic environment arising from lessened transpiration.

4b. What are your views, if any, on the need for local experiments to confirm the effects of selective logging before allowing it as a substitute for clear-cut logging?

Summary Answer: Comprehensive before/after impact observations lasting at least three years and involving at least five controls, five clear-cut and five selectively cut 1st order lakes where walleye is present should be initiated in order to derive forestry practises that are respectful of the aquatic environment.

Full Answer: As already stated under 2a, hydrological conditions at the Québec site are different from those prevailing in Northwestern Ontario. For this reason, the Québec results can probably not be directly applied to the Whiskey Jack region. Nevertheless, the Québec results strongly suggest that the Ontario MNR should be concerned about the potential local link between clear-cut logging and Hg contamination. Comprehensive before/after impact observations lasting at least three years and involving at least five controls, five clear-cut and five selectively cut 1st order lakes where walleye is present should be initiated in order to derive forestry practises that are respectful of the aquatic environment.

4c. What are your views, if any, on whether modified clear-cut logging methods such as measures to prevent soil damage, increased buffers, increased residuals, timing restrictions, measures to prevent hydrological disruption, etc., would prevent, or not prevent, mercury impacts to water/fish?

Full Answer: As stated above, the Québec studies indicate that it is the substantial rise of the water table during several years following clear-cut logging that leads to increased Hg in fish. Mitigating measures such as soil damage prevention, increased buffers, increased residuals and timing restrictions may alleviate the problem, but will have very little effects on the rise of the water table, increased runoff following a clear-cut, and the increase in Hg contamination. Region-specific guidelines should be derived from a region-specific study on the impacts of logging on the aquatic Hg cycle.

5. What is your general overall conclusion in light of your research on the capacity of clear-cut logging to increase mercury levels in fish in bodies of water in the Whiskey Jack Forest?

My general conclusion is that there is a clear risk of increased Hg contamination, but that a site-specific impact study will definitely be necessary to orient sustainable forestry practices in the Whiskey Jack Forest.

FIGURES

Figure 1. Box plots showing median values and 10th, 25th, 75th, and 90th percentiles of Hg in 560-mm northern pike, expressed on a dry weight basis, from logged (*N* = 4), burned (*N* = 7), and reference lakes (*N* = 8). Letters on top of the boxes indicate between-treatment differences: boxes with different letters are significantly different (Wilcoxon–Mann–Whitney test, $p < 0.01$). Note that in burned lakes, the highest Hg concentration was found in a lake with a partially (50.1%) burned watershed; when this lake is removed from the dataset, logged and burned lakes become significantly different. From Garcia and Carignan (2000).

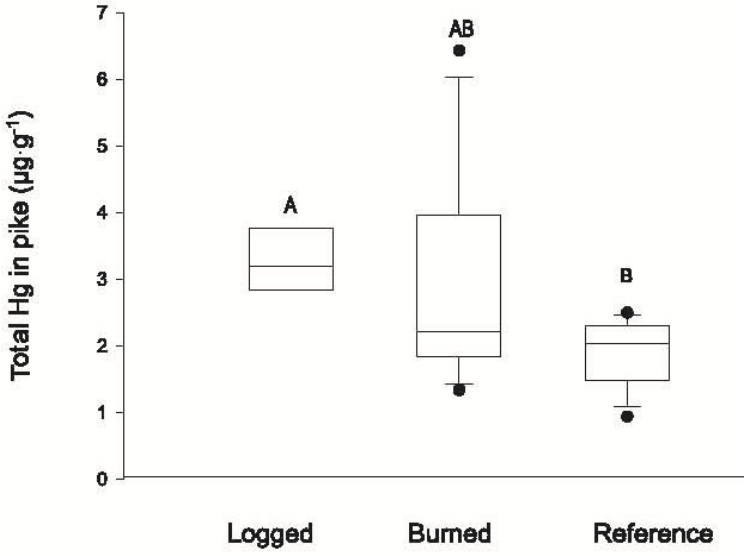

Figure 2. Periphyton methylmercury concentrations (MeHg; ng Hg·g–1 dry mass (DM); mean ± standard error) in experimental lakes sampled before and two consecutive summers after logging. Different letters indicate significant mean differences within years (one-way analysis of variance, $p < 0.01$). From Desrosiers et al. (2006).

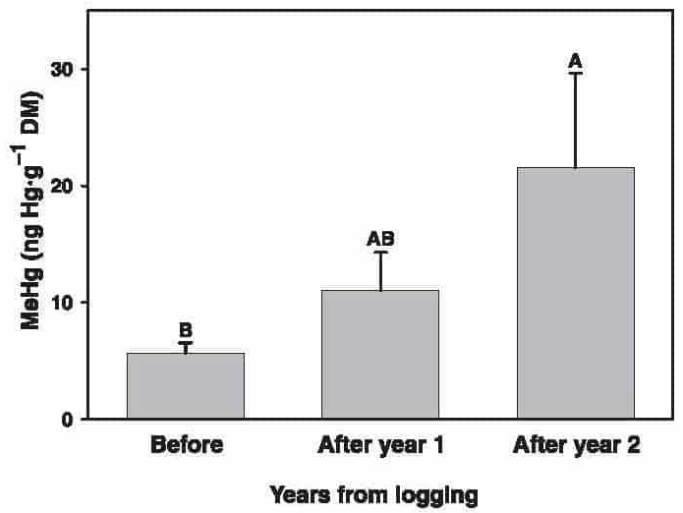

Figure 3. Box plots showing median values with the 25th and 75th and the 5th and 95th percentiles of annual average concentrations of dissolved constituents and of the light extinction coefficient ePAR in reference (open boxes, *n* = 17), cut (hatched boxes, *n* = 7), and burnt lakes (cross-hatched boxes, *n* = 9). The thick horizontal lines indicate between-treatment differences: for a given year, boxes with different levels are significantly different. Arrows on top of the boxes indicate significant increasing or decreasing trends with time compared with the reference group (paired RMA). Two lakes (C40 and C44) where only a small portion of the catchment had been harvested are excluded from these analyses. From Carignan et al. (2000).

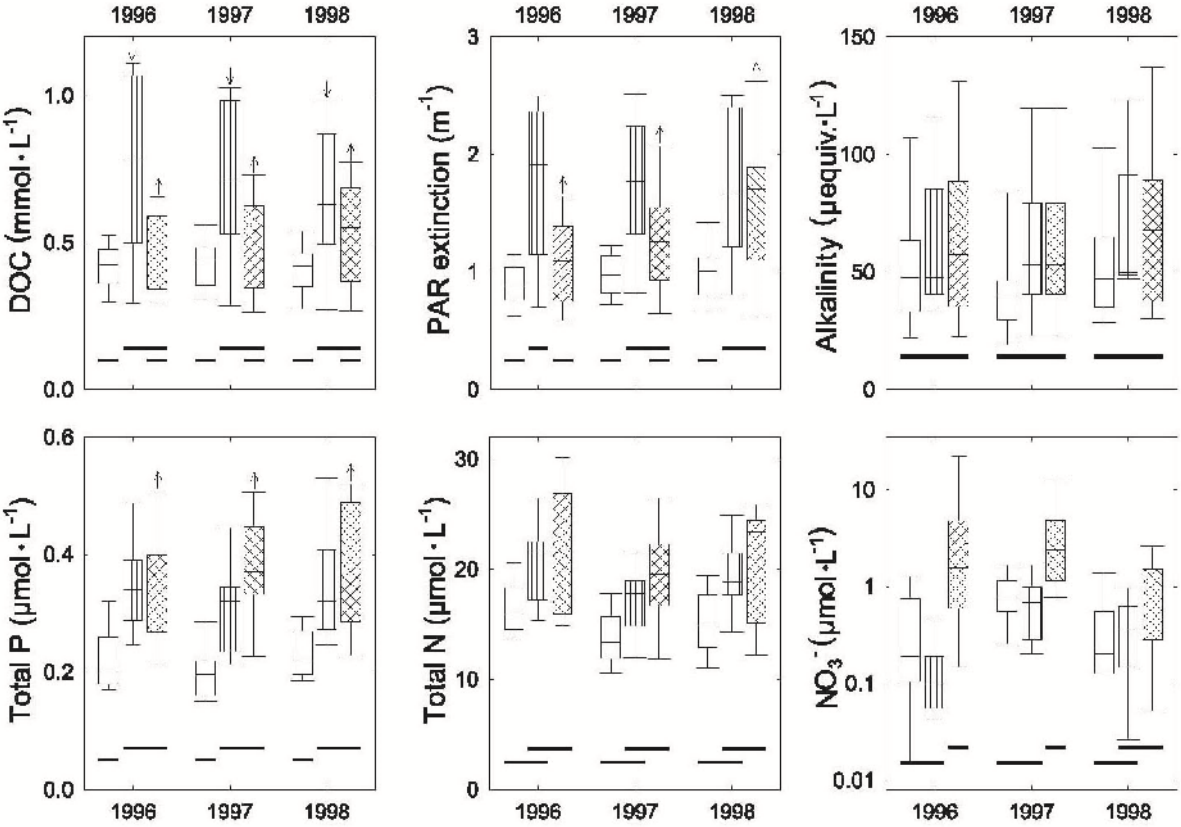

Figure 4. (A) MeHg levels in zooplankton and (B) DOC in water from logged (*N* = 9), burned (*N* = 9), and reference lakes (*N* = 20). Values are averages for each sample period. Error bars represent 1 SE. From Garcia and Carignan (1999),

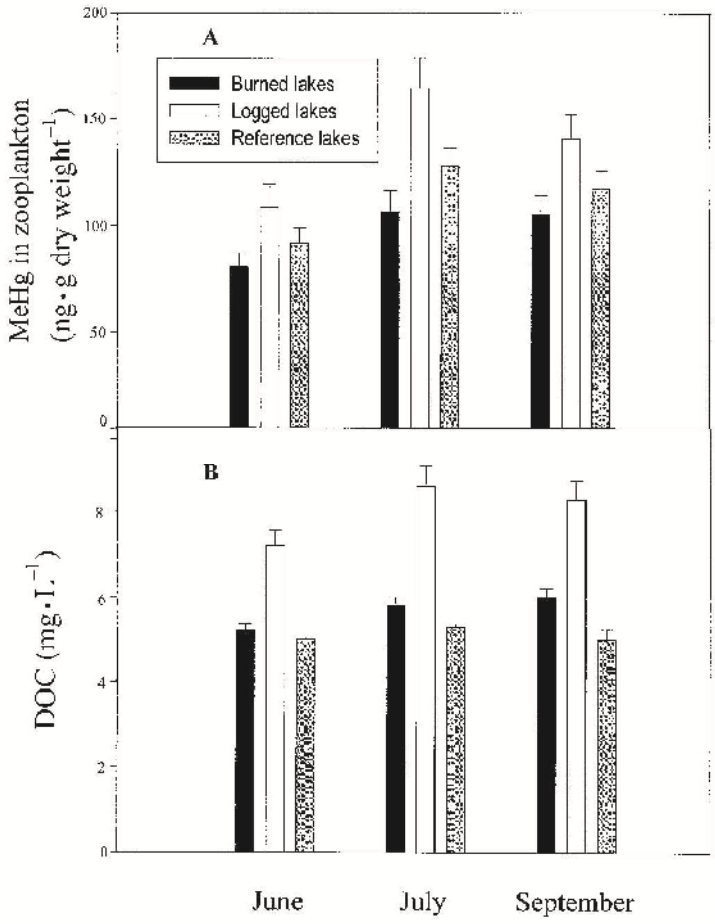

Figure 5. Relationships between mercury (Hg) concentrations in fish (on a dry-mass basis) normalized to baseline corrected d15N and ratio of logged area to lake area (r = 0.74, p , 0.01). From Garcia and Carignan (2005).

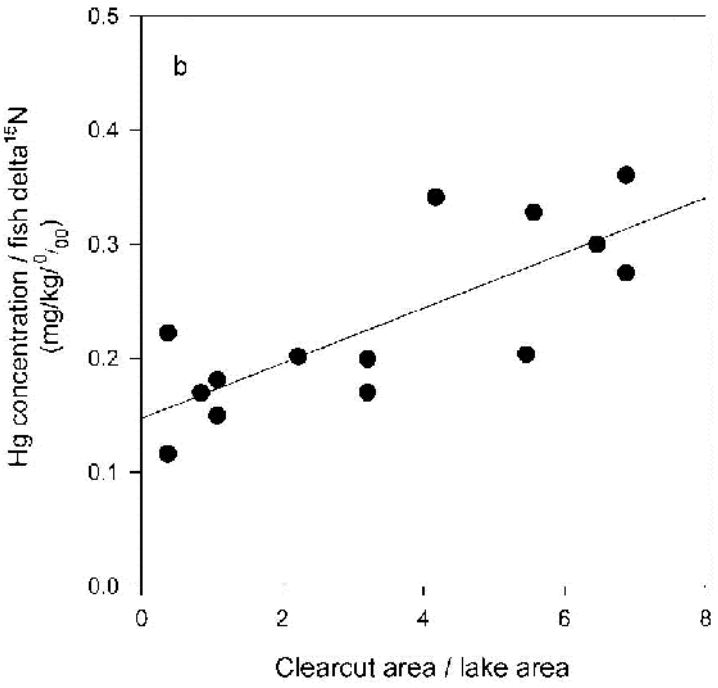

Table 1. Morphometric and watershed properties of selected lakes in the Whiskey Jack Forest. Lakes where the %clear-cut and the %clear-cut/lake area ratio appear excessive in terms of Hg contamination if the Québec models are applied are highlighted in blue.

Appendix A – Curriculum Vitae

Conseil de recherches en sciences naturelles et en génie du Canada | Natural Sciences and Engineering Research Council of Canada

FORMULAIRE 100
Formulaire de renseignements personnels
PARTIE I

Date: 2016/01/11

Nom de famille	Prénom	Initiale(s) de tous les prénoms	N° d'identification personnel (NIP)
Carignan	Richard	R	Valide 13928

☐ J'occupe un poste au sein du corps professoral d'un collège canadien admissible (remplissez les annexes B-1 et C).

☐ Je n'occupe pas de poste ou n'en occuperai aucun au sein du corps professoral d'un établissement postsecondaire canadien. Lieu d'emploi autre qu'un établissement postsecondaire canadien (indiquez-en l'adresse à l'annexe A).

NOMINATION À UN ÉTABLISSEMENT POSTSECONDAIRE

Titre du poste: Professeur

Département: Sciences biologiques

Campus:

Établissement postsecondaire canadien: Montréal

Une nomination universitaire/collégiale permanente ou menant à la permanence — Oui [X] Non [ ]

Nomination à temps partiel [ ] Nomination à plein temps [X]

- Pour les nominations universitaires qui ne sont pas permanentes ou qui ne mènent pas à la permanence et pour les postes de professeurs émérites, remplissez les annexes B et C.
- Pour les postes de professeurs émérites à plein temps et les postes à temps partiel, remplissez l'annexe C.

FORMATION UNIVERSITAIRE

Diplôme	Nom de la discipline	Établissement	Pays	Date aaaa/mm
Baccalauréat	Biologie sp. écologie	Québec à Montréal	CANADA	1975 / 06
Doctorat	Limnologie	McGill	CANADA	1981 / 06

PERSONNEL HAUTEMENT QUALIFIÉ (PHQ)

Précisez le nombre d'étudiants, de stagiaires et d'autres personnels de recherche que vous supervisez ou avez supervisés :

	Actuellement		Au cours des six dernières années (à l'exception de l'année en cours)		
	Supervision	Cosupervision	Supervision	Cosupervision	Total
Étudiants de 1er cycle	2		28		30
Étudiants à la maîtrise	1	1	5	2	9
Étudiants au doctorat			2	2	4
Stagiaires postdoctoraux	1		3		4
Autres	2		4		6
Total	6	1	42	4	53

Formulaire 100 (2009 W) Canada

Les renseignements personnels figurant dans ce formulaire et dans les annexes seront intégrés dans le fichier de renseignements personnels du programme approprié.
PROTÉGÉ UNE FOIS REMPLI

PARTIE II. CONTRIBUTIONS À LA RECHERCHE

1. LISTE DES CONTRIBUTIONS À LA RECHERCHE

1.1 Contributions les plus importantes

Carignan, R., C. Vis et D. Planas (2000). Planktonic production and respiration in oligotrophic Shield lakes **Limnology and Oceanography** 45: 189-199. Ces travaux portent sur un aspect fondamental de notre compréhension des écosystèmes aquatiques. Ils montrent que, contrairement aux hypothèses récentes, le métabolisme global des lacs oligotrophes est essentiellement autotrophe et dépend peu des sources de carbone organique externes. *This study, highlighted by the Editors in the January 2000 issue of L&O, focuses on a fundamental aspect of global metabolism in aquatic ecosystems. It shows that, contrary to current hypotheses, lakes are essentially autotrophic systems and rely only marginally on external organic carbon supply.*

Carignan, R., P. D'Arcy et S. Lamontagne (2000). Comparative impacts of fire and forest harvesting in Boreal Shield Lakes. **Can. J. Fish. Aquat. Sci.** 57(suppl. 2): 105-117. Ces travaux distinguent, pour la première fois en Amérique du Nord, les effets de la coupe forestière de ceux causés par les feux de forêt sur la qualité des eaux dans les lacs de la forêt boréale. De plus, ils proposent des modèles de gestion forestière permettant de minimiser les impacts des coupes. *This work contrasts, for the first time in North America, the differential impacts of clear cutting and wildfires on water quality in boreal lakes.*

Carignan, R., A.-M. Blais, et C. Vis (1998). Measurement of primary production and community respiration in oligotrophic lakes using the Winkler method. **Can. J. Fish. Aquat. Sci.** 55: 1078-1084. Ce travail démontre, pour la première fois, qu'il est possible de mesurer avec précision la production et la respiration planctoniques dans les eaux peu productives par dosage électrochimique de l'oxygène dissous. La méthodologie décrite est susceptible de remplacer la méthode du ^{14}C en océanographie et en limnologie. *This work shows, for the first time, that planktonic production and respiration can be accurately measured in oligotrophic waters using the oxygen method. The new protocol is likely to replace the ^{14}C method in oceanography and limnology in the near future.*

Carignan, R. (1998). Automated measurement of carbon dioxide, oxygen and nitrogen partial pressures in surface waters. **Limnol. Oceanogr.** 43: 969-975. L'instrument décrit permet, pour la première fois, de mesurer avec très grande précision et simultanément les concentrations de CO_2, O_2 et N_2 dans les eaux de surface. Il permet, entre autres, d'étudier la balance production-respiration au niveau de l'écosystème entier, et de mesurer les coefficients d'échange gazeux à l'interface air-eau. *This new intrument allows, for the first time, accurate and automated measurements of CO_2, O_2 and N_2 concentrations in surface waters. It allows the study of the global production-respiration balance at the ecosystem level, and the determination of gas tranfer coefficients at the air-water interface.*

Carignan, R., et D. Planas (1994). Recognition of nutrient and light limitation in turbid mixed layers: Three approaches compared in the Paraná floodplain (Argentina). **Limnol. Oceanogr.** 39: 580-596. Ce travail montre, pour la première fois, que les lacs de la plaine inondable du fleuve

Parana sont limités par la lumière ou l'azote, et non pas par le phosphore. De plus, les résultats montrent que seule la fertilisation de lacs entiers permet de mettre en évidence le rôle limitant de l'azote et de la lumière. *This work shows, for the first time, that nitrogen and light - and not phosporus - are limiting factors in the Parana River floodplain lakes. The results also show that the limiting roles of nitrogen and light can be unambiguously demonstrated only with whole-lake fertilization experiments.*

1.2 Contributions à la recherche

1.21 Contributions avec comité de lecture

RC01- Forget, M.-H., Carignan, R. et C. Hudon (2009). Influence of diel cycles of respiration, chlorophyll, and photosynthetic parameters on the summer metabolic balance of temperate lakes and rivers. **Can. J. Fish. Aquat. Sci.** (66: 1048-1058).

RC02- Dubois, K., R. Carignan et Jan Veizer (2009). Can pelagic net heterotrophy account for carbon fluxes from eastern Canadian lakes? **Applied Geochemistry** 24: 998-988.

RC03- Roy, V., M. Amyot et R. Carignan (2009). Beaver ponds increase methylmercury and nutrient levels in Canadian shield streams. **Environmental Sci. & Technol.** 43: 5605-5611.

RC04- Roy, V., M. Amyot et R. Carignan (2009). Seasonal methylmercury trends in waters draining three beaver impoundements. **Journal of Geophysical Research** 114 doi:10.1029/2008JG000763.

RC05- Hudon, C. et R. Carignan (2008). Hydrological influence on water quality in Lake Saint-Pierre (St. Lawrence River, Quebec, Canada). **Can. J. Fish. Aquat. Sci.** (65: 1165-1180).

RC06- Lambert, D., Cattaneo, A, et R. Carignan (2008). Periphyton as an early indicator of eutophication in recreational lakes. **Can. J. Fish. Aquat. Sci.** 65: 258-265.

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Richard Carignan. I live in Montreal in the Province of Quebec.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

SUPPLEMENTARY AFFIDAVIT OF RICHARD CARIGNAN

I, RICHARD CARIGNAN, of the City of Montreal, in the Province of Quebec, MAKE OATH AND SAY AS FOLLOWS:

1. I am a professional limnologist and ecologist. I hold a doctorate in limnology from McGill University and a Bachelor of Science degree in ecology from the University of Quebec at Montreal. I am currently a professor in the Department of Biological Sciences at the Université de Montreal where I teach courses in such subjects as ecotoxicology,

limnology, advanced limnology, and research methods with respect to these areas. I am also a member of the Interuniversity Research Group on Limnology and the Aquatic Environment and I have been an associate editor of the Canadian Journal of Fisheries and Aquatic Sciences. I am qualified to research and analyze issues involving freshwater lakes and effects on fish in such lakes from the introduction of materials arising from human and natural activities. I have conducted field research projects at such lakes in the Boreal forest of Quebec studying the effects of clear-cut logging on mercury levels in fish. I have published on this subject in a variety of peer-reviewed scientific journals. In this regard, I have reviewed the Forest Management Plan approved by the Ontario Ministry of Natural Resources and Forestry in December 2013 that allows clear-cut logging for the portion of the northwestern Ontario Boreal Forest known as the Whiskey Jack Forest. I have also reviewed related documents, such as the Ministry's Stand and Site Guide, which addresses mercury mitigation measures in relation to logging activities. A copy of my curriculum vitae is attached to Exhibit "A", below.

2. In December 2015 I was asked by counsel for Grassy Narrows to answer certain further questions in a report on the potential effects of the December 2013 Forest Management Plan on mercury contamination in fish. The questions and my answers to them appear as part of my February 2016 supplementaty expert report attached as Exhibit "A" to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "B" to my Affidavit.

SWORN BEFORE ME in the City of Montreal, in the Province of Quebec, this ___ day of _____, 2016.

A Commissioner, etc.

Introduction

I am a professional limnologist and ecologist. I hold a doctorate in limnology from McGill University and a Bachelor of Science degree in ecology from the University of Quebec at Montreal. I am currently a professor at the Department of Biological Sciences at the Université de Montreal where I teach courses in such subjects as ecotoxicology, limnology, advanced limnology, and research methods with respect to these areas. I am also a member of the Interuniversity Research Group on Limnology and the Aquatic Environment and I have been an associate editor of the Canadian Journal of Fisheries and Aquatic Sciences. I am qualified to research and analyze issues involving freshwater lakes and effects on fish in such lakes from the introduction of materials arising from human and natural activities. I have conducted field research projects at such lakes in the Boreal forest of Quebec studying the effects of clear-cut logging on mercury levels in fish. I have published on this subject in a variety of peer-reviewed scientific journals. In this regard, I have reviewed the Forest Management Plan approved by the Ontario Ministry of Natural Resources and Forestry in December 2013 that allows clear-cut logging for the portion of the northwestern Ontario Boreal Forest known as the Whiskey Jack Forest. I have also reviewed related documents, such as the Ministry's Stand and Site Guide, which addresses mercury mitigation measures in relation to logging activities. My curriculum vitae appears in Appendix A of this Expert Report.

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association on behalf of Grassy Narrows First Nation to prepare a further expert report that responds to several additional questions. I am solely responsible for the preparation of this report.

Questions

1. For the documents referred to in A. below, please indicate on a document by document basis if the views expressed in those documents that relate to the subject matter of your first expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your second expert report the corrections, if any, that should be made with respect thereto:

A. The Grassy Narrows-Earthroots request, dated January 2014 (pages noted below[1]), of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated [B.] May 2014 (pages noted below[2]), and [C.] November 2014 (pages noted below[3]), insofar as they relate to your area of expertise and the subject matter of your first expert report.

2. What are your views on matters within your area of expertise and the subject matter of your first expert report that are addressed in the Ministry of Natural Resources and Forestry July 2014 response to the Grassy Narrows-Earthroots May 2014 submissions referred to in Question 1 (pages noted below[4])?

3. What are your views on the December 2014 Ministry of the Environment decision's treatment of evidence provided by the Ministry of Natural Resources and Forestry where matters within your area of expertise are discussed (pages noted below[5])?

Answers to Questions

Question:

1. For the documents below, please indicate on a document by document basis if the views expressed in those documents that relate to the subject matter of your first expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate the corrections, if any, that should be made with respect thereto:

A. The Grassy Narrows-Earthroots request, dated January 2014 (pages noted below), of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), insofar as [it] relate[s] to your area of expertise and the subject matter of your first expert report.

Volume 3 of Applicants' Application Record in Case No. 446/15 – pages 001246-001248 also identified as pages 3-5.

Answer: This document correctly summarises results by Carignan et al. and by many others. However, its conclusions that 1- "Clearcutting on Grassy Narrows Territory **will** cause the discharge of mercury into the aquatic environment" and 2- "Clearcutting in Grassy Narrows Territory **will** result in the harmful alteration of fish habitat by causing levels of methyl mercury in the fish's environment and food chain to be elevated." are extrapolations of studies conducted under different geo-climatic regimes. It would have been preferable to replace "will" by "will likely" in conclusions 1 and 2 above. Only a site-specific study of the type sought in the IEA request and for which I discussed the need in my first expert report, could establish with confidence the impacts of clearcutting on mercury in fish in the Grassy Narrows Territory.

Volume 3 of Applicants' Application Record in Case No. 446/15 – pages 001256-001265 also identified as pages 13-22.

Answer: The views attributed to Carignan et al. and Garcia at al, are accurate. Furthermore, the Applicants' conclusions on the "Fundamental Problems with MNR Rationale" are essentially correct: (A) Natural disturbance (wildfire) emulation is not appropriate for mercury management because fire and logging have different impacts on the behavior of mercury in watersheds; a fully burnt forest releases its mercury to the atmosphere, whereas a clearcut forest releases its mercury to the watershed.
(B) MNR cannot mitigate mercury bioaccumulation using measures for which there is no experimental evidence; (C) MNR provides no scientific experimental evidence that their mercury mitigation measures are effective.

Volume 3 of Applicants' Application Record in Case No. 446/15 – pages 001267-001268 also identified as pages 24-25.

Answer: The preamble, conclusion and views attributed to Carignan et al. and Garcia at al. in these pages are correct. The impacts of releasing mercury into the environment in Grassy Narrows through clearcut logging are likely to last at least a decade in fish, and at least one human lifespan beyond that in people.

Volume 3 of Applicants' Application Record in Case No. 446/15 – pages 001270-001277 also identified as pages 27-34.

Answer: The comments attributed to Carignan et al., Garcia et al. and Garcia, Carignan and Lean are correct.

Volume 3 of Applicants' Application Record in Case No. 446/15 – pages 001287-001293 also identified as pages 44-50.

Answer: The question (Q2) raised in the MNR Stand and Site Guide about whether *"the fine filter direction will retain sufficient residual forest within catchments to ensure that hydrological effects resulting from forest management operations: i) do not exceed those observed in naturally disturbed catchments and ii) do not exceed acceptable levels for specific parameters (e.g., methyl mercury)?"* is legitimate and stems from a large body of scientific evidence acquired in Quebec and Europe.

On the other hand, the MNR Stand and Site Guide Rationale misinterprets the scientific evidence by stating that the "Removal of trees from catchments by timber harvest **or** wildfire is associated with **generally similar** changes in the hydrology, chemistry, and biota of lakes and streams." (MNR, Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales: Background and Rationale for Direction, July 15, 2010, at page 24). Our observations in Quebec show that forest removal by fire and logging has widely different impacts on water quality and methyl-mercury contamination in receiving lakes. As I noted above and in my first expert report, a (fully) burnt forest releases its mercury to the atmosphere, whereas a clearcut forest releases its mercury to the watershed.

Question:

1. For the documents below, please indicate on a document by document basis if the views expressed in those documents that relate to the subject matter of your first expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate the corrections, if any, that should be made with respect thereto:

….

B. The Grassy Narrows-Earthroots….supplementary submissions made to the Ministry [of the Environment] dated May 2014 (pages noted below), insofar as they relate to your area of expertise and the subject matter of your first expert report.

Volume 3 of Applicants' Application Record in Case No. 446/15 – pages 001351-001355 also identified as pages 3-7.

Answer: Regarding the MNR argument that: "The range of Hg levels in fish in harvested watersheds was within the range of those in burned watersheds (Garcia and Carignan 2000, 2005)."

Grassy Narrows/Earthroots replied that:

1- Garcia and Carignan indicate that intense fires do not significantly raise mercury levels in fish (logging did);
2-Intense fires may form a pathway for mercury out of the total forest mercury pool (terrestrial + aquatic) (logging does not);
3- "Most area burned in N American boreal forests is by high intensity crown fires, and this is likely to continue in the future" (de Groot et al., 2003, p.363);
4- Therefore, the total mercury pool in a logging dominated landscape may be higher than a fire dominated landscape. (i.e. not within the natural range for the landscape);
5- The total aquatic mercury pool in a logging dominated landscape may also be higher than in a fire dominated landscape;
6- When looking at the statistical trend line (rather than the data points) Fig. 4 of Garcia and Carignan shows that logging generally led to higher levels of mercury in fish than fire did.

Replies 1 through 6 by Grassy Narrows/Earthroots are correct. However, because the precipitation/evapotranspiration regimes of Northwestern Ontario and Quebec boreal zones are different, site-specific studies would be required to establish the effects of clearcut logging on methyl-mercury contamination of the aquatic biota of Northwestern Ontario. Nevertheless, in a study on post-logging mercury export near Thunder Bay (Allan et al., 2009) found a doubling of mercury flux due to a doubling of flow and expected the increase in mercury export to last at least ten years. They estimated that 20% of mercury in NW Ontario fish was due to logging. The Allan et al. (2009) study is reproduced in Volume 5 of the Applicants' Application Record in Case No. 446/15 – pages 001630-001638.

Volume 3 of Applicants' Application Record in Case No. 446/15 – pages 001361 (bottom half of page) - 001369 also identified as pages 13-21.

Answer: The Grassy Narrows/Earthroots interpretation of the Carignan et al. studies is essentially correct.

Question:

1. For the documents below, please indicate on a document by document basis if the views expressed in those documents that relate to the subject matter of your first expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate the corrections, if any, that should be made with respect thereto:

….

C. The Grassy Narrows-Earthroots…. supplementary submissions made to the Ministry [of the Environment] dated….November 2014 (pages noted below), insofar as they relate to your area of expertise and the subject matter of your first expert report.

Volume 4 of the Applicants' Application Record in Case No. 446/15 – 001495-001496 also identified as pages 8-9.

Answer: The views expressed by Grassy Narrows/Earthroots are accurate in every material respect.

Question:

2. What are your views on matters within your area of expertise and the subject matter of your first expert report that are addressed in the Ministry of Natural Resources and Forestry July 2014 response to the Grassy Narrows-Earthroots May 2014 submissions referred to in Question 1 (pages noted below)?

Volume 5 of the Applicants' Application Record in Case No. 446/15 – pages 001712-001715.

Answer: In January 2014, Grassy Narrows First Nation/Earthroots requested an IEA for the Whiskey Jack Forest Management Plan. The requestors' indicated that the plan fails to adequately deal with the impacts of logging on mercury levels in boreal water and fish, and that the fine filter (a mitigation measure such as limiting soil disruption/ hydrological disturbance on a micro scale) is designed to minimize upland and lowland disruptions, not mercury impacts on aquatic ecosystems. In April 2014, MNR filed a science response to the IEA request. In May 2014, Grassy Narrows/Earthroots submitted a reply. In July 2014, MNRF produced a further response. Salient points in the July 2014 MNRF science response to the Grassy Narrows First Nation/Earthroots material included the following (with MNRF material appearing in *italics* and my answer appearing immediately below it for each of the following three points):

1- ***MNRF July 2014: [****While] "the" [Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales – Background and Rationale for Direction] "SSG does not contain direction specifically intended to mitigate mercury impacts… there is, however, other direction in the SSG intended to mitigate other undesirable impacts including soil disturbance, hydrologic disruption and disturbance to riparian and wetland areas….it was concluded that these actions may also help reduce the mobilization of mercury during forest management" (page 001713).*

   Answer: Based on our data in lakes impacted by logging or fire in Quebec, the increased dissolved organic matter and mercury contamination observed in logged lakes relative to burnt and pristine lakes is likely attributable to the elevation of the water table following logging or fire. While severe fires virtually eliminate the organic- and mercury-rich forest floor and volatilize its mercury, logging not only preserves the organic, mercury-rich forest floor but promotes the export of dissolved organic matter and mercury to streams and lakes, as observed in many studies in Quebec, Ontario and elsewhere in the world.

2- ***MNRF July 2014:*** *"…the potential effects of climate change on mercury methylation do need to be considered. Based on a predicted warmer and dryer climate, both upland-mineral and lowland-organic soils would become dryer, and methyl mercury production rates will likely be lower than current levels" (page 001713).*

   Answer: These MNRF comments are based on hypothetical grounds and just confuse the issue. A dryer climate will lower the water table in all watersheds impacted or not by fire/logging. Because logging preserves mercury stocks in soils compared to fire, mercury export to lakes impacted by logging will likely be higher. Whether this phenomenon is important or not in the Whiskey Jack Forest, where the climate is already dryer, is unknown. However, observations conducted in Quebec and elsewhere

fully justify the implementation of a long-term site-specific study on the effects of fire/logging on mercury levels in fish.

3- ***MNRF July 2014: "…****the [January 2014] IEA request, which stated that 'logging and forest fire have nearly opposite effects on mercury '…is not supported by any scientific studies". [The MNRF concludes that]: "Simply put, the study [Garcia and Carignan, 2005] provides evidence that forest disturbance within a given lake's watershed is associated with increased levels of mercury in fish but it does not provide evidence that mercury levels of fish differ consistently between lakes of harvested watersheds and those with intensively or extensively burned watersheds" (page 001714).*

Answer: To illustrate its point, the MNRF chose to only comment on one figure (Figure 4 in Garcia and Carignan 2005) where mercury in fish is related to trophic level estimated using ^{15}N in 63 populations of fish sampled in 38 lakes (20 reference, 9 logged and 9 **partially** or completely burnt). The MNRF ignored here that the burned lakes of Figure 4 included two watersheds where mercury was highest and where fire was only partial in terms of extent and severity. In these partially burnt watersheds, forest removal by fire still raised the water table of residual forest which promoted mercury export to streams and lakes. Moreover, the MNRF ignored other studies (Carignan et al. 1999; Garcia and Carignan, 1999, 2000; Desrosiers et al. 2006) suggesting a clear effect of logging on the water quality and mercury contamination in other components of the food web such as zooplankton and periphyton. The Grassy Narrows/Earthroots position on this issue essentially reflects the results of our comparative studies on the impacts of logging and fire which clearly indicate that both disturbances are not comparable in terms of mercury mobilization.

In short, the MNRF response to the Grassy Narrows/Earthroots IEA request is reliant on the adequacy of the SSG. But elsewhere, the MNRF states that it makes "no claims that SSG direction and application…will mitigate or eliminate Hg [mercury] mobilization" (Volume 3 of the Applicants' Application Record in Case No. 446/15 at pages 001323, 001333 – MNR April 23, 2014 Response to January 2014 IEA Request). Resolving the clearcut logging/mercury issue in the Whiskey Jack Forest requires examination that could come from the IEA requested by Grassy Narrows/Earthroots and the type of study I recommended in my first expert report.

Question:

3. What are your views on the December 2014 Ministry of the Environment decision's treatment of evidence provided by the Ministry of Natural Resources and Forestry where matters within your area of expertise are discussed)?

Volume 1 of the Applicants' Application Record in Case No. 446/15 – pages 000031-000033.

Answer: There are four issues raised by Grassy Narrows that are addressed in the Ministry of the Environment's treatment of, and reliance on, MNRF's evidence that are of concern to me. I first set out the issue (in **boldface**), then the MNRF evidence relied on by the Ministry of the Environment (in *italics*), and finally my answer to it (in regular text).

Issue 1 (page 000031): Clearcut logging and the construction of access roads will disturb the soil causing mercury to travel through the water system, amplifying mercury contamination.

The MNRF responses to this issue are that "the Stand and Site Guide provides direction to minimize site disturbance, sediment transport and hydrologic disruption*. These reduce the potential for existing mercury mobilization as a result of forest disturbances. The MNRF… informed the Ministry of the Environment and Climate Change (MOECC) that mobilization of mercury following forest disturbance may not be any different than that experienced during natural disturbances. The MNRF is currently undertaking research to gain further understanding of the potential connections between forestry operations and mercury".*

Answer: Our studies in Quebec were not designed to address the effects of mechanical soil disturbance during logging on mercury contamination. Rather, our studies suggest that mercury mobilization in clearcut watersheds is proportional to the size of clearcuts relative to the size of the receiving lake. Because current SSG directions contain no measure to limit the clearcut/lake size ratio, they do not reduce the potential for mercury mobilization. Further, our comparative studies on the impacts of logging and fire clearly indicate that both disturbances are not comparable in terms of mercury mobilization. As I noted above and in my first expert report, a (fully) burnt forest releases its mercury to the atmosphere, whereas a clearcut forest releases its mercury to the watershed. The exact protocols supporting the research currently undertaken by the MNRF on this issue should be clearly laid out.

Issue 2 (page 000031): An increase in mercury will harm fish and terrestrial animals that eat fish, including humans, for a long time period.

The MNRF states "that increases in methylmercury concentrations following clearcuts are generally limited to cases when soils are disturbed", and the SSG contains "a methodology for minimizing soil disturbance".

Answer: The MNRF has very little scientific evidence to support its claim. Three Swedish studies (Sorensen et al., 2009; Eklof et al., 2012, 2013) have looked at the effects of stump harvest and scarification on total mercury and methyl-mercury concentrations in runoff across large (1 000 km north-south) temperature and runoff gradients and found mixed responses. However, all three studies found an increase in mercury export relative to reference sites. According to the Quebec studies, measures implemented by the MNRF at the WJFMU such as natural disturbance emulation, limiting ruts and harvesting only in winter on shallow soils will not reduce the risk of mercury contamination in animals and fish.

Issue 3 (page 000032): Clearcut logging leads to an increase in mercury, whereas forest fires remove mercury.

MNRF states that: "fire intensity is an important factor that influences mercury response. High intensity fires volatilize mercury in the organic soil layer whereas low intensity fires leave this layer undisturbed, with mercury subsequently being mobilized as water tables rise and surface runoff increases…studies conducted by various research groups have found that the highest mercury levels in fish are from watersheds impacted by low intensity fires and lower mercury

levels are in fish from watersheds with high intensity fires". The MNRF further adds that out of the 745,748 ha of productive forest concerned in the WJFMU, prescribed burns will occur on 1,069 (or 0.14%) of the productive forest.

Answer: The first paragraph of the MNRF response to this issue quoted in part above clearly indicates that, contrary to its responses to issues 1 and 2 above, MNRF fully understands the results and conclusions of studies conducted in Quebec and elsewhere on the differential impacts of logging and fire on mercury contamination. However, the second and third paragraphs of the MOECC summary of the MNRF response defy logic. The MNRF claims that, contrary to what is stated in the first paragraph, "increases in mercury due to clearcut operations would be no different than those experienced for natural occurrences" and that "emulating natural disturbance patterns, harvesting only in winter on shallow soils, and reinforcing slopes and banks in the WJFMU" will mitigate mercury contamination. In summary, the MNRF response appears inconsistent for two reasons. First, as noted above, a (fully) burnt forest releases mercury to the atmosphere, whereas a clearcut forest releases mercury to its watershed. Second, MNRF stated to MOECC that it makes "no claims that SSG direction and application…will mitigate or eliminate Hg [mercury] mobilization". Furthermore, as I noted earlier, our Quebec studies suggest that mercury mobilization in clearcut watersheds is proportional to the size of clearcuts relative to the size of the receiving lake. Because current SSG directions contain no measure to limit the clearcut/lake size ratio, they do not reduce the potential for mercury mobilization. Therefore, the measures MNRF proposes to rely on in the Whiskey Jack Forest, such as natural disturbance emulation (also known as coarse filter), limiting ruts, and harvesting only in winter on shallow soils, will not reduce the risk of mercury contamination in animals and fish.

Issue 4 (page 000033): The MNRF does not have the science and information to develop prescriptions to mitigate the effect of mercury on terrestrial or aquatic ecosystems.

The MOECC decision notes that: "…MNRF is currently supporting research projects that are examining patterns in fish mercury bioaccumulation, evaluating the levels of mercury runoff from forest and wetland soils to aquatic systems", and "results from its ongoing research will be used during the required periodic review of the Stand and Site Guide".

Answer: The MNRF response summarized under issue 4 appears well-intentioned. However, no details are given about how the MNRF will achieve these goals. Furthermore, it remains unclear how the current MNRF research projects will help to refine the natural disturbance paradigm by resolving the issue of differential impacts of **fire and logging** on mercury cycling in the aquatic systems of the WJFMU.

PARTIE II. CONTRIBUTIONS À LA RECHERCHE

1. LISTE DES CONTRIBUTIONS À LA RECHERCHE

1.1 Contributions les plus importantes

Carignan, R., C. Vis et D. Planas (2000). Planktonic production and respiration in oligotrophic Shield lakes **Limnology and Oceanography** 45: 189-199. Ces travaux portent sur un aspect fondamental de notre compréhension des écosystèmes aquatiques. Ils montrent que, contrairement aux hypothèses récentes, le métabolisme global des lacs oligotrophes est essentiellement autotrophe et dépend peu des sources de carbone organique externes. *This study, highlighted by the Editors in the January 2000 issue of L&O, focuses on a fundamental aspect of global metabolism in aquatic ecosystems. It shows that, contrary to current hypotheses, lakes are essentially autotrophic systems and rely only marginally on external organic carbon supply.*

Carignan, R., P. D'Arcy et S. Lamontagne (2000). Comparative impacts of fire and forest harvesting in Boreal Shield Lakes. **Can. J. Fish. Aquat. Sci.** 57(suppl. 2): 105-117. Ces travaux distinguent, pour la première fois en Amérique du Nord, les effets de la coupe forestière de ceux causés par les feux de forêt sur la qualité des eaux dans les lacs de la forêt boréale. De plus, ils proposent des modèles de gestion forestière permettant de minimiser les impacts des coupes. *This work contrasts, for the first time in North America, the differential impacts of clear cutting and wildfires on water quality in boreal lakes.*

Carignan, R., A.-M. Blais, et C. Vis (1998). Measurement of primary production and community respiration in oligotrophic lakes using the Winkler method. **Can. J. Fish. Aquat. Sci.** 55: 1078-1084. Ce travail démontre, pour la première fois, qu'il est possible de mesurer avec précision la production et la respiration planctoniques dans les eaux peu productives par dosage électrochimique de l'oxygène dissous. La méthodologie décrite est susceptible de remplacer la méthode du ^{14}C en océanographie et en limnologie. *This work shows, for the first time, that planktonic production and respiration can be accurately measured in oligotrophic waters using the oxygen method. The new protocol is likely to replace the ^{14}C method in oceanography and limnology in the near future.*

Carignan, R. (1998). Automated measurement of carbon dioxide, oxygen and nitrogen partial pressures in surface waters. **Limnol. Oceanogr.** 43: 969-975. L'instrument décrit permet, pour la première fois, de mesurer avec très grande précision et simultanément les concentrations de CO_2, O_2 et N_2 dans les eaux de surface. Il permet, entre autres, d'étudier la balance production-respiration au niveau de l'écosystème entier, et de mesurer les coefficients d'échange gazeux à l'interface air-eau. *This new intrument allows, for the first time, accurate and automated measurements of CO_2, O_2 and N_2 concentrations in surface waters. It allows the study of the global production-respiration balance at the ecosystem level, and the determination of gas tranfer coefficients at the air-water interface.*

Carignan, R., et D. Planas (1994). Recognition of nutrient and light limitation in turbid mixed layers: Three approaches compared in the Paraná floodplain (Argentina). **Limnol. Oceanogr.** 39: 580-596. Ce travail montre, pour la première fois, que les lacs de la plaine inondable du fleuve

Parana sont limités par la lumière ou l'azote, et non pas par le phosphore. De plus, les résultats montrent que seule la fertilisation de lacs entiers permet de mettre en évidence le rôle limitant de l'azote et de la lumière. *This work shows, for the first time, that nitrogen and light - and not phosporus - are limiting factors in the Parana River floodplain lakes. The results also show that the limiting roles of nitrogen and light can be unambiguously demonstrated only with whole-lake fertilization experiments.*

RC22- Carignan, R. (2011). Évolution de la qualité des eaux au lac Heney entre mars 2007 et juin 2011. 38 p.

1.26 Collaborations

- Centro de ecología aplicada del litoral (Argentine,Prof. J.J. Neiff, Directeur). Sujet: écologie de la plaine inondable du Paraná.
- UQAM (Dr. D. Planas). Sujet: écologie du Paraná (Argentine) et métabolisme lacustre.
- Centre Saint-Laurent (Dr. C. Hudon). Sujet: métabolisme fluvial.

1.27 Explication des contributions à la recherche

L'examen de la section 1 révèlera une préférence pour la qualité et l'originalité des publications plutôt que la quantité. La majorité des périodiques choisis (Geochimica et Cosmochimica Acta, Limnology and Oceanography, Environmental Science and Technology, Canadian Journal of Fisheries and Aquatic Sciences, Biogeochemistry) sont les mieux cotés de leur discipline. Noter que certaines publications extensives auraient pu être scindées en plusieurs publications d'envergure moindre.

3. AUTRES PREUVES DE CONTRIBUTIONS ET D'INCIDENCES

- Membre du Comité 1503 du CRSNG (2010-2013).
- Éditeur associé de la revue Canadian Journal of Fisheries and Aquatic Sciences (2001-2007).
- Environ 2 conférences internationales par étudiant par année.
- Environ 20 conférences locales à la province (MDDEP), aux MRC et aux municipalités sur la gestion durable des lacs.
- Directeur de la Station de biologie des Laurentides de l'Université de Montréal (1999-2006).
- Co-Leader du Réseau de centres d'excellence CRSNG "Sustainable Forest Management" (1995-2001).
- Révision de 15 à 20 articles par année pour Limnology and Oceanography, Can. J. Fish. Aquat. Sci., Geochimica et Cosmochimica Acta, Biogeochemistry, Marine Chemistry, Environ. Sci. Technol., Hydrobiologia, etc...

AFFIDAVIT OF DONNA MERGLER

I, DONNA MERGLER, of the City of Montreal, in the Province of Quebec, MAKE OATH AND SAY AS FOLLOWS:

1. I am a professor emerita at the *Université du Québec à Montréal* (UQAM), where I was a professor in the Department of Biological Sciences from 1970 to 2006. I hold a doctorate in physiology from McGill University. I am a former chair of the department (1982-1984), head of the doctoral program in environmental sciences (1993) and chair of the UQAM Institute for Environmental Sciences (2001-2003). I founded the Center

for Interdisciplinary Research on Well-being, Health, Environment and Society (CINBIOSE) in 1985, and was director at different periods until 2000. From 1998 to 2013, I was director of the CINBIOSE World Health Organization-Pan American Health Organization Collaborating Center for the Prevention of Work and Environment-related illnesses. I was co-coordinator of the Latin American Community of Practice in Ecosystem Approaches to Human Health (2005-2013). Since 2008, I head a pan-Canadian research team on Gender, Environment and Health. I have been a member of the Quebec Council for Science and Technology (1984-1989) and the science advisory board of the International Joint Commission of the Great Lakes (2001-2011). My teaching, research and writing have focused on the early neurotoxic effects in humans of environmental pollutants generally, including mercury. In 2006, I chaired an international scientific group which wrote a consensus document on mercury and human health. I have authored over 150 peer-reviewed scientific articles, including 50 scientific papers on the subject of mercury exposure and effects in freshwater fish-eating populations. I have given keynote addresses on mercury and human health at major international conferences and numerous presentations on the subject at national and international meetings, including the Office of Science and Technology Policy of the United States' White House (1988). I have written reports on mercury and health as it relates to the members of Grassy Narrows First Nation. My curriculum vitae appears in Appendix A of this Expert Report.

2. In February 2015 I was asked by counsel for Grassy Narrows to answer certain questions in a report on the health effects of mercury generally, and on the people of Grassy

Narrows, in particular. The questions and my answers to them appear as part of my Novemberr 2015 expert report attached as Exhibit "A" to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "B" to my Affidavit.

SWORN BEFORE ME in the City of Montreal, in the Province of Quebec, this 6h day of November, 2015.

Part 2

Overview 29

1. Mercury is highly toxic to human health. Impacts include fetal and child development, neurological disorders and cardiovascular changes. 30
2. Adults can be impacted at levels well below the old threshold level for risk of 50 µg/g in hair. 32

PAGE

3. Foetuses and children can be impacted at far lower levels than adults 34
4. Mercury is bio-concentrated across the placenta. 35
5. Population level impacts can be found at much lower levels of exposure than clear individual impacts 36
6. Developmental impacts of mercury have life-long impacts. 37
7. The health impacts of mercury exposure in adults can take a long time to manifest and can be long lasting and degenerative. 40
8. Fish is the most important source of mercury in humans. Other sources of mercury in humans include fish eating wildlife (ducks, otters, etc.) and dental fillings 42
9. In 1979 the Health and Welfare Canada recommended a limit of 0.2 ppm in fish as a fish consumption limit for Grassy Narrows and White Dog. 43
10. The Canadian reference dose for preventing fetal neurotoxicity and developmental impacts is double that recommended by US EPA. 44
11. Eating fish has a number of important health benefits. 44
12. The Ontario Guide for Sport Fish Eaters 47
13. People who have already experienced elevated mercury exposure 47
14. Conclusions with respect to Grassy Narrows 48

Appendix A – Curriculum Vita

INTRODUCTION

I am a professor emerita at the *Université du Québec à Montréal* (UQAM), where I was a professor in the Department of Biological Sciences from 1970 to 2006. I hold a doctorate in physiology from McGill University. I am a former chair of the department (1982-1984), head of the doctoral program in environmental sciences (1993) and chair of the UQAM Institute for Environmental Sciences (2001-2003). I founded the Center for Interdisciplinary Research on Well-being, Health, Environment and Society (CINBIOSE) in 1985, and was director at different periods until 2000. From 1998 to 2013, I was director of the CINBIOSE World Health Organization-Pan American Health Organization Collaborating Center for the Prevention of Work and Environment-related illnesses. I was co-coordinator of the Latin American Community of Practice in Ecosystem Approaches to Human Health (2005-2013). Since 2008, I head the pan-Canadian research team on Gender, Environment and Health. I have been a member of the Quebec Council for Science and Technology (1984-1989) and the Science Advisory Board of the International Joint Commission of the Great Lakes (2001-2011). My teaching, research and writing have focused on the early neurotoxic effects in humans of environmental pollutants generally, including mercury. In 2006, I chaired an international scientific group that wrote a consensus document on mercury and human health. I have authored over 150 peer-reviewed scientific articles, including 50 scientific papers on the subject of mercury exposure and effects in freshwater fish-eating populations. I have given keynote addresses on mercury and human health at major international conferences and numerous presentations on the subject at national and international meetings, including the Office of Science and Technology Policy of the United States' White House (1988). I have written reports on mercury and health as it relates to the members of Grassy Narrows First Nation. My curriculum vita appears in Appendix A of this Expert Report.

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association on behalf of Grassy Narrows First Nation to prepare an expert report that responds to several questions. I am solely responsible for the preparation of this report.

QUESTIONS

1. For the documents referred to below, please indicate if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto.

A. The Grassy Narrows-Earthroots request, dated January 2014, of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May, July, September and November 2014 insofar as they relate to your area of expertise and the subject matter for your report.

B. Literature Review of the Mercury Disability Board, dated September 2010. This document (consisting of two reviews) is referred to in the September 2014 submission.

1.1 For the documents referred to below, please indicate your views on them to the extent they relate to the subject matter of your expert report and are within your area of expertise:

C. The article by Harada, et al. entitled "Mercury Poisoning in First Nations Groups in Ontario: 35 Years of Minamata Disease in Canada" (translated from the Japanese version published in the Journal of Minamata Studies in 2011).

D. The article by Takaoka, et al. entitled "Signs and Symptoms of methylmercury contamination in a First Nations community in Northwestern Ontario, Canada" published in the journal Science of the Total Environment in 2014.

2. Regarding the subject of mercury and human health:

a. Is mercury toxic to humans? If so, on the scale of toxic substances in the environment, where does mercury rank in terms of overall toxicity risk to humans?
b. If so, what are the clinical human health impacts of mercury?
c. Does exposure to mercury increase the risk of other health problems developing and, if so, identify those other health problems?

3. At what levels of exposure to mercury have adverse clinical health impacts on adults been documented in the scientific literature?

4. Does exposure to mercury affect the development of foetuses and children and, if so, what are the effects, and for what duration of time, if any, will those effects persist? At what exposure levels have these developmental effects been documented in the scientific literature?

5. Are there sub-clinical effects:

a. *In a community where mercury-related neurologic clinical disorders are present, could there be other persons with sub-clinical signs and symptoms?*
b. *What is the nature of these effects at each exposure level that have been documented in the scientific literature; and*
c. *Are developmental effects of mercury exposure affected by low socio-economic status based on such factors as education, income, etc.?*

6. *What are the sub-clinical population level effects, if any, of exposure to mercury? Compare these effects to individual clinical effects and to the mercury levels at which they are found? Comment on the nature and severity of the effect of these impacts at a community level?*

7. *Does mercury bio-concentrate across the placenta and, if so, what is the average concentration factor? What is the concentration factor at the 95th percentile?*

8. *Is there a delay in the manifestation of health effects following exposure to mercury? How do mercury impacts change with aging?*

9. *What evidence is there, if any, that mercury changes the rate or severity of degenerative neurological conditions such as Alzheimer, ALS, etc.?*

10. *What is the most important source of mercury in humans? How would you characterize the levels of mercury, if any, in piscivorous wildlife, such as ducks, loons, and otters? What effect, if any, do dental fillings have on human mercury body burden? How would you characterize the risk of methylmercury exposure from eating wild fish alone compared to the total mercury risk in an Aboriginal population that also eats ducks, otters, store fish, and has dental fillings?*

11. *What is the Health Canada – World Health Organization recommended fish mercury content limit (measured in parts per million – ppm) for subsistence eaters? What is the mercury limit measured in ppm for legal possession of lake fish meant for sale in Ontario?*

12. *In general, what is a reference dose? Compare the Canadian reference dose for preventing fetal neurotoxicity and developmental impacts with the reference dose adopted by the Environmental Protection Agency in the United States ("USEPA")? What caveats, if any, come with using the USEPA reference dose? Which of the two reference doses, in your professional opinion, is more appropriate and safe to use (1) for the general population, and (2) at Grassy Narrows, and why?*

13. *How does the USEPA reference dose, if at all, account for bio-concentration across the placenta? If it does not account for bio-concentration, how would it need to be modified in order to do so? How does the Canadian reference dose, if at all, account for bio-concentration across the placenta?*

14. *What are the health benefits, if any, of eating fish? What are the health benefits, if any, of the practice of fishing?*

15. *If there are health benefits to eating fish what, in your professional opinion and in the scientific literature of which you are aware, should be done with respect to practices that lead to the bio-accumulation of mercury in fish? How would this principle apply at Grassy Narrows?*

16. *How would you characterize the appropriateness of the health guidance contained in the Ontario Guide for Sport Fish Eaters for indigenous communities who eat fish? Which reference dose is used in developing the Guide?*

17. *Compare with the general population, the level of sensitivity of those who already have experienced elevated mercury exposure, or show symptoms of mercury poisoning, upon further exposure? Comment on the appropriateness of intake guidelines designed for the general population when applied to people exhibiting symptoms consistent with mercury poisoning?*

Grassy Narrows

18. *For document B listed above, and if not already addressed in response to question 1, please indicate the following:*

    a. *What role, if any, did you play in the preparation of document B?*
    b. *Are the findings and conclusions contained in document B still valid today? If not, indicate what material changes have occurred since the release of document B that would cause the need for significant revisions in its findings and conclusions?*
    c. *What would be the revised findings and conclusions, if any?*

19. *If not otherwise answered in response to question 1, above, please indicate if the statements are accurate that are contained in the first six pages of the September 2014 supplementary submission listed in item A that are attributed to your document B report?*

20. *Are you aware of a more thorough long-term study than that of Dr. Harada and his colleagues from Japan (including Takaoka and Fujino, et al.), on the issue of mercury exposure and effects at Grassy Narrows?*

21. *What risks, if any, do current mercury levels in pike and walleye present to the people of Grassy Narrows who eat fish caught from local waters?*

22. What risk is there, if any, to the health of people at Grassy Narrows who eat fish caught from local waters if mercury levels were to increase? How low an increase in fish mercury level would pose a health risk, if any?

ORGANIZATION OF EXPERT REPORT

The Expert Report is organized into two parts. Part 1 provides short summary answers to the questions listed above.

Part 2 updates the review of the scientific literature presented in the document entitled *Literature Review: The Impact of Mercury on Human Health* prepared by Dr. H.M. Chan and myself for the Mercury Disability Board in 2009, and in 2010 with a review of Dr. Harada's studies (Document B). Taken together, these provide the greater context and scientific background for the summary answers provided in Part 1.

PART 1

SUMMARY ANSWERS TO QUESTIONS

Question 1:

1. For the documents referred to below, please indicate if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto.

> ***A. The Grassy Narrows-Earthroots request, dated January 2014, of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May, July, September and November 2014 insofar as they relate to your area of expertise and the subject matter for your report.***

Answer to Question 1A: The information contained in these documents as concerns my expertise on mercury exposure and human health are accurate, with the following details

- **[IEA request, supplemental information, September, 2014 p. 3]** I verified this information with a colleague at the Minamata Institute, Dr. Mineshi Sakamoto, who informed me that the diagnostic criteria for Minamata disease have not changed. These

are the same diagnostic criteria that Dr. Harada used in Grassy Narrows. In Japan, a Law Concerning Special Measures to Provide Relief to Minamata Disease Victims, passed in 2009 was enacted in April, 2010[1]. On May 1, 2010, then Prime Minister Hatoyama attended and gave prayers at the Memorial Service for the Victims of Minamata Disease and was the first prime minister to do so. On the same day, the acceptance of applications for relief started, and eligible persons began to receive a lump sum payment in October 2010. By 2012, there were 48,327 applications for lump-sum payment and 16,824 applications for Minamata Disease Victims' Passbook. It is noteworthy that as early as 1977, the Japanese Ministry of the Environment initiated dredging because "even though the discharge of the methylmercury compound was stopped, the residual presence of mercury in the substratum of nearby waters could still cause the contamination of water and marine lives, making it necessary to remove the contaminated base sediment"[2].

- **[IEA request, supplemental information, September, 2014 p. 8]** The information written up in the Toronto Star (2003) was, in part, in error. I verified this information with Dr. Laurie Chan. While Dr. Chan did express his alarm at the high prevalence of persons still suffering from neurological symptoms after 30 years, he did not head a Health Canada financed study of neurological effects in Grassy Narrows. He did examine mercury in fish, fish consumption patterns and human exposure in Grassy Narrows[3].

- **[IEA request. Supplemental information, November, 2014]** While the psychological, social and economic impacts, cited in the Donnan 1986 report, are accurate, they do not do justice to the overall impact of mercury contamination and the ensuing reduced consumption of fish on the physical and mental health and well-being within the Grassy Narrow community.

- **[IEA request. Supplemental information, November, 2014; p. 13]** More precisely, the value for fish advisories at 0.049 µg/g is the EPA screening value for fish; it was derived specifically for subsistence fishers[4]. (see answer to Question 11)

- **[IEA request. Supplemental information, November, 2014; p. 13]** More precisely, as indicated in the text, the 0.2 µ/g wet weight was a recommendation made by the Medical Services Branch of Health and Welfare Canada for Grassy Narrows and White Dog in 1979.

[1] Japan Ministry of the Environment. Lessons from Minamata Disease and Mercury Management in Japan, (2013)
[2] Japan Ministry of the Environment Lessons from Minamata Disease and Mercury Management in Japan, (2013) p. 15
[3] Chan (2005)
[4] EPA Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories Volume 2 Risk Assessment and Fish Consumption Limits Third Edition, p. 1-6 (2000)

- **[IEA request. Supplemental information, November, 2014; p. 15]** I would rephrase the term 'the scientific literature recommends' in the following terms: There is scientific evidence to support that the EPA RfD, based on cord blood, may be too high since cord blood contains 60-70% more mercury than maternal blood, and approximately 100% higher for the upper 5% and recent studies have observed neurotoxic effects in children at these levels of prenatal exposure (see question 7 and Part 2; section 4).

B. Literature Review of the Mercury Disability Board, dated September 2010. This document (consisting of two reviews) is referred to in the September 2014 submission

Answer to Question 1B:

I was co-author of these reports and the information contained in these reports is still timely. Studies since that time further support and confirm the conclusions of these reports.

Question 1.1: For the documents referred to below, please indicate your views on them to the extent they relate to the subject matter of your expert report and are within your area of expertise:

C. The article by Harada, et al. entitled "Mercury Poisoning in First Nations Groups in Ontario: 35 Years of Minamata Disease in Canada" (translated from the Japanese version published in the Journal of Minamata Studies in 2011).

Answer to question 1.1 C.

In the article, Dr. Harada describes his experience over the past 35 years in the diagnosis of Minamata Disease in Grassy Narrows and White Dog. Dr. Harada was a clinical neurologist, with world-renowned expertise on Minamata Disease. He began examining patients with Minamata disease in 1961 and was the first to describe Fetal Minamata Disease from prenatal mercury exposure.

He relates in this article that since 1975 he has examined persons from Grassy Narrows and White Dog for signs and symptoms of Minamata Disease. Over the years, he has diagnosed many cases of Minamata Disease in these two communities. The studies up to 2004 are reviewed in our report to the Mercury Disability Board (see Document B).

In 2010, he lead a team, which included 5 neurologists/psychiatrists and internal medicine specialists in neurology. In Grassy Narrows, they examined 73 persons above the age of 20 years on the basis of the diagnostic criteria applied in Japan since 1975 for Minamata Disease. The

team identified 30 persons with Minamata Disease and a further 12 persons with "suspected Minamata Disease", among whom there were 5 cases reminiscent of Minamata developmental disorders from fetal exposure. Dr. Harada notes in this report that "fetal influence remains to be studied … there is no plan of investigation as of now."

The article reflects a great degree of thoughtfulness and care on the part of the physicians involved and, as Dr. Harada so aptly stated, ".. the undoubtable fact that Minamata Disease occurred in the corresponding districts in Canada, based on [their] long term investigation result."

D. The article by Takaoka, et al. entitled "Signs and Symptoms of methylmercury contamination in a First Nations community in Northwestern Ontario, Canada" published in the journal Science of the Total Environment in 2014.

Answer to question 1.1D.

In this article Takaoka and co-authors describe a comparison of signs and symptoms of 80 residents from Grassy Narrows above the age of 16 years with 88 mercury exposed Japanese residents and 164 Japanese non-exposed control residents. The group from Grassy Narrows was divided into 2 groups according to age: the older group from 45 years old to 76 years old and the younger (less than 45 years of age). The age of the two Japanese groups were similar to the older Grassy Narrows group. Their findings were:

- Although the Japanese exposed group reported more subjective symptoms, the more specific mercury related complaints were similar for the Japanese exposed and the Grassy Narrows older group.

- Neurological findings and quantitative sensory measurements were similar in the Grassy Narrows Older and Japanese Exposed groups than in the Japanese Control group.

- The results for the younger Grassy Narrows group fell between those of the Grassy Narrow Older and the Japanese Control groups.

- The authors mention the limitations of such a comparison due primarily to different living conditions and cultures, but emphasize the diagnostic validity of the examination.

- The authors conclude that the data collected from methylmercury-exposed indigenous residents of Grassy Narrows suggest that they were poisoned by methylmercury. The health abnormalities also appear to exist in a milder form in the younger generations from Grassy Narrows.

The findings of this study are consistent with the scientific literature on mercury poisoning. In

the absence of an epidemiologic study on neurotoxic effects of mercury exposure in Grassy Narrows, the study presents an innovative way of examining similarities and differences in signs and symptoms in communities who have been exposed to mercury. Ideally, it would have been useful to examine the signs and symptoms in Grassy Narrow residents with respect to past and present exposure and use a local reference group.

Question 2: Regarding the subject of mercury and human health:

a. Is mercury toxic to humans? If so, on the scale of toxic substances in the environment, where does mercury rank in terms of overall toxicity risk to humans?

Answer to Question 2a

Mercury is definitely toxic to humans. Every few years, the United States Agency for Toxic Substances establishes a Priority List of Hazardous Substances, which includes substances that have been determined to be of greatest public health concern to persons at or near National Priority List sites[12]. While this list considers aspects other than toxicity, it includes a measure of toxicity. The 2013, Registry[3] gives mercury the highest attributable toxicity points, at the same levels as arsenic and polychlorinated biphenyls (PCBs) and ranks mercury ranks third (after arsenic and lead) on the overall priority scoring list of 785 hazardous substances. It is noteworthy that mercury has held this ranking since 1991, when the first list was established.

b. If so, what are the clinical human health impacts of mercury?

The most severe clinical impacts of fetal and adult exposure to methylmercury are the neurodegenerative diseases: Fetal Minamata Disease and Minamata Disease, respectively.

Clinical effects in adults : Gait disturbance, loss of balance, speech disturbance constriction of visual fields, sensory disturbances (numbness, loss of feeling or tingling in extremities and around the mouth), hearing disturbances, muscle weakness, muscle cramps.

Clinical effects of in utero exposure: severe cerebral palsy-like symptoms, even when their mothers have mild or no manifestation of the poisoning: mental retardation, cerebellar ataxia (coordination and balance problems), primitive reflexes (present in infants, which normally disappear in adulthood), dysarthria (muscle speech disorders), and hyperkinesia (uncontrolled muscular movements).

[1] Agency for Toxic Substances Registry (http://www.atsdr.cdc.gov/spl/)
[2] It should be noted that this priority list is not a list of "most toxic" substances, but rather a prioritization of substances based on a combination of their frequency, toxicity, and potential for human exposure at NPL sites ((http://www.atsdr.cdc.gov/spl/))
[3] Agency for Toxic Substances Registry. Support Document to the 2013 list of hazardous substances that will be the subject of toxicological profiles.

c. Does exposure to mercury increase the risk of other health problems developing and, if so, identify those other health problems?

Mercury has been shown to increase the risk for learning disabilities in children and, in adults, the risk for cardiovascular disorders, such as myocardial infarction and hypertension. There is some evidence of an association between mercury exposure and metabolic syndrome, diabetes and autoimmune disorders, but more studies are required to confirm or not these associations (see Part 2, section 1)

Question 3: At what levels of exposure to mercury have adverse clinical health impacts on adults been documented in the scientific literature? What are the reported adverse clinical health effects in adults at these levels?

Answer to Question 3:

For clinical neurological effects in adults, there are case reports of moderate to severe neurological symptoms in patients with blood mercury concentrations from 12 – 38 μg/L[1,2].

It should be noted that, for adults, it is difficult to establish a level of exposure since mercury-related subtle neurological alterations may have existed since conception and the biomarkers of mercury exposure (hair and blood) only represent recent exposure. Thus, adults who have been prenatally exposed to mercury, with continued exposure through childhood and early adulthood, may suffer clinical effects that are not related to their current mercury exposure, but to their past exposure. Furthermore, the large majority of studies on adults include persons who eat marine fish, which have considerably higher concentrations of beneficial nutrients such as omega-3 fatty acids and selenium, compared to freshwater fish.

Question 4: Does exposure to mercury effect the development of foetuses and children and, if so, what are the effects, and for what duration of time, if any, will those effects persist? At what exposure levels have these developmental effects been documented in the scientific literature?

Answer to Question 4:

There is a very substantial scientific literature showing prenatal and early childhood exposure to mercury is associated with a decrease in children's intellectual capacities. This has been

[1] Silbernagel et al. (2011)
[2] Groth (2008)

confirmed in animal studies and in brain imaging and electrophysiological examinations (see Part 2; sections 5 and 6).

Follow-up studies of mercury-exposed children indicate that these deficits persist over time. For example, a study of Canadian Inuit children at 8 years of age, exposed prenatally to mercury, showed that 17.2% of the children whose cord blood mercury was above 7.5µg/L were below the clinical cut-off for learning disabilities compared to 4.3% for the others[1].

A 22-year follow-up study of children of mothers with high mercury exposure[2] shows that there are still deficits in major domains of brain function as well as general intelligence in relation to their cord blood mercury concentrations; the geometric mean of their current blood mercury concentrations was 2.53µg/L and hair mercury 0.68µg/g.

The lowest reference dose for the protection of foetus and children is the US EPA reference dose (5.8 µg/L blood mercury; 1 µg/g hair mercury), which includes a tenfold uncertainty factor[3]. However, since the mercury in the cord blood is higher than in mother's blood, it may be too high (see part 2, section 4).

Question 5: Are there sub-clinical effects:

a. *In a community where mercury-related neurologic clinical disorders are present, could there be other persons with sub-clinical signs and symptoms?*
b. *Nature of these effects at each exposure level that have been documented in the scientific literature; and*
c. *Developmental effects of mercury, if any, in children in families with low socio-economic status based on such factors as education, income, etc.?*

Answer to Question 5a:

Clinical manifestations of mercury poisoning constitute the tip of the iceberg with respect to the harmful health effects of mercury exposure. In a contaminated environment, for every person with clinical manifestations, there are many more with sub-clinical signs and symptoms and even more with symptoms of decreased well-being, which affect a person's physical, mental and social capacities.

Answer to Question 5b:

[1] Jacobson et al. (2005)
[2] Debes et al. (2015)
[3] Rice (2004)

In adults, the tip of the iceberg is composed of people with the most severe classical symptoms of mercury poisoning (described in answer to question 2b), a higher number of mercury-exposed persons present signs and symptoms that are less severe, but debilitating, such as poorer cognition, motor deficits, vision problems and cataracts. Cognitive deficits have been observed in freshwater fish-eating communities with hair mercury concentrations that ranged from 0.56 to 13.6 µg/g, with half of the participants having levels below 6 µg/g.

For cardiovascular effects, an analysis of existing studies by an expert committee indicate a twofold increased risk for myocardial infarction at equivalent hair concentrations less than 1.66µg/L[1] (see Part 2, section 1)

In children, the most severe classical symptoms of mercury exposure in their development years are described in question 2b. Many more children are exposed to lesser concentrations.

There is consensus on the fact that mercury exposure is associated with delayed learning, shortened attention span, memory deficits, delayed language acquisition, poorer motor control or coordination (see part 2, sections 5 and 6)

Even at very low concentrations of prenatal and early childhood exposures (maternal mean hair mercury 0. 0.53 (range 0–2.3) µg/g)[2], some of these effects are present in the developing child and the frequency and severity of these problems increases with the exposure dose.

In the study of Inuit children mentioned above, mothers' hair mercury at birth ranged from 1.4µg/g – 15 µg/g.

Electrophysiological and neuro-imaging techniques have confirmed altered brain activity in children with prenatal exposure to mercury.

Answer to Question 5c.

In addition to mercury exposure, children's development can be affected by other factors, such as poor nutrition and housing, pre-existing diseases and parents' unhealthy lifestyle, little access to health care, poor schooling, minimal parental stimulation (see Part 2, section 6).

Developmental mercury exposure can compound the effects of these conditions, resulting in, for example, a larger percentage of children with learning disabilities (see Part 2, Section 6, Figures 4,5 and 6)).

Question 6: What are the sub-clinical population level affects, if any, of exposure to mercury? Comment on the nature and severity of the effect of these impacts at a community level?

[1] Guallar et al. (2002)
[2] Oken et al. (2008)

What are the levels of mercury exposure documented in the scientific literature at which these effects can occur?

Answer to Question 6:

For adults, sub-clinical effects include poorer cognitive functions, poorer vision, poor motor function and earlier age-related cataracts. These affect people's capacity to earn their living and carry out daily activities (see part 2 sections 5, 6 and 7). Overall the community's capacity to develop is hindered. In some studies, cardiovascular and metabolic changes have been reported in relation to mercury exposure, but results are inconsistent and co-factors, such as nutritional status and lifestyle, may play a role (see Part 2, sections 1 and 2).

For children, even a small decrease in average cognitive function has striking repercussions for the community. For example, an average decrease of 5 IQ points, among exposed children means that in a community twice as many children have severe learning difficulties and half as many children are gifted (see Part 2, sections 5 and 6).

When other harmful factors (poor nutrition, lack of stimulation, poor education) are present, the effects of mercury may be greater (see Part 2, section 6). In a study of an Inuit community, an average loos of 4.8 IQ points resulted in over four times more children with learning disability[1]. (Part 2, section 6)

The loss of cognitive function has life-long effects for these children who do less well in school. Educational level is an important determinant of later-life earning capacity and health status.

Question 7: Does mercury bio-concentrate across the placenta and, if so, what is the average concentration factor? What is the concentration factor at the 95th percentile?

Answer to question 7:

Throughout pregnancy, the placenta concentrates methylmercury and blood mercury concentration in the umbilical cord, which nourishes the foetus, is higher than in the mother's blood.

At birth, the average cord mercury blood concentration is almost double that of the mother, while for one in twenty, that concentration is over three and a half times higher. (see part 2, section 4)

[1] Jacobson (2015)

Question 8: Is there a delay in the manifestation of health effects following exposure to mercury? How do mercury impacts change with aging?

Answer to Question 8:

Minamata Disease is a progressive disorder and some infants, who had a normal appearance at birth, slowly developed the disease over time.[1]

Studies of persons from the Minamata region show that even those that do not have the diagnosed disease show more signs of aging compared to persons from other regions (see Part 2, section 7 and Figure 6).

The aging brain is more sensitive to toxic assault and studies of aging fish-eaters exposed to mercury have shown mercury-related progressive visual disorders, even when exposure was reduced, and a higher prevalence of age-related cataracts. (see Part 2, section 7)

Question 9: What evidence is there, if any, that mercury changes the rate or severity of degenerative neurological conditions such as Alzheimer, ALS, etc.?

Answer to Question 9:

To my knowledge, there is no evidence of a higher prevalence of Alzheimer disease or amyotrophic lateral sclerosis (ALS). The features of fetal Minamata Disease are similar to cerebral palsy. However, because of the pervasive neurologic effects of mercury exposure, there may be misdiagnoses.

Question 10: What is the most important source of mercury in humans? How would you characterize the levels of mercury, if any, in piscivorous wildlife, such as ducks, loons, and otters? What effect, if any, do dental fillings have on human mercury body burden? How would you characterize the risk of methylmercury exposure from eating wild fish alone compared to the total mercury risk in an Aboriginal population that also eats ducks, otters, store fish, and has dental fillings?

Answer to Question 10:

The most important source of mercury exposure in humans is from the consumption of fish and fish-eating animals (see Part 2, section 8).

[1] Maruyama et al, (2012)

Mercury is accumulated and biomagnified through the food chain; the process is initiated through the action of bacteria that transform inorganic mercury, present in the water, to methylmercury.

Larger fish eat many small fish, incorporating all of their mercury. Fowl and mammals that eat fish will likewise accumulate mercury in the same way.

At the top of the food chain are humans. The risk depends on the total amount of mercury from each of the foods.

The risk for mercury exposure in Aboriginal populations that eat fish and fish-eating animals has been shown to be considerably higher than in other populations

A study of adult dietary practices among 7 Eeyou Istchee (Cree) communities in the James Bay area showed that blood mercury concentrations 3 – 20 times higher than those reported in the Canadian Health Measures Survey (CHMS) [1], which did not include Aboriginal communities living on reserves. (see Part 2, section 9).

In the study of the Cree community mentioned above, the geometric mean for blood mercury of persons with the highest traditional food intake was 5.3µg/L, for those who consumed the least traditional food, it was 3µg/L,[2] while for the general adult Canadian population, it is approximately 0.8 µg/L[3].

A further source of methylmercury exposure may come from wild rice that grows in sediments that have been contaminated with mercury.

Mercury in dental amalgams is inorganic mercury that can be measured in blood and urine, but not in hair. In the Canadian Health Measures Survey, blood mercury concentrations increased with the number of dental amalgams. The geometric mean for those with no mercury-based dental amalgams is 0.6 µg/L, while for those who have over 26 amalgams, it is 1.24µg/L[4].

Question 11: What is the Health Canada – World Health Organization recommended fish mercury content limit (measured in parts per million – ppm) for subsistence eaters? What is the mercury limit measured in ppm for legal possession of lake fish meant for sale in Ontario?

Answer to Question 11:

[1] Johnson-Down et al. (2015)
[2] Johnson-Down et al. (2012)
[3] Lye et al. (2013)
[4] Lye et al. (2013)

There are different types of recommended limits concerning fish consumption: (i) amount of mercury in the fish (expressed in mg/kg, µg/g or ppm); (ii) the amount of mercury considered safe to consume on a daily basis, considering persons' weight (µg/kg/day) over a lifetime; (iii) the average amount of fish that should be eaten (g/day or fish meals/month), based on a risk assessment of risks and benefits. Table 1 contains some of these recommendations from different agencies.

Table 1 Recommendations by different national and international agencies for limits for mercury on fish, mercury consumption and fish consumption

	Canada	Ontario	US-EPA	WHO/FAO
MERCURY IN FISH				
Commercial sale	0.5 ppm[a]			
Fishing for sale				
Recreational			0.4 ppm[c]	
Women of child-bearing age and children under 15		0.26 ppm[b] Do not eat: 0.52 ppm		
Others		0.61 ppm[b] Do not eat: 1.84 ppm		
Subsistence	0.2 ppm[h]		0.049 ppm[c]	
METHYLMERCURY IN THE PLATE				
Intake dose	0.2µg/kg body weight/day[d]		0.1µg/kg body weight/day[e]	0.23µg/kg body weight/day[f]
FISH CONSUMPTION				
General				
1-4 year old	10g/day[g]			
5-11 year old	14g/day[g]			
Adults	22g/day[g]			
Subsistence fishing				
1-4 year old	20g/day[g]			
5-11 year old	33g/day[g]			
Adults	40g/day[g]			

a. There are some exceptions to this for a few marine fish, with higher concentrations
b. These are the values used by the *Ontario Guide for Sport Fisher Eaters (2013-2014)* to

provide information on fish consumption for anglers (and their families) who consume moderate quantities of fish. The consumption advice is intended to protect individuals who follow the advice in the guide and consume no more than 8 meals per month of the fish they catch. Specific information is available for each lake.

h. Health and Welfare Canada recommendation for Grassy Narrows and White Dog in 1979.

Question 12: In general, what is a reference dose? Compare the Canadian reference dose for preventing fetal neurotoxicity and developmental impacts with the reference dose adopted by the Environmental Protection Agency in the United States ("USEPA")? What caveats, if any, come with using the USEPA reference dose? Which of the two reference doses, in your professional opinion, is more appropriate and safe to use (1) for the general population, and (2) at Grassy Narrows, and why?

Answer to Question 12:

The US-EPA uses the term Reference Dose (RfD), defined as ''an estimate of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects during a lifetime.''[1] Some scientists have raised the issue that this RfD may be too high because it is based on cord blood and does not take into account methylmercury accumulation in the placenta[2].

Canada uses Toxicity Reference Values (TRVs) to derive Total Daily Intake, (TDI) defined as "the maximum amount of a chemical that can be ingested on a daily basis over a lifetime without increased risk of adverse health effects.

As indicated in the table above, for methylmercury, the US-EPA RfD is 0.1µg/kg body weight/day, while the Canadian TDI is 0.2µg/kg body weight/day.

My opinion is that the US-EPA reference offers better protection against the harmful effects of

[1] cited in Rice (2004)
[2] Stern (2005)

exposure to methylmercury to all populations. Mercury intake for most of the general Canadian population is well below this intake.

In 2003, Chan[1] calculated the intake of mercury in the Grassy Narrow community and estimated mercury intake from fish consumption using the actual values that were measured in fish species from the various lakes and the reported portion size per fish meal.

In Grassy Narrows, in 2003, the average mercury intake over the year was 0.2µg/kg body weight/day, with men having higher average intakes compared to women (0.3 µg/kg body weight/day vs. 0.1µg/kg body weight/day). The average intakes included people who don't eat fish; if the analysis had included only fish-eaters, the average mercury intake would have been higher.

By season, the highest mercury intake was by men in summer and spring (3.7 µg/kg body weight/day). Approximately 25% had estimated intakes above the Canadian TDI and 41% were above the US-EPA RfD.

The average mercury intake for Grassy Narrows women in 2003 was above the US-EPA RfD of 0.1 µg/kg body weight/day. It should be noted that this includes all women who were surveyed, including those that don't eat fish.

Cord blood data from Grassy Narrows between 1978 and 1992 shows that the concentration mercury was much higher, particularly in the earlier period (see Part 2, section 14a and Figure 8). Today, these persons are between the ages of 23 and 37 years old.

Given the information on estimated methylmercury intake from past and present exposures in Grassy Narrows, there are already effects on their health and well-being from mercury exposure and the EPA RfD would be more suitable for the Grassy Narrows population. However, this does not take into account the health, social and economic benefits of fishing and fish consumption.

Question 13: How does the USEPA reference dose, if at all, account for bio-concentration across the placenta? If it does not account for bio-concentration, how would it need to be modified in order to do so? How does the Canadian reference dose, if at all, account for bio-concentration across the placenta?

Answer to Question 13:

The US-EPA reference dose, which is based on cord blood, does not take into account bio-concentration across the placenta. It is based on a cord blood concentration of 58 µ/L and then

[1] Chan (2005)

uses a tenfold security factor to arrive at a cord blood concentration of 5.8µg/L from which mercury intake is derived as 0.1µg/kg body weight/day. Mahaffey, who was one of the committee members who set the EPA RfD, suggests that it should be based on a value of 3.5 µg/L to take into account bioconcentration[1]. The relation between maternal mercury intake and cord blood is not necessarily linear[2] and what one can say at this point is that it would be lower than 0.1µg/kg body weight/day.

The Canadian Total Daily Intake is based on maternal hair at birth[3] and did not take into account placental bioconcentration and thus did not account for the fact that hair mercury concentrations decrease over pregnancy (see Part 2; figure 2).

Question 14: What are the health benefits, if any, of eating fish? What are the health benefits, if any, of the practice of fishing?

Answer to Question 14:

Fish is a highly nutritious food, providing a wide variety of nutrients, including omega-3 fatty acids (see Part 2, section 11).

In utero and throughout lifespan, omega-3 fatty acids are likewise positive physical and mental health outcomes, including children's neurodevelopment, visual functions, blood pressure, cardiac function, vascular reactivity and lipids

Studies of children exposed to mercury through fish consumption show the negative effects of mercury exposure and the positive effects of omega-3 fatty acids on neurodevelopment. Studies of adults, as well, have shown the opposing effects of mercury and omega-3 fatty acids and visual function, as well as for the risk of myocardial infarction (Part 2, section 11, Figure 7)

The US-EPA advisory for subsistence fishing was developed in collaboration with representatives from Native American tribes. It indicates: "EPA recognizes, however, that Native American subsistence fishers are a unique subsistence fisher population that needs to be considered separately. For Native American subsistence fishers, eating fish is not simply a dietary choice that can be completely eliminated if chemical contamination reaches unacceptable levels; rather eating fish is an integral part of their lifestyle and culture. This traditional lifestyle is a living religion that includes values about environmental responsibility and community health as taught by elders and tribal religious leaders. Therefore, methods for balancing benefits and risks from eating contaminated fish must be evaluated differently than for the general fisher

[1] Mahaffey (2009)
[2] Stern (2003)
[3] Legrand et al (2010)

population"[1]."

Question 15: If there are health benefits to eating fish what, in your professional opinion and in the scientific literature of which you are aware, should be done with respect to practices that lead to the bio-accumulation of mercury in fish? How would this principle apply at Grassy Narrows?

Answer to Question 15:

In my professional opinion, based on the existing scientific literature, fish-eating practices should seek to maximize the nutritional benefits from fish consumption and minimize the toxic risk from mercury and other contaminants.

The Grassy Narrows community has been exposed to high concentrations mercury in fish for many years and individuals and the community are suffering the effects. **It would only add toxic insult to toxic injury to further expose this population to mercury**

While the community needs the nutrition from the fish, their intake of mercury needs to be minimal. To achieve this there needs to be a comprehensive plan:

- to reduce mercury at the source in the lake sediments;
- to never increase the mercury load in this environment;
- to eat more fish with little mercury;
- to initiate schooling and health programs to address the issue of mercury poisoning in this community.

Question 16: How would you characterize the appropriateness of the health guidance contained in the Ontario Guide for Sport Fish Eaters for indigenous communities who eat fish? Which reference dose is used in developing the Guide?

Answer to Question 16:

The Ontario Guide for Sport Fish Eaters is designed for "anglers (and their families) who consume moderate quantities of fish. The consumption advice is intended to protect individuals who follow the advice in the guide and consume no more than 8 meals per month of the fish they catch." The Guide notes that the advisory is based on the Canadian TDI. Their fish advisory recommends that "for women of child-bearing age and children under 15 years old, restrictions on consuming sport fish containing mercury begin at levels of 0.26 parts per million. Complete restriction (i.e., do not eat) is advised for levels above 0.52 parts per million. For the general population, consumption restrictions begin at levels above 0.61 parts per million. Complete

[1] US Environmental Protection Agency *Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories Volume 2 Risk Assessment and Fish Consumption Limits Third Edition (2000) p. 16*

restriction is advised for levels above 1.84 parts per million."[1]

The guide clearly indicates that it is not for heavy fish eaters. In Grassy Narrows, using the 2003 information on fish consumption from Chan, approximately 16% of persons eat more than 9 fish meals/month, and the average mercury content for several of the fish species in many of the lakes is above 0.52 ppm.

Question 17: Compare with the general population, the level of sensitivity of those who already have experienced elevated mercury exposure, or show symptoms of mercury poisoning, upon further exposure? Comment on the appropriateness of intake guidelines designed for the general population when applied to people exhibiting symptoms consistent with mercury poisoning?

Answer to Question 17:

There is ample evidence from animal and human studies that mercury modifies normal functioning of many systems, and in particular, the nervous system. While some of these changes result in symptoms and signs of damage, many remain undetectable because of the body's capacity to adapt. There is, however, a limit to this physiological adaptation and further exposure will build on the damage already present.

The guidelines for mercury intake refer to "over a lifetime". If exposures have been higher in the past than at present, the intake guidelines do not apply since over the lifespan, one's intake will be higher than those recommended by the guidelines.

Grassy Narrows

Question 18: For document B listed above, and if not already addressed in response to question 1, please indicate the following:

- ***a. What role, if any, did you play in the preparation of document B?***
- ***b. Are the findings and conclusions contained in document B still valid today? If not, indicate what material changes have occurred since the release of document B that would cause the need for significant revisions in its findings and conclusions?***
- ***c. What would be the revised findings and conclusions, if any?***

Answer to Question 18a:

I prepared document B in collaboration with Dr. Laurie Chan, Professor and holder of the Canada Research Chair in Toxicology and Environmental Health.

[1] Ontario Ministry of the Environment. 2013-2014 Guide to Eating Ontario Sport Fish, p. 16,

Answer to Question 18b:

The findings and conclusion of document B, which was submitted to the Mercury Disability Board in 2010, are still valid today. Since that time the science of mercury exposure and its effects on human health has continued to advance substantially and Part 2 of the present document updates the scientific evidence since that time. Studies published since 2010 on the effects of mercury on health and well-being, confirm the conclusions contained in Document B.

Answer to Question 18c:

The more recent studies indicate effects of mercury exposure are present at lower levels than previously thought and that they are long-lasting.

Question 19: If not otherwise answered in response to question 1, above, please indicate if the statements are accurate that are contained in the first six pages of the September 2014 supplementary submission listed in item A that are attributed to your document B report?

Answer to Question 19:

The statements are accurate and the scientific literature of the past 5 years provides strong confirmation. One further update: The law Concerning Special Measures to Provide Relief to Minamata Disease Victims, passed in 2009 was enacted in April, 2010 (see question 1 above).

Question 20: Are you aware of a more thorough long-term study than that of Dr. Harada and his colleagues from Japan (including Takaoka and Fujino, et al.), on the issue of mercury exposure and effects at Grassy Narrows?

Answer to Question 20:

Dr. Harada was a clinical neurologist, with world-renowned expertise on Minamata Disease, who began examining patients with Minamata Disease in 1961. He carried out a most thorough study of clinical manifestations of Minamata Disease in Grassy Narrows. No other group of scientists have carried extensive health studies with this community, although, as we indicated in the MDB report and Dr. Harada mentions in his 2011 report, there is a need for studies on the long-term effects of fetal exposure and the overall impact of mercury exposure on the physical and mental well-being of this community.

Question 21: What risks, if any, do current mercury levels in pike and walleye present to the people of Grassy Narrows who eat fish caught from local waters?

Answer to Question 21:

According to the 2005 report by Chan[1], the average mercury concentration in walleye in the lakes that are around Grassy Narrows (Ball Lake, Garden Lake and Indian Lake) are above almost all fish advisories guidelines for consumption. They are between twelve to twenty times higher than the US-EPA screening value for subsistence fish-eating. Northern Pike from these lakes are twelve to eighteen times higher than the screening value. Using the Ontario Fish advisories, all of the walleye and northern pike from these lakes are above the 'do not eat' concentration for women of child-bearing age and children (0.52 µg/g), while for the others, there would be restrictions for Ball and Indian Lake since the average mercury concentration in fish is above 0.62 µg/g).

Historical data from the English-Wabigoon River system from 1975 onwards show that there were much higher exposures in the past. While these high concentrations for walleye and northern pike declined rapidly from 1975 to 1985, the decline was much less and often stable until 2010[2].

When estimating the risk for mercury poisoning in Grassy Narrows, it is necessary to take into account past exposures (including prenatal exposure), as well as present exposures,. Even without actual data, it is clear that the risk for mercury poisoning is very high for walleye and northern pike fish-eaters.

It should also be mentioned that particularly for *in utero* exposures, immediately after ingestion of the fish, there would be a very large peak of mercury exposure at a critical moments in fetal development. Prenatal effects may differ depending upon the moment of this peak exposure during fetal development.

Question 22: What risk is there, if any, to the health of people at Grassy Narrows who eat fish caught from local waters if mercury levels were to increase?

Answer to Question 22:

There is no question that the mercury already present in the Grassy Narrow area poses important risks to health and well-being to the community and that any further addition of

[1] Chan (2005)
[2] Neff et al. (2012)

mercury would increase that risk. It would, indeed be adding insult to injury. In my opinion, based on the scientific literature and Dr. Harada's work, it would be shameless, and I would call it irresponsible, to add more mercury to this mercury-laden environment. The health and well being of this community has already been harmed not only through mercury poisoning of those who continue to eat fish, but also and by depriving important nutrients to those who reduced their fish consumption because of the mercury.

PART 2

OVERVIEW

> *"At first, methylmercury research was impaired by inappropriate attention to narrow case definitions and uncertain chemical speciation. It also ignored the link between ecotoxicity and human toxicity. As a result, serious delays affected the recognition of methylmercury as a cause of serious human poisonings in Minamata, Japan. Developmental neurotoxicity was first reported in 1952, but despite accumulating evidence, the vulnerability of the developing nervous system was not taken into account in risk assessment internationally until approximately 50 years later. Imprecision in exposure assessment and other forms of uncertainty tended to cause an underestimation of methylmercury toxicity and repeatedly led to calls for more research rather than prevention."*
>
> *Grandjean et al, 2010*

This review on general mercury and health facts sought to provide the most up-to-date information on mercury and human health, building on the information contained in the document entitled *Literature Review: The Impact of Mercury on Human Health* prepared by Dr. H.M. Chan and myself for the Mercury Disability Board in 2009, updated in 2010 with a review of Dr. Harada's studies. The two documents provide the scientific background for the answers to the questions above. Since 2010, over 800 articles have been published on methylmercury and fish, with half in the medical domain. Figure 1 shows the evolution of articles on methylmercury and fish since 1966. Approximately half of these are on health issues.

Figure 1 Evolution of scientific articles on methylmercury and fish since 1966

The literature review, here, is not exhaustive and serves to provide background for the questions that were posed. Relevant published scientific reviews and studies, since we wrote the report for the Mercury Disability Board in 2010 were identified, and where, possible, an

emphasis placed on those that examined methylmercury exposure and health effects in Canadian First Nation and Inuit communities.

The studies of the past years, reviewed here, support the following conclusions:

- There is no doubt that at the levels of exposure experienced in Grassy Narrows, the community has suffered and continues to suffer from mercury poisoning, individually and collectively.
- The scientific literature continues to provide evidence for Dr. Masazumi Harada and colleagues' clinical findings, reviewed by Chan and Mergler for the MDB[1] on the similarities between the neurologic signs and symptoms of persons from Grassy Narrows and White Dog and Minamata Disease in Japan. Using the diagnostic criteria for Minamata Disease, in Harada's 2010 he diagnosed Minamata Disease in 30 people from Grassy Narrows and 12 persons with 'suspected MInamata Disease.' (see question 1 C).
- The reduction of consumption of local fish and wildlife resulting from mercury pollution of the area deprived the people of Grassy Narrows of healthful nutrients, which have been shown to be beneficial for a large number of physiological functions and to be preventive for many and diseases.
- It is surprising that although the Japanese neurologists have identified many cases of Minamata Disease in Grassy Narrows and many persons have illnesses that have been associated with mercury intoxication, there has never been a scientifically sound epidemiologic study of the impact of pre and post natal mercury exposure on the health and well-being of this community.
- Any increase of exposure to this already 'sensitive' community to mercury contamination from sources, such as mining, logging and reservoirs, would further compound the harm to the health and well-being of the present and future generations.

1. Mercury is highly toxic to human health. Impacts include fetal and child development, neurological disorders and cardiovascular changes.

The effects of mercury from fish consumption on the nervous system has been extensively studied since the Minamata disaster and there is consensus on mercury neurotoxicity and its harmful neurologic effects during fetal and child development and in adults. Epidemiologic studies of exposed populations show increased risk for neurodevelopmental deficits, loss of cognitive and motor functions and visual deficits[2]. Changes in brain functioning in methylmercury-exposed persons have been confirmed in electrophysiological[3] and brain

[1] Chan and Mergler (2010)
[2] Grandjean et al. (2010)
[3] Ethier et al, (2012)

imaging[1] studies. Experimental studies with mercury-exposed animals provide extensive information on the mechanisms that underlie mercury toxicity[2].

More recently, the possible effects of mercury on other health endpoints have been examined. In 2011, the Environmental Protection Agency of the United States convened a workshop of experts on methylmercury exposure and cardiovascular endpoints[3]. The authors concluded that there was strong evidence for the relation between biomarkers of mercury exposure, measures in toenails or hair and myocardial infarction (MI). It is noteworthy that the range of the equivalent hair mercury exposure of the studies reviewed by this committee was from 0.34µg/g to 1.66µg/g[4]. Among the studies, upon which their conclusions were based, was an international study that showed a doubling of the risk for a first myocardial infarction for men in the highest quintile of hair mercury.

In addition, several studies have shown associations between biomarkers of methylmercury exposure and other cardiovascular disorders**,** including hypertension and changes in heart rate variability profiles[5]. In a study of Cree adults[6], the authors observed a positive association between altered heart rate variability parameters and blood mercury, after considering fish nutrients (omega-3 fatty acids and selenium) and other contaminants (lead and polychlorinated biphenyls) that are also present in the traditional diet of this population.

There is some evidence that mercury exposure increases the risk for Type II diabetes, but it is inconsistent. A recent 18-year follow-up study[7] of 3875 young United States' adults (20-32 years old), free of diabetes at the onset of the study, showed that those with the highest mercury exposure (equivalent of 1.2 – 1.5 µg/g hair mercury) had an elevated risk for diabetes compared to those with the lowest exposure, while another follow-up study of 2 cohorts did not show an association of incident cases of Type 2 diabetes and toenail mercury concentrations[8]. An analysis of data from the Korean National Health and Nutrition Examination Survey showed and increased risk for metabolic syndrome in men with respect to blood mercury, but not in women[9].

A recent study used the data from the United States' National Health and Nutrition Evaluation on 1352 women of reproductive age women (16 – 49 years) to examine biomarkers of the immune system. Low levels of blood and hair mercury, generally considered safe, were

[1] White et al. (2011)
[2] Fretham et al. (2012)
[3] Roman et al. (2011)
[4] Guallar et al, (2002)
[5] Houston (2011)
[6] Valera et al (2011)
[7] He et al (2013)
[8] Mozaffarian et al. (2013)
[9] Chung et al, (2014)

associated with subclinical autoimmunity among reproductive-age females.[1]. The authors put forward that methylmercury exposure may be relevant to future autoimmune disease risk.

2. Adults can be impacted at levels well below the old threshold level for risk of 50 µg/g in hair.

With the increasing information from research on risks of methylmercury exposure and the evolution in our understanding of how subtle functional alterations in many individuals can translate into important risks for a community (see Part 2, section 5), regulatory agencies continue to revise recommended threshold levels for risk.

In Canada in the 1970's, the agency that later became the First Nation and Inuit Health Branch of Health Canada considered blood mercury levels below 20 µg/L (or 6 mg/kg in hair) as being "acceptable" and levels greater than 100 µg/L in blood (or 30 mg/kg in hair) as "at risk" based on the knowledge at that time and the unusually high mercury concentrations observed in Grassy Narrows and Whitedog[2]. Today, Health Canada provides different threshold levels for risk depending on age and sex. Legrand and co-authors[3] summarized existing Health Canada methylmercury blood guidance values for the general population and expanded them to include a harmonized provisional interim blood guidance value. The threshold action levels for pregnant women, women from birth to 49 years and men less than 18 years was reduced but those for women above 50 years and men over 18 years, they are the same as in the 1970s. The table below is adapted from the table in the article by Legrand et al. in 2010 entitled:

Table 2 Overview of Health Canada Existing and Harmonized Blood Methylmercury Guidance Values

	Blood mercury threshold action levels			
	1	2	3	4
• pregnant women • women from birth to 49 years • men less than 18 years	less than 8 µg/L	8 – 40 µg/L	above 40 µg/L	
• women above 50 years • men above 18	less than 20 µg/L	20 -100 µg/L		
• women and men all ages				above 100µg/L

[1] Somers et al. (2015)
[2] Legrand et al. (2010)
[3] Legrand et al. (2010)

Action levels:

1. No follow-up required
2. Repeat blood/hair test in 6 months; provide dietary advice
3. Repeat blood/hair test immediately; schedule an appointment with a public health professional to review exposure history to identify sources of mercury exposure; provide dietary advice;
4. Repeat blood/hair test immediately; schedule an appointment with a public health professional to review exposure history to identify sources of mercury exposure; provide dietary advice; refer study participant to a physician or medical toxicologist for assessment and follow-up in terms of checking basic neurological signs and symptoms and making a decision concerning appropriateness of any therapeutic intervention

Other regulatory agencies have one reference dose for all, based on the studies of prenatal exposure and effects. The US-EPA reference dose for oral exposure to methylmercury is 0.1µg/kg body weight/day, which corresponds to mercury concentration of 5.8 µg/L (1 µg/g hair mercury)[1]. The Joint Expert Committee on Food Additives and Contaminants (JECFA) of the Food and Agriculture Organization (FAO) and the World Health Organization (WHO) proposed 1.6µ/kg body weight/ week (0.23µg/kg body weight/day)[2]. However, a recent review of the JEFCA guidelines by the European Food Safety Authority (EFSA)[3], published in 2012 and based on European data for fish consumption, proposed that the tolerable weekly intake be reduced to 1.3 µg/kg/week (0.19µg/kg body weight/day).

It is difficult to propose a threshold value for adults since few studies have focused on adult men and non-pregnant women since the developing foetus and child are more vulnerable to toxics and mercury is actively transported from the mother to the foetus. Moreover, the results on the studies on adults are inconsistent, probably due to the fact that the adults under study have different life histories (including prenatal exposure), life styles and nutrition (including difference in consumption of marine and fresh-water fish). The Health Canada guidelines in the Table above consider blood mercury of 20µg/L, which is approximately 10µg/g hair mercury.

A study of Taiwanese 240 adults (36 – 70 years old), who had lived in the region of a chloralkali plant that had been in operation between 1942 and 1985, was undertaken in 2005[4]. Mean total blood mercury was 17.3 ± 10.9 µg/L, with 90% methylmercury. Comparison of those in the 75th percentile (greater or equal to 19.2µg/L; mean 27.1 ± 10.9) to the others (mean 11.6 ± 4.7 µg/L) showed higher abnormality rates for tests of remote memory, mental manipulation, orientation and verbal fluency, but not for tests covering recent memory, attention, abstract thinking, language and drawing. The authors indicate that they do not have information on historic exposures.

[4] Chang et al. (2008)

3. Foetuses and children can be impacted at far lower levels than adults.

There is now a very large number of studies on prenatal exposure to mercury and adverse health effects, most notably on children's neurodevelopment. In their review of the literature, EFSA[1] identified 34 articles of children's neurodevelopment in relation to prenatal exposure since 2003; the results of these studies motivated their recommendation to reduce the threshold for intake from 1.6µ/kg body weight/week to 1.3 µ/kg body weight/week, which would correspond to a decrease in blood mercury from 12 µg/L to 9.6 µg/L. As noted above, Health Canada considers a guidance level for blood mercury of 8 µg/L (hair mercury 2µg/g considering a ratio of 250:1) for pregnant women and women of reproductive age.

The lowest reference dose for the protection of foetus and children is the US EPA reference dose, which was based on three cohort studies of fish-eating populations[2]. It was derived by taking the lower limit of the benchmark dose[3] for cord blood and dividing it by an uncertainty factor of ten to account for variability in elimination half-life and pharmacodynamics variability[4]. It does not take into account bioaccumulation of mercury across the placenta (see section 4 below). Recent studies, however, suggest that measurable neurobehavioral effects may be present at cord blood concentrations near the US EPA reference dose.[5,6,7]

It is noteworthy that the birth cohort studies of mother-child pairs in the Seychelles[8] Islands continue to show little or no effects of mercury exposure despite concentrations similar and even higher than those which have demonstrated mercury-related effects on performance on neuropsychological tests and on electrophysiological and imaging. However, the authors of the Seychelles' studies note that the benchmark dose estimates that serve as the basis for regulatory decision-making have been largely comparable across the Seychelles, Faroese and New Zealand studies. Several hypotheses have been proposed to explain the differences between this fish-eating population and others, such as nutrients in the ocean fish in this area and possible genetic heritage factors. Indeed, in longitudinal analysis of young children's development, positive effects of omega-3 fatty acids were observed as well as small negative effects of prenatal mercury[9] and a study of school achievement showed a slight negative association with postnatal mercury in boys[10].

---

4. Mercury is bio-concentrated across the placenta.

Throughout pregnancy, the placenta concentrates methylmercury and blood mercury concentration in the umbilical cord, which nourishes the foetus, is higher than in the mother's blood. A recent meta-analysis of cord to maternal blood ratios for methylmercury from 10 studies, using different modeling techniques, shows a mean cord to maternal blood ratio of 1.89 with the uppermost 95th percentile of 3.63.[1]. Thus, at birth, the average cord mercury blood concentration will be almost double that of the mother, while for one in twenty that concentration can be over three and a half times more.

Because methylmercury is concentrated across the placenta, biomarkers of maternal methylmercury decrease throughout pregnancy as the placenta takes up the methylmercury. Figure 2 shows the decline in hair mercury concentrations during pregnancy for women with different frequencies of fish consumption[2].

For biomonitoring purposes, blood mercury concentrations are measured in women of childbearing age and not in cord blood. In the study illustrated in the figure below mean maternal blood methylmercury in the first trimester was 0.48 µg/L and at birth 0.26 µg/L. Mean cord blood concentrations (0.45 µg/L) were similar to mothers' blood methylmercury concentrations in early pregnancy.

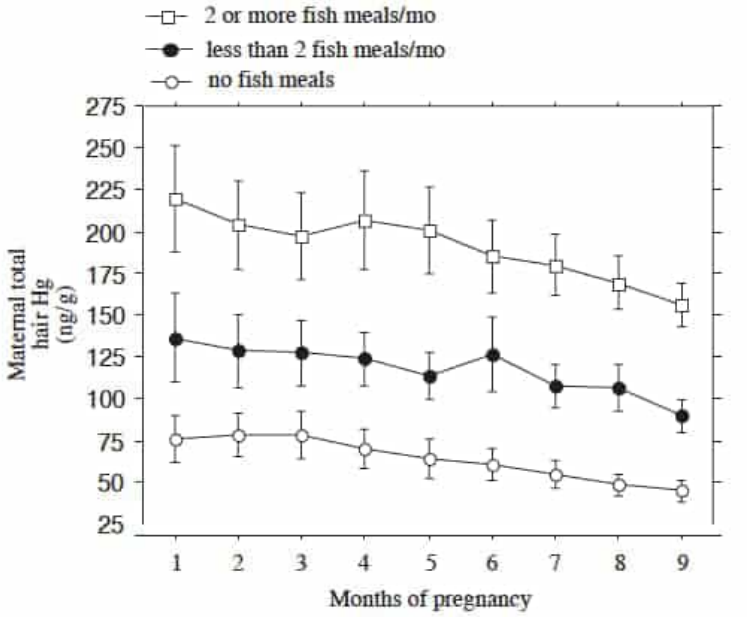
Figure 2. Decline in Hair Mercury Concentrations During Pregnancy for Women with Different Frequencies of Fish Consumption



from Morrissette et al. (2004)

5. Population level impacts can be found at much lower levels of exposure than clear individual impacts (e.g. lower IQ). These can have major impacts at a community level.

The threshold concentrations of all of the above-mentioned agencies were based on neurobehavioral outcomes and not on illnesses. These statistically significant but individually subtle effects can greatly impact a community.

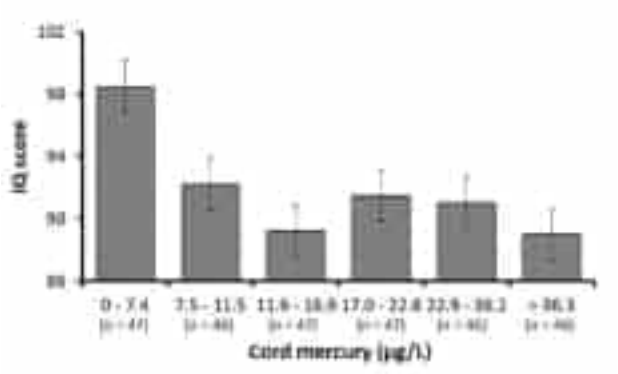
A recent video made by Dr. Bruce Lanphear of Simon Fraser University entitled 'Little Things Matter' (https://www.youtube.com/watch?v=E6KoMAbz1Bw) well describes the impact of very small quantities of toxic substances on children's neurodevelopment. Even **a small decrease in the learning capacity of children in a community has striking repercussions for the community**[1]. For example, an average decrease of 5 IQ points, among exposed children means that, in this community, twice as many children have severe learning difficulties and half as many children are gifted. The effects are amplified if the children have other problems, including poor nutrition, low intellectual stimulation or other toxicant exposures.

In a study of school-age Inuit children from 14 villages in Artic Quebec, children with **cord blood mercury equal to or greater than ≥ 7.5 µg/L were four times as likely to have an IQ score**

[1] Lanphear B. (2015)

below 80, the clinical cut-off for borderline intellectual disability[1], compared to those with lower cord mercury. It is noteworthy that since some of the IQ sub-tests are culturally sensitive, for this study, these tests were modified and validated for this population. The scores ranged from 61 – 125.

Figure 3. Test scores with respect to cord blood mercury in Inuit children 8-14 years old



from Jacobson et al, 2015

6. Developmental impacts of mercury have life-long impacts.

There is increasing evidence that prenatal exposure to mercury has lifelong effects. Subsequent to the Minamata disaster, many children born to asymptomatic mothers with high concentrations of methylmercury during pregnancy, appeared normal at birth but developed a progressive neurological disorder called Minamata fetal disease[2]. At lower levels, prenatal exposure to methylmercury is associated with a decrease in children's later cognitive functions, affecting their learning capacity and success in school and in later life.

Recent studies which have examined long term effect of low-level prenatal exposure on brain activity**,** using electrophysiological or neuro-imaging techniques, have confirmed altered brain activity in children with prenatal exposure to mercury[3,4,5,6]

In the United States, researchers have calculated that neurodevelopmental effects of

[1] Jacobson et al. (2015)
[2] Grandjean et al. (2010)
[3] White et al. (2011)
[4] Ethier et al. (2012)
[5] Yorifuji et al. (2013)
[6] Boucher et al. (2010)

methylmercury in that country accounts for a loss of $8.7 billion dollars annually in earning capacity[1]. The authors of the above-mentioned study of prenatal exposure and cognitive effects in Inuit children point out that intellectual disability on school-age IQ is a measure that is predictive of occupational success in adulthood.

In the above-mentioned study of Inuit children, the adjusted[1] mean IQ of the **lowest exposure group was 4.8 points (5%) higher than the others**. However comparing the percentage below 80, the clinical cut-off for borderline intellectual disability: **only 4.3% of the lowest exposure group** were in this category compared to **17.2% for the more exposed.**

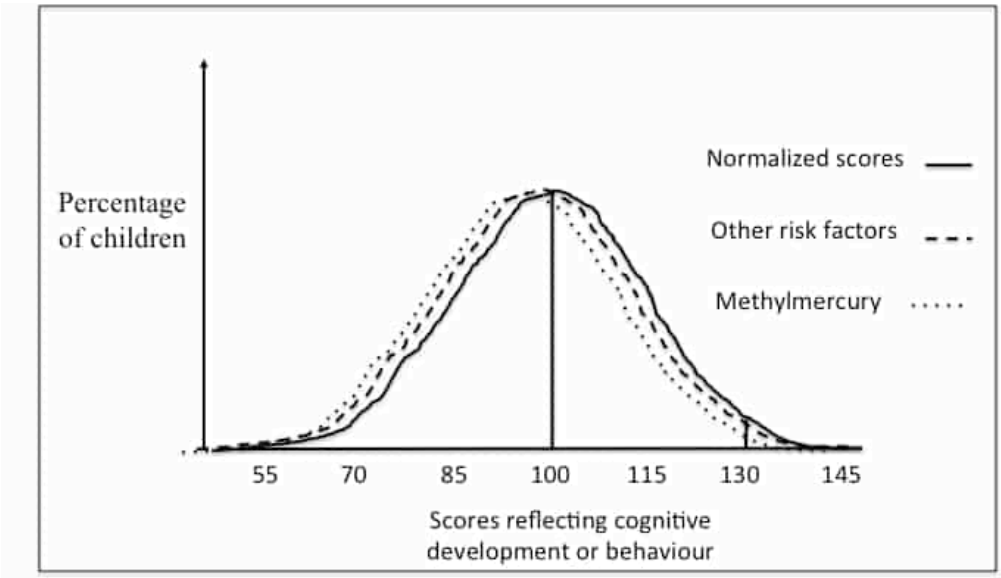
In addition, some studies suggest that there may be associations between attention deficits and/or impulsive or hyperactive behaviour in relation to methylmercury exposure. The birth cohort study of **8 – 14 year old Inuit children** shows that **problems of attention and teacher reported symptoms of attention deficits/hyperactive disorders (ADHD) were associated with higher prenatal mercury concentrations, but not current exposures**[2]. In a study in the United States of 8 year old children living near a contaminated site (superfund site), increased risk for inattention impulsive/hyperactive behaviour for boys, but not for girls, was associated with maternal hair mercury, measured close to child's birth, equal to or above 1µg/g.

Several authors have raised the issue of the combined effects of toxic exposures on children's development in communities with other risk factors, such as poor nutrition and housing, pre-existing diseases and parents' unhealthy lifestyle. Weiss and Bellinger[3] refer to the "social ecology of children's vulnerability to environmental pollutants". The impact of toxic exposures on children who are vulnerable because of other risk factors is greater on the community.

Figure 4 below shows how methylmercury compounds the effects of other risk factors on intellectual capacities. Children's average cognitive capacities or behaviour are influenced by factors such as poor nutrition and housing, pre-existing diseases and parents' unhealthy lifestyle, pushing the normal curve towards the left, with more children suffering from learning difficulties. Methylmercury exposure further pushes the curve towards the left.

[1] In this study, to assess the contribution of mercury, IQ scores were adjusted for cord lead, current PCB153, cord DHA, cord selenium, social environment
[2] Boucher et al. (2012)
[3] Weiss and Belanger (2006)

Figure 4 Estimated distribution of intellectual capacities with methylmercury exposure combined with other factors. The normal curve moves towards the left, towards lower scores.



The impact of exposure may also be passed on from one generation to the next[1], not only through the fetal environment, but also through the care that parents, who function less well because of their exposure, are able to give to their children. It can become a vicious circle, as shown in Figure 5. The way in which boys and girls experience these effects may differ[2]. Boys and girls who drop out of school may occupy poorer jobs or no jobs and act out their dissatisfaction in different ways. For girls, early pregnancy may be a further consequence. Although associations between early pregnancy and school achievement, living conditions and income have been studied in aboriginal and non-aboriginal communities[3], the possible contribution of exposure to contaminants to these situations has not been examined.

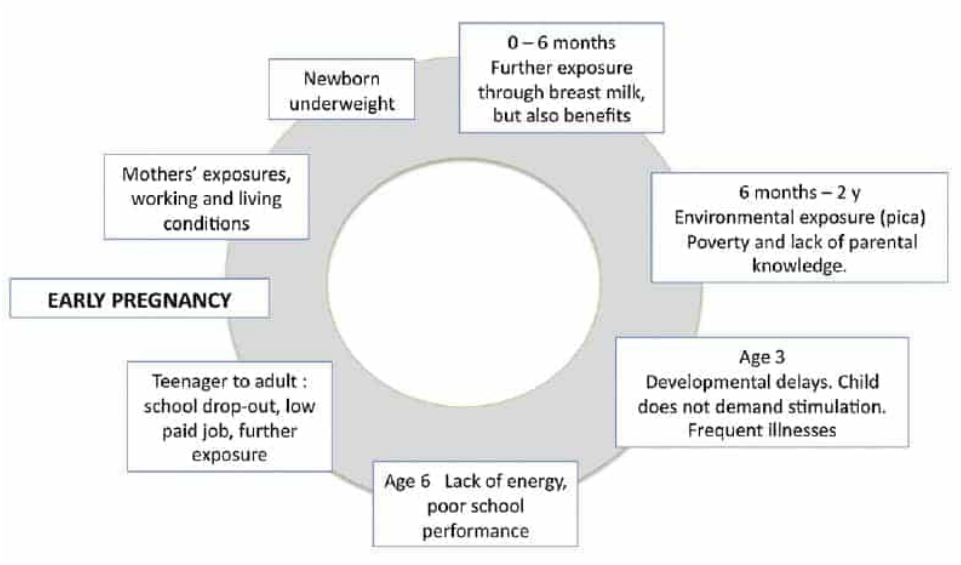
Figure 5 Impact of Environmental Exposure from One Generation to the Next



from Mergler (2012)

7. The health impacts of mercury exposure in adults can take a long time to manifest and can be long lasting and degenerative.

Adverse effects of methylmercury exposure in adults can result from pre-natal and childhood exposure and/or exposure during adulthood. However, the harm may not be immediately evident. Even with high exposures during adulthood, such as those that occurred in Iraq and in Minamata, there was often a delay between exposure and mild to severe neurological effects exposure, varying from weeks to years[1]. A study in Japan[2] compared the subjective complaints and activities of daily living (ADL score) of a randomly chosen sample of 750 persons, classified into three groups with respect to estimated previous exposure to methylmercury; all had lived in their current residence for over 40 years. While no difference was observed between exposure categories for the 40-49 year olds, as they got older there was a strong dose-effect relation, with those in the higher group showing the worst scores. Further data from Minamata and the surrounding areas suggest that, in later life, exposed persons display a higher prevalence of psychiatric problems[3], hypertension[4] and lower urinary tract disorders[5].

[1] Weiss et al. (2002)
[2] Ushijima et al. (2012)
[3] Yorifuji et al. (2011)
[4] Yorifuji et al. (2009)
[5] Hara et al. (2013)

In adult subsistence fish-eaters of the Brazilian Amazon region, hair mercury concentrations have been associated with deficits in visual functions[1] and motor performance[2]. Age-related decrease in near visual acuity and the prevalence of age-related cataracts were higher among those with higher exposures to mercury[3,4]. In a follow-up study of persons in this region, who continued to eat the same amount of fish, but preferentially those with less mercury, the resulting decrease in hair mercury was associated with an improvement in motor functions, but visual functions continued to decrease in relation to their past exposure levels[5].

Studies of non-human primates dosed with methylmercury, the latency period for signs and symptoms increased as the dose decreased[6]. In Figure 6, taken from Weiss (2002), the impact of slight increases in loss of functional capacity with age is illustrated. Like with small decrements in IQ in children, which have a large impact on society, small decrements in functional capacity with age likewise impact the aging process. Again with poor nutrition, living conditions and access to health facilities, the decrease in functional capacities is greater.

[6] Weiss (2002)

To better understand the mechanisms involved in adult exposure to methylmercury, researchers have examined the brains of animals chronically exposed to methylmercury over a period of time. These studies show extensive alterations in the cortical regions of the brain[1,2] Autopsies performed on the brains of children and adults from the Minamata disaster show different patterns of mercury related impairment, more diffuse in children and more concentrated in specific areas in adults[3].

Methylmercury from fish consumption has also been associated with chronic conditions in adults although the contribution of previous prenatal and/or postnatal exposure vs. current exposure is difficult to determine. In the study cited above of a Taiwanese population living near a deserted chloralkali plant, there was no historical data and the researchers were unable to determine the contribution of past exposures to their neurologic deficits, which were associated with current exposure concentrations. In this same population, the authors found that current mercury blood concentrations were associated with increased risk of insulin resistance[4].

8. Fish is the most important source of mercury in humans. Other sources of mercury in humans include fish eating wildlife (ducks, otters, etc.), dental fillings, etc. Estimates of mercury impacts based on MeHg or fish alone may underestimate the total impact.

Humans are exposed to both inorganic mercury and organic mercury (usually in the form of methylmercury). Exposure to inorganic mercury is usually through mercury vapours from occupational and industrial sources; mercury amalgams in dental fillings can also be a source of exposure to inorganic mercury. When inhaled or swallowed, this form of mercury passes passively into the blood and is excreted through the urine. Contrary to methylmercury, tissues, such as the brain or the placenta, do not actively take it up and the concentration in mother's blood is similar to that in cord blood[5].

Methylmercury has been used in industrial processes; the methylmercury poisoning disaster in Iraq in the early seventies was due to the methylmercury containing fungicide that was consumed by humans[6]. However, outside of accidental exposures, human exposure to methylmercury is very largely through fish consumption and to a lesser extent through consumption of fish-eating birds and mammals.

To estimate the total intake of methylmercury, one needs to consider the entire diet, including

[1] Dasari et al. (2010)

[3] Eto et al. (2010)
[4] Chang et al . (2011)
[5] Morisette et al. (2004)
[6] Grandjean et al. (2010)

fish-eating birds and mammals. The Environment Canada website on mercury in the food chain, updated in 2013 well describes how mercury accumulates through the food chain (https://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=D721AC1F-1).

Some salient points are made in this document:

- *Because mercury is a persistent substance, it can build up, or bioaccumulate, in living organisms, inflicting increasing levels of harm on higher order species such as predatory fish and fish eating birds and mammals through a process know as "biomagnification".*
- *In the environment, particularly lakes, waterways and wetlands, mercury can be converted to a highly toxic, organic compound called methylmercury through biogeochemical interactions.*
- *The most important pathway for mercury bioaccumulation is through the food chain. In the water, plants and small organisms like plankton take up mercury through passive surface absorption or through food intake. … Methylmercury biomagnifies through the food chain as predators eat other organisms and absorb the contaminants that their food sources contained.*
- *Over time, an individual who consumes plants or prey contaminated with methylmercury will acquire levels greater than in either its habitat or its food. As a result, top predators acquire greater body burdens of mercury than the fish they consume.*
- *In some cases, methylmercury levels in carnivorous fish, such as freshwater bass, walleye and pike … bioaccumulate up to a million times greater than in the surrounding water.*
- *Piscivorous (fish eating) predators such as loons, merganser ducks, osprey, eagles, herons, and kingfishers, generally have very high concentrations of mercury.*
- *In addition, mercury has been found in predatory mammals such as otters from south central Ontario.*

9. In 1979 the Health and Welfare Canada recommended a limit of 0.2 ppm in fish as a fish consumption limit for Grassy Narrows and White Dog. The limit for possession of fish for sale is 0.5 ppm wet weight.

In 1973, a Task Force on Organic Mercury in the Environment was established by the Minister of National Health and Welfare (currently Health Canada) "in order to respond to the problem of high and unusual mercury levels in relation to the health and well-being of residents of Grassy Narrows and Whitedog, Ontario"[1]. A biomonitoring program was initiated. In 1979, The Health and Welfare Canada recommended a limit of 0.2 ppm in fish for consumption in Grassy Narrows and Whitedog.

[1] cited in Legrand et al. (2010)

The Canadian limit of fish for commercial purposes of 0.5 ppm wet weight is based on the fact that in the general population, fish consumption is not very high. Data from the 2007-2009 Canadian Health Measures Survey (CHMS), which does not include people living on reserves or in remote regions, show that most Canadians eat (82.6%) eat less than three meals of fish and/or shellfish per week. Overall blood mercury levels are low, with median values at 0.81µg/L and the 95th percentile 4.70 µg/L. Blood mercury levels increase with fish consumption. Among pregnant women, 98% are below the Health Canada guideline for blood mercury (8µg/L).

In contrast, a study of diet among 7 Istchee (Cree) communities in the James Bay area showed that blood mercury concentrations 3 – 20 times higher than those reported in the CHMS; blood mercury increased with inland traditional food intake[1]. Another study of persons from the Wapekeka and Kasabonika communities[2] showed hair mercury concentrations 1.5 times higher in persons who ate more than 1 meal of wildlife/week (age adjusted hair mercury concentration (2.96 ± 0.3 µg/g)

10. The Canadian reference dose for preventing fetal neurotoxicity and developmental impacts is double that recommended by US EPA.

In section 2, the different guidelines for mercury exposures are presented. The guidelines were developed to recommend **tolerable daily intake (TDI) or weekly intake (TWI)** of mercury. The Canadian provisional tolerable daily intake for pregnant women, women of reproductive age and infants of 0.2µg/kg body weight/day is twice the US EPA of 0.1µg/kg body weight/day and slightly higher than the proposed revision of the FAO/WHO reference dose (0.19µg/kg body weight/day) (see section 2). The US EPA reference dose is based on **cord blood concentrations**, while the JECFA and Canadian recommendations are based on **hair concentrations**. The Canadian recommendation used a 5-fold uncertainty factor to account for inter-individual variability[3]. The studies that support this recommendation used maternal hair mercury concentrations at birth that are lower than those at the beginning of pregnancy due to placental accumulation (see figure 2 in section 4). All of these reference doses are high for Grassy Narrow since the population has already been exposed to levels that are higher, and in many cases, considerably higher than these.

11. Eating fish has a number of important health benefits. Serious efforts should be made to avoid practices that lead to bio-accumulation of mercury in fish so that the health benefits of fish can be enjoyed while minimizing health impacts from mercury.

Fish is a highly nutritious food, providing a wide variety of nutrients, including omega-3 fatty

[1] Johnson-Down et al. (2015)
[2] Seabert et al. (2014)
[3] Legrand et al. (2010)

acids. In a review of the cardio vascular benefits of omega-3 fatty acids, Mori[1] writes: "Many clinical and epidemiological studies have shown that the polyunsaturated n-3 fatty acids EPA and DHA from fish and fish oils, provide cardiovascular protection, particularly in the setting of secondary prevention. Omega-3 fatty acids beneficially influence a number of cardiometabolic risk factors including blood pressure, cardiac function, vascular reactivity and lipids, as well as having anti-platelet, anti-inflammatory and anti-oxidative actions". Omega-3 fatty acids are likewise positively associated with neuropsychological and neurophysiological outcomes throughout the lifespan.[2,3] Indeed, **today, most studies of mercury toxicity from consumption of fish and fish-eating animals take into account the positive effects of omega-3 fatty acids.**

An article describing a study of myocardial infarction in a Swedish and Finnish cohort well illustrates the benefits associated with omega-3 fatty acids and risks associated with methylmercury from fish consumption[4]. Their model of risk, presented in Figure 7, shows that at lower concentrations of methylmercury, even a small increase in omega-3 fatty acids can have an important impact in reducing the risk of myocardial infarction, but at higher concentrations of methylmercury, the beneficial effects are counteracted.

[1] Mori (2014)
[2] Bernard et al (2013)
[3] Virtanen et al. (2013)
[4] Wennberg et al (2012)

Figure 7. Risk for Myocardial Infarction with respect to hair mercury concentrations and the percentage of omega -3 fatty acids (s-PUFA) in blood

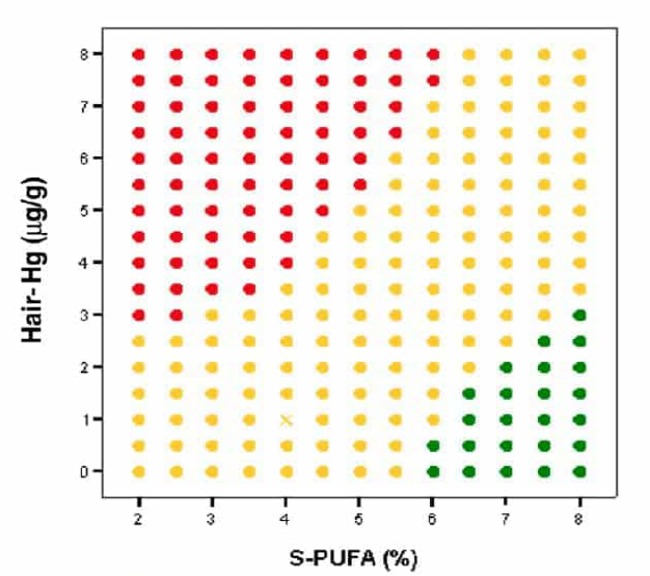

FIGURE 3. Associations of concentrations of long-chain n−3 S-PUFA and Hair-Hg with risk reduction (green circles; upper 95% CI limit for model-based RR <1.0) or increased risk of myocardial infarction (red circles; lower 95% CI limit RR >1.0), with the reference point (RR = 1.0; yellow X) set to S-PUFA = 4.0% and Hair-Hg = 1.0 µg/g; yellow circles denote no statistical evidence of an effect. Hair-Hg, amount of mercury in hair; S-PUFA, PUFAs in serum.

From Wennberg et al. (2012)

Like in many other birth cohort studies, the studies of Inuit children described above, which showed negative effects of prenatal mercury exposure on school-aged children's performance on neurobehavioral tests[1,2], likewise show positive effects of **cord blood DHA**; the benefits and risks are likewise reflected in electrophysiological measurements[3.]

In adult freshwater fish eaters from the Brazilian Amazon, although omega-3 fatty acid concentrations are low compared to consumers of marine fish and mammals, positive effects of omega-3 fatty acids have been observed with better visual functions[4]

The serum omega-3 fatty acids in First Nation inland communities increases with proportion of

[1] Boucher et al, (2011)
[2] Jacobson et al. (2015)
[3] Boucher et al (2011)
[4] Fillion et al, (2011)(2013)

traditional diet meals[1,2]

12. The Ontario Guide for Sport Fish Eaters is not appropriate for Indigenous communities who eat fish as part of their cultural practice. It assumes that fish are eaten relatively infrequently.

The Ontario Guide for Sport Fisher Eaters (2013-2014) indicates: "The advice in this guide is designed for anglers (and their families) who consume moderate quantities of fish. The consumption advice is intended to protect individuals who follow the advice in the guide and consume no more than 8 meals per month of the fish they catch. This maximum recommended consumption frequency was based on the results of surveys indicating that most anglers do not consume sport fish more frequently than 8 meals per month. However, many of these fish can be safely consumed more frequently. Anyone who consumes sport fish more frequently than 8 meals per month is advised to contact the Sport Fish Contaminant Monitoring Program (416-327-6816 or 1-800-820-2716, sportfish.moe@ontario.ca." [3]

The US-EPA developed a guide for subsistence fishing with the collaboration of representatives from Native American tribes. It indicates: "EPA recognizes, however, that Native American subsistence fishers are a unique subsistence fisher population that needs to be considered separately. For Native American subsistence fishers, eating fish is not simply a dietary choice that can be completely eliminated if chemical contamination reaches unacceptable levels; rather eating fish is an integral part of their lifestyle and culture. This traditional lifestyle is a living religion that includes values about environmental responsibility and community health as taught by elders and tribal religious leaders. Therefore, methods for balancing benefits and risks from eating contaminated fish must be evaluated differently than for the general fisher population"[4].

13. People who have already experienced elevated mercury exposure, or are showing symptoms of mercury poisoning, may be more sensitive to further exposure than the general population.

Both animal and human studies have shown long latency effects of methylmercury exposure.[5] Adding further toxic exposure can add further harm to systems that have already been affected. A large number of human and animal studies have shown neuronal and metabolic changes in the absence of manifest signs and symptoms. Persons whose systems have already been altered by previous exposures are more sensitive than the general population.

14. CONCLUSIONS WITH RESPECT TO GRASSY NARROWS

This updated analysis of the scientific literature provides substantial further support and confirm the Chan and Mergler conclusions in the report to the Mercury Disability Board (MDB) in 2009[1]:

14a There is no doubt that at the levels of exposure experienced in Grassy Narrows, many people have suffered and are suffering from mercury poisoning.

- Further scientific knowledge of the past 6 years informs us that damage occurs at concentrations much lower than those previously considered harmless, with important impacts not only for individuals but also on the entire community.
- A growing number of birth cohort studies show that the foetus is particularly sensitive to methylmercury neurotoxicity and even very low concentrations of exposure can affect future cognitive capacity and behaviour.
- In 1996, the Research and Development, Environmental Contaminants, Medical Services Branch of Health Canada presented a report on the mercury and child development research project for the Grassy Narrows Band Council[2]. Although the report has numerous methodological problems as regards data analyses[3] and data presentation is confusing, there is information on children's exposure:
    - For the 139 children included in the study, the authors report that between 1978 and 1990 average cord blood concentrations was 8.67 µg/L, with a maximum value of 78.5 µg/L and 10% above 20 µg/L.
    - One child born in 1979, who was not included in the study, had a cord blood mercury concentration above 120 µg/g, while another born in 1978 had over 80 µg/g.
    - Overall, there was an important decrease in cord blood mercury concentrations between 1978 and 1991, however, in 1992, there appears to be an increase.
    - The mean hair mercury concentration of the participants at the time of the study was 3.90 µg/g with the maximum at 26 µg/g.
    - Figure 8, taken from this report, shows the cord mercury concentrations measured in Grassy Narrows over time.

[1] Chan and Mergler (2009)
[2] Research and Development, Environmental Contaminants, Medical Services Branch of Health Canada (1996)
[3] The analyses that were carried out were insufficient to arrive at any conclusions and particularly the conclusion that there were no effects.

- **At these cord blood concentrations, there is consensus from the current scientific literature that there would be effects on children's neurodevelopment.**

Figure 8 Umbilical cord blood levels/year measured in Grassy Narrows

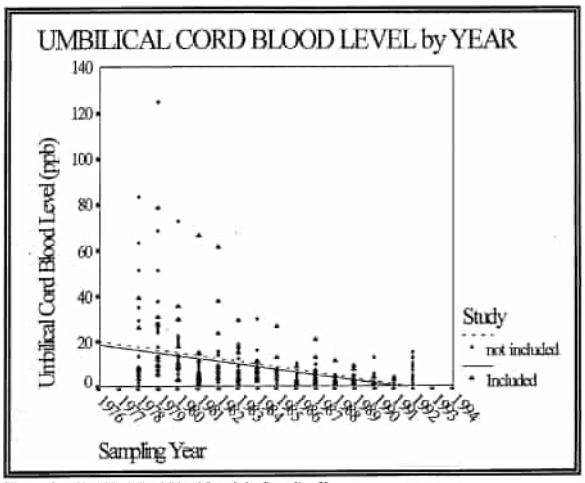

Figure 1. Umbilical Cord Blood Levels by Sampling Years

From the Mercury and Child Development Research Project, Grassy Narrows, Research and Development, Environment Contaminants, Medical Services Branch, Health Canada (1996)

- In a history of Minamata Disease published in 1995[1], Harada describes the diagnosis of the initial cases in 1956. He recounts that by 1960, "while the number of grave cases with acute Minamata Disease in the initial stage was decreasing, the numbers of chronic Minamata patients who manifested symptoms gradually over an extended period of time was on the increase."
- Recent studies from MInamata, supported by findings from animal research, show that methylmercury accelerates the aging process.
- A large number of animal studies and several human electrophysiological and imaging studies are elucidating the mechanistic basis for mercury neurotoxicity.
- While the nervous system is the primary target organ for methylmercury, studies indicate that the cardiovascular system and metabolic pathways may also be affected by methylmercury.

[1] Harada (1995)

14 b. The scientific literature continues to support Dr. Masazumi Harada and colleagues' clinical findings, reviewed by Chan and Mergler for the MDB[1] on the similarities between the neurologic signs and symptoms of persons from Grassy Narrows and White Dog and Minamata Disease in Japan.

- In their early reports[2,3], Harada and colleagues had examined 89 persons from Grassy Narrows and Whitedog and indicated that no one presented all of the classical signs and symptoms of Minamata Disease, although many persons presented one or more classical signs of the disease. Although they did not carry out statistical analyses, they provide evidence of dose-effect relations.

- In 2002[4], the same neurologists examined 57 persons of whom 9 had been examined in 1975. The authors classified 11 of the 57 persons with Minamata Disease, 12 with Minamata Disease and other complications and 22 with "light Minamata Disease".

- None of the persons Harada found with levels over 50 in 1975 survived to be re-tested in 2002. Of the 9 who were re-examined none fell into the Minamata Disease category, but for 7 of the 9, symptoms and signs had worsened.

- In 2004, this team examined 187 persons, among whom they identified 60 of Minamata Disease and 54 cases of the disease with complications. Twenty-seven had participated as well in 1975. In their review of Dr. Harada's follow-up studies (1975 - 2004)[5], the **Chan and Mergler report point outs that the most valuable information of this report was the evolution of neurologic signs and symptoms consistent with mercury poisoning in those that were tested in the two periods.**

- In 2011, Harada and his co-workers[6] wrote a review of the work that they had carried out in Grassy Narrows and White Dog since 1975, including a further study carried out in 2010. In 2010, they performed neurologic assessments of 73 persons from Grassy Narrows and 87 from White Dog over 20 years old. The report indicated that under the diagnostic criteria used in Minamata City, 33.7% of the group that they examined were diagnosed as Minamata Disease patients; and 25.0% as suspected Minamata Disease cases (see more details in answer to question 1.1 c).

[1] Chan and Mergler (2010)
[2] Harada et al. (1976)
[3] Harada et al. (1977)
[4] Harada et al. (2005)
[5] Harada et al. (unpublished report)
[6] Harada et al. (2011)

- Using the findings from the 2010 examinations, Takoaka and coworkers[1] compared the neurologic signs and symptoms of 80 volunteers aged 16 to 76 from Grassy Narrows and Japanese exposed and control groups. From the observed similarities, particularly between the Grassy Narrows older group and the Japanese exposed group, the authors conclude that "clinical signs and symptoms of the residents of Grassy Narrows are almost the same as those recorded for Minamata disease in Japan." (see more details in answer to question 1.1 d)
- It should be noted that Dr. Harada and his team sought to determine whether persons exposed to mercury in Grassy Narrows and White Dog presented a neurological clinical profile similar to Minamata Disease. While they identified cases and possible cases using the Minamata Disease criteria, they did not examine the possible contribution of mercury into other disorders or the impact of more subtle changes of nervous system functions, particularly during fetal exposure and childhood, which occur at lower concentrations of exposure. .
- Both Harada et al (2011) and Takaoka et al (2014) mention that the participants in their studies presented a high prevalence of several health disorders, including hypertension and diabetes among the participants, **but the possible contribution of mercury to these conditions has not been examined.**

14 c. Because of mercury contamination in the region, the people of Grassy Narrows were obliged to reduce their consumption of local fish and wildlife and were thus deprived of healthful nutrients, which have been shown to be beneficial for a large number of physiological functions and to be preventive for many and diseases.

- The historically high mercury concentrations in fish forced the community to greatly decrease their fish and wildlife consumption, depriving them of the nutritional and social benefits[2] of a traditional diet.
- In a 2003 study of 87 persons from Grassy Narrows[3], 61% reported that they currently fish in the surrounding area, 31% reported that they used to but no longer had fished in the area, and 8% reported they have never fished in the area. Of these participants, 9% reported eating more traditional food compared to 10 years ago, 55% reported eating about the same, and 36% reported eating less. Reasons provided for a decrease in the consumption of traditional foods included:
    - changes in the family structure;
    - decreased hunting and fishing practices;
    - decreased availability;

[1] Takaoka et al. (2014)
[2] Wheatley and Wheatley (2000)
[3] Chan (2005)

- concerns about the safety/contamination of the food;
- the convenience of market foods.

- Although there has been marked decrease in mercury in fish in the English-Wabigoon River system,[1] recent concentrations of mercury in fish[2] and fish-eating wildlife[3] oblige the community to limit consumption of fish and wildlife.
- Kinghorn et al[4] analyzed fish mercury concentrations in 4 fish species from seven lakes in the Grassy Narrows territory and describe the relation between fish length with respect to mercury concentration. They note that the fish harvested from Grassy Narrows lakes show stronger associations between fish length and mercury compared to those from the Wabaseemong territory. The authors indicate that this may be because "these lakes are closest to the Dryden spill site. Higher levels of mercury in the sediment of these lakes may affect the rate of uptake of mercury in the fish that live predominantly within them."
- For a report in 2005, Chan calculated mercury intake and hair concentrations for 87 persons from Grassy Narrows and 55 from Wabaseemoong measured in 2003. In Grassy Narrows, the average yearly local fish consumption in Grassy Narrows was 20g/day, but in older men (+61 years of age) it averaged 60g/day. When all of the hair segments were analyzed, mean hair mercury was 1.3 µg/g with a maximum of 7.1 µg/g. The highest individual hair segment was 15.5 µg/g. Hair mercury increased with mercury intake from fish consumption. In 2004, Harada reported that one person had a concentration of 25 µg/g and in 2003, Chan reported that persons from the White Dog area had hair concentrations of 60µg/g.
- The 2012 report on fish Contaminant Monitoring near Grassy Narrows First Nation by the Environmental Monitoring and Reporting Branch Ontario Ministry of the Environment[5] shows elevated mercury in the 50 km area around Grassy Narrows in walleye and much lower concentrations in Whitefish. For walleye, with the exception of one site where the report indicates that fish can be eaten with restriction, all the other sites indicate DO NOT EAT. Whitefish present much lower concentrations, which may still pose a risk to subsistence eaters.
- The 2012 above-mentioned report presents separate values for sensitive populations, defined as women of child-bearing age and children under 15 years old, and for the general population. Given the recent information on mercury reviewed above, a population that has already suffered effects from mercury contamination and other harmful risk factors for poor health may also be considered 'sensitive'.

[1] Neff et al. (2012)
[2] Kinghorn et al. (2007)
[3] Sellers et al. (2010)
[4] Kinghorn et al (2007)
[5] Ontario Ministry of the Environment (2012)

Grassy Narrows: a sensitive population

- Prior to the events and poisoning that occurred due to mercury contamination, the Grassy Narrows community had undergone important upheaval that negatively impacted their lives and lifestyle.[1,2,3] The toxic effects of mercury would compound the effects of these stresses on the nervous system and their health status.

- Because of the high prevalence of disease, coupled to mercury intoxication, in the communities of Grassy Narrows and White Dog, in the 2010 MDB report, Chan and Mergler point out " It is paramount that members of the two communities receive the necessary medical care and support. In contrast, residents in Minamata, Japan enjoy superb health care from neurologists and therapists even they had not officially been classified as victims of Minamata Disease".

- It is surprising that although the Japanese neurologists have identified many cases of Minamata Disease in Grassy Narrows and many persons have illness that have been associated with mercury intoxication, there has never been a scientifically sound epidemiologic study of the impact of pre and post natal mercury exposure on the health and well-being of this community.

- There are many sources of mercury contamination. The river and lake systems around Grassy Narrows have been polluted by industrial activities; hydro-electric reservoirs and logging can also contribute to the mercury burden in this ecosystem. Any increase of exposure to this already 'sensitive' community would further compound the harm to the health and well-being of the present and future generations.

APPENDIX A – CURRICULUM VITAE

Curriculum Vita

Donna Mergler PhD

Professor Emerita

Université du Québec à Montréal

Name: Donna Mergler
Address: Centre for Interdisciplinary Studies on Biology, Health, Environment and Society (CINBIOSE): http://www.cinbiose.uqam.ca/
Université du Québec à Montréal,
Montréal, Québec, Canada
H3C 3P8
Telephone : +1 514 987 3000 (3355#)
Fax : +1 514 987 6183
e-mail : mergler.donna@uqam.ca

Academic Degrees

1965	B.Sc, (honours physiology) McGill University, Montreal, Quebec, Canada
1973	Ph.D.(physiology) McGill University, Montreal, Quebec, Canada

Academic Positions

2006-	Professor Emerita, Department of Biological Sciences, UQAM
l970-06	Professor, Department of Biological Sciences, University of Quebec at Montreal (UQAM) (full professor since 1980)
1998-	Director, World Health Organization – Pan-American Health Organization Collaborating Center or the Prevention of Occupational and Environmental Illnesses
2002-04	Director, Institute of Environmental Sciences, UQAM
1995-00	Director of the Center for the study of Biology, Health and the Environment (CINBIOSE), UQAM
1994-95	Invited Professor. Pesticide Program, National University, Costa Rica
1993-	Adjunct professor, McGill University Centre for Studies on Aging
1993	Head of the Doctoral Program in Environmental Sciences, UQAM
1990-91	Director of the Center for the study of Biology, Health and the Environment (CINBIOSE), UQAM
l982-84	Chair of the Department of Biological Sciences, UQAM
l985-89	Co-director of the Research-action group in Work Biology, UQAM (associated to the Quebec Institute for Research in Occupational Health and Safety)
1987-88	Visiting scholar: University of California, Berkeley: Department of Biomedical and Environmental Health Sciences; Northern California Occupational Health Centre. Labor Occupational Health Program

Awards/Recognition

1990	Muriel Duckworth Award for Women's Studies
1994	Woman of Merit Award in Science and Technology, given by the YWCA
1995	Michel-Jurdant Award for Environmental Sciences, given by ACFAS
1999-2002	International Development Research Centre (IDRC) Ecosystem and Health Academic Fellowship
2001	Silver Award for Environmental Health. (Canadian Minister of the Environment and Canadian Geographic Magazine)
2003	Phenix Circle for the Environment (Government of Quebec)
2005	Écodéfi Award from the Network on Women and Environment
2008	Distinguished Woman in Ecohealth Research (IDRC)
2011	*Bâtisseuse de la science* (Faculty of Science, UQAM)
2014	Fellow of the Collegium Ramazzini

Government Advisory Boards

1984 - 88	Member of the Advisory Board on Women's Studies of the Canadian Secretary of State
l984 - 89	Member of the Quebec Council for Science and Technology
1990 - 92	Member of the Expert Committee on Mental Health Subcommittee of the Quebec Minister of Social Affairs
2001	Member of the Sub-committee on Environmental Health of the National Round Table on the Economy and the Environment
2001-11	Member of the Scientific Advisory Board of the International Commission on the Great Lakes
2008-09	Member of the Scientific Council of the health component of the *Plan Chlordécone* (France : *Insitut de Veille Sanitaire* and *Institut national de la santé et de la recherche médicale* (INSERM)

Funded Research Projects (since 1987)

(**IDRC** : International Development Research Centre of Canada; **CIHR** : Canadian Institutes for Health Research; **NSERC** : National Science and Engineering Research Council; **CQRS** : *Conseil québécois pour la recherche sociale;* **FCAR** : *Fonds pour la formation des chercheurs et l'aide à la recherche;* **FRSQ** : *Fonds de la recherche en santé du Québec*; **SSHRC** : Social Sciences and Humanities Research Council; **TSRI** : Toxic Substances Research Initiative; **US-EPA** : United States' Environmental Protection Agency; **IRSST** : *Institut de recherche en santé et en sécurité du Québec)*
(**PI** : principal investigator)

Years	Project	Funding Agency
2008-2014	CIHR Team on Gender, Environment and Health (PI)	CIHR
2011-2012	Prenatal manganese exposure from mancozeb use: expanding knowledge from a birth cohort study on pesticides and children's development (PI).	Health Canada
2009-2013	A community of practice on ecosystem approaches to promote research and policy in Latin America and the Caribbean (co-PI)	IDRC
2008-2010	*Relever le défi analytique intégré des études en écosystème et santé (PI)*	IDRC
2008-2009	Mercury, nutrition and health in the Brazilian Amazon: community appropriation of research results (PI)	CIHR
2008-2011	A Canadian Community of Practice in Ecosystem Approaches to Human Health (co-investigator)	IDRC
2007–2010	Does manganese in water affect children's neurodevelopment? (PI)	CIHR
2005-2008	A community of practice on ecosystem approaches to promote research and policy for reducing toxic exposures and improving collective health in Latin America and the Caribbean (co-PI)	IDRC
2005-2008	Effects of methylmercury exposure on visual functions in the Brazilian Amazon (PI)	CIHR
2003-2006 :	Combining traditional knowledge to maximise use of traditional food and minimise toxic risk (co-PI)	CIHR
2003-2006	*Manganèse et vieillissement cognitif et moteur: étude de suivi de cohorte 12 ans après l'arrêt de l'exposition professionnelle (PI)*	CIHR
2003-2004	An ecosystem approach to environmental and occupational health in developing countries (PI)	CIHR
2002-2005	*Exposition au mercure, santé des écosystèmes et des populations humaines en Amazonie: de l'échelle locale à l'échelle régionale: CARUSO III.(co-PI)*	IDRC
2002-2003	Development of a protocol for gender-based standards in the export industries in Central America (co-PI)	Inter-American Development Bank

2002-2003	Finalizing a research proposal and realizing a financial set up for a project on sustainable tropical agriculture models through the reinforcement of an international network (co-investigator)	NSERC
2001-2006	Mercury and Ecosystem Health: A Collaborative Mercury Research Network: COMERN (co-investigator)	NSERC
2001-2004	*L'invisible qui fait mal: mondialisation et santé des femmes au travail* (co-investigator)	CQRS
2000-2003	*Travail atypique: protection légale des conditions minimales et de la santé au travail* (co-investigator) :	FCAR
1999-2002	*Chercheure émérite en santé et ecosystèmes* (Fellowship)	IDRC
2001-2004	*Santé au travail: interaction des sciences bio-médicales et juridiques dans l'indemnisation et la prévention* (co-investigator)	FCAR
2001-2004	*Conséquences thérapeutiques et anti-thérapeutiques de certains régimes d'indemnisation: programmes actuels et modèles alternatifs* (co-investigator)	SSHRC
1999-2002	Mercury in The Brazilian Amazon : Building Solutions with the Community (co-PI):	IDRC
1999-2002	Assessment of toxicological risks of environmental contamination by manganese (co-investigator)	TSRI
1999-2002	Effects of fish consumption from the St-Lawrence river on hormonal balance and calcium transport in pregnancy (co-PI)	TSRI
2001-2002	Assessment of Neurotoxic effects in a First Nation Community Exposed to Polychlorinated biphenyls (PCBs) (co-PI)	TSRI
1998-2001	*Santé au travail: démonstrations dans les sciences naturelles et juridiques*	FCAR
1999-2000	Manganese in well water of the Eastern Townships of Quebec (Canada). Is there a problem ?	FRSQ
1997-2000	*L'invisible qui fait mal: vers une approche de recherche et d'intervention en santé qui tient compte de la division sexuelle du travail (co-invesitgator)*	CQRS
1996-1999	Source, dispersion and impact of mercury pollution in the Brazilian Amazon (co-PI)	IDRC
1995-1999	Early signs and symptoms of manganese neurotoxicity in environmentally exposed human populations (PI)	US-EPA
1994-1996	*Santé mentale et vie familiale chez des personnes exposées aux substances neurotoxiques*	FRSQ-CQRS
1994-1995	*Projet pilote : Exposition de l'environnement et des humains au mercure (Brésil)* (co-PI)	IDRC
1993-1995	*L'invisible qui fait mal: Impact du travail sur la santé des femmes* co-investigator)	CQRS
1992-1994	*Surveillance des effets neurotoxiques de l'exposition au styrène en milieu de travail: Phase II* (co-PI)	IRSST

1992-1994	*Facteurs de risque pour la santé mentale en milieu de travail* (co-PI)	FRSQ-CQRS
1989-1992	*Etude des effets neurotoxiques précoces chez des travailleurs exposés au manganèse dans une usine de production d'alliages de ferro- et de silico-manganèse* (PI)	IRSST
1990-1992	*Appréciation des risques associés à l'exposition aux solvants organiques chez les personnels de laboratoire* (co-PI)	Min. Recherche (France)
1990-1992	*Méthodologie épidémiologique et statistique en pathologie industrielle* (co-PI)	IRSST
1990-1991	*Etude des lésions musculo-squelettiques aux membres supérieurs dues au travail répétitif dans les abattoirs de porcs* (co-PI)	IRSST
1990-1991	*Surveillance des effets neurotoxiques de l'exposition au styrène en milieu de travail* (PI)	IRSST
1990-1991	Ergonomic analysis of work activity and work practices in jobs originally designed for men and now done by women (co-investigator)	SSHRC
1989-1990	*Effets de l'exposition au toluène sur les systèmes nerveux et rénaux des travailleurs qui appliquent un ciment imperméabilisant* (PI)	IRSST
1988-1989	*Développement et application d'une batterie de tests pour évaluer la perte sensorielle associée à l'exposition professionnnelle aux solvants organiques* (PI)	Health Canada
1988-1989	*Mesure des effets de l'utilisation d'un écran de visualisation monochromatique sur l'indice de confusion chromatique par le test Lanthony D-15 désaturé* (PI)	Health Canada
1987-1990	*Dépistage d'altérations biologiques. Infrastructure d'équipe associée* (co-PI)	IRSST
1987-1989	*Etude des conditions et de l'activité de travail des buandières soumises saisonnièrement à une ambiance thermique chaude et des conséquences sur leur santé* (PI).	SSHRC
1987-1988	*Caractérisation de la discrimination chromatique des travailleurs d'imprimerie en fonction du degré et de la durée de l'exposition aux solvants organiques* (PI)	IRSST

Graduate student supervision

Diploma	Thesis	year
M.Sc Biology		
Nicole Vézina	*La prévalence de verrues chez les travailleurs et travailleuses des abattoirs de volaille : une approche environnementale*	1982
Sylvie de Grosbois	*Analyse descriptive des effets neurotoxiques de l'éther éthylique et de l'alcool éthylique : une approche en milieu de travail.*	1985
Lucie Blain	*Utilisation de la vision des couleurs comme indice biologique d'exposition aux solvants organiques.*	1986
Suzanne Legault-Bélanger	*La discrimination chromatique chez des personnes exposées aux encres d'imprimerie.*	1988
Sylvie Bédard	*L'inconfort thermique et la thermorégulation des calandreuses.*	1989
Isabel Fortier	*La perception olfactive chez les personnes exposées aux solvants organiques en milieu de travail*	1990
Ginette Plouffe	*La contribution de l'exposition au froid aux maux musculo-squelettique chez des travailleurs et des travailleuses d'une industrie de transformation de poissons.*	1990
Luc Martin	*La perception vibrotactile chez des travailleurs exposés au manganèse.*	1992
Dave Campagna	*Altération de fonctions visuelles chez des travailleurs exposés au styrène.*	1993
Marie-Pascale Sassine	*Variations des catécholamines chez des travailleurs et travailleuses exposés au styrène.*	1995
Jean-Pierre Lagacé	*La vision des couleurs chez les opérateurs et opératrices des écrans cathodiques.*	1995
Julie Dolbec	*Motricité et exposition au méthylmercure dans l'Amazonie*	1998
Bahya Bovyahia	*Validation d'un test neuromoteur, le test des mouvements altérnants de Branches. (BAMT).*	2000
Laura Alida Castillo	*Fonctions visuelles et exposition aux solvants.*	2000
Kathy Fortin	*Contribution rélative de l'exposition à l'aluminium et la prédisposition génétique à la maladie d'Alzheimer*	2000
Ludivine Chateau-Degat	*Sécretion du cortisol et mémoire chez des travailleurs exposés aux solvants organiques.*	2000
Maryse Bouchard	*Effets neurotoxiques du manganèse*	2002
Joëlle Morissette	*Mercure chez des femmes enceintes du sud-ouest du Québec.*	2003

Silmara Souza de Morais	*Effets neurotoxiques de l'exposition au méthylmercure dans l'Amazonie brésilienne*	2006

M.Sc. Environmental Sciences

Rosemarie Schneeberger	*Comparaison du taux de pollen d'herbe à poux dans quelques municipalités et zones de la région de Lanaudière.*	1990
Chantal Jetté	*La caractérisation de la discrimination chromatique chez des travailleurs et travailleuses d'une imprimerie.*	1991
Julie Desharnais	*Etude descriptive des problèmes menstruels chez des femmes d'une industrie de montage de microélectronique exposées aux solvants organiques multiples.*	1991
François Demers	*Influence de la cristalochimie surla toxicité des silicotes.*	1991
Dominique Léger	*Exposition professionnelle et environnementale aux solvants incidences sur la fonction reproductrice des femmes*	1992
Pauline Gagnon	*Variations de l'odorat lors de l'exposition contrôlée aux substances polluantes.*	1993
Annick Girard	*Etude des effets neuropsychologiques d'une exposition au manganèse comparé au Parkinsonisme.*	1995
Louis Bilodeau	*Étude des facteurs influençant le taux de manganèse sanguin dans une population*	1998
Nathalie Risse	*Les effets de la consommation de poissons constaminés sur la réussite scolaire des enfants. (1999)*	1999
Carlos Jose Passas	*Une étude communautaire pour réduire la contamination par le mercure basée sur les régimes alimentaires traditionnels une recherche participative*	2002
Geneviève St-Amour	*Densité de circulation et exposition au manganèese chez des nouveaux-nés.*	2002
Simon Lajeunesse	*Évaluation du manganèse dans les puits des Cantons de l'Est*	2001
Jennifer Webb	*Exposition au mercure chez des populations de l'Amazonie écuadorienne.*	2004
Myriam Filion	*Exposition au mercure et qualité de vie des populations riveraines du Tapajós en Amazonie brésilienne*	2005
Mélanie Lemire	*Le sélenium dans le régime alimentaire des populations riveraines du Tapajós en Amazonie brésilienne*	2005
Ugo Lachapelle	*Intégrer la santé dans des études d'impacts sur la circulation automobile dans le Nord et le Sud (co-rection avec Laurent Lepage*	2005
François Laforest	*Exposition au manganèse par l'eau potable municipale*	2009

Ph.D. Environmental Sciences

Carole Brabant	*Intérêt de la fréquence cardiaque en tant que résultante des contraintes gestuelles, posturales et thermique en situation de travail sédentaire et répétitif*	1991
Audrey Smargiassi	*Marqueurs périphériques du système dopaminergique*	1996
Jean Lebel	*Mercure et santé environnementale en Amazonie.*	1997
Maryse Bouchard	*Effets à long terme de l'exposition aux neurotoxiques sur la santé mentale et la qualité de vie.*	2006
Carlos Jose Passos	*Une approche écosystémique à l'étude de l'influence de la consommation de fruits tropicaux le mercure chez des populations riveraines de l'Amazonie brésilienne*	2007
Frédéric Mertens	*Le rôle des réseaux sociaux dans la diffusion d'innovations préventives complexes dans le cadre d'une recherche participative pour réduire l'exposition au mercure en Amazonie (Co-direction avec Johanne St-Charles)*	2010
Mélanie Lemire	*Effets de l'exposition au Sélénium dans l'Amazonie brésilienne*	2010
Myriam Fillion	*Effets combinés de mercure et sélénium sur les systèmes visuels et moteurs en Amazonie brésilienne*	2011

Ph.D. Biological Sciences

Nadia Abdelouahab	*Exposition multiple aux contaminants par la consommation des poissons : effets neurocomportementaux et hormonaux*	2010
Laura Atikessé	*L'exposition au mercure et aux contaminants et leurs effets chez les Innus de Labrabor une approche écosystémique (Co-direction avec Sylvie de Grosbois)*	2010

Post-doctotal Fellows

Takser, Larissa	*Expositions multiples et effets sur la santé*	2002
Aline Philibert	*Analyses biostatistiques de données épidémiologiques*	2005-07

Other

Antonio Menezes	*Exposition et effets de manganèse chez des enfants qui résident proche d'une industrie de transformation de manganèse (tutrice pour Mount Sinai Medical Centre, New York)*	2010

Conferences

Dr. Mergler has given hundreds of seminars and conferences at national and international conventions, universities and government committees. Below is selected list of some of these events

- 1st African Regional Conference of the International Association of Ecohealth, Côte d'Ivoire (2013) keynote address
- Haninën Lecture at the Joint meeting of the International Neurotoxicology Association and the International Congress on Occupational Health International Symposium on Neurobehavioral Methods and Effects in Occupational and Environmental Health, Xian, China (2011) keunote address
- 9th International Conference on Mercury as a Global Pollutant, Guiyang, China (2009) keynote address
- 7th International Conference on Mercury as a Global Pollutant, Madison, USA (2006) keynote address
- International Conference on Rivers and Civilizations, La Crosse, USA (2006) key note address
- Children's Environmental Health, Almaty, Khazakstan (2005) panel presentation
- 3rd Conference on Occupational and Environmental Health in the Americas. San Jose, Costaa Rica (2005) keynote address
- Health Canada Annual Forum. Ottawa, Canada (2004) conference to government scientists and policy-makers
- 8th International Symposium on Neurobehavioral Methods and Effects in Occupational and Environmental Health, Brescia, Italy (2002) keynote address

- 7th International Symposium on Neurobehavioral Methods and Effects in Occupational and Environmental Health. Stockholm, Sweden (1999) keynote address
- PREMUS-ISEOH, Helsinki (1998) keynote address
- Office of Science and Technology of the White House, Triangle Park, USA (1998) (presentation to a government committee) panel presentation to government scientists and policy-makers
- US National Academy of Science's Committee on Mercury, Washington, USA (1998) presentation to the committee on the toxicological effects of methylmercury
- 15ième International Conference of Neurotoxicology, Little Rock' USA (1997) keynote address

Respondents

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Donna Mergler. I live in Montreal in the Province of Quebec.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

AFFIDAVIT OF ANNA WILLOW

I, ANNA WILLOW, of the City of Delaware, in the State of Ohio, in the country of the United States of America, MAKE OATH AND SAY AS FOLLOWS:

1. I hold a master's and a doctorate in anthropology from the University of Wisconsin as well as a master's in natural resources and environment from the University of Michigan. I am currently an associate professor of anthropology at Ohio State University. My professional training and research experience have been in the areas of cultural and

environmental anthropology especially concerning Anishinaabe environmental relationships, uses and values. I have broad experience and expertise concerning boreal forest First Nations peoples and cultures and knowledge about their sociocultural responses to environmental transformations resulting from natural resources extraction. I have conducted multiple independent research projects, including long-term ethnographic participant-observation research at Grassy Narrows First Nation. I also have published a book, numerous peer-reviewed journal articles, professional reports, and delivered numerous papers at conference proceedings in my field of study. A copy of my curriculum vitae is attached to Exhibit "A", below.

2. In February 2015 I was asked by counsel for Grassy Narrows to answer certain questions in a report on the importance of fishing and the consumption of fish as part of the traditional cultural activity and identity of the people of Grassy Narrows First Nation. The questions and my answers to them appear as part of my February 2016 expert report attached as Exhibit "A" to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "B" to my Affidavit.

SWORN BEFORE ME in the City of Marion, in the State of Ohio, in the United States of America, this ___ day of _____, 2016.

A Commissioner, etc.

_____
Anna Willow

EXPERT REPORT

Grassy Narrows First Nation and Sherry Fobister, William Fobister, Senior, Simon Fobister and Chief Roger Fobister, Senior on their own behalf and on behalf of all other members of Grassy Narrows First Nation v. Minister of Natural Resources and Forestry (Ontario) and Minister of the Environment and Climate Change (Ontario), and the Attorney General of Ontario

Ontario Superior Court of Justice

I. Area of Expertise and Qualifications

My professional training and extensive research experience qualify me as an expert in the areas of cultural and environmental anthropology, especially concerning Anishinaabe environmental relationships, uses, and values. I have broad expertise concerning boreal forest First Nations peoples and cultures and I am knowledgeable about sociocultural responses to environmental transformations resulting from natural resource extraction. I earned a PhD in Anthropology from the University of Wisconsin (2008). Additionally, I hold two Masters Degrees, one from the University of Wisconsin in the field of Anthropology (2003) and the other from the University of Michigan in the field of Natural Resources and Environment (2001). Since the autumn of 2009, I have been employed at the Ohio State University. I was promoted from assistant to associate professor of anthropology in June of 2015. I have conducted multiple independent research projects, including long-term ethnographic participant-observation research at Grassy Narrows First Nation (which took place mainly from June 2004 to April 2005, with additional shorter visits between May 2003 and August 2007). As my CV (Appendix B) details, I have to date published one book, thirteen peer-reviewed journal articles, and two professional reports in the areas of my expertise. I have also delivered numerous papers at professional conferences in my field of study.

The report that follows combines extensive reviews of published ethnohistorical and social scientific literature with observations and conversations derived from my time at Grassy Narrows First Nation. Some of the material contained in this report is excerpted and adapted from my own previously published works, especially including the following three items:

Willow, Anna. 2012. *Strong Hearts, Native Lands: Anti-Clearcutting Activism at*

Grassy Narrows First Nation. Winnipeg: University of Manitoba Press (Concurrently published in the United States as *Strong Hearts, Native Lands: The Cultural and Political Landscape of Anishinaabe Anti-Clearcutting Activism.* Albany: State University of New York Press).

Willow, Anna. 2011. Conceiving Kakipitatapitmok: The Political Landscape of Anishinaabe Anti-Clearcutting Activism. *American Anthropologist* 13(2):262-276.

Willow, Anna. 2009. Clear-cutting and Colonialism: The Ethnopolitical Dynamics of Indigenous Environmental Activism in Northwestern Ontario. *Ethnohistory* 56(1):35-67.

II. Instructions, Nature of Opinion Sought, and Questions

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association to prepare an expert report that answers twelve questions. The primary purpose of this report is to describe the importance of fishing and the consumption of fish as part of the traditional cultural activity and identity of the people of Grassy Narrows First Nation. My answers to the questions are contextualized by my anthropological understanding of Grassy Narrow First Nation's cultural and geographic affiliation, Anishinaabe subsistence patterns of the past and present, and broader patterns of human-environment relationships among the indigenous peoples of the Canadian boreal region. The report documents the ongoing relevance of traditional Anishinaabe culture, the importance of fishing as a form of land-based subsistence, and the continuing cultural impacts of mercury contamination.

I was provided with and asked to review four relevant documents (Item A):

A. The Grassy Narrows-Earthroots request, dated January 2014, of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May, July, September and November 2014 insofar as they relate to your area of expertise and the subject matter for your report.

B. The Lovisek Report, dated June 2008.

C. *Keewatin v. Ontario*, 2011 selected factual findings from the trial judgment pertinent to your report (Exhibit "A").

D. Ontario Ministry of Natural Resources and Forestry approved 2012-2022 Forest Management Plan for the Whiskey Jack Forest.

I was also asked to answer twelve questions in four general areas. I list the twelve questions here and include my summary and full detailed answers—along with reasons for those answers—in the subsequent section.

A: General

1. For the documents referred to in item A, above, please indicate if the views expressed in those documents that relate to the subject matter of this report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your report the corrections that should be made with respect thereto. In responding to this question, please also address the questions that follow.

B: Historical Importance of Fishing

2. What factual findings are made in the 2011 trial judgment of Keewatin v. Ontario, if any, that are relevant to the subject matter of your report respecting:

a. The traditional activities the ancestors of Grassy Narrows engaged in with respect to the Grassy Narrows Homeland/Traditional Land Use Area ("TLUA") before and following their signing of Treaty No. 3?

b. The definition of the historical seasonal round of Grassy Narrows and, in particular and to the extent not discussed in response to question 2(a) above, the historical importance of fishing to the culture, sustenance, and economy of Grassy Narrows?

3. If not answered in response to question 2(b) above what has been the historical importance of fishing, if any, to the culture, economy, and sustenance of the people of Grassy Narrows?

C: Contemporary Importance of Fishing

4. How important today is fishing to the culture, economy, and sustenance of the people of Grassy Narrows and, if not discussed in response to questions 1, 2, or 3 above, the relationship of the TLUA of Grassy Narrows to the Whiskey Jack Forest?

5. Which fish species are eaten by the people of Grassy Narrows, from which geographic areas, and why? In particular, what traditional factors, if any, apply to the bodies of water, and fish species a member of Grassy Narrows may fish for in the area?

6. What role, if any, does fishing play in the identity and society of the people of Grassy Narrows? Is this role different, and if so how, from non-aboriginal Canadian society in the region, and from the urban aboriginal population in the region?

7. Taking into account your responses to the above questions regarding the importance of fishing and the consumption of fish caught, how effective have been measures used by the federal or provincial governments, such as consumption advisories and the provision of freezer fish, in protecting the people of Grassy Narrows from mercury impacts? Please explain your answer.

D: Impacts of Mercury Exposure on the Culture and Community of the People of Grassy Narrows

8. What has been the impact of past mercury exposure from industrial discharges on the culture and community of Grassy Narrows, and what inferences can be drawn from this history when considering future activities, such as clear-cut logging, and whether they could introduce new sources of mercury exposure through fish consumption?

9. If not answered in response to question 8 above, what have been the community level psychological impacts of past mercury exposure from industrial discharges on the people of Grassy Narrows and what additional community level psychological impacts are currently experienced or anticipated from planned future activities, such as clear-cut logging, and whether they could introduce new sources of mercury exposure?

10. Are the impacts at the community level in Grassy Narrows from past mercury exposure, and those anticipated in future from new sources of mercury exposure, experienced differently by gender and age and, if so, how?

11. If not answered in response to questions 8, 9 and 10 above, how does the experience at Grassy Narrows compare with the documented experience of other aboriginal communities that have faced environmental contamination problems?

12. What community level responses have occurred in response to past mercury exposure, and what community level responses are possible in future to activities that could add mercury to bodies of water used by the people of Grassy Narrows for fishing and other traditional pursuits?

III. Summary and Full Answers to Questions and Reasons for Opinions

In this core section of the report, I provide both summary and full answers to the questions I was asked to consider and explain the reasons—based on my review of the relevant literature and on observations made as a trained anthropological observer—for my opinions.

A: General

1. For the documents referred to in item A, above, please indicate if the views expressed in those documents that relate to the subject matter of this report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your report the corrections that should be made with respect thereto. In responding to this question, please also address the questions that follow.

Summary Answer:

Regarding all of these documents, I agree with the information that is within my area of expertise to assess. I found no errors related to the subject matter of this report.

Full Answer:

A. The Grassy Narrows-Earthroots Request

Concerning the Grassy Narrows-Earthroots request of January 2014 for individual environmental assessment (IEA) and its subsequent supplementary submissions, I agree with the information that is within my area of expertise to assess and found no errors related to the subject matter of this report. I am not qualified to offer an expert opinion regarding the effects of clearcutting on mercury levels, nor on its implications for wildlife or human physiology. I would like to reiterate the importance and accuracy of several of the points contained in the Grassy Narrows-Earthroots submissions as they relate to my area of expertise:

1. The initial request (dated January 22, 2014) draws attention to the fact that the English and Wabigoon watersheds and their Aboriginal residents have already experienced serious harm as a result of mercury contamination (p. 1, p. 22). Because impacts on indigenous subsistence and culture are cumulative in nature, any future activities that could adversely impact the subsistence and culture of First Nations residents must be considered in this light.

2. The initial submission states that fish caught in the waters surrounding Grassy Narrows and consumed by community residents already have mercury levels that are above or approaching limits for safe human consumption (p. 6). This has long been the case and is well-known among environmental management professionals and environmental social science researchers in Canada.

3. The initial submission states that Grassy Narrows has consistently objected to the OMNRF's planning process (p. 10). Based on my experience at Grassy Narrows, I can attest to community members' long-term concern with the planning process, with public objections dating back to the late 1990s and internally-voiced complaints possibly extending further back in time. As described below, the residents of Grassy Narrows have also expressed specific concerns about mercury contamination for many years.

4. The initial submission points out that the people of Grassy Narrows have experienced multiple, mutually-compounding industrial activities that have been harmful to their health, culture, and livelihood (p. 22). Based on my knowledge of the case, I know this to be accurate.

5. The September 8, 2014 supplementary submission states that people at Grassy Narrows continue to perceive the risk of mercury pollution to be high, that sufficient levels of communication and trust have not been developed between Grassy Narrows residents and scientific/health professionals, and that the detrimental consequences of mercury contamination extend beyond its effects on physical health (p. 5). The report that follows supports and elaborates on these points.

6. The supplementary submission dated November 14, 2014 states that the impacts of mercury have been disproportionately experienced by those Grassy Narrows residents who practice a traditional way of life that includes fishing (p. 5). I agree with this point and elaborate on its significance below.

7. I agree with the points set out in the supplementary submission dated November 14, 2014 regarding the inappropriate nature of sports fishing consumption guidelines for First Nations peoples (p. 10-11) and the general importance of fishing for the people of Grassy Narrows (p. 18-19). I elaborate on these topics below.

B. *Keewatin v. Ontario,* 2011: Selected Factual Findings from the Trial Judgment Arising from the Lovisek Report

Regarding the Lovisek Report, dated June 2008, I found the material that is within my area of expertise (Anishinaabe ethnohistory and subsistence) to be accurate.

It is noteworthy that the ability to access and utilize the region's rich fisheries was viewed as especially important by Anishinaabe negotiators to Treaty Three, so much so that Commissioner Simon Dawson noted the following in his report:

> I am in a position to say that, as an inducement to the Indians to sign the Treaty, the commissioners pointed out to them that, along with the land reserves and money payments, they would forever have the use of their fisheries. This point was strongly insisted on and it had great weight with the Indians, who for some years previously had persistently refused to enter into any Treaty (Dawson 1873:50; cited on p. 161 of the Lovisek report).

Twine for the manufacture of fishing nets, Lovesick accordingly points out, was a key Saulteaux demand (p. 87, 91, 119). In short, when Anishinaabe negotiators signed Treaty Three in 1873, they did so with the confidence that their people would retain the ability to utilize the region's rich fisheries as a healthy and traditional dietary staple. For Anishinaabe people today, the ability to access and safely consume fish and other traditionally harvested resources throughout their customary Land Use Area (or traditional territory) remains extremely important.

One way in which I diverge with Lovisek is not a matter of accuracy, but one of preferred ethnonym. Because it is their own self-designation, I use the terms *Anishinaabe* and *Anishinaabeg* (plural) throughout this report to refer to the Aboriginal people also known in the literature as Ojibwe/a, Ojibway, and Saulteaux. This reflects our different disciplinary backgrounds (ethnohistory vs. cultural anthropology) and temporal research emphasis (historical documents vs. contemporary speech). Where I cite the work or documents of others, I use the term found in the original.

I also agree with the three selected excerpts that were identified as pertinent to this report (paragraphs 475, 772, and 773), reproduced here:

> [475] Lovisek gave evidence that in 1873, the Ojibway were primarily concerned about preserving their way of life, including their right to continue hunting, fishing and trapping as in the past. They valued their seasonal round, the pursuit of their livelihood through traditional harvesting. Their culture and

> identities were intimately connected with hunting, trapping, fishing and harvesting wild rice as their ancestors had done since time immemorial.
>
> [772] The Treaty 3 Ojibway loved their lives and their country (Lovisek, November 16, 2009 at p. 39). They relished their way of life, including their seasonal round of trapping, hunting, fishing and harvesting over the breadth of their territories. They valued their customs and were not prepared to give them up….
>
> [773] I accept the evidence of Lovisek…that they were prepared to embrace a Euro-Canadian presence **only** if it would be compatible with their cherished way of life, and would not cause serious interference with their hunting, fishing and trapping – central aspects of their distinctive culture central to their identity.

Furthermore, I found accurate and relevant information in the trial judgment regarding the Ojibway seasonal round (paragraphs 229-230, 1153, 1158-1164) and the assumed compatibility of Aboriginal and Euro-Canadian uses of the land (paragraphs 913, 1233). These paragraphs are reproduced in Appendix C of this report.

D. 2012-2022 Forest Management Plan for the Whiskey Jack Forest

Silviculture and forest management planning are outside my area of expertise and I am not qualified to identify inaccuracies in this area. However, as an anthropologist concerned with the sociocultural elements of systems that include both ecological and human components, I note the following matters relevant to my report:

> 1. There is no mention in the Forest Management Plan of the previous opposition of Grassy Narrows First Nation members to clearcutting within their Traditional Land Use Area (traditional territory), which has included high-profile direct action protest as well as sustained opposition to the forest management planning process itself. The Plan notes that "Abitibi surrendered the Whiskey Jack Forest SFL to MNR in 2009" (p. 18), but the context of that surrender (which was informed, among other factors, by years of protest by members of Grassy Narrows First Nation and the entry into a memorandum of understanding to initiate formal negotiations to resolve the ongoing dispute) is not mentioned in any manner. This lack is again conspicuous on pages 109-111 in the Forest Management Plan's very general section on Aboriginal Interests.
>
> This contrasts with an independent audit that notes that a separate process is now underway to address Grassy Narrows community members' concerns about forest management. The independent audit supports Grassy Narrows First Nation's view that the Forest Management Planning process, as currently practiced, does not constitute

adequate consultation. The *Whiskey Jack Forest Independent Forest Audit, 2004-2009* draws attention to "fundamental differences in the viewpoints between GNFN and MNR regarding forest management principles and practices" and goes on to state:

> "it is the audit team's opinion that these differences cannot be resolved without the Province setting aside many of the requirements to manage the Whiskey Jack Forest under the CFSA and the FMPM, and relinquishing significant authority to the First Nation to manage portions of the Whiskey Jack Forest according to the desires of the GNFN community. The audit team further believes that the forest management planning process did not anticipate, nor was it designed to resolve the type of dispute currently being experienced on the Whiskey Jack Forest" (KBM Forestry Consultants 2010:7).

2. The Plan notes that 84% of the area in question falls into the category of "Managed, Crown land" (p. 20). While this is technically accurate, there is no mention of the fact that this overlaps considerably with the area Grassy Narrows residents understand to be their Traditional Land Use Area or traditional territory.

3. Although the region's important fisheries resource is discussed (p. 68-70), there is no mention of mercury in the report. First Nations fishing is discussed briefly (p. 102), but the English-Wabigoon River's serious mercury problem is not noted. This is especially concerning because the contamination case is well-known in northwestern Ontario and among environmental and social science researchers across Canada.

4. The Plan includes summaries of the demographic profiles of communities that "receive significant social and economic benefits from the Whiskey Jack Forest" (p. 86), but does not acknowledge the possibility that these communities might also face significant social and environmental risks or harms as a result of the activities described in the Forest Management Plan. While the concept of "net impact" is recognized with regards to recreation and tourism (p. 218), there is no explicit consideration of the possibility that Aboriginal communities could be adversely impacted by forestry activities. This is in spite of the fact that supplementary documentation in the Plan itself acknowledges that "subsistence hunting, fishing, and gathering of resources from within the forest are an integral part of community existence" (p. 26).

5. While wildlife habitat, visual aesthetics, tourism agreements, and fuelwood are included in the Plan's Harvest Selection Criteria (p. 187-189), Aboriginal Interests are not.

B: Historical Importance of Fishing

2. What factual findings are made in the 2011 trial judgment of Keewatin v. Ontario, if any, that are relevant to the subject matter of your report respecting:

a. The traditional activities the ancestors of Grassy Narrows engaged in with respect to the Grassy Narrows Homeland/Traditional Land Use Area ("TLUA") before and following their signing of Treaty No. 3?

Summary Answer:

Factual findings from the trial judgement concerning the acknowledged importance of subsistence harvesting at the time of the Treaty are relevant to the subject of this report. Treaty commissioners knew that traditional harvesting—specifically including fishing—was essential to Anishinaabe people.

Full Answer:

In addition to the selected excerpts noted above, the following additional findings in the *Keewatin v. Ontario* judgment are relevant to the historical importance of fishing at Grassy Narrows First Nation:

1. It was widely understood by the Treaty Three Commissioners that traditional harvesting was of the utmost importance to the Anishinaabe and that they would be unlikely to agree to a treaty if harvesting was not protected. As stated at Paragraph 747, "All three Treaty Commissioners understood the importance of harvesting to the Ojibway and therefor the importance of promising continuing Harvesting Rights to induce the Ojibway to enter into the Treaty."

2. The judgment accepts that the Treaty Commissioners knew most of the Treaty Three area was unsuitable for agriculture. They were aware of the general pattern of Anishinaabe subsistence and expected it to continue. Along these lines, paragraph 750 states that "Morris made it clear to the treaty 3 Ojibway that he expected their gardening <u>to supplement, not replace</u>, their traditional harvesting." Similarly, paragraph 759 states, "…from Canada's perspective, the continuation of the hunting, trapping and fishing rights was important to ensuring that the Ojibway did not become dependent upon relief or welfare delivered by the Department of Indian Affairs"

b. The definition of the historical seasonal round of Grassy Narrows and, in particular

and to the extent not discussed in response to question 2(a) above, the historical importance of fishing to the culture, sustenance, and economy of Grassy Narrows?

Summary Answer:

Factual findings concerning the centrality of fishing to the Anishinaabe seasonal round are relevant to the subject of this report. Fishing was historically—and remains today—a staple subsistence activity at Grassy Narrows First Nation.

Full Answer:

Findings relevant to the historical seasonal round, especially fishing, are also present in *Keewatin v. Ontario:*

1. Paragraph 229 gives a broad overview of the Anishinaabe subsistence strategy, emphasizing seasonal mobility and adaptability to the availability of diverse boreal forest resources. The following paragraph (Paragraph 230) quotes a letter from Simon Dawson to the Minister of Public Works (dated December 19, 1870) which states that in summer, "the grand occupation is fishing, and this is to them the happiest season of the year" and goes on to broadly but accurately describe the activities undertaken in each season.

2. While not specific to the people of the English-Wabigoon River region, Paragraph 1053 describes complaints following Treaty Three made by Anishinaabe leaders of the Rainy River, Rainy Lake, and Seine River Bands who were in 1909 experiencing opposition to their traditional subsistence activities. The loss of hunting grounds and interference by outsiders with hunting is noted. Regarding fishing, the1909 petition includes the following statement: "We also wish to Fish for ourselves all the year and no reserve seasons for us. It's our daily food."

3. The evidence of William Fobister (Paragraphs 1153-1164) presents an accurate description of recent historical Anishinaabe subsistence patterns. Fobister describes the early summer gardening season at the pre-relocation Reserve, the summer blueberry harvest, the late summer wild rice harvest, the garden harvest, travel to the winter trapline, and the hunting and trapping of autumn and winter. The judgment also notes based on Fobister's evidence, which states:

   > "The Grassy Narrows people fished for their own consumption and for sale to others until 1970, when mercury poisoning was discovered in the Wabigoon and English River system and adjacent lakes. Fish were

declared unsafe to eat. Fishing ended. The tourist industry, formerly the main employer in the area, collapsed. Welfare was introduced for the first time" (Paragraph 1173).

I believe this assessment to reflect what Fobister witnessed in the early 1970s. Today, however, many people at Grassy Narrows do continue to fish for their own subsistence, in ways and for reasons that are outlined below. Commercial fishing continues to be curtailed by contamination. Guiding for the tourist industry, although less significant than prior to mercury contamination, continues to employ some Grassy Narrows residents. Grassy Narrows members now work as fishing guides employed by Ball Lake Lodge and Grassy Narrows Lodge, both which are owned by the Grassy Narrows band. There also exists at least one independent family-owned guiding business.

4. The trial judge acknowledges that "In the case of the Grassy Narrows Ojibway, the life of Fobister is illustrative of the continuing reality that they were still pursuing the seasonal round without significant Euro-Canadian influence, at least into the 1960s and that Euro-Canadian uses and traditional harvesting were compatible" (Paragraph 1233).

3. If not answered in response to question 2(b) above what has been the historical importance of fishing, if any, to the culture, economy, and sustenance of the people of Grassy Narrows?

Summary Answer:

Since time immemorial, fishing has provided a primary source of food for Anishinaabe residents of Grassy Narrows and the surrounding region. Historically, it was an essential component of Grassy Narrows First Nation's economy as well as an important aspect of Anishinaabe cultural life.

Full Answer:

Fishing has been a significant activity and a staple source of food for countless generations of Grassy Narrows citizens. In both the traditional hunting-gathering economy and the more recent mixed economy, the role of fishing is central. Historically, fishing was an essential component of the seasonal round, with summer activities revolving around fishing and seasonal residence locations chosen based on proximity to productive fishing grounds. When reminiscing about times on the trapline in decades past, Grassy Narrows elders speak of fishing with nets (with walleye and northern noted as the main edible catch) as a principal activity. Beginning in the 1940s and continuing until the 1970 discovery of mercury, commercial fishing also became an

important source of wage labor income for Grassy Narrows residents. Employment of community members as fishing guides for the tourist industry began in the same period and continues today.

Prior to Euro-Canadian interference, Grassy Narrows Anishinaabeg lived a semi-nomadic lifestyle, moving within their homeland according to seasonal patterns of resource availability. In northwestern Ontario, the traditional Anishinaabe land-based seasonal subsistence cycle (or "annual round") (see Densmore 1979 [1929], Danziger 1979) shared many similarities with that observed in other parts of the North American subarctic. Through December, January, February, and March, primary subsistence activities included ice fishing and the trapping of furbearers. With families dispersed for the season, some opportunistic large game hunting also took place in the winter. In late April and early May, waterfowl returning to boreal forest lakes or passing through along their migration routes to more northerly destinations offered a welcome source of food. As soon as the ice broke up, people began fishing the waters of the English-Wabigoon River, often concentrating their earliest efforts on rapids or known spawning zones. From its commencement in May until the waters turned icy with fall, open water fishing was the dominant subsistence activity. With many families gathered together at prime fishing locations, summer was also the most social of the seasons. Late summer was a time of particular bounty. In August, Anishinaabeg picked several varieties of berries and harvested the annual crop of wild rice. Both resources, together with dried meat and fish, were processed for storage in underground caches. With fall's arrival, hunting for migratory waterfowl once again became a central activity. Large mammals—moose, white-tailed deer, and bear—were hunted most intensively in the autumn months. As fall gave way to winter, families once again dispersed, resuming trapping and recommencing the annual cycle.

Throughout most of the eighteenth and nineteenth centuries, Anishinaabe people moved within their homeland according to the seasons and the demands of the fur trade (see *Keewatin v. Ontario* paragraph 230). Family and extended family groups traveled with the seasons and land-based subsistence was the core of economic life (Hickerson 1970). Over time, particular groups became associated with specific trading posts operated by the Hudson Bay Company, where they traded furs for firearms, steel traps, cloth, and other provisions each spring and often remained to fish through the summer months. One of these posts, located just up the English River from present-day Grassy Narrows at Lac Seul, attracted a loose confederacy of Anishinaabe families (Shkilnyk 1985). At the time Treaty Three was signed in 1873, the Anishinaabeg gathered at Lac Seul were under the traditional hereditary leadership of Chief Sakatcheway. In the years following the Treaty, the government established reserves for each group of signatory Indians. In 1882, the people associated with Lac Seul were divided into the two groups that became Grassy Narrows and the smaller Wabauskang First Nation. The two communities remain closely linked today through ties of family and friendship.

Participation in the fur trade implied the emergence of a mixed economy (i.e., a living made through a combination of traditional land-based subsistence and wage/cash income) but in no way undermined the forest-based way of life. Anishinaabe people continue to hunt, fish, and gather as in generations past. Through the first half of the twentieth century, people from Grassy Narrows sold furs and blueberries for cash and a handful participated in various types of wage labor, but the bulk of the community's subsistence still came directly from the forest and from the region's lakes and rivers. A small Hudson Bay Company store operated on the Old Reserve (the common term used to denote the pre-relocation community), but its limited inventory and high prices meant that Grassy Narrows residents purchased only basic supplies—equipment to facilitate land-base subsistence, flour, sugar, and lard—regularly. The people of Grassy Narrows remained highly mobile and spent most of their winters out on their traplines. Contacts with non-Native Canadian society in this era were limited to semi-annual visits from Indian Health Service doctors and ceremonial Treaty Day visits from an Indian Agent and RCMP officer (Shkilnyk 1985).

It was only in the late 1940s that wage labor came to play a significant role in Grassy Narrows First Nation's local economy. Following World War II, a businessman from Minnesota built a luxurious lodge on Ball Lake, located several kilometers upriver from Grassy Narrows. From that time on, men from the First Nation community participated seasonally in a burgeoning tourism industry, working as fishing guides for wealthy anglers. Commercial fishing was also economically important in this period.

C: Contemporary Importance of Fishing

4. How important today is fishing to the culture, economy, and sustenance of the people of Grassy Narrows and, if not discussed in response to questions 1, 2, or 3 above, the relationship of the TLUA of Grassy Narrows to the Whiskey Jack Forest?

Summary Answer:

Fishing remains essential to the culture, economy, and sustenance of Grassy Narrows First Nation residents. As a key component of a land-based Anishinaabe way of life, fishing overlaps with many other traditional activities and reinforces enduring ties the community's Traditional Land Use Area.

Full Answer:

Fishing remains a very important part of life at Grassy Narrows and must be understood as a key component of a land-based way of life which also includes many other complementary activities. The economy and diet experienced by contemporary Grassy Narrows residents differs from that of past generations, yet First Nation members' land-based subsistence activities diverge more in

quantity than in quality from the historical pattern described above. Every family group still includes individuals who hunt, fish, and/or trap. Many community members continue to gather each season's characteristic wild resources despite the social and economic upheavals of the past fifty years (i.e., relocation and road construction in the 1960s, mercury contamination in the 1970s, clearcut logging in the 1990s and beyond). Furthermore, those who are unable to participate regularly in land-based subsistence eagerly await traditional products shared by others and maintain genuine respect for community members who engage frequently in traditional subsistence pursuits.

At Grassy Narrows today, trapping remains the dominant cold-season subsistence activity, although ice fishing also takes place during the winter. Grassy Narrows trappers hold over 30 registered traplines scattered throughout the Traditional Land Use Area surrounding the community. Travel to and within traplines usually occurs by snowmobile and trips are usually completed in one day, although some trappers maintain cabins that make longer stays feasible. In these cases, people fish and hunt for much of their food during their time out on the trapline. In addition to registered trapline holders, official "assistants" and younger relatives frequently accompany trappers in order to develop their own skills. The most commonly sought furbearers include beaver—trapped not only for fur but also as a food source—and members of the weasel family: pine marten, river otter, fisher, mink, and wolverine. Red fox, lynx, wolf, and muskrat are also trapped periodically. Trapping provides supplementary income for many Grassy Narrows families.

In late summer, people at Grassy Narrows eagerly await the ripening of two important wild foods: wild rice and blueberries. The availability of these resources varies according to weather conditions. Additionally, a large portion of the region's wild rice remains at the mercy of the dams that now constrain the English-Wabigoon River system; if water levels are raised while the rice is still in its vulnerable floating leaf stage, an entire harvest can be damaged beyond recovery. If, however, conditions have been favorable, both crops can be remarkably rich. Harvesting wild rice requires access to a boat and considerable skill, but a handful of Grassy Narrows residents collect the aquatic grain each year and share the products of their labor widely. Abundant and accessible, hundreds of First Nation residents take part in the seasonal harvest of wild blueberries.

In the fall—and to a lesser extent throughout winter and into early spring—First Nation members hunt moose and white-tailed deer by firearm. Most frequently, two or three people set out together in the morning or evening, hunting with the aid of a boat or vehicle for transportation. Meat from these large animals is shared widely while fresh and frozen for consumption throughout the year. In both fall and spring, migratory waterfowl are also harvested.

Despite anxiety about mercury and other toxic substances, fishing is the dominant warm-season subsistence activity and is undertaken by Grassy Narrows residents of all ages on waterbodies

throughout the Traditional Land Use Area, including the English-Wabigoon River and its constituent lakes as well as headwater lakes. Men, women, and children fish with rod and reel (this usually means jigging from boats or casting from the rocky shoreline with inexpensive jigheads and rubber lures) and some gather to snare fish with wire during the spring spawning season. In spring, people travel long distances by truck to reach areas of moving water (i.e. rapids) which are already free of ice and where they can fish from shore.[1] In summer, those who are able travel by truck and car to widely scattered sites that are known to be productive shore-fishing sites and by boat to numerous productive locations away from shore. Nets are set for the procurement of fish in both the summer and winter seasons and are especially important when a large number of fish are needed for a feast event.

In addition to the consumption of fish for household-level subsistence, some individuals at Grassy Narrows earn money through participation in fishing-related labor, although the commercial fishery and guiding industries are smaller than they were prior to the 1970 announcement of mercury contamination. The continuing significance of commercial fishing income and the continuing severity of mercury contamination in the waters of the English-Wabigoon River system are both substantiated by the 2006 conviction of a Grassy Narrows First Nation commercial fisherman who attempted to sell "tainted" fish caught in Grassy Narrows Lake to a fish processing plant in Kenora. The charged individual held an approved license for commercial fishing on Oak Lake, located north of Grassy Narrows within the community's Traditional Land Use Area (Kenora Daily Miner and News 2006). Statistics Canada data from 2006 indicate that of 415 individuals at Grassy Narrows over the age of 15, 75 were in the labor force but unemployed and 195 were not in the labor force. The official unemployment rate of 33.3% does not account for the numerous individuals who have removed themselves from the search for employment. The same data set shows that of the 190 individuals included in the experienced labor force, 70 listed sales and service as their occupation, which would include fishing and guiding.[2]

Although a large portion of food consumed at Grassy Narrows now comes from the supermarkets of Kenora, it would be highly erroneous to assume that wild foods are inconsequential for sustenance. Indeed, wild foods—especially including fish—are the most valued part of contemporary Grassy Narrows residents' diet. Wild foods are viewed as more nutritious than store-bought foods, especially the highly-processed items typically accessible on a small budget. Fresh foods are unavailable for purchase in Grassy Narrows and obviously non-nutritious convenience and snack items (e.g., chips, soda pop, candy) are ubiquitous in the community, especially among youth and families with children.

[1] Fieldnotes, April 29, 2004.
[2] See http://www12.statcan.gc.ca/census-recensement/2006/dp-pd/prof/92-594/details/Page.cfm?Lang=E&Geo1=CSD&Code1=3560058&Geo2=PR&Code2=35&Data=Count&SearchText=Grassy&SearchType=Begins&SearchPR=01&B1=All&Custom= (accessed April 22, 2015).

For some families in some parts of the year, wild meat, fish, wild rice, and berries complete many meals. While I was in Grassy Narrows, I regularly witnessed (and more frequently heard about) households running out of money and food as the end of the payment month approached. For many Grassy Narrows residents, the experience of scarcity is a recurring, taken-for-granted part of life. Statistics Canada data from 2005 show a median income at Grassy Narrows First Nation of only $6,112, with 66.7% from earned income and 31.9% from government transfers. Grassy Narrows residents have a significantly lower median income than recorded for Aboriginal Ontario residents as a whole ($18,808), as well as a lower percentage of earned income and a higher percentage of government transfers (the figures for all Aboriginal residents of Ontario indicate 77.2% of income from earnings and 16.6% of income from government transfers).[3] For comparison, the mean income for all residents of Canada in 2005 was $30,000 for females and $46,900 for males.[4] Grassy Narrows residents thus look to fish at times when they are unable to afford other foods. Given the high unemployment rate in the community and the fact that welfare payments are insufficient to meet many families' needs, catching fish often means the difference between hunger and satiation. This point is especially important because while other wild foods are unharvestable at certain times of the year, fish are available year round.

Despite its continuing importance, there are several factors that limit First Nation members' participation in time-intensive and geographically-dispersed forms of land-based subsistence. Children, for one thing, must remain close to school. In my time at Grassy Narrows, I heard of a few parents who took their children out of school for a land-based subsistence event they deemed important, but on no known occasion did this extend beyond a day or two. Travel into the bush also requires transportation in the form of a snowmobile, boat, and/or truck as well as the gas to get it there. This requires money. Somewhat paradoxically, the same adults who hold regular jobs are most able to afford such travel, but are often too busy with other demands to undertake it regularly. As described below, local walleye fishing is not limited in these ways.

The people of Grassy Narrows have a close and enduring relationship with a large territory known as the "Grassy Narrows Traditional Land Use Area," which has been occupied by their forbearers since time immemorial (see *Keewatin v. Ontario* paragraph 475). I have viewed the map that shows the "Area of Requestors IEA Request" and found the delineated region to be consistent with my knowledge of the Traditional Land Use Area. Based on historical reports, publications, and my observations of active use, I believe the entire Area of Interest to be included within Grassy Narrows First Nation's area of traditional land use, but also note that this Area does not necessarily include all of land historically and currently utilized by Grassy Narrows First Nation members.

[4] See http://www.statcan.gc.ca/tables-tableaux/sum-som/l01/cst01/labor01a-eng.htm (accessed October 12, 2015).

For present day citizens of Grassy Narrows, connection to this homeland is enacted through land-based subsistence and comprehended through stories told by living elders of seasonal movements throughout the region and life prior to the community's relocation in the early 1960s. Although considerably overlapped by the OMNRF-designated Whiskey Jack Forest, the Grassy Narrows Traditional Land Use Area is essential for the livelihood and cultural identity of the people of Grassy Narrows. It is the setting in which the vast majority of traditional land-based subsistence takes place and provides a material base on which Grassy Narrows residents are able to learn and live traditional Anishinaabe culture. Fishing is a critical part of these place-based activities and, as noted above, supplementary documentation within the Forest Management Plan itself acknowledges that "subsistence hunting, fishing, and gathering of resources from within the forest are an integral part of community existence" (p. 26).

5. Which fish species are eaten by the people of Grassy Narrows, from which geographic areas, and why? In particular, what traditional factors, if any, apply to the bodies of water, and fish species a member of Grassy Narrows may fish for in the area?

Summary Answer:

Walleye is the favored and most consumed fish species at Grassy Narrows. While Grassy Narrows residents fish throughout their entire Traditional Land Use Area, the English-Wabigoon River system that flows through the contemporary reserve community is the most accessible and, therefore, the most widely utilized and productive source of fish.

Full Answer:

Walleye are Grassy Narrows residents' most often consumed, most favored, and most important species of fish. Especially in the months of open water, walleye are consumed very frequently (the exact frequency depends on the individual or family in question, but most people I came into contact with ate walleye at least once a week and some ate considerably more). Fish species such as trout, whitefish, and pike are also occasionally consumed by Grassy Narrows residents, but much less frequently than walleye. This is partially because not all fish species are found in all areas. Lake trout and whitefish, for example, tend to occur only in cold deep lakes, whereas pike and walleye inhabit relatively warmer and more accessible lakes and rivers. And while walleye are a favored food source, pike are not a desirable food species and are sometimes returned to the water if caught. While walleye can be caught easily with a simple rod and reel—sometimes only steps from most Grassy Narrows residents' front doors—species such as whitefish and trout require a boat and/or net. Given the level of poverty on the reserve, many people do not have consistent access to these items and, compared to walleye, these species are rarely harvested.

Grassy Narrows First Nation members fish on all of the waterbodies within their Traditional Land Use Area. Fishing continues to be an important activity for those who spend time on traplines, with Grassy Narrows residents utilizing of all of the small lakes within their own trapline areas and readily acknowledging that other residents do the same. While smaller headwater lakes that are not fed by the river system are especially important to families who customarily use and/or have registered traplines in their vicinity, several factors—including (1) traditional family use patterns, (2) officially registered (OMNRF) traplines, (3) existing commercial fishing licenses, (4) the availability of vehicles/boats/trailers, (5) knowledge of waterways and their hazards, (6) expertise concerning the harvest of particular species, and (7) the availability of fishing gear—combine to constrain fishing location options. Critically, people at Grassy Narrows are not able to relocate to other fisheries within or outside of their traditional territory if the waterbodies they customarily fish become contaminated, as they now have been for decades. If Grassy Narrows residents were to travel outside of their own traditional territory to harvest fish or other resources, they would require the consent of the First Nation whose territory they seek to utilize. Furthermore, their treaty-guaranteed traditional harvesting rights may not necessarily be protected outside of their own territory.

Grassy Narrows residents are thus limited in the species they can catch due to tradition, taste, knowledge concerning the locations and time of year particular species can be caught, access to sites and required equipment, and proficiency with equipment. While all lakes and rivers are utilized by some residents at some time, the English-Wabigoon River is the most easily accessible body of water to the reserve community. Every home on the reserve is within easy walking distance of the river and fishing from shore can occur even in the absence of prohibitively costly vehicles, boats, gasoline, and specialized equipment. While not the First Nation's only source of fish, the river is thus the most widely utilized and the most productive.

6. What role, if any, does fishing play in the identity and society of the people of Grassy Narrows? Is this role different, and if so how, from non-aboriginal Canadian society in the region, and from the urban aboriginal population in the region?

Summary Answer:

Fishing is an essential component of contemporary Anishinaabe cultural identity as well as an important intergenerational social and educational activity for Grassy Narrows residents. Its deeply emplaced social significance differs from fishing practices and meanings among non-aboriginal Canadians and urban Aboriginal populations.

Full Answer:

The relationship between the harvest and consumption of wild foods is extremely important to Anishinaabe cultural identity, which is critical to community members' collective psychological

well-being. For many people at Grassy Narrows, land-based subsistence is much more than simply a source of livelihood; it is deeply symbolic of a way of life. Anthropologists identify land-based subsistence as the most quintessential aspect of indigenous subarctic peoples' cultural lives. As Paul Nadasdy (2003:63) explains, "to First Nations people living in the Arctic and Subarctic, hunting is synonymous with life itself."[5] Kirk Dombrowski (2001) similarly points out that subsistence is both an identity and a livelihood, both a way of life and a way to live. In the past, the truth of these statements was quite literal. While the transitions of recent decades mean that a mixed economy emphasizing land-based subsistence supplemented with a small amount of wage labor and other sources of monetary income has become a mixed economy in which (at least from a strictly material point of view) the reverse is true, indigenous peoples of the north continue to depend on land-based subsistence for physical as well as psychological sustenance. Like other Aboriginal boreal forest residents, the people of Grassy Narrows hold wild foods—including walleye and other fish, moose meat, venison, beaver, wild rice, and blueberries—in much higher regard than the commodities available for purchase, not only for their nutritional value, but also for the links to cultural identity and healthy-living they imply.

Not only do they consider such items healthier, but the acts of gathering and consuming wild foods are important markers of contemporary Anishinaabe identity. By fishing and trapping, by gathering berries and rice, people at Grassy Narrows are able to forge tangible and embodied connections to their heritage. Critically, land-based subsistence also constructs an affirmative Anishinaabe sense of self and gives people a way to define themselves that breaks free of mainstream society's pessimistic comparisons and categorizations. The devastating poverty of Canada's First Nations has been well documented (e.g. York 1990), even if not fully grasped by the general Canadian public. Although they lament the blatant economic disparities that divide them from their Euro-Canadian neighbors, many Anishinaabe people feel that their cultural, spiritual, and social richness far outweighs their material poverty. Keeping culturally distinct patterns of land-based subsistence alive lies at the core of this perceived wealth.

Given the centrality of fishing to the land-based Anishinaabe way of life, arguments about the inextricability of subsistence, culture, and identity clearly apply to the harvest, consumption, and sharing of fish. As Peter Usher et al. state, "fish are part of the Ojibwa heritage, and like other country food, have meaning beyond simply eating. This meaning lies in the skills, knowledge and labor of obtaining food, as well as the social links which are perpetuated by sharing it. Fish are the end product of a way of life" (1979:11). I concur with Usher et al. on this point and believe it to be just as relevant in the twenty-first century as it was 35 years ago.

At Grassy Narrows today, fishing remains an intensely social activity, with the harvesting and eating of fish both occurring communally. Unlike large-game hunting and trapping (both which require extensive training and supplies), fishing is undertaken by a very large portion of Grassy Narrows First Nation's population. Fishing is a source of pride; a way for any individual of any

[5] Hunting in this statement categorically includes fishing and trapping activities.

age or status to proudly supply food for his or her family. Frequently taking place in intergenerational family groups, fishing is a way of socializing children as well as a vehicle for the fulfillment of culturally distinctive economic bonds and obligations (also noted by Usher et al. 1979:364). Today as in years past, fish are shared widely among Anishinaabe people. In many cases, when an individual catches more than he or she can consume, a portion of the catch is given to family members, friends, and/or elders. Fish are also shared in a larger-scale and more intentional manner as a ubiquitous dish at ceremonial and social feasts.

This is quite different from the role of fishing among members of non-Aboriginal Canadian society in the region. In my experience (which includes significant interactions with Euro-Canadian residents of Kenora, Ontario), non-Aboriginal individuals fish for several reasons. Most often, they fish for sport and recreation. In some cases, non-Aboriginal people do consume and appreciate the nutritional value of the fish they catch. Time spent fishing is seen as a valuable form of social interaction and intergenerational learning by some (but certainly not all) non-Aboriginal fishers. However, there are significant sociocultural differences between non-Aboriginal and Grassy Narrows Anishinaabe fishing behavior. Unlike non-Aboriginals, Grassy Narrows residents associate fishing with attachment to homeland, assertion of cultural rights, and expression of cultural identity; those who maintain such connections are perceived to enjoy a higher level of wellbeing than those who do not. Fish are also less likely to be consumed in social settings or shared in communal feasts among non-Aboriginal citizens. My experience with urban Aboriginal populations is limited to individuals who are affiliated with Grassy Narrows (i.e., people who have relatives at Grassy Narrows and/or have previously lived on the reserve). My general sense is that while urban Aboriginal residents may also experience poverty and fish for subsistence when and where it is possible as well as for family enjoyment, they tend not to experience the deep connections to specific places and the social significance of fishing described above unless it is within the context of their home reserve community.

7. Taking into account your responses to the above questions regarding the importance of fishing and the consumption of fish caught, how effective have been measures used by the federal or provincial governments, such as consumption advisories and the provision of freezer fish, in protecting the people of Grassy Narrows from mercury impacts? Please explain your answer.

Summary Answer:

Measures employed in attempt to limit or replace Grassy Narrows residents' consumption of contaminated fish have been ineffective due to the irreplaceability of distinctive social and cultural values associated with the harvesting of local fish.

Full Answer:

For several reasons, measures taken to limit Grassy Narrows residents' consumption of fish from the English-Wabigoon River have been ineffective, both in the past and the present. Following the discovery of mercury, people at Grassy Narrows had trouble coming to terms with the enormity of the crisis they faced. Throughout the 1970 season, the government attempted to discourage people from eating the contaminated fish. Signs that read "Fish for Fun" in bold letters and featured an image of a fish in a frying pan with an "X" over it were posted at boat landings (Troyer 1977). It didn't take the media long to point out that the Fish for Fun campaign did Native commercial and subsistence fishers no good (CBC 1970). Many of the signs were quickly marked by graffiti or ripped down and none were posted in subsequent years. Most Grassy Narrows residents continued doing what they had always done—eating fish—even after hearing of its potential toxicity.

Few people I spoke with between 2003 and 2005 about the initial announcement of mercury recalled the community's reaction as a dramatic one. Several factors may explain their response (or lack thereof). The river's large and plentiful walleye had long been a favored source of protein. Additionally, fish were one the most accessible remaining sources of wild food on the post-relocation reserve. Compounding these factors, First Nation residents observed as tourists continued to eat their catch with no adverse effects (Hutchison and Wallace 1977). Furthermore, as described above, harvesting and consuming fish made it possible for people at Grassy Narrows to maintain a culturally distinct Anishinaabe identity associated with a land-based way of life.

Today, a disconcerting number of Grassy Narrows residents are able to recite offhand the parts-per-billion (ppb) of mercury in their own bodies.[6] And, as they have now for decades, harvesters continuously weigh the economic and cultural benefits of consuming wild foods against the known physical risks.[7] They struggle to reconcile their desire to retain their land-based way of life with the risks inherent in eating the products of their labor. At Grassy Narrows, fish in the absence of fishing (i.e., the consumption of frozen fish harvested elsewhere and supplied to the community) lack the critical cultural and social connections associated with fish harvested locally by community residents. Connections to cultural identity, history, and socialization derived from the process of fishing cannot be replaced by freezer fish. Nor can the pride of self-sufficiency. If we acknowledge that fishing accomplishes much more than just the production of fish, the choice of many Grassy Narrows residents to continue consuming fish harvested from the contaminated English-Wabigoon River begins to make sense. Some Grassy Narrows residents state that they persist in consuming fresh fish from the river because the available frozen fish are not of the type or quality they are accustomed to. Beyond such matters of preference, however, the profound social and cultural importance (described above) of the harvesting/preparation/consumption process cannot be replaced.

[6] Fieldnotes, June 17, 2004.
[7] Fieldnotes, June 2, 2003.

Even as people at Grassy Narrows remain deeply concerned about the presence of mercury in fish (and potentially in other wild foods) and insist that these risks be minimized, many feel that the benefits of consuming such items thus outweigh the risks. Grassy Narrows residents' reactions to the health risks associated with toxins in the environment highlight the cultural significance of land-based subsistence. Judy DaSilva—a well-known community leader and mother of five children—once expressed her concerns about contaminants at a public forum. An outsider attending the event suggested a simple solution: Why, he asked, didn't they simply stop eating wild foods? Judy had been taken aback. Reflecting on this exchange, she emphatically told me, "It's not just something you quit. It's not just food for us; it's spiritual."[8]

D: Impacts of Mercury Exposure on the Culture and Community of the People of Grassy Narrows

8. What has been the impact of past mercury exposure from industrial discharges on the culture and community of Grassy Narrows, and what inferences can be drawn from this history when considering future activities, such as clear-cut logging, and whether they could introduce new sources of mercury exposure through fish consumption?

Summary Answer:

The effects of past mercury exposure at Grassy Narrows have been severe and have included serious health problems, challenges to traditional subsistence and cultural identity, economic hardship, and social strain within the community. Newly introduced mercury would exacerbate these detrimental effects.

Full Answer:

Until the discovery of mercury in 1970, the local fishery was central to Grassy Narrows First Nation's economic production, supplying household subsistence as well as commercial fishing income (Usher et al. 1979:364). The original request for Individual Environmental Assessment more fully describes the history and health impacts of mercury contamination at Grassy Narrows. Based on my knowledge of the case, I agree with these submissions. The mercury originated in effluent released by a factory located in far upstream Dryden, Ontario. From 1962 to 1970, roughly 20,000 pounds of the substance entered the river and followed its gradual northwesterly course (Erickson and Vecsey 1980; Shkilnyk 1985; Troyer 1977). As the water flowed on, anaerobic bacteria in the riverbed transformed the mercury from the comparatively benign inorganic compound released by the plant into a deadly bioaccumulating form. Already facing

[8] Fieldnotes, January 29, 2005.

the detrimental impacts of relocation, mercury contamination was a major blow for the community.

After relocation, the community's transition from a relatively independent, subsistence livelihood to participation in the wider wage labor economy accelerated. Citizens of Grassy Narrows depended on the river more than ever before for their living, with a majority of the First Nation's employed population earning wages either in the local commercial fishery or in the tourism and guiding industry. These economic opportunities evaporated after the discovery of mercury. By the spring of 1970, fish from ten lakes within the English-Wabigoon River system—including Clay, Ball, Indian, and Grassy Narrows Lakes—were deemed unsafe for consumption. Almost overnight, unemployment at Grassy Narrows jumped from twenty to eighty percent due to mercury related job losses (Troyer 1977) and an estimated ninety percent of men in the community were out of work (Erikson and Vecsey 1980). The welfare economy tightened its grip on the people of Grassy Narrows, so that by 1977 the community was economically dependent upon steadily increasing transfer payments from the Canadian government, with 37.2 percent of all income deriving from unearned sources and the government functioning as the community's principal employer (Shkilnyk 1985:148).

Significant physical, economic, and psychological (described below) repercussions of mercury contamination continue to this day. I am not trained to trace the pathways of mercury through ecological systems, but based on what I know regarding (1) mercury's bioaccumulation and persistence over time, (2) the sound science linking clearcutting to increased levels of mercury in waterways, (3) the specific history of adverse impacts in the English-Wabigoon River region, and (4) the cumulative effects of numerous additional threats to the Anishinaabe way of life, any activity that increases mercury levels in the traditional diet of Grassy Narrows Anishinaabeg will have serious detrimental impacts. These impacts may entail enduring health effects for adult residents, lives curtailed by health problems for today's children, and anxiety for the health of those who are not yet born. Collective consequences may also include continued affronts to traditional subsistence and cultural identity, economic hardship, and mounting frustration over a long-term problem left inadequately unaddressed.

Two key facts make Grassy Narrows First Nation's case unique. First of all, the historical and contemporary pattern of land-based subsistence—which includes as its centerpiece the practice of fishing on the English-Wabigoon River—must be taken into consideration. Second, the people of Grassy Narrows have been forced to face the persistent physical and cultural impacts of mercury contamination for 45 years. In other words, citizens of Grassy Narrows not only rely on fish and other wild foods as a crucial component of their diet and essential element of their culture, but they have also been previously exposed to mercury. For these reasons, a healthy future for the people of Grassy Narrows and for generations yet to come requires that industrial activities do not increase mercury levels in the fish harvested by Grassy Narrows First Nation residents.

9. If not answered in response to question 8 above, what have been the community level psychological impacts of past mercury exposure from industrial discharges on the people of Grassy Narrows and what additional community level psychological impacts are currently experienced or anticipated from planned future activities, such as clear-cut logging, and whether they could introduce new sources of mercury exposure?

Summary Answer:

Due to the presence of mercury in the English-Wabigoon River system, residents of Grassy Narrows have experienced substantial fear and anxiety for their health. Cultural beliefs about reciprocal relationships between Anishinaabe people and non-human components of the environment and the perceived ability to live a traditional way of life have been jeopardized.

Full Answer:

The impact of mercury contamination was both cultural and material; to this day, the once sustaining English-Wabigoon River is perceived by some Grassy Narrows residents as a "river of poison."[9] I agree with previously submitted material stating that the experience of mercury poisoning has caused serious psychological problems among Grassy Narrows residents, especially including fear and anxiety (noted in Supplementary Submissions, based on Donnan 1986), but also confusion, grief, suspicion, and anger. While I am not a psychologist, it is within my disciplinary area of expertise to document shared socio-cultural trauma. Community-level effects that follow a distressing event or process often result in what Kai Erikson calls *collective trauma*, described as "a blow to the basic tissues of social life" (Erikson 1976:154). Such trauma has undoubtedly occurred at Grassy Narrows First Nation. I also find Usher et al.'s assessments to be both correct and highly relevant today; Usher et al. conclude that mercury pollution stands out as a major event in the First Nation's history, one "which eliminated a central economic activity and a major source of income, and endangered health and aroused anxiety in regard to the same" (Usher et al. 1979:368).

On page 23 of this report, I stated that most Grassy Narrows residents I talked to between 2003-2005 did not recall the initial announcement of mercury as a dramatic event. Over time, however, Grassy Narrows residents began to correlate the unusual medical symptoms they and their loved ones had suffered in recent years with the presence of *pijibowin*—poison. In the fall of 1972, Tom Strong, a forty-two-year-old trapper and fishing guide, died unexpectedly (Hutchison and Wallace 1977). Although Strong had always been healthy, he began to experience slurred speech, weight loss, and chest pains in the summer of that year. He was camped with his family harvesting the annual crop of wild rice when he died of an apparent

[9] Fieldnotes, September 1, 2004.

massive heart attack. In the same year, a boy was born to a fishing guide and his wife with what looked like a full-blown case of acute mercury poisoning, also known as Minamata disease. It was not lost on Grassy Narrow residents that, in both cases, the victims and their families were heavy consumers of fish.

Erikson and Vecsey made the following observation regarding mercury poisoning at Grassy Narrows:

> The discovery of mercury in the local waters has presented a psychological and perhaps even spiritual problem, for the apprehensions and uncertainties that follow such a discovery can affect the mind as surely as the poison itself can affect the body. This process is a subtle one and difficult to document, but it takes the form of a pervasive fear that the world of nature and the world of men are now contaminated and can no longer be trusted in the old way (1980:159).

At Grassy Narrows, the cultural consequences of mercury contamination were substantial. People at Grassy Narrows felt powerless to control their situation. Their customary comprehension of human-environment relationships taught that respectful reciprocity with powerful "other-than-human persons" was necessary to the achievement of *bimaadiziwin*—a good life free of illness and misfortune (Hallowell 1975, 1992; Nesper 2002).[10] But mercury contamination defied patterns of explanation and order that had served them well in their boreal forest homeland for hundreds of years. Human beings, distant both geographically and culturally, had unleashed the toxins that were now disrupting Anishinaabe lives. Most individuals at Grassy Narrows had no knowledge of the Dryden mill and no use for its products. They had done nothing to upset their delicately balanced relationship with the natural world nor to diminish the river's capacity to sustain life.

Although the fundamental cultural ties that bind Grassy Narrows residents to their homeland remain strong, important changes have taken place. Critically, many contemporary Grassy Narrows residents feel that the positive, sustaining nature of their environment can no longer be unreservedly trusted. Relied upon for generations to provide for their people, the river is now a source of *pijibowin* and a site of trepidation. Instead of offering nourishment and the satisfaction of self-sufficiency, the river can now make them sick. It is significant that those within the community who continue to practice traditional Anishinaabe subsistence to the greatest degree are most impacted—and most troubled—by the presence of mercury in the environment.

If additional mercury is allowed to enter the regional ecosystem, these effects can be expected to persist and probably worsen over time. Detrimental consequences of additional mercury

[10] This term has been spelled in various ways, including *pīmädäzīwin* (Hallowell 1975) and *pimadiziwin* (Nesper 2002). I use the double-vowel spelling found in Nichols and Nyholm's *Concise Dictionary of Minnesota Ojibwe* (1995).

exposure are likely to parallel those seen at Grassy Narrows since 1970 and can be expected to include fear, anxiety, and grief associated with a loss of connection to emplaced cultural activities. When communication about risks is not sufficient or trusted, confusion, suspicion, and anger are also likely to ensue. Recent press releases from the community suggest that fear and anxiety are already increasing as a result of the Forest Management Plan's allowance of additional clearcutting. In a release issued in response to the rejection of the community's request for an Individual Environmental Assessment in late 2014, Joseph (J.B.) Fobister stated:

> "Ontario has ignored our voices and is planning to force more devastating clearcuts on our people without even applying their own Individual Environmental Assessment process...It makes me sad that our people will become even sicker if the government allows the logging industry to poison the fish that we eat."

Grassy Narrows residents' association with their traditional landbase must be understood as a comprehensive and holistic package of land-based subsistence and culture rather than as a series of distinct, isolated harvesting activities. As a result, the aggregate impacts of hydroelectric dams, mercury contamination, and clearcutting are greater than the sum of their parts. A trapper who no longer feels safe obtaining fish while out on the trapline may spend less time in the bush. An Anishinaabe youth who experiences anxiety due to the presence of mercury while at a land-based healing camp may rejoin friends partying on the reserve. Mercury contamination—alone as well as in conjunction with other known challenges—poses a serious threat to the Anishinaabe way of life.

10. Are the impacts at the community level in Grassy Narrows from past mercury exposure, and those anticipated in future from new sources of mercury exposure, experienced differently by gender and age and, if so, how?

Summary Answer:

Based on their roles as primary caregivers, their ability to bring new life into the world, and their cultural duties as protectors of water, women at Grassy Narrows are disproportionately impacted by past, present, and future mercury exposure.

Full Answer:

In addition to its disproportionate effects on traditional harvesters and their families, mercury's impacts on the women of Grassy Narrows have been especially profound. Gender roles and family structures at Grassy Narrows largely follow a traditional Anishinaabe pattern (see Landes 1997 [1938]). Historically, subsistence pursuits among the Anishinaabe proceeded according to a gendered division of labor, with men the primary hunters and trappers and women completing the bulk of gathering and domestic work. While some women at Grassy Narrows do work

outside the home (especially in office and education service positions), this is still largely the case regarding land-based subsistence activities. In my time at Grassy Narrows, I observed members of both genders participate regularly in fishing and in the processing of animal products, while men remained the most frequent hunters and trappers and women remained the most common gatherers of wild plant products. Following from generations past, when women were in charge of the construction of *wiigiwaaman*—dwellings (Densmore 1979 [1929]), contemporary Anishinaabe women have primary obligation for maintenance of the home.

As bearers of the next generation and primary caretakers of children, disabled individuals, and elders, women bear a burden over and above others in the community. This includes the additional time, effort, and stress associated with caring for those who are disabled (or less-abled) as a result of mercury's physical and/or psychological effects. It also includes the anxiety and fear catalyzed by the congenital effects of mercury contamination (i.e., worries that a fetus will be born with defects as a result of the mother's consumption of fish) and the disproportionate impacts of mercury on the developing brains of children.

The customary relationship between Anishinaabe women and water merits special mention. Water is perceived by many Anishinaabeg to be the source of all life and is viewed by individuals of both genders as "women's business." Women's symbolic duty as protectors or "carriers" of water is enacted through the central role of women in traditional water ceremonies. Anishinaabe women explain their relationship with water in reference to the prominence of water in the processes of bringing new life into being (i.e., through pregnancy and childbirth). By extension, Anishinaabe people comprehend rivers as metaphorically equivalent to the veins of mother earth.[11] Given this context of belief, women's traditional capacity is greatly disrupted by the degradation of water resources and waterborne contamination. When water is contaminated, upholding these traditional duties becomes more onerous.

11. If not answered in response to questions 8, 9 and 10 above, how does the experience at Grassy Narrows compare with the documented experience of other aboriginal communities that have faced environmental contamination problems?

Summary Answer:

While other First Nations communities have experienced mercury contamination, Grassy Narrows has faced sustained and persistent environmental transformations over many years that have resulted in cumulative detrimental effects.

Full Answer:

[11] Fieldnotes, June 22, 2004.

In many ways, Grassy Narrows residents' experience of mercury has been similar to other communities facing such contamination. Ronald Niezen (1998:88), for example, describes comparable reactions to the discovery of mercury among the James Bay Cree (a group related linguistically and culturally to the Grassy Narrows Anishinaabe), pointing out that "such dramatic changes to the land as flooding and contamination of fish can only lead to a sense of sorrow or spiritual malaise among those accustomed to a careful scrutiny of human relationships with animals and the environment." Although the origin of mercury contamination in the James Bay region differed from the English-Wabigoon River's industrial pollution, the anxiety and sense of vulnerability—as well as the widespread refusal to cease harvesting and consuming fish—that resulted from the substance's presence did not.[12] Margaret Wheatley suggests that among First Nations peoples, the social and cultural impacts of mercury contamination are often more severe than the physical risks and often serve to amplify them (1997). While not specific to mercury, reactions of anxiety, confusion, and the need to weigh risks and benefits of traditional land-based subsistence have been documented among Aboriginal populations at Walpole Island (VanWynsberge 2002), Aamjiwnaang (Jackson 2011), and Akwesasne (Grande and Johansen 1995) as well as among American Indian peoples facing contamination in the United States (see Grinde and Johansen 1995; LaDuke 1999).

Still, the Grassy Narrows case is unique in the cumulative and persistent nature of environmental impacts. Grassy Narrows First Nation's recent history has been punctuated by several episodes of unsolicited—and largely undesirable—change, which have combined to create aggregate effects more damaging than even the most dramatic alteration could produce independently. The people of Grassy Narrows saw their immediate environment transformed without their consent for the first time in the late 1920s, when hydroelectric dams were constructed along the English River to generate power for Euro-Canadian settlements and industries (Kenora Daily Miner and News Staff and the Canadian Press 1984). These dams led to localized flooding and unpredictable water-level fluctuations. More recently, Grassy Narrows has faced large-scale industrial logging throughout its Traditional Land Use Area. These changes compound one another by limiting access to some areas and by reducing community members' trust in the land to provide for their needs. Since the late 1990s, residents have responded to industrial logging within their territory with formal letters of complaint, media campaigns, litigation, and a peaceful direct action blockade.

12. What community level responses have occurred in response to past mercury exposure, and what community level responses are possible in future to activities that could add mercury to bodies of water used by the people of Grassy Narrows for fishing and other traditional pursuits?

[12] Mercury became a problem in the James Bay region following hydroelectric development and subsequent flooding. Richard Scott (2001) traces the James Bay Cree experience of mercury poisoning as well as the history of mercury poisoning in Canadian First Nations more generally.

Summary Answer:

Residents of Grassy Narrows are extremely worried about the presence of mercury in the environment and in their own bodies. They have worked for many years to draw attention to the mercury contamination that has impacted their community and are deeply concerned by the documented relationship between clearcutting and increased mercury levels.

Full Answer:

Based on my firsthand experience at Grassy Narrows, I can attest that people in the community are extremely worried about the continuing impacts of mercury contamination on their health and their immediate environment. They have discussed this issue publically for many years in many different forums. I witnessed numerous discussions reflecting these concerns between 2003 and 2007 and have continued to follow developments since that time.

During my period of research at Grassy Narrows, mercury was a topic of frequent conversation and a matter of collective concern. Specifically, I was present for one of Dr. Harada's visits to Grassy Narrows, which was attended by dozens of Anishinaabe citizens who came to the reserve clinic to be examined by the doctor and his team. [13] All were searching for solutions to health problems they believed to be associated with mercury contamination. I also observed activities related to a community wild food contaminant study, which was designed to shed light on the specific quantities of mercury and other toxins in wild foods and help harvesters understand which species were at risk of contamination.[14] After 2007, Grassy Narrows residents continued to voice concern regarding mercury. While not witnessed firsthand, I am aware of several more recent events designed to draw attention to mercury contamination that have been organized by Grassy Narrows residents—most notably the River Runs of 2010 and 2012—as a result of my use of Facebook and other electronic media. As they did during the previous period of intensive clearcutting and proposed cutblocks within the Traditional Land Use Area that ended in 2008, many residents of Grassy Narrows are already experiencing detrimental anticipatory anxiety. They are fearful that portions of their homeland and way of life may be further degraded as a result of additional clearcutting and associated mercury contamination. As Deputy Chief Randy Fobister recently declared "That's all we know—fishing. Mercury destroyed that once. If they allow more cutting, we'll never be able to sustain ourselves" (Porter 2015).

Residents of Grassy Narrows have been concerned about mercury contamination for 45 years and about clearcutting for 20 years. Since at least 2010, members of the community have publically discussed the link between the two sources of industrial impact (see initial submission, p. 10-11). Furthermore, Anishinaabe people believe strongly that the various components of the

[13] Fieldnotes, August 29, 2004. For Dr. Harada's findings, see Harada et al. 2005.
[14] Fieldnotes, July 29, 2004.

boreal forest ecosystem are interconnected and have long observed and voiced concern regarding logging's impacts on water quality and the habitats of forest species.

For the people of Grassy Narrows First Nation, firsthand experience with environmental degradation—most especially the discharge of mercury into the English-Wabigoon River system—instilled a harsh lesson: if the environment becomes further degraded, traditional land-based subsistence and the rich set of cultural beliefs and practices that are bound to it will be severely curtailed. Based on my experience at Grassy Narrows, I believe community members wish to avoid being forced to choose between (1) giving up traditional activities that are central to their individual and collective identity by ceasing to eat fish they catch in the area in order to protect their health and (2) exposing themselves to further harm caused by exposure to new sources of mercury in order to continue eating fish as part of their traditional way of life.

Appendix C: Relevant factual findings from *Keewatin v. Ontario*, 2011

[229] From season to season, the Ojibway moved from area to area, travelling by birch bark canoe in summer, snow shoe in winter. They gathered resources for their sustenance whenever and wherever they were available.

[230] In a letter to the Minister of Public Works dated December 19, 1870 [Ex. 1, Vol. 4, tab 103], to which I have earlier referred in other respects in the section on Euro-Canadian perspective, Dawson, anticipating that after the Treaty was made, the Ojibway would be treated as minors and that they would come under the care of the Dominion Government, provided a detailed description of their habits and means of obtaining their subsistence:

> In spring, as the navigation opens, the Indians leave their hunting grounds, and betake themselves to the Lakes and Rivers and, as the fish literally swarm in these inland waters, in the early part of Summer, they then have no difficulty in obtaining food, and the means of communication being easy to their light canoes, they can congregate in considerable numbers. Rainy River is the Chief resort, and it is there that their Councils are held, and their Feasts celebrated, but Rainy River, although the Sturgeon abound in its waters, cannot support the whole tribe, and the number which assemble there is generally limited to 600 or a thousand people, including men, women and children. Last summer, however, the number was greater than usual, there having been at one time full 1500 people in the vicinity of Fort Frances.
> …
> … early in Summer, the grand occupation is fishing, and this is to them the happiest season of the year, as they have then an opportunity of uniting after a long winter of isolation. Food is abundant and the time passes pleasantly under circumstances of peculiar fascination to the Savage. With his gun in readiness for the wild fowl, and his spear for the fish, he can, with little labour, secure enough for his immediate wants, and the future troubles him not. The produce of the winter's hunt affords him the means of renovating his garments and bedecking himself to his tastes; marriages and dances are the order of the day with the young, and the old and experienced meet in Council to deliberate on the affairs of the Community, while matrons with some regard to the future, dry the flesh of the sturgeon in the sun, and store it past a day of want.
>
> The fishing season lasts til the rivers began to fall, in the beginning of July, and the busy season commences, numbers then proceed to sandy plains, or rocky islets, where blueberries are in such abundance. These the women and children gather in great quantities and dry in the sun, or compress into cakes which they store past for future use; but a still more important harvest than that of berries soon waits them, and the whole tribe sets off for the rice fields.

> In certain parts of the Lake of the Woods, and on the upper reaches of the Winnipeg, the water spreads out into vast lagoons or shallow marshes, and in these the wild rice grows up from the bottom and rises high over the water, covering extensive areas ... When this crop is ripe, the canoes are perfectly watertight and pushed at will through the standing rice, the method of securing it being to bend it over the gunwale and thresh the ears out with sticks, the grain falling on mats prepared to receive it in the bottom of the canoe; meantime the harvest is disputed by other gleaners in the shape of vast flocks of aquatic fowl, and of these the Indians can easily secure all that they can consume.
> At the time of the rice harvest, the authority and patience of the Chiefs are put to the test, in deciding disputed claims and meting out justice to all ...
>
> It may be maintained that the rice is not always a sure crop. If the water should be too high, it in a measure fails, and even when it promises well, if heavy rains and strong gales occur when it is ripening, it is beaten down to the water and rendered valueless, and the moment it begins to ripen the wild fowl attack it, sometimes in such numbers as to impair the harvest.
>
> Besides the resources as far enumerated, the Indians have crops other than those which nature unaided produces. When the first French explorers came among them they found them growing maize on the banks of the Rainy River, and on the islands of the Lake of the Woods. Two centuries have since elapsed and Indian corn is still grown in the little gardens which produced it then, although not to the same extent. But the Indians have now added to the growth of maize, the culture of potatoes and this at least shows some taste for farming operations, which if properly encouraged, might lead to important results.
>
> When the rice harvest is gathered, and autumn approaching, the Indians having provided themselves with ammunition, and such articles of clothing as they can get at the trading posts, set out for their hunting grounds, in single families, and are once more separated, not to meet again until the following summer. …

[913] The Ojibway understood they were agreeing to share the use of their whole territory and resources with Euro-Canadians, so long as the sharing would not significantly interfere with their own Harvesting Rights. They did not agree to give up their means of making a living, i.e., their own use of resources or their continuing rights to subsistence harvesting on that land. The Commissioners recognized that that was their condition for entering into the Treaty, and they expressly promised the Ojibway could keep those rights to induce them to do so.

[1153] Into the 20th century, the Indian Agents reported every year that the principal activities of the Ojibway at Grassy Narrows were hunting, fishing, berry picking and the harvesting of wild rice.

[1158] **Seasonal Round.** From May to June, the family would be at the Reserve, where they planted potatoes, corn, cabbage and onions in their gardens. In July, they would paddle and portage a freighter canoe to a location about 30 kilometres from the Reserve. They would spend

two to three weeks there, living in tents and harvesting blueberries that they canned or dried over the open fire for winter use or for sale to others.

[1159] After the blueberry harvest, his family would return to the Reserve for a week or so to check on their gardens. Then they would journey 10-15 kilometres in another direction to harvest and preserve wild rice, living in tents or cabins. A great deal of work was involved. One family member would sit in front of a canoe and paddle. Another would sit at the back and hit the rice into the canoe with a stick. While the rice dried, they would dig holes. Then they would place the dried rice in them and dance on the rice to remove the husks. They would sell some of the wild rice and keep some for winter use.

[1160] After that harvest, they would return to the Reserve to harvest their gardens. His parents, who did not have a root cellar, would bury the produce, surrounded with dry grass, in a hole in a sandy area of the bush to preserve it until the winter.

[1161] In mid-September, after they had gathered and stored wood for the older family members who wintered at the Reserve, the family travelled two-three days by freighter canoe to their winter trap line. Along the way, they would hunt and trap. After reaching their trap line, they would ensure their cabin was well maintained, and gather and store wood for the winter. His older brothers helped their father hunt, setting traps and snares to catch beaver, otter, mink and other animals.

[1162] When he was very young, Fobister would remain in the cabin with his mother and learn from her how to preserve animal pelts. He would help her bring in wood and haul water. She made moccasins, gloves, jackets and pants from the pelts. His father sold fur and pelts to the HBC.

[1163] They lived on their trap line throughout the winter and into the spring, eating deer, moose, beaver, lake trout, walleye, northerns and sucker meat, supplemented with wild rice, dried blueberries and produce preserved from their gardens. A dog team was used to haul wood and meat and to travel to buy food at the closest store, about 15-20 kilometres away.

[1164] In April after the wolf and fox moulted, the family would move to another location to trap muskrat, otter and beaver. They would then return to the Reserve and prepare the garden for another year.

[1233] In the case of the Grassy Narrows Ojibway, the life of Fobister is illustrative of the continuing reality that they were still pursuing the seasonal round without significant Euro-Canadian interference, at least into the 1960s and that Euro-Canadian uses and traditional harvesting were compatible.

AFFIDAVIT OF JUSTIN PODUR

I, JUSTIN PODUR, of the City of Toronto, in the Province of Ontario, MAKE OATH AND SAY AS FOLLOWS:

1. I hold a master's and a doctorate in forestry from the University of Toronto. I am currently an associate professor at the Faculty of Environmental Studies, York University. My teaching, research and writing have focused on forest fires in Ontario, including their spatial and temporal patterns, increases in their numbers and area burned.

My research methods in this field of study have included using mathematical and computer models to study fire and ecological problems. I have published in a variety of peer and non-peer reviewed journals on the subject of forest fires, including the Canadian Journal of Forest Research, Ecological Modeling, Ecological Applications, and the International Journal of Wildland Fire. I am also affiliated with the University of Toronto Forest Fire Management Systems Laboratory. A copy of my curriculum vitae is attached to Exhibit “A”, below.

2. In February 2015 I was asked by counsel for Grassy Narrows to answer certain questions in a report on fire in the northwestern Ontario boreal forest, in particular, natural and human-caused disturbances. The questions and my answers to them appear as part of my December 2015 expert report attached as Exhibit “A” to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit “B” to my Affidavit.

SWORN BEFORE ME in the City of Toronto, in the Province of Ontario, this ___ day of _____, 2015.

A Commissioner, etc.

Introduction

I hold a masters and a doctorate in forestry from the University of Toronto. I am currently an associate professor at the Faculty of Environmental Studies, York University. My teaching, research and writing have focused on forest fires in Ontario, including their spatial and temporal patterns, increases in their numbers and area burned. My research methods in this field of study have included using mathematical and computer models to study fire and ecological problems. I have published in a variety of peer and non-peer reviewed journals on the subject of forest fires, including the Canadian Journal of Forest Research, Ecological Modeling, Ecological Applications, and the International Journal of Wildland Fire. I am also affiliated with the University of Toronto Forest Fire Management Systems Laboratory. My curriculum vitae appears in Appendix A of this Expert Report.

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association on behalf of Grassy Narrows First Nation to prepare an expert report that responds to several questions. I am solely responsible for the preparation of this report.

Questions

1. For the documents referred to below, please indicate on a document by document basis if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto:

> A. The Grassy Narrows-Earthroots request, dated January 2014 (pages 16-19), of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May (pages 3-5, 13-14, 19-21), and November 2014 (pages 8-9) insofar as they relate to your area of expertise and the subject matter for your report.

2. What are your views on matters within your area of expertise and the subject matter of this report that are addressed under the heading “Fire vs harvest impacts on Hg dynamics” in the Ministry of Natural Resources and Forestry July 2014 response to the Grassy Narrows-Earthroots May 2014 submissions?

3. What proportion:

> (a) of the boreal landscape in Ontario is burned by large vs. small fires in a “natural” scenario?;
>
> (b) of the boreal landscape in the specific eco-climatic fire zone in which the Whiskey Jack Forest is situated is burned by large vs. small fires in a “natural” scenario?

4. What proportion:

(a) of the boreal landscape in Ontario is burned by large vs. small fires in a fire suppression scenario?;

(b) of the boreal landscape in the specific eco-climatic fire zone in which the Whiskey Jack Forest is situated is burned by large vs. small fires in a fire suppression scenario?

5. Is there a relationship between fire size and fire intensity and severity? If so, what is that relationship?

6. How are fire size, frequency, and intensity expected to change, if at all, as a result of climate change in:

(a) the boreal forest of Ontario?;

(b) in the area of the Whiskey Jack Forest?

7. What amount of mercury, if any, would you expect to be volatized into the atmosphere from Grassy Narrows Traditional Territory in an average fire decade?

8. What are the implications of the natural fire regime for the Whiskey Jack Forest on mercury levels in soil, and on mercury bio-accumulation in fish?

9. How does this compare to the mercury impacts of the logging and fire suppression cycle on mercury levels in soil, and on mercury bio-accumulation in fish?

10. Overall, do logging and fire have similar, or dis-similar, impacts on mercury in the boreal forest?

Organization of Expert Report

The Expert Report is organized into two parts. Part 1 provides short summary answers to the questions that are listed above. Part 2 of the Expert Report is designed to provided greater detail in support of the summary answers set out in Part 1.

Part 1

Summary Answers to Questions

1. For the documents referred to below, please indicate on a document by document basis if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto:

A. The Grassy Narrows-Earthroots request, dated January 2014 (pages 16-19), of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May (pages 3-5, 13-14, 19-21), and November 2014 (pages 8-9) insofar as they relate to your area

of expertise and the subject matter for your report.

Answer to Question 1: The Grassy Narrows-Earthroots request for an IEA is accurate in every material respect as it relates to forest fires. The supplementary submissions made to the Ministry dated May, and November 2014 are accurate in every material respect as they related to forest fires.

2. What are your views on matters within your area of expertise and the subject matter of this report that are addressed under the heading "Fire vs harvest impacts on Hg dynamics" in the Ministry of Natural Resources and Forestry July 2014 response to the Grassy Narrows-Earthroots May 2014 submissions?

Answer to Question 2: The MNRF July 2014 response argues that the statement that "logging and forest fire have nearly opposite impacts on mercury", "is not supported by scientific studies". Elsewhere, the response argues that there is a lack of evidence "that mercury levels of fish differ consistently between lakes with harvested watersheds and those with intensively or extensively burned watersheds."

The MNRF response ignores the physical and chemical changes caused by the combustion of forest fuels, as well as the changes to the forest due to the removal of biomass due to harvesting. Large-scale boreal fires of the kind that account for 90% or more of burned areas, result in atmospheric emissions of mercury that travel long distances before being redeposited, thus reducing the total pool of mercury in the local watershed. Whereas forestry (clearcutting) operations release mercury into local water bodies.

3. What proportion:

(a) of the boreal landscape in Ontario is burned by large vs. small fires in a "natural" scenario?;

(b) of the boreal landscape in the specific eco-climatic fire zone in which the Whiskey Jack Forest is situated is burned by large vs. small fires in a "natural" scenario?

Answer to Question 3:

a) 1.3% of fires larger than 200 ha burned 96% of the area for the period 1976-2004 in the portion of boreal Ontario under active fire suppression. For a "natural" scenario I would expect the proportion of area burned by large fires to be even higher.

b) In the Whiskey Jack Forest for the period 1960-2013, 1.1% of large fires burned 95% of the area. For a "natural" scenario I would expect the proportion of area burned by large fires to be even higher.

4. What proportion:

(a) of the boreal landscape in Ontario is burned by large vs. small fires in a fire suppression scenario?;

(b) of the boreal landscape in the specific eco-climatic fire zone in which the Whiskey Jack Forest is situated is burned by large vs. small fires in a fire suppression scenario?

Answer to Question 4:

a) 1.3% of fires larger than 200 ha burned 96% of the area for the period 1976-2004 in boreal Ontario.

b) In the Whiskey Jack Forest for the period 1960-2013, 1.1% of large fires burned 95% of the area.

5. Is there a relationship between fire size and fire intensity and severity? If so, what is that relationship?

Answer to Question 5: There is a positive correlation between fire size and fire intensity and severity. Most of the boreal forest is under active fire suppression. It is more intense fires that tend to become large fires. These fires are also more severe and tend to leave fewer unburned islands.

6. How are fire size, frequency, and intensity expected to change, if at all, as a result of climate change in:

(a) the boreal forest of Ontario?;

(b) in the area of the Whiskey Jack Forest?

Answer to Question 6:

a) Fire size, frequency, and intensity are all expected to increase as a result of climate change. All forest fire models, when run with climate change simulation model data, predict increased fire size, frequency, and intensity. This is equally true for the entire boreal forest and for b) the area of the Whiskey Jack Forest.

7. What amount of mercury, if any, would you expect to be volatized into the atmosphere from Grassy Narrows Traditional Territory in an average fire decade?

Answer to Question 7:

There is a high amount of variability in decadal area burned, but the historical figures range from 498 g in the 2000s to 56 000 g in the 1980s.

8. What are the implications of the natural fire regime for the Whiskey Jack Forest on mercury levels in soil, and on mercury bio-accumulation in fish?

Answer to Question 8:

Because of the role of combustion in volatilizing mercury into the atmosphere, the natural fire regime results in an amount of mercury released into the atmosphere proportional to the area burned. Larger, more intense, and more severe fires all result in a higher amount of mercury being removed into the atmosphere.

9. How does this compare to the mercury impacts of the logging and fire suppression cycle on mercury levels in soil, and on mercury bio-accumulation in fish?

Answer to Question 9:

Harvesting operations increase mercury output into water bodies, and hence increase mercury bio-accumulation in fish.

10. Overall, do logging and fire have similar, or dis-similar, impacts on mercury in the boreal forest?

Answer to Question 10:

Overall, fire and logging have dissimilar impacts on mercury in the boreal forest.

Part 2

Forest management and fire: two distinct types of disturbance

In the comparison of natural disturbance with forest management, there are stand-level and landscape-level considerations. These are discussed in a general way by Bergeron et al. (1999).

Stand-level considerations

Stand level considerations include the effect on forest soils and the exposure of the soil post-fire vs. post-logging, the amount of wood volume and snags left behind after the disturbance, which depends on the intensity of the fire, and the presence of residual trees or unburned islands after a fire. With these considerations in mind, a fire in a jack pine, spruce, or aspen/poplar stand can be contrasted to a clear-cut with retention. In the clear cut, the soil has not been burned, the wood volume is decreased relative to the surface fire, and snags are absent, post clear-cut.

Landscape-level considerations

Greater differences appear at the landscape level. These include differences in age-class, size-class, and spatial distributions of stands.

Age-class distribution. The purpose of logging is the extraction of trees from the forest for their economic value. It is economically wasteful to allow trees above the rotation age to remain in the forest. The age structure, or age-class distribution, of a managed forest will, in the long-term, contain stands that are, at their oldest, the rotation age (typically planned to be 60-100 years in the boreal). By contrast, because the probability of burning is independent of stand age, the age-class distribution of a forest under a natural fire regime will have a large portion (Bergeron et al. 1999 give a figure of 37%, citing Johnson and Van Wagner 1985b) of stands that are older than the rotation age.

Size-class distribution. The spatial pattern of logging activity is organized by forest management principles, including ease of access and removal as well as age-class considerations discussed above. By contrast, fire is a random, or stochastic process, which produces a random distribution of fire sizes. Fire size has been modeled as a Pareto distribution (Ward et al. 2001), a Weibull distribution (Reed and McKelvey 2002), and others (cited in Podur et al. 2009), and aggregate area burned by a compound Poisson distribution (Podur et al. 2009). The random pattern of different sizes of fires distributed on the landscape results in a mosaic of patches, some of which are small, some of which can be very large. Different spatial mosaics have different implications for wildlife habitat, among other considerations.

Shape and distribution of burned stands. The stochastic nature of the fire process goes beyond fire size distribution, however, as the shapes of the stands and their physical distribution across the landscape is an even more complex process involving topography, wind, and forest fuel conditions at the times that the fires took place.

Two distinct types of disturbance

Because of all of these important differences, logging and fire are viewed by forest landscape and fire ecologists as completely distinct ecological processes in the boreal forest landscape. The OMNR produces guidelines for forest management with the intent to make forest management emulate natural disturbance with tree retention, specific types and shapes of cuts, a range of clearcut sizes, and the retention of downed woody debris (OMNR 2014). All of these measures may increase the ecological integrity of logged stands, but fire and logging remain distinct disturbances from an ecological point of view.

A natural fire regime in the boreal forest

The boreal forest of Ontario is characterized by a fire regime that includes a high proportion of area burned by a small number of large, high-intensity fires.

Area burned is dominated by large fires

Stocks et al. (2002), studying the Canadian boreal forest, found for 1959-1997 that fires over 200 ha in size were 3% of the fires occurring in Canada but 97% of the total area burned. Podur and Wotton (2010) studied the zones of active fire suppression in Ontario for 1976-2004 and found that only 1.3% of fires grew to > 200 ha, but these fires resulted in 96% of the area burned in the region. In areas not under fire suppression, an even higher proportion of area burned would be due to large fires, as fewer fires would naturally stop at a small size.

Weather drives large fires more than fuels or suppression

Podur and Martell (2009) studied the fuels, or forest types, burned by fires for 594 fires larger than 40 ha that occurred in Ontario's boreal forest between 1996-2006, finding that fuels burned in the proportion they were available. This suggests that weather is dominant in controlling large fires. Podur and Martell (2007) found that fire suppression does, however, reduce area burned, even in large fires, by suppressing a class of fires that would have escaped had there been no suppression. In severe fire years, however, there remain a number of fires that are too intense for suppression to succeed, and these fires, which become large in size and have high burn severity, make up the most important portion of area burned. Podur and Wotton (2010) found that the number of these large, uncontrollable fires was likely to increase under climate change, with the potential to overwhelm fire suppression capacity.

Weather drives large fires. These studies all found that weather drives large fires and that large fires drive area burned. This is true throughout boreal Ontario, in managed forests and unmanaged, in forests where fire suppression is active and in areas where fire is monitored and not actively suppressed. This includes the Whiskey Jack forest in northwestern Ontario.

Differences between fire and logging in mercury (Hg) release

Large fires release Hg into the atmosphere

Sigler et al. (2003) studied a series of fires in the severe 2002 Quebec fire season, in which 250 fires burned 1,000,000 ha over a 1-month period. They measured gaseous mercury (Hg) at the Harvard Forest and provided a measure of Hg emissions from large-scale boreal forest fires. Scaling up, they provide global estimates of Hg emissions from boreal forest fires. The important point here is that large-scale boreal forest fires of the kind that account for 90% or more of the area burned result in atmospheric emissions of Hg. Turetsky et al. (2006) reinforce this point, quantifying organic soil Hg stocks in the boreal forest and estimating atmospheric emission of Hg due to increased boreal forest fire activity under climate change. They conclude that increased fire activity will result in greater release of Hg from boreal forest soils into the atmosphere.

Logging operations release Hg into local water bodies

Bishop et al. (2009) summarized a series of studies showing Hg accumulation downstream of forestry operations, finding a "forestry effect" on Hg accumulation in fish. In a study of Hg concentrations in fish in 38 boreal lakes, Garcia and Carignan (2005) found higher Hg concentrations in fish from logged and "partially burnt" lakes (i.e., lakes where small-scale fires had occurred).

The Whiskey Jack Forest - historical fires and estimated mercury emissions

The part of the Whiskey Jack Forest subject to the Grassy Narrows legal action is 631 413 ha in extent. The National Fire Database lists a total of 1222 fires in this area for the period 1960-2013. These fires burned a total of 18 541 ha. 17 662 ha, or 95% of the area, of this was burned by 14 fires, or 1.1% of the fires, which were larger than 200 ha. The pattern of large fires driving area burned also applies here. A higher number of large fires and a higher area burned would be expected in a natural fire scenario with no fire suppression.

The overall mean burn fraction for the boreal zone of Ontario calculated from the national fire database is 0.001 (the median burn fraction for the boreal zone of Ontario is much lower, 0.0003).

The burn fraction in all years except four for the study area was less than 0.001. The highest burn fraction was 0.016 (in 1983). The other three years were 1988 (0.005), 1976 (0.004), and 1980 (0.002). These low and highly variable burn fractions illustrate the difficulty of estimating a quantity like fire return interval or fire cycle from the burn fraction. Reed (2006) recommended the abandonment of the concept of fire cycle based on these difficulties, though the concept continues to be used: MNR analysts estimate a pre-suppression fire cycle of 81 years, or a burn fraction of 0.01, compared to a post-suppression fire cycle of 299 years, or a burn fraction of 0.003. The mean burn fraction in the region based on the national fire database (1960-2013) was 0.0007 - on average, 0.07% of the study area burned each year. The median burn fraction in the study area was 0.00001, an order of magnitude smaller.

Decadal average area burned and burn fraction for the study area are summarized in Table 1 below.

Table 1. Decadal average area burned for the study area

Decade	Area Burned (ha)	Burn fraction
1960-1969	810	0.0005
1970-1979	6143	0.0039
1980-1989	37330	0.0239
1990-1999	1117	0.0007
2000-2009	332	0.0002
2010-2013	84.3	0.00005
Totals	45817	0.0294

Using Turetsky et al. (2006) figure of 2.62 mg/m2 or 3.8 g/ha Hg stocks in upland forest soils, we arrive at an estimate of about 5.92 t of Hg in the soil of the study area. Sigler et al. (2003) estimate an Hg flux density of 1.5g Hg/ha. This means that a conservative estimate for the decadal mercury

emissions into the atmosphere from the study area ranged between 498g in the 2000s to 55995g, or 56kg in the 1980s. This is a conservative estimate because Turetsky (2006) calculates higher Hg stocks for boreal peatlands (25.14 mg/m2 in a drought scenario).

There is much higher Hg volatilization to the atmosphere in a natural non-fire suppression scenario, than in a fire suppression scenario with harvesting. Woodruff and Cannon (2010) found that high soil burn severity has the potential to reduce the concentration of mercury in burned soils for tens to hundreds of years post-fire. In Prince Albert National Park, Saskatchewan, Friedli et al. (2007) measured an increase in mercury stock from 1.01 mg/m2 for a 39-year old stand to 3.45 mg/m2 for a 130-year old stand. MNR analysts estimate a pre-suppression fire cycle of 81 years, or a burn fraction of 0.01, compared to a post-suppression fire cycle of 299 years, or a burn fraction of 0.003. If these estimates are correct and suppression results in older stands, higher mercury stocks are to be expected in these stands.

In a "natural fire" scenario a high proportion of these stocks are released into the atmosphere. In a suppression + harvesting scenario, a larger proportion of these mercury stocks are released into the water.

The Whiskey Jack Forest - estimated mercury release in a logging scenario

Bishop et al. (2009) estimate that if 100% of an area is harvested (clearcut), a two- to fourfold increase in loading and bioaccumulation of Hg can be expected in fish in the logged catchment area for 10 years. In the total landscape with 1% harvested annually, they estimate an increase of 10-30% in bioaccumulation compared to an unmanaged landscape, and an even higher increase if silviculture activities such as soil scarification and thinning also have mercury impacts. Bishop et al. (2009) provide untested silvicultural recommendations to minimize the impacts on Hg bioaccumulation after forestry operations, but possible reductions due to these impacts have not been quantified - we cannot know how much these silvicultural changes will reduce Hg bioaccumulation.

Conclusions

Forestry and forest fires are ecologically different processes at stand and landscape levels. The area affected by forest fires is primarily due to a small number of large, intense, severe fires. In these large fires, Hg is released into the atmosphere, traveling long distances before being redeposited, reducing the total mercury pool in the local watershed. In forestry operations, Hg is released into local water bodies. A small portion of the Whiskey Jack Forest has been affected by fire since 1960, releasing a small amount of Hg into the atmosphere. Projected forestry operations in the Whiskey Jack Forest can be expected to release a larger amount of Hg into local water bodies.

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Justin Podur. I live in Toronto in the Province of Ontario.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

AFFIDAVIT OF STEPHEN KILBURN

I, STEPHEN KILBURN, of the City of Guelph, in the Province of Ontario, AFFIRM AND SAY AS FOLLOWS:

1. I hold a Bachelor's degree in Environmental Studies, Urban and Regional Planning and a Master's degree in Regional Planning and Resources Development from the University of Waterloo. I am a Registered Professional Planner and member of the Ontario Professional Planning Institute and the Canadian Institute of Planners. I am a consultant

specializing in the application of geographic information system (GIS) methods in the fields of resource management and planning. GIS is a computer technology that allows users to store, manage, manipulate, analyze, and interact with geospatial information, and to create maps and other information products. I have provided GIS and related services to federal, provincial, territorial, municipal, and First Nation governments and agencies across Canada. I have also published and spoken widely in this field. A copy of my curriculum vitae is attached to Exhibit “A”, below.

2. In April 2015 I was asked by counsel for Grassy Narrows to prepare a series of maps on planned and recent clearcut logging in the Whiskey Jack Forest. The maps and a short report explaining the methodology I used in preparing them appear as part of my January 2016 expert report attached as Exhibit “A” to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit “B” to my Affidavit.

AFFIRMED BEFORE ME in the City of Toronto, in the Province of Ontario, this 29th day of January, 2016.)

A Commissioner, etc.)

Introduction

I hold a Bachelor's degree in Environmental Studies, Urban and Regional Planning and a Master's degree in Regional Planning and Resource Development from the University of Waterloo. I am a Registered Professional Planner and member of the Ontario Professional Planning Institute and the Canadian Institute of Planners. I am a consultant specializing in the application of geographic information system (GIS) methods in the fields of resource management and planning. GIS is a computer technology that allows users to store, manage, manipulate, analyze, and interact with geospatial information, and to create maps and other information products. I have provided GIS and related services to federal, provincial, territorial, municipal, and First Nation governments and agencies across Canada. I have also published and spoken widely in this field. My curriculum vitae appears in Appendix B of this Expert Report.

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association, on behalf of Grassy Narrows First Nation, to prepare a report and a series of watershed maps of planned and recent clearcut logging in the Whiskey Jack Forest of northwestern, Ontario. I am solely responsible for the preparation of this report and the accompanying maps.

Documentation for Maps in this Report

The following is an explanation of the data sources and methods used to create the maps in this report.

In the description below, sections of the document Ministry of Natural Resources (2009), *FIM Forest Management Planning Technical Specifications 2009* are referenced to provide reference for the meaning of attribute values. The abbreviation "FMPTS 2009" is used for this document.

The maps were prepared using ArcGIS software, version 10.1, SP1. Maps all use NAD 1983 datum and Universal Transverse Mercator (UTM) zone 15 north projection.

Two categories of maps are included behind Appendix A: trap line area maps (Appendix A.1), and watershed area maps (Appendix A.2). The former have been included because they cover a larger geographic area and, therefore, provide greater context for the location of the latter. For example, the trap line area map entitled "Trapping Area KE038" contains the watershed area entitled "Watershed Noname 20 near Campfire Lake". A blown-up version of the latter may be viewed by examining the separate watershed area map entitled "Watershed Noname 20 near Campfire Lake".

Base Features

Base features were mapped using the following data sources:

- Water lines and water areas were sourced from Land Information Ontario OHNWCRS and OHNWBDY datasets.

- Roads were sourced from Land Information Ontario MNRRDSEG.
- Wetland areas were extracted from the Whisky Jack Forest Management Plan (FMP) Planning Composite Inventory (PCI) using the attribute definition *POLYTYPE in ('TMS', 'OMS')* (i.e., treed muskeg and open muskeg, respectively [FMPTS 2009, A1.1.4]).
- Trapping areas were sourced from Land Information Ontario TRAPLINE.
- Watershed areas were sourced from Ontario Flow Assessment Tool III.
- Planned clearcuts and contingency clearcuts for 2012-2022 were extracted from the Whisky Jack FMP 2012-2022 dataset MU490_12PHR00.

Areas of Relevance

Areas of relevance for forestry planning and mercury impacts were mapped from the following sources:

- **Naturally Unforested Areas:** These were extracted from the PCI by excluding polygons with the POLYTYPE attributes 'TMS', 'OMS', 'FOR', 'WAT' (treed muskeg, open muskeg, productive forest, and water, respectively). This category includes exposed rock, brush and alder, islands less than 8 hectares in size. As well, it includes areas with the attribute definition *"DEVSTAGE" = 'LOWNAT' AND "YRDEP" < 1968* (i.e., areas disturbed before 1968 by natural causes where the area currently is below regeneration standards).
- **Forest:** Naturally forested areas were extracted from the PCI using the attribute definitions *POLYTYPE = 'FOR'* (i.e., productive forests, [FMPTS 2009, A1.1.4]); *YRDEP<1* (i.e., no recorded disturbance year [FMPTS 2009, A1.1.11]); and *DEVSTAGE ='FTGNAT'* (i.e., free-to-grow mainly natural regeneration, which includes both naturally regenerated forests and original forest [FMPTS 2009, A1.1.10]). Subsets younger and older than 45 years were extracted using the additional attribute queries *AGE<46* and *AGE>45*, respectively.
- **Forest, Depleted Before 1968:** Forested areas depleted before 1968 were extracted using the attribute definitions *YRDEP < 1968* and *YRDEP > 0* (i.e., areas that have recorded depletions before 1968); and *DEVSTAGE in (FTGPLANT, FTGSEED, FTGNAT)* (free-to-grow planted, seeded, and natural regeneration [FMPTS 2009, A1.1.10]).
- **Depletions After 1967:** This category is the best approximation of historical logging using the data provided by MNRF (see discussion below about the data provided). Depletion areas were extracted with subsets being defined using YRDEP attribute ranges (1968-1977, 1978-1987, 1988-1997, and 1998-2007) and using the attribute definition *NOT (DEVSTAGE in ('DEPNAT', 'LOWNAT')*, (i.e., areas with recorded disturbance years in the specified ranges where the original disturbance was not recorded as natural). In addition, the following natural depletion areas were excluded.

- **Fire Disturbances:** This identifies areas disturbed by fire based on the FIRE_DISTURBANCE_AREA polygons obtained from Land Information Ontario. We considered salvage logged areas to be primarily fire disturbed. To exclude salvage logged areas from the general depletion areas (above), FIRE_DISTURBANCE_AREA polygons were spatially intersected with a subset of the FRI where *YRDEP>0* (i.e., any area with a recorded depletion). From the resulting dataset, any areas where a fire event was recorded (*FIRE_YEAR > 0*) and the last disturbance year recorded in the FMP Land Classification was the same as or within 5 years after the fire year was mapped as fire disturbances.

- **Blowdown Disturbances:** To identify areas of blowdown disturbance, FOREST_ABIOTIC_DAMAGE_EVENT polygons were obtained from Land Information Ontario. These were spatially intersected with the FMP Land Classification Dataset. From the resulting dataset, any areas where a blowdown event was recorded (EVENT_NAME = 'Blowdown') and the last recorded disturbance year was after 1967 were mapped as blowdown disturbances.

- **Other Natural Disturbances:** Areas of potentially productive forest disturbed by natural events that have not met regeneration standards were extracted using the attribute definition *DEVSTAGE='LOWNAT'* and areas recently disturbed by natural events extracted using the attribute definition DEVSTAGE = 'DEPNAT'.

- **Confirmed Logging Since 1970:** There is a map titled "Area Harvested in the Whiskey Jack Forest between 1970 and the Present Time" in the Whiskey Jack Forest 2009-2019 Forest Management Plan 1.1.7.11 Historic Forest Condition, Tab 2, page 26 by David Anderson, Area Forester, Oct 24, 2006. Areas marked as logged in that dataset (shapefile WJF_1970) are marked as "Confirmed Logging since 1970" on our maps.

Discussion

Our primary intention was to produce maps that accurately represent the currently proposed clearcuts and contingency clearcuts in the context of mature productive forested areas, naturally disturbed forested areas, and areas that have been disturbed by previous forest cutting since 1968. The year 1968 was chosen because it likely captures all, or nearly all, historical logging in the area of interest. This is corroborated by the fact that the FMP map of historical logging uses 1970 as a start date.

A challenge to achieving this was presented by omission of an important attribute from the FMP land classification data (Planning Composite Inventory) provided by the MNRF. According to an MNRF presentation, "The Enhanced Forest Resources Inventory, January 22nd, 2013," (available online from the Canadian Institute of Forestry, http://www.cif-ifc.org/wp-content/uploads/2014/05/Banton.pdf), the FRI data should include a depletion type attribute (DEPTYPE) that "identifies the disturbance that occurred in the year recorded in the companion attribute YRDEP," (p.40) and includes entries that would allow harvest disturbances to be differentiated from natural disturbances.

When we requested the DEPTYPE attribute data The MNRF wrote to us that “The external link to the Forest Management Planning Tech Spec. http://www.ontario.ca/document/forest-management-planning-technical-specifications. This applies to the Planning Composite Inventory (PCM) that was provided as part of the current approved 2012 Whiskey Jack plan. The forest resource inventory (FRI) that this PCM was based upon unfortunately did not include a DEPTYPE field. The original FRI was developed prior to FIM and as such did not have an appropriate Tech. Spec.”

Because we lacked this attribute, we were forced to attempt to differentiate harvest depletions from natural depletions using other attributes. As well, at the recommendation of the MNR we obtained from Land Information Ontario the complementary datasets FIRE_DISTURBANCE_AREA, FOREST_ABIOTIC_DAMAGE_EVENT, FOREST_DISEASE_DAMAGE_EVENT, FOREST_INSECT_DAMAGE_EVENT, and FOREST_MISC_DAMAGE_EVENT. Of these, only the fire disturbance area dataset appears to be complete. As documented above, we made use of the abiotic damage event dataset to map blowdown areas, but note that the earliest recorded event is 2001, suggesting that the dataset is not complete. After inspecting their content, we determined that we could not make use of the other three datasets. The whole content of the disease damage event dataset was five polygons covering 1.82 square kilometres, all denoting “Ink spot of aspen” disease in 2009 and 2010. Even the subset of polygons in the insect damage event dataset for “Spruce Budworm” damage appear to be grossly generalized and not amenable to use with data of the accuracy of the FRI; and cover an area of approximately 295,000 square kilometres – nearly one third of the WJ Forest. The miscellaneous damage event dataset comprised five polygons covering 175,000 square kilometres, all denoting “Aspen decline” in 2009 and 2010.

Recent depletions that are not marked as confirmed logging likely reflect logging after the endpoint of the data used for “Area Harvested in the Whiskey Jack Forest between 1970 and the Present Time.” The presence of a road network in these areas corroborates this. Old depletions that are not marked as confirmed logging are likely natural disturbances but may be old logging overlooked in the FMP map

Conclusions

Despite these challenges we are confident that our mapping reasonably represents the landscape and the depletions that have occurred since 1968 to the best of our ability using the data that the MNRF has shared. Most importantly, the planned and contingency cutblocks are represented as accurately as in the FMP data.

Stephen Kilburn

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Stephen Kilburn. I live in Guelph in the Province of Ontario.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

Respondents

AFFIDAVIT OF STEVEN FOBISTER, SENIOR

I, STEVEN FOBISTER, SENIOR, of Grassy Narrows, in the District of Kenora, AFFIRM AS FOLLOWS:

1. I am a member of Grassy Narrows First Nation ("Grassy Narrows"). At various times I have served my people as the Deputy Chief of the Grassy Narrows Band Council, the elected Chief of Grassy Narrows, and the Grand Chief of Treaty Three. As such, I have knowledge of the matters hereinafter deposed to.

2. Clearcut logging recently was approved by the Respondents as part of a Forest Management Plan for the Whiskey Jack Forest for the period 2012 to 2022 (the "Plan"). Most of the Whiskey Jack Forest is the traditional territory of our people. My whole life, I have eaten fish from the many lakes, streams, and waters that form part of the watershed of the English-Wabigoon River System, which runs through the Whiskey Jack.

3. I was born in 1952 at the hospital in Dryden and have lived on Grassy Narrows' traditional territory for most of my life. I was raised the traditional Anishinaabe way. Growing up, I lived primarily on my family's trapline eating a traditional diet rich in fish and wild plants, with some wild game. We moved frequently throughout our traditional territory according to the seasons and the availability of food. Although poor in material goods, we were spiritually rich and felt our connection to the land deeply. The land gave us food and shelter, and it always sustained us. I loved that life.

4. Our way of life followed a circle. In the spring we hunted migratory birds; in the summer I would guide American sport fishers. There was really good subsistence and commercial fishing in the fall. In the winter we went to our traplines.

5. I am intimately familiar with the land in my trapline area and the areas where I used to guide sport fishers, including lakes whose watersheds are scheduled for clearcutting under the Plan. For example, the lake identified in the watershed and trapline maps found behind Exhibit "A" to this affidavit is in my trapline area. The maps come from Stephen Kilburn's Expert Report, and I am very familiar with the area identified in the maps. The

lake identified in the maps as watershed Noname 20 near Campfire Lake is named Zagaatigooning-zaaga'iganish – in English, the Little Lake of the Dense Woods. It is a beautiful little lake. It is a good place to camp, and when I was younger I used to camp there all the time. It lies at the end of a long portage from Campfire Lake and it is crystal clear, surrounded by old growth forest. There are lots of fish in this lake – in fact, all of the lakes in this area are incredibly productive. I used to catch trout from the stream entering this lake with a snare. Besides being a good lake for fishing, Zagaatigooning-zaaga'iganish is a good place to harvest traditional medicines. The area KE038 shown in the second map in Exhibit "A" is my trapline area where I sustained myself and earned my livelihood as a young man. I know that area well and I have traveled, fished, trapped, and hunted throughout the area. I hope to pass that area on to my grandchildren so that they can enjoy it as I have.

6. The forest around Zagaatigooning-zaaga'iganish is slated for heavy clearcutting under the Plan, as shown in the maps behind Exhibit "A". I fear that this clearcutting will not only destroy the beauty and cultural value of a place I cherish, but will also increase the mercury levels in the water and in the fish that live there.

7. I ate fish almost every day growing up, and when I was guiding I would often eat fish multiple times a day. I would also bring home fish for my wife and children. I mostly ate walleye, but I would eat other fish too. Walleye is my favourite; it tastes better than the other fish.

8. The full impact of the mercury pollution hit us in 1970, when the government announced that the Dryden plant had contaminated our waters. After that we couldn't live off the land anymore. The guiding industry slowed to a trickle and our commercial fisheries had to close. Where we had been self-sufficient, we were forced to become dependent on welfare. Our community suffered greatly.

9. I continued to work as a sport fishing guide for years after the mercury was discovered. Unemployment was very high and I felt lucky to have work. The tourist camp operators encouraged us to eat fish to show our guests that it was safe. I kept eating fish as frequently as I had before the mercury was discovered.

10. I continue to eat fish from the English-Wabigoon River System to this day because it is an important part of my culture. Also, my precarious financial situation means I cannot afford to cut wild fish out of my diet.

11. I believe that my exposure to mercury has affected me terribly. My body is breaking down one piece at a time. I experience shaking and loss of balance. I have difficulty swallowing, weakness in my hands, and my speech is slurred. I have difficulty walking and I need to use a riding lawnmower to get around because I don't have a motorized wheelchair. I feel deep sadness and depression about the loss of my health and my traditional way of life due to mercury pollution and logging. When I look at the land, look at our situation, I feel despair. There are so many sick people here, so much

destruction of our land and our way of life. You can't imagine how it feels when the land and water that have always sustained you can suddenly kill you.

12. I have been examined by the Mercury Disability Board and diagnosed with symptoms consistent with mercury poisoning. I receive $250.00 each month from the Mercury Disability Board. Dr. Masazumi Harada examined me in 2010 and diagnosed me with mercury poisoning. I have now also been diagnosed with amyotrophic lateral sclerosis (ALS).

13. In April 2010, I was interviewed by the CBC regarding the effects I have experienced due to exposure to mercury. Exhibit "B" to my affidavit contains excerpts of my comments to the CBC in 2010. The CBC included some footage from a much earlier interview in the 2010 piece, and I identify the source of each comment in this paragraph. In the earlier interview, I stated: "I don't think, you know, it's right to say, look, you know, you don't have to go trapping. You can live on welfare." In my comments to the CBC in 2010, I stated: "My whole nervous system is out of whack, you know, I can't barely walk and, you know, I have to hold my jaw to talk because my muscles are practically gone…[As a fishing guide, he] had [to eat what he caught even after the mercury was discovered.] We had to do this in order to appease our guests that the fish was ok. The tourist camp owners encouraged us to do it. […] [I recall Dr. Harada during his return to Grassy Narrows in March 2010 saying to me,] 'You know you have some kind of a metal poisoning,' and the closest definition to [Harada's] examination…it's got to be mercury. […] I only have one granddaughter. She's the one who kind of possesses violent

seizures." I have reviewed these excerpts and they are true and accurate. I have clarified in the remarks that appear in the next to last square bracket what was unclear about who was speaking as set out in Exhibit "B". These excerpts were included in a larger document Grassy Narrows filed with the Ministry of the Environment in September, 2014 in an attempt to persuade the Ministry to examine the effects of mercury from clearcut logging authorized by the Respondents for the Plan.

14. Also contained in Exhibit "B" are excerpts from a 2003 interview of me by a reporter for the Toronto Star regarding the mercury issue. I advised the reporter that I have serious neurological disease: "I can't hardly tie my shoes anymore." I also said that I blame clearcut logging in the area for the continuing high levels of mercury contamination. These excerpts were also included in the September 2014 document referred to above. I have reviewed these excerpts and they are true and accurate.

15. I fear that continued clearcutting in our traditional territory will expose us to further mercury poisoning. I am extremely concerned about future mercury exposure if additional mercury is released from the forest as a result of clearcutting. I am afraid of the physical effects of exposing our bodies to yet another round of mercury, and I am also afraid of the psychological effects. For me and for many others, the psychological effects of mercury poisoning – including, but not limited to, depression and anxiety – are unspeakably painful. Being out on the land and water allows us to escape, however briefly, from the negative mental and emotional states that are associated with living in a community struggling with mercury poisoning. I fear clearcutting would add to our

mercury burden, which would add to the negativity, and also raze the forest, thereby removing a vital form of retreat and healing.

16. I also fear for the health of our land and our ability to practice an Anishinaabe lifestyle if clearcutting is allowed to continue under the Plan. Large portions of the forest on my trapline area have already been clearcut. The map entitled KE038 in Exhibit "A" is my trapline area, and this map shows the extent of the planned and recent clearcutting for the area. I want my great-grandchildren and great-great-grandchildren to have a safe environment so they can grow up healthy and strong in our Anishinaabe traditions. I am strongly opposed to any Forest Management Plan that includes clearcutting. If the clearcut logging recently authorized by the Respondents under the Plan goes ahead, I fear it will release yet more mercury into the English-Wabigoon watershed, poison the fish we eat from those waters, and harm our health and well-being. This would violate our rights under the *Canadian Charter of Rights and Freedoms*. We have a right to be secure from the threats to us posed by mercury. By imposing clearcutting in our traditional territory, the government risks our health and discriminates against us because of our way of life, which includes fishing for walleye, and eating the fish we catch, as a central core of our identity as Anishinaabe people.

17. Clearcut logging on our territory is destroying our way of life. Our forest and our people need a break, we've had enough. We're going to stand up. My health is deteriorating, and I can feel that this may be my last fight. But after I have passed on, my children, grand-

children, and great-grand-children will continue to fight to preserve our land, our health, and way of life.

18. I affirm this affidavit in support of the within application for judicial review, and for no other or improper purpose.

AFFIRMED before me in the District of Kenora, in the Province of Ontario, this ___ day of _____, 2016.

A Commissioner, etc.

Thirty years after a Japanese researcher identified Canada's biggest case of mercury poisoning, he has returned to discover that the problem is far from resolved and may be getting worse. Masazumi Harada's new research raises troubling fresh questions about the sources and effects of mercury contamination present in water and fish in many parts of the country. The results of Harada's study are particularly sobering for aboriginal people who depend on a diet rich in fresh fish. It had been expected that the health of First Nations people on the Grassy Narrows and White Dog reserves near Kenora would improve after a mill stopped dumping mercury in the English and Wabigoon river systems in 1970. But when Harada returned to the area last fall, he found evidence of continuing, pervasive health problems consistent with Minamata disease, a neurological disorder caused by mercury. The results of Harada's study have not been published but were summarized by Steve Fobister Sr., deputy chief of ...Grassy Narrows, who has seen them. Of approximately 60 First Nations people who were examined at the Grassy Narrows and White Dog reserves last fall, 70 per cent showed symptoms of neurological disorder, said Fobister. Symptoms included blurred vision, slurred speech, twitching, numbness, shaking, and poor muscle co-ordination. The symptoms of eight people who were part of the study in the 1970s had become more severe.

Fobister says that he himself has serious neurological disease. "I can hardly tie my shoes any more", he said in an interview. Even children in the community are showing serious problems, including seizures, he said. Fobister blames clear-cut logging in the area for the continuing high levels of mercury contamination – a theory for which there is some scientific support, although debate continues. A University of Montreal researcher reported in 2001 that mercury levels were up to 100 per cent higher in heavily logged watersheds than in lakes where there was no logging nearby. The theory is airborne mercury from sources such as coal-fired power plants and incinerators tends to be held in the soil and foliage of an intact forest, but runs into waterways in areas that have been clear-cut. Health Canada is funding a new study of neurological disease in the Grassy Narrows area in the light of the recent research developments. "It is alarming to see there are so many people still suffering neurological symptoms in this community after 30 years", said Laurie Chan of McGill University, who is leading the study.[3]

family....' . Bill Fobister: 'During the '60s, we were in full bloom, fishing, guiding, everything, that we did and we thought everything was okay. But not until we're seeing some of our fish acting weird and dying off, that's when ...there is something wrong.' Bill Fobister: 'My symptoms is my numbness and loss of sensation and my vision. My speech is kind of getting pretty sloppy. My taste, I lost my taste. I lost my smell. I can't smell any more.' Steve Fobister: 'I don't think, you know, it's right to say, look, you know, you don't have to go trapping. You can live on welfare....My whole nervous system is out of whack, you know, I can't barely walk and, you know, I have to hold my jaw to talk because my muscles are practically gone...[As a fishing guide, he] had [to eat what he caught even after the mercury was discovered] We had to do this in order to appease our guests that the fish was ok. The tourist camp owners encouraged us to do it...[Dr. Harada, during his return to Grassy Narrows in March 2010, said to Steve Fobister] 'You know you have some kind of a metal poisoning' And the closest definition to [Harada's] examination...it's got to be mercury'...'I only have one granddaughter. She's the one who kind of possesses violent seizures.' Sherry Fobister: '[Ms Fobister ate fish when she was pregnant]...it's [eating fish] a part of life, you know...I love eating fish. It's a delicacy...it's part of our lifestyle. I don't know, I still eat it to this day. [no one told her not to eat fish when she was pregnant].[6]

AFFIDAVIT OF ANNA WILLOW

I, ANNA WILLOW, of the City of Delaware, in the State of Ohio, in the country of the United States of America, MAKE OATH AND SAY AS FOLLOWS:

1. I hold a master's and a doctorate in anthropology from the University of Wisconsin as well as a master's in natural resources and environment from the University of Michigan. I am currently an associate professor of anthropology at Ohio State University. My professional training and research experience have been in the areas of cultural and

environmental anthropology especially concerning Anishinaabe environmental relationships, uses and values. I have broad experience and expertise concerning boreal forest First Nations peoples and cultures and knowledge about their sociocultural responses to environmental transformations resulting from natural resources extraction. I have conducted multiple independent research projects, including long-term ethnographic participant-observation research at Grassy Narrows First Nation. I also have published a book, numerous peer-reviewed journal articles, professional reports, and delivered numerous papers at conference proceedings in my field of study. A copy of my curriculum vitae is attached to Exhibit "A", below.

2. In February 2015 I was asked by counsel for Grassy Narrows to answer certain questions in a report on the importance of fishing and the consumption of fish as part of the traditional cultural activity and identity of the people of Grassy Narrows First Nation. The questions and my answers to them appear as part of my February 2016 expert report attached as Exhibit "A" to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit "B" to my Affidavit.

SWORN BEFORE ME in the City of Marion, in the State of Ohio, in the United States of America, this ___ day of _____, 2016.

A Commissioner, etc.

_____
Anna Willow

EXPERT REPORT

Grassy Narrows First Nation and Sherry Fobister, William Fobister, Senior, Simon Fobister and Chief Roger Fobister, Senior on their own behalf and on behalf of all other members of Grassy Narrows First Nation v. Minister of Natural Resources and Forestry (Ontario) and Minister of the Environment and Climate Change (Ontario), and the Attorney General of Ontario

I. Area of Expertise and Qualifications

My professional training and extensive research experience qualify me as an expert in the areas of cultural and environmental anthropology, especially concerning Anishinaabe environmental relationships, uses, and values. I have broad expertise concerning boreal forest First Nations peoples and cultures and I am knowledgeable about sociocultural responses to environmental transformations resulting from natural resource extraction. I earned a PhD in Anthropology from the University of Wisconsin (2008). Additionally, I hold two Masters Degrees, one from the University of Wisconsin in the field of Anthropology (2003) and the other from the University of Michigan in the field of Natural Resources and Environment (2001). Since the autumn of 2009, I have been employed at the Ohio State University. I was promoted from assistant to associate professor of anthropology in June of 2015. I have conducted multiple independent research projects, including long-term ethnographic participant-observation research at Grassy Narrows First Nation (which took place mainly from June 2004 to April 2005, with additional shorter visits between May 2003 and August 2007). As my CV (Appendix B) details, I have to date published one book, thirteen peer-reviewed journal articles, and two professional reports in the areas of my expertise. I have also delivered numerous papers at professional conferences in my field of study.

The report that follows combines extensive reviews of published ethnohistorical and social scientific literature with observations and conversations derived from my time at Grassy Narrows First Nation. Some of the material contained in this report is excerpted and adapted from my own previously published works, especially including the following three items:

Willow, Anna. 2012. *Strong Hearts, Native Lands: Anti-Clearcutting Activism at*

Grassy Narrows First Nation. Winnipeg: University of Manitoba Press (Concurrently published in the United States as *Strong Hearts, Native Lands: The Cultural and Political Landscape of Anishinaabe Anti-Clearcutting Activism.* Albany: State University of New York Press).

Willow, Anna. 2011. Conceiving Kakipitatapitmok: The Political Landscape of Anishinaabe Anti-Clearcutting Activism. *American Anthropologist* 13(2):262-276.

Willow, Anna. 2009. Clear-cutting and Colonialism: The Ethnopolitical Dynamics of Indigenous Environmental Activism in Northwestern Ontario. *Ethnohistory* 56(1):35-67.

II. Instructions, Nature of Opinion Sought, and Questions

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association to prepare an expert report that answers twelve questions. The primary purpose of this report is to describe the importance of fishing and the consumption of fish as part of the traditional cultural activity and identity of the people of Grassy Narrows First Nation. My answers to the questions are contextualized by my anthropological understanding of Grassy Narrow First Nation's cultural and geographic affiliation, Anishinaabe subsistence patterns of the past and present, and broader patterns of human-environment relationships among the indigenous peoples of the Canadian boreal region. The report documents the ongoing relevance of traditional Anishinaabe culture, the importance of fishing as a form of land-based subsistence, and the continuing cultural impacts of mercury contamination.

I was provided with and asked to review four relevant documents (Item A):

A. The Grassy Narrows-Earthroots request, dated January 2014, of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May, July, September and November 2014 insofar as they relate to your area of expertise and the subject matter for your report.

B. The Lovisek Report, dated June 2008.

C. *Keewatin v. Ontario*, 2011 selected factual findings from the trial judgment pertinent to your report (Exhibit "A").

D. Ontario Ministry of Natural Resources and Forestry approved 2012-2022 Forest Management Plan for the Whiskey Jack Forest.

I was also asked to answer twelve questions in four general areas. I list the twelve questions here and include my summary and full detailed answers—along with reasons for those answers—in the subsequent section.

A: General

1. For the documents referred to in item A, above, please indicate if the views expressed in those documents that relate to the subject matter of this report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your report the corrections that should be made with respect thereto. In responding to this question, please also address the questions that follow.

B: Historical Importance of Fishing

2. What factual findings are made in the 2011 trial judgment of Keewatin v. Ontario, if any, that are relevant to the subject matter of your report respecting:

a. The traditional activities the ancestors of Grassy Narrows engaged in with respect to the Grassy Narrows Homeland/Traditional Land Use Area ("TLUA") before and following their signing of Treaty No. 3?

b. The definition of the historical seasonal round of Grassy Narrows and, in particular and to the extent not discussed in response to question 2(a) above, the historical importance of fishing to the culture, sustenance, and economy of Grassy Narrows?

3. If not answered in response to question 2(b) above what has been the historical importance of fishing, if any, to the culture, economy, and sustenance of the people of Grassy Narrows?

C: Contemporary Importance of Fishing

4. How important today is fishing to the culture, economy, and sustenance of the people of Grassy Narrows and, if not discussed in response to questions 1, 2, or 3 above, the relationship of the TLUA of Grassy Narrows to the Whiskey Jack Forest?

5. Which fish species are eaten by the people of Grassy Narrows, from which geographic areas, and why? In particular, what traditional factors, if any, apply to the bodies of water, and fish species a member of Grassy Narrows may fish for in the area?

6. What role, if any, does fishing play in the identity and society of the people of Grassy Narrows? Is this role different, and if so how, from non-aboriginal Canadian society in the region, and from the urban aboriginal population in the region?

7. Taking into account your responses to the above questions regarding the importance of fishing and the consumption of fish caught, how effective have been measures used by the federal or provincial governments, such as consumption advisories and the provision of freezer fish, in protecting the people of Grassy Narrows from mercury impacts? Please explain your answer.

D: Impacts of Mercury Exposure on the Culture and Community of the People of Grassy Narrows

8. What has been the impact of past mercury exposure from industrial discharges on the culture and community of Grassy Narrows, and what inferences can be drawn from this history when considering future activities, such as clear-cut logging, and whether they could introduce new sources of mercury exposure through fish consumption?

9. If not answered in response to question 8 above, what have been the community level psychological impacts of past mercury exposure from industrial discharges on the people of Grassy Narrows and what additional community level psychological impacts are currently experienced or anticipated from planned future activities, such as clear-cut logging, and whether they could introduce new sources of mercury exposure?

10. Are the impacts at the community level in Grassy Narrows from past mercury exposure, and those anticipated in future from new sources of mercury exposure, experienced differently by gender and age and, if so, how?

11. If not answered in response to questions 8, 9 and 10 above, how does the experience at Grassy Narrows compare with the documented experience of other aboriginal communities that have faced environmental contamination problems?

12. What community level responses have occurred in response to past mercury exposure, and what community level responses are possible in future to activities that could add mercury to bodies of water used by the people of Grassy Narrows for fishing and other traditional pursuits?

III. Summary and Full Answers to Questions and Reasons for Opinions

In this core section of the report, I provide both summary and full answers to the questions I was asked to consider and explain the reasons—based on my review of the relevant literature and on observations made as a trained anthropological observer—for my opinions.

A: General

1. For the documents referred to in item A, above, please indicate if the views expressed in those documents that relate to the subject matter of this report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your report the corrections that should be made with respect thereto. In responding to this question, please also address the questions that follow.

Summary Answer:

Regarding all of these documents, I agree with the information that is within my area of expertise to assess. I found no errors related to the subject matter of this report.

Full Answer:

A. The Grassy Narrows-Earthroots Request

Concerning the Grassy Narrows-Earthroots request of January 2014 for individual environmental assessment (IEA) and its subsequent supplementary submissions, I agree with the information that is within my area of expertise to assess and found no errors related to the subject matter of this report. I am not qualified to offer an expert opinion regarding the effects of clearcutting on mercury levels, nor on its implications for wildlife or human physiology. I would like to reiterate the importance and accuracy of several of the points contained in the Grassy Narrows-Earthroots submissions as they relate to my area of expertise:

1. The initial request (dated January 22, 2014) draws attention to the fact that the English and Wabigoon watersheds and their Aboriginal residents have already experienced serious harm as a result of mercury contamination (p. 1, p. 22). Because impacts on indigenous subsistence and culture are cumulative in nature, any future activities that could adversely impact the subsistence and culture of First Nations residents must be considered in this light.

2. The initial submission states that fish caught in the waters surrounding Grassy Narrows and consumed by community residents already have mercury levels that are above or approaching limits for safe human consumption (p. 6). This has long been the case and is well-known among environmental management professionals and environmental social science researchers in Canada.

3. The initial submission states that Grassy Narrows has consistently objected to the OMNRF's planning process (p. 10). Based on my experience at Grassy Narrows, I can attest to community members' long-term concern with the planning process, with public objections dating back to the late 1990s and internally-voiced complaints possibly extending further back in time. As described below, the residents of Grassy Narrows have also expressed specific concerns about mercury contamination for many years.

4. The initial submission points out that the people of Grassy Narrows have experienced multiple, mutually-compounding industrial activities that have been harmful to their health, culture, and livelihood (p. 22). Based on my knowledge of the case, I know this to be accurate.

5. The September 8, 2014 supplementary submission states that people at Grassy Narrows continue to perceive the risk of mercury pollution to be high, that sufficient levels of communication and trust have not been developed between Grassy Narrows residents and scientific/health professionals, and that the detrimental consequences of mercury contamination extend beyond its effects on physical health (p. 5). The report that follows supports and elaborates on these points.

6. The supplementary submission dated November 14, 2014 states that the impacts of mercury have been disproportionately experienced by those Grassy Narrows residents who practice a traditional way of life that includes fishing (p. 5). I agree with this point and elaborate on its significance below.

7. I agree with the points set out in the supplementary submission dated November 14, 2014 regarding the inappropriate nature of sports fishing consumption guidelines for First Nations peoples (p. 10-11) and the general importance of fishing for the people of Grassy Narrows (p. 18-19). I elaborate on these topics below.

B. *Keewatin v. Ontario,* 2011: Selected Factual Findings from the Trial Judgment Arising from the Lovisek Report

Regarding the Lovisek Report, dated June 2008, I found the material that is within my area of expertise (Anishinaabe ethnohistory and subsistence) to be accurate.

It is noteworthy that the ability to access and utilize the region's rich fisheries was viewed as especially important by Anishinaabe negotiators to Treaty Three, so much so that Commissioner Simon Dawson noted the following in his report:

> I am in a position to say that, as an inducement to the Indians to sign the Treaty, the commissioners pointed out to them that, along with the land reserves and money payments, they would forever have the use of their fisheries. This point was strongly insisted on and it had great weight with the Indians, who for some years previously had persistently refused to enter into any Treaty (Dawson 1873:50; cited on p. 161 of the Lovisek report).

Twine for the manufacture of fishing nets, Lovesick accordingly points out, was a key Saulteaux demand (p. 87, 91, 119). In short, when Anishinaabe negotiators signed Treaty Three in 1873, they did so with the confidence that their people would retain the ability to utilize the region's rich fisheries as a healthy and traditional dietary staple. For Anishinaabe people today, the ability to access and safely consume fish and other traditionally harvested resources throughout their customary Land Use Area (or traditional territory) remains extremely important.

One way in which I diverge with Lovisek is not a matter of accuracy, but one of preferred ethnonym. Because it is their own self-designation, I use the terms *Anishinaabe* and *Anishinaabeg* (plural) throughout this report to refer to the Aboriginal people also known in the literature as Ojibwe/a, Ojibway, and Saulteaux. This reflects our different disciplinary backgrounds (ethnohistory vs. cultural anthropology) and temporal research emphasis (historical documents vs. contemporary speech). Where I cite the work or documents of others, I use the term found in the original.

I also agree with the three selected excerpts that were identified as pertinent to this report (paragraphs 475, 772, and 773), reproduced here:

> [475] Lovisek gave evidence that in 1873, the Ojibway were primarily concerned about preserving their way of life, including their right to continue hunting, fishing and trapping as in the past. They valued their seasonal round, the pursuit of their livelihood through traditional harvesting. Their culture and

> identities were intimately connected with hunting, trapping, fishing and harvesting wild rice as their ancestors had done since time immemorial.
>
> [772] The Treaty 3 Ojibway loved their lives and their country (Lovisek, November 16, 2009 at p. 39). They relished their way of life, including their seasonal round of trapping, hunting, fishing and harvesting over the breadth of their territories. They valued their customs and were not prepared to give them up….
>
> [773] I accept the evidence of Lovisek…that they were prepared to embrace a Euro-Canadian presence **only** if it would be compatible with their cherished way of life, and would not cause serious interference with their hunting, fishing and trapping – central aspects of their distinctive culture central to their identity.

Furthermore, I found accurate and relevant information in the trial judgment regarding the Ojibway seasonal round (paragraphs 229-230, 1153, 1158-1164) and the assumed compatibility of Aboriginal and Euro-Canadian uses of the land (paragraphs 913, 1233). These paragraphs are reproduced in Appendix C of this report.

D. 2012-2022 Forest Management Plan for the Whiskey Jack Forest

Silviculture and forest management planning are outside my area of expertise and I am not qualified to identify inaccuracies in this area. However, as an anthropologist concerned with the sociocultural elements of systems that include both ecological and human components, I note the following matters relevant to my report:

> 1. There is no mention in the Forest Management Plan of the previous opposition of Grassy Narrows First Nation members to clearcutting within their Traditional Land Use Area (traditional territory), which has included high-profile direct action protest as well as sustained opposition to the forest management planning process itself. The Plan notes that "Abitibi surrendered the Whiskey Jack Forest SFL to MNR in 2009" (p. 18), but the context of that surrender (which was informed, among other factors, by years of protest by members of Grassy Narrows First Nation and the entry into a memorandum of understanding to initiate formal negotiations to resolve the ongoing dispute) is not mentioned in any manner. This lack is again conspicuous on pages 109-111 in the Forest Management Plan's very general section on Aboriginal Interests.
>
> This contrasts with an independent audit that notes that a separate process is now underway to address Grassy Narrows community members' concerns about forest management. The independent audit supports Grassy Narrows First Nation's view that the Forest Management Planning process, as currently practiced, does not constitute

adequate consultation. The *Whiskey Jack Forest Independent Forest Audit, 2004-2009* draws attention to "fundamental differences in the viewpoints between GNFN and MNR regarding forest management principles and practices" and goes on to state:

> "it is the audit team's opinion that these differences cannot be resolved without the Province setting aside many of the requirements to manage the Whiskey Jack Forest under the CFSA and the FMPM, and relinquishing significant authority to the First Nation to manage portions of the Whiskey Jack Forest according to the desires of the GNFN community. The audit team further believes that the forest management planning process did not anticipate, nor was it designed to resolve the type of dispute currently being experienced on the Whiskey Jack Forest" (KBM Forestry Consultants 2010:7).

2. The Plan notes that 84% of the area in question falls into the category of "Managed, Crown land" (p. 20). While this is technically accurate, there is no mention of the fact that this overlaps considerably with the area Grassy Narrows residents understand to be their Traditional Land Use Area or traditional territory.

3. Although the region's important fisheries resource is discussed (p. 68-70), there is no mention of mercury in the report. First Nations fishing is discussed briefly (p. 102), but the English-Wabigoon River's serious mercury problem is not noted. This is especially concerning because the contamination case is well-known in northwestern Ontario and among environmental and social science researchers across Canada.

4. The Plan includes summaries of the demographic profiles of communities that "receive significant social and economic benefits from the Whiskey Jack Forest" (p. 86), but does not acknowledge the possibility that these communities might also face significant social and environmental risks or harms as a result of the activities described in the Forest Management Plan. While the concept of "net impact" is recognized with regards to recreation and tourism (p. 218), there is no explicit consideration of the possibility that Aboriginal communities could be adversely impacted by forestry activities. This is in spite of the fact that supplementary documentation in the Plan itself acknowledges that "subsistence hunting, fishing, and gathering of resources from within the forest are an integral part of community existence" (p. 26).

5. While wildlife habitat, visual aesthetics, tourism agreements, and fuelwood are included in the Plan's Harvest Selection Criteria (p. 187-189), Aboriginal Interests are not.

B: Historical Importance of Fishing

2. What factual findings are made in the 2011 trial judgment of Keewatin v. Ontario, if any, that are relevant to the subject matter of your report respecting:

a. The traditional activities the ancestors of Grassy Narrows engaged in with respect to the Grassy Narrows Homeland/Traditional Land Use Area ("TLUA") before and following their signing of Treaty No. 3?

Summary Answer:

Factual findings from the trial judgement concerning the acknowledged importance of subsistence harvesting at the time of the Treaty are relevant to the subject of this report. Treaty commissioners knew that traditional harvesting—specifically including fishing—was essential to Anishinaabe people.

Full Answer:

In addition to the selected excerpts noted above, the following additional findings in the *Keewatin v. Ontario* judgment are relevant to the historical importance of fishing at Grassy Narrows First Nation:

1. It was widely understood by the Treaty Three Commissioners that traditional harvesting was of the utmost importance to the Anishinaabe and that they would be unlikely to agree to a treaty if harvesting was not protected. As stated at Paragraph 747, "All three Treaty Commissioners understood the importance of harvesting to the Ojibway and therefor the importance of promising continuing Harvesting Rights to induce the Ojibway to enter into the Treaty."

2. The judgment accepts that the Treaty Commissioners knew most of the Treaty Three area was unsuitable for agriculture. They were aware of the general pattern of Anishinaabe subsistence and expected it to continue. Along these lines, paragraph 750 states that "Morris made it clear to the treaty 3 Ojibway that he expected their gardening <u>to supplement, not replace</u>, their traditional harvesting." Similarly, paragraph 759 states, "…from Canada's perspective, the continuation of the hunting, trapping and fishing rights was important to ensuring that the Ojibway did not become dependent upon relief or welfare delivered by the Department of Indian Affairs"

b. The definition of the historical seasonal round of Grassy Narrows and, in particular

and to the extent not discussed in response to question 2(a) above, the historical importance of fishing to the culture, sustenance, and economy of Grassy Narrows?

Summary Answer:

Factual findings concerning the centrality of fishing to the Anishinaabe seasonal round are relevant to the subject of this report. Fishing was historically—and remains today—a staple subsistence activity at Grassy Narrows First Nation.

Full Answer:

Findings relevant to the historical seasonal round, especially fishing, are also present in *Keewatin v. Ontario:*

1. Paragraph 229 gives a broad overview of the Anishinaabe subsistence strategy, emphasizing seasonal mobility and adaptability to the availability of diverse boreal forest resources. The following paragraph (Paragraph 230) quotes a letter from Simon Dawson to the Minister of Public Works (dated December 19, 1870) which states that in summer, "the grand occupation is fishing, and this is to them the happiest season of the year" and goes on to broadly but accurately describe the activities undertaken in each season.

2. While not specific to the people of the English-Wabigoon River region, Paragraph 1053 describes complaints following Treaty Three made by Anishinaabe leaders of the Rainy River, Rainy Lake, and Seine River Bands who were in 1909 experiencing opposition to their traditional subsistence activities. The loss of hunting grounds and interference by outsiders with hunting is noted. Regarding fishing, the1909 petition includes the following statement: "We also wish to Fish for ourselves all the year and no reserve seasons for us. It's our daily food."

3. The evidence of William Fobister (Paragraphs 1153-1164) presents an accurate description of recent historical Anishinaabe subsistence patterns. Fobister describes the early summer gardening season at the pre-relocation Reserve, the summer blueberry harvest, the late summer wild rice harvest, the garden harvest, travel to the winter trapline, and the hunting and trapping of autumn and winter. The judgment also notes based on Fobister's evidence, which states:

   > "The Grassy Narrows people fished for their own consumption and for sale to others until 1970, when mercury poisoning was discovered in the Wabigoon and English River system and adjacent lakes. Fish were

declared unsafe to eat. Fishing ended. The tourist industry, formerly the main employer in the area, collapsed. Welfare was introduced for the first time" (Paragraph 1173).

I believe this assessment to reflect what Fobister witnessed in the early 1970s. Today, however, many people at Grassy Narrows do continue to fish for their own subsistence, in ways and for reasons that are outlined below. Commercial fishing continues to be curtailed by contamination. Guiding for the tourist industry, although less significant than prior to mercury contamination, continues to employ some Grassy Narrows residents. Grassy Narrows members now work as fishing guides employed by Ball Lake Lodge and Grassy Narrows Lodge, both which are owned by the Grassy Narrows band. There also exists at least one independent family-owned guiding business.

4. The trial judge acknowledges that "In the case of the Grassy Narrows Ojibway, the life of Fobister is illustrative of the continuing reality that they were still pursuing the seasonal round without significant Euro-Canadian influence, at least into the 1960s and that Euro-Canadian uses and traditional harvesting were compatible" (Paragraph 1233).

3. If not answered in response to question 2(b) above what has been the historical importance of fishing, if any, to the culture, economy, and sustenance of the people of Grassy Narrows?

Summary Answer:

Since time immemorial, fishing has provided a primary source of food for Anishinaabe residents of Grassy Narrows and the surrounding region. Historically, it was an essential component of Grassy Narrows First Nation's economy as well as an important aspect of Anishinaabe cultural life.

Full Answer:

Fishing has been a significant activity and a staple source of food for countless generations of Grassy Narrows citizens. In both the traditional hunting-gathering economy and the more recent mixed economy, the role of fishing is central. Historically, fishing was an essential component of the seasonal round, with summer activities revolving around fishing and seasonal residence locations chosen based on proximity to productive fishing grounds. When reminiscing about times on the trapline in decades past, Grassy Narrows elders speak of fishing with nets (with walleye and northern noted as the main edible catch) as a principal activity. Beginning in the 1940s and continuing until the 1970 discovery of mercury, commercial fishing also became an

important source of wage labor income for Grassy Narrows residents. Employment of community members as fishing guides for the tourist industry began in the same period and continues today.

Prior to Euro-Canadian interference, Grassy Narrows Anishinaabeg lived a semi-nomadic lifestyle, moving within their homeland according to seasonal patterns of resource availability. In northwestern Ontario, the traditional Anishinaabe land-based seasonal subsistence cycle (or "annual round") (see Densmore 1979 [1929], Danziger 1979) shared many similarities with that observed in other parts of the North American subarctic. Through December, January, February, and March, primary subsistence activities included ice fishing and the trapping of furbearers. With families dispersed for the season, some opportunistic large game hunting also took place in the winter. In late April and early May, waterfowl returning to boreal forest lakes or passing through along their migration routes to more northerly destinations offered a welcome source of food. As soon as the ice broke up, people began fishing the waters of the English-Wabigoon River, often concentrating their earliest efforts on rapids or known spawning zones. From its commencement in May until the waters turned icy with fall, open water fishing was the dominant subsistence activity. With many families gathered together at prime fishing locations, summer was also the most social of the seasons. Late summer was a time of particular bounty. In August, Anishinaabeg picked several varieties of berries and harvested the annual crop of wild rice. Both resources, together with dried meat and fish, were processed for storage in underground caches. With fall's arrival, hunting for migratory waterfowl once again became a central activity. Large mammals—moose, white-tailed deer, and bear—were hunted most intensively in the autumn months. As fall gave way to winter, families once again dispersed, resuming trapping and recommencing the annual cycle.

Throughout most of the eighteenth and nineteenth centuries, Anishinaabe people moved within their homeland according to the seasons and the demands of the fur trade (see *Keewatin v. Ontario* paragraph 230). Family and extended family groups traveled with the seasons and land-based subsistence was the core of economic life (Hickerson 1970). Over time, particular groups became associated with specific trading posts operated by the Hudson Bay Company, where they traded furs for firearms, steel traps, cloth, and other provisions each spring and often remained to fish through the summer months. One of these posts, located just up the English River from present-day Grassy Narrows at Lac Seul, attracted a loose confederacy of Anishinaabe families (Shkilnyk 1985). At the time Treaty Three was signed in 1873, the Anishinaabeg gathered at Lac Seul were under the traditional hereditary leadership of Chief Sakatcheway. In the years following the Treaty, the government established reserves for each group of signatory Indians. In 1882, the people associated with Lac Seul were divided into the two groups that became Grassy Narrows and the smaller Wabauskang First Nation. The two communities remain closely linked today through ties of family and friendship.

Participation in the fur trade implied the emergence of a mixed economy (i.e., a living made through a combination of traditional land-based subsistence and wage/cash income) but in no way undermined the forest-based way of life. Anishinaabe people continue to hunt, fish, and gather as in generations past. Through the first half of the twentieth century, people from Grassy Narrows sold furs and blueberries for cash and a handful participated in various types of wage labor, but the bulk of the community's subsistence still came directly from the forest and from the region's lakes and rivers. A small Hudson Bay Company store operated on the Old Reserve (the common term used to denote the pre-relocation community), but its limited inventory and high prices meant that Grassy Narrows residents purchased only basic supplies—equipment to facilitate land-base subsistence, flour, sugar, and lard—regularly. The people of Grassy Narrows remained highly mobile and spent most of their winters out on their traplines. Contacts with non-Native Canadian society in this era were limited to semi-annual visits from Indian Health Service doctors and ceremonial Treaty Day visits from an Indian Agent and RCMP officer (Shkilnyk 1985).

It was only in the late 1940s that wage labor came to play a significant role in Grassy Narrows First Nation's local economy. Following World War II, a businessman from Minnesota built a luxurious lodge on Ball Lake, located several kilometers upriver from Grassy Narrows. From that time on, men from the First Nation community participated seasonally in a burgeoning tourism industry, working as fishing guides for wealthy anglers. Commercial fishing was also economically important in this period.

C: Contemporary Importance of Fishing

4. How important today is fishing to the culture, economy, and sustenance of the people of Grassy Narrows and, if not discussed in response to questions 1, 2, or 3 above, the relationship of the TLUA of Grassy Narrows to the Whiskey Jack Forest?

Summary Answer:

Fishing remains essential to the culture, economy, and sustenance of Grassy Narrows First Nation residents. As a key component of a land-based Anishinaabe way of life, fishing overlaps with many other traditional activities and reinforces enduring ties the community's Traditional Land Use Area.

Full Answer:

Fishing remains a very important part of life at Grassy Narrows and must be understood as a key component of a land-based way of life which also includes many other complementary activities. The economy and diet experienced by contemporary Grassy Narrows residents differs from that of past generations, yet First Nation members' land-based subsistence activities diverge more in

quantity than in quality from the historical pattern described above. Every family group still includes individuals who hunt, fish, and/or trap. Many community members continue to gather each season's characteristic wild resources despite the social and economic upheavals of the past fifty years (i.e., relocation and road construction in the 1960s, mercury contamination in the 1970s, clearcut logging in the 1990s and beyond). Furthermore, those who are unable to participate regularly in land-based subsistence eagerly await traditional products shared by others and maintain genuine respect for community members who engage frequently in traditional subsistence pursuits.

At Grassy Narrows today, trapping remains the dominant cold-season subsistence activity, although ice fishing also takes place during the winter. Grassy Narrows trappers hold over 30 registered traplines scattered throughout the Traditional Land Use Area surrounding the community. Travel to and within traplines usually occurs by snowmobile and trips are usually completed in one day, although some trappers maintain cabins that make longer stays feasible. In these cases, people fish and hunt for much of their food during their time out on the trapline. In addition to registered trapline holders, official "assistants" and younger relatives frequently accompany trappers in order to develop their own skills. The most commonly sought furbearers include beaver—trapped not only for fur but also as a food source—and members of the weasel family: pine marten, river otter, fisher, mink, and wolverine. Red fox, lynx, wolf, and muskrat are also trapped periodically. Trapping provides supplementary income for many Grassy Narrows families.

In late summer, people at Grassy Narrows eagerly await the ripening of two important wild foods: wild rice and blueberries. The availability of these resources varies according to weather conditions. Additionally, a large portion of the region's wild rice remains at the mercy of the dams that now constrain the English-Wabigoon River system; if water levels are raised while the rice is still in its vulnerable floating leaf stage, an entire harvest can be damaged beyond recovery. If, however, conditions have been favorable, both crops can be remarkably rich. Harvesting wild rice requires access to a boat and considerable skill, but a handful of Grassy Narrows residents collect the aquatic grain each year and share the products of their labor widely. Abundant and accessible, hundreds of First Nation residents take part in the seasonal harvest of wild blueberries.

In the fall—and to a lesser extent throughout winter and into early spring—First Nation members hunt moose and white-tailed deer by firearm. Most frequently, two or three people set out together in the morning or evening, hunting with the aid of a boat or vehicle for transportation. Meat from these large animals is shared widely while fresh and frozen for consumption throughout the year. In both fall and spring, migratory waterfowl are also harvested.

Despite anxiety about mercury and other toxic substances, fishing is the dominant warm-season subsistence activity and is undertaken by Grassy Narrows residents of all ages on waterbodies

throughout the Traditional Land Use Area, including the English-Wabigoon River and its constituent lakes as well as headwater lakes. Men, women, and children fish with rod and reel (this usually means jigging from boats or casting from the rocky shoreline with inexpensive jigheads and rubber lures) and some gather to snare fish with wire during the spring spawning season. In spring, people travel long distances by truck to reach areas of moving water (i.e. rapids) which are already free of ice and where they can fish from shore.[1] In summer, those who are able travel by truck and car to widely scattered sites that are known to be productive shore-fishing sites and by boat to numerous productive locations away from shore. Nets are set for the procurement of fish in both the summer and winter seasons and are especially important when a large number of fish are needed for a feast event.

In addition to the consumption of fish for household-level subsistence, some individuals at Grassy Narrows earn money through participation in fishing-related labor, although the commercial fishery and guiding industries are smaller than they were prior to the 1970 announcement of mercury contamination. The continuing significance of commercial fishing income and the continuing severity of mercury contamination in the waters of the English-Wabigoon River system are both substantiated by the 2006 conviction of a Grassy Narrows First Nation commercial fisherman who attempted to sell "tainted" fish caught in Grassy Narrows Lake to a fish processing plant in Kenora. The charged individual held an approved license for commercial fishing on Oak Lake, located north of Grassy Narrows within the community's Traditional Land Use Area (Kenora Daily Miner and News 2006). Statistics Canada data from 2006 indicate that of 415 individuals at Grassy Narrows over the age of 15, 75 were in the labor force but unemployed and 195 were not in the labor force. The official unemployment rate of 33.3% does not account for the numerous individuals who have removed themselves from the search for employment. The same data set shows that of the 190 individuals included in the experienced labor force, 70 listed sales and service as their occupation, which would include fishing and guiding.[2]

Although a large portion of food consumed at Grassy Narrows now comes from the supermarkets of Kenora, it would be highly erroneous to assume that wild foods are inconsequential for sustenance. Indeed, wild foods—especially including fish—are the most valued part of contemporary Grassy Narrows residents' diet. Wild foods are viewed as more nutritious than store-bought foods, especially the highly-processed items typically accessible on a small budget. Fresh foods are unavailable for purchase in Grassy Narrows and obviously non-nutritious convenience and snack items (e.g., chips, soda pop, candy) are ubiquitous in the community, especially among youth and families with children.

[1] Fieldnotes, April 29, 2004.
[2] See http://www12.statcan.gc.ca/census-recensement/2006/dp-pd/prof/92-594/details/Page.cfm?Lang=E&Geo1=CSD&Code1=3560058&Geo2=PR&Code2=35&Data=Count&SearchText=Grassy&SearchType=Begins&SearchPR=01&B1=All&Custom= (accessed April 22, 2015).

For some families in some parts of the year, wild meat, fish, wild rice, and berries complete many meals. While I was in Grassy Narrows, I regularly witnessed (and more frequently heard about) households running out of money and food as the end of the payment month approached. For many Grassy Narrows residents, the experience of scarcity is a recurring, taken-for-granted part of life. Statistics Canada data from 2005 show a median income at Grassy Narrows First Nation of only $6,112, with 66.7% from earned income and 31.9% from government transfers. Grassy Narrows residents have a significantly lower median income than recorded for Aboriginal Ontario residents as a whole ($18,808), as well as a lower percentage of earned income and a higher percentage of government transfers (the figures for all Aboriginal residents of Ontario indicate 77.2% of income from earnings and 16.6% of income from government transfers).[3] For comparison, the mean income for all residents of Canada in 2005 was $30,000 for females and $46,900 for males.[4] Grassy Narrows residents thus look to fish at times when they are unable to afford other foods. Given the high unemployment rate in the community and the fact that welfare payments are insufficient to meet many families' needs, catching fish often means the difference between hunger and satiation. This point is especially important because while other wild foods are unharvestable at certain times of the year, fish are available year round.

Despite its continuing importance, there are several factors that limit First Nation members' participation in time-intensive and geographically-dispersed forms of land-based subsistence. Children, for one thing, must remain close to school. In my time at Grassy Narrows, I heard of a few parents who took their children out of school for a land-based subsistence event they deemed important, but on no known occasion did this extend beyond a day or two. Travel into the bush also requires transportation in the form of a snowmobile, boat, and/or truck as well as the gas to get it there. This requires money. Somewhat paradoxically, the same adults who hold regular jobs are most able to afford such travel, but are often too busy with other demands to undertake it regularly. As described below, local walleye fishing is not limited in these ways.

The people of Grassy Narrows have a close and enduring relationship with a large territory known as the "Grassy Narrows Traditional Land Use Area," which has been occupied by their forbearers since time immemorial (see *Keewatin v. Ontario* paragraph 475). I have viewed the map that shows the "Area of Requestors IEA Request" and found the delineated region to be consistent with my knowledge of the Traditional Land Use Area. Based on historical reports, publications, and my observations of active use, I believe the entire Area of Interest to be included within Grassy Narrows First Nation's area of traditional land use, but also note that this Area does not necessarily include all of land historically and currently utilized by Grassy Narrows First Nation members.

[3] See http://www12.statcan.gc.ca/census-recensement/2006/dp-pd/prof/92-594/details/Page.cfm?Lang=E&Geo1=CSD&Code1=3560058&Geo2=PR&Code2=35&Data=Count&SearchText=Grassy&SearchType=Begins&SearchPR=01&B1=All&Custom= (accessed April 22, 2015).
[4] See http://www.statcan.gc.ca/tables-tableaux/sum-som/l01/cst01/labor01a-eng.htm (accessed October 12, 2015).

For present day citizens of Grassy Narrows, connection to this homeland is enacted through land-based subsistence and comprehended through stories told by living elders of seasonal movements throughout the region and life prior to the community's relocation in the early 1960s. Although considerably overlapped by the OMNRF-designated Whiskey Jack Forest, the Grassy Narrows Traditional Land Use Area is essential for the livelihood and cultural identity of the people of Grassy Narrows. It is the setting in which the vast majority of traditional land-based subsistence takes place and provides a material base on which Grassy Narrows residents are able to learn and live traditional Anishinaabe culture. Fishing is a critical part of these place-based activities and, as noted above, supplementary documentation within the Forest Management Plan itself acknowledges that "subsistence hunting, fishing, and gathering of resources from within the forest are an integral part of community existence" (p. 26).

5. Which fish species are eaten by the people of Grassy Narrows, from which geographic areas, and why? In particular, what traditional factors, if any, apply to the bodies of water, and fish species a member of Grassy Narrows may fish for in the area?

Summary Answer:

Walleye is the favored and most consumed fish species at Grassy Narrows. While Grassy Narrows residents fish throughout their entire Traditional Land Use Area, the English-Wabigoon River system that flows through the contemporary reserve community is the most accessible and, therefore, the most widely utilized and productive source of fish.

Full Answer:

Walleye are Grassy Narrows residents' most often consumed, most favored, and most important species of fish. Especially in the months of open water, walleye are consumed very frequently (the exact frequency depends on the individual or family in question, but most people I came into contact with ate walleye at least once a week and some ate considerably more). Fish species such as trout, whitefish, and pike are also occasionally consumed by Grassy Narrows residents, but much less frequently than walleye. This is partially because not all fish species are found in all areas. Lake trout and whitefish, for example, tend to occur only in cold deep lakes, whereas pike and walleye inhabit relatively warmer and more accessible lakes and rivers. And while walleye are a favored food source, pike are not a desirable food species and are sometimes returned to the water if caught. While walleye can be caught easily with a simple rod and reel—sometimes only steps from most Grassy Narrows residents' front doors—species such as whitefish and trout require a boat and/or net. Given the level of poverty on the reserve, many people do not have consistent access to these items and, compared to walleye, these species are rarely harvested.

Grassy Narrows First Nation members fish on all of the waterbodies within their Traditional Land Use Area. Fishing continues to be an important activity for those who spend time on traplines, with Grassy Narrows residents utilizing of all of the small lakes within their own trapline areas and readily acknowledging that other residents do the same. While smaller headwater lakes that are not fed by the river system are especially important to families who customarily use and/or have registered traplines in their vicinity, several factors—including (1) traditional family use patterns, (2) officially registered (OMNRF) traplines, (3) existing commercial fishing licenses, (4) the availability of vehicles/boats/trailers, (5) knowledge of waterways and their hazards, (6) expertise concerning the harvest of particular species, and (7) the availability of fishing gear—combine to constrain fishing location options. Critically, people at Grassy Narrows are not able to relocate to other fisheries within or outside of their traditional territory if the waterbodies they customarily fish become contaminated, as they now have been for decades. If Grassy Narrows residents were to travel outside of their own traditional territory to harvest fish or other resources, they would require the consent of the First Nation whose territory they seek to utilize. Furthermore, their treaty-guaranteed traditional harvesting rights may not necessarily be protected outside of their own territory.

Grassy Narrows residents are thus limited in the species they can catch due to tradition, taste, knowledge concerning the locations and time of year particular species can be caught, access to sites and required equipment, and proficiency with equipment. While all lakes and rivers are utilized by some residents at some time, the English-Wabigoon River is the most easily accessible body of water to the reserve community. Every home on the reserve is within easy walking distance of the river and fishing from shore can occur even in the absence of prohibitively costly vehicles, boats, gasoline, and specialized equipment. While not the First Nation's only source of fish, the river is thus the most widely utilized and the most productive.

6. What role, if any, does fishing play in the identity and society of the people of Grassy Narrows? Is this role different, and if so how, from non-aboriginal Canadian society in the region, and from the urban aboriginal population in the region?

Summary Answer:

Fishing is an essential component of contemporary Anishinaabe cultural identity as well as an important intergenerational social and educational activity for Grassy Narrows residents. Its deeply emplaced social significance differs from fishing practices and meanings among non-aboriginal Canadians and urban Aboriginal populations.

Full Answer:

The relationship between the harvest and consumption of wild foods is extremely important to Anishinaabe cultural identity, which is critical to community members' collective psychological

well-being. For many people at Grassy Narrows, land-based subsistence is much more than simply a source of livelihood; it is deeply symbolic of a way of life. Anthropologists identify land-based subsistence as the most quintessential aspect of indigenous subarctic peoples' cultural lives. As Paul Nadasdy (2003:63) explains, "to First Nations people living in the Arctic and Subarctic, hunting is synonymous with life itself."[5] Kirk Dombrowski (2001) similarly points out that subsistence is both an identity and a livelihood, both a way of life and a way to live. In the past, the truth of these statements was quite literal. While the transitions of recent decades mean that a mixed economy emphasizing land-based subsistence supplemented with a small amount of wage labor and other sources of monetary income has become a mixed economy in which (at least from a strictly material point of view) the reverse is true, indigenous peoples of the north continue to depend on land-based subsistence for physical as well as psychological sustenance. Like other Aboriginal boreal forest residents, the people of Grassy Narrows hold wild foods—including walleye and other fish, moose meat, venison, beaver, wild rice, and blueberries—in much higher regard than the commodities available for purchase, not only for their nutritional value, but also for the links to cultural identity and healthy-living they imply.

Not only do they consider such items healthier, but the acts of gathering and consuming wild foods are important markers of contemporary Anishinaabe identity. By fishing and trapping, by gathering berries and rice, people at Grassy Narrows are able to forge tangible and embodied connections to their heritage. Critically, land-based subsistence also constructs an affirmative Anishinaabe sense of self and gives people a way to define themselves that breaks free of mainstream society's pessimistic comparisons and categorizations. The devastating poverty of Canada's First Nations has been well documented (e.g. York 1990), even if not fully grasped by the general Canadian public. Although they lament the blatant economic disparities that divide them from their Euro-Canadian neighbors, many Anishinaabe people feel that their cultural, spiritual, and social richness far outweighs their material poverty. Keeping culturally distinct patterns of land-based subsistence alive lies at the core of this perceived wealth.

Given the centrality of fishing to the land-based Anishinaabe way of life, arguments about the inextricability of subsistence, culture, and identity clearly apply to the harvest, consumption, and sharing of fish. As Peter Usher et al. state, "fish are part of the Ojibwa heritage, and like other country food, have meaning beyond simply eating. This meaning lies in the skills, knowledge and labor of obtaining food, as well as the social links which are perpetuated by sharing it. Fish are the end product of a way of life" (1979:11). I concur with Usher et al. on this point and believe it to be just as relevant in the twenty-first century as it was 35 years ago.

At Grassy Narrows today, fishing remains an intensely social activity, with the harvesting and eating of fish both occurring communally. Unlike large-game hunting and trapping (both which require extensive training and supplies), fishing is undertaken by a very large portion of Grassy Narrows First Nation's population. Fishing is a source of pride; a way for any individual of any

[5] Hunting in this statement categorically includes fishing and trapping activities.

age or status to proudly supply food for his or her family. Frequently taking place in intergenerational family groups, fishing is a way of socializing children as well as a vehicle for the fulfillment of culturally distinctive economic bonds and obligations (also noted by Usher et al. 1979:364). Today as in years past, fish are shared widely among Anishinaabe people. In many cases, when an individual catches more than he or she can consume, a portion of the catch is given to family members, friends, and/or elders. Fish are also shared in a larger-scale and more intentional manner as a ubiquitous dish at ceremonial and social feasts.

This is quite different from the role of fishing among members of non-Aboriginal Canadian society in the region. In my experience (which includes significant interactions with Euro-Canadian residents of Kenora, Ontario), non-Aboriginal individuals fish for several reasons. Most often, they fish for sport and recreation. In some cases, non-Aboriginal people do consume and appreciate the nutritional value of the fish they catch. Time spent fishing is seen as a valuable form of social interaction and intergenerational learning by some (but certainly not all) non-Aboriginal fishers. However, there are significant sociocultural differences between non-Aboriginal and Grassy Narrows Anishinaabe fishing behavior. Unlike non-Aboriginals, Grassy Narrows residents associate fishing with attachment to homeland, assertion of cultural rights, and expression of cultural identity; those who maintain such connections are perceived to enjoy a higher level of wellbeing than those who do not. Fish are also less likely to be consumed in social settings or shared in communal feasts among non-Aboriginal citizens. My experience with urban Aboriginal populations is limited to individuals who are affiliated with Grassy Narrows (i.e., people who have relatives at Grassy Narrows and/or have previously lived on the reserve). My general sense is that while urban Aboriginal residents may also experience poverty and fish for subsistence when and where it is possible as well as for family enjoyment, they tend not to experience the deep connections to specific places and the social significance of fishing described above unless it is within the context of their home reserve community.

7. Taking into account your responses to the above questions regarding the importance of fishing and the consumption of fish caught, how effective have been measures used by the federal or provincial governments, such as consumption advisories and the provision of freezer fish, in protecting the people of Grassy Narrows from mercury impacts? Please explain your answer.

Summary Answer:

Measures employed in attempt to limit or replace Grassy Narrows residents' consumption of contaminated fish have been ineffective due to the irreplaceability of distinctive social and cultural values associated with the harvesting of local fish.

Full Answer:

For several reasons, measures taken to limit Grassy Narrows residents' consumption of fish from the English-Wabigoon River have been ineffective, both in the past and the present. Following the discovery of mercury, people at Grassy Narrows had trouble coming to terms with the enormity of the crisis they faced. Throughout the 1970 season, the government attempted to discourage people from eating the contaminated fish. Signs that read "Fish for Fun" in bold letters and featured an image of a fish in a frying pan with an "X" over it were posted at boat landings (Troyer 1977). It didn't take the media long to point out that the Fish for Fun campaign did Native commercial and subsistence fishers no good (CBC 1970). Many of the signs were quickly marked by graffiti or ripped down and none were posted in subsequent years. Most Grassy Narrows residents continued doing what they had always done—eating fish—even after hearing of its potential toxicity.

Few people I spoke with between 2003 and 2005 about the initial announcement of mercury recalled the community's reaction as a dramatic one. Several factors may explain their response (or lack thereof). The river's large and plentiful walleye had long been a favored source of protein. Additionally, fish were one the most accessible remaining sources of wild food on the post-relocation reserve. Compounding these factors, First Nation residents observed as tourists continued to eat their catch with no adverse effects (Hutchison and Wallace 1977). Furthermore, as described above, harvesting and consuming fish made it possible for people at Grassy Narrows to maintain a culturally distinct Anishinaabe identity associated with a land-based way of life.

Today, a disconcerting number of Grassy Narrows residents are able to recite offhand the parts-per-billion (ppb) of mercury in their own bodies.[6] And, as they have now for decades, harvesters continuously weigh the economic and cultural benefits of consuming wild foods against the known physical risks.[7] They struggle to reconcile their desire to retain their land-based way of life with the risks inherent in eating the products of their labor. At Grassy Narrows, fish in the absence of fishing (i.e., the consumption of frozen fish harvested elsewhere and supplied to the community) lack the critical cultural and social connections associated with fish harvested locally by community residents. Connections to cultural identity, history, and socialization derived from the process of fishing cannot be replaced by freezer fish. Nor can the pride of self-sufficiency. If we acknowledge that fishing accomplishes much more than just the production of fish, the choice of many Grassy Narrows residents to continue consuming fish harvested from the contaminated English-Wabigoon River begins to make sense. Some Grassy Narrows residents state that they persist in consuming fresh fish from the river because the available frozen fish are not of the type or quality they are accustomed to. Beyond such matters of preference, however, the profound social and cultural importance (described above) of the harvesting/preparation/consumption process cannot be replaced.

[6] Fieldnotes, June 17, 2004.
[7] Fieldnotes, June 2, 2003.

Even as people at Grassy Narrows remain deeply concerned about the presence of mercury in fish (and potentially in other wild foods) and insist that these risks be minimized, many feel that the benefits of consuming such items thus outweigh the risks. Grassy Narrows residents' reactions to the health risks associated with toxins in the environment highlight the cultural significance of land-based subsistence. Judy DaSilva—a well-known community leader and mother of five children—once expressed her concerns about contaminants at a public forum. An outsider attending the event suggested a simple solution: Why, he asked, didn't they simply stop eating wild foods? Judy had been taken aback. Reflecting on this exchange, she emphatically told me, "It's not just something you quit. It's not just food for us; it's spiritual."[8]

D: Impacts of Mercury Exposure on the Culture and Community of the People of Grassy Narrows

8. What has been the impact of past mercury exposure from industrial discharges on the culture and community of Grassy Narrows, and what inferences can be drawn from this history when considering future activities, such as clear-cut logging, and whether they could introduce new sources of mercury exposure through fish consumption?

Summary Answer:

The effects of past mercury exposure at Grassy Narrows have been severe and have included serious health problems, challenges to traditional subsistence and cultural identity, economic hardship, and social strain within the community. Newly introduced mercury would exacerbate these detrimental effects.

Full Answer:

Until the discovery of mercury in 1970, the local fishery was central to Grassy Narrows First Nation's economic production, supplying household subsistence as well as commercial fishing income (Usher et al. 1979:364). The original request for Individual Environmental Assessment more fully describes the history and health impacts of mercury contamination at Grassy Narrows. Based on my knowledge of the case, I agree with these submissions. The mercury originated in effluent released by a factory located in far upstream Dryden, Ontario. From 1962 to 1970, roughly 20,000 pounds of the substance entered the river and followed its gradual northwesterly course (Erickson and Vecsey 1980; Shkilnyk 1985; Troyer 1977). As the water flowed on, anaerobic bacteria in the riverbed transformed the mercury from the comparatively benign inorganic compound released by the plant into a deadly bioaccumulating form. Already facing

[8] Fieldnotes, January 29, 2005.

the detrimental impacts of relocation, mercury contamination was a major blow for the community.

After relocation, the community's transition from a relatively independent, subsistence livelihood to participation in the wider wage labor economy accelerated. Citizens of Grassy Narrows depended on the river more than ever before for their living, with a majority of the First Nation's employed population earning wages either in the local commercial fishery or in the tourism and guiding industry. These economic opportunities evaporated after the discovery of mercury. By the spring of 1970, fish from ten lakes within the English-Wabigoon River system—including Clay, Ball, Indian, and Grassy Narrows Lakes—were deemed unsafe for consumption. Almost overnight, unemployment at Grassy Narrows jumped from twenty to eighty percent due to mercury related job losses (Troyer 1977) and an estimated ninety percent of men in the community were out of work (Erikson and Vecsey 1980). The welfare economy tightened its grip on the people of Grassy Narrows, so that by 1977 the community was economically dependent upon steadily increasing transfer payments from the Canadian government, with 37.2 percent of all income deriving from unearned sources and the government functioning as the community's principal employer (Shkilnyk 1985:148).

Significant physical, economic, and psychological (described below) repercussions of mercury contamination continue to this day. I am not trained to trace the pathways of mercury through ecological systems, but based on what I know regarding (1) mercury's bioaccumulation and persistence over time, (2) the sound science linking clearcutting to increased levels of mercury in waterways, (3) the specific history of adverse impacts in the English-Wabigoon River region, and (4) the cumulative effects of numerous additional threats to the Anishinaabe way of life, any activity that increases mercury levels in the traditional diet of Grassy Narrows Anishinaabeg will have serious detrimental impacts. These impacts may entail enduring health effects for adult residents, lives curtailed by health problems for today's children, and anxiety for the health of those who are not yet born. Collective consequences may also include continued affronts to traditional subsistence and cultural identity, economic hardship, and mounting frustration over a long-term problem left inadequately unaddressed.

Two key facts make Grassy Narrows First Nation's case unique. First of all, the historical and contemporary pattern of land-based subsistence—which includes as its centerpiece the practice of fishing on the English-Wabigoon River—must be taken into consideration. Second, the people of Grassy Narrows have been forced to face the persistent physical and cultural impacts of mercury contamination for 45 years. In other words, citizens of Grassy Narrows not only rely on fish and other wild foods as a crucial component of their diet and essential element of their culture, but they have also been previously exposed to mercury. For these reasons, a healthy future for the people of Grassy Narrows and for generations yet to come requires that industrial activities do not increase mercury levels in the fish harvested by Grassy Narrows First Nation residents.

9. If not answered in response to question 8 above, what have been the community level psychological impacts of past mercury exposure from industrial discharges on the people of Grassy Narrows and what additional community level psychological impacts are currently experienced or anticipated from planned future activities, such as clear-cut logging, and whether they could introduce new sources of mercury exposure?

Summary Answer:

Due to the presence of mercury in the English-Wabigoon River system, residents of Grassy Narrows have experienced substantial fear and anxiety for their health. Cultural beliefs about reciprocal relationships between Anishinaabe people and non-human components of the environment and the perceived ability to live a traditional way of life have been jeopardized.

Full Answer:

The impact of mercury contamination was both cultural and material; to this day, the once sustaining English-Wabigoon River is perceived by some Grassy Narrows residents as a "river of poison."[9] I agree with previously submitted material stating that the experience of mercury poisoning has caused serious psychological problems among Grassy Narrows residents, especially including fear and anxiety (noted in Supplementary Submissions, based on Donnan 1986), but also confusion, grief, suspicion, and anger. While I am not a psychologist, it is within my disciplinary area of expertise to document shared socio-cultural trauma. Community-level effects that follow a distressing event or process often result in what Kai Erikson calls *collective trauma*, described as "a blow to the basic tissues of social life" (Erikson 1976:154). Such trauma has undoubtedly occurred at Grassy Narrows First Nation. I also find Usher et al.'s assessments to be both correct and highly relevant today; Usher et al. conclude that mercury pollution stands out as a major event in the First Nation's history, one "which eliminated a central economic activity and a major source of income, and endangered health and aroused anxiety in regard to the same" (Usher et al. 1979:368).

On page 23 of this report, I stated that most Grassy Narrows residents I talked to between 2003-2005 did not recall the initial announcement of mercury as a dramatic event. Over time, however, Grassy Narrows residents began to correlate the unusual medical symptoms they and their loved ones had suffered in recent years with the presence of *pijibowin*—poison. In the fall of 1972, Tom Strong, a forty-two-year-old trapper and fishing guide, died unexpectedly (Hutchison and Wallace 1977). Although Strong had always been healthy, he began to experience slurred speech, weight loss, and chest pains in the summer of that year. He was camped with his family harvesting the annual crop of wild rice when he died of an apparent

[9] Fieldnotes, September 1, 2004.

massive heart attack. In the same year, a boy was born to a fishing guide and his wife with what looked like a full-blown case of acute mercury poisoning, also known as Minamata disease. It was not lost on Grassy Narrow residents that, in both cases, the victims and their families were heavy consumers of fish.

Erikson and Vecsey made the following observation regarding mercury poisoning at Grassy Narrows:

> The discovery of mercury in the local waters has presented a psychological and perhaps even spiritual problem, for the apprehensions and uncertainties that follow such a discovery can affect the mind as surely as the poison itself can affect the body. This process is a subtle one and difficult to document, but it takes the form of a pervasive fear that the world of nature and the world of men are now contaminated and can no longer be trusted in the old way (1980:159).

At Grassy Narrows, the cultural consequences of mercury contamination were substantial. People at Grassy Narrows felt powerless to control their situation. Their customary comprehension of human-environment relationships taught that respectful reciprocity with powerful "other-than-human persons" was necessary to the achievement of *bimaadiziwin*—a good life free of illness and misfortune (Hallowell 1975, 1992; Nesper 2002).[10] But mercury contamination defied patterns of explanation and order that had served them well in their boreal forest homeland for hundreds of years. Human beings, distant both geographically and culturally, had unleashed the toxins that were now disrupting Anishinaabe lives. Most individuals at Grassy Narrows had no knowledge of the Dryden mill and no use for its products. They had done nothing to upset their delicately balanced relationship with the natural world nor to diminish the river's capacity to sustain life.

Although the fundamental cultural ties that bind Grassy Narrows residents to their homeland remain strong, important changes have taken place. Critically, many contemporary Grassy Narrows residents feel that the positive, sustaining nature of their environment can no longer be unreservedly trusted. Relied upon for generations to provide for their people, the river is now a source of *pijibowin* and a site of trepidation. Instead of offering nourishment and the satisfaction of self-sufficiency, the river can now make them sick. It is significant that those within the community who continue to practice traditional Anishinaabe subsistence to the greatest degree are most impacted—and most troubled—by the presence of mercury in the environment.

If additional mercury is allowed to enter the regional ecosystem, these effects can be expected to persist and probably worsen over time. Detrimental consequences of additional mercury

[10] This term has been spelled in various ways, including *pīmädäzīwin* (Hallowell 1975) and *pimadiziwin* (Nesper 2002). I use the double-vowel spelling found in Nichols and Nyholm's *Concise Dictionary of Minnesota Ojibwe* (1995).

exposure are likely to parallel those seen at Grassy Narrows since 1970 and can be expected to include fear, anxiety, and grief associated with a loss of connection to emplaced cultural activities. When communication about risks is not sufficient or trusted, confusion, suspicion, and anger are also likely to ensue. Recent press releases from the community suggest that fear and anxiety are already increasing as a result of the Forest Management Plan's allowance of additional clearcutting. In a release issued in response to the rejection of the community's request for an Individual Environmental Assessment in late 2014, Joseph (J.B.) Fobister stated:

> "Ontario has ignored our voices and is planning to force more devastating clearcuts on our people without even applying their own Individual Environmental Assessment process...It makes me sad that our people will become even sicker if the government allows the logging industry to poison the fish that we eat."

Grassy Narrows residents' association with their traditional landbase must be understood as a comprehensive and holistic package of land-based subsistence and culture rather than as a series of distinct, isolated harvesting activities. As a result, the aggregate impacts of hydroelectric dams, mercury contamination, and clearcutting are greater than the sum of their parts. A trapper who no longer feels safe obtaining fish while out on the trapline may spend less time in the bush. An Anishinaabe youth who experiences anxiety due to the presence of mercury while at a land-based healing camp may rejoin friends partying on the reserve. Mercury contamination—alone as well as in conjunction with other known challenges—poses a serious threat to the Anishinaabe way of life.

10. Are the impacts at the community level in Grassy Narrows from past mercury exposure, and those anticipated in future from new sources of mercury exposure, experienced differently by gender and age and, if so, how?

Summary Answer:

Based on their roles as primary caregivers, their ability to bring new life into the world, and their cultural duties as protectors of water, women at Grassy Narrows are disproportionately impacted by past, present, and future mercury exposure.

Full Answer:

In addition to its disproportionate effects on traditional harvesters and their families, mercury's impacts on the women of Grassy Narrows have been especially profound. Gender roles and family structures at Grassy Narrows largely follow a traditional Anishinaabe pattern (see Landes 1997 [1938]). Historically, subsistence pursuits among the Anishinaabe proceeded according to a gendered division of labor, with men the primary hunters and trappers and women completing the bulk of gathering and domestic work. While some women at Grassy Narrows do work

outside the home (especially in office and education service positions), this is still largely the case regarding land-based subsistence activities. In my time at Grassy Narrows, I observed members of both genders participate regularly in fishing and in the processing of animal products, while men remained the most frequent hunters and trappers and women remained the most common gatherers of wild plant products. Following from generations past, when women were in charge of the construction of *wiigiwaaman*—dwellings (Densmore 1979 [1929]), contemporary Anishinaabe women have primary obligation for maintenance of the home.

As bearers of the next generation and primary caretakers of children, disabled individuals, and elders, women bear a burden over and above others in the community. This includes the additional time, effort, and stress associated with caring for those who are disabled (or less-abled) as a result of mercury's physical and/or psychological effects. It also includes the anxiety and fear catalyzed by the congenital effects of mercury contamination (i.e., worries that a fetus will be born with defects as a result of the mother's consumption of fish) and the disproportionate impacts of mercury on the developing brains of children.

The customary relationship between Anishinaabe women and water merits special mention. Water is perceived by many Anishinaabeg to be the source of all life and is viewed by individuals of both genders as "women's business." Women's symbolic duty as protectors or "carriers" of water is enacted through the central role of women in traditional water ceremonies. Anishinaabe women explain their relationship with water in reference to the prominence of water in the processes of bringing new life into being (i.e., through pregnancy and childbirth). By extension, Anishinaabe people comprehend rivers as metaphorically equivalent to the veins of mother earth.[11] Given this context of belief, women's traditional capacity is greatly disrupted by the degradation of water resources and waterborne contamination. When water is contaminated, upholding these traditional duties becomes more onerous.

11. If not answered in response to questions 8, 9 and 10 above, how does the experience at Grassy Narrows compare with the documented experience of other aboriginal communities that have faced environmental contamination problems?

Summary Answer:

While other First Nations communities have experienced mercury contamination, Grassy Narrows has faced sustained and persistent environmental transformations over many years that have resulted in cumulative detrimental effects.

Full Answer:

[11] Fieldnotes, June 22, 2004.

In many ways, Grassy Narrows residents' experience of mercury has been similar to other communities facing such contamination. Ronald Niezen (1998:88), for example, describes comparable reactions to the discovery of mercury among the James Bay Cree (a group related linguistically and culturally to the Grassy Narrows Anishinaabe), pointing out that "such dramatic changes to the land as flooding and contamination of fish can only lead to a sense of sorrow or spiritual malaise among those accustomed to a careful scrutiny of human relationships with animals and the environment." Although the origin of mercury contamination in the James Bay region differed from the English-Wabigoon River's industrial pollution, the anxiety and sense of vulnerability—as well as the widespread refusal to cease harvesting and consuming fish—that resulted from the substance's presence did not.[12] Margaret Wheatley suggests that among First Nations peoples, the social and cultural impacts of mercury contamination are often more severe than the physical risks and often serve to amplify them (1997). While not specific to mercury, reactions of anxiety, confusion, and the need to weigh risks and benefits of traditional land-based subsistence have been documented among Aboriginal populations at Walpole Island (VanWynsberge 2002), Aamjiwnaang (Jackson 2011), and Akwesasne (Grande and Johansen 1995) as well as among American Indian peoples facing contamination in the United States (see Grinde and Johansen 1995; LaDuke 1999).

Still, the Grassy Narrows case is unique in the cumulative and persistent nature of environmental impacts. Grassy Narrows First Nation's recent history has been punctuated by several episodes of unsolicited—and largely undesirable—change, which have combined to create aggregate effects more damaging than even the most dramatic alteration could produce independently. The people of Grassy Narrows saw their immediate environment transformed without their consent for the first time in the late 1920s, when hydroelectric dams were constructed along the English River to generate power for Euro-Canadian settlements and industries (Kenora Daily Miner and News Staff and the Canadian Press 1984). These dams led to localized flooding and unpredictable water-level fluctuations. More recently, Grassy Narrows has faced large-scale industrial logging throughout its Traditional Land Use Area. These changes compound one another by limiting access to some areas and by reducing community members' trust in the land to provide for their needs. Since the late 1990s, residents have responded to industrial logging within their territory with formal letters of complaint, media campaigns, litigation, and a peaceful direct action blockade.

12. What community level responses have occurred in response to past mercury exposure, and what community level responses are possible in future to activities that could add mercury to bodies of water used by the people of Grassy Narrows for fishing and other traditional pursuits?

[12] Mercury became a problem in the James Bay region following hydroelectric development and subsequent flooding. Richard Scott (2001) traces the James Bay Cree experience of mercury poisoning as well as the history of mercury poisoning in Canadian First Nations more generally.

Summary Answer:

Residents of Grassy Narrows are extremely worried about the presence of mercury in the environment and in their own bodies. They have worked for many years to draw attention to the mercury contamination that has impacted their community and are deeply concerned by the documented relationship between clearcutting and increased mercury levels.

Full Answer:

Based on my firsthand experience at Grassy Narrows, I can attest that people in the community are extremely worried about the continuing impacts of mercury contamination on their health and their immediate environment. They have discussed this issue publically for many years in many different forums. I witnessed numerous discussions reflecting these concerns between 2003 and 2007 and have continued to follow developments since that time.

During my period of research at Grassy Narrows, mercury was a topic of frequent conversation and a matter of collective concern. Specifically, I was present for one of Dr. Harada's visits to Grassy Narrows, which was attended by dozens of Anishinaabe citizens who came to the reserve clinic to be examined by the doctor and his team. [13] All were searching for solutions to health problems they believed to be associated with mercury contamination. I also observed activities related to a community wild food contaminant study, which was designed to shed light on the specific quantities of mercury and other toxins in wild foods and help harvesters understand which species were at risk of contamination.[14] After 2007, Grassy Narrows residents continued to voice concern regarding mercury. While not witnessed firsthand, I am aware of several more recent events designed to draw attention to mercury contamination that have been organized by Grassy Narrows residents—most notably the River Runs of 2010 and 2012—as a result of my use of Facebook and other electronic media. As they did during the previous period of intensive clearcutting and proposed cutblocks within the Traditional Land Use Area that ended in 2008, many residents of Grassy Narrows are already experiencing detrimental anticipatory anxiety. They are fearful that portions of their homeland and way of life may be further degraded as a result of additional clearcutting and associated mercury contamination. As Deputy Chief Randy Fobister recently declared "That's all we know—fishing. Mercury destroyed that once. If they allow more cutting, we'll never be able to sustain ourselves" (Porter 2015).

Residents of Grassy Narrows have been concerned about mercury contamination for 45 years and about clearcutting for 20 years. Since at least 2010, members of the community have publically discussed the link between the two sources of industrial impact (see initial submission, p. 10-11). Furthermore, Anishinaabe people believe strongly that the various components of the

[13] Fieldnotes, August 29, 2004. For Dr. Harada's findings, see Harada et al. 2005.
[14] Fieldnotes, July 29, 2004.

boreal forest ecosystem are interconnected and have long observed and voiced concern regarding logging's impacts on water quality and the habitats of forest species.

For the people of Grassy Narrows First Nation, firsthand experience with environmental degradation—most especially the discharge of mercury into the English-Wabigoon River system—instilled a harsh lesson: if the environment becomes further degraded, traditional land-based subsistence and the rich set of cultural beliefs and practices that are bound to it will be severely curtailed. Based on my experience at Grassy Narrows, I believe community members wish to avoid being forced to choose between (1) giving up traditional activities that are central to their individual and collective identity by ceasing to eat fish they catch in the area in order to protect their health and (2) exposing themselves to further harm caused by exposure to new sources of mercury in order to continue eating fish as part of their traditional way of life.

Academic Positions

Associate Professor
Current Position
The Ohio State University
Department of Anthropology/Marion Campus
Courses taught at the Ohio State University: Anthropology 2202/202: Peoples and Cultures: Introduction to Cultural Anthropology; Anthropology 3420/421.08: Indians of North America; Anthropology 620: Anthropology of Religion; Anthropology 699: Undergraduate Research; Anthropology 5624: The Anthropology of Food: Culture, Society, and Eating; Anthropology 3525: History of Anthropological Theory

Assistant Professor
Fall 2009-Spring 2015
The Ohio State University
Department of Anthropology/Marion Campus

Lecturer and Honorary Fellow
2008-2009
University of Wisconsin-Madison
Anthropology and American Indian Studies
Courses: Anthropology 343: The Anthropology of Religion; American Indian Studies 450: American Indians and the Environment: Environmental Justice

Lecturer
Spring 2006, Spring 2007, Fall 2007
University of Wisconsin Colleges
Department of Anthropology and Sociology
Fond du Lac and Fox Valley Campuses
Courses*:* Anthropology/American Indian Studies 314: The Indians of North America

Teaching Assistant
Fall 2001, Spring 2002, Fall 2005, Spring 2008
University of Wisconsin-Madison
Department of Anthropology
Courses**:** Anthropology 104: Cultural Anthropology and Human Diversity, Anthropology/American Indian Studies 314: The Indians of North America

Project (Research) Assistant
2007
University of Wisconsin-Madison
Department of Anthropology
Project**:** Big Lake/Rice Creek Traditional Cultural Property Analysis (Cultural Resource Management in collaboration with the Lac du Flambeau Band of Lake Superior Chippewa (Ojibwe) and the Bureau of Land Management). *Supervisor*: Dr. Larry Nesper

2002-2004
University of Wisconsin-Madison
Department of Anthropology
Project**:** A Cultural Analysis of Kluane First Nation Land Claims. Negotiations. *Supervisor*: Dr. Paul Nadasdy

Appendix C: Relevant factual findings from *Keewatin v. Ontario*, 2011

[229] From season to season, the Ojibway moved from area to area, travelling by birch bark canoe in summer, snow shoe in winter. They gathered resources for their sustenance whenever and wherever they were available.

[230] In a letter to the Minister of Public Works dated December 19, 1870 [Ex. 1, Vol. 4, tab 103], to which I have earlier referred in other respects in the section on Euro-Canadian perspective, Dawson, anticipating that after the Treaty was made, the Ojibway would be treated as minors and that they would come under the care of the Dominion Government, provided a detailed description of their habits and means of obtaining their subsistence:

> In spring, as the navigation opens, the Indians leave their hunting grounds, and betake themselves to the Lakes and Rivers and, as the fish literally swarm in these inland waters, in the early part of Summer, they then have no difficulty in obtaining food, and the means of communication being easy to their light canoes, they can congregate in considerable numbers. Rainy River is the Chief resort, and it is there that their Councils are held, and their Feasts celebrated, but Rainy River, although the Sturgeon abound in its waters, cannot support the whole tribe, and the number which assemble there is generally limited to 600 or a thousand people, including men, women and children. Last summer, however, the number was greater than usual, there having been at one time full 1500 people in the vicinity of Fort Frances.
> …
> … early in Summer, the grand occupation is fishing, and this is to them the happiest season of the year, as they have then an opportunity of uniting after a long winter of isolation. Food is abundant and the time passes pleasantly under circumstances of peculiar fascination to the Savage. With his gun in readiness for the wild fowl, and his spear for the fish, he can, with little labour, secure enough for his immediate wants, and the future troubles him not. The produce of the winter's hunt affords him the means of renovating his garments and bedecking himself to his tastes; marriages and dances are the order of the day with the young, and the old and experienced meet in Council to deliberate on the affairs of the Community, while matrons with some regard to the future, dry the flesh of the sturgeon in the sun, and store it past a day of want.
>
> The fishing season lasts til the rivers began to fall, in the beginning of July, and the busy season commences, numbers then proceed to sandy plains, or rocky islets, where blueberries are in such abundance. These the women and children gather in great quantities and dry in the sun, or compress into cakes which they store past for future use; but a still more important harvest than that of berries soon waits them, and the whole tribe sets off for the rice fields.

> In certain parts of the Lake of the Woods, and on the upper reaches of the Winnipeg, the water spreads out into vast lagoons or shallow marshes, and in these the wild rice grows up from the bottom and rises high over the water, covering extensive areas ... When this crop is ripe, the canoes are perfectly watertight and pushed at will through the standing rice, the method of securing it being to bend it over the gunwale and thresh the ears out with sticks, the grain falling on mats prepared to receive it in the bottom of the canoe; meantime the harvest is disputed by other gleaners in the shape of vast flocks of aquatic fowl, and of these the Indians can easily secure all that they can consume.
> At the time of the rice harvest, the authority and patience of the Chiefs are put to the test, in deciding disputed claims and meting out justice to all ...
>
> It may be maintained that the rice is not always a sure crop. If the water should be too high, it in a measure fails, and even when it promises well, if heavy rains and strong gales occur when it is ripening, it is beaten down to the water and rendered valueless, and the moment it begins to ripen the wild fowl attack it, sometimes in such numbers as to impair the harvest.
>
> Besides the resources as far enumerated, the Indians have crops other than those which nature unaided produces. When the first French explorers came among them they found them growing maize on the banks of the Rainy River, and on the islands of the Lake of the Woods. Two centuries have since elapsed and Indian corn is still grown in the little gardens which produced it then, although not to the same extent. But the Indians have now added to the growth of maize, the culture of potatoes and this at least shows some taste for farming operations, which if properly encouraged, might lead to important results.
>
> When the rice harvest is gathered, and autumn approaching, the Indians having provided themselves with ammunition, and such articles of clothing as they can get at the trading posts, set out for their hunting grounds, in single families, and are once more separated, not to meet again until the following summer. …

[913] The Ojibway understood they were agreeing to share the use of their whole territory and resources with Euro-Canadians, so long as the sharing would not significantly interfere with their own Harvesting Rights. They did not agree to give up their means of making a living, i.e., their own use of resources or their continuing rights to subsistence harvesting on that land. The Commissioners recognized that that was their condition for entering into the Treaty, and they expressly promised the Ojibway could keep those rights to induce them to do so.

[1153] Into the 20th century, the Indian Agents reported every year that the principal activities of the Ojibway at Grassy Narrows were hunting, fishing, berry picking and the harvesting of wild rice.

[1158] **Seasonal Round.** From May to June, the family would be at the Reserve, where they planted potatoes, corn, cabbage and onions in their gardens. In July, they would paddle and portage a freighter canoe to a location about 30 kilometres from the Reserve. They would spend

two to three weeks there, living in tents and harvesting blueberries that they canned or dried over the open fire for winter use or for sale to others.

[1159] After the blueberry harvest, his family would return to the Reserve for a week or so to check on their gardens. Then they would journey 10-15 kilometres in another direction to harvest and preserve wild rice, living in tents or cabins. A great deal of work was involved. One family member would sit in front of a canoe and paddle. Another would sit at the back and hit the rice into the canoe with a stick. While the rice dried, they would dig holes. Then they would place the dried rice in them and dance on the rice to remove the husks. They would sell some of the wild rice and keep some for winter use.

[1160] After that harvest, they would return to the Reserve to harvest their gardens. His parents, who did not have a root cellar, would bury the produce, surrounded with dry grass, in a hole in a sandy area of the bush to preserve it until the winter.

[1161] In mid-September, after they had gathered and stored wood for the older family members who wintered at the Reserve, the family travelled two-three days by freighter canoe to their winter trap line. Along the way, they would hunt and trap. After reaching their trap line, they would ensure their cabin was well maintained, and gather and store wood for the winter. His older brothers helped their father hunt, setting traps and snares to catch beaver, otter, mink and other animals.

[1162] When he was very young, Fobister would remain in the cabin with his mother and learn from her how to preserve animal pelts. He would help her bring in wood and haul water. She made moccasins, gloves, jackets and pants from the pelts. His father sold fur and pelts to the HBC.

[1163] They lived on their trap line throughout the winter and into the spring, eating deer, moose, beaver, lake trout, walleye, northerns and sucker meat, supplemented with wild rice, dried blueberries and produce preserved from their gardens. A dog team was used to haul wood and meat and to travel to buy food at the closest store, about 15-20 kilometres away.

[1164] In April after the wolf and fox moulted, the family would move to another location to trap muskrat, otter and beaver. They would then return to the Reserve and prepare the garden for another year.

[1233] In the case of the Grassy Narrows Ojibway, the life of Fobister is illustrative of the continuing reality that they were still pursuing the seasonal round without significant Euro-Canadian interference, at least into the 1960s and that Euro-Canadian uses and traditional harvesting were compatible.

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Anna Willow. I live in Delaware in the State of Ohio.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

AFFIDAVIT OF JUSTIN PODUR

I, JUSTIN PODUR, of the City of Toronto, in the Province of Ontario, MAKE OATH AND SAY AS FOLLOWS:

1. I hold a master's and a doctorate in forestry from the University of Toronto. I am currently an associate professor at the Faculty of Environmental Studies, York University. My teaching, research and writing have focused on forest fires in Ontario, including their spatial and temporal patterns, increases in their numbers and area burned.

My research methods in this field of study have included using mathematical and computer models to study fire and ecological problems. I have published in a variety of peer and non-peer reviewed journals on the subject of forest fires, including the Canadian Journal of Forest Research, Ecological Modeling, Ecological Applications, and the International Journal of Wildland Fire. I am also affiliated with the University of Toronto Forest Fire Management Systems Laboratory. A copy of my curriculum vitae is attached to Exhibit “A”, below.

2. In February 2015 I was asked by counsel for Grassy Narrows to answer certain questions in a report on fire in the northwestern Ontario boreal forest, in particular, natural and human-caused disturbances. The questions and my answers to them appear as part of my December 2015 expert report attached as Exhibit “A” to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit “B” to my Affidavit.

SWORN BEFORE ME in the City of Toronto, in the Province of Ontario, this ___ day of _____, 2015.

A Commissioner, etc.

Introduction

I hold a masters and a doctorate in forestry from the University of Toronto. I am currently an associate professor at the Faculty of Environmental Studies, York University. My teaching, research and writing have focused on forest fires in Ontario, including their spatial and temporal patterns, increases in their numbers and area burned. My research methods in this field of study have included using mathematical and computer models to study fire and ecological problems. I have published in a variety of peer and non-peer reviewed journals on the subject of forest fires, including the Canadian Journal of Forest Research, Ecological Modeling, Ecological Applications, and the International Journal of Wildland Fire. I am also affiliated with the University of Toronto Forest Fire Management Systems Laboratory. My curriculum vitae appears in Appendix A of this Expert Report.

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association on behalf of Grassy Narrows First Nation to prepare an expert report that responds to several questions. I am solely responsible for the preparation of this report.

Questions

1. For the documents referred to below, please indicate on a document by document basis if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto:

> A. The Grassy Narrows-Earthroots request, dated January 2014 (pages 16-19), of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May (pages 3-5, 13-14, 19-21), and November 2014 (pages 8-9) insofar as they relate to your area of expertise and the subject matter for your report.

2. What are your views on matters within your area of expertise and the subject matter of this report that are addressed under the heading “Fire vs harvest impacts on Hg dynamics” in the Ministry of Natural Resources and Forestry July 2014 response to the Grassy Narrows-Earthroots May 2014 submissions?

3. What proportion:

> (a) of the boreal landscape in Ontario is burned by large vs. small fires in a “natural” scenario?;
>
> (b) of the boreal landscape in the specific eco-climatic fire zone in which the Whiskey Jack Forest is situated is burned by large vs. small fires in a “natural” scenario?

4. What proportion:

(a) of the boreal landscape in Ontario is burned by large vs. small fires in a fire suppression scenario?;

(b) of the boreal landscape in the specific eco-climatic fire zone in which the Whiskey Jack Forest is situated is burned by large vs. small fires in a fire suppression scenario?

5. Is there a relationship between fire size and fire intensity and severity? If so, what is that relationship?

6. How are fire size, frequency, and intensity expected to change, if at all, as a result of climate change in:

(a) the boreal forest of Ontario?;

(b) in the area of the Whiskey Jack Forest?

7. What amount of mercury, if any, would you expect to be volatized into the atmosphere from Grassy Narrows Traditional Territory in an average fire decade?

8. What are the implications of the natural fire regime for the Whiskey Jack Forest on mercury levels in soil, and on mercury bio-accumulation in fish?

9. How does this compare to the mercury impacts of the logging and fire suppression cycle on mercury levels in soil, and on mercury bio-accumulation in fish?

10. Overall, do logging and fire have similar, or dis-similar, impacts on mercury in the boreal forest?

Organization of Expert Report

The Expert Report is organized into two parts. Part 1 provides short summary answers to the questions that are listed above. Part 2 of the Expert Report is designed to provided greater detail in support of the summary answers set out in Part 1.

Part 1

Summary Answers to Questions

1. For the documents referred to below, please indicate on a document by document basis if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto:

A. The Grassy Narrows-Earthroots request, dated January 2014 (pages 16-19), of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May (pages 3-5, 13-14, 19-21), and November 2014 (pages 8-9) insofar as they relate to your area

of expertise and the subject matter for your report.

Answer to Question 1: The Grassy Narrows-Earthroots request for an IEA is accurate in every material respect as it relates to forest fires. The supplementary submissions made to the Ministry dated May, and November 2014 are accurate in every material respect as they related to forest fires.

2. What are your views on matters within your area of expertise and the subject matter of this report that are addressed under the heading "Fire vs harvest impacts on Hg dynamics" in the Ministry of Natural Resources and Forestry July 2014 response to the Grassy Narrows-Earthroots May 2014 submissions?

Answer to Question 2: The MNRF July 2014 response argues that the statement that "logging and forest fire have nearly opposite impacts on mercury", "is not supported by scientific studies". Elsewhere, the response argues that there is a lack of evidence "that mercury levels of fish differ consistently between lakes with harvested watersheds and those with intensively or extensively burned watersheds."

The MNRF response ignores the physical and chemical changes caused by the combustion of forest fuels, as well as the changes to the forest due to the removal of biomass due to harvesting. Large-scale boreal fires of the kind that account for 90% or more of burned areas, result in atmospheric emissions of mercury that travel long distances before being redeposited, thus reducing the total pool of mercury in the local watershed. Whereas forestry (clearcutting) operations release mercury into local water bodies.

3. What proportion:

(a) of the boreal landscape in Ontario is burned by large vs. small fires in a "natural" scenario?;

(b) of the boreal landscape in the specific eco-climatic fire zone in which the Whiskey Jack Forest is situated is burned by large vs. small fires in a "natural" scenario?

Answer to Question 3:

a) 1.3% of fires larger than 200 ha burned 96% of the area for the period 1976-2004 in the portion of boreal Ontario under active fire suppression. For a "natural" scenario I would expect the proportion of area burned by large fires to be even higher.

b) In the Whiskey Jack Forest for the period 1960-2013, 1.1% of large fires burned 95% of the area. For a "natural" scenario I would expect the proportion of area burned by large fires to be even higher.

4. What proportion:

(a) of the boreal landscape in Ontario is burned by large vs. small fires in a fire suppression scenario?;

(b) of the boreal landscape in the specific eco-climatic fire zone in which the Whiskey Jack Forest is situated is burned by large vs. small fires in a fire suppression scenario?

Answer to Question 4:

a) 1.3% of fires larger than 200 ha burned 96% of the area for the period 1976-2004 in boreal Ontario.

b) In the Whiskey Jack Forest for the period 1960-2013, 1.1% of large fires burned 95% of the area.

5. Is there a relationship between fire size and fire intensity and severity? If so, what is that relationship?

Answer to Question 5: There is a positive correlation between fire size and fire intensity and severity. Most of the boreal forest is under active fire suppression. It is more intense fires that tend to become large fires. These fires are also more severe and tend to leave fewer unburned islands.

6. How are fire size, frequency, and intensity expected to change, if at all, as a result of climate change in:

(a) the boreal forest of Ontario?;

(b) in the area of the Whiskey Jack Forest?

Answer to Question 6:

a) Fire size, frequency, and intensity are all expected to increase as a result of climate change. All forest fire models, when run with climate change simulation model data, predict increased fire size, frequency, and intensity. This is equally true for the entire boreal forest and for b) the area of the Whiskey Jack Forest.

7. What amount of mercury, if any, would you expect to be volatized into the atmosphere from Grassy Narrows Traditional Territory in an average fire decade?

Answer to Question 7:

There is a high amount of variability in decadal area burned, but the historical figures range from 498 g in the 2000s to 56 000 g in the 1980s.

8. What are the implications of the natural fire regime for the Whiskey Jack Forest on mercury levels in soil, and on mercury bio-accumulation in fish?

Answer to Question 8:

Because of the role of combustion in volatilizing mercury into the atmosphere, the natural fire regime results in an amount of mercury released into the atmosphere proportional to the area burned. Larger, more intense, and more severe fires all result in a higher amount of mercury being removed into the atmosphere.

9. How does this compare to the mercury impacts of the logging and fire suppression cycle on mercury levels in soil, and on mercury bio-accumulation in fish?

Answer to Question 9:

Harvesting operations increase mercury output into water bodies, and hence increase mercury bio-accumulation in fish.

10. Overall, do logging and fire have similar, or dis-similar, impacts on mercury in the boreal forest?

Answer to Question 10:

Overall, fire and logging have dissimilar impacts on mercury in the boreal forest.

Part 2

Forest management and fire: two distinct types of disturbance

In the comparison of natural disturbance with forest management, there are stand-level and landscape-level considerations. These are discussed in a general way by Bergeron et al. (1999).

Stand-level considerations

Stand level considerations include the effect on forest soils and the exposure of the soil post-fire vs. post-logging, the amount of wood volume and snags left behind after the disturbance, which depends on the intensity of the fire, and the presence of residual trees or unburned islands after a fire. With these considerations in mind, a fire in a jack pine, spruce, or aspen/poplar stand can be contrasted to a clear-cut with retention. In the clear cut, the soil has not been burned, the wood volume is decreased relative to the surface fire, and snags are absent, post clear-cut.

Landscape-level considerations

Greater differences appear at the landscape level. These include differences in age-class, size-class, and spatial distributions of stands.

Age-class distribution. The purpose of logging is the extraction of trees from the forest for their economic value. It is economically wasteful to allow trees above the rotation age to remain in the forest. The age structure, or age-class distribution, of a managed forest will, in the long-term, contain stands that are, at their oldest, the rotation age (typically planned to be 60-100 years in the boreal). By contrast, because the probability of burning is independent of stand age, the age-class distribution of a forest under a natural fire regime will have a large portion (Bergeron et al. 1999 give a figure of 37%, citing Johnson and Van Wagner 1985b) of stands that are older than the rotation age.

Size-class distribution. The spatial pattern of logging activity is organized by forest management principles, including ease of access and removal as well as age-class considerations discussed above. By contrast, fire is a random, or stochastic process, which produces a random distribution of fire sizes. Fire size has been modeled as a Pareto distribution (Ward et al. 2001), a Weibull distribution (Reed and McKelvey 2002), and others (cited in Podur et al. 2009), and aggregate area burned by a compound Poisson distribution (Podur et al. 2009). The random pattern of different sizes of fires distributed on the landscape results in a mosaic of patches, some of which are small, some of which can be very large. Different spatial mosaics have different implications for wildlife habitat, among other considerations.

Shape and distribution of burned stands. The stochastic nature of the fire process goes beyond fire size distribution, however, as the shapes of the stands and their physical distribution across the landscape is an even more complex process involving topography, wind, and forest fuel conditions at the times that the fires took place.

Two distinct types of disturbance

Because of all of these important differences, logging and fire are viewed by forest landscape and fire ecologists as completely distinct ecological processes in the boreal forest landscape. The OMNR produces guidelines for forest management with the intent to make forest management emulate natural disturbance with tree retention, specific types and shapes of cuts, a range of clearcut sizes, and the retention of downed woody debris (OMNR 2014). All of these measures may increase the ecological integrity of logged stands, but fire and logging remain distinct disturbances from an ecological point of view.

A natural fire regime in the boreal forest

The boreal forest of Ontario is characterized by a fire regime that includes a high proportion of area burned by a small number of large, high-intensity fires.

Area burned is dominated by large fires

Stocks et al. (2002), studying the Canadian boreal forest, found for 1959-1997 that fires over 200 ha in size were 3% of the fires occurring in Canada but 97% of the total area burned. Podur and Wotton (2010) studied the zones of active fire suppression in Ontario for 1976-2004 and found that only 1.3% of fires grew to > 200 ha, but these fires resulted in 96% of the area burned in the region. In areas not under fire suppression, an even higher proportion of area burned would be due to large fires, as fewer fires would naturally stop at a small size.

Weather drives large fires more than fuels or suppression

Podur and Martell (2009) studied the fuels, or forest types, burned by fires for 594 fires larger than 40 ha that occurred in Ontario's boreal forest between 1996-2006, finding that fuels burned in the proportion they were available. This suggests that weather is dominant in controlling large fires. Podur and Martell (2007) found that fire suppression does, however, reduce area burned, even in large fires, by suppressing a class of fires that would have escaped had there been no suppression. In severe fire years, however, there remain a number of fires that are too intense for suppression to succeed, and these fires, which become large in size and have high burn severity, make up the most important portion of area burned. Podur and Wotton (2010) found that the number of these large, uncontrollable fires was likely to increase under climate change, with the potential to overwhelm fire suppression capacity.

Weather drives large fires. These studies all found that weather drives large fires and that large fires drive area burned. This is true throughout boreal Ontario, in managed forests and unmanaged, in forests where fire suppression is active and in areas where fire is monitored and not actively suppressed. This includes the Whiskey Jack forest in northwestern Ontario.

Differences between fire and logging in mercury (Hg) release

Large fires release Hg into the atmosphere

Sigler et al. (2003) studied a series of fires in the severe 2002 Quebec fire season, in which 250 fires burned 1,000,000 ha over a 1-month period. They measured gaseous mercury (Hg) at the Harvard Forest and provided a measure of Hg emissions from large-scale boreal forest fires. Scaling up, they provide global estimates of Hg emissions from boreal forest fires. The important point here is that large-scale boreal forest fires of the kind that account for 90% or more of the area burned result in atmospheric emissions of Hg. Turetsky et al. (2006) reinforce this point, quantifying organic soil Hg stocks in the boreal forest and estimating atmospheric emission of Hg due to increased boreal forest fire activity under climate change. They conclude that increased fire activity will result in greater release of Hg from boreal forest soils into the atmosphere.

Logging operations release Hg into local water bodies

Bishop et al. (2009) summarized a series of studies showing Hg accumulation downstream of forestry operations, finding a "forestry effect" on Hg accumulation in fish. In a study of Hg concentrations in fish in 38 boreal lakes, Garcia and Carignan (2005) found higher Hg concentrations in fish from logged and "partially burnt" lakes (i.e., lakes where small-scale fires had occurred).

The Whiskey Jack Forest - historical fires and estimated mercury emissions

The part of the Whiskey Jack Forest subject to the Grassy Narrows legal action is 631 413 ha in extent. The National Fire Database lists a total of 1222 fires in this area for the period 1960-2013. These fires burned a total of 18 541 ha. 17 662 ha, or 95% of the area, of this was burned by 14 fires, or 1.1% of the fires, which were larger than 200 ha. The pattern of large fires driving area burned also applies here. A higher number of large fires and a higher area burned would be expected in a natural fire scenario with no fire suppression.

The overall mean burn fraction for the boreal zone of Ontario calculated from the national fire database is 0.001 (the median burn fraction for the boreal zone of Ontario is much lower, 0.0003).

The burn fraction in all years except four for the study area was less than 0.001. The highest burn fraction was 0.016 (in 1983). The other three years were 1988 (0.005), 1976 (0.004), and 1980 (0.002). These low and highly variable burn fractions illustrate the difficulty of estimating a quantity like fire return interval or fire cycle from the burn fraction. Reed (2006) recommended the abandonment of the concept of fire cycle based on these difficulties, though the concept continues to be used: MNR analysts estimate a pre-suppression fire cycle of 81 years, or a burn fraction of 0.01, compared to a post-suppression fire cycle of 299 years, or a burn fraction of 0.003. The mean burn fraction in the region based on the national fire database (1960-2013) was 0.0007 - on average, 0.07% of the study area burned each year. The median burn fraction in the study area was 0.00001, an order of magnitude smaller.

Decadal average area burned and burn fraction for the study area are summarized in Table 1 below.

Table 1. Decadal average area burned for the study area

Decade	Area Burned (ha)	Burn fraction
1960-1969	810	0.0005
1970-1979	6143	0.0039
1980-1989	37330	0.0239
1990-1999	1117	0.0007
2000-2009	332	0.0002
2010-2013	84.3	0.00005
Totals	45817	0.0294

Using Turetsky et al. (2006) figure of 2.62 mg/m2 or 3.8 g/ha Hg stocks in upland forest soils, we arrive at an estimate of about 5.92 t of Hg in the soil of the study area. Sigler et al. (2003) estimate an Hg flux density of 1.5g Hg/ha. This means that a conservative estimate for the decadal mercury

emissions into the atmosphere from the study area ranged between 498g in the 2000s to 55995g, or 56kg in the 1980s. This is a conservative estimate because Turetsky (2006) calculates higher Hg stocks for boreal peatlands (25.14 mg/m2 in a drought scenario).

There is much higher Hg volatilization to the atmosphere in a natural non-fire suppression scenario, than in a fire suppression scenario with harvesting. Woodruff and Cannon (2010) found that high soil burn severity has the potential to reduce the concentration of mercury in burned soils for tens to hundreds of years post-fire. In Prince Albert National Park, Saskatchewan, Friedli et al. (2007) measured an increase in mercury stock from 1.01 mg/m2 for a 39-year old stand to 3.45 mg/m2 for a 130-year old stand. MNR analysts estimate a pre-suppression fire cycle of 81 years, or a burn fraction of 0.01, compared to a post-suppression fire cycle of 299 years, or a burn fraction of 0.003. If these estimates are correct and suppression results in older stands, higher mercury stocks are to be expected in these stands.

In a "natural fire" scenario a high proportion of these stocks are released into the atmosphere. In a suppression + harvesting scenario, a larger proportion of these mercury stocks are released into the water.

The Whiskey Jack Forest - estimated mercury release in a logging scenario

Bishop et al. (2009) estimate that if 100% of an area is harvested (clearcut), a two- to fourfold increase in loading and bioaccumulation of Hg can be expected in fish in the logged catchment area for 10 years. In the total landscape with 1% harvested annually, they estimate an increase of 10-30% in bioaccumulation compared to an unmanaged landscape, and an even higher increase if silviculture activities such as soil scarification and thinning also have mercury impacts. Bishop et al. (2009) provide untested silvicultural recommendations to minimize the impacts on Hg bioaccumulation after forestry operations, but possible reductions due to these impacts have not been quantified - we cannot know how much these silvicultural changes will reduce Hg bioaccumulation.

Conclusions

Forestry and forest fires are ecologically different processes at stand and landscape levels. The area affected by forest fires is primarily due to a small number of large, intense, severe fires. In these large fires, Hg is released into the atmosphere, traveling long distances before being redeposited, reducing the total mercury pool in the local watershed. In forestry operations, Hg is released into local water bodies. A small portion of the Whiskey Jack Forest has been affected by fire since 1960, releasing a small amount of Hg into the atmosphere. Projected forestry operations in the Whiskey Jack Forest can be expected to release a larger amount of Hg into local water bodies.

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Justin Podur. I live in Toronto in the Province of Ontario.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

AFFIDAVIT OF STEPHEN KILBURN

I, STEPHEN KILBURN, of the City of Guelph, in the Province of Ontario, AFFIRM AND SAY AS FOLLOWS:

1. I hold a Bachelor's degree in Environmental Studies, Urban and Regional Planning and a Master's degree in Regional Planning and Resources Development from the University of Waterloo. I am a Registered Professional Planner and member of the Ontario Professional Planning Institute and the Canadian Institute of Planners. I am a consultant

specializing in the application of geographic information system (GIS) methods in the fields of resource management and planning. GIS is a computer technology that allows users to store, manage, manipulate, analyze, and interact with geospatial information, and to create maps and other information products. I have provided GIS and related services to federal, provincial, territorial, municipal, and First Nation governments and agencies across Canada. I have also published and spoken widely in this field. A copy of my curriculum vitae is attached to Exhibit “A”, below.

2. In April 2015 I was asked by counsel for Grassy Narrows to prepare a series of maps on planned and recent clearcut logging in the Whiskey Jack Forest. The maps and a short report explaining the methodology I used in preparing them appear as part of my January 2016 expert report attached as Exhibit “A” to my Affidavit.

3. A copy of my Acknowledgement of Expert's Duty form is attached as Exhibit “B” to my Affidavit.

AFFIRMED BEFORE ME in the City of Toronto, in the Province of Ontario, this 29th day of January, 2016.)

A Commissioner, etc.)

Introduction

I hold a Bachelor's degree in Environmental Studies, Urban and Regional Planning and a Master's degree in Regional Planning and Resource Development from the University of Waterloo. I am a Registered Professional Planner and member of the Ontario Professional Planning Institute and the Canadian Institute of Planners. I am a consultant specializing in the application of geographic information system (GIS) methods in the fields of resource management and planning. GIS is a computer technology that allows users to store, manage, manipulate, analyze, and interact with geospatial information, and to create maps and other information products. I have provided GIS and related services to federal, provincial, territorial, municipal, and First Nation governments and agencies across Canada. I have also published and spoken widely in this field. My curriculum vitae appears in Appendix B of this Expert Report.

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association, on behalf of Grassy Narrows First Nation, to prepare a report and a series of watershed maps of planned and recent clearcut logging in the Whiskey Jack Forest of northwestern, Ontario. I am solely responsible for the preparation of this report and the accompanying maps.

Documentation for Maps in this Report

The following is an explanation of the data sources and methods used to create the maps in this report.

In the description below, sections of the document Ministry of Natural Resources (2009), *FIM Forest Management Planning Technical Specifications 2009* are referenced to provide reference for the meaning of attribute values. The abbreviation "FMPTS 2009" is used for this document.

The maps were prepared using ArcGIS software, version 10.1, SP1. Maps all use NAD 1983 datum and Universal Transverse Mercator (UTM) zone 15 north projection.

Two categories of maps are included behind Appendix A: trap line area maps (Appendix A.1), and watershed area maps (Appendix A.2). The former have been included because they cover a larger geographic area and, therefore, provide greater context for the location of the latter. For example, the trap line area map entitled "Trapping Area KE038" contains the watershed area entitled "Watershed Noname 20 near Campfire Lake". A blown-up version of the latter may be viewed by examining the separate watershed area map entitled "Watershed Noname 20 near Campfire Lake".

Base Features

Base features were mapped using the following data sources:

- Water lines and water areas were sourced from Land Information Ontario OHNWCRS and OHNWBDY datasets.

- Roads were sourced from Land Information Ontario MNRRDSEG.
- Wetland areas were extracted from the Whisky Jack Forest Management Plan (FMP) Planning Composite Inventory (PCI) using the attribute definition *POLYTYPE in ('TMS', 'OMS')* (i.e., treed muskeg and open muskeg, respectively [FMPTS 2009, A1.1.4]).
- Trapping areas were sourced from Land Information Ontario TRAPLINE.
- Watershed areas were sourced from Ontario Flow Assessment Tool III.
- Planned clearcuts and contingency clearcuts for 2012-2022 were extracted from the Whisky Jack FMP 2012-2022 dataset MU490_12PHR00.

Areas of Relevance

Areas of relevance for forestry planning and mercury impacts were mapped from the following sources:

- **Naturally Unforested Areas:** These were extracted from the PCI by excluding polygons with the POLYTYPE attributes 'TMS', 'OMS', 'FOR', 'WAT' (treed muskeg, open muskeg, productive forest, and water, respectively). This category includes exposed rock, brush and alder, islands less than 8 hectares in size. As well, it includes areas with the attribute definition *"DEVSTAGE" = 'LOWNAT' AND "YRDEP" < 1968* (i.e., areas disturbed before 1968 by natural causes where the area currently is below regeneration standards).
- **Forest:** Naturally forested areas were extracted from the PCI using the attribute definitions *POLYTYPE = 'FOR'* (i.e., productive forests, [FMPTS 2009, A1.1.4]); *YRDEP<1* (i.e., no recorded disturbance year [FMPTS 2009, A1.1.11]); and *DEVSTAGE ='FTGNAT'* (i.e., free-to-grow mainly natural regeneration, which includes both naturally regenerated forests and original forest [FMPTS 2009, A1.1.10]). Subsets younger and older than 45 years were extracted using the additional attribute queries *AGE<46* and *AGE>45*, respectively.
- **Forest, Depleted Before 1968:** Forested areas depleted before 1968 were extracted using the attribute definitions *YRDEP < 1968* and *YRDEP > 0* (i.e., areas that have recorded depletions before 1968); and *DEVSTAGE in (FTGPLANT, FTGSEED, FTGNAT)* (free-to-grow planted, seeded, and natural regeneration [FMPTS 2009, A1.1.10]).
- **Depletions After 1967:** This category is the best approximation of historical logging using the data provided by MNRF (see discussion below about the data provided). Depletion areas were extracted with subsets being defined using YRDEP attribute ranges (1968-1977, 1978-1987, 1988-1997, and 1998-2007) and using the attribute definition *NOT (DEVSTAGE in ('DEPNAT', 'LOWNAT')*, (i.e., areas with recorded disturbance years in the specified ranges where the original disturbance was not recorded as natural). In addition, the following natural depletion areas were excluded.

- **Fire Disturbances:** This identifies areas disturbed by fire based on the FIRE_DISTURBANCE_AREA polygons obtained from Land Information Ontario. We considered salvage logged areas to be primarily fire disturbed. To exclude salvage logged areas from the general depletion areas (above), FIRE_DISTURBANCE_AREA polygons were spatially intersected with a subset of the FRI where *YRDEP>0* (i.e., any area with a recorded depletion). From the resulting dataset, any areas where a fire event was recorded (*FIRE_YEAR > 0*) and the last disturbance year recorded in the FMP Land Classification was the same as or within 5 years after the fire year was mapped as fire disturbances.

- **Blowdown Disturbances:** To identify areas of blowdown disturbance, FOREST_ABIOTIC_DAMAGE_EVENT polygons were obtained from Land Information Ontario. These were spatially intersected with the FMP Land Classification Dataset. From the resulting dataset, any areas where a blowdown event was recorded (EVENT_NAME = 'Blowdown') and the last recorded disturbance year was after 1967 were mapped as blowdown disturbances.

- **Other Natural Disturbances:** Areas of potentially productive forest disturbed by natural events that have not met regeneration standards were extracted using the attribute definition *DEVSTAGE='LOWNAT'* and areas recently disturbed by natural events extracted using the attribute definition DEVSTAGE = 'DEPNAT'.

- **Confirmed Logging Since 1970:** There is a map titled "Area Harvested in the Whiskey Jack Forest between 1970 and the Present Time" in the Whiskey Jack Forest 2009-2019 Forest Management Plan 1.1.7.11 Historic Forest Condition, Tab 2, page 26 by David Anderson, Area Forester, Oct 24, 2006. Areas marked as logged in that dataset (shapefile WJF_1970) are marked as "Confirmed Logging since 1970" on our maps.

Discussion

Our primary intention was to produce maps that accurately represent the currently proposed clearcuts and contingency clearcuts in the context of mature productive forested areas, naturally disturbed forested areas, and areas that have been disturbed by previous forest cutting since 1968. The year 1968 was chosen because it likely captures all, or nearly all, historical logging in the area of interest. This is corroborated by the fact that the FMP map of historical logging uses 1970 as a start date.

A challenge to achieving this was presented by omission of an important attribute from the FMP land classification data (Planning Composite Inventory) provided by the MNRF. According to an MNRF presentation, "The Enhanced Forest Resources Inventory, January 22nd, 2013," (available online from the Canadian Institute of Forestry, http://www.cif-ifc.org/wp-content/uploads/2014/05/Banton.pdf), the FRI data should include a depletion type attribute (DEPTYPE) that "identifies the disturbance that occurred in the year recorded in the companion attribute YRDEP," (p.40) and includes entries that would allow harvest disturbances to be differentiated from natural disturbances.

When we requested the DEPTYPE attribute data The MNRF wrote to us that “The external link to the Forest Management Planning Tech Spec. http://www.ontario.ca/document/forest-management-planning-technical-specifications. This applies to the Planning Composite Inventory (PCM) that was provided as part of the current approved 2012 Whiskey Jack plan. The forest resource inventory (FRI) that this PCM was based upon unfortunately did not include a DEPTYPE field. The original FRI was developed prior to FIM and as such did not have an appropriate Tech. Spec.”

Because we lacked this attribute, we were forced to attempt to differentiate harvest depletions from natural depletions using other attributes. As well, at the recommendation of the MNR we obtained from Land Information Ontario the complementary datasets FIRE_DISTURBANCE_AREA, FOREST_ABIOTIC_DAMAGE_EVENT, FOREST_DISEASE_DAMAGE_EVENT, FOREST_INSECT_DAMAGE_EVENT, and FOREST_MISC_DAMAGE_EVENT. Of these, only the fire disturbance area dataset appears to be complete. As documented above, we made use of the abiotic damage event dataset to map blowdown areas, but note that the earliest recorded event is 2001, suggesting that the dataset is not complete. After inspecting their content, we determined that we could not make use of the other three datasets. The whole content of the disease damage event dataset was five polygons covering 1.82 square kilometres, all denoting “Ink spot of aspen” disease in 2009 and 2010. Even the subset of polygons in the insect damage event dataset for “Spruce Budworm” damage appear to be grossly generalized and not amenable to use with data of the accuracy of the FRI; and cover an area of approximately 295,000 square kilometres – nearly one third of the WJ Forest. The miscellaneous damage event dataset comprised five polygons covering 175,000 square kilometres, all denoting “Aspen decline” in 2009 and 2010.

Recent depletions that are not marked as confirmed logging likely reflect logging after the endpoint of the data used for “Area Harvested in the Whiskey Jack Forest between 1970 and the Present Time.” The presence of a road network in these areas corroborates this. Old depletions that are not marked as confirmed logging are likely natural disturbances but may be old logging overlooked in the FMP map

Conclusions

Despite these challenges we are confident that our mapping reasonably represents the landscape and the depletions that have occurred since 1968 to the best of our ability using the data that the MNRF has shared. Most importantly, the planned and contingency cutblocks are represented as accurately as in the FMP data.

Stephen Kilburn

APPENDIX A.1 – TRAP LINE AREA MAPS

Planned and recent clearcut logging
Trapping Area KE050

Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1 2 4 km

1:125,000

Planned and recent clearcut logging
Trapping Area RL033

Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 0.5 1 2 km

1:59,000

Planned and recent clearcut logging
Trapping Area KE038

2069

Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1 2 4 km

1:109,000

Planned and recent clearcut logging
Trapping Area RL052

2070

Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1 2 4 km

1:103,000

Planned and recent clearcut logging
Trapping Area KE049

Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1 2 4 km

1:111,000

Planned and recent clearcut logging
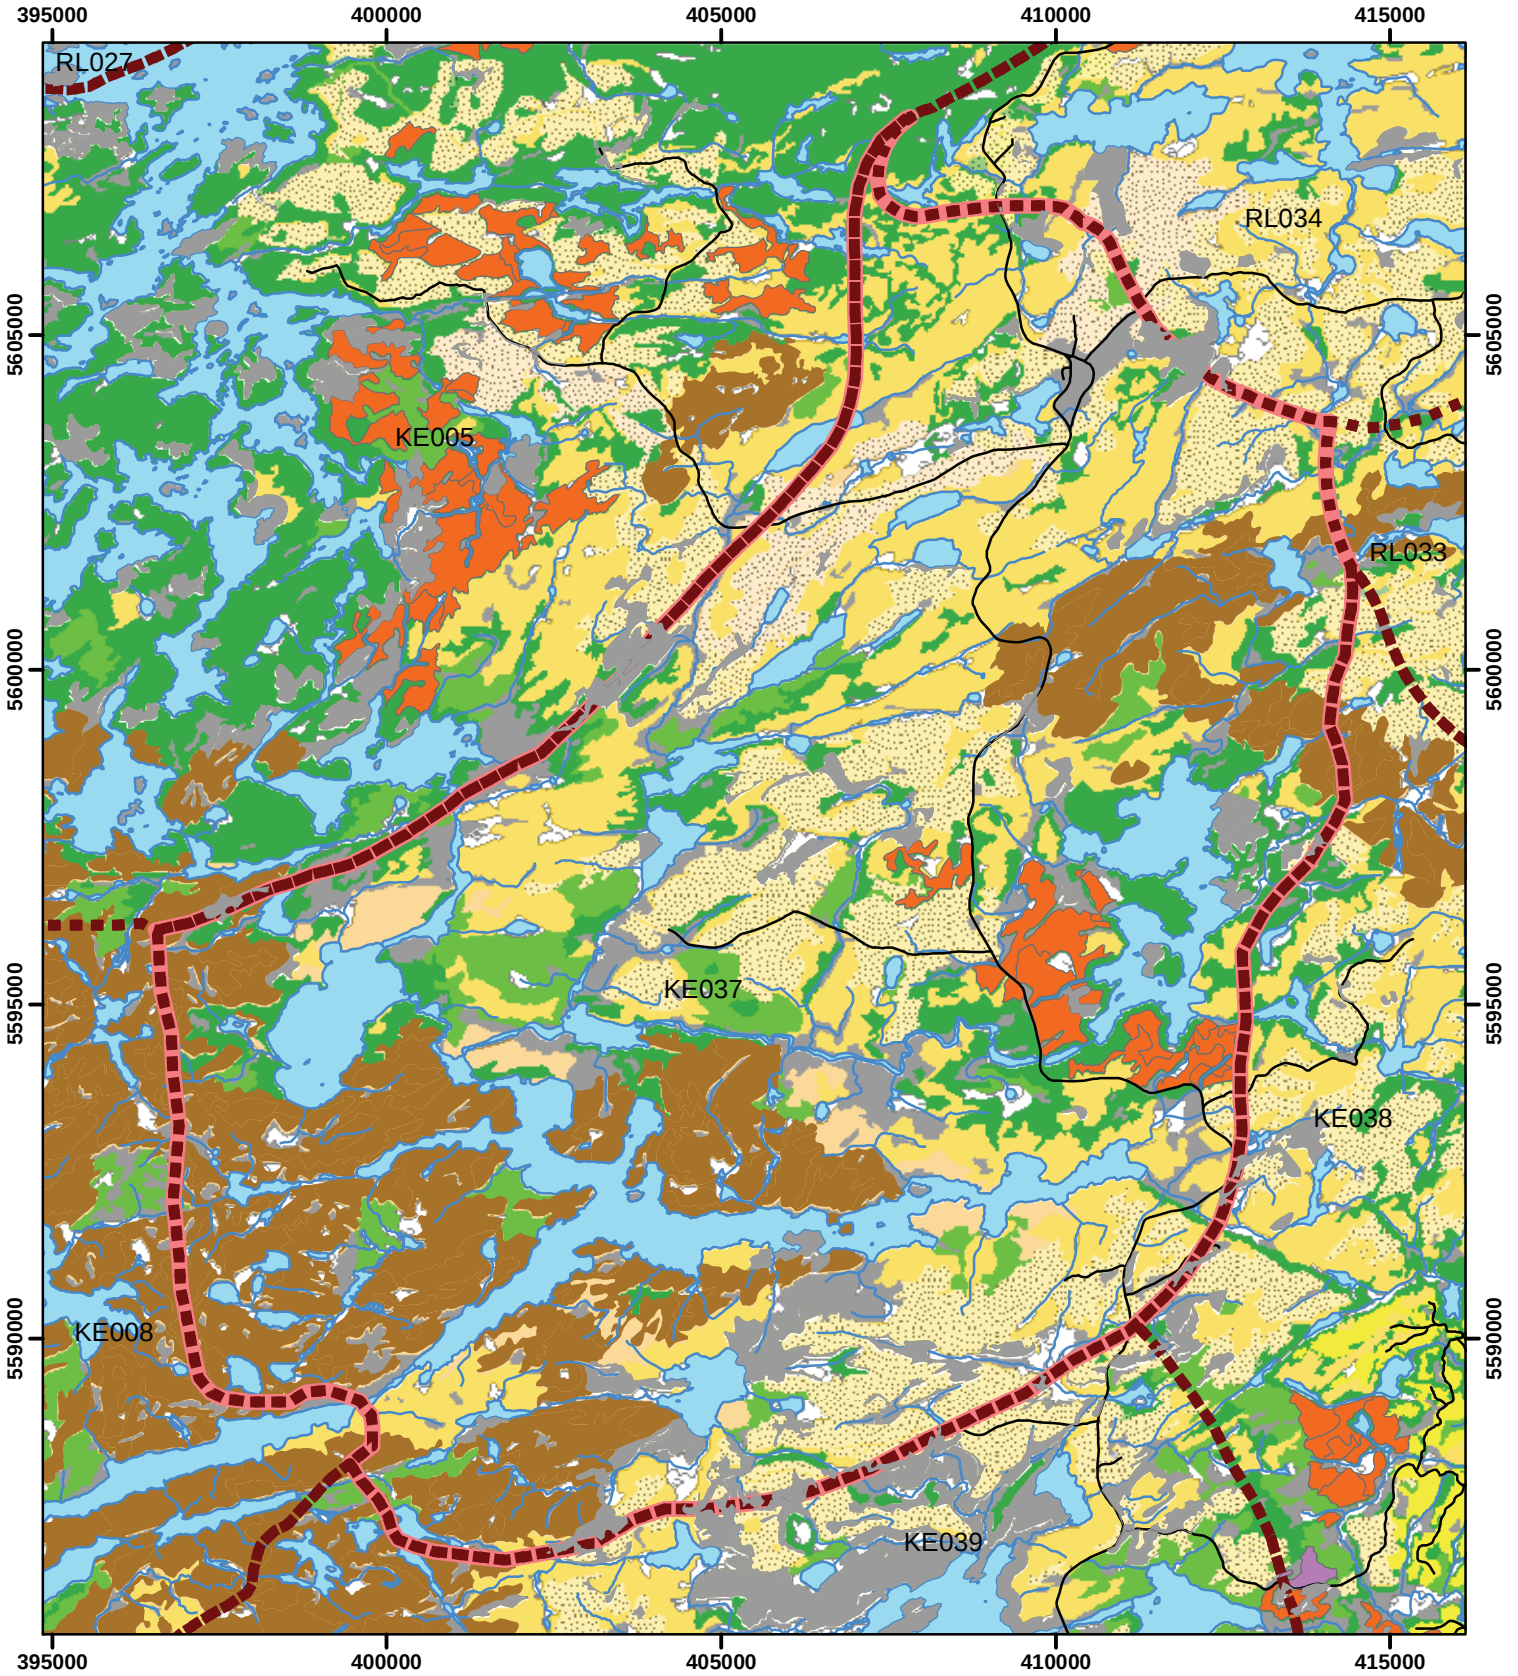
Trapping Area KE037

2072



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

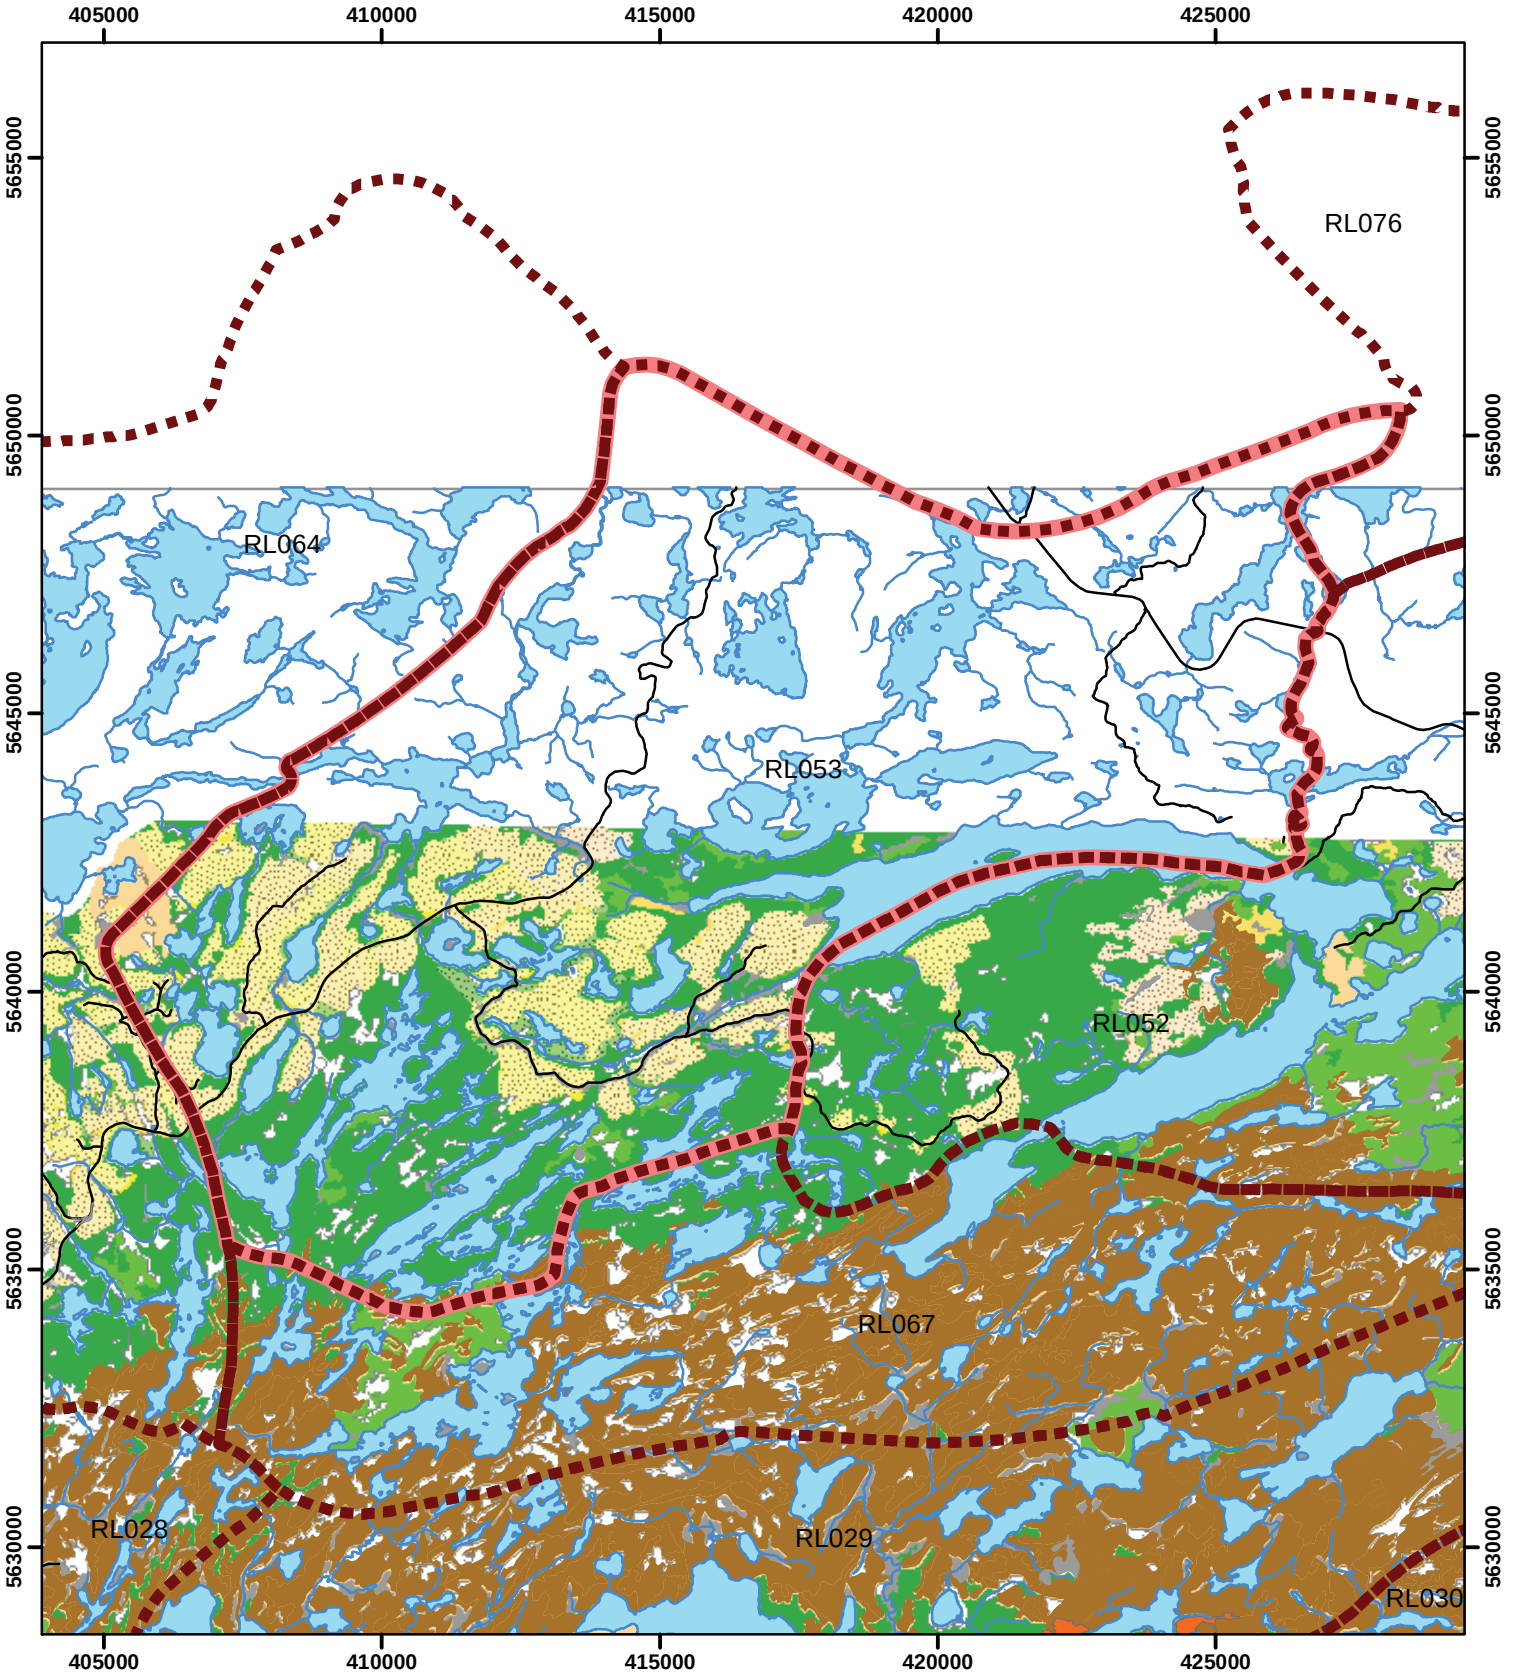
Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1 2 4 km

1:113,000

Planned and recent clearcut logging
Trapping Area RL053



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

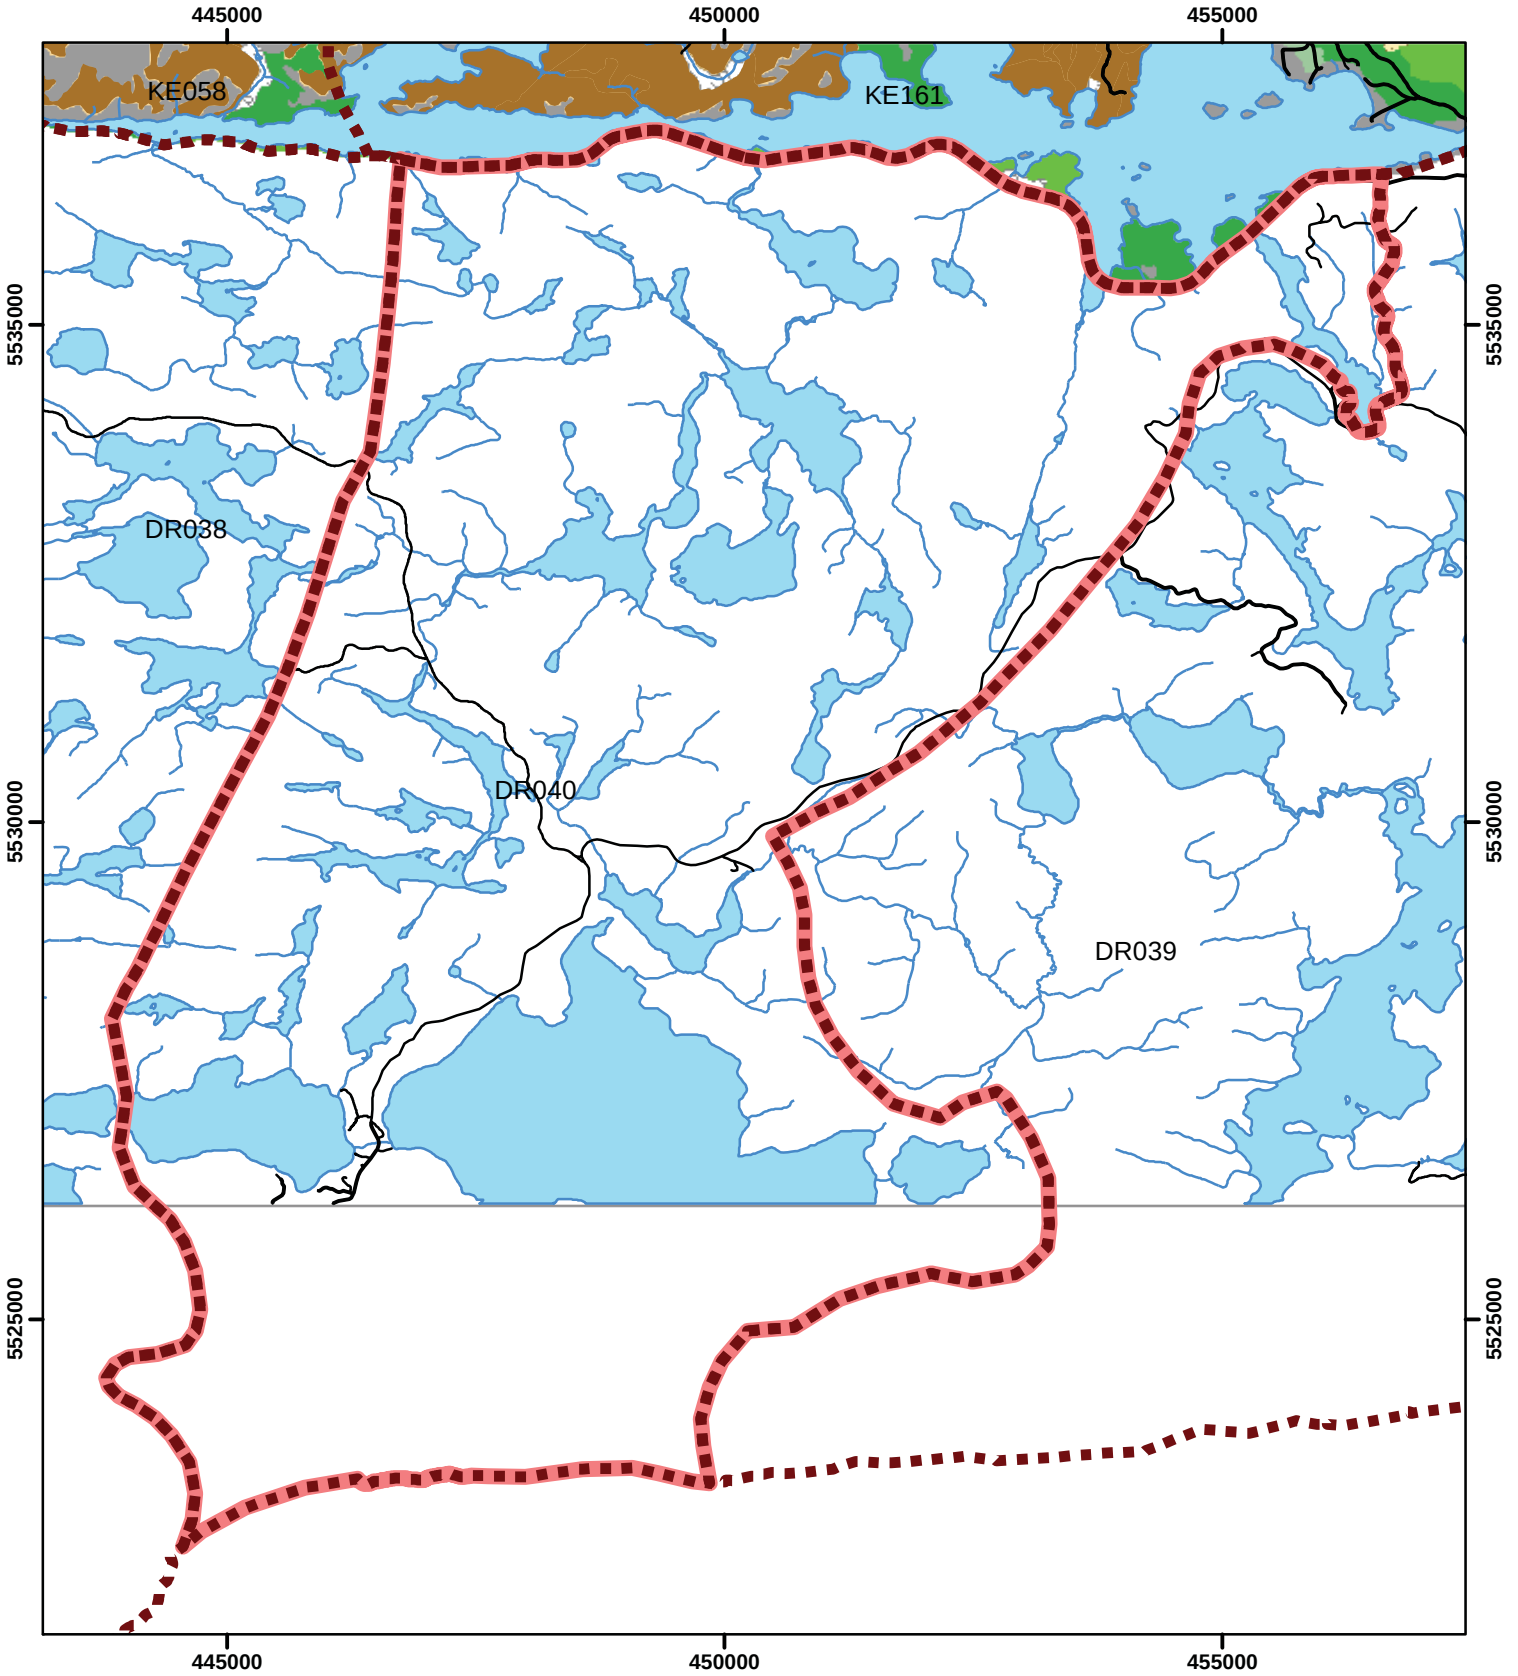
Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1.25 2.5 5 km

1:136,000

Planned and recent clearcut logging
Trapping Area DR040

2074



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

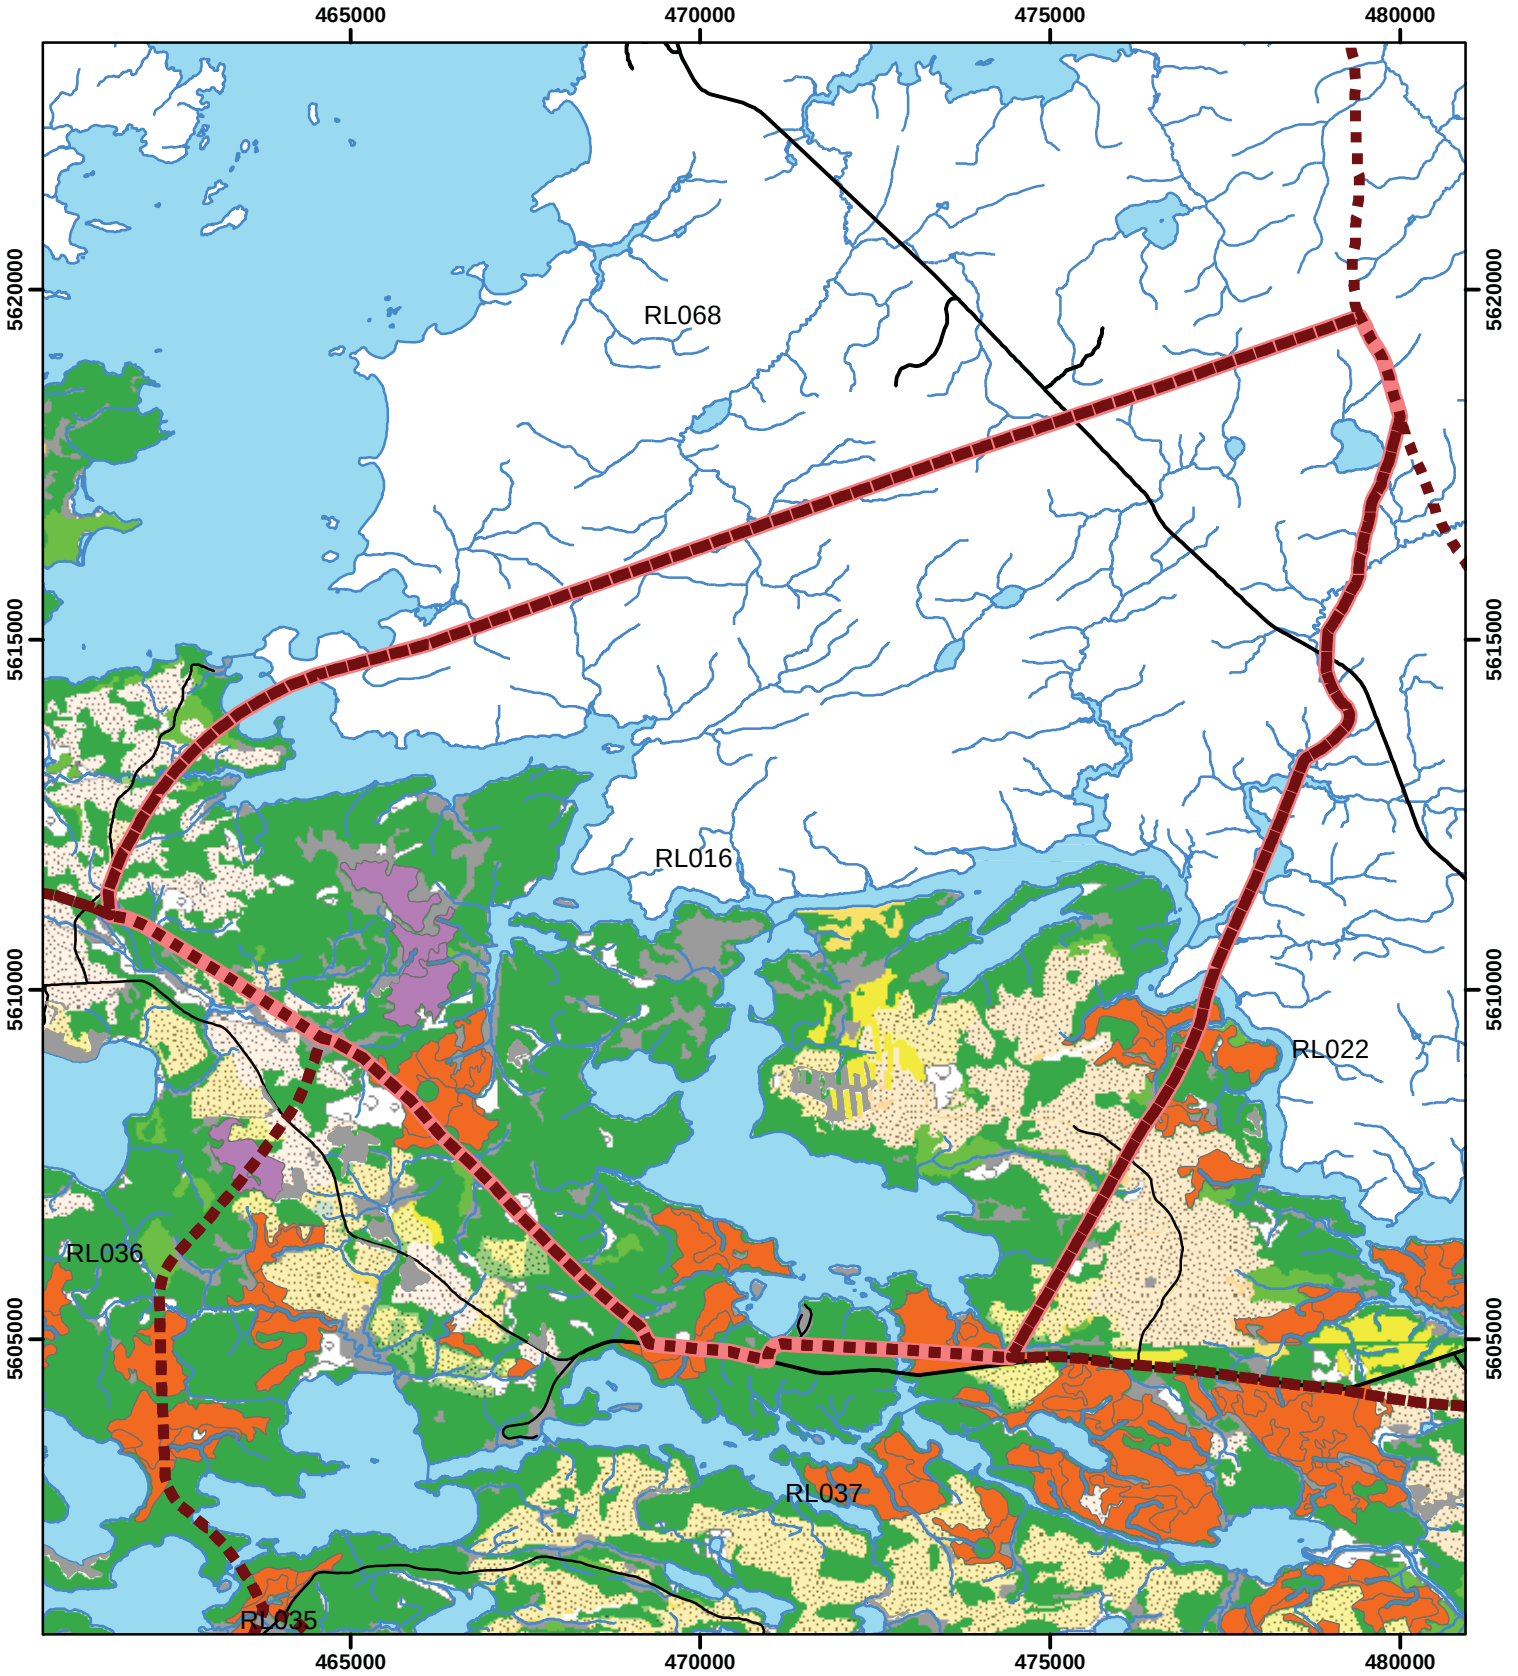
Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 0.5 1 2 km

1:76,000

Planned and recent clearcut logging
Trapping Area RL016



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

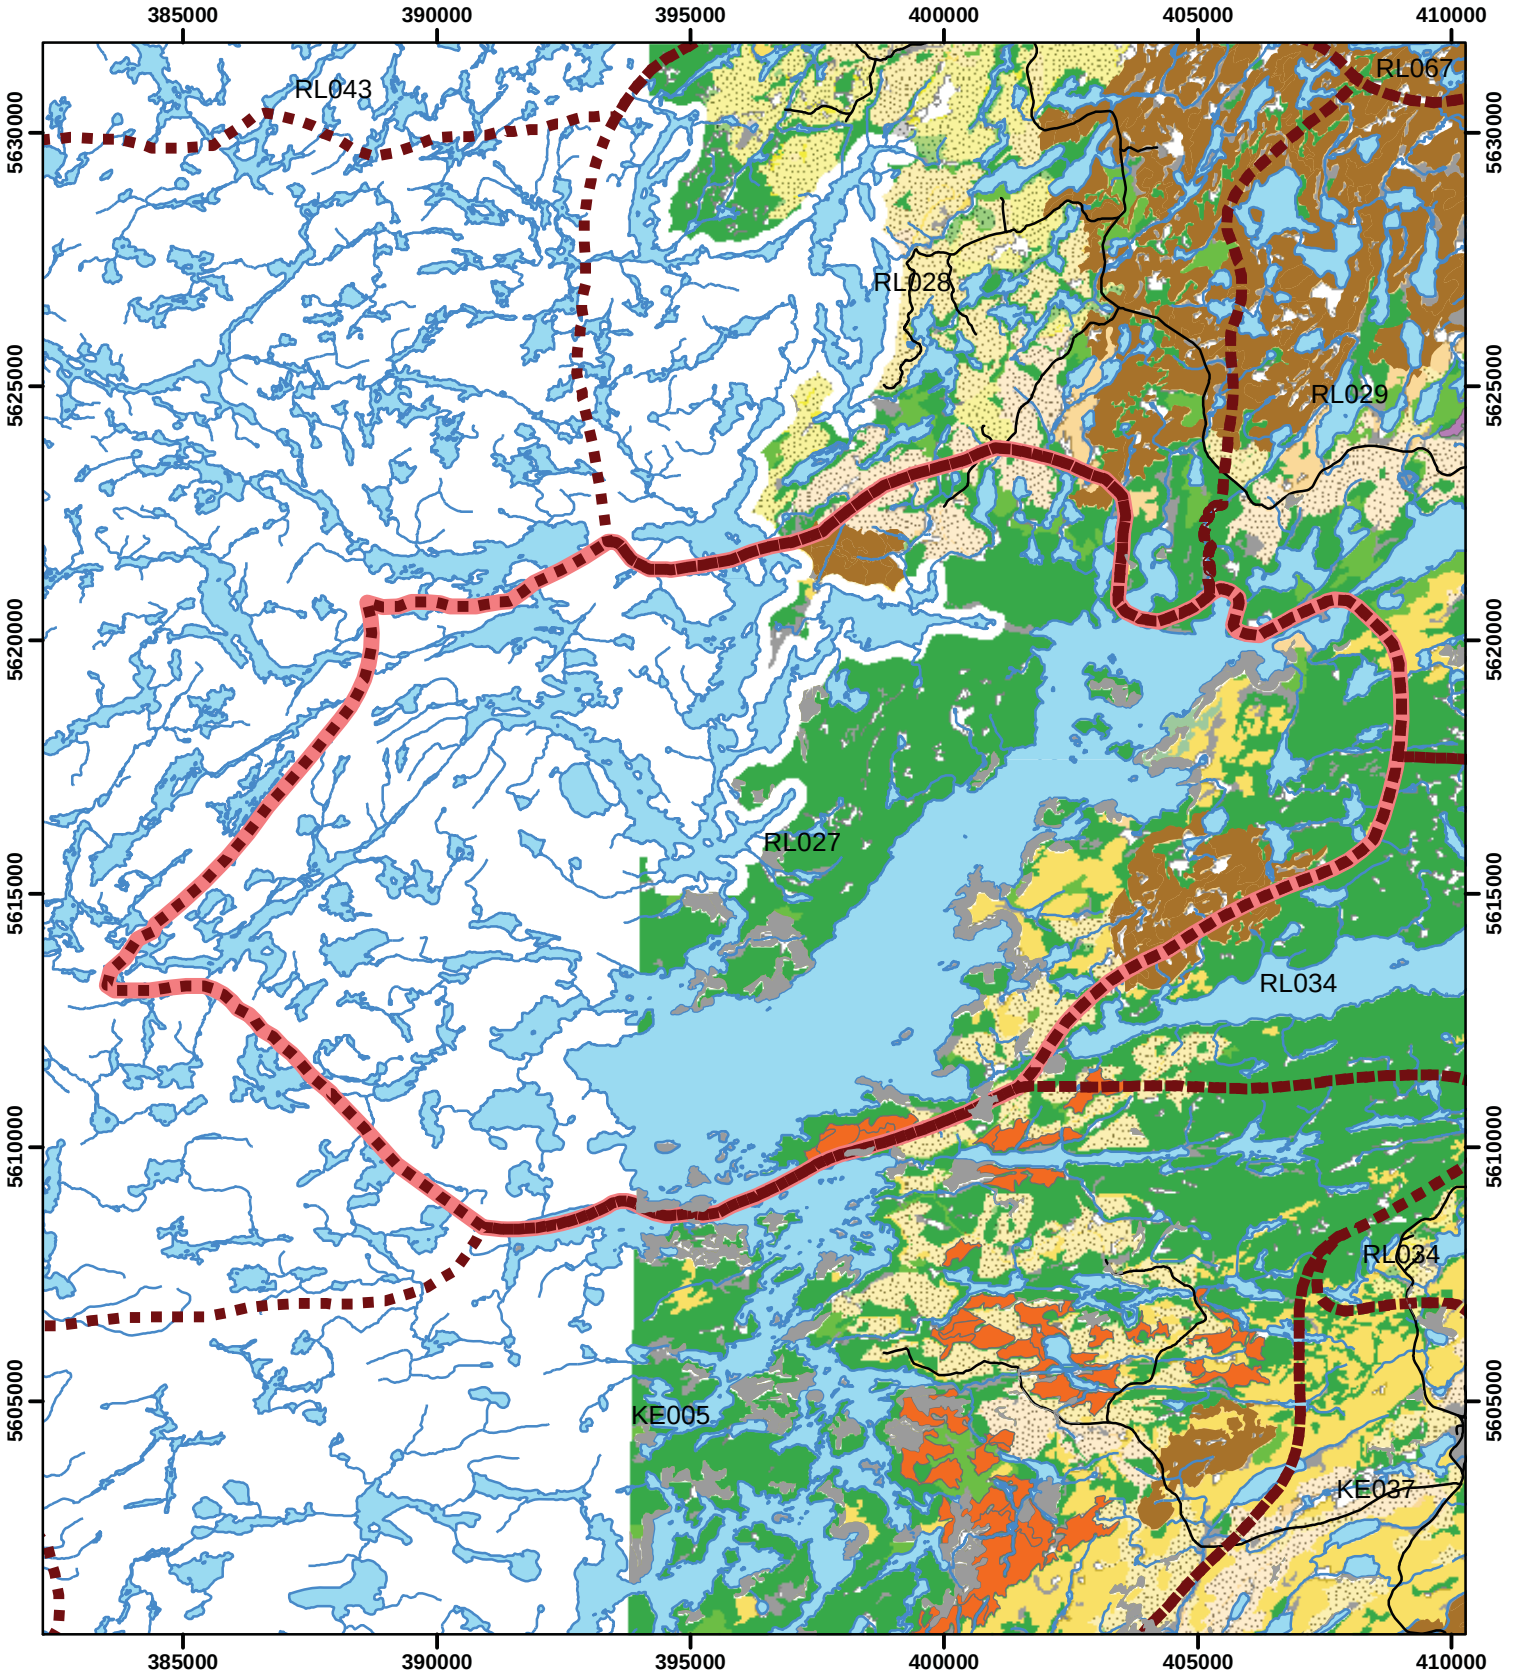
Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1 2 4 km

1:108,000

Planned and recent clearcut logging
Trapping Area RL027



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

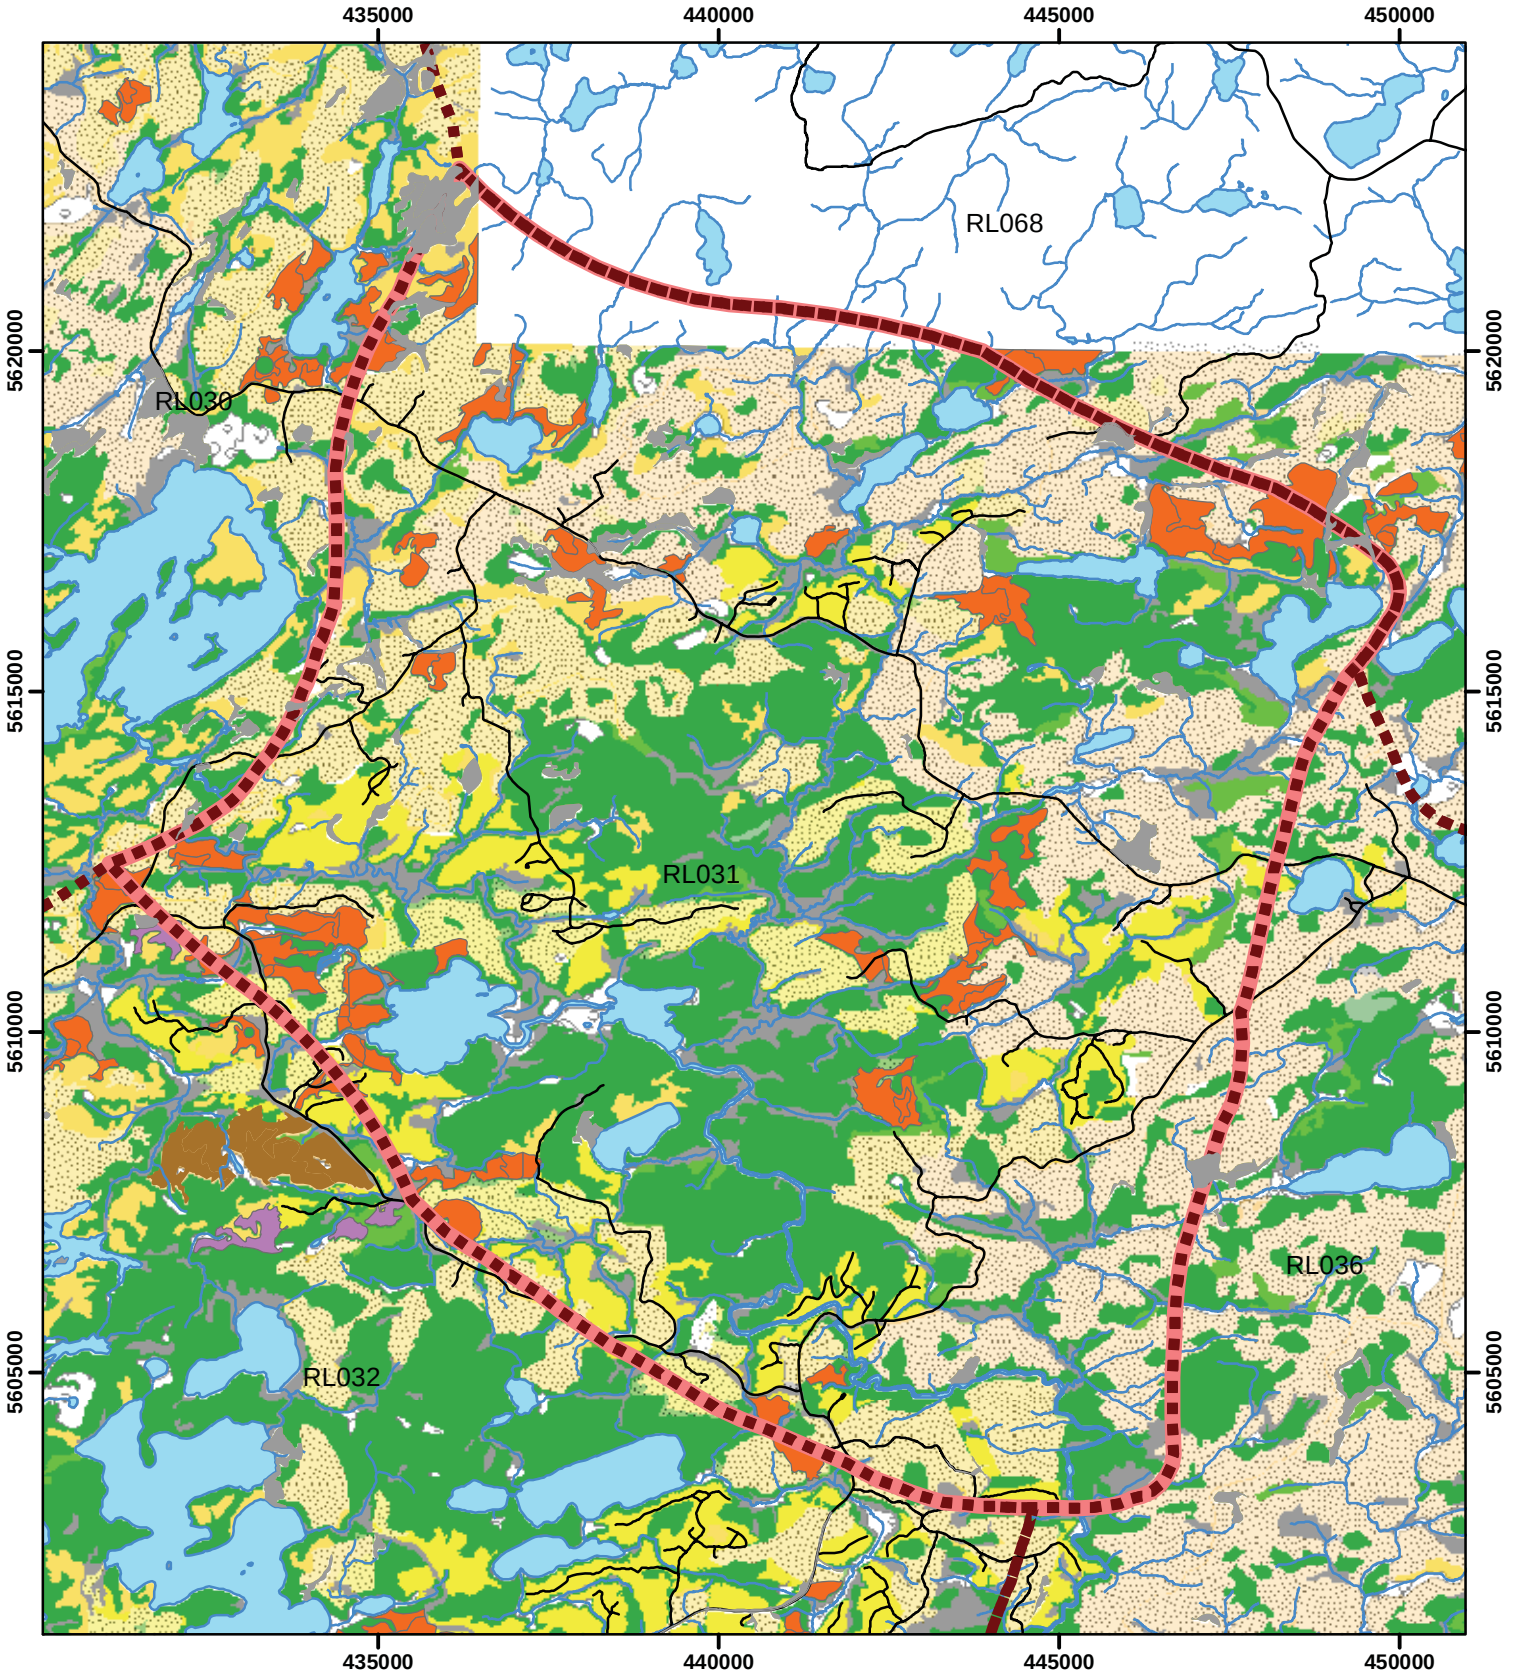
Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1.25 2.5 5 km

1:149,000

Planned and recent clearcut logging
Trapping Area RL031



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

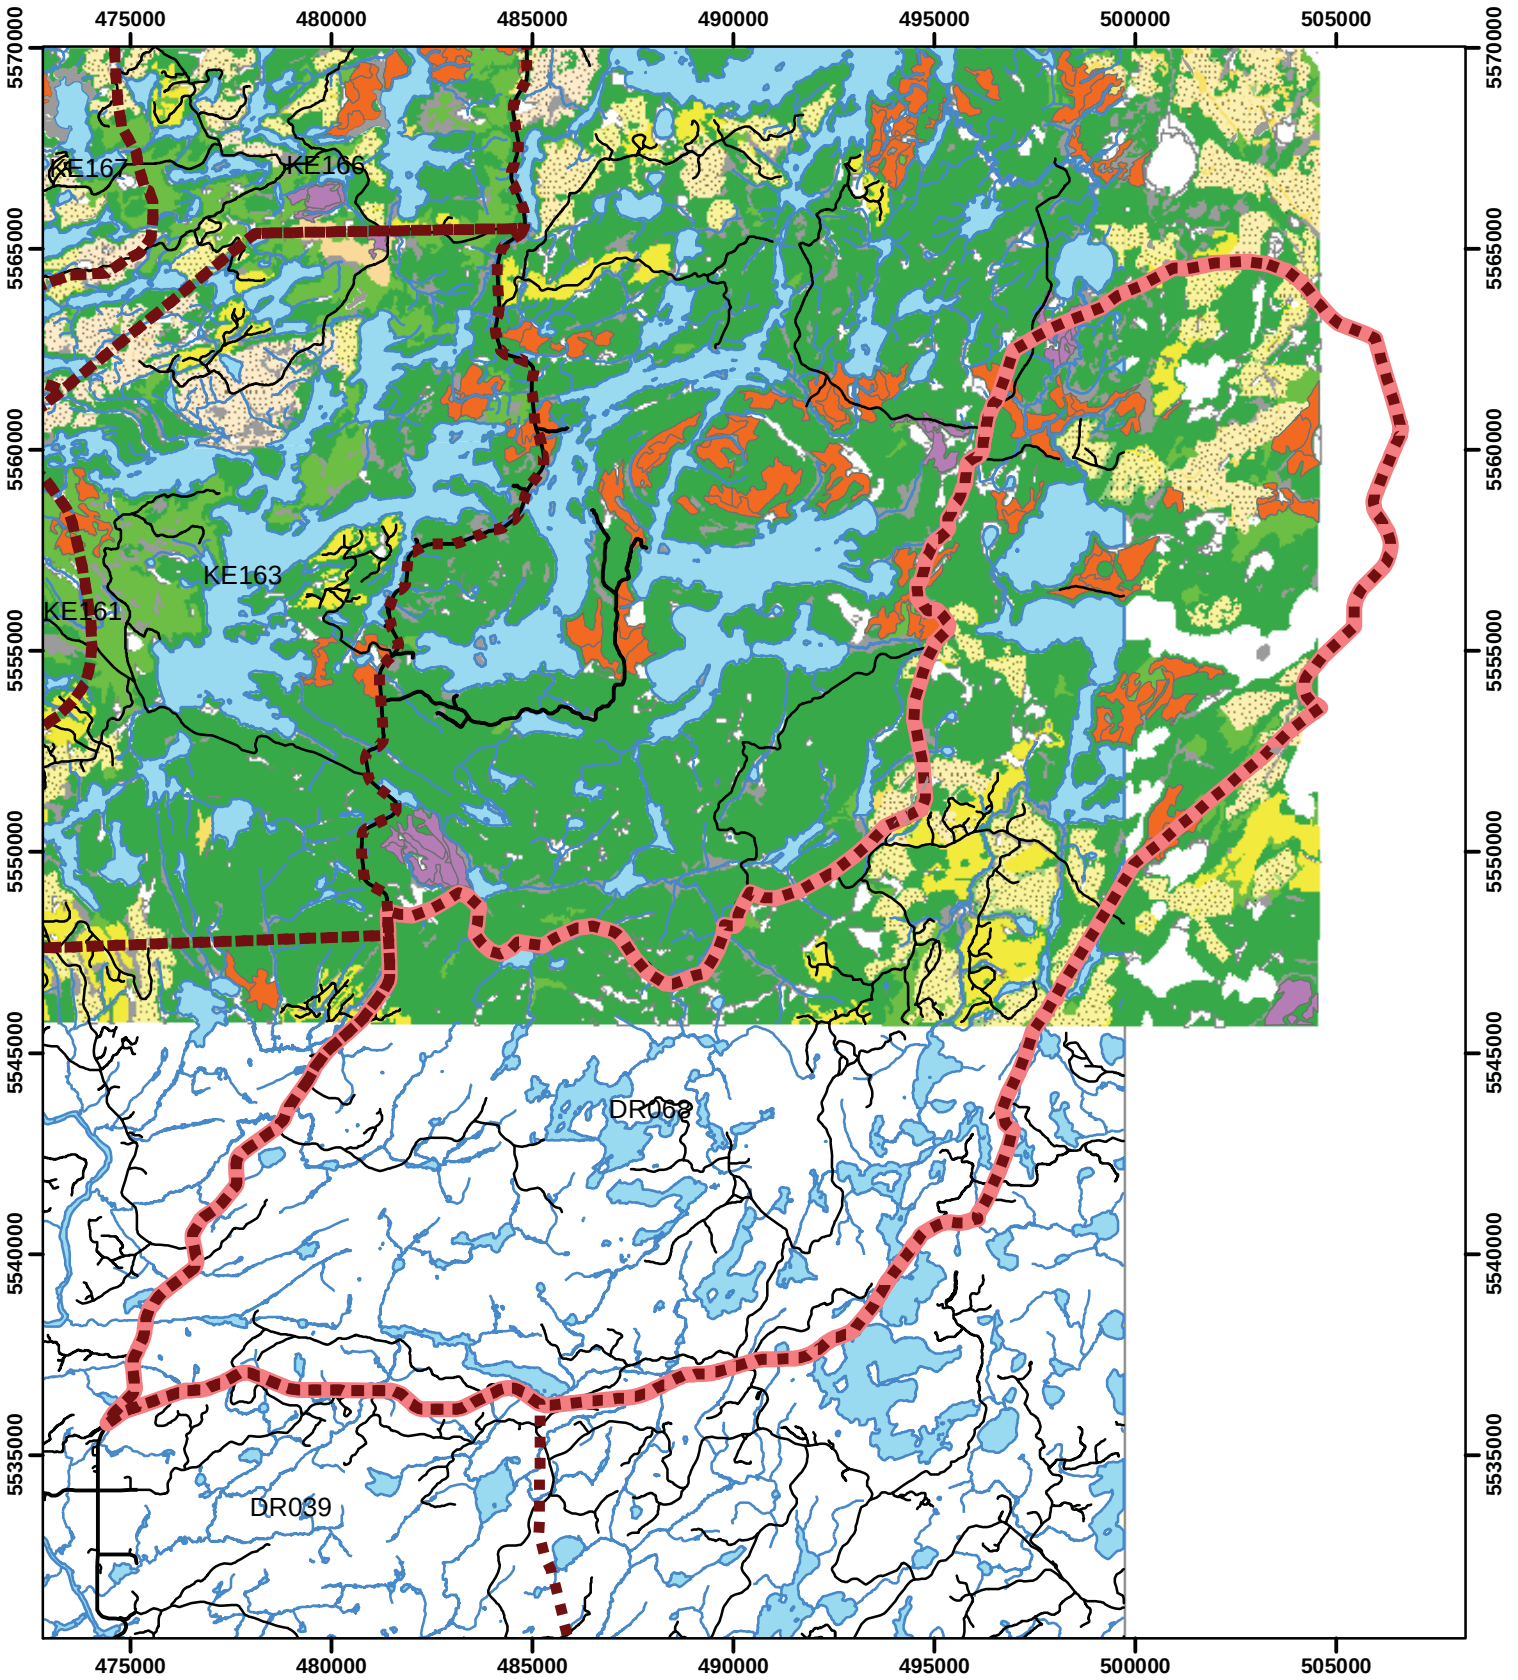
Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1 2 4 km

1:111,000

Planned and recent clearcut logging
Trapping Area DR068



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

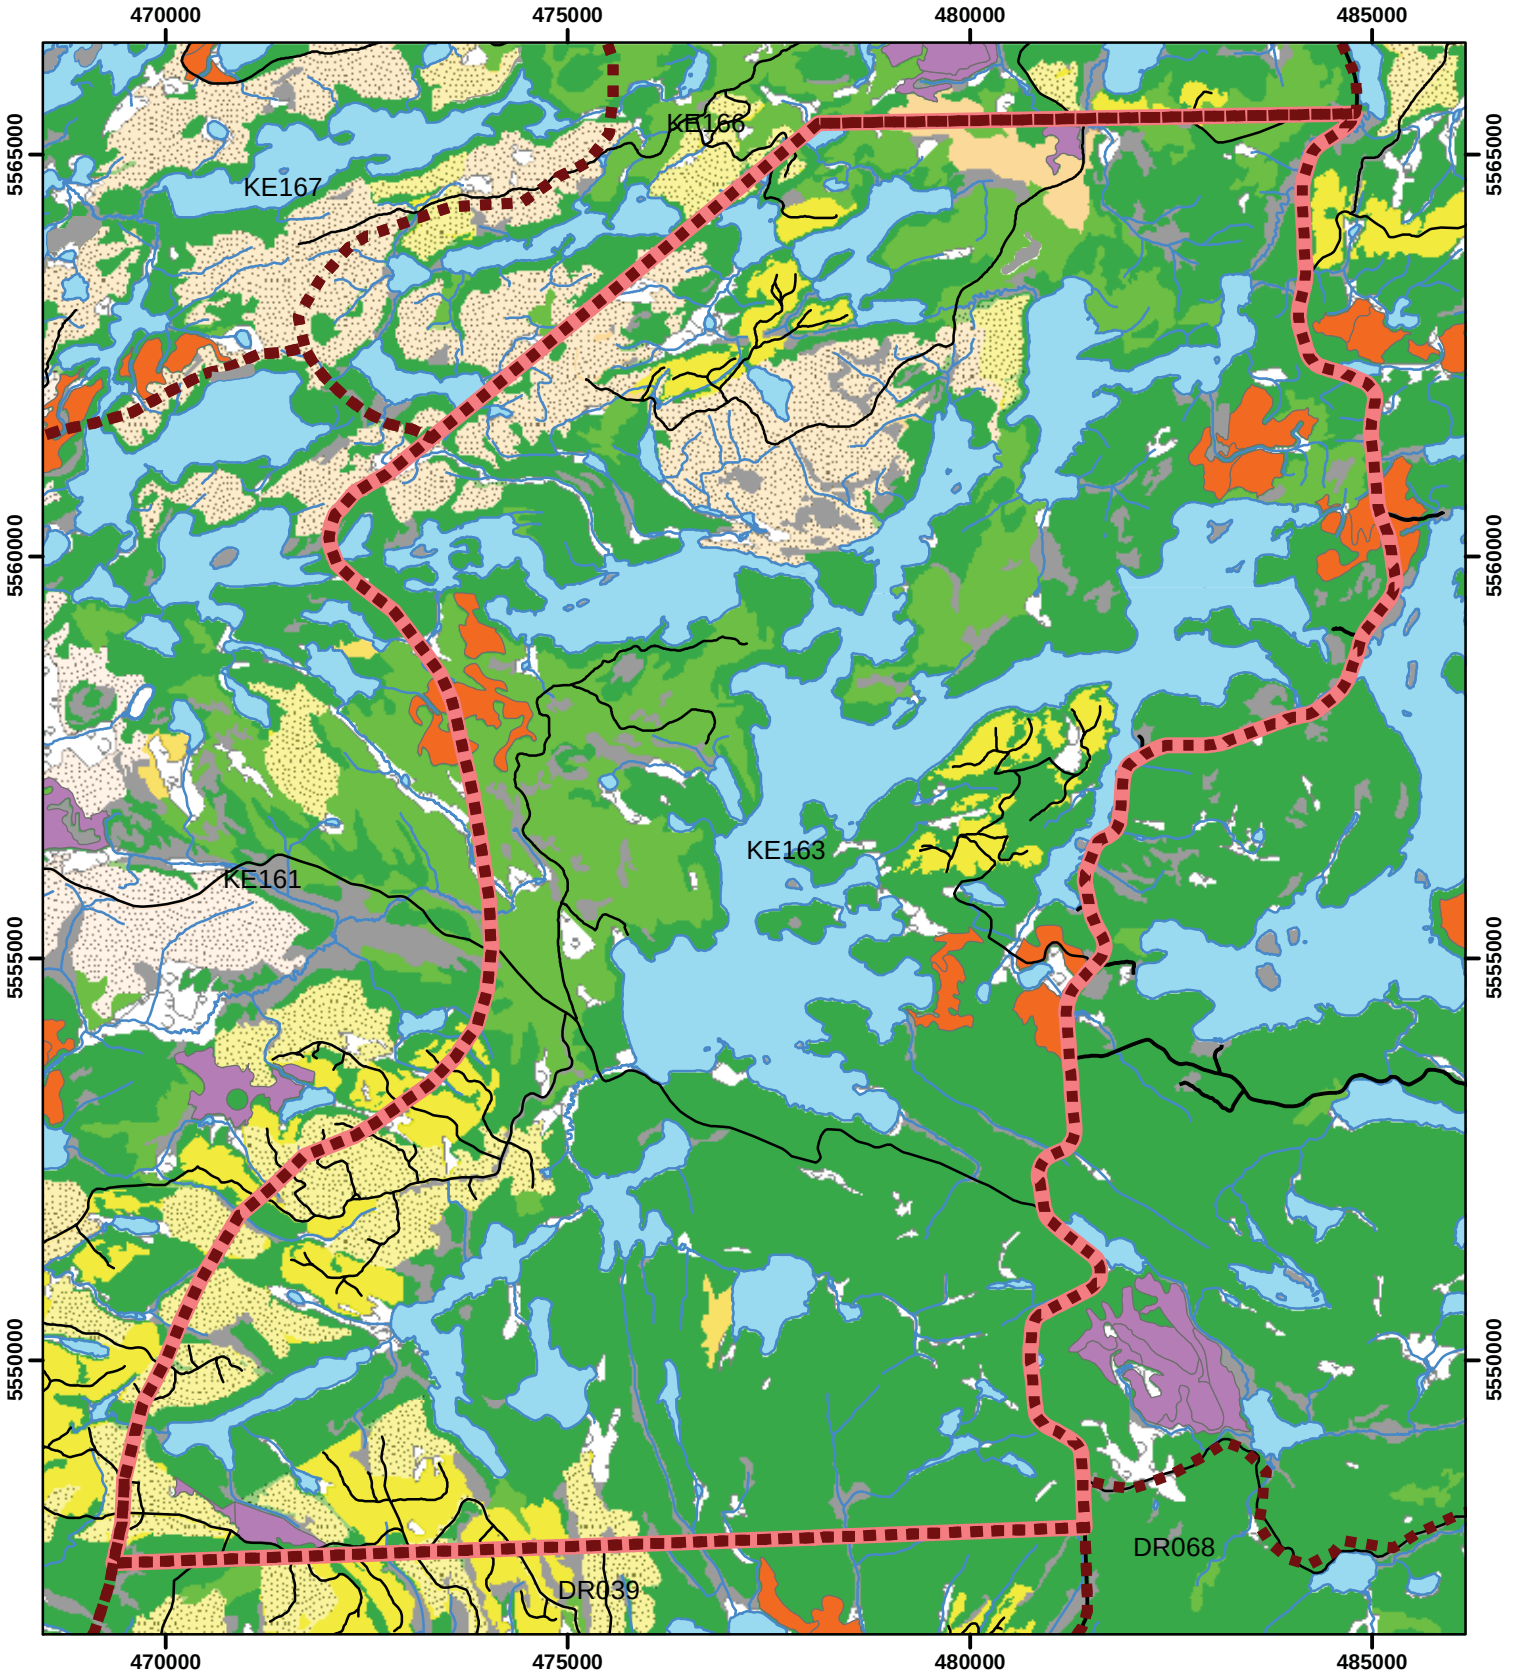
Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1.75 3.5 7 km

1:188,000

Planned and recent clearcut logging
Trapping Area KE163



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

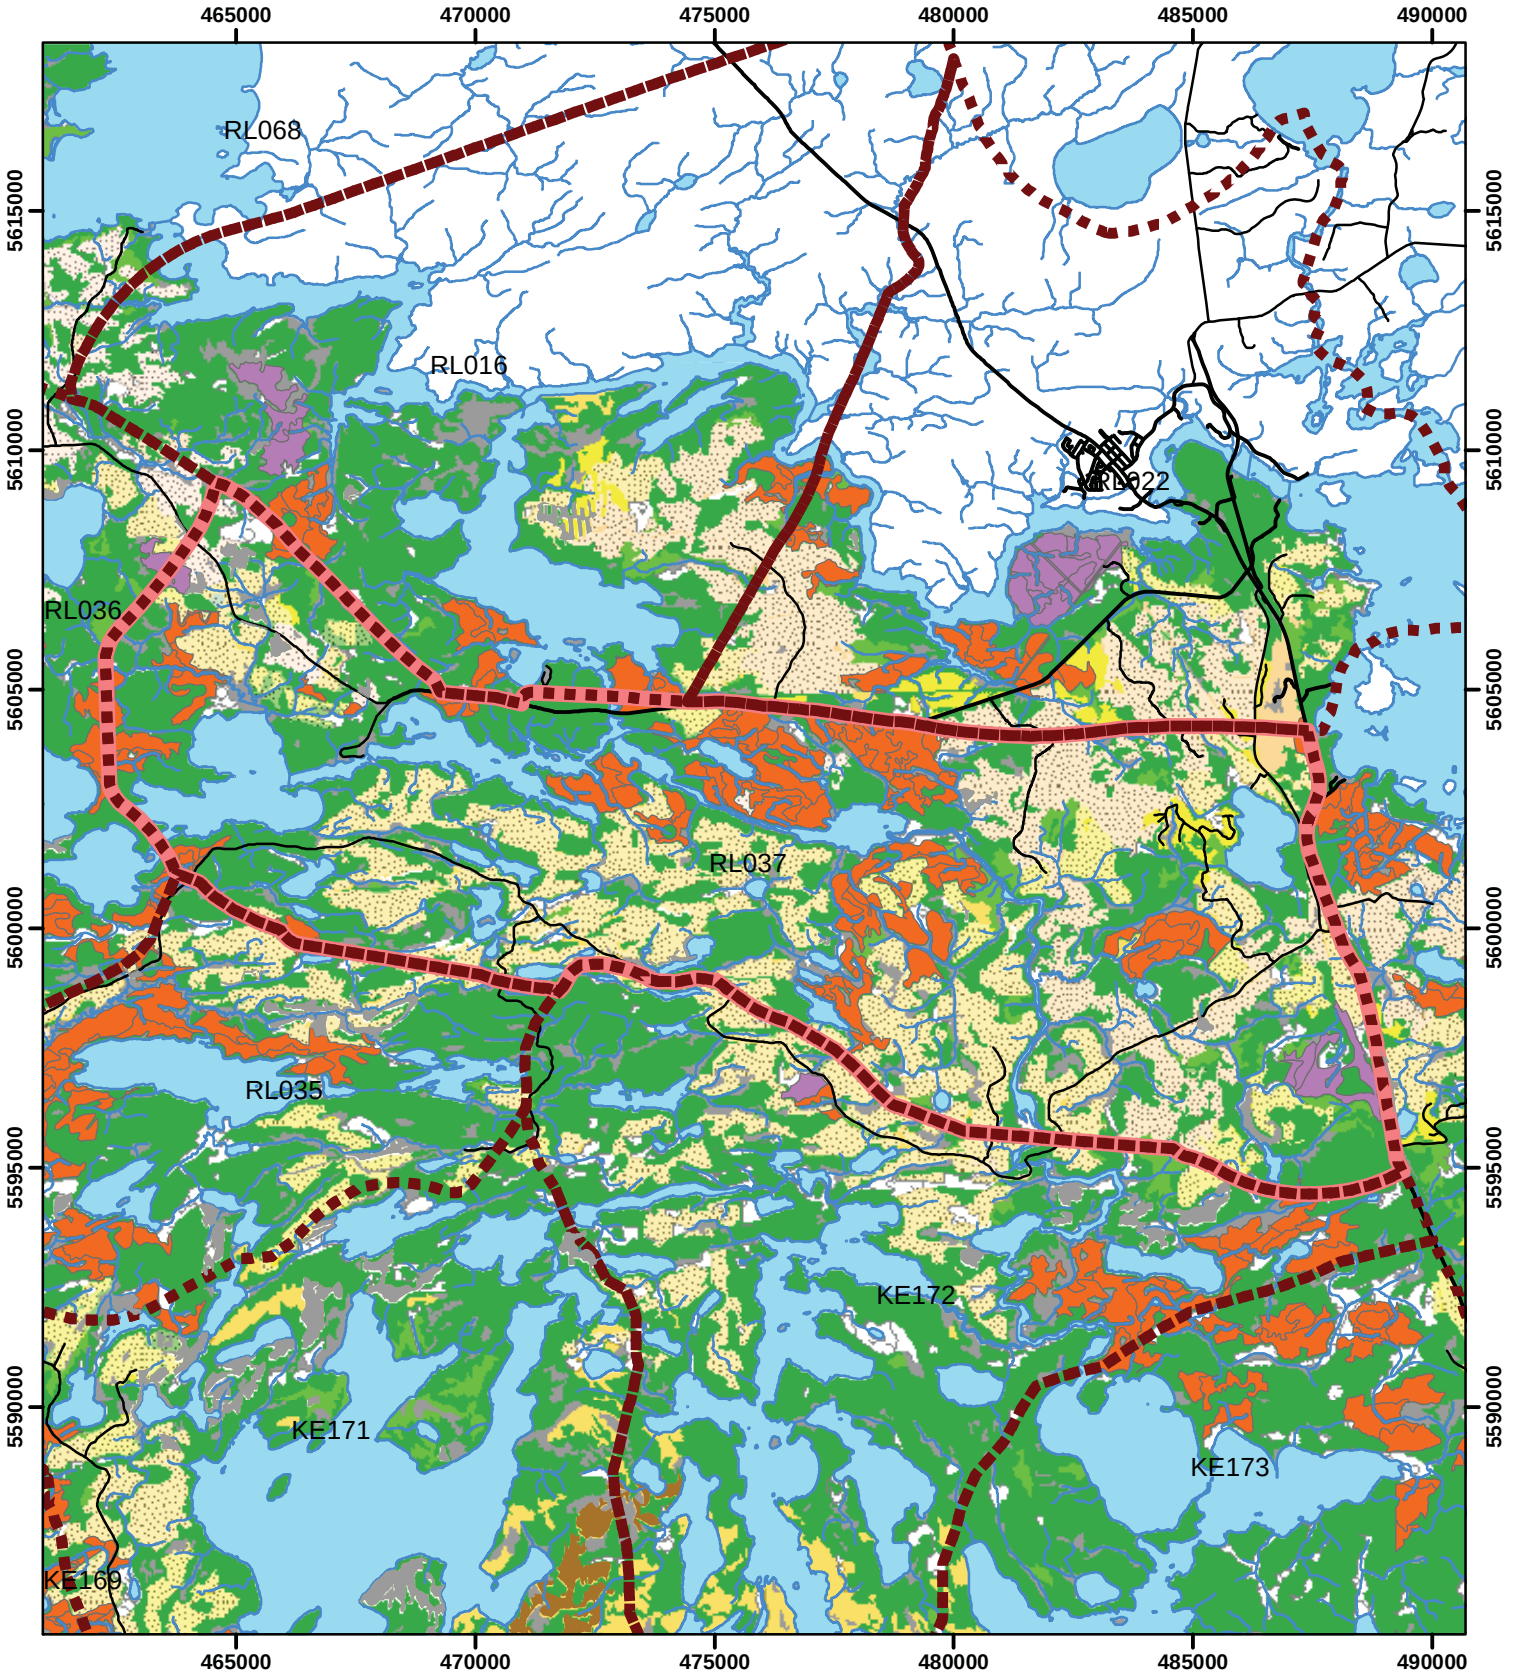
Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 0.75 1.5 3 km

1:94,000

Planned and recent clearcut logging
Trapping Area RL037



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

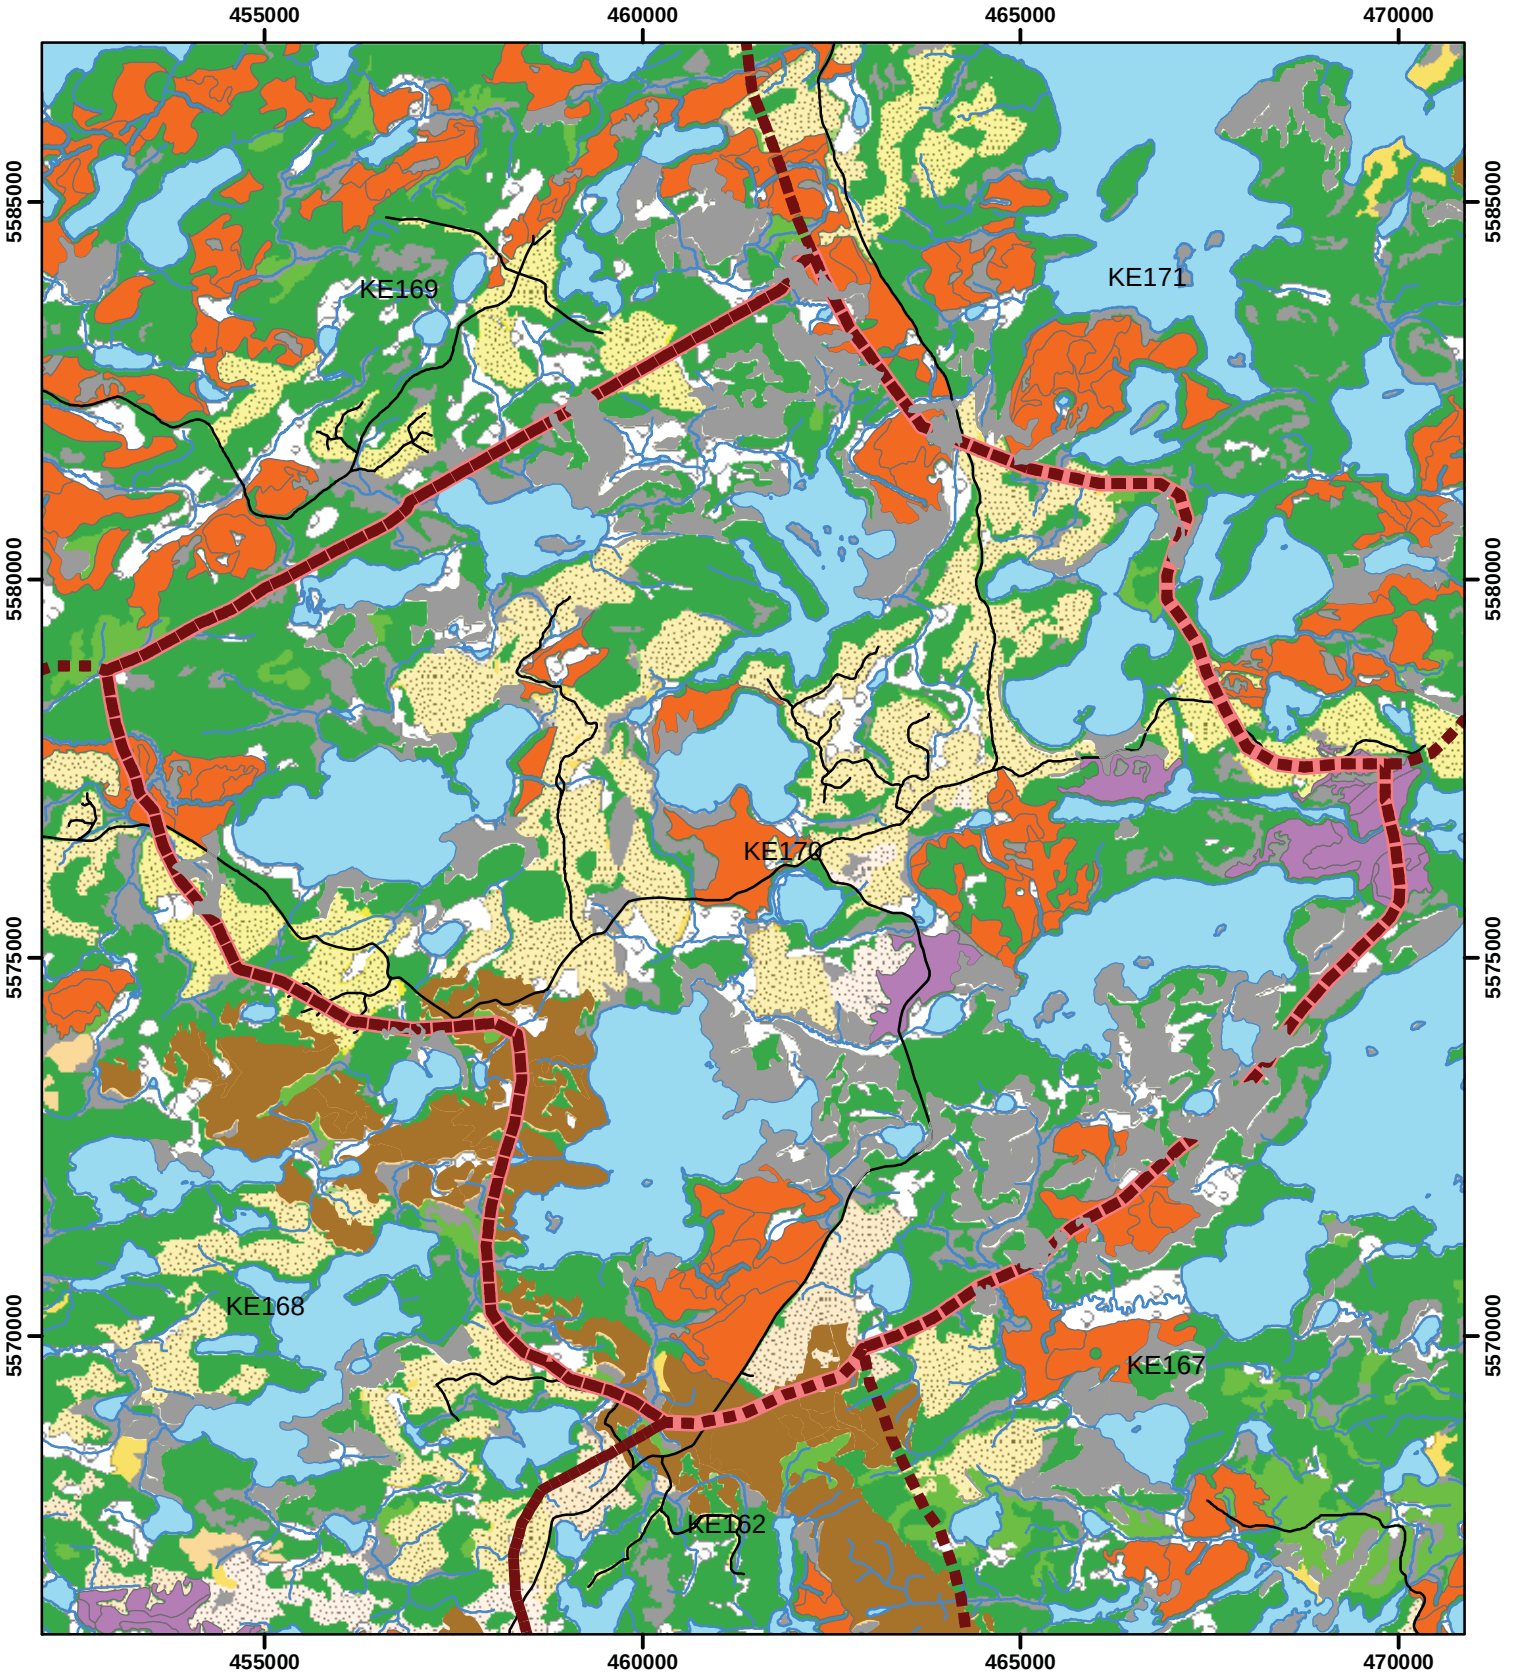
Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 1.5 3 6 km

1:158,000

Planned and recent clearcut logging
Trapping Area KE170



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

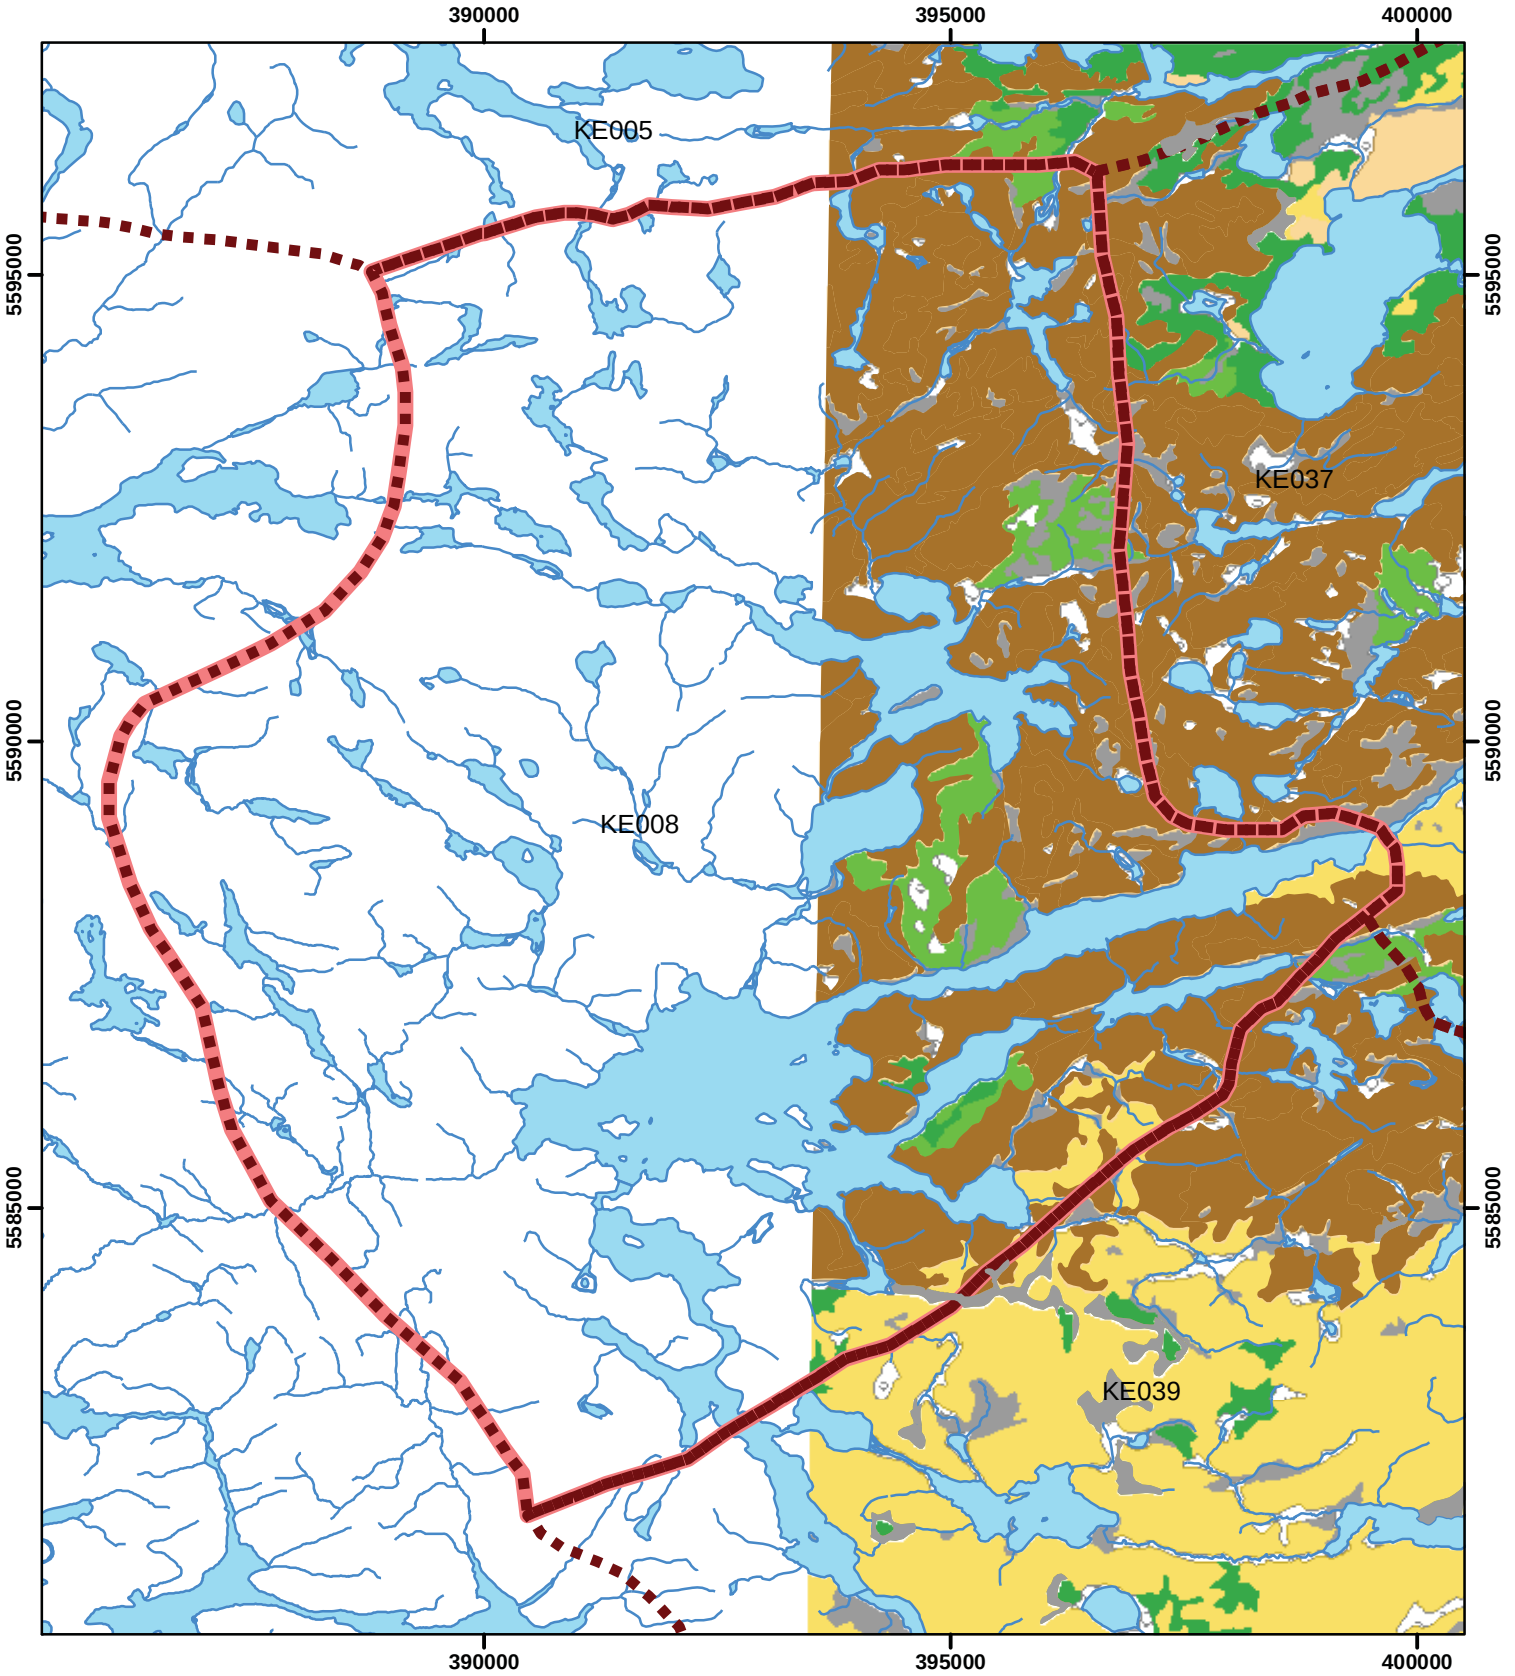
Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas
Wetland

0 0.75 1.5 3 km

1:100,000

Planned and recent clearcut logging
Trapping Area KE008



Trapping Area Boundaries

Planned Clearcuts, 2012-2022
Contingency Clearcuts, 2012-2022
Forest, 45 Years Or Younger
Forest, Older Than 45 Years
Forest, Depleted Before 1968

Depletions 1998-2007
Depletions 1988-1997
Depletions 1978-1987
Depletions 1968-1977
Confirmed Logged Since 1970

Blowdown Disturbances
Fire Disturbances
Other Natural Disturbances
Naturally Unforested Areas

APPENDIX B – CURRICULUM VITAE

Stephen A. Kilburn, *BES, MA, MCIP, RPP*

Education

M.A., Regional Planning and Resource Development
University of Waterloo, Waterloo, Ontario, Canada 1996

Bachelor of Environmental Studies, Honours Urban and Regional Planning
University of Waterloo, Waterloo, Ontario, Canada 1988

Memberships

Registered Professional Planner (RPP), Ontario Professional Planning Institute

Member, Canadian Institute of Planners (MCIP)

Selected Work Experience

Wolasoqey Nation Energy East Proposal Impact Assessment
St. Mary's, Woodstock, Tobique, Madawaska, Kingsclear, and Oromocto, New Brunswick 2015-present

Cheam Indian Band and Chawathil First Nation Trans Mountain Pipeline Twinning Proposal Impact Assessment
Rosedale and Hope, British Columbia 2015

Pimicikamak Manitoba Hydro Proposal Impact Assessment
Cross Lake, Manitoba 2014-2015

Migmawei Mawiomi Secretariat Port-Daniel-Gascons Cement Plant EA
Berens River, Manitoba 2013-2016

Sagamok Use-and-Occupancy Project
Sagamok Anishnawbek, Massey, Ontario 2013-present

Berens River First Nation Hydro Dam Environmental Assessment
Berens River, Manitoba 2014

Nunavik Marine Region Plan Development
Nunavik Marine Region Planning Commission, Kuujjuak, Quebec 2011-present

Kitchenuhmaykoosib Inninuwug Cultural Mapping and Spatial Aspects of Traditional Ecological Knowledge Projects
Kitchenuhmaykoosib Inninuwug Lands and Environment Unit, Big Trout Lake, Ontario 2010-present

Town of Orangeville Cultural Plan
Town of Orangeville, Ontario 2013-2014

Inuvialuit and Nanuq: Polar Bear and Sea Ice Traditional Knowledge Research Project
Inuvialuit Joint Secretariat, Inuvik, Northwest Territories 2012-2015

Fort Severn First Nation Cultural Mapping Support
Fort Severn First Nation, Fort Severn, Ontario 2012-2014

NMRPC Info Base Project
Nunavik Marine Region Planning Commission, Kuujjuak, Quebec 2012-2013

Kawacatoose First Nation Cultural Research
Kawacatoose First Nation, Raymore, Saskatchewan 2012-2013

Kineepik Métis Local Cultural Research Project
Kineepik Métis Local, Pinehouse, Saskatchewan 2011-2013

Cultural Land Use Mapping Project Workshop
Grand Council of the Crees (Eeyou Istchee), Mistissini, Quebec 2013

Land Use Planning Workshop
Nunavik Marine Region Planning Commission, Kuujjuaq, Quebec 2011

Wolf Lake First Nation and Timiskaming First Nation Data Audit
Algonquin Nation Secretariat, Timiskaming, Ontario 2011

James Smith Cree Nations Use-and-Occupancy Support

and THE ATTORNEY GENERAL OF ONTARIO

Respondents

ACKNOWLEDGEMENT OF EXPERT'S DUTY

1. My name is Stephen Kilburn. I live in Guelph in the Province of Ontario.

2. I have been engaged by or on behalf of Grassy Narrows First Nation to provide evidence in relation to the above-noted court proceeding.

3. I acknowledge that it is my duty to provide evidence in relation to this proceeding as follows:

   (a) to provide opinion evidence that is fair, objective and non-partisan;

   (b) to provide opinion evidence that is related only to matters that are within my area of expertise; and

   (c) to provide such additional assistance as the court may reasonably require, to determine a matter in issue.

4. I acknowledge that the duty referred to above prevails over any obligation which I may owe to any party by whom or on whose behalf I am engaged.

Respondents

AFFIDAVIT OF STEVEN FOBISTER, SENIOR

I, STEVEN FOBISTER, SENIOR, of Grassy Narrows, in the District of Kenora, AFFIRM AS FOLLOWS:

1. I am a member of Grassy Narrows First Nation ("Grassy Narrows"). At various times I have served my people as the Deputy Chief of the Grassy Narrows Band Council, the elected Chief of Grassy Narrows, and the Grand Chief of Treaty Three. As such, I have knowledge of the matters hereinafter deposed to.

2. Clearcut logging recently was approved by the Respondents as part of a Forest Management Plan for the Whiskey Jack Forest for the period 2012 to 2022 (the "Plan"). Most of the Whiskey Jack Forest is the traditional territory of our people. My whole life, I have eaten fish from the many lakes, streams, and waters that form part of the watershed of the English-Wabigoon River System, which runs through the Whiskey Jack.

3. I was born in 1952 at the hospital in Dryden and have lived on Grassy Narrows' traditional territory for most of my life. I was raised the traditional Anishinaabe way. Growing up, I lived primarily on my family's trapline eating a traditional diet rich in fish and wild plants, with some wild game. We moved frequently throughout our traditional territory according to the seasons and the availability of food. Although poor in material goods, we were spiritually rich and felt our connection to the land deeply. The land gave us food and shelter, and it always sustained us. I loved that life.

4. Our way of life followed a circle. In the spring we hunted migratory birds; in the summer I would guide American sport fishers. There was really good subsistence and commercial fishing in the fall. In the winter we went to our traplines.

5. I am intimately familiar with the land in my trapline area and the areas where I used to guide sport fishers, including lakes whose watersheds are scheduled for clearcutting under the Plan. For example, the lake identified in the watershed and trapline maps found behind Exhibit "A" to this affidavit is in my trapline area. The maps come from Stephen Kilburn's Expert Report, and I am very familiar with the area identified in the maps. The

lake identified in the maps as watershed Noname 20 near Campfire Lake is named Zagaatigooning-zaaga'iganish – in English, the Little Lake of the Dense Woods. It is a beautiful little lake. It is a good place to camp, and when I was younger I used to camp there all the time. It lies at the end of a long portage from Campfire Lake and it is crystal clear, surrounded by old growth forest. There are lots of fish in this lake – in fact, all of the lakes in this area are incredibly productive. I used to catch trout from the stream entering this lake with a snare. Besides being a good lake for fishing, Zagaatigooning-zaaga'iganish is a good place to harvest traditional medicines. The area KE038 shown in the second map in Exhibit "A" is my trapline area where I sustained myself and earned my livelihood as a young man. I know that area well and I have traveled, fished, trapped, and hunted throughout the area. I hope to pass that area on to my grandchildren so that they can enjoy it as I have.

6. The forest around Zagaatigooning-zaaga'iganish is slated for heavy clearcutting under the Plan, as shown in the maps behind Exhibit "A". I fear that this clearcutting will not only destroy the beauty and cultural value of a place I cherish, but will also increase the mercury levels in the water and in the fish that live there.

7. I ate fish almost every day growing up, and when I was guiding I would often eat fish multiple times a day. I would also bring home fish for my wife and children. I mostly ate walleye, but I would eat other fish too. Walleye is my favourite; it tastes better than the other fish.

8. The full impact of the mercury pollution hit us in 1970, when the government announced that the Dryden plant had contaminated our waters. After that we couldn't live off the land anymore. The guiding industry slowed to a trickle and our commercial fisheries had to close. Where we had been self-sufficient, we were forced to become dependent on welfare. Our community suffered greatly.

9. I continued to work as a sport fishing guide for years after the mercury was discovered. Unemployment was very high and I felt lucky to have work. The tourist camp operators encouraged us to eat fish to show our guests that it was safe. I kept eating fish as frequently as I had before the mercury was discovered.

10. I continue to eat fish from the English-Wabigoon River System to this day because it is an important part of my culture. Also, my precarious financial situation means I cannot afford to cut wild fish out of my diet.

11. I believe that my exposure to mercury has affected me terribly. My body is breaking down one piece at a time. I experience shaking and loss of balance. I have difficulty swallowing, weakness in my hands, and my speech is slurred. I have difficulty walking and I need to use a riding lawnmower to get around because I don't have a motorized wheelchair. I feel deep sadness and depression about the loss of my health and my traditional way of life due to mercury pollution and logging. When I look at the land, look at our situation, I feel despair. There are so many sick people here, so much

destruction of our land and our way of life. You can't imagine how it feels when the land and water that have always sustained you can suddenly kill you.

12. I have been examined by the Mercury Disability Board and diagnosed with symptoms consistent with mercury poisoning. I receive $250.00 each month from the Mercury Disability Board. Dr. Masazumi Harada examined me in 2010 and diagnosed me with mercury poisoning. I have now also been diagnosed with amyotrophic lateral sclerosis (ALS).

13. In April 2010, I was interviewed by the CBC regarding the effects I have experienced due to exposure to mercury. Exhibit "B" to my affidavit contains excerpts of my comments to the CBC in 2010. The CBC included some footage from a much earlier interview in the 2010 piece, and I identify the source of each comment in this paragraph. In the earlier interview, I stated: "I don't think, you know, it's right to say, look, you know, you don't have to go trapping. You can live on welfare." In my comments to the CBC in 2010, I stated: "My whole nervous system is out of whack, you know, I can't barely walk and, you know, I have to hold my jaw to talk because my muscles are practically gone…[As a fishing guide, he] had [to eat what he caught even after the mercury was discovered.] We had to do this in order to appease our guests that the fish was ok. The tourist camp owners encouraged us to do it. […] [I recall Dr. Harada during his return to Grassy Narrows in March 2010 saying to me,] 'You know you have some kind of a metal poisoning,' and the closest definition to [Harada's] examination…it's got to be mercury. […] I only have one granddaughter. She's the one who kind of possesses violent

seizures." I have reviewed these excerpts and they are true and accurate. I have clarified in the remarks that appear in the next to last square bracket what was unclear about who was speaking as set out in Exhibit "B". These excerpts were included in a larger document Grassy Narrows filed with the Ministry of the Environment in September, 2014 in an attempt to persuade the Ministry to examine the effects of mercury from clearcut logging authorized by the Respondents for the Plan.

14. Also contained in Exhibit "B" are excerpts from a 2003 interview of me by a reporter for the Toronto Star regarding the mercury issue. I advised the reporter that I have serious neurological disease: "I can't hardly tie my shoes anymore." I also said that I blame clearcut logging in the area for the continuing high levels of mercury contamination. These excerpts were also included in the September 2014 document referred to above. I have reviewed these excerpts and they are true and accurate.

15. I fear that continued clearcutting in our traditional territory will expose us to further mercury poisoning. I am extremely concerned about future mercury exposure if additional mercury is released from the forest as a result of clearcutting. I am afraid of the physical effects of exposing our bodies to yet another round of mercury, and I am also afraid of the psychological effects. For me and for many others, the psychological effects of mercury poisoning – including, but not limited to, depression and anxiety – are unspeakably painful. Being out on the land and water allows us to escape, however briefly, from the negative mental and emotional states that are associated with living in a community struggling with mercury poisoning. I fear clearcutting would add to our

mercury burden, which would add to the negativity, and also raze the forest, thereby removing a vital form of retreat and healing.

16. I also fear for the health of our land and our ability to practice an Anishinaabe lifestyle if clearcutting is allowed to continue under the Plan. Large portions of the forest on my trapline area have already been clearcut. The map entitled KE038 in Exhibit "A" is my trapline area, and this map shows the extent of the planned and recent clearcutting for the area. I want my great-grandchildren and great-great-grandchildren to have a safe environment so they can grow up healthy and strong in our Anishinaabe traditions. I am strongly opposed to any Forest Management Plan that includes clearcutting. If the clearcut logging recently authorized by the Respondents under the Plan goes ahead, I fear it will release yet more mercury into the English-Wabigoon watershed, poison the fish we eat from those waters, and harm our health and well-being. This would violate our rights under the *Canadian Charter of Rights and Freedoms*. We have a right to be secure from the threats to us posed by mercury. By imposing clearcutting in our traditional territory, the government risks our health and discriminates against us because of our way of life, which includes fishing for walleye, and eating the fish we catch, as a central core of our identity as Anishinaabe people.

17. Clearcut logging on our territory is destroying our way of life. Our forest and our people need a break, we've had enough. We're going to stand up. My health is deteriorating, and I can feel that this may be my last fight. But after I have passed on, my children, grand-

children, and great-grand-children will continue to fight to preserve our land, our health, and way of life.

18. I affirm this affidavit in support of the within application for judicial review, and for no other or improper purpose.

AFFIRMED before me in the District of Kenora, in the Province of Ontario, this ___ day of _____, 2016.

A Commissioner, etc.

Thirty years after a Japanese researcher identified Canada's biggest case of mercury poisoning, he has returned to discover that the problem is far from resolved and may be getting worse. Masazumi Harada's new research raises troubling fresh questions about the sources and effects of mercury contamination present in water and fish in many parts of the country. The results of Harada's study are particularly sobering for aboriginal people who depend on a diet rich in fresh fish. It had been expected that the health of First Nations people on the Grassy Narrows and White Dog reserves near Kenora would improve after a mill stopped dumping mercury in the English and Wabigoon river systems in 1970. But when Harada returned to the area last fall, he found evidence of continuing, pervasive health problems consistent with Minamata disease, a neurological disorder caused by mercury. The results of Harada's study have not been published but were summarized by Steve Fobister Sr., deputy chief of ...Grassy Narrows, who has seen them. Of approximately 60 First Nations people who were examined at the Grassy Narrows and White Dog reserves last fall, 70 per cent showed symptoms of neurological disorder, said Fobister. Symptoms included blurred vision, slurred speech, twitching, numbness, shaking, and poor muscle co-ordination. The symptoms of eight people who were part of the study in the 1970s had become more severe.

Fobister says that he himself has serious neurological disease. "I can hardly tie my shoes any more", he said in an interview. Even children in the community are showing serious problems, including seizures, he said. Fobister blames clear-cut logging in the area for the continuing high levels of mercury contamination – a theory for which there is some scientific support, although debate continues. A University of Montreal researcher reported in 2001 that mercury levels were up to 100 per cent higher in heavily logged watersheds than in lakes where there was no logging nearby. The theory is airborne mercury from sources such as coal-fired power plants and incinerators tends to be held in the soil and foliage of an intact forest, but runs into waterways in areas that have been clear-cut. Health Canada is funding a new study of neurological disease in the Grassy Narrows area in the light of the recent research developments. "It is alarming to see there are so many people still suffering neurological symptoms in this community after 30 years", said Laurie Chan of McGill University, who is leading the study.[3]

SUPERIOR COURT OF JUSTICE
(Divisional Court)

B E T W E E N:

GRASSY NARROWS FIRST NATION
and
SHERRY FOBISTER,
WILLIAM FOBISTER, SENIOR, SIMON FOBISTER
and
CHIEF ROGER FOBISTER, SENIOR
on their own behalf and on behalf of all other
members of
GRASSY NARROWS FIRST NATION

Applicants

-and-

MINISTER OF NATURAL RESOURCES AND FORESTRY (ONTARIO)
and MINISTER OF THE ENVIRONMENT AND CLIMATE CHANGE (ONTARIO),
and THE ATTORNEY GENERAL OF ONTARIO

Respondents

SUPPLEMENTARY AFFIDAVIT OF DAVID SONE

I, DAVID SONE, of the City of Toronto, in the Province of Ontario, MAKE OATH AND SAY AS FOLLOWS:

1. I am the Director, Northern Ontario Campaigns at Earthroots Coalition ("Earthroots") and, as such, have knowledge of the matters hereinafter deposed to.

2. I have been with Earthroots since 2010. Earthroots is a non-profit organization dedicated to the conservation of wilderness, wildlife, and watersheds in Canada, with a focus on Ontario.

BACKGROUND

3. As noted at paragraphs 19 and 20 of my affidavit sworn August 21, 2015, and Exhibits "N", "O" and "P" therein, now found at Volume 5, behind Tab 10 of the Applicants' Application Record in the within matter, in January 2015 I submitted requests, under the *Freedom of Information and Protection of Privacy Act* ("*FIPPA*"), for information in the possession of the Ministry of the Environment and Climate Change ("MOECC"). The requested information, identified by MOECC as consisting of information in its confidential and public files, pertained to the issue of potential release of mercury to bodies of water from clearcut logging activity arising from the Ministry of Natural Resources and Forestry ("MNRF") approval of the 2012-2022 Forest Management Plan ("Plan") for the Whiskey Jack Forest ("WJF") in northwestern, Ontario. In particular, information was sought that was in the possession of, or relied on by, MOECC that preceded its December 2014 decision to reject the January 2014 request of Grassy Narrows First Nation ("Grassy Narrows") and Earthroots Coalition ("Earthroots") for a bump-up, or Individual Environmental Assessment ("IEA") under the *Environmental Assessment Act* ("bump-up request" or "IEA request"), of the Plan.

PRELIMINARY INFORMATION RECEIVED FROM MOECC (FILE A-2015-00157) LATE SEPTEMBER 2015 ARISING FROM FIPPA REQUEST

4. In late September 2015, arising from my January 7, 2015 *FIPPA* request (found behind Exhibit "O" referred to above), I received approximately 1,400 pages of information from the MOECC. A copy of pertinent parts of this information, identified as MOECC file A-2015-00157, is attached as **Exhibit "A"** to my affidavit. What the information in Exhibit "A" shows is organized under the sub-headings set out below.

Frequent Contact/Collaboration Between MOECC and MNRF During IEA Request Process in the Absence of Grassy Narrows and Earthroots

5. The information from MOECC contained in Exhibit "A" shows that from the time of the January 2014 IEA request right up to the December 2014 MOECC decision not to grant the request, MOECC and MNRF were in frequent contact and collaborated with each other (by email, telephone/conference call, face-to-face meetings, and via exchange of draft documents) regarding the substance and outcome of, the IEA request, including potential conditions as part of a decision not to grant the request. Neither Grassy Narrows nor Earthroots were privy to these communications or discussions, or advised that such on-going contact and collaboration was taking place. This is exemplified by the following (with any reference in the emails contained in Exhibit "A" to "ENE" or "MOE" being a reference to the MOECC and any reference to "MNR" being to MNRF):

   (a) inquiry by MNRF of MOECC as to whether MOECC has assigned a project evaluator to the IEA request so "MNR[F] and MOE[CC] can begin dialogue on the issues…" (MNRF email to MOECC, January 28, 2014 – page 433 – all page references hereinafter being to those found in the upper right-hand corner of material attached to Exhibit "A");

(b) MNRF sharing a document about mercury with MOECC (MNRF email to MOECC, February 11, 2014 – pages 437, 438-440) that Grassy Narrows/Earthroots was not advised of, or invited to comment upon;

(c) MOECC and MNRF planning a teleconference "to chat about the GN [Grassy Narrows] issue/bump-up" so that they are "on the same page" and "can relay/convey ideas on how to proceed" (MOECC emails, February 18, 2014 – page 442);

(d) MNRF wanting to "facilitate MOE[CC] and MNR[F] science folks getting together for" a discussion "on the mercury issues involved in both IEA requests to see what support we can provide each other" (MNRF/MOECC email exchange, February 18, 2014 – page 443);

(e) MNRF providing MOECC with a "draft science perspective on the issues raised in the IEA requests on the WJF" and seeking an initial response from [MOECC] on whether MOE[CC] believes this additional response is helpful and whether MOECC suggests "any changes/additions/deletions"; MOECC sending its completed review of MNRF's draft science perspective back to MNRF for its review (MNRF/MOECC email exchange, April 16-17, 2014 – page 493; attachment referred to in email was not included by MOECC in *FIPPA* information disclosed);

(f) MOECC forwarding to MNRF the Grassy Narrows/Earthroots May 2014 reply submissions and scheduling a meeting with MNRF so that an "open discussion of relevant information may occur" (MOECC/MNRF email exchange, May 29-30, 2014 – pages 500-502);

(g) MNRF responding to MOECC questions regarding the stand and site guide's treatment of mercury (MNRF email to MOECC, June 3, 2014 – page 506) and MNRF providing information to MOECC on aquatic effects and mercury (MNRF email to MOECC, June 3, 2014 – page 505) that Grassy Narrows/Earthroots was not advised of, or invited to comment upon;

(h) MOECC indicating internally that a July 2014 response it received from MNRF to the May 2014 Grassy Narrows/Earthroots reply submission would be considered by the MOECC director in coming to a decision on the IEA request and Grassy Narrows/Earthroots could go through the *FIPPA* process "to gain access" to the response document (MOECC email exchange, July 15, 17, 2014 – page 512; MNRF email to MOECC, July 10, 2014 – page 508);

(i) MNRF confirming with MOECC conditions respecting the IEA request MOECC proposed during a telephone call with MNRF, and MNRF confirming that the conditions were feasible to implement (MNRF email to

MOECC, October 24, 2014 – page 520; MOECC email, October 22, 2014 – page 517);

(j) MNRF requesting an update from MOECC on the status of the IEA request as it "has been sometime since we had our teleconference on the approach MOECC was taking with making a decision on this request" (MNRF email to MOECC, December 15, 2014 – page 537).

6. Regarding paragraph 5(h), above, and as I stated at paragraph 18 of my affidavit of August 21, 2015, I was not aware of the existence of, and did not obtain, the July 2014 MNRF response document from MOECC until I reviewed MOECC files in January 2015 after the IEA decision had been made. The July 2014 MNRF response document is now attached to my August 21, 2015 affidavit as Exhibit "M" found at Volume 5, Tab 10 of the Applicants' Application Record in the within matter.

Almost Complete Lack of Contact Between MOECC and Grassy Narrows During the Same Time-Period

7. MOECC did not encourage this type of on-going contact with Grassy Narrows/Earthroots during the January-December 2014 period of MOECC's consideration of the IEA request:

(a) MOECC noting in internal email that due to the IEA request, MOECC could not get into the specifics of the review with Grassy Narrows/Earthroots, but could listen to their concerns at a forthcoming meeting (MOECC email, March 26, 2014 – page 465).

8. In fact, Grassy Narrows and Earthroots were advised by MNRF that the IEA process was MOECC's process and it was being conducted, in effect, in an arms-length manner:

    (a) MNRF advising Grassy Narrows and Earthroots that the IEA request, the process for review, and decision-making are out of MNRF's hands and the responsibility of MOECC (MNRF email to Earthroots, October 14, 2014 – page 522).

9. MOECC met with Grassy Narrows/Earthroots once during the 12-month decision-making process surrounding the IEA request. Earthroots initiated the meeting, which I attended in person and Joseph Fobister of Grassy Narrows attended by conference call. The purpose of the meeting was to clarify the substance of the IEA request, answer any questions MOECC might have arising from the IEA request, and address an MNRF request for concurrence by Grassy Narrows that certain non-logging related activities be allowed to occur in the WJF while the IEA request was being considered by MOECC (Earthroots email to MOECC/MNRF, March 12, 2014 – pages 463 and 464; MOECC internal email, March 26, 2014 – page 465). At the meeting, MOECC did not discuss its views on the IEA request or the scientific basis for any decision it might make on the request.

Whiskey Jack Forest is Grassy Narrows' Traditional Territory

10. MOECC acknowledges that "Grassy Narrows…is one of the key Aboriginal communities with hunting and fishing rights in the Whiskey Jack Forest. The Grassy Narrows…reserve is located within the Whiskey Jack Forest Unit; much of the forest is

within the First Nation's asserted traditional land use area. Grassy Narrows is an indigenous Anishinabe community located within the Treaty 3 area" (MOECC, Information Note: Whiskey Jack Forest Management Plan, March 14, 2014 – page 455).

Importance of Fish to Grassy Narrows

11. MOECC acknowledges that: "Fish is a main food source for the [Grassy Narrows] community" (MOECC, Information Note: Whiskey Jack Forest Management Plan, March 14, 2014 – page 454).

Historic Impacts of Mercury on Grassy Narrows

12. MOECC stated during its consideration of, and immediately following its decision respecting, the IEA request that:

    (a) "Grassy Narrows…has had a historic problem with mercury contamination dating back to the Dryden Paper Company in the 1970s. The amount of mercury present in fish as of 2012 was low, but a health advisory remains in effect" (MOECC, Information Note: Whiskey Jack Forest Management Plan, March 14, 2014 – page 454); and

    (b) "The [Grassy Narrows] community has suffered the effects of mercury poisoning" (MOECC internal email, January 8, 2015 – page 543).

Mercury is a Toxic Substance

13. A Questions and Answers document prepared by MOECC for release with its decision refusing to grant the IEA request, contains the following statements about mercury toxicity and exposure pathways:

(a) Mercury is toxic, inherently persistent and bio-accumulative;

(b) In water and sediments mercury can be converted into the highly toxic form known as methylmercury, which accumulates in the tissues of fish and other animal life;

(c) Methylmercury is a potent neurotoxin that may impair brain function and adversely affect neurological development in wildlife and people (especially children);

(d) Fish consumption is one of the main pathways for wildlife and human exposure to methylmercury, and is a major cause of restrictions on fish consumption guidelines, especially for inland lakes and rivers in Ontario (MOECC internal email, December 23, 2014 – page 531 attaching MOECC Questions and Answers, Whiskey Jack Forest: Request for Individual Environmental Assessment – pages 533-534);

Status of Mercury Monitoring Measures

14. MNRF confirmed with MOECC that the: "[Forest Management Plan] contains no requirements for ongoing monitoring of mercury levels in the area affected by the IEA

request to determine if in fact approved forest operations once implemented would (further) elevate mercury levels in catchment areas…MNR[F]'s Forest EA Act approval and the Forest Management Planning Manual (FMPM) contain planning requirements for the monitoring of forest management activities in a forest management plan; however, do not include requirements to monitor specific effects of individual activities" (MNRF email to MOECC/MNRF, May 30, 2014 – page 503).

15. MNRF also confirmed that it contemplates no changes to its current effectiveness monitoring approach other than what might arise as a result of review of the Stand and Site Guide expected to be completed by the end of 2015; MNRF identified mercury, catchment scale effects, and rutting standards as three "known unknowns" it was planning to investigate during the review (MNRF email to MOECC/MNRF, June 3, 2014 – page 506).

FURTHER INFORMATION RECEIVED FROM MOECC (FILE A-2015-00158) EARLY JANUARY 2016 ARISING FROM FIPPA REQUEST

16. In early January 2016, arising from my January 8, 2015 *FIPPA* request (found behind Exhibit "P" of my August 21, 2015 affidavit and referred to above at paragraph 3 of this my supplementary affidavit), I received approximately 1,100 additional pages of information from the MOECC. A copy of pertinent parts of this information, identified as MOECC file A-2015-00158, is attached as **Exhibit "B"** to my affidavit. What the information in Exhibit "B" shows is organized under the sub-headings set out below.

Further Examples of Contact/Collaboration Between MOECC and MNRF During IEA Request Process in the Absence of Grassy Narrows and Earthroots

17. The information from MOECC contained in Exhibit "B" shows further contact and collaboration between MOECC and MNRF, without the knowledge of Grassy Narrows and Earthroots, during the period the IEA request was being considered by MOECC. This is exemplified by the following (with any reference in the emails contained in Exhibit "B" to "ENE" or "MOE" being a reference to the MOECC and any reference to "MNR" being to MNRF):

(a) MOECC confirming its intention to attend a meeting with MNRF, referred to above at paragraphs 5(c) and (d), respecting the Whiskey Jack Forest Management Plan (MOECC emails, February 21, 2014 – page 545);

(b) MNRF setting up a March 20, 2014 meeting between MOECC and MNRF managers to "discuss Hg [mercury] issues", anticipating "that the scientists would meet prior to that date and their outcomes/thoughts would be the basis for our meeting" at which the managers could "discuss gaps in our knowledge" (MOECC/MNRF email exchange, February 28, 2014 – page 546);

(c) reference to meeting between MOECC and MNRF that took place in March 2014 relating to the IEA request where the discussion included "hearing another perspective on Hg [mercury]" than just "focusing so much on water" and considering the "balance between political sensitivity for a specific watershed/community and the implications for forestry management on a

broader provincial scale" (MOECC internal email, March 20, 2014 – page 000547);

(d) MNRF providing MOECC with a "draft science perspective on the issues raised in the IEA request on the WJF" and seeking "an initial response from [MOECC] as to whether [MOECC] believes this additional response is helpful and whether [MOECC]" suggests "any changes/additions/deletions"; MOECC passing MNRF's document on for internal MOECC review (MNRF/MOECC email exchange, April 16, 2014 – pages 548-561; attachment referred to in email included by MOECC in *FIPPA* information disclosed).

18. The information contained in the attachment referred to in paragraph 17(d) above as a "draft science perspective" is a draft of what was filed by MNRF one week later (April 23, 2014) with MOECC as MNRF's official response to the Grassy Narrows-Earthroots January 2014 IEA request. Because of a copying error, an incomplete version of the MNRF April 23, 2014 response document appears in Volume 3, Tab 5, behind Exhibit "E" (Joint Affidavit of Amber Ellis and David Sone, sworn August 21, 2015) of the Applicants' Application Record in the within matter. A copy of the complete version of the April 23, 2014 MNRF response document is attached behind **Exhibit "C"** to this my supplementary affidavit.

Importance of Fish to Grassy Narrows

19. MOECC noting that: "[The community of Grassy Narrows] relies on fish from the [English-Wabigoon] river system…the fish from this system are an important source of food for their community…restrictions on consumption of fish remain in place, yet the community continues to consume fish from their doorstep lakes/rivers…MNRF provides the community with 'clean' fish, but the community has not taken full advantage of the whitefish provided, as culturally they prefer walleye or pike" (MOECC Information Note: Grassy Narrows First Nation Mercury Contamination, September 10, 2014 – page 564).

Mercury and Human Health at Grassy Narrows

20. MOECC noting that: "In September 2002, Dr. Masazumi Harada, a Japanese researcher specializing in mercury poisoning, visited Grassy Narrows…at the request of the [Grassy Narrows] Chief. Dr. Harada found an increase in, and new cases of, mercury poisoning on the reserve". MOECC noting further that: "Harada's research team first visited [the] Grassy Narrows [community] in 1975 and collected hair and blood samples for mercury analyses and assessed…residents for symptoms of Minamata Disease (neurological disorder). Some residents had mercury levels in hair above the 'safety guideline of 50 ppm'" (MOECC Information Note: Grassy Narrows First Nation Mercury Contamination, September 18, 2012 – page 577; and MOECC Information Note: Grassy Narrows First Nation Mercury Contamination, July 28, 2014 – page 593).

Declines of Mercury Levels May Have Slowed Down Because of Logging

21. MOECC acknowledging that "[O]ne of the factors that might have slowed down the [decline of mercury in local waterways despite restrictions placed on mercury releases at the Dryden pulp and paper plant] in the last two decades could be logging activities in the area that began around the 1980s". The "cessation of logging" since 2008 may result in a "resumption of faster downward trend for mercury in fish" (MOECC email exchange, June 6-7, 2012 – pages 597-599; MOECC Information Note: Grassy Narrows First Nation Mercury Contamination, July 28, 2014 – page 593).

Logging Releases Mercury into the Aquatic Environment and it Accumulates in Fish

22. MOECC noting that: "…it's not just possible increased mercury loading due to logging but also other factors such as possible increased loading of organic material may affect how and how much of increased/decreased mercury in the system gets bioaccumulated in fish. Even if overall mercury loading and water (and sediment) 'total' mercury concentrations decline, you may see increased fish mercury levels due to increased methylation under changed conditions (e.g. water chemistry)" (MOECC email exchange, June 6-7, 2012 – pages 597-599).

23. MOECC acknowledging that "ongoing logging will increase Hg [mercury] mobilization and nobody is tracking the downstream implications" (MOECC email exchange, August 7, 2013 – page 600).

24. MOECC being advised in early 2014 that the Grassy Narrows community "is already sensitive to the effects of Hg [mercury]. This should be recognized when logging rights

are being considered in this area, and it should be advised that a precautionary approach be considered. The community [has] peer reviewed studies showing that logging activities can result in the release of Hg [mercury] into the natural environment" (Ministry of Aboriginal Affairs email to MOECC, January 10, 2014 – page 601).

Potential Study of Clearcutting on Mercury Levels in Fish

25. MOECC acknowledging that "Yes, logging introduces Hg [mercury]!" and considering a study on the issue: "Do we have funding to conduct this study (I would love to explore) as this question itself is a research project on its own??!!!" (MOECC email exchange, June 6-7, 2012 – pages 597-599).

26. MOECC acknowledging that in 2012 "MOE and MNR [were] to discuss a potential study looking at the effects of logging and clear cutting on mercury levels in fish"; that Grassy Narrows had expressed concerns that inappropriate logging on Crown land impacts traditional practices; and that there is a "general body of knowledge illustrating that logging practices promote mercury release to rivers; however, any impacts to the English-Wabigoon system [are] unclear and could not be evaluated without further analysis" (MOECC email exchange, September 18, 2012 – pages 570-571; and MOECC Information Note: Grassy Narrows First Nation Mercury Contamination, September 18, 2012 – pages 572-579).

27. MOECC inquiring in 2013 about "Whatever happened to the project you were trying to set up looking [at] the effects of [clearcut] logging on Hg [mercury] concentrations in fish" (MOECC internal email, February 5, 2013 – page 580).

28. MOECC acknowledging in 2013 that it "has been working with MNR to try and set up a study…to see if we see any relationship between different logging practices and Hg [mercury] in fish. This has been a slow process though and we haven't quite managed to get it up and running yet". MOECC Director of Environmental Monitoring and Reporting Branch responding that: "I'm not surprised it's slow…ongoing logging will increase Hg [mercury] mobilization and nobody is tracking the downstream implications" (MOECC email exchange, August 7, 2013 – page 600).

29. MOECC repeating in 2014 what it said in 2012 that "MOE and MNR are discussing a potential study looking at the effects of logging and clear cutting on mercury levels in fish"; that Grassy Narrows "has expressed concerns that inappropriate logging on Crown land impacts traditional practices"; and that there is a "general body of knowledge illustrating that logging practices promote mercury release to rivers; however, any impacts to the English-Wabigoon system [are] unclear and could not be evaluated without analysis" (MOECC Information Note: Grassy Narrows First Nation Mercury Contamination, July 28, 2014 – pages 589-590).

Adequacy of Mercury Monitoring under Approved Whiskey Jack Forest Management Plan

30. MOECC Daily Issues Alert stating, with respect to decision to reject IEA request, that: "The ministry is confident that the Whiskey Jack forest management plan has been developed with monitoring and mitigation measures that will ensure any mercury

migration is limited. As a precaution, we have imposed conditions on the project to reduce mercury movement. Conditions include, monitoring soil disturbances…" (MOECC Daily Issues Alert, December 30, 2014 – pages 603-606).

31. MOECC Director of Environmental Monitoring and Reporting Branch stating with respect to the above statements in the Alert: "Note the 'monitoring' is of soils and not the aquatic ecosystem. Just curious – were we approached by EAAB [Environmental Assessment and Approvals Branch] for any input to the decision re: impacts on mercury in fish?" (MOECC internal email exchange, December 30, 2014 – page 603).

APPEAL OF NON-DISCLOSURE OF CERTAIN DOCUMENTS

32. In September 2015, MOECC indicated that it was only providing partial access to the information I had requested in my January 7, 2015 *FIPPA* request, identified by MOECC as file A-2015-00157. Upon receiving the records and reviewing the decision letter, I filed an appeal under *FIPPA* on or about October 28, 2015. A copy of my appeal letter and material in support of the appeal is attached as **Exhibit "D"**. As of the date of my supplementary affidavit, MOECC has not disclosed further information pursuant to this appeal.

33. In January 2016, MOECC indicated that it was only providing partial access to the information I had requested in my January 8, 2015 *FIPPA* request, identified by MOECC as file A-2015-00158. Upon receiving the records and reviewing the decision letter, I filed an appeal under *FIPPA* on or about January 22, 2016. A copy of my appeal letter

and material in support of the appeal is attached as **Exhibit "E"**. As of the date of my supplementary affidavit, MOECC has not disclosed further information pursuant to this appeal.

34. I swear this supplementary affidavit in support of the within application for judicial review, and for no other or improper purpose.

SWORN before me in the City of Toronto, in the Province of Ontario, this ___ day of _____, 2016.

A Commissioner, etc.

Dear David Sone:

RE: *Freedom of Information and Protection of Privacy Act* Request
Our File # A-2015-00157

This letter is further to your request made pursuant to the *Freedom of Information and Protection of Privacy Act* relating to Records contained in the confidential MOECC file for the Whiskey Jack 2012-2022 Forest Management Plan project, and any other records related to the Ministry's decisions on the request for individual environmental assessment of the Plan.

Attached is a copy of the records.

If you have any questions regarding this matter, please contact Oksana Budjko oksana.budjko@ontario.ca.

Yours truly,

H. Ritscher

Subject: FW: Request for Individual Environmental Assessment of the Whiskey Jack Forest Management Plan 2012-2022

Hello Kurt,

I am the Project Evaluator assigned to the Whiskey Jack Forest Management Plan Part II Order request. I am not sure if you have received a copy of the request (as you are not on the cc'ed email below), so I am attaching it to this email. The request does not specify a particular area within the Forest Management Plan that the requesters have issue with, but raise the entire Whiskey Jack Forest Management Plan as a concern. The request also outlines concerns with the impacts of logging on mercury levels in fish and water in respect to protection of aboriginal treaty rights. If the MNR has any consultation records/documents that you deem would be beneficial to our review please forward them to me. s.19 Please do not hesitate to contact me if you have further questions.

Thanks,

Devon Wills

Subject: Whiskey Jack IEA

Hi Solange:

MNR is aware that an IEA request has been submitted jointly from Grassy Narrows First Nation and Earthroots on the 2012-2022 Whiskey Jack FMP. As the 30 day Plan Inspection period plus the 7 day grace period for the public to request an IEA ends tomorrow January 29, 2014, I am assuming that this IEA request will be the only one that MOE will have to review for this FMP. With that said, I was wondering if a project evaluator has been assigned to this IEA request so MNR and MOE can begin dialogue on the issues, geography affected within the request.

Thanks

John

Hi there,
Solange I received a call from Rachael Fletcher (EMRB Manager) who is on route to Grassy Narrows and she is looking to speak to someone about the file above. Can you email her with a contact name. Rachael is currently on route to Winnipeg and will be touching base with your contact once she lands.

Rachael, Solange is the supervisor who manages the unit that reviews these files so she is the best person to assist you. Hope you two e-connect.
Happy Wednesday and please let me know if you need anything more
Cheers k.

Devon:

I was just trying to get myself more informed on the mercury issue and found the attached and thought I would share it with you.

Paul

Mercury Cycling in the Environment

Mercury cycling pathways in aquatic environments are very complex. The various forms of mercury can be converted from one to the next; most important is the conversion to methylmercury (CH3Hg+), the most toxic form. Ultimately, mercury ends up in the sediments, fish and wildlife, or evades back to the atmosphere by volatilization.

Aquatic Mercury Cycle

At right, Figure 6 shows a schematic drawing of mercury cycling in an aquatic ecosystem.[1] With the exception of isolated cases of known point sources, the ultimate source of mercury to most aquatic ecosystems is deposition from the atmosphere, primarily associated with rainfall.

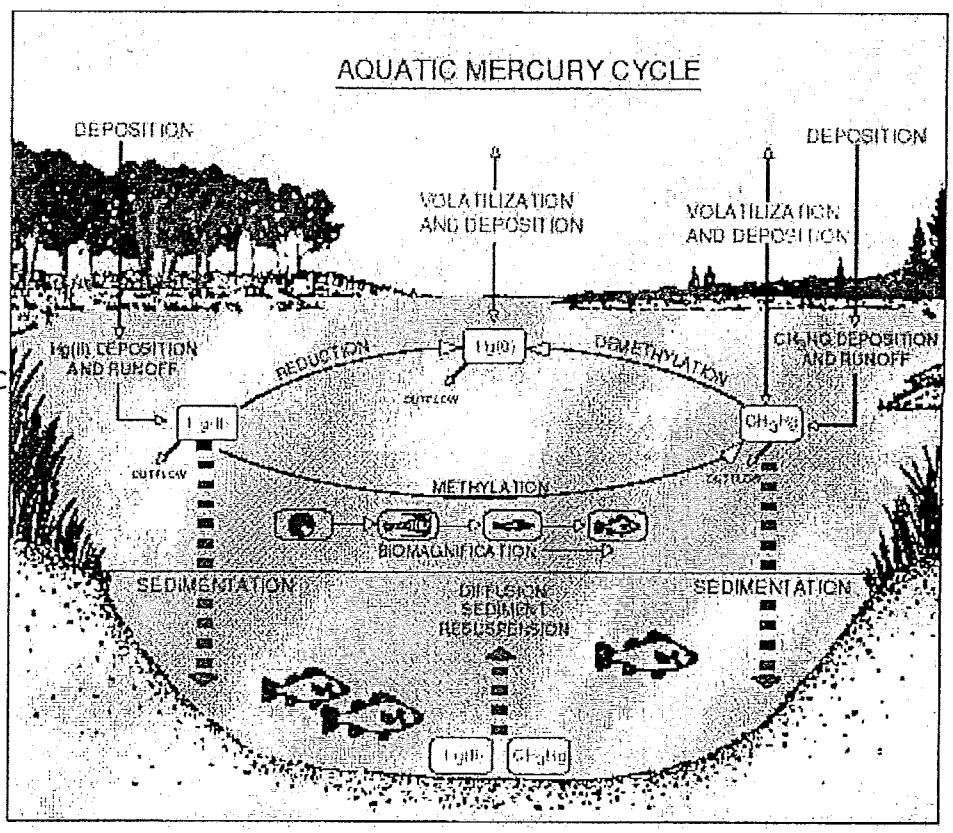

Figure 6. Mercury cycling pathways in aquatic environments are very complex. The various forms of mercury can be converted from one to the next; most important is the conversion to methylmercury (CH_3Hg^+), the most toxic form. Ultimately, mercury ends up in the sediments, fish and wildlife, or evades back to the atmosphere by volatilization. Reprinted with permission from Mercury Pollution: Integration and Synthesis. Copyright Lewis Publishers, an imprint of CRC Press.

As depicted in this figure, atmospheric deposition contains the three principal forms of mercury, although the majority is as inorganic mercury (Hg2+, ionic mercury). Once in surface water, mercury enters a complex cycle in which one form can be converted to another. It can be brought to the sediments by particle settling and then later released by diffusion or resuspension. It can enter the food chain, or it can be released back to the atmosphere by volatilization.

The concentration of dissolved organic carbon (DOC) and pH have a strong effect on the ultimate fate of mercury in an ecosystem. Studies have shown that for the same species of fish taken from the same region, increasing the acidity of the water (decreasing pH) and/or the DOC content generally results in higher body burdens in fish. Many scientists currently think that higher acidity and DOC levels enhance the mobility of mercury in the environment, thus making it more likely to enter the food chain.

Many of the details of the aquatic mercury cycle are still unknown, however, and remain areas of active research.

How does mercury enter the food chain?

The exact mechanism(s) by which mercury enters the food chain remain largely unknown, and probably vary among ecosystems. We do know, however, that certain bacteria play an important early role. Studies have shown that bacteria that process sulfate (SO4=) in the environment take up mercury in its inorganic form, and through metabolic processes convert it to methylmercury. The conversion of inorganic mercury to methylmercury is important for two reasons: (1) methylmercury is much more toxic than inorganic mercury, and (2) organisms require considerably longer to eliminate methylmercury. At this point, the methylmercury-containing bacteria may be consumed by the next higher level in the food chain, or the bacteria may release the methylmercury to the water where it can quickly adsorb to plankton, which are also consumed by the next level in the food chain.

Where does atmospheric mercury come from?

There are many sources of mercury to the environment, both natural and man related. Natural sources include volcanoes, natural mercury deposits, and volatilization from the ocean. The primary human-related sources include: coal combustion, chlorine alkali processing, waste incineration, and metal processing. Best estimates to date suggest that human activities have about doubled or tripled the amount of mercury in the atmosphere, and the atmospheric burden is increasing by about 1.5 percent per year.

Has there always been mercury contamination, or is this a recent problem?

This is a difficult question to answer, in part because of a lack of adequately preserved fish specimens of preindustrial age to compare against

contemporary samples. However, several lines of evidence from recent studies on Wisconsin lakes suggest that increase pemissions to the atmosphere, and subsequent higher deposition rates to lakes, likely translate into higher mercury levels in fish. Although the total amount of mercury delivered to one of these lakes annually is very small it is strongly absorbed by organic material floating in the water such as plankton or bacteria. These microorganisms are consumed by organisms higher in the food chain, or after dying, settle to the bottom of the lake and are incorporated into bottom sediments. Studies of sediment cores show that younger sediments deposited since industrialization have mercury concentrations that are about 3-5 times that of historical sediments. Thus, the fact that these sediments are primarily composed of dead microorganisms that were once the bottom of the food chain would suggest that modern levels of mercury in the food chain are elevated over preindustrial times.

If human-related emissions could be eliminated or reduced, how long would it take for ecosystems to recover?

The only way to attempt to answer this question is to incorporate all the best information currently available on how mercury behaves in the environment into a computer model. Such a model was constructed as part of the research effort on northern Wisconsin lakes. Modeled scenarios predict that if emissions could be reduced by 5 percent, it would take 8 years before any change in fish concentrations would be observed, and the decrease would be small.

Subject: Returning IEA Requester's Maps to MOE including Merged Map of Area Affected by IEA Request
Attachments: Map1_Submitted_Traplines_Feb13_2014.jpg; Map2 _Submitted_GNFN_Study_Area_Feb13_2014.jpg; Map3_Submitted_CP_Map_Feb13_ 2014.jpg; 2014_02_18 MNR narative response to IEA Requesters Maps of Affected Areas Whiskey Jack Forest.docx

Devon:

MNR has reproduced the maps you provided using GIS and MNR's information base. This has provided a consistent map base and enabled consolidation of the maps into a final product (i.e., the area affected by the IEA request).

Attached are 5 maps as follows: (Actually only three maps attached, remaining two in subsequent email)

Map 1-3 – IEA requester's original maps
Map 4 – Combined overlay of IEA requester's 3 maps
Map 5 – IEA requester's 3 maps merged into the "area affected by the IEA request".

Also attached is a narrative piece that should help you to understand the maps.

I anticipate that over the next few days you will bring these back to the IEA requesters for confirmation that they meet their intent. After you have confirmed this and the issues in the request, MNR and MOE will meet to discuss the issues in the submission and the area affected and address any outstanding concerns. Please note, MNR does have concerns with respect to the area affected by the IEA request that has been identified by the IEA requesters but will reserve comment until our meeting to discuss Appendix 1. I hope you will be able to get the IEA requester's response within a few days and we should be able to meet this Friday or Monday of next week to walk through our discussion of Appendix 1.

Any thoughts or concerns, let me know.

Hello Rachael,

That sounds like a good idea. I ran it by Solange (my supervisor) and she said it would be a good idea to set up another teleconference for MNR. We have been speaking to them as well, but not in a group format so that we can relay/convey ideas on how to proceed. Can you propose a time that you and Paul want to discuss the Project, so that I may run it our staff?

Thanks,

Rachael:

Thank-you for your call on Friday.

I have connected with the two science managers here in MNR that have staff involved in related activities. There may be another manager in our Aquatics section as well that should be linked in and I leave that to Wayne and Ed to figure out.

Bottom line, I want to facilitate MOE and MNR science folks getting together for the discussion we talked about on Friday on the mercury issues involved in both IEA requests to see what support we can provide each other.

I will forward a meeting request later today for a meeting on Thursday or Friday to discuss. Can you please suggest some agenda items or structure for the discussion so we can get everyone on the same page. Much appreciated.

Paul

INFORMATION NOTE:
Whiskey Jack Forest Management Plan
DATE: March 14, 2014

ISSUE

The Ministry of the Environment has received one Part II Order request to require an individual environmental assessment for the Ministry of Natural Resources-proposed Whiskey Jack Forest Management Plan in the northwest region of Ontario.

KEY MESSAGES

- The Ministry of the Environment is working with the Ministry of Natural Resources to ensure that the Whiskey Jack Forest Management Plan is protective of both human health and the environment.
- The province promotes good environmental planning by assessing the potential effects of forest management activities through the Environmental Assessment Act.
- In order to ensure the protection of the environment, proponents of forest management activities of this type are required to follow the process under the Ministry of Natural Resources Class Environmental Assessment for Forest Management on Crown Lands in Ontario.
- This Class Environmental Assessment requires a comprehensive consultation program and is an effective means to evaluate the potential environmental effects of a project.

BACKGROUND

Whiskey Jack Forest

- The Whiskey Jack Forest is approximately 450 kilometres west of Thunder Bay and contains over 1.1 million hectares of forested area. 750,000 hectares are considered to be productive forestlands.
- Communities in or next to the Whiskey Jack Forest include the City of Kenora, Sioux Narrows, Redditt, Vermilion Bay, Ear Falls and Red Lake.
- First Nations communities include Asubpeeschoseewagong Netum Anishinabek (Grassy Narrows First Nation), Wabaseemoong Independent Nations and Ochiichagwe'babigo'inning (Dalles First Nation), Wabauskang First Nation, and Naotkamegwanning (Whitefish Bay First Nation).
- The Whiskey Jack Forest has been a Crown Management Unit since Abitibi Company of Canada surrendered the Sustainable Forest Licence in August 2009.

- The project's forest management planning activities and operations are administered by the Kenora District Ministry of Natural Resources (MNR).

- MNR, in consultation with the public, has the responsibility of completing a forest management plan (FMP) of the Whiskey Jack Forest.

Forest Management Plan

- The primary objective of the FMP on Crown land is to ensure the long-term health of forest ecosystems. MNR's FMP process allows forest managers to ensure that the Crown forests of Ontario will remain healthy enough to provide sustainable benefits such as timber and commercial products, wildlife habitat, and recreation opportunities for Ontarians.

- The planning history for the Whiskey Jack FMP has had many alterations due to changes in strategic planning timeframes and the incorporation of contingency plans.

- The current Whiskey Jack FMP has been prepared for a 10-year period from April 1, 2012 to March 31, 2022. The management plan describes forest management activities, such as timber harvesting, road construction and forest regeneration that will take place during the plan period.

- The Whiskey Jack FMP indicates that 51,941 hectares of forest are expected to be clearcut harvested during the 10-year period. The plan also includes forest renewal and maintenance activities with a total forest regeneration area of 53,470 hectares.

- The preparation of the plan occurs in two phases:
    - Phase I – The strategic, long-term planning and the planning of the first five years of operation
    - Phase II – Details operations for the second five-year phase of this plan, with operational planning starting approximately a year in advance

- Throughout the project, MNR has hosted several meetings and Aboriginal Information Centres.

- On December 23, 2013, MNR posted a notification for the Whiskey Jack FMP providing a 30-day public and agency review period, ending on January 22, 2014.

Part II Order request

- MOE received one combined Part II Order request for the project from the Grassy Narrows First Nation and a non-profit environmental group, Earthroots.

- The main issue raised in the Part II Order request is the concern that clear cutting will cause further mercury contamination issues in local waterways which may potentially affect human and ecosystem health and adversely impact Aboriginal and Treaty rights.

- Grassy Narrows First Nation has had a historic problem with mercury contamination dating back to the Dryden Paper Company in the 1970s. The amount of mercury present in fish as of 2012 was low, but a health advisory remains in effect. Fish is a main food source for the community.

Previous FMP and Part II Order Request

- MNR had a previous 2004-2024FMP for the Whiskey Jack Forest. This FMP was prepared using the 1996 Forest Management Planning Manual and the original Timber Environmental Assessment decision as a basis for planning, requiring a 20-year planning horizon with one five-year operation plan, after which both expire.

- In 2003, the Ministry of the Environment (MOE) amended MNR's FMP framework from a 20-year strategic plan having a five-year operational plan to a strategic plan lasting 10 years with a 5-year operational plan. A five-year plan was implemented in 2004 outlining operational activities until the year 2009. Two consecutive two-year contingency plans were completed in 2010 and 2012 for the Whiskey Jack Forest due to extra consultations with Grassy Narrows First Nation (see Appendix).

- In the previous 2004-2024 Whiskey Jack FMP, the Grassy Narrows First Nation submitted a Part II Order request indicating issues related to:
    - infringement on trapping and hunting rights
    - displaced trappers
    - roads and herbicide application negatively affecting the trappers and hunters
    - habitat guidelines and the class EA planning process
    - inaccurate assumptions about wood supply, regeneration rates and natural disturbance incidences

- That Part II Order request was denied on August 31, 2005, with conditions requiring MNR to:
    - consult with the Grassy Narrows First Nation on native values
    - monitor and assess the impacts of forestry operations on habitat
    - implement Area of Concern prescriptions
    - adhere to the requirements and provisions of the FMP

Request for Concurrence

- A request for concurrence was received by the MOE on March 11, 2014. MNR is seeking approval from the Director, EAB to commence with regular forest operations in areas of the forest management unit that are unaffected by the outstanding Part II Order request. This would allow MNR to engage in access, harvest, renewal, site preparation, and tending operations.

- In areas that are affected by the Part II Order Request, only maintenance of existing roads, renewal and tending operations (i.e. tree planting and thinning) would be permitted in this area.

- MNR has requested the MOE to provide a response on the concurrence request by March 14, 2014, although there is no formal timeframe for doing so. This timeline

would allow the commencement of forestry operations as noted above, by April 1, 2014.

- If concurrence is not granted, MNR notes that this may cause social and economic impact to those that rely on the Whiskey Jack forest industry.

- The Director, EAB is currently reviewing MNR's concurrence request and will advise MNR once a decision is made.

Next Steps

- A decision must be made on the request for concurrence by the Director, EAB.

- MOE is in the process of reviewing documentation and comments from MNR and is currently conducting a risk analysis of the ministry's Duty to Consult.

- A decision must be made on the request for an Individual Environmental Assessment by the Environmental Approvals Branch director within 45 days of receiving all necessary information. A decision is not invalid if not made within the timeframe.

STAKEHOLDER CONSIDERATIONS

Earthroots

- Earthroots is a grassroots, non-profit conservation organization that opposes the project. They are dedicated to the preservation of wilderness, wildlife and watersheds in Canada, with a focus on Ontario.

Grassy Narrows First Nation

- The Grassy Narrows First Nation is one of the key Aboriginal communities with hunting and fishing rights in the Whiskey Jack Forest. The Grassy Narrows First Nations reserve is located within the Whiskey Jack Forest Unit; much of the forest is within the First Nation's asserted traditional land use area. The Grassy Narrows First Nation is an indigenous Anishinabe community located within the Treaty 3 area.

- The Grassy Narrows First Nation is the lead claimant in the landmark case, Keewatin vs. Ontario, disputing whether the Ontario government has the same rights as the federal government (per Treaty 3) to use or permit the use of forest resources in the Treaty area. The project is within the Keewatin litigation lands.

- On September 19, 2013, the Supreme Court of Canada granted Grassy Narrows First Nation leave to appeal the Keewatin vs. Ontario (MNR) decision rendered by the Ontario Court of Appeal on March 18, 2013 which had affirmed Ontario's unilateral right to use the lands.

- The appeal is likely to be heard before the Supreme Court in May 2014.

- Until the Supreme Court of Canada decides the appeal, the decision of the Court of Appeal stands, confirming that Ontario has the jurisdiction to administer the public lands and forests in the Province of Ontario, without federal oversight, and including areas within the Treaty 3.

INVOLVEMENT OF OTHER MINISTRIES

- MNR has undertaken consultation where appropriate for the Whiskey Jack Forest Management Plan as part of the Class Environmental Assessment for Forest Management on Crown Lands in Ontario.

Hi Devon,

I hope that you are doing well.

Can we set up a meeting with Earthroots, yourself, and any other relevant people at the MOE to discuss our IEA request before you make your decision? If possible, the meeting space should have call-in capability so that Joseph Fobister can join us if he wishes.

This would be a opportunity to answer any questions, provide supplementary information or elaboration where required, and discuss the request without prejudice.

I look forward to meeting you in person.

Take care,

David

Hi Devon,

This map appears to accurately depict the area affected by the IEA request (assuming that the bodies of water are included in the IEA area and that the eastern boundary is based on the Grassy Narrows traplines). This is without prejudice to a proper determination of the extent of Grassy Narrows Territory.

Thanks to you and the MNR for making this map.

Please go ahead with your review.

Take care,

David

Subject: Re: Whiskey Jack Forest Management Plan request for IEA

Hi Devon,

It is good to meet you. Thank you for your work reviewing our request.

Our request applies to Grassy Narrows Territory within the Whiskey Jack Forest. I do not know of any definitive map of this area. As part of the Iaccobucci Process, Ontario was to fund Grassy Narrows to complete a thorough land use and occupancy study which could have shed light on this question. However, funding was cut off before the completion of that study.

As a provisional measure you may consider the request to apply to the overlay sum of the following three mapped areas:
i) Grassy Narrows MNR trapline areas (first attachmet);
ii) MNR Grassy Narrows Study Area (second attachement);
iii) The area avoided during the creation of the recent Whiskey Jack Contingency Plan (orange, pink, and green areas on the third attachment).

This is without prejudice to any future determination that Grassy Narrows may make about the extent of their Territory.

I believe that the MNR has GIS shapefiles that should make this overlay to visualize.

The specific proposed forest management activities of concern are:
a) harvesting;
b) tending;
c) new road building; and
d) any other activities that may elevate mercury levels in water and fish.

I hope that this provides you with the information that you require.

The best way to contact Earthroots is by contacting me using this email address.

Joseph Fobister is the contact for Grassy Narrows and can be reached by email at jbfobister@gmail.com.

Please copy both Joseph, and me, on any communications regarding our joint request.

If you have any further questions, please do not hesitate to contact us.

Take care,

David Sone

On Fri, Mar 21, 2014 at 2:46 PM, Garcia-Wright, Agatha (ENE) <Agatha.GarciaWright@ontario.ca> wrote:

Good afternoon Mr. David Sone,

We would like to take this opportunity to follow up on your email dated March 12, 2014 (cited below). In this email, Earthroots objects to the use of herbicides and renewal and tending activities leading to increased mercury levels, due to soil disturbance within the Individual Environmental Assessment (IEA) area.

We have been able to confirm with the Ministry of Natural Resources (MNR) that there will be no herbicide application in the IEA request area. Further, the renewal and tending activities in this area will be limited to tree planting and thinning with physical work to be carried out with a brush saw (ie. no heavy machinery), which will not result in soil disturbance.

Operations outside of the IEA request area within the Whiskey Jack Forest will be subject to the forest management activities that are present within the Whiskey Jack FMP.

We would be pleased to meet with you to discuss your IEA request. If you have any questions about the ministry's review of your request or would like to set up a meeting, please contact Mr. Devon Wills, Project Evaluator for this Project, directly at 416-314-8259 or at devon.wills@ontario.ca.

Yours sincerely,

Agatha Garcia-Wright

Subject: Re: Whiskey Jack Forest concurrence request

Hi All,

I hope that you are doing well.

Earthroots objects to the part of this request that seeks concurrence to allow all renewal and tending operations to proceed within the area of concern while the IEA request is being considered.

Renewal and tending activities are likely to have mercury impacts due to soil disturbance by scarification/ mechanical site preparation for renewal, and machine access for mechanical tending/thinning (see Bishop et al., 2009).

Tending also often includes the use of herbicides which Grassy Narrows has long objected to for a number of reasons.

It is also plausible that the use of herbicides would pose a mercury risk due to:

a. the increase in decaying organic matter as a result of broad leafed species being killed by the herbicides, which could lead to increased export of dissolved organic carbon;

b. the loss of living root structure and decreased evapotranspiration which could lead to an increase in water flux, erosion, and DOC transport.

We do not object to specific renewal activities that do not involve machine access, including manual planting without site preparation, and aerial seeding.

We believe that the impact of delaying some renewal and tending activities on this area during the IEA would not be significant as these activities can be done later if/when they are determined to be safe.

Earthroots would also like to request a meeting with the MOE to discuss our IEA request without prejudice. This will facilitate effective communication and provide an opportunity for us to help clarify any questions that may have arisen from the request. We presume that the MOE will be meeting with MNR to discuss the IEA request, so it is fair that we also receive an opportunity to discuss the request in person.

Sincerely,

David Sone

Subject: RUSH: Proactive Update: Whiskey Jack Forest Management Plan - due ASAP
Importance: High

Due ASAP
Hi Dan,
s.N/R
Can you please provide responses to the two questions below?
Thanks,
Mark

Question:
Would concurrence pose any risk to the Crown?
Proposed Response:

s.13

the decision was made on the actual IEA request if that request is ultimately denied (and again, the nature of the challenge would likely be that the decision was unreasonable).
Duty to consult: There is a low risk of successful challenge based on a failure to discharge the duty to consult because the effect of the specific decision (i.e. the decision on the part of MNR to request concurrence and the decision on the part of MOE to grant the concurrence) would only permit the operations identified in the FMP (assuming that the FMP process discharged its duty to consult) to proceed as planned and consulted on in a narrow section of the Management Unit.

Question:
Re: the following bullet, **what is MNR doing to potentially resolve this concern? Could MNR find a way to consider how to be responsive to the concern?**

a. Grassy Narrows First Nation indicated that it objected to the granting of concurrence for the individual EA request area as the community had not received any financial benefits associated with the tending and renewal activities which would occur if concurrence was granted. Grassy Narrows First Nation also suggested that the MOE consult with the First Nations who are located in the non-individual EA request area.

Proposed Response:

s.13

Hi Mark,

We had a couple follow up questions, need answers asap:

1. Would concurrence pose any risk to the Crown?
2. Re: the following bullet, what is MNR doing to potentially resolve this concern? Could MNR find a way to consider how to be responsive to the concern?
    a. Grassy Narrows First Nation indicated that it objected to the granting of concurrence for the individual EA request area as the community had not received any financial benefits associated with the tending and renewal activities which would occur if concurrence was granted. Grassy Narrows First Nation also suggested that the MOE consult with the First Nations who are located in the non-individual EA request area.

Please send me what answers you can get by 1030 AM this morning.

Justin

Subject: Proactive Update: Whiskey Jack Forest Management Plan

Please see updates regarding a request for concurrence for the Whiskey Jack Forest Management Plan. Updates include:

- A request for concurrence was received by the MOE on March 11, 2014. MNR is seeking approval from the Director of the Environmental Approvals Branch to commence with regular forest operations in areas of the forest management unit that are unaffected by the outstanding Part II Order request.

- In areas that are affected by the Part II Order Request, only maintenance of existing roads, renewal and tending operations (i.e. tree planting and thinning) would be permitted.

- On March 12, 2014, Earthroots wrote to the MOE identifying that it would not support granting concurrence if doing so would result in allowing mechanical tending and tree planting, and the use of herbicides, in the individual Environmental Assessment (EA) request area.

- On March 21, 2014 after verifying with MNR, the MOE wrote to both Earthroots and Grassy Narrows First Nation to confirm that only non-mechanical tending would be permitted in the Part II Order request area and that the application of herbicides would not be permitted.

- On March 27, 2014, the ministry met with Earthroots and Grassy Narrows First Nation. Grassy Narrows First Nation indicated that it objected to the granting of concurrence for the individual EA request area as the community had not received any financial benefits associated with the tending and renewal activities which would occur if concurrence was granted. Grassy Narrows First Nation also suggested that the MOE consult with the First Nations who are located in the non-individual EA request area.

- The Director is now considering whether to grant concurrence

- If concurrence is not granted, MNR notes that this may cause social and economic impact to those that rely on the Whiskey Jack Forest industry.

Thanks,
Justin

Paul,

As far as I understood it, the MOE was waiting for you to respond to my March 11, 2014 email containing the MOE finalized Appendix 1 and 6 documents. I believe that I worked on getting them finalized with John Sullivan who was your backup while you were on vacation. I will forward you that email.

Hello,

The Appendix 1 and 6 documents are attached to this email for your review. The documents have been reviewed by staff at the MOE and have been finalized. Is there any further information that MNR would feel beneficial to our review that could be included in Appendix 1- Issue 7 (e.g. issue resolution)? Please convey the additional information required by March 12, 2014, and I will update the document accordingly.

Subject: RE: Whiskey Jack info -

No problem Ross!

This is a long answer, and may be confusing - I will try to make clear. If it isn't, do feel free to give me a call and I can probably do a better job verbally!

Background: The FMP has high level objectives that need to be met. Part of these high level objectives mean you have to balance the economics, the social and ecological aspects. We do this by identifying various species and age of wood and running them thru models to make sure we are balanced as best we can (this is the planning phase). For example: if we were to harvest red pine, we would want to spread that harvest out over time and over an area. We would not want to focus on an area, deplete it and move on We want to balance out the different age classes of the species and ensure this species of tree is on the landscape. A good plan balances the economics, social and ecological concerns. Therefore areas are "planned" for all over the Whiskey Jack forest for sustainability.

When MNR did not do a FMP (due to trying to work things out with Grassy) – our only avenue was to do a 2 yr Contingency plan. Normally a contingency plan is done once, in this case we did 2 contingency plans, (for a total of 5 years of contingency plan). Again a second contingency plan was to once again to attempt to work with Grassy and get them) again we made every sincere effort to try to work with Grassy on their concerns (hence two mediations with Judge Iacobucci and the Process agreement).

The 2012-2014 contingency plan had harvest areas "planned" for - to meet the objectives of the FMP, the mediation/Process agreement; to provide opportunities for Grassy, should Grassy wish to harvest as well as follow Judge Iacobucci mediation agreements for Grassy to allow for some harvesting. There has been several attempts as I have mentioned in previously, where grassy members had wanted to do something, however did not move forward with these plans. There was also renewal work identified in this plan: surveys for free to grow and brushing were identified. There was no aerial herbicide identified in the contingency plan.

Please note:

- Within the 2012-2022 FMP, the average area planned for harvest is only 0.6% of the total forested lands in the Whiskey Jack Forest
- Within the proposed 2014/15Annual Work Schedule – only harvest identified is outside of the self-declared TLUA of Grassy - this represents a harvest area of 0.1% of total forested lands.
- The harvest level – since 2008 – has been outside of the self-declared TLUA of Grassy. This average harvest is 640ha, this is averaged over 10 years – a significant reduction on this forest!!

Call me if you need clarification.

Thanks Deb – much appreciated. This helps a lot!

One final question (I hope!). under the contingency plan which expired yesterday, what sort of forestry activities would have been permitted in the grassy narrows territory. I assume it was limited to tending, maintenance etc as I believe you had indicated no logging had occurred in the grassy narrows territory since 2008 if you could confirm that would be great.

Thanks

Hi Deb,

Wondering if you could assist me with a few questions? Would appreciate any insights you can provide asap. Thanks very much!

1) When the previous contingency plans were approved, did this create a concern in the community?

2) Can you advise as to when MNR would next be speaking with Grassy Narrows with respect to future opportunities for tending/tree planting contracts, should the community wish to seek such contracts.

3) Does MNR publicly post concurrence? If so, how and when would that occur?

Subject: Whiskey Jack IEA Request File

Hi Devon,

I hope that you are doing well.

I recently received a copy of the following documents from the MNR:

Response_cover_letter.pdf,
Appendix_6_Response_April_23.pdf,
Aboriginal_involvement_2012_2022_FMP.pdf,
File: Appendix_A.zip.

Earlier I received a copy of the MNR's request for concurrence.

Are there any other documents related to our IEA Request in the MOE file (or elsewhere)? For example, beyond responding to the MOE's questions about our request in the document above, has the MNR submitted any other response? Has the MNR submitted an opinion or recommendation for the MOE's future decision on our IEA request?

If so, please send me an electronic copy of those documents. If it is not possible to send them electronically, I would like to come in to make photocopies this week.

Take care,

Wills, Devon (MOECC)

Subject: Whiskey Jack IEA Request File

Hi Devon,

I hope that you are doing well.

I recently received a copy of the following documents from the MNR:

Response_cover_letter.pdf,
Appendix_6_Response_April_23.pdf,
Aboriginal_involvement_2012_2022_FMP.pdf,
File: Appendix_A.zip.

Earlier I received a copy of the MNR's request for concurrence.

Are there any other documents related to our IEA Request in the MOE file (or elsewhere)? For example, beyond responding to the MOE's questions about our request in the document above, has the MNR submitted any other response? Has the MNR submitted an opinion or recommendation for the MOE's future decision on our IEA request?

If so, please send me an electronic copy of those documents. If it is not possible to send them electronically, I would like to come in to make photocopies this week.

Take care,

David

Devon:

Thank you for the opportunity to clarify and, in some cases, correct typographical errors in our earlier submission. We have revised the "Summary of Aboriginal Involvement for the Whiskey Jack Forest 2012-2022 FMP" and provided accompanying documentation (i.e., letters) to respond to the questions you asked about our submission.

In addition, You have asked for additional clarification of MNR's response to the following issue identified in Appendix 1 – Issue 3:

Harvest – FMP contains no requirements for ongoing monitoring of mercury levels in the area affected by the IEA request to determine if in fact approved forest operations once implemented would (further) elevate mercury levels in catchment areas.

Forest management plans are implementation mechanisms that take direction from legislation, policy and guides and implement that direction. MNR's Forest EA Act approval and the Forest Management Planning Manual (FMPM) contain planning requirements for the monitoring of forest management activities in a forest management plan; however, do not include requirements to monitor specific effects of individual activities. The requirements include providing a description of:

- the monitoring of forest operations, with specific provisions for Areas of Concern to ensure operations are in compliance with the Forest Management Plan;
- the monitoring to be used to determine the effectiveness of any silvicultural treatments which are exceptions to the silvicultural guides;
- the monitoring to be used to determine the effectiveness of any operational prescriptions for Areas of Concern which are exceptions in the applicable forest management guides; and,
- the monitoring of regeneration success within a management unit.

The prevention, minimization and mitigation of the effects of forest management on the environment are addressed in forest management planning through the application of the appropriate guides required by Condition 38 of Declaration Order MNR-71. The development, review and revision of these guides is also mandated by this same condition of the Declaration Order, and directs MNR to assess the effectiveness of guides through appropriate scientific research projects and does not implicate ongoing monitoring in the context of individual forest management plans. Concerns such as those identified in this IEA request are addressed during the periodic review, and potential revision, of the guides and given the nature of this IEA request, MNR has already embarked on a process to

further consider this specific issue in the review of the relevant guide which is scheduled for review in the short term.

In addition, MOE has established in the Declaration Order a requirement for the formulation and implementation of a Provincial Forest Technical Committee, whose role will be to ensure that Guides are kept current with respect to scientific knowledge and management practices, by acting as a review board for proposed changes to existing guides and recommending priorities for new or existing guides. It would be most appropriate for this committee, primarily made up of non-MNR members chosen for their technical expertise, to direct and support guide related work.

Specifically:

Condition 38(f) requires each revised, amalgamated or new Guide to contain a description on an approach that shall be undertaken to monitor the effectiveness of the guide.

Condition 38(d) speaks to the requirement to review guides to ensure they reflect current scientific knowledge as it applies to Ontario. Factors that will be considered in the reviews include the results of applicable scientific research and the results of relevant and appropriate monitoring programs, along with other factors.

Condition 38(c) speaks to the role of the Provincial Forest Technical Committee in the review of existing Guides, and the setting of priorities for the revision, amalgamation or preparation of new Guides.

Further, Condition 31 requires that scientific studies be used to assess the effectiveness of guide direction.
I trust this response addresses your information requirements.

Thank you for the opportunity to clarify these points. If you have any further questions, please do not hesitate to contact Paul Glassford, Senior Advisor, Forest Environmental Assessment, Policy Division, Forests Branch.

Subject: mercury mentioned in 5 year ea report

Aquatic Effects Program

MNR's long-term aquatic effects program to assess the effectiveness of direction regarding aquatic ecosystems continued during the reporting period. The program includes both empirical measurement and modeling of the effects of harvest on aquatic ecosystems, and the evaluation of efforts to emulate natural disturbance patterns in watersheds and riparian zones in Northern Ontario. During the reporting period, the main initiative of the program was the development and implementation of an effectiveness monitoring program related to the Stand and Site Guide direction to maintain ecological functions of aquatic ecosystems. The purpose of the initiative was to ensure that application of the direction in the guide effectively minimizes physical disturbance within catchments (i.e., areas drained by rivers or bodies of water) so that hydrological, chemical and biological effects resulting from forest management activities do not exceed those observed in naturally disturbed catchments, and do not exceed acceptable levels for specific parameters such as methyl mercury. This project involves the development of modeling tools and survey methodology, and the validation of indicators of stream ecosystem structure and function (e.g., fish abundance, invertebrate community, temperature, water chemistry).

The program included a project which monitored small, forested watersheds for two years before and five years after harvest. Results indicate that forest harvesting causes increased water yield and an increased rate of movement of nutrients (e.g., nitrogen, potassium) and metals (e.g., mercury). However, subsequent research showed that mercury levels in fish and invertebrates in small, boreal streams were not related to the extent of forest harvesting. To help mitigate these impacts, program staff have developed a number of GIS-based tools to predict the location of small unmapped streams that may serve as fish habitat, and the hydrologic connection between aquatic and terrestrial areas. The tools, which are used to reduce site disturbance, were validated through field surveys and shared with MNR staff and the forest industry to help support forest management planning.

Subject: Stand and Site Review Questions

Hey Devon:

In response to your questions on the Stand and Site guide that you discussed with me today on the phone:

- The guide review will begin later this fall, with most of the work in the 2015 calendar year; completion date is Dec. 31, 2015
- Provincial Forest Technical Committee (requirement of EA approval) will be briefed on the review plan at their fall meeting; they know that the guide will be reviewed in 2015, but haven't been told of any details since we're still working on them
- Review will include anyone involved in the development of the original guide, plus anyone else who we think can add some value will be contacted during the review; this includes scientists (MNR, CFS, CWS, universities, etc.), practitioners (MNR and industry field staff), analysts, etc.; we will cast a wide net
- A draft terms of reference and timeline have been developed and they provide an idea of the scope of the review; it also shows that we've been thinking about this for some time, not just since the IEA request was made (i.e. it's part of normal business). I have not included but could forward if required.
- No changes to our current effectiveness monitoring approach are contemplated other than what we have already told you in our earlier response
- Revision would occur post completion of the review

Mercury is certainly one of the topics that we are planning on investigating during the review, as are a few other questions and 'known unknowns' (e.g. calcium, catchment scale effects, rutting standards).

In addition, I am preparing a briefing deck to enable the involvement of our affected Directors in the discussion with Agatha if you and Ross continue to think that is the next step. Finally, MNR is still reviewing the response by Earthroots and considering whether a response will be provided.

Paul

Sent: July-25-14 3:44 PM
To: Panko, Dan (ENE)
Subject: Whiskey Jack

Hey Dan,

As discussed, the issue of methyl mercury in the Project is a difficult one to analyze. The requester (Eathroots/Grassy Narrows) raises issues by quoting from various accredited scientific studies and tries to relate this to the Whiskey Jack Forest, and states that MNR has not enough scientific evidence to discount the effects of methyl mercury. MNR has refuted the claims by stating that the cited scientific evidence presented by the requesters were taken out of context and are misleading. MNR reiterates the fact that the methyl mercury is still not well understood in science. MNR feels that there are no studies which identify or evaluate mitigation measures to minimize mercury mobilization following disturbance. Thus, their Stand and Site Guide does not specifically mention methyl mercury mitigation, but does provide direction to minimize site disturbance, sediment transport and hydrologic disruption all of which may be associated with increased mercury mobilization. MNR also feels that the Stand and Site Guide is based on the best science we have available today, but upon its revision at a later date, it can be modified to suite new methyl mercury information.

Subject: Whiskey Jack - IEA Request Status Update

Annamaria,
The email from Myra is below. Devon and I worked on the following info email bullets to provide status update. Please let me know if there are any questions.
Thanks,
Kristina

- On January 22, 2014 the Ministry of the Environment and Climate Change received one combined Part II Order request for the project from the Grassy Narrows First Nation (GNFN) and a non-profit environmental group, Earthroots. On May 2, 2014, the EAB Director granted concurrence to MNRF which permits forestry operators to continue with forestry operations in areas that are unaffected by the outstanding IEA request.

- The main issue raised in the Part II Order request by GNFN is that mercury contamination in local waterways will occur as a result of clear cutting and may ultimately affect human and ecosystem health. GNFN is concerned that this will adversely impact their Aboriginal and Treaty rights.

- MNRF is of the opinion that no further analysis on mercury is required at this time given that MNRF has followed appropriate mitigation measures per the current guide. MNRF has indicated that it will review how mercury may have an impact on forestry operations when they review/revise the Stand and Sight Guide in 2015.

- During the preliminary review of the individual environmental assessment requests, it was determined that MNRF's Aboriginal consultation was not adequately documented. MNRF provided revised documentation on Aboriginal consultation in June 2014.

Subject: Feasibility of potential conditions on Whiskey Jack Forest IEA reqest

Follow Up Flag: Follow up
Flag Status: Flagged

Hi Kristina and Anne,

Thanks for the call yesterday where you put forward a couple of prospective conditions relating to the Whiskey Jack request for an Individual Environmental Assessment.

In my words, these conditions were ...

1) That MNRF follow through with what the Forest Management Plan specifies with regard to monitoring soil disturbance

2) That if Ontario's Stand and Site Guide is revised during the life of the Forest Management Plan and if it prescribes different levels of protection for soil disturbance or alternate forms of monitoring that we incorporate these elements into our management of the Whiskey Jack.

Those of us in MNRF involved in the different planning, implementation and policy perspectives had a short discussion following this call and we all feel that these conditions would be feasible to implement. #2 would likely be handled through an amendment to the FMP should that be necessary.

I appreciate the opportunity to discuss this and we look forward to working with you on the actual wording when the appropriate time comes.

Thanks,
Kevin

Hi Devon,

I hope that you are doing well.

Can you please send me GIS shapefile or TABfile boundaries for the areas in my earlier request to the MNRF? They told me to ask MOECC

If they are not too large, please send them by email. If not, please send them using a file transfer service.

Thanks very much.

Take care,

David

To: David Sone <david@earthroots.org>

Mr. Sone:

MOECC is currently reviewing all the information provided by MNRF, including the area affected, and the issues identified in the IEA request in order to make an informed decision. As you are aware, the IEA process is a separate process led by MOECC, as MNRF Regional Director has already approved the FMP. MNRF, at this point, simply provides supporting information to help the Director, MOECC make a decision on the IEA request. IEA request, the process for the review, and decision making are out of MNRF's hands and the responsibility of MOECC. If Earthroots is requesting information they should be requesting it from MOECC. If MOECC is unable to provide them the information, MOECC may seek our assistance if they so choose.

Hi Kurt,

I hope that you are doing well.

Can you please send me GIS shapefiles for the following:

1. The Grassy Narrows IEA request area as shown on the map MNR prepared for MOE.

2. The areas used to create that map:

   i) Grassy Narrows MNR trapline areas (first attachmet);

   ii) MNR Grassy Narrows Study Area (second attachement);

   iii) The area avoided during the creation of the recent Whiskey Jack Contingency Plan (orange, pink, and green areas on the third attachment).

Thanks for your help.

Take care,

Cameron, Anne (MOECC)

Subject: Whiskey Jack FMP - questions

Hi Shawn,

I have a few questions regarding the consultation that was done for the Whiskey Jack FMP. Can you please provide me a response by the end of this week at the latest? If this is not possible please let me know.

1. It was stated in MNRF's Appendix 6: Additional Forestry Discussions with GNFN – that in 2013, MNRF began discussions with Grassy Narrows First Nation to explore a new forest tenure relationship and transition to an enhanced SFL for the Whiskey Jack Forest to give First Nations communities a greater say in the resource management.
   Are these discussions still on-going? Yes. Grassy Narrows continues to participate in discussions with MNRF regarding forestry tenure for the Whiskey Jack Forest. This stage of discussion is referred to as pre-engagement.

2. It was stated in MNRF's Appendix 6 response that Earthroots submitted correspondence to the MNRF (Oct 31, 2013) regarding mercury concerns.

Did MNRF provide a response to Earthroots' letter? If so when and can I have a copy of it? See attached letter "MNR Response Earthroots"

3. As per the attached consultation record – page 2 re: LTMD - Grassy Narrows First Nation submitted a letter to the MNRF on June 13, 2012 requesting information and providing an overview of their concerns. The attached document indicates that MNRF responded on July 6, 2012.
   Can I have a copy of the July 6, 2012 letter? If not can you please describe what the letter was about? See attached letter "DM Letter GNFN Lucille McKenzie 2012.07.06".

4. As per the attached consultation record – page 2 re: Stage 3 - On April 3, 2013 the MNRF sent a letter to Grassy Narrows First Nation asking if the community would like an information session to be held.
   Did Grassy Narrows First Nation respond? If so can I have a copy of the letter? Grassy Narrows did not respond directly to our letter (See attached letter "2013.04 03_cdsenttochief") though we did receive a letter addressed to the Regional Director "2013.10.28_ANA_Letter_RD" which outlines Grassy Narrows FN's position.

5. It was mentioned in MNRF's April 17, 2014 letter to Grassy Narrows that Grassy Narrows First Nation had a councillor, and additional representatives, attend some planning team meetings.
   When was this? The attached consultation record indicates that Grassy Narrows First Nation did not participate on the Planning Team. Grassy Narrows FN sent representatives to a couple planning team meetings (PTs-31 May 24, 2012 and PTs-32 June 14, 2012) but attended as "observers" only, and on a separate occasion met with MNRF staff seeking to better understand forest management planning. See attached Planning Team Minutes. Responses were sent Grassy Narrows FN regarding the concerns raised at the Planning Team; see attached letters "DM Letter GNFN Lucille McKenzie 2012.07.06" and " 2012.08.30mnrrestognfncomments".

Subject: Whiskey Jack Conditions

Agatha,
Here are the DRAFT conditions s.19 for the Whiskey Jack FMP (we anticipate tweaking the wording a bit still):

s.13

With respect to MNRF contacts, these are the individuals that were directly involved or whom Anne has dealt with (not that BOTH Operations and Policy divisions were involved):

Shawn Stevenson, Resources Management Supervisor (Regional Ops Division)
Dan Pyke, Manager – forest management planning section (Policy Division)
Kevin Ride, Regional Resources Planning Supervisor (Ops div)
Neil Peterson, Regional FMP Specialist (Ops Div)
John Sullivan (Policy Division)
Paul Glassford (Policy Division)
Deb Weedon, District Manager (Ops)
Allan Willcocks, Regional Director (Ops)

I will send Jennie an email advising her to inform ADMO that Director is anticipating making a decision on Whiskey Jack FMP within the next week (+/- a few days) and let her know that we are working with Comms Branch (Michel Finn) to develop comms material. I will ask that she inform up for awareness and let us know what ADMO may need from us.

Thanks,
Kristina

Subject: Whiskey Jack Forest Management Plan

Hi Michel,

I wanted to contact you regarding the preparation of a Q & A and a Communications Plan for the MNRF's Whiskey Jack Forest Management Plan (FMP). As you may know, the MOECC received a request that MNRF undertake an individual environmental assessment for the FMP. The project may be deemed contentious as Grassy Narrows First Nation is one of the requesters.

As the Director of EAB is going to be making a decision on the request shortly there is some urgency to this request and I am happy to provide you with any information you require.

Thanks,

Anne Cameron

Questions and Answers
Whiskey Jack Forest: Request for Individual Environmental Assessment

KEY MESSAGES:

- After careful review, we are denying a request for an Individual Environmental Assessment for the Ministry of Natural Resources and Forestry's Whiskey Jack forest management plan.
- We are satisfied the project will be protective of the environment and human health and have imposed conditions to limit any mercury movements. The conditions include:
  - monitoring soil disturbances, and
  - reporting any changes to research methodology.
- The ministry is also satisfied that the forest will be regenerated through planting and seeding, thereby helping the absorption and conversion of greenhouse gases.
- Additionally, the plan includes measures to minimize soil disturbance such as harvesting only in the winter on shallow soil sites and reinforcing slopes and banks.
- Ontario's environmental assessment program promotes good environmental planning by requiring consultation and determining the potential effects of projects before decisions are made.

QUESTIONS AND ANSWERS:

Q1. What is the Whiskey Jack Forest Management Plan?

The forest management plan is in place to ensure the long-term health of forest ecosystems. The plan is usually in place for periods of ten years with the current plan valid from 2012 to 2022.

The Whiskey Jack Forest is approximately 450 kilometres west of Thunder Bay in northwest Ontario and contains over 1.1 million hectares of forested area. The Ministry of Natural Resources and Forestry, in consultation with the public, is responsible for the forest management plan for the area.

Q2. Why is the ministry denying the Individual Environmental Assessment request for the Whiskey Jack Forest Management Plan?

After careful review, the ministry has denied with conditions a request for an Individual Environmental Assessment for the Whiskey Jack Forest Management Plan including requirements for:

- monitoring soil disturbances, and

- reporting any changes to research methodology.

The Whiskey Jack forest management plan includes measures, such as harvesting only in the winter on shallow soil sites and reinforcing slopes and banks, which will be taken to minimize soil disturbance in order to minimize mercury movement.

Q3. How will the ministry ensure the local waterways are protected from mercury contamination?

The Whiskey Jack forest management plan includes measures, such as harvesting only in the winter on shallow soil sites and reinforcing slopes and banks, which will be taken to minimize soil disturbance in order to minimize mercury movement.

As a preventive measure, we are requiring the Ministry of Natural Resources and Forestry to:

- monitor soil disturbances, and
- report any changes to research methodology.

Q4. How can the ministry deny an Individual Environment Assessment given the mercury contamination?

As part of the assessment process for the Whiskey Jack Forest Management Plan, the Ministry of Natural Resources and Forestry conducted a very thorough review and assessment process as outlined in the Forest Management Planning Manual.

Conducting an Individual Environmental Assessment for forest management in the Whiskey Jack forest would not provide different responses to mercury concerns that were raised in the individual environmental assessment request. Rather, the ministry is imposing conditions to ensure that monitoring is undertaken and that the most current and updated guidance material is used for the Whiskey Jack forest management plan.

Q5. Why isn't the ministry concerned with the risks of mercury contamination?

The ministry is confident that the Whiskey Jack forest management plan has been developed with monitoring and mitigation measures that will ensure mercury mobilization is limited.

As well, the Ministry of Natural Resources and Forestry has the expertise to undertake monitoring and analysis of mercury and will incorporate its findings into the guidance material and forest management planning procedures.

Q6. How dangerous is mercury to human health and the environment?

Mercury is toxic, inherently persistent and bio-accumulative.

In water and sediments mercury can be converted into the highly toxic form known as methylmercury, which accumulates in the tissues of fish and other animal life.

Methylmercury is a potent neurotoxin that may impair brain function and adversely affect neurological development in wildlife and people (especially children).

Fish consumption is one of the main pathways for wildlife and human exposure to methylmercury, and is a major cause of restrictions on fish consumption guidelines, especially for inland lakes and rivers in Ontario.

Please visit Ontario.ca/fishguide for recommendations on the type and size of fish that is safe to eat.

Q7. Is there a provincial standard for mercury?

The provincial water quality objective for mercury is based on both mercury concentration in water and mercury concentration in fish tissue.

For water, the objective is 200 nanograms per litre. A nanogram is equal to one-billionth of a gram. To put this into perspective, 200 nanograms per litre is comparable with the passage of 200 seconds during a period of 32 years.

These standards are based on direct toxicity to fish and do not take into account effects on the food chain (i.e. bioaccumulation). It is possible that waters meet these standards for mercury, but effects in fish and wildlife may still occur due to bioaccumulation.

The provincial objective for fish tissue is that mercury should not exceed 0.5 micrograms per gram (wet weight) in whole fish for the protection of fish consuming birds and aquatic life.

Q8. Were Aboriginal communities consulted?

Six communities were consulted throughout the planning process:

1) Grassy Narrows First Nation
2) Wabaseemoong Independent Nations
3) Dalles First Nation
4) Wabauskang First Nation
5) Whitefish Bay First Nation, and
6) Kenora Metis Council.

Multiple Open Houses and meetings were held with communities who requested such. Notices of Public Information Centres and opportunities to review documents were sent to the communities. The Ministry of the Environment and Climate Change is satisfied that the Duty to Consult requirements were met.

Q9. Can this decision be appealed?

The Director's decision is final. The decision cannot be appealed to the Minister.

Q10. Both the Ministry of the Environment and Climate Change and the Ministry of Natural Resources and Forestry are ministries of the Ontario Government.

How can we be certain that the proper monitoring and abatement actions will take place?

The Ministry of Natural Resources and Forestry (MNRF) is required to undertake monitoring and abatement actions under the Crown Forest Sustainability Act.

They are required to maintain a program of scientific studies to assess the effectiveness of forest management guides.

The MNRF is currently supporting research projects and results will be used during the required periodic reviews of guidance material, such as the Stand and Site Guide which is used to develop forest management plans. The Stand and Site Guide provides direction to minimize site disturbance, sediment transport and hydrologic disruption in forest management plans.

As oversight, the Ministry of the Environment and Climate Change is imposing a condition requiring the MNRF to update the guidance material if new research comes to light. In addition, a condition is being imposed requiring the Ministry of Natural Resources and Forestry to report back to the Ministry of Environment and Climate Change if any updates are made.

Q11. Grassy Narrows First Nations has a history of mercury issues. How are they supposed to believe that mercury will not pose a risk to their health?

Mitigation measures, such as harvesting only in the winter on shallow soil sites and reinforcing slopes and banks, will be taken to minimize soil disturbance in order to minimize mercury movement. Minimizing mercury movement will decrease the likelihood of Grassy Narrows First Nations community members being affected by mercury.

In addition, the Ministry of the Environment and Climate Change is imposing conditions requiring the Ministry of Natural Resources and Forestry to follow the most current guidelines for monitoring.

Q12. What is an Individual Environment Assessment?

Individual Environmental Assessments are prepared for large-scale, complex projects with the potential for significant environmental effects. They require approval from the Ministry of the Environment and Climate Change.

Individual Environmental Assessments require more extensive review and public consultation and requires approval by the Minister of the Environment and Climate Change as well as Cabinet.

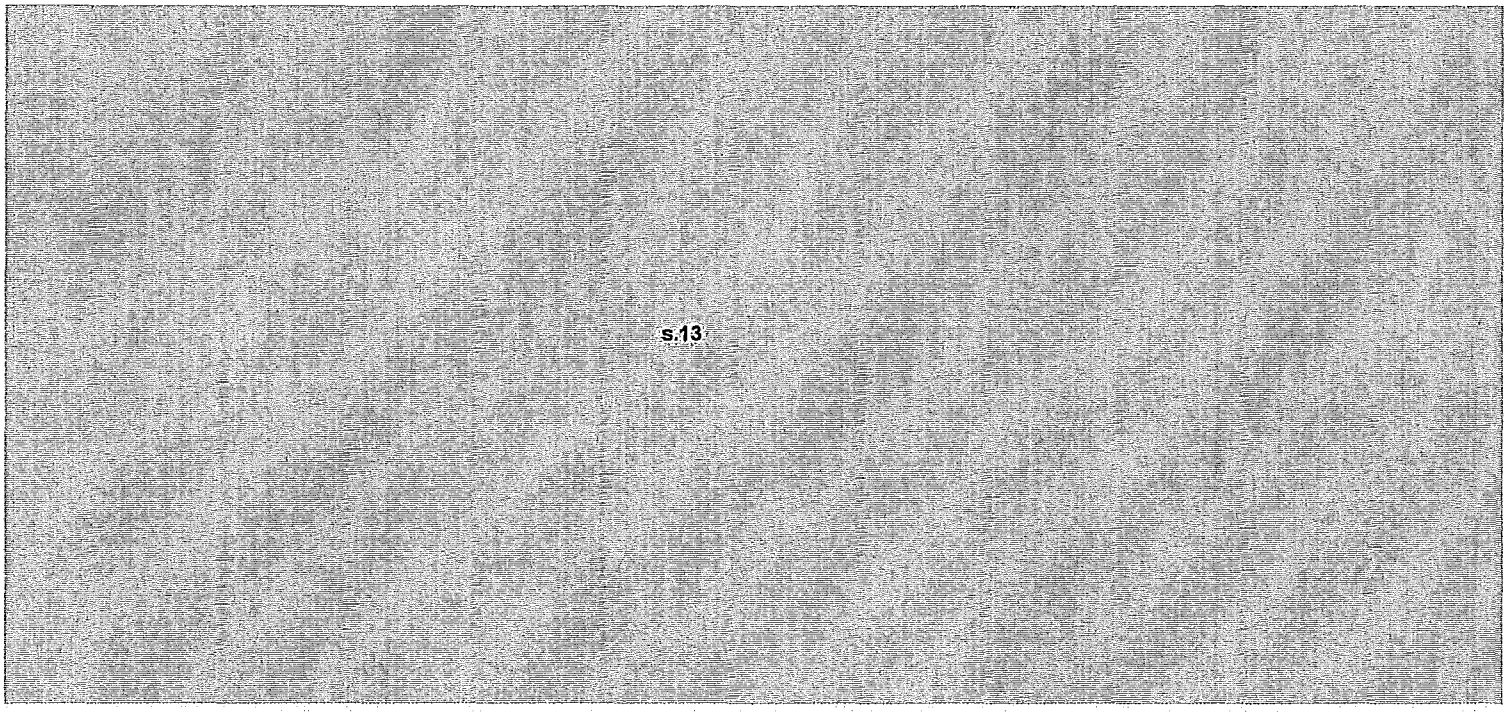
Anne,

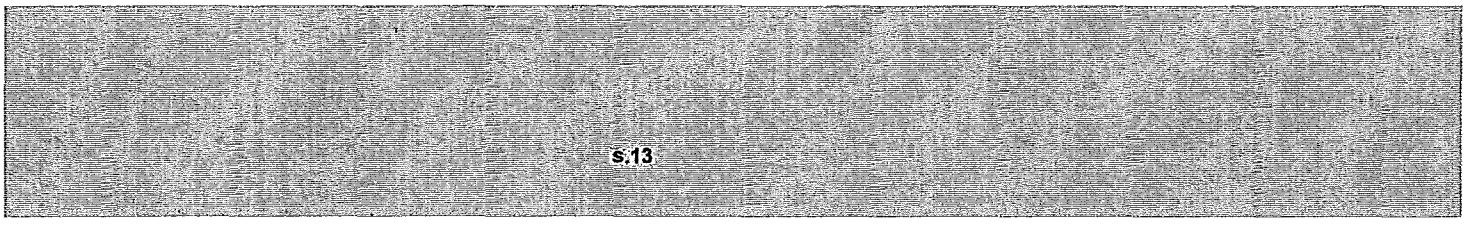
This is a start. If you guys think of other questions, please add them.



From: Cameron, Anne (MOECC)
Sent: December-18-14 1:26 PM
To: Finn, Michel (MOECC)
Subject: RE: Whiskey Jack

Hi Michel,

Thank you for your voicemail of earlier today. EAB has made some preliminary edits to the Q&A document (please see attached).



I started gathering some information from the Decision Note that may be helpful:

The MNRF advised MOECC that mercury is currently present in forests throughout Ontario, including the WJFMU. The MNRF has informed the MOECC that mobilization of mercury following forest disturbance may not be any different than that experienced during natural disturbances. Scientific studies conducted by a variety of research groups have found that if soil disturbance during forest operations is limited, the potential impact of mercury on fish and possible bioaccumulation is decreased. In the Whiskey Jack FMP there are measures, such as harvesting only in the winter on shallow soil sites and reinforcing slopes and banks, which will be taken to minimize soil disturbance in order to minimize mercury movement.

The MNRF is currently undertaking research to gain further understanding of the potential connection between forestry operations and mercury. This will help inform the development of guidance material used for forest management planning. As the MNRF has the expertise and is well positioned to undertake monitoring and analysis of mercury, the MOECC is imposing a condition requiring the MNRF to conduct monitoring, including monitoring of soil disturbance, in accordance with the Whiskey Jack FMP and the Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (Stand and Site Guide). In addition, a condition requiring the MNRF to follow the most current version of the Stand and Site Guide will be imposed to ensure that the best available guidance is being used for the development of forest management planning.

I also changed some things to acronyms which I'm not sure if that allowed in terms of formatting (just let me know and I can delete them).

Thanks,

Anne Cameron

To: Jordan, Kate (MOECC)
Cc: Berlin, Hayley (MOECC); Cross, Annamaria (MOECC)
Subject: RE: Whisky Jack Forest FMP Decision - Grassy Narrows FN Comment

Both. The decision was on the 22nd. That was when the letter was dated and mailed out.
Also – the bullets below are manager approved and modified from what we originally sent.
Thanks,
Kristina

- The IEA request for the Whiskey Jack FMP was received by the MOECC in January 2013.
- MOECC undertook a thorough review of the issues that were raised in the request. MOECC reviewed the IEA request to identify issues, ensure that the IEA requester has provided the necessary information and undertook preliminary discussions with MNRF on the issues.
- A request for concurrence was received by the MOECC on March 11, 2014. MNRF sought approval from the Director to commence with regular forest operations in areas of the forest management unit that are unaffected by the outstanding IEA request. On May 2, 2014, the EAB Director granted concurrence. This would allow MNRF to engage in access, harvest, renewal, site preparation, and tending operations.
- The length of the ministry review of an IEA request depends on a number of factors including the complexity of the issues raised. MOECC reviewed documentation to ensure it meet the requirements of the Declaration Order and consulted with MNRF on the issues raised by the requestors.

Kate,
Further to our discussion, letters were sent (mailed) to Grassy Narrows First Nation and to Earthroots on December 22, 2014. An email was not sent to either GNFN or to Earthroots. MNRF was informed of the decision by email. Also, please note some minor edits to the bullets below.

Thanks,
Kristina

Subject: FW: Whisky Jack Forest FMP Decision - Grassy Narrows FN Comment

Hayley,

The Grassy Narrows First Nation has released/circulated a statement regarding the MOECC's denial of its elevation request for the Whisky Jack Forest FMP. Kate has been fielding calls and has been using the messaging and information provided previously, but called to ask me to find out the timing of the decision (i.e. proximity to Christmas).

Is there anything we can say regarding the timing?

RELEASE Monday Dec. 29, 2014

ON says 'no' to environmental assessment of clearcut mercury impacts in Grassy Narrows

Science indicates that clearcuts will deepen the tragedy of mercury poisoning

*Grassy Narrows *– On the night before Christmas Grassy Narrows First Nation received notice that Ontario is rejecting the community's request for an Individual Environmental Assessment of the mercury impacts from the controversial final plan for clearcut logging on their homeland. Grassy Narrows is concerned that the planned clearcut logging will harm the health of their families by raising mercury poison levels in local fish – a traditional staple.

Ontario's logging plan makes no mention of mercury, and contains no special measures to account for the fact that Grassy Narrows' homeland is the site of Canada's most infamous case of mercury poisoning arising from 9,000 kg of mercury that was dumped into their river by a paper mill upstream in the 1960's. Scientific studies indicate that clearcut logging in the boreal forest can raise mercury in fish to unsafe levels.

"Ontario has ignored our voices and is planning to force more devastating clearcuts on our people without even applying their own Individual Environmental Assessment process," said Joseph Fobister, a Grassy Narrows land-user and businessman. "It makes me sad that our people will become even sicker if the government allows the logging industry to poison the fish that we eat."

"I am disheartened by this hurtful decision," said Chief Roger Fobister Sr. of Grassy Narrows. "It seems that our health and our culture do not matter to the government as they attempt to force their clearcut plans on us. The only honourable way forward here is to work together to gain our agreement before our land and water are used."

Grassy Narrows' request was an important test of Ontario's environmental laws. People with concerns can request an Individual Environmental Assessment (IEA) of a logging plan if they believe that environmental and human health are not being protected. However, such requests are rarely, if ever, granted since the current regulatory regime was established in 1994. The Timber Class Environmental Assessment for all logging which was approved in 1994 did not consider the mercury impacts from logging as they were not known until 1997.

"This is a glaring failure to use our environmental laws to ensure that the health of people and our environment are safe from the harmful impacts of industrial clearcut logging," explained Amber Ellis, Executive Director of Earthroots, which supported Grassy Narrows in their request. "It is hard to imagine a situation that requires an Individual Environmental Assessment more than the mercury issue in Grassy Narrows. What use is an Individual Environmental Assessment process when every request is rejected?"

The Ontario Ministry of Natural Resources and Forestry (MNRF) writes that "[t]he potential for forest management activities to result in mobilization of terrestrial mercury into aquatic systems is well documented and a serious concern." MNRF also admits that "[T]here are not mitigation measures specific to mercury in the [logging rules]," and "[t]here are no claims that the [logging rules] direction and application of the [logging rules] will mitigate or eliminate Hg mobilization."

And yet the Ontario Ministry of Environment and Climate Change has given the green light to the MNRF to authorize clearcut logging in one of the most mercury impacted parts of the planet, against the loud objections of Grassy Narrows where many families already suffer the debilitating symptoms of mercury poisoning.

Subject: Re: Grassy Narrows meeting

The working group was pulled together to work with the community to address their concerns resulting from the mercury spill in the 70/80s. The community has suffered the effects of mercury poisoning. In 2012 when the working group was set up as a result of a commitment made by them minister wynne. the primary objective was to address a set of 'demands' they had: mercury disability, environment, health and economic development. The 3 primary agencies involved are MAA (lead), MOHLTC, and MOECC. MNDM and MTC have also attended meetings. I was involved because of the work we do with mercury contaminants in fish as this was and still is to an extent their primary environmental concern. The commonity initially asked that MNRF not be included on the working group. The community have now requested MNRFs involvement and a new MOU has been developed to include them but has yet to be signed by the community. We are also working with HC to be involed with the group.

Hi Rachael,

Thanks for the invitation this morning. It was interesting to hear another perspective on Hg since we have been focusing so much on water. It will be interesting to see that balance between political sensitivity for a specific watershed/community and the implications for forestry management on a broader provincial scale. I liked the approach taken by Rob Makreth that looked a at hydrological consideration s on the watershed scale, to avoid areas that play a key role in methylation (i.e. wetlands) and possibly harvesting in the winter to minimize mercury transport.

MNR Science review for the request for an Individual Environmental Assessment (IEA) of the Whiskey Jack forest management plan (EBR Registry No. 010-9240)

Introduction:

The IEA requestors contend that the Whiskey Jack forest management plan "fails to adequately deal with the impacts of logging on mercury levels in boreal water and fish" and that the plan will "harm water quality, fish habitat, wildlife and the health of people who eat the fish". To support their concern the requestors present as evidence a number of research studies that have shown that forest disturbance (both forest management and fire) result in changes to mercury dynamics within watersheds which may increase the movement of terrestrial bound mercury into aquatic systems and may be associated with higher levels of mercury in aquatic organisms.

The requestors also argue that the forest management guidelines, provided in the Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (the Stand and Site Guide or SSG), do not adequately address the issue of forest management impacts on mercury dynamics.

The IEA request is presented in 15 sections which address various related concerns. In the MNR science team's attempt to evaluate the scientific basis of the request and provide comments on current forest management policies and guidelines related to the issue, we have divided the sections into 4 general themes and we will address the scientific evidence and the interpretation of this evidence that is presented in themes A and B:

A) Concerns arising from research on mercury and forest management

1. Clearcutting Impacts Water Quality Through Mercury Contamination
2. Clearcutting Elevates Mercury Levels in Fish
3. Elevated Mercury Levels Impact Wildlife
11. Duration and Intensity of Impacts

B) Concerns associated with forest management policy (SSG)

7. Measures in the Logging Plan to Deal with the Mercury Problem
8. Stand and Site Guide Rationale on Mercury
9. Fundamental Problems with MNR Rationale
    - A. Natural Disturbance Emulation Not Appropriate for Mercury Safety
    - B. Mitigation Science is Not Sufficiently Developed
    - C. Log Now, Test Later Approach.
12. Changes to Guidelines Are Likely to Make Mercury Problem Worse
    - A. Logging to the Shoreline
    - B. Catchment Disturbance Thresholds Removed
13. Specific Deficiencies in MNR Mitigation Measures

C) Concerns arising from historical contamination

4. Fish in Grassy Narrows Have Critical Levels of Mercury
5. Mercury Impacts Human Health in Grassy Narrows

D) Concerns arising from the planning process (not directly linked to science/research)

6. Efforts to Raise the Mercury Issue
10. Delay and Hardship
14. Need for an Individual Environmental Assessment
15. Remedy Requested

A) Concerns arising from research on mercury and forest management

Mercury is a natural element that occurs in air, water, soil and biota in the boreal forest. Mercury, which exists in several inorganic, or elemental, forms (Hg) and as organic methylmercury (MeHg), alternates between forms and cycles among different components of the ecosystem as part of a complex biogeochemical process. Natural levels of mercury are spatially variable depending on geology, soil and forest characteristics; however, the global atmospheric pool of mercury has increased two to five fold over pre-industrial times (Linberg *et al.* 2007). There is clear evidence from a number of studies that forest management is one of a large number of factors that influence mercury dynamics within watersheds. In sections 1, 2, 3 and 11 the IEA requestors provide quotations from some of these studies to support their conclusions regarding the risk of mercury increases associated with forest management. The following is a review of these sections:

1. Clearcutting Impacts Water Quality Through Mercury Contamination

The requestors contend that forest management activities will result in an increase in Hg and MeHg in waterbodies in the area. As evidence to support this conclusion they present results from several studies conducted in Quebec, Sweden and Finland, much of which is summarized in a review paper by Bishop et al (2009).

MNR review:

- Increased mobilization of mercury within watersheds following forest disturbance has been documented in several studies done in Canada, Sweden and Finland.
- Disturbance impacts include increases in the concentration of Hg and MeHg in surface runoff (increased concentration) and increases in runoff, thereby increasing the movement of Hg even without concentration changes (transport or flux).
- Changes in Hg dynamics are highly variable among watersheds depending on a large number of factors, including watershed characteristics and the extent of disturbance. For example, Bishop et al (2009) show post-harvest Hg concentration response ranging from a 4 fold increase in a Finnish study to no increase found in a study done in Northwestern Ontario.
- Very little work is available which directly compares Hg mobilization between harvested and burned watersheds. Studies done in Quebec measured increases in dissolved organic carbon (DOC), to which Hg is bound in surface water runoff, following harvest under some conditions (large disturbance area within the watershed and a large watershed to lake area ratio) but not consistently (Carignan et al 2000).
- No research has been conducted to test the effectiveness of specific forest management planning or operational measures at mitigating increases in Hg mobilization. Bishop et al (2009) provide some recommended practices which are similar to direction provided in the SSG (see discussion in theme B below).

Conclusion: There is strong evidence, based on a number of studies, that the rate of movement of Hg and MeHg from terrestrial to aquatic areas will increase following forest disturbance. There is not sufficient evidence to conclude that the magnitude of Hg response to forest management disturbance differs significantly from natural disturbance events in all cases; however, the mechanism of response is likely different. There is also no research available which tests the effectiveness of guidelines to mitigate changes in watershed Hg dynamics arising from forest disturbance.

2. Clearcutting Elevates Mercury Levels in Fish

The IEA requestors state that forest management activities in the Whiskey Jack forest will increase Hg inputs into aquatic systems which will harmfully alter fish habitat and result in an increase in MeHg levels in fish and other aquatic organisms. As evidence they present a number of quotes from Bishop et al (2009) as well as from Garcia and Carignan (2005). It should be noted that the Bishop et al (2009) paper is a review of previous research and all information presented on fish Hg levels come from a study by Garcia and Carignan (2000, 2005) so the evidence comes from a single study.

MNR review

- The study by Garcia and Carignan (2000,2005) which included 38 lakes (9 cut, 9 burned and 20 reference) is likely the most comprehensive study on the association between watershed disturbance and fish mercury levels.
- Fish in disturbed watersheds (cut and burned) had higher mercury levels than fish in undisturbed reference lakes
- Fish mercury levels were highly variable and were strongly positively correlated with fish size (fig 1) and fish trophic position (fig 4) (Garcia and Carignan 2005)
- Based on fig 4 (Garcia and Carignan 2005) more than 3 times more variability in fish mercury is associated with trophic position than with watershed disturbance and there is very little difference between fish mercury levels in cut and burned lakes when trophic position is controlled for.
- 'The highest Hg concentrations were observed in fish from two partially burnt lakes' (pg 690, Garcia and Carignan 2005). It appears that fire intensity (proportion of the watershed burned and the amount of organic layer burned) has a substantial impact on mercury dynamics in the watershed and the potential response of aquatic organisms.
- Through elevating DOC export from soils, an enhanced vector of Hg export to aquatic ecosystems occurs.

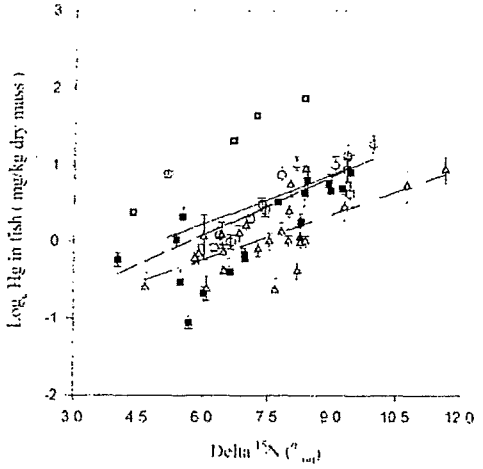

Fig. 4. Relationships between mercury (Hg) concentrations and fish $\delta^{15}N$ for reference lakes (triangles and dash-dot-dot line), and for lakes with cut (open circles and solid line) and burnt catchments (black and dotted squares for completely and partially burnt catchments, respectively, and dashed lines). Points represent fish of a standardized length from 62 populations. The $\delta^{15}N$ values are corrected for baseline variations. Error bars correspond to standard deviation.

From: Garcia and Carignan 2005

Conclusion: The comprehensive study of Quebec lakes provides evidence that fish in disturbed watersheds tend to have higher Hg concentrations than those in undisturbed watersheds. The study does not provide strong evidence that fish Hg concentrations consistently differ between burned and harvested watersheds. When trophic position is included in the analysis, fish Hg levels in harvested watersheds fall within the broader range of fish Hg levels in burned watersheds (fig 4, Garcia and Carignan 2005). This single study, despite being a very comprehensive, does not provide sufficient information to understand all the factors that influence fish Hg levels or how these factors may interact. Given the complexity of how disturbance impacts Hg dynamics and how aquatic systems may respond, it is unlikely that identical results would be seen in other regions of the boreal zone.

3. Elevated Mercury Levels Impact Wildlife

The IEA requestors express a concern that the mercury levels in a number of wildlife species, presumably those that consume fish, may increase if fish mercury levels increase. They provide evidence, primarily citing Environment Canada websites, which explains that mercury contamination can have negative impacts on the growth, development, behaviour and reproduction of wildlife species.

MNR review

- There is strong evidence that high body burdens of mercury may have toxic effects on certain wildlife species and lead to a number of health issues.
- Elemental mercury (Hg) in water and plants is not toxic to animals and is not stored in animal tissue; however, methylmercury (MeHg) is toxic and is stored and bioaccumulated in muscle and fat tissue. The main source of MeHg for terrestrial animals is the consumption of fish.
- We are unaware of any studies that directly examine the relationship between forest disturbance and wildlife Hg levels.

Conclusion: While it may be reasonable to assume that increases in fish Hg levels could lead to Hg increases in piscivorous wildlife species, the relationship between forest disturbance and fish Hg is not well understood (see section 2) and the further connection to wildlife is likely very complex and associated with a large number of interacting factors.

11. Duration and Intensity of Impacts

The requesters state on page 24 that "if further clearcutting is allowed without proven mitigation measures, and methyl mercury levels in local fish are elevated as a result, the impacts would likely be grave and long lasting." They further contend that "the impacts of releasing mercury into the environment in Grassy Narrows through clearcut logging are likely to last at least a decade in fish, and at least one human lifespan beyond that in people". They base their conclusions on data from studies conducted in (1) Ontario, Québec, Finland, and Sweden, much of which are summarized in studies by Bishop et al. (2009) and Garcia and Carignan (2005).

MNR review:

- The proponents state that "clearcutting has been found to increase MeHg bioaccumulation in boreal lakes by two to four fold, and sometimes as much as eight fold (Bishop et al., 2009)" (Page, 24). The further state that "As much as 37% of Hg in fish across a managed landscape would result from the increased Hg outputs associated with felling and thinning". Bishop et al. (2009) actually calculated that forest harvesting may contribute 9 to 23% of MeHg fluxes from the soil following harvesting. They also made

the point that many uncertainties existed in the calculations (e.g., small number of samples and a large range of impacts across studies).

- Few studies have been published regarding the effects of clearcut harvesting on fish MeHg concentrations. Those studies suggest that although MeHg concentrations in fish may increase following clearcut operations, it is generally limited to cases when soils are disturbed, and not to the harvesting of trees. This was alluded to by Bishop et al. (2009), as well as reported in findings and discussions of other studies (Povari et al., 2003, Sørensen et al., 2009, Eklöf et al., 2012, 2013). Soil disturbance contributes to elevated fish concentrations in upland catchments via particulate matter (organic and mineral) transport from forest soils to streams and lakes. Whereas, soil disturbance of lowland (e.g., wetlands and riparian zones) catchments increase MeHg runoff to streams and lakes via enhanced dissolved organic carbon (DOC) transport. Therefore, no evidence exists contrary to the protection of soils from disturbance as described in the Stand and Site Guide as a mitigation measure minimizing forest harvesting operation effects on fish MeHg concentrations.

- The requesters further contend on pages 24 – 25 that "impacts of clearcutting on mercury have been found to persist for at least five years, with no known endpoint" and "the increased in Hg loading effect has also been observed to persist up to at least 5 years, and there are no examples so far of the logging effect having dissipated (Bishop et al., 2009)". In fact, Skyllberg et al. (2009) assessed stream MeHg concentration in Sweden by comparing 47 clearcut stands dominated by Norway spruce to 10 mature Norway spruce-dominated stands. They showed stream MeHg concentrations were elevated in stands 0 to 4 years after harvested, but no differences occurred in MeHg concentration in streams 4 to 10 years after harvested. Skyllberg et al. (2009) suggested these results were attributed to increased organic matter added by logging residue stimulating Hg methylating bacteria in the soil, and by 4 to 10 years, this effect dissipated.

- The Hg in fish higher in the food chain continued to increase several years after harvest (Garcia and Carignan 2000, 2005, as cited in Bishop et al., 2009 (Page 24).
See response to section 2 for discussion of fish Hg response.

- The requesters contend on pages 25 – 26 that logging is likely to (1) further elevate mercury in fish in previously contaminated lakes due to increasing methylation rates of newly added mercury and stored mercury in lake sediments, (2) prolong the length of time for which fish in previously contaminated lakes remain unsafe to eat, (3) elevate mercury levels in fish in marginally safe lakes above safety limit, and (4) elevate mercury levels in fish in currently safe lakes above the safety limit.

  Skyllberg et al. (2009) reported that 17% of MeHg in streams came from methylation of stored mercury, while 73% arose from methylation of newly added mercury from logging debris and that TOC (total organic carbon in non-filtered water samples) and its structure did not differ between streams draining clearcut and mature forest catchments. Furthermore, Neff et al. (2012) conducted an intensive study of lake mercury levels in the English-Wabigoon River system. They examined long-term (1970 – 2010) monitoring data to assess temporal trends in mercury in walleye, northern pike, and lake-whitefish in 4 lakes along a chain of lakes occurring from closest to furthest locations from a paper mill source (approximately 10 tonnes Hg input between 1962 and 1970); Clay, Ball, Separation, and Tetu Lakes, respectively. Neff et al. (2012) found that for all lakes and fish species, mercury declined by 35 to 94% through time, although walleye and northern pike mercury concentrations were above (Clay Lake) or near (Ball and Separation Lakes) the human consumption guideline of 0.5 µg g-1 of fish tissue. Additionally, the authors summarized mercury concentrations of walleye (45 cm length) and northern pike (50 cm length) based on 143 and 123 locations in northwestern Ontario. Neff et al., (2012) reported median values near the 0.5 µg g-1 guideline for walleye (25th – 75th percentiles

= 0.38 and 0.75 µg g-1, respectively) and median of 0.38 (25th – 75th percentiles = 0.25 and 0.60 µg g-1, respectively) for northern pike.

Most rapid declines in fish mercury concentrations occurred between 1970 and 1985; however declines slowed from the late 1980s to 2010. Contributions to the slower declines are many and include (1) the lakes approaching baseline values prior to mercury contamination, (2) climate change enhancement of (a) area burned and severity of soil organic matter and mercury combustion or (b) extended drought followed by intense precipitation events, (3) catchment cover types and the wetland-to-lake ratio, and (4) connectivity of wetlands, streams, rivers, and lakes in a drainage basin.

- The proponents also suggest on pages 25 – 26 that "clearcutting leads to higher DOC compared to reference lakes and burned lakes (Garcia and Carignan, 2005), stimulating bacterial methylation, decreasing photo-oxidation of MeHg to Hg^{2+}, and possibly decreasing photo-reduction of Hg^{2+} to gaseous mercury. Those processes were suggested to elevate mercury levels in fish.

Research has shown in the temperate and boreal regions of North America (Couture et al., 2012) and Europe (Laudon et al., 2013) that climate change is the primary cause of elevated DOC concentrations in lakes. Moreover, although studies (e.g., Haines et al., 1994; Sellers et al., 1996) suggest elevated DOC concentrations may inhibit photo-oxidation of MeHg and reduction of Hg^{2+} to gaseous mercury these results are far from universal. For example, although DOC is an important transport vector for Hg^{2+} and MeHg, this DOC is highly recalcitrant (e.g., low bacterial degradability). Whereas bacterial methylation is dependent upon the presence of easily degradable DOC concentrations (as well as electron acceptors such as sulphate); thus increasing DOC-Hg transport from soil to lakes does not necessarily translate into greater rates of mercury-methylation.

Conclusion: For forest harvesting to further exacerbate walleye and northern pike mercury concentrations in lakes situated in the English-Wabigoon River System, any mercury input to upstream catchments will need to traverse a myriad of interconnected wetlands, streams, and lakes within the river system. However, we are aware of no published studies addressing potentially elevated long-range mercury transport in large drainage basins. In terms of MeHg (and assuming it is elevated in headwater catchments), some of it would be removed from the water column of lakes through (1) MeHg photo-oxidation to Hg^{2+} and its subsequent reduction to gaseous mercury and loss to the atmosphere or (2) settling of DOC- and particulate matter-bonded mercury from the water column to the sediments as water moves downstream. While much variation occurs in the photo-oxidation rates of MeHg to Hg^{2+} and its reduction to gaseous mercury, the current scientific evidence indicates that protecting soils from disturbance during harvesting operations as spelled out in the Stand and Site Guide will minimize total and methyl mercury loading from soils to streams and lakes in a catchment. Furthermore, it can be reasonably argued that any MeHg-containing water resulting from harvesting in headwater catchments will be diluted prior to reaching the English and Wabigoon Rivers and their connected lakes, thereby contributing little to mercury concentrations in the river system's lakes.

B) Concerns associated with forest management policy (SSG)

Direction in the SSG was based on a thorough review of existing literature, and discussions with and review by ecological researchers, practitioners, policy makers, stakeholders, and members of the public to ensure that direction would be effective in meeting ecological objectives, while also being feasible to implement and socially palatable. *'In all cases, the direction in the Stand and Site Guide represents a series of predictions or hypotheses. Those with a high degree of uncertainty have been identified as a high priority for testing through an effectiveness monitoring program (see Section 7). The results of this monitoring program, along with other sources of information, will be used during periodic reviews of the Stand and Site Guide to help determine*

when the guide needs to be revised' (SSG section 1.3.5, pg 5). The SSG therefore represents a summary of the best available direction to meet MNR's objectives and legislative requirements for sustainable forest management and incorporates an adaptive management approach to evaluate and improve direction in areas of uncertainty.

Section 1.3 of the SSG summarizes the guide's approach to conserving forest biodiversity using guidance characterized as coarse and fine filters. This direction is based on the principles of the *Crown Forest Sustainability Act, 1994* (CFSA) which a key piece of legislation regulating forest management. Specifically the CFSA states:

> *The long term health and vigor of Crown forests should be provided for by using forest practices that, within the limits of silvicultural requirements, emulate natural disturbances and landscape patterns* [coarse filter] *while minimizing adverse effects on plant life, animal life, water, soil, air and social and economic values, including recreational values and heritage values* [fine filters] (CFSA s. 2(3)2).

The coarse filter approach to the emulation of natural disturbance and landscape patterns is intended to maintain the natural diversity of forest condition and ecological processes in order to conserve forest biodiversity and is a legal requirement under the CFSA. The coarse filter is not intended as a specific mitigation measure but rather an approach to maintain the state of all elements of the forest ecosystem within a natural range. Fine filter direction is included when there is evidence that additional mitigation measures will improve the protection of specific values.

During the development of the SSG, MNR did an extensive review of the body of scientific literature examining the relationship between forest disturbance and mercury dynamics. A summary of this review and the resulting decision on guide direction are provided in the SSG Background and Rationale document (pg 23-25) which is included as an appendix in the IEA request. The key points from the review were:

- The potential for forest management activities to result in mobilization of terrestrial mercury into aquatic systems is well documented and a serious concern.
- The nature and magnitude of changes in mercury dynamics within a watershed following disturbance are complex and related to a number of interacting factors including area disturbed, changes to hydrology, the amount and type of wetland in the area and soil disturbance.
- There is limited information on the potential for fish Hg levels to be influenced by harvest disturbance but the best available evidence shows that fish in lakes with disturbed watersheds had higher mercury levels than those in undisturbed watersheds and that the range of Hg levels in fish in harvested watersheds was within the range of those in burned watersheds (Garcia and Carignan 2000, 2005).
- There is a high degree of uncertainty regarding Hg response to forest management and the issue should be a high priority area for guide effectiveness monitoring.

Because there are no studies which identify or evaluate mitigation measures to minimize mercury mobilization following disturbance there are no mitigation measures specific to mercury in the SSG. The guide does provide direction to minimize site disturbance, sediment transport and hydrologic disruption (listed on pg 24 of the SSG Background and Rationale) all of which may be associated with increased mercury mobilization. In a review paper published following the release of the SSG, Bishop et al (2009) conclude that "An understanding of the processes controlling the output of Hg from catchments to surface waters, and subsequent bioaccumulation, is not sufficiently developed to confidently recommend ameliorative measures for forestry" (pg 378). They do offer some suggested practices, which include minimizing site disturbance and hydrological disruption and protecting wetlands. Direction in the SSG is entirely consistent with the recommendations of Bishop et al (2009).

The IEA request raises a few specific concerns about the SSG which suggest that they have misinterpreted the direction in the guide:

- In section 8 the requestors interpret the SSG rationale on mercury as stating "1. Logging is essentially equivalent to fire so attempts to emulate fire will eliminate Hg impacts". The SSG does not suggest that emulation of natural disturbance patterns will eliminate Hg impacts. The emulation of natural disturbance patterns within watersheds is expected to result in watershed scale hydrologic changes that are within the range that would occur as a result of natural disturbance processes. The SSG provides additional direction to minimize site disturbance associated with harvest and road construction, particularly in areas that are expected to have higher soil moisture levels. The SSG acknowledges that Hg dynamics will likely change within the watershed as a result of any type of forest disturbance and that further research and monitoring is required to refine direction in the guide.

- In section 9 the requestors state that "logging and forest fire have nearly opposite impacts on mercury" (pg. 16). This statement is demonstrably false as all the literature they cite as evidence shows that Hg is mobilized and/or bioaccumulated following both fire and harvest disturbance. The mechanism and magnitude of Hg response almost certainly differs between burned and harvested watersheds but all of the studies cited found some level of Hg response following disturbance by fire. Fire intensity is likely an important factor that influences Hg response with high intensity fires volatilizing Hg bound in the organic soil layer and low intensity fires leaving this layer undisturbed and Hg subsequently being mobilized as water tables rise and surface runoff increases. In their study of fish Hg levels, Garcia and Carignan (2000, 2005) found the highest Hg levels in fish from watersheds impacted by low intensity fires and lower Hg levels in fish from watersheds with high intensity fires. Fish Hg levels in harvested watersheds fell within this range (Garcia and Carignan, 2000, 2005). (Note that the requestors appear to use fire size and fire intensity interchangeably when in fact these measure different things)

Conclusion: The Stand and Site Guide and accompanying Background and Rationale document clearly acknowledge the potential for forest management activities to mobilize mercury, provide a comprehensive summary of available scientific literature on the topic, provide a clear rationale for guide direction and acknowledge the uncertainty associated with this direction. There are no claims that SSG direction will mitigate or eliminate Hg mobilization.

Summary of past, current and future research projects related to mercury in Ontario being conducted by the Ontario Ministry of Natural Resources, Science and Research Branch.

Mercury related research led by Dr. Jim McLaughlin, Forest Soils Research Scientist, Forest Research and Monitoring Section, Sault Ste. Marie

1) Climate change effects on total and methyl mercury runoff from peatlands.
    a) Intact peat cores collected in 2012 from peatland located near White River.
    b) Cores transported to BIOTON at the University of Western Ontario.
    c) Cores exposed to varying atmospheric CO_2 concentrations, air temperature, and soil moisture.
    d) Establishing a field-based experimental system for the evaluation of the effects of elevated temperature and elevated atmospheric carbon dioxide (CO2) on total and methyl mercury runoff peatlands.
2) Establishing baseline conditions for Far North peat total mercury storage.
    a) All collected peat samples are analyzed for total mercury concentration, bulk density, and peat depth to mineral sediment recorded.
    b) Mercury concentration, bulk density, and depth are used to calculate the amount of total mercury stored at each coring location, then scaled to total peatland area of the Far North.
3) Establishing baseline conditions for forest soil mercury storage.
    a) National Forest Inventory grid.
    b) Organic and mineral soil samples collected at selected locations and analyzed for total mercury and bulk density, and soil horizon thickness.
    c) Mercury concentration, bulk density, and soil horizon depth are used to calculate the amount of total mercury stored at each sampling location, then scaled to area of forest cover types in the Far North.
4) Baseline conditions for terrestrial ecosystem soil mercury storage.
    a) Calculated from numbers 2 and 3 above.
5) Synthesis of land use (e.g., mining, hydroelectric, forest harvesting and regeneration) effects on watershed total and methyl mercury cycling and export.

Mercury related research projects led by Dr. Tom Johnston, Research Scientist, Aquatic Research and Monitoring Section, Cooperative Freshwater Ecology Unit, Vale Living with Lakes Centre, Laurentian University, Sudbury.

1) Update fish mercury information to improve consumption guidelines and assist with community-based land-use planning. All fish mercury information we collect, whether near north or far north, fits this objective.

2) Determine temporal changes in fish mercury bioaccumulation, 1970s to present. Mostly sampling in the near north but some in the far north as well. This was the basis for Rex Tang's MSc thesis and has already been published (Tang et al. 2013. Sci. Tot. Environ.). But, we still sample a few lakes to try to fill in the geographic coverage of the analysis. I have also considered repeating the analysis over shorter (more recent) time windows, but have not pursued this yet.

3) Assess relative importance of food web position and growth rate in shaping interspecific variability in piscivore mercury concentrations (Johnston et al., ongoing). I usually call this the multi-predator project. We are targetting lakes that have co-habiting populations of lake trout, burbot, walleye, and northern pike. This will allow us to control (somewhat) for the lake effect when making interspecific comparisons.

4) Determine roles of physical-chemical limnology and food web structure in shaping fish mercury patterns in lakes across a climatic gradient (Sumner MSc project, started 2013). She will examine lakes across the near north and far north, comparing the role of climate (inferred from latitude or GDD) with the role of other factors. She may include some landscape factors (e.g., area or vegetation cover of drainage basin) in the analysis. This is probably the closest my research program comes to examining effects of forest harvesting on fish mercury.

5) Determine spatial variation in fish mercury concentrations from headwaters to James Bay in the Attawapiskat River drainage basin (Lescord PhD project, started 2013). This is restricted to the far north and looks at mercury dynamics following a river continuum framework. She will compare how mercury moves through the food web at various points along the continuum from the headwater lakes of the shield, to the main stem river of the lowlands.

Mercury related projects led by Dr. Rob Mackereth, Research Scientist, Centre for Northern Forest Ecosystem Research, Lakehead University, Thunder Bay.

1) Ongoing monitoring of mercury in small stream biota to evaluate the association between the rate of bioaccumulation and biomagnification of mercury and stream characteristics, including catchment disturbance. Sampling of periphyton, benthic invertebrates and fish have been conducted in watersheds having different forest management histories. Results to date show that mercury is present in all stream biota and tends to be higher in small streams compared to large. We have found no differences in fish mercury levels based on forest management activities in the watershed. Fish and invertebrate mercury concentrations tend to be associated with local conditions including pH, conductivity, stream gradient and temperature. Future work will focus on measuring fish and invertebrate mercury levels in streams within burned watersheds.

2) The Escape Lake experimental watershed study was initiated to evaluate the impacts of forest management activity on the hydrologic connectivity between terrestrial and aquatic habitats and to observe the catchment scale hydrologic (groundwater levels, surface water flow, water chemistry) and soil chemistry response. Beginning in March 2003, the watershed was surveyed (high resolution DEM, vegetation plots, soil pits) instrumented (wells and pizometers in wetland and along 3 experimental and 1 reference hillslope transect, resin bag transects) and monitored for 1.5 years. Experimental clearcut harvesting was carried out in June 2004, and included harvesting merchantable trees within the prescribed 30m buffer. Water quality constituents examined include major cations (Ca^{2+}, Mg^{2+}, K^{+}, Na^{+}) and anions (SO_4^{2-}, Cl^{-}), nutrients (NO^{3-}, NH^{4+}, TN, ortho-P, TP), TSS, turbidity, DOC, SRSI and metals (Al, Fe, Mn, Cu, Cd, Pb, Zn, Ni and MeHg and THg). Mercury concentration in ground and surface waters did not increase; however, following harvest, catchment water yield approximately doubled relative to pre-harvest resulting in an increase in Hg flux.

3) The associations between watershed and lake scale characteristics with THg in piscivorous fish were examined as part of an MSc research project (Victoria Danco). ArcGIS was used to delineate the waterbody catchment area and extract waterbody catchment characteristics for 243 of northern Ontario's lakes. Walleye (*Sander vitreus,* n= 121 lakes), lake trout (*Salvelinus namaycush,* n= 60 lakes), brook trout (*Salvelinus fontinalis*, n= 18 lakes), northern pike (*Esox lucius,* n =107 lakes), smallmouth bass (*Micropterus dolomieu*, n = 37 lakes), and burbot (*Lota lota,* n= 4 lakes) populations were standardized to the mean length of the populations by using power-series regressions. Multivariate analysis (non-metric multidimensional scaling) and univariate analysis were used to determine the associations between total mercury concentrations in fish and watershed scale and lake scale variables. Watershed and lake chemistry characteristics poorly described the variability in THg concentrations. Forest harvesting and natural disturbance were not associated with fish mercury concentrations.

FYI – updated to reflect a visit by Japanese scientists last week in the First Nations community, as well as recent meeting between their Minister and the community.

Darius Byrne
Supervisor, Issues and Media Relations
Ministry of the Environment and Climate Change

INFORMATION NOTE: Grassy Narrows First Nation Mercury Contamination
DATE: September 10, 2014

ISSUE

The Asubpeeschoseewagong Netum Anishinabek (ANA), formerly Grassy Narrows First Nations, has expressed concerns with the mercury levels from historical contamination in the fish from the English-Wabigoon River system. An inter-ministerial working group with the ANA continues to discuss this and other issues facing the community.

KEY FACTS

- During the 1960s and 1970s, mercury pollution occurred in the English-Wabigoon River system in northwestern Ontario from the operation of the chlor-alkali plant in Dryden (refer to Appendix 1).

- The ANA has expressed concerns with the mercury levels from historical contamination in the fish from the English-Wabigoon River system; their concerns primarily relate to:
    - Mercury Disability Board (MDB)- processes and procedures;
    - Environmental Issues - mercury in the environment;
    - Health - impacts of mercury on human health;
    - Economic Development – impact of mercury levels on commercial fishing.

- Testing has shown that mercury levels in sport fish in parts of the river system have declined as much as 87 percent since the 1970s, although consumption advisories remain in effect.

- The ministry tests the pulp and paper mill effluent at Dryden on an annual basis for mercury; mercury has not been detectable in the mill's effluent since at least 1989.

- In 2012, the Ministry of Aboriginal Affairs (MAA) established a working group with ANA in an effort to address community concerns. Member include the ANA, along with the ministries of Aboriginal Affairs, Environment and Climate Change, Health and Long-Term Care, and when required Northern Development and Mines and Training, Colleges and Universities.

    - MAA is drafting a Memorandum of Understanding with ANA to continue this working group which will also include the Ministry of Natural Resources and Forestry (MNRF) and the Federal government.

- A staff level working group (representatives from MOECC and MAA) meets quarterly to discuss environmental issues.

- The ministry is working with the community to address their environmental concerns. As part of this, the ministry is looking at their potential involvement in the Sport Fish Contaminant Monitoring Program and the Drinking Water Surveillance Program.

BACKGROUND

- Studies by the federal and provincial governments were conducted in the 1980s in the Wabigoon River to determine the location and the extent of contamination. In general, a clean up was not advisable due to the possible remobilization of mercury.

- Natural sedimentation within the system over the past 30+ years to provide for a cap was considered and is a viable remediation option for mercury contamination. Surveys suggest that mercury concentrations in the sediments have gone down and could be at levels comparable to other lakes in the area.

- The ANA relies on fish from the river system for food and obtains its drinking water from lakes within the river system and has expressed concerns with the mercury levels from historical contamination since the fish from this system are an important source of food for their community.

- Despite significant declines in mercury levels, restrictions on consumption of fish remain in place, yet the community continues to consume fish from their doorstep lakes/rivers. Under an arrangement with MNRF, MNRF provides the community with "clean" fish, but the community has not taken full advantage of the whitefish provided, as culturally they prefer walleye or pike.

- Under a 1985 Settlement Agreement, benefits continue to be paid to ANA and Wabaseemoong Independent Nations members who demonstrate symptoms consistent with mercury poisoning (through MDB). The MAA continues to financially support the MDB in administering the Mercury Disability Fund and making awards for eligible people.

- A main concern of the community is that the government has never formally recognised/acknowledged that community members are suffering from symptoms similar to that of people with Minamata disease (neurological disorder). The community is asking for:
    1. MDB be restructured to compensate fairly people with mercury poisoning and related illnesses;

    2. A specific tripartite protocol between ON/CAN/Grassy Narrows via the MDB to pay all medical and related expenses for hospitalization for those with chronic disabilities and illnesses; and,

3. A facility built on the reserve similar to the one in Japan (Minamata) where people with similar mercury-related medical conditions can be cared for together.

Recent Developments:

- On August 27, 2014 MAA met with a Japanese Research team in Kenora, Ontario, to hear the Japanese doctors' presentations and to observe their testing techniques on volunteer community members. MDB staff were also invited.
    - The MDB oversees testing and compensation for people with symptoms reasonably consistent with mercury poisoning, and will carefully review the information and research shared by the Japanese researchers.

- On August 20, 2014, the Minister of Aboriginal Affairs met with the Grassy Narrows First Nation community to discuss and better understand their concerns and to confirm the parties' commitment to work together.

- On August 1, 2014 the ANA Community sent a letter to the Minister of the Environment and Climate Change, requesting a meeting to discuss funding an environmental center.

- On July 31, 2014, members of the ANA and supporters marched on Queen's Park demanding the government address the impacts of mercury contamination in the Wabigoon River.

- Media reports indicate that a 2010 report, entitled "Literature Review: The Impact of Mercury Poisoning on Human Health," was commissioned by the MDB. The MDB contracted Drs. Chan and Mergler to review all literature worldwide to ensure up to date information on the impact of mercury on human health. The 2010 report by Drs. Chan and Mergler was made available to the Chiefs of ANA and Wabaseemoong and presented to a joint MDB/Search committee meeting.

Drinking Water Surveillance Program (DWSP)

- On June 10, 2014, at the request of the Band Council, MOECC staff visited the community to initiate monitoring for the community's drinking water under DWSP (a voluntary program that monitors trends and contaminant levels for a wide variety of parameters in drinking water).

- The ministry had concerns related to the treatment system; these were reported to Health Canada and documented in a letter to the Chief of the Band Council.

ANA - Ontario Working Group

- The Working Group was established in November 2012, to continue efforts to address concerns related to mercury, health and social issues in the ANA community that are within provincial jurisdiction. Members include the Chair of the MDB and representatives from ANA, MAA, MOECC, MOHLTC (Ministry of Northern Development and Mines (MNDM) and the Ministry of Training, Colleges and Universities (MTCU) are included when required).

- The Working Group has met between 4 to 6 times each year since its inception, most recently in June 2014. At the last meeting the Kenora/Dryden Public Health Unit was in attendance for discussions surrounding infant health care within the community.

- At the end of the June 2014 meeting, ANA members indicated they would only continue with Working Group meetings if a federal representative was present. MAA is drafting a Memorandum of Understanding with ANA to continue this working group.

- Through the working group, MOECC is providing leadership and support for the community on environmental issues/processes:
    - Working to set up a fish sampling project to collect and analyze fish form lakes where there is limited/outdated information to identify where the community can safely fish. Recovery of the fish from historical mercury contamination will also be monitored through this program. The high school has expressed interest in taking on this project and incorporating it into their curriculum;
    - In partnership with the MAA and MNRF, identifying river/lake systems where the community could re-establish its commercial fishery;
    - Participating in the ministry's DWSP through a special project to address the community's concerns about mercury in their drinking water; and,
    - Funded by MAA, initiated a study by Dr. Patricia Sellers (a researcher selected by the community) to conduct a literature review and gap analysis of existing knowledge on the current environmental condition of the English Wabigoon River system.

University of Ottawa-Health Canada Study on Food Nations Food Nutrition

- Dr. Chan, from the University of Ottawa, completed a study on First Nations food nutrition throughout Ontario; the study was funded by Health Canada and released to the community in June 2014. Although the ministry provided sport fish data to support the study, it was not provided with a copy of the report by either the researcher or community.

Meetings with ANA

- On July 31, 2012, then Minister of Aboriginal Affairs, Kathleen Wynne, accompanied by representatives from the MAA, the MOECC, and MOHLTC, visited the ANA to discuss concerns about mercury contamination in the community. The ANA raised five key issues: concerns with the MDB; community health issues; education; economic development; and environmental concerns.

- During the meeting, and in a CBC radio interview on August 3, 2012, the Minister of Aboriginal Affairs committed to:
  - re-engage the federal government about the community's concerns;
  - revitalize Ontario's Inter-ministerial Committee on Grassy Narrows (an internal advisory committee to the provincial government) to formalize next steps;
  - address specific issues raised by the community; and,
  - re-engage with the Chair of the MDB about the concerns raised about benefits.

Stakeholder Considerations

- In October 2013, the ANA issued a News Release rejecting the Whiskey Jack Forest Management Plan, due to concerns about the potential release of mercury resulting from logging activities.

- On August 28, 2013, protesters marched on Premier Wynne's home over mercury levels in the ANA community. The protest did not seem to be sanctioned by the ANA.

- In June 2012, the ANA held a series of events to raise awareness about the mercury poisoning (walk from north of Kenora to Toronto; Queens Park rally). The ANA has also called for a moratorium on industrial projects in their community.

- In August 2012, MNRF sent a letter to Kenora area businesses warning them not to purchase illegally caught walleye, pike, sauger and sturgeon from the English and Winnipeg River systems.

- In a May 30, 2012 a fish fry invitation was sent to the Premier and various MPPs, including the Minister of MAA. The ANA requested that the MOECC help their community establish a permanent ANA-run environmental monitoring station to inform and protect their people from damage from pollution and logging.

Appendix 1: Mercury pollution in the English-Wabigoon River system

GENERAL INFORMATION	
PREPARED BY: Dr. Rachael Fletcher Dr. Satyendra Bhavsar, EMRB	**TEL.:** 416-327-2935 416-327-5863
BRANCH APPROVAL: Ian Smith, Director, EMRB	**TEL.:** 416-235-6160
DIVISION APPROVAL: Anne Neary, ADM, ESSD	**TEL.:** 416-314-6310
DIVISION APPROVAL DATE:	10/September/2014
OTHER CONTACTS: Trina Rawn, NR, Operations Division	**TEL.:** 807-468-2734

Appendix 1: Mercury pollution in the English-Wabigoon River system

- From 1963 to 1970, approximately 10 metric tonnes of mercury from a chlor-alkali plant in Dryden, Ontario were released into the Wabigoon River. In 1970, this release was reduced by 99%, and by 1975 the chlor-alkali plant had converted to a process that did not use mercury.

- In 1970, commercial fishing was banned in the river system due to contamination of the fish stock; the pollution has impacted both the economies and health of the ANA and Wabaseemoong Independent Nations. As a precautionary measure, the ministry tests the pulp and paper mill effluent at Dryden annually for mercury. To date, it has not been detectable at 20 parts per trillion.

- The ministry is not aware of any current point sources of mercury into the natural environment in the English-Wabigoon River system.

- While various remediation techniques, such as dredging to remove the most contaminated sediment, have been suggested, there is no evidence that significant efforts at remediation were conducted. This is likely because they were not feasible.

- Currently, there are 12 locations on the Wabigoon River system under consideration for waterpower development. If lands are flooded during these projects, some increases in fish mercury concentrations may be expected for a number of years.

- There is no provincial program through which the mercury levels in land animals in Ontario are tested, nor has the province been provided with any such scientific data from a third party.

- MOECC and MNRF are discussing a potential study looking at the effects of logging and clear cutting on mercury levels in fish. ANA has expressed concerns that inappropriate logging on crown land impacts traditional practices. There is a general body of knowledge illustrating that logging practices promote mercury release to rivers; however, any impacts to the English-Wabigoon River system is unclear and could not be evaluated without analysis.

Subject: ADVICE NEEDED: #2878 - Grassy Narrows First Nation - due 11am Tuesday, Oct 16

Hi Satyendra and Rachael,

The Grassy Narrows First Nation requests a meeting with the Minister to discuss their opposition to the Contingency Plan for the Whiskey Jack Forest 2012-2014. The request has gone to OD, but we've been asked to provide a few bullets for the attached Meeting Note about our past interactions re. Sport Fish.

Our bullets are **due 11am on Tuesday, October 16.**

Perhaps the bullets below (from the Info Note) would work?

- MOE (in collaboration with MNR) conducted an internal study for MAA in January 2011 to assess long-term mercury trends as a result of historical contamination in the Wabigoon/English River system. The study was completed and shared with MAA in March 2011.
- The study showed that overall, mercury concentrations in fish from four representative lakes in affected areas of the English and Wabigoon Rivers, and surrounding lakes have declined since elevated mercury concentrations in fish were discovered in the 1970s (approximate 80% decline in sport fish), but are still above the sport fish consumption guidelines and background levels especially in the lakes close to the historical mercury discharge point.
- The ministry also authored a journal paper based on the findings of the internal study. On July 11, 2012, the paper titled "Long-term changes in fish mercury levels in historically impacted English-Wabigoon River system (Canada)" was published in the Journal of Environmental Monitoring.
- The Minister of MAA led a meeting with the Grassy Narrows Chief and Council on July 31, 2012. MOE also attended and presented information from the ministry's published paper on mercury levels in the English-Wabigoon river system.
- The presentation focussed on declines in mercury levels walleye over the last 40 years and how concentrations, while still severely elevated, are within the range of other northern Ontario lakes. Results were also provided for similar size whitefish, whose mercury levels are much lower, making them safer to eat.

Good Afternoon,

Attached is the ADM approved updated Grassy Narrows IN.

Anne also had one follow-up comment, pertaining to the logging issue:

- Please ensure our folks are doing this in step with the Centre for Northern Forest Ecosystem Research (MNR) – Ed Iwachewski is the contact.

Thank you,

Kat

Subject: Unsolicited updated IN: Grassy Narrows

Afternoon all,

Please find attached unsolicited update Grassy Narrows IN.

Key updates are as follows:

- As a result of the discussion on the presentation, the following next steps are underway:

- A follow-up Grassy Narrows First Nation Inter-ministry Working Group teleconference was held on September 7, 2012 with the Chief and community. Another one will be scheduled later in September 2012 to discuss the next steps;
- MOE will contact Chief and Council after the next teleconference to discuss the possibility of working together to collect fish for continued monitoring on the recovery of the English-Wabigoon system from the historical mercury discharges, and to provide fish consumption advisories based on the latest measurements;
- MOE and MNR to discuss a potential study looking at the effects of logging and clear cutting on mercury levels in fish
    - Grassy Narrows First Nation has expressed concerns that inappropriate logging on crown land impacts traditional practices. There is a general body of knowledge illustrating that logging practices promote mercury release to rivers; however, any impacts to the English-Wabigoon system is unclear and could not be evaluated without further analysis.
- MOE will review the sediment study Grassy Narrows First Nation had commissioned; and,
- A multi-agency group meeting with Grassy Narrows First Nation fall 2012 (TBD).

INFORMATION NOTE: Grassy Narrows First Nation Mercury Contamination
DATE: September 18, 2012

ISSUE

The Grassy Narrows First Nation has expressed concerns with the mercury levels from historical contamination as the fish from the Wabigoon River system are an important source of food for their community.

KEY MESSAGES

- **The Ministry of the Environment is committed to protecting Ontario's natural environment, our watersheds and our resources now and for future generations.**
- **The unfortunate mercury contamination that occurred in the Wabigoon river system in the 1960s and early 1970s predated the controls the Ministry of the Environment puts on industrial discharges today.**
- **We now have tough laws, standards and conditions in place to protect our environment from sources of contamination, including mercury.**
- **The Ministry of Aboriginal Affairs (MAA) has established a cross-ministry team made up of the Ministries of Health, Natural Resources and Environment to address issues such as health, mercury contamination and fish testing and economic development.**
- **Recently the Ministry of Environment presented our published findings to the First Nation on mercury contaminant levels in fish from the English Wabigoon river system and how they have changed over time. Minister Wynne also attended the meeting.**

IF ASKED ABOUT CLEAN UP

Has there been any clean up to date? Why not?

Extensive studies by the federal and provincial governments were conducted in the 1980s in the Wabigoon River to determine the location and the extent of contamination. It was determined that a clean up was not advisable due to the possible remobilization of mercury.

Natural sedimentation within the system over the past 30+ years has likely created a cap which is a viable remediation option for mercury contamination.

BACKGROUND

- During the 1960s and 1970s, mercury pollution occurred in the Wabigoon/English River system in northwestern Ontario from the operation of the chlor-alkali plant in Dryden.
- The Grassy Narrows First Nation relies on fish from the river system for food and obtains its drinking water from lakes within the river system.
- Grassy Narrows First Nation has expressed concerns with the mercury levels from historical contamination since the fish from this system are an important source of food for their community.

Grassy Narrows Sport Fish Study

- MOE (in collaboration with MNR) conducted an internal study for MAA in January 2011 to assess long-term mercury trends as a result of historical contamination in the Wabigoon/English River system. The study was completed and shared with MAA in March 2011.
- The study showed that overall, mercury concentrations in fish from four representative lakes in affected areas of the English and Wabigoon Rivers, and surrounding lakes have declined since elevated mercury concentrations in fish were discovered in the 1970s (approximate 80% decline in sport fish), but are still above the sport fish consumption guidelines and background levels especially in the lakes close to the historical mercury discharge point.
- The ministry also authored a journal paper based on the findings of the internal study. On July 11, 2012, the paper titled "Long-term changes in fish mercury levels in historically impacted English-Wabigoon River system (Canada)" was published in the Journal of Environmental Monitoring.

Meetings with Grassy Narrows First Nation

- In June 2011, MAA met with the chief his staff to discuss the community's concerns.
- The Minister of MAA led a meeting with the Grassy Narrows youth on July 30, 2012 and Chief and Council on July 31, 2012. MOE also attended and presented information from the ministry's published paper on mercury levels in the English-Wabigoon river system.
- The presentation focussed on declines in mercury levels in walleye over the last 40 years and how concentrations, while still severely elevated, are within the range of other northern Ontario lakes. Results were also provided for similar size whitefish, whose mercury levels are much lower, making them safer to eat.
- As a result of the discussion on the presentation, the following next steps are underway:
    - A follow-up Grassy Narrows First Nation Inter-ministry Working Group teleconference was held on September 7, 2012 with the Chief and community. Another one will be scheduled later in September 2012 to discuss the next steps;
    - MOE will contact Chief and Council after the next teleconference to discuss the possibility of working together to collect fish for continued monitoring on the

recovery of the English-Wabigoon system from the historical mercury discharges, and to provide fish consumption advisories based on the latest measurements;

- MOE and MNR to discuss a potential study looking at the effects of logging and clear cutting on mercury levels in fish
  - Grassy Narrows First Nation has expressed concerns that inappropriate logging on crown land impacts traditional practices. There is a general body of knowledge illustrating that logging practices promote mercury release to rivers; however, any impacts to the English-Wabigoon system is unclear and could not be evaluated without further analysis.
- MOE will review the sediment study Grassy Narrows First Nation had commissioned; and,
- A multi-agency group meeting with Grassy Narrows First Nation fall 2012 (TBD).

Stakeholder Considerations

- In a May 30, 2012 letter and fish fry invitation to the minister, the Grassy Narrows First Nation requested that the ministry help their community establish a permanent Grassy Narrows-run environmental monitoring station to inform and protect their people from damage from pollution and logging.

- From June 4 to 8, 2012, the Grassy Narrows First Nation held a series of events to raise awareness about mercury poisoning in their area. The events included a walk from north of Kenora to Toronto, and a rally on June 8, 2012 at Queens Park.

- Grassy Narrows First Nation has also called for a moratorium on industrial projects.

- Under a 1985 Settlement Agreement, benefits continue to be paid to Grassy Narrows and Wabaseemoong First Nation members who demonstrate symptoms consistent with mercury poisoning. This is done through the Mercury Disability Board. The MAA continues to financially support the Mercury Disability Board in its role of administering the Mercury Disability Fund and making awards for eligible people.

- In August 2012, MNR sent a letter to local businesses in the Kenora area warning them not to purchase illegally caught walleye, pike, sauger and sturgeon from the English and Winnipeg River systems.

Appendix 1: Mercury pollution in the Wabigoon/English River system
Appendix 2: Results of the Sport Fish Report and Fish Consumption Advisories
Appendix 3: Dr. Masazumi Harada
Appendix 4: MOU to address communities' issues
Appendix 5: Xeneca Waterpower Projects FIT contracts

Appendix 1: Mercury pollution in the Wabigoon/English River system

- From 1963 to 1970, approximately 9-11 metric tonnes of mercury from a chlor-alkali plant in Dryden, Ontario were released into the Wabigoon River. In 1970, this release was reduced by 99%, and by 1975 the chlor-alkali plant had converted to a process that did not use mercury.

- In 1970, commercial fishing was banned in the river system due to contamination of the fish stock; the pollution has impacted both the economies and health of the Grassy Narrows and Wabaseemoong First Nations.

- As a precautionary measure, the ministry tests the pulp and paper mill effluent at Dryden on an annual basis for mercury. To date, it has not been detectable at 20 parts per trillion (ng/L).

- The ministry is not aware of any current point sources of mercury into the natural environment in the Wabigoon/English River system.

- While various remediation techniques, such as dredging to remove the most contaminated sediment, were suggested, there is no evidence that significant efforts at remediation were conducted likely because they were not feasible.

- Currently, there are 12 locations on the Wabigoon River system under consideration for waterpower development. If lands are flooded during these projects, some increases in fish mercury concentrations may be expected for a number of years.

- There is no provincial program through which the mercury levels in land animals in Ontario are tested, nor has the province been provided with any such scientific data from a third party.

- The study showed that overall, mercury concentrations in fish from four representative lakes in affected areas of the English and Wabigoon Rivers, and surrounding lakes have declined since elevated mercury concentrations in fish were discovered in the 1970s (approximate 80% decline in sport fish), but are still above the sport fish consumption guidelines and background levels especially in the lakes close to the historical mercury discharge point.

- The fish mercury levels in the Wabigoon and English Rivers continue to decrease; however, current fish mercury levels remain elevated. The rate of decrease is expected to be slow relative to the earlier, more rapid declines.

- Mercury concentrations in some fish in Tetu Lake, where the English River joins the Winnipeg River system, are similar to background concentrations.

- Based on fish mercury data collected by the MOE and MNR, restrictive fish consumption advisories are also in place for lakes surrounding Grassy Narrows community (namely Grassy Narrows Lake, Indian Lake, Garden Lake, Toothpick Lake, Delaney Lake, and Meandering Lake).

Sport fish Consumption Advisories

- Sport fish consumption advisories are provided through a biennial publication called the Guide to Eating Ontario Sport Fish (published since 1978).

- Ontario's sport fish consumption advisories are generally based on Health Canada's Tolerable Daily Intakes (the estimated quantity of a contaminant that can be ingested daily over a lifetime without posing a significant risk to health). Separate advisories are provided for the general population and the sensitive population (women of child-bearing age and children under 15).

- Sport fish consumption advice is based on a combination of fish size, species and location. The *Guide* lists the number of meals per month of the particular sizes and species of fish that can be safely consumed per month.

- There is currently one lodge on Clay Lake, which caters to anglers and hunters. Clay Lake also has a public access point. MNR indicated that they are not aware of lodges giving warnings regarding the consumption of fish from Clay Lake.

- The Guide advises that consumption of most sizes and species of fish from this lake is not recommended for sensitive populations (women of childbearing age and children under 15).

- The consumption advisories for fish become less stringent as you get closer to Grassy Narrows within the English/Wabigoon River system for the lakes within the Guide.

- It should also be noted that there are restrictive consumption advisories on almost every lake that is monitored across the province.

Appendix 3: Dr. Masazumi Harada

- In September 2002, Dr. Masazumi Harada, a Japanese researcher specializing in mercury poisoning, visited the Grassy Narrows First Nation at the request of the Chief. Dr. Harada found an increase in, and new cases of, mercury poisoning on the reserve.
- In August 2003, the ministry received a summary of Dr. Harada's report. The MOHLTC reviewed the summary; the ministry of the Environment did not participate in the review.
- Dr. Harada made a follow-up visit to Grassy Narrows in August 2004.

Dr. Harada's report: *Long-term study on the effects of mercury contamination on two indigenous communities in Canada (1975-2004).*

- Harada's research team first visited Grassy Narrows and Whitedog First Nation communities in 1975 and collected hair and blood samples for mercury analyses and assessed 89 residents for symptoms of Minamata Disease (neurological disorder). Some residents had mercury levels in hair above the "safety guideline of 50 ppm".
- In 1975 he concluded "mild Minamata Disease" was evident in residents based on hair and blood mercury levels plus assessment of neurological and sensory disturbances, but no "severe or typical " cases were observed.
- The Harada research team returned 27 years later in 2002 and 2004 and assessed 156 residents from the communities of Grassy Narrows and Whitedog FN (hair and blood analyses, physical and neurological testing), including 27 residents that were assessed in both 1975 and 2002/04.
- Even though mercury levels in hair and blood had fallen since 1975 Harada concluded that 79% of the residents assessed in 2002/04 had one or more physical or neurological symptoms characteristic of Minamata Disease, claiming "long-term low exposure in the past must have caused the symptoms".
- Harada's report acknowledges that the Ontario government issued warnings against taking fish for food in 1970. Since 1977 the ministry has been publishing the "*Guide to Eating Ontario Sport Fish*", broadening the scope of sport fish monitoring and reporting in Ontario.
- For the 27 residents examined in both 1975 and 2002/04, in all cases the disease symptoms had worsened. The report states that no new cases of Minamata Disease are expected considering the current low levels of mercury in the Indigenous residents from the Grassy Narrows and Whitedog First Nations.
- Harada also concluded it is possible to contract "chronic type" Minamata Disease even if hair levels are below the "safety guideline" (50 ppm earlier referenced). The research team also suggested the possibility of congenital Minamata Disease because of the presence of some disease symptoms in children born after the period of high environmental exposure.

Appendix 4: MOU to address communities' issues

- There have been two separate means for addressing the communities' issues - the 1978 Memorandum of Understanding (MOU) which focused on socio-economic issues, and the 1985 Settlement Agreement out of which the Mercury Disability Board was formed to compensate members of the two First Nations who demonstrate symptoms consistent with mercury poisoning. In Ontario, the ministry of Aboriginal Affairs is the lead on these activities.

- Under the 1978 MOU, the Grassy Narrows First Nation and Ontario pursued a further agreement on socio-economic issues. Despite considerable efforts, an agreement was not achieved.

- Ontario has met its obligations under the 1985 Settlement Agreement with the two First Nations relating to the discharge of mercury. The two First Nations received $2 million from Ontario, as well as additional funding from the federal government, into the Mercury Disability Fund, which was established as part of the Agreement signed by all parties.

- Ontario has a statutory obligation to maintain the Mercury Disability Fund above $100,000 as per the Ontario legislation Ontario English and Wabigoon River Systems Mercury Contamination Settlement Agreement Act, 1986, S.O. 1986, c.23, (the "Ontario Act").

Appendix 5: Xeneca Waterpower Projects Feed-in-Tariff (FIT) contracts with Ontario Power Authority

Xeneca Waterpower Projects has submitted three FIT applications to the Ontario Power Authority. Of these, two were rejected at the application stage, and only one application at Quibell is currently still active. The Quibell application is currently in the application queue and has not been processed.

NO LOGGING, NO MERCURY: Noise Demo at Kathleen Wynne's home!

There will be a protest on the 24th led by the Grassy Narrows band as per the banner above.

MAA is leading preparation of the materials for the PO responding to the five (5) demands being made – one demand relates to controlling logging upstream of their water intake, GN contending logging is releasing mercury that they are drinking. Another demand is for $$ to support an "environmental health monitoring program" on GN. MAA is leading an inter-ministerial team on GN issues (year 2 now) with MOHLTC and MOE as key members – not sure Frank if MNR is a member, think not – interesting in light of the concerns about logging.

INFORMATION NOTE: Grassy Narrows First Nation Mercury Contamination
DATE: July 28, 2014

ISSUE

The Asubpeeschoseewagong Netum Anishinabek (formerly Grassy Narrows First Nations), has expressed concerns with the mercury levels from historical contamination in the fish from the English-Wabigoon River system. An inter-ministerial working group with the ANA continues to discuss this and other issues facing the community.

KEY MESSAGES

- The Ministry of the Environment and Climate Change is committed to protecting Ontario's natural environment, our watersheds and our resources now and for future generations.
- The unfortunate mercury contamination that occurred in the English-Wabigoon River system in the 1960s and early 1970s predated the controls the Ministry of the Environment and Climate Change puts on industrial discharges today.
- We now have tough laws, standards and conditions in place to protect our environment from sources of contamination, including mercury.
- Testing has shown that mercury levels in sport fish in parts of the river system have declined as much as 87 percent since the 1970s, although consumption advisories remain in effect.
- The ministry tests the pulp and paper mill effluent at Dryden on an annual basis for mercury. The results show that mercury has not been detectable in the mill's effluent since at least 1989.
- The Ministry of Aboriginal Affairs established a cross-ministry team made up of the Ministries of Health and Long-Term Care, Natural Resources and Forestry and Environment and Climate Change to address issues such as health, mercury contamination and fish testing, and economic development.
- A working group was developed with Asubpeeschoseewagong Netum Anishinabek to discuss the community's issues. The group consists of members from the First Nation along with the ministries of Aboriginal Affairs, Environment and Climate Change, Northern Development and Mines, Health and Long-Term Care, and Training, Colleges and Universities.

- The province is currently working with the community to develop a monitoring program and will consider the Grassy Narrows First Nation's request for an environmental monitoring station as part of this review.

- The ministry is working with the community to enhance their participation in monitoring activities, such as the Drinking Water Surveillance Program and the Sport Fish Contaminant Monitoring Program.

IF ASKED ABOUT CLEAN UP

Has there been any clean up to date? Why not?

Studies by the federal and provincial governments were conducted in the 1980s in the Wabigoon River to determine the location and the extent of contamination. In general, a clean up was not advisable due to the possible remobilization of mercury.

Natural sedimentation within the system over the past 30+ years to provide for a cap was considered and is a viable remediation option for mercury contamination. Surveys suggest that mercury concentrations in the sediments have gone down and could be at levels comparable to other lakes in the area.

BACKGROUND

- During the 1960s and 1970s, mercury pollution occurred in the English-Wabigoon River system in northwestern Ontario from the operation of the chlor-alkali plant in Dryden (refer to Appendix 1).

- The Asubpeeschoseewagong Netum Anishinabek (ANA) relies on fish from the river system for food and obtains its drinking water from lakes within the river system and has expressed concerns with the mercury levels from historical contamination since the fish from this system are an important source of food for their community.

Recent Developments:

- ANA recently announced their intent march to Queens Park (arriving on July 29, 2014) to protest against health related mercury issues and forestry activities.

- A main concern of the community is that the government has never formally recognised/acknowledged that community members are suffering from symptoms similar to that of people with Minamata disease (neurological disorder). The community is asking for:
    1. Mercury Disability Board (MDB) be restructured to compensate fairly people with mercury poisoning and related illnesses;

2. A specific tripartite protocol between ON/CAN/Grassy Narrows via the MDB to pay all medical and related expenses for hospitalization for those with chronic disabilities and illnesses; and,

3. A facility built on the reserve similar to the one in Japan (Minamata) where people with similar mercury-related medical conditions can be cared for together.

- Former Chief Steven Forbister met with the Minister of Aboriginal Affairs on July 27, 2014, and while he still intends on protesting mercury compensation, he will not be undertaking a hunger strike.

- Media reports indicate that a 2010 report, entitled "Literature Review: The Impact of Mercury Poisoning on Human Health," was commissioned by the Mercury Disability Board. The Mercury Disability Board contracted Drs. Chan and Mergler to review all literature worldwide to ensure up to date information on the impact of mercury on human health. The 2010 report by Drs. Chan and Mergler was made available to the Chiefs of ANA and Wabaseemoong and presented to a joint Mercury Disability Board/Search committee meeting.

Drinking Water Surveillance Program (DWSP)

- On June 10, 2014, at the request of the Band Council, MOECC staff visited the community to initiate monitoring for the community's drinking water under DWSP (a voluntary program that monitors trends and contaminant levels for a wide variety of parameters in drinking water). The MOECC collected information about the treatment processes and determined if and where water samples could be collected. Ministry concerns related to the treatment system were reported to Health Canada.

- On July 24, 2014, at the request of First Nations' counsel, a written summary of MOECC observations and concerns was sent to the Chief of the Band Council which included: non-functioning chemical dosing equipment; no online turbidity or chlorine monitors; lack of operator training; and, elevated treated water turbidity. Recommendations were made to follow up with the First Nations' Environmental Health Officer to fix the treatment equipment and online monitors, to have proper operator training, and to consider other upgrades to the treatment process.

ANA - Ontario Working Group

- The ANA-Ontario Working Group met on June 10 and 11, 2014. Issues of discussion included Drinking Water Surveillance and Fishing, Prenatal Health Care, Health/Environmental Literature Reviews, and Health Survey. The Kenora/Dryden Public Health Unit was in attendance for discussions surrounding infant health care within the community.

- At the end of the 2 day meeting, ANA members announced that they did not want to continue with Working Group meetings until a federal representative was present. MAA and MOHLTC are working with Health Canada on this request.

University of Ottawa-Health Canada Study on Food Nations Food Nutrition

- Dr. Chan, from the University of Ottawa, completed a study on First Nations food nutrition throughout Ontario; the study was funded by Health Canada and released to the community in June 2014. Although the ministry provided sportfish data to support the study, it was not provided with a copy of the report by either the researcher or community.

- The study is based on sampling conducted in 2011 on a random sample of 100 people from 100 different households in the community. Each person participated in a dietary survey and health questionnaire, and provided researchers with a sample of 30 types of traditional food they believed to be contaminated (including fish) for contaminant analysis. They were also asked to provide hair samples for contaminant analysis.

Grassy Narrows Sport Fish Study

- In January 2011, the ministry (in collaboration with the Ministry of Natural Resources [MNR]) conducted an internal study for MAA to assess mercury contaminants in fish as a result of historical contamination in the English-Wabigoon River system.

- Findings were published in the Journal of Environmental Monitoring (July 2012, (refer to Appendix 2), and showed that overall, mercury concentrations in fish from four representative lakes in affected areas of the English and Wabigoon Rivers, as well as surrounding lakes have declined since elevated mercury concentrations in fish were discovered in the 1970s (approximate 80% decline in sport fish). However, levels are still above the sport fish consumption guidelines and background levels, especially in the lakes close to the historical mercury discharge point (refer to Appendix 3).

Meetings with ANA

- On July 31, 2012, then Minister of Aboriginal Affairs, Kathleen Wynne, accompanied by representatives from the MAA, the MOECC, and MOHLTC, visited the ANA to discuss concerns about mercury contamination in the community. The ANA raised five key issues: concerns with the Mercury Disability Board (MDB); community health issues; education; economic development; and environmental concerns.

- During the meeting, and in a CBC radio interview on August 3, 2012, the Minister of Aboriginal Affairs committed to:
  - re-engage the federal government about the community's concerns;
  - revitalize Ontario's Inter-ministerial Committee on Grassy Narrows (an internal advisory committee to the provincial government) to formalize next steps;
  - address specific issues raised by the community; and,
  - re-engage with the Chair of the MDB about the concerns raised about benefits.

- Committee teleconferences were held in the fall of 2012 to discuss the next steps and review short and long-term strategies developed by MAA, and to plan for a follow-up meeting with the ANA.
  - Short-term Objectives:
    - Review list of key issues raised by the community;
    - Develop an approach for reporting back to the community;
    - Set out a collaborative engagement process between ANA and the province;
    - Initiate review of concerns related to MDB procedures and processes;
    - Involve Health Canada on community-based health education initiatives and identifying any gaps between provincial and federal programs.

  - Long-term Strategy:
    - Develop a proactive approach to re-establishing a meaningful relationship with ANA and to maintaining momentum from the July 31, 2012 meeting;
    - Work across Ontario ministries to develop responses and action items related to the key issues;
    - Consider the short and long-term role of the MDB; and,
    - Revisit mediation agreement issue.

ANA - Ontario Working Group

- Established in November 2012, the Working Group's function is to formalize the relationship between Ontario and ANA, and to continue efforts to address concerns related to mercury, health and social issues in the ANA community that are within provincial jurisdiction. Members include the Chair of the MDB and representatives from ANA, MAA, MOECC, MOHLTC, Ministry of Northern Development and Mines (MNDM), and the Ministry of Training, Colleges and Universities (MTCU).

- On February 6, 2013, the first face to face meeting of the working group was held. Discussions centered around the possibility of working together to collect fish for continued monitoring, the ANA's participating in the ministry's Drinking Water Surveillance Program (DWSP), and, working collaboratively to assess past work done in the area, review gaps in knowledge and assess current environmental conditions.

- During an April 25, 2013 teleconference, the ANA expressed interest learning more about DWSP, possible external funding opportunities for fish collections, and information on discharges from the Ear Falls station and the Dryden mill. They also asked the ministry to review a sediment study commissioned by the community.

- During the June 25, 2013, in person meeting, the ministry presented an overview of DWSP and discussed information on discharges from the Ear Falls station and the Dryden mill.

- On October 1, 2013, the Ontario-ANA Working Group met to identify key research questions on environmental concerns related to mercury, review maps of the area, and discussed how to conduct sampling.

- In mid-January 2014, the Working Group met to discuss health issues and the Mercury Disability Board, environmental issues and the river system, and planning site visits to areas of concern in May 2014.

Stakeholder Considerations

- On October 31, 2013, the ANA issued a News Release in relation to the Whiskey Jack Forest Management Plan (which they have rejected), and included an October 24, 2013 letter to the Premier.

- In a May 30, 2012 a fish fry invitation was sent to the Premier and various MPPs, including the Minister of MAA. The ANA requested that the MOE help their community establish a permanent ANA-run environmental monitoring station to inform and protect their people from damage from pollution and logging.

- From June 4 to 8, 2012, the ANA held a series of events to raise awareness about the mercury poisoning (walk from north of Kenora to Toronto; Queens Park rally). The ANA has also called for a moratorium on industrial projects in their community.

- Under a 1985 Settlement Agreement, benefits continue to be paid to ANA and Wabaseemoong Independent Nations members who demonstrate symptoms consistent with mercury poisoning (through MDB). The MAA continues to financially support the MDB in administering the Mercury Disability Fund and making awards for eligible people.

- In August 2012, MNR sent a letter to Kenora area businesses warning them not to purchase illegally caught walleye, pike, sauger and sturgeon from the English and Winnipeg River systems.

- On August 28, 2013, protesters marched on Premier Wynne's home over mercury levels in the ANA community. The protest did not seem to be sanctioned by the ANA.

Appendix 3: Fish Consumption Advisories
Appendix 4: Dr. Masazumi Harada
Appendix 5: MOU to address communities' issues
Appendix 6: Xeneca Waterpower Projects FIT contracts

Appendix 1: Mercury pollution in the English-Wabigoon River system

- From 1963 to 1970, approximately 10 metric tonnes of mercury from a chlor-alkali plant in Dryden, Ontario were released into the Wabigoon River. In 1970, this release was reduced by 99%, and by 1975 the chlor-alkali plant had converted to a process that did not use mercury.

- In 1970, commercial fishing was banned in the river system due to contamination of the fish stock; the pollution has impacted both the economies and health of the ANA and Wabaseemoong Independent Nations. As a precautionary measure, the ministry tests the pulp and paper mill effluent at Dryden annually for mercury. To date, it has not been detectable at 20 parts per trillion.

- The ministry is not aware of any current point sources of mercury into the natural environment in the English-Wabigoon River system.

- While various remediation techniques, such as dredging to remove the most contaminated sediment, have been suggested, there is no evidence that significant efforts at remediation were conducted. This is likely because they were not feasible.

- Currently, there are 12 locations on the Wabigoon River system under consideration for waterpower development. If lands are flooded during these projects, some increases in fish mercury concentrations may be expected for a number of years.

- There is no provincial program through which the mercury levels in land animals in Ontario are tested, nor has the province been provided with any such scientific data from a third party.

- At the request of ANA, MOECC reviewed the wild animal food contaminant study the community had had commissioned and provide comments:
  - The ministry agrees with the findings, that conclude the wild food in the territories have very low levels of the chemical contaminants considered in the study.
  - The ministry supports the advice that the consumption of certain organs of wild animals should be limited or avoided.
  - The suggestion of limiting consumption of pickerel and northern pike flesh is reflected in the fish consumption advisories issued by the ministry.
  - The report recommends future contaminant screening needs to consider dioxins and furans measurements in flesh of predatory fish. The ministry has collected measurements of dioxins and furans in whitefish; the measurements were low and do not pose any major health concerns.

- MOECC and MNRF are discussing a potential study looking at the effects of logging and clear cutting on mercury levels in fish. ANA has expressed concerns that inappropriate logging on crown land impacts traditional practices. There is a general body of knowledge illustrating that logging practices promote mercury release to

rivers; however, any impacts to the English-Wabigoon River system is unclear and could not be evaluated without analysis.

Appendix 2 – Results of the Sport Fish Report and Journal of Environmental Monitoring Article

- The study showed that overall, mercury concentrations in fish from four representative lakes in affected areas of the English and Wabigoon Rivers, and surrounding lakes have declined since elevated mercury concentrations in fish were discovered in the 1970s (approximate 80% decline in sport fish), but are still above the sport fish consumption guidelines and background levels especially in the lakes close to the historical mercury discharge point.

- The fish mercury levels in the Wabigoon and English Rivers continue to decrease; however, current fish mercury levels remain elevated. The rate of decrease is expected to be slow relative to the earlier, more rapid declines.

- Mercury concentrations in some fish in Tetu Lake, where the English River joins the Winnipeg River system, are similar to background concentrations.

- Based on fish mercury data collected by the MOECC and MNRF, restrictive fish consumption advisories are also in place for lakes surrounding ANA community (namely Grassy Narrows Lake, Indian Lake, Garden Lake, Toothpick Lake, Delaney Lake, and Meandering Lake).

Appendix 3 - Sport Fish Consumption Advisories

- Sport fish consumption advisories are provided through a biennial publication called the Guide to Eating Ontario Sport Fish (published since 1978).
- Ontario's sport fish consumption advisories are generally based on Health Canada's Tolerable Daily Intakes (the estimated quantity of a contaminant that can be ingested daily over a lifetime without posing a significant risk to health). Separate advisories are provided for the general population and the sensitive population (women of child-bearing age and children under 15).
- Sport fish consumption advice is based on a combination of fish size, species and location. The Guide lists the number of meals per month of the particular sizes and species of fish that can be safely consumed per month.
- There is currently one lodge on Clay Lake, which caters to anglers and hunters. Clay Lake also has a public access point. MNR indicated that they are not aware of lodges giving warnings regarding the consumption of fish from Clay Lake.
- The Guide advises that consumption of most sizes and species of fish from this lake is not recommended for sensitive populations (women of childbearing age and children under 15).
- The fish consumption advisories in the Guide, become less stringent the closer the fish are to Grassy Narrows within the English-Wabigoon River system for the lakes.
- It should also be noted that there are restrictive consumption advisories on almost every lake that is monitored across the province.

Appendix 4: Dr. Masazumi Harada

- In September 2002, Dr. Masazumi Harada, a Japanese researcher specializing in mercury poisoning, visited the Grassy Narrows First Nation at the request of the Chief. Dr. Harada found an increase in, and new cases of, mercury poisoning on the reserve.

- In August 2003, the ministry received a summary of Dr. Harada's report. The MOHLTC reviewed the summary; the MOE did not participate in the review.

- Dr. Harada made a follow-up visit to Grassy Narrows in August 2004.

Dr. Harada's report: *Long-term study on the effects of mercury contamination on two indigenous communities in Canada (1975-2004).*

- Harada's research team first visited ANA and Whitedog First Nations (a part of the Wabaseemoong Independent Nations) communities in 1975 and collected hair and blood samples for mercury analyses and assessed 89 residents for symptoms of Minamata Disease (neurological disorder). Some residents had mercury levels in hair above the "safety guideline of 50 ppm".

- In 1975 he concluded "mild Minamata Disease" was evident in residents based on hair and blood mercury levels plus assessment of neurological and sensory disturbances, but no "severe or typical" cases were observed.

- The Harada research team returned 27 years later in 2002 and 2004 and assessed 156 residents from the communities of Grassy Narrows and Whitedog First Nations (hair and blood analyses, physical and neurological testing), including 27 residents that were assessed in both 1975 and 2002/04.

- Even though mercury levels in hair and blood had fallen since 1975 Harada concluded that 79% of the residents assessed in 2002/04 had one or more physical or neurological symptoms characteristic of Minamata Disease, claiming "long-term low exposure in the past must have caused the symptoms".

- Harada's report acknowledges that the Ontario government issued warnings against taking fish for food in 1970. Since 1978, the ministry has been publishing the "Guide to Eating Ontario Sport Fish", broadening the scope of sport fish monitoring and reporting in Ontario.

- For the 27 residents examined in both 1975 and 2002/04, in all cases the disease symptoms had worsened. The report states that no new cases of Minamata Disease are expected considering the current low levels of mercury in the Indigenous residents from the ANA and Whitedog First Nations.

- Harada also concluded it is possible to contract "chronic type" Minamata Disease even if hair levels are below the "safety guideline" (50 ppm). The research team also suggested the possibility of congenital Minamata Disease because of the presence of some disease symptoms in children born after the period of high environmental exposure.

Appendix 5: MOU to address communities' issues

- There have been two separate means for addressing the communities' issues:
  - In 1978, representatives of the Government of Canada, the Province of Ontario and the two communities signed a Memorandum of Understanding (MOU), which focused on socio-economic issues
  - 1985 Settlement Agreement out of which the Mercury Disability Board was formed to compensate members of the two First Nations who demonstrated symptoms consistent with mercury poisoning.

  In Ontario, the Ministry of Aboriginal Affairs is the lead on these activities.

- Under the 1978 MOU, the ANA and Ontario pursued a further agreement on socio-economic issues. Despite considerable efforts, an agreement was not achieved.

- Ontario has met its obligations under the 1985 Settlement Agreement with the two First Nations relating to the discharge of mercury. The two First Nations received $2 million from Ontario, as well as additional funding from the federal government, into the Mercury Disability Fund, which was established as part of the Agreement signed by all parties.

- Ontario has a statutory obligation to maintain the Mercury Disability Fund above $100,000 as per the Ontario legislation Ontario English and Wabigoon River Systems Mercury Contamination Settlement Agreement Act, 1986, S.O. 1986, c.23, (the "Ontario Act").

Appendix 6: Xeneca Waterpower Projects Feed-in-Tariff (FIT) contracts with Ontario Power Authority

Xeneca Waterpower Projects has submitted three FIT applications to the Ontario Power Authority. Of these, two were rejected at the application stage, and only one application at Quibell is currently still active. The Quibell application is currently in the application queue and has not been processed.

Subject: RE: Hg declines in walleye from Clay Lake

Although overall logic you presented seems a possibility, unfortunately it is a little more complicated -- which prevents us from making a confident statement. For example, it's not just possible increased mercury loading due to logging but also other factors such as possible increased loading of organic material may affect how and how much of increased/decreased mercury in the system gets bioaccumulated in fish. Even if overall mercury loading and water (and sediment) "total" mercury concentrations decline, you may see increased fish mercury levels due to increased methylation under changed conditions (e.g., water chemistry). It is as clear as mother's milk (this is a phrase a long time sport fish monitoring staff, Andre -- now retired, used to say)!!!

Subject: RE: Hg declines in walleye from Clay Lake

So the Hg loading from soil erosion that accompanies logging (to clay lake) introduces a signal on-top of the signal from the Hg levels than the contaminated sediments? So during logging there might be a "top-up" of Hg – but once the logging ceases to load sediments to the water column those sediments will be cleaner that the historically contaminated sediments so overall there should be reduced hg cycling into the fish, because the sediments are cleaner near the top, yes?

Where did the information come from on hg releases by logging? Ela?

I imagine its not the logging but the erosion of soils?

I other words is the hg released from the slash or from the soils?

Sent: June-06-12 2:59 PM
To: Bhavsar, Satyendra (ENE); Fletcher, Rachael (ENE)
Cc: Coordinator, EMRB (ENE)
Subject: RE: Hg declines in walleye from Clay Lake

So logging introduces Hg? Could be?

It also introduces sediments – if they are cleaner than clay lake aren't we actually enhancing recovery of the system if we have logging?

Which trend overpowers the other – is logging more important to Hg trends than sedimentation?

Cc: Coordinator, EMRB (ENE)
Subject: RE: Hg declines in walleye from Clay Lake

To my knowledge: One of the factors that might have slowed down the mercury declines in the last two decades could be logging activities in the area that began around the 1980s. Logging in the area has been mostly suspended since Abitibi Bowater surrendered their license in June 2008 under intense pressure from grassroots blockades, boycotts, and

legal action. In 2011, ON Court of Appeal ordered no logging without consent on Grassy Narrows Territory north of the English River, and Government of Ontario has agreed to it. However, the order may be appealed to the Supreme Court of Canada. So not sure what is going to happen in future.

In light of this new development (cessation of logging), we may see resumption of faster downward trend for mercury in fish (Note: I am not sure how imp logging activity is for fish mercury in the English-Wabigoon River). If we are going to track such changes, 10 year sampling frequency will not be powerful enough to detect them.

Ian, I'm not sure we are comfortable providing a strong statement as to when Hg levels will ever reach 0.5ug/g. Over the last 30 years levels have fluctuated within a very narrow range. The apparent downward trend is not statistically significant. We are seeing similar trends, and even apparent upward trends in the great Lakes (eg lake Erie) areas of the states and globally. There is debate in the scientific community as to whether Hg is actually increasing or not. It is just too soon to tell.

Alves, Tanya (MOECC)

From: Fletcher, Rachael (ENE)
Sent: January 10, 2014 6:32 PM
To: Schaus, Susan (MAA)
Cc: Walker, Elizabeth S. (MOHLTC)
Subject: Suggested wording

At the meeting, the community expressed their concerns over logging in the Grassy Narrows area. the community is already sensitive to the effects of Hg. This should be recognized when logging rights are being considered in this area, and it should be advised that a precautionary approach be considered. The community have peer reviewed studies showing that logging activities can result in the release of Hg into the natural environment. At the meeting concern was raised that all the work the inter agency working group has been doing to address the community's concerns could be negated if logging is allowed to continue in the area.

s.13

It should also be noted that the community expressed that they are considering a protest sometime around march to raise awareness of the logging issue as well as the Hg disability issue.

MOECC RESPONSE:

The ministry is confident that the Whiskey Jack forest management plan has been developed with monitoring and mitigation measures that will ensure any mercury migration is limited.

As a precaution, we have imposed conditions on the project to reduce any mercury movement. Conditions include, monitoring soil disturbances, and reporting any changes to research methodology. Additionally, measures to minimize soil disturbance such as harvesting only in the winter on shallow soil sites and reinforcing slopes and banks will be carried out.

It is worth pointing out that testing has shown that mercury levels in sport fish in parts of the river system have declined as much as 87 percent since the 1970s, although consumption advisories remain in effect. The ministry tests the pulp and paper mill effluent at Dryden on an annual basis for mercury. The results show that mercury has not been detectable in the mill's effluent since at least 1989.

In terms of timing, the decision was made on Dec 22nd and letters notifying the requesters of the decision were mailed that day.

RE: MNR RESPONSE TO MOE REQUEST FOR INFORMATION FOR THE 2012 TO 2022 FOREST MANAGEMENT PLAN FOR THE WHISKEY JACK FOREST

Dear Agatha:

The Ministry of Natural Resources (MNR) has received your request to provide information in relation to issues identified in the Individual Environmental Assessment (IEA) request on the 2012-2022 Forest Management Plan (FMP) for the Whiskey Jack Forest.

MNR has completed the response to the Ministry of the Environment (MOE) request and is pleased to provide it to you at this time. I have attached the response, containing the information requested.

If you have any questions regarding this response, please feel free to contact the MNR District Contact, Kurt Pochailo at (807) 468-2597 or kurt.pochailo@ontario.ca.

Sincerely,

Deb Weedon

MNR Response to 2012-2022 Whiskey Jack FMP IEA Request

Introduction

The Director, Environmental Approvals Branch (EAB), Ministry of the Environment (MOE), has requested MNR provide specific documentation for consideration in its review of a joint request for an Individual Environmental Assessment on the 2012-2022 Whiskey Jack Forest Management Plan (FMP). This joint request was submitted by former Chief Simon Fobister, previous Chief of Grassy Narrows First Nation (GNFN), on behalf of Grassy Narrows First Nation, and Amber Ellis, Earthroots Executive Director, on behalf of Earthroots.

Documentation requested by MOE includes:

1. A detailed description of the involvement of the IEA requesters in the planning process;
2. A detailed description, with supporting documentation, of how the issues raised in the IEA requests;
    a. Were addressed in the planning process;
    b. Will be addressed in the implementation of forest operations and/or through additional commitments; and
3. A summary of Aboriginal involvement in the preparation of the FMP.

Potential mercury contamination appears to be the focus of the IEA requester's issues with the FMP. As this issue was raised late in the FMP process by the requesters, there is very little documentation of the issue in the FMP process as is explained in the following responses to MOE's questions. As a result, MNR has included an additional component in this response from MNR's forest science experts that should help MOE understand how MNR has been and will continue to investigate mercury issues through science and whether MNR is providing current science perspectives in the guides used to support the development of FMPs.

Further, MNR has a long standing relationship with Grassy Narrows First Nation and has been in ongoing discussions /negotiations on many topics, including forest management topics, for many years. MNR has included a brief summary of those topics and discussions to illustrate to MOE that MNR is making every attempt to address the first nation's interests and concerns.

Response to MOE's Questions

The MNR's response is structured to follow the information requested and is linked to the stages of consultation associated with the preparation of a FMP. For each stage of consultation, the response provides a brief overview of the requester's involvement in the planning process (Tables 1 and 2), and how the issues raised in the IEA request were addressed in the planning process

1. **A detailed description of the involvement of the IEA requestors in the planning process.**

Public consultation for the 2012-2022 Whiskey Jack FMP (Phase I) was developed in accordance with the requirements outlined in the 2009 Forest Management Planning Manual (FMPM).

The MNR's response is structured to follow the information requested and is linked to the following five stages of consultation for the development of the FMP; recognizing the preparation of the 2012-2022 Whiskey Jack FMP was interrupted by the preparation of a two year Contingency Plan (CP). The 2012-2014 CP was initiated during the planning process mainly to provide additional time to work with GNFN. The CP encompassed the first two years of operations developed for the 2012-2022 FMP. The endorsed CP Proposal can be found in Appendix A.

The resulting consultation stages for the 2012-2022 Whiskey Jack FMP are outlined as follows and include the stages of consultation for the preparation of the CP:

- Phase I: Stage One – Invitation to Participate
- Phase I: Stage Two – Review of Proposed Long-Term Management Direction

- Contingency Plan – Information Centre: Review of Proposed Operations
- Contingency Plan – Inspection of MNR-approved Contingency Plan

- Phase I: Stage Three – Information Centre: Review of Proposed Operations
- Phase I: Stage Four – Information Centre: Review of Draft Forest Management Plan
- Phase I: Stage Five – Inspection of MNR-approved Forest Management Plan

Prior to the commencement of the formal public consultation process for the preparation of the 2012-202 Whiskey Jack FMP, the Kenora District Manager, in accordance with

Part A, Section 4.4 of the FMPM, invited GNFN to discuss the development of a consultation approach for forest management planning with the community (i.e., customized consultation approach). GNFN indicated verbally to the Kenora District Manager that they did not want to discuss the preparation of the 2012-2022 Whiskey Jack FMP.

GNFN and Earthroots representatives received written notices for all stages of the consultation process in the preparation of the 2012-2014 CP and the 2012-2022 FMP, as required by the FMPM. In addition, at each stage of consultation, direct written notices were provided to some members of GNFN (e.g., trappers), public notices were placed in local newspapers, and an Information Notice was placed on the Environmental Registry website. Tables 1 and 2 provide a brief overview of the requester's involvement in the planning process for the 2012-2014 CP and the 2012-2022 FMP. The correspondence identified in Tables 1 and 2 can be found in Appendix A.

Table 1: Timeline and Correspondence Summary of Grassy Narrows First Nation in the FMP Process.

Date (dd/mm/yy)	Stage of Consultation and Contact
Stage One: Invitation to Participate	
20-Apr-09	Letter to Chief (6 months prior to Invitation to Participate) notifying of 2012-2022 FMP planning starting in November 2009.
3-Feb-10	Notification letter sent regarding the commencement of forest management planning process on the Whiskey Jack Forest (WJF)
2-Feb-10	Media Notice 2012-2022 FMP - Kenora Daily Miner
3-Feb-10	Media Notice 2012-2022 FMP - Red Lake Northern Sun News
6-Feb-10	Media Notice 2012-2022 FMP - Lake of the Woods Enterprise
10-Feb-10	Media Notice 2012-2022 FMP - Dryden Observer
18-Feb-10	Media Notice 2012-2022 FMP - Wawatay News
Stage Two: Long Term Management Direction	
14-Dec-11	Notification letter to review and comment on LTMD for the 2012-2022 FMP for the WJF
14-Dec-11	Media Notice 2012-2022 FMP - Kenora Daily Miner
17-Dec-11	Media Notice 2012-2022 FMP - Lake of the Woods Enterprise
19-Dec-11	Requested maps of LTMD were picked up by consultant and GNFN band member.
21-Dec-11	Media Notice 2012-2022 FMP - Dryden Observer
22-Dec-11	Media Notice 2012-2022 FMP - Wawatay News
2012-2014 Contingency Plan Development	

31-May-12	Registered letter sent to the Chief to bring GNFN up to date on the preparation of the 2012-2022 Whiskey Jack FMP. Notification of planning for Contingency Plan.
31-May-12	Media Notice 2012-2014 CP – Draft Plan Review – Kenora Lake of the Woods Enterprise
31-May-12	Media Notice 2012-2014 CP – Draft Plan Review – Wawatay News
1-Jun-12	Media Notice 2012-2014 CP – Draft Plan Review – Daily Miner
6-Jun-12	Media Notice 2012-2014 CP – Draft Plan Review – Northern Sun News
6-Jun-12	Media Notice 2012-2014 CP – Draft Plan Review – Dryden Observer
13-Jun-12	GNFN letter about the 2012-2022 FMP, presented at the CP planning team meeting on June 14th.
18-Jun-12	2012-2014 CP – Information Centre - Kenora
19-Jun-12	2012-2014 CP – Information Centre – Sioux Narrows
20-Jun-12	2012-2014 CP – Information Centre – Red Lake
21-Jun-12	2012-2014 CP – Information Centre – Ear Falls
30-Jul-12	Emails between District Manager and GNFN representative regarding planning of Aug 3rd meeting with GNFN.
3-Aug-12	Meeting with GNFN to discuss Whiskey Jack CP – GNFN would not discuss CP and left meeting – notes attached.
30-Aug-12	Letter to GNFN thanking them for their letter of June 13/2012 submitted to the planning team. This letter was in response to the 2012-2014 Draft CP.
18-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Daily Miner
19-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Northern Sun News
19-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Dryden Observer
20-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Kenora Lake of the Woods Enterprise
20-Sep-12	Media Notice 2012-2014 CP – Notice of Approval – Wawatay News
25-Sep-12	Letter to Chief – Invitation to inspect Approved CP
Stage Three: Review of Proposed Operations	
31-Jan-13	Registered letter to GNFN providing notification of upcoming Public Information Centres – offer in letter to have an information centre held at the community. No response received.
28-Jan-13	Media Notice 2012-2022 FMP Stage 3 - Lake of the Woods Enterprise
29-Jan-13	Media Notice 2012-2022 FMP Stage 3 - Kenora Daily Miner
2-Feb-13	Media Notice 2012-2022 FMP Stage 3 - Dryden Observer
2-Feb-13	Media Notice 2012-2022 FMP Stage 3 - Red Lake Northern Sun News
14-Feb-13	Media notice 2012-2022 FMP Stage 3 - Wawatay News
26-Feb-13	Letter sent to GNFN Chief reminding them of the upcoming Information Centres.
4-Mar-13	Information Centre 2012-2022 FMP Stage 3 - Kenora

5-Mar-13	Information Centre 2012-2022 FMP Stage 3 - Sioux Narrows
6-Mar-13	Information Centre 2012-2022 FMP Stage 3 - Red Lake
7-Mar-13	Information Centre 2012-2022 FMP Stage 3 - Ear Falls
3-Apr-13	Letter sent to GNFN Chief with CD containing maps and information on Stage 3 – Proposed Operations. Letter extended offer to hold an Information Centre in the community.
Stage Four: Review of Draft Plan	
30-Jul-13	Letter sent to GNFN inviting them to the upcoming Information Centres and provided a copy of GNFN Report on the Protection of Identified Aboriginal Values for review and comment. No comments were received from GNFN.
1-Aug-13	Media Notice 2012-2022 FMP Stage 4 - Lake of the Woods Enterprise
1-Aug-13	Media notice 2012-2022 FMP Stage 4 - Wawatay News
2-Aug-13	Media Notice 2012-2022 FMP Stage 4 - Kenora Daily Miner
7-Aug-13	Media Notice 2012-2022 FMP Stage 4 - Red Lake Northern Sun News
7-Aug-13	Media Notice 2012-2022 FMP Stage 4 - Dryden Observer
3-Sep-13	Information Centre 2012-2022 FMP Stage 4 - Sioux Narrows
4-Sep-13	Information Centre 2012-2022 FMP Stage 4 - Red Lake
5-Sep-13	Information Centre 2012-2022 FMP Stage 4 - Ear Falls
6-Sep-13	Information Centre 2012-2022 FMP Stage 4 - Kenora
24-Oct-13	Premier received letter regarding Draft Plan from GNFN
28-Oct-13	Received comments from GNFN on Draft Plan - Sent to Regional Director
Stage 5: Inspection of MNR Approved Plan	
19-Dec-13	Media notice 2012-2022 FMP Stage 5 - Wawatay News
23-Dec-13	Notification of MNR-approved FMP and 30 day Plan Inspection period
23-Dec-13	Media Notice 2012-2022 FMP Stage 5 - Kenora Daily Miner
24-Dec-13	Media Notice 2012-2022 FMP Stage 5 - Dryden Observer
25-Dec-13	Media Notice 2012-2022 FMP Stage 5 - Red Lake Northern Sun News
27-Dec-13	Media Notice 2012-2022 FMP Stage 5 - Lake of the Woods Enterprise

Table 2: Timeline and Correspondence Summary of Earthroots in the FMP Process.

Date	Stage of Consultation and Contact
Stage One: Invitation to Participate	
No correspondence received	
Stage Two: Long Term Management Direction	
22-Mar-12	Email from Earthroots requesting GIS files and past harvest information for the Whiskey Jack Forest
05-Apr-12	MNR responded to March 22, 2012 email requesting information – provided a list of requested materials and inquired if this would fulfill the requestors needs

05-Apr-12	Earthroots requested additional planning information in subsequent email
10-Apr-12	MNR response to April 5, 2012 email from Earthroots and directed them to the information requested.
2012-2014 Contingency Plan Development	
21-Jun-12	Received email from Earthroots requesting a specific individual is added to the Whiskey Jack Forest mailing list as well as a map and digital information of the plan.
Stage Three: Review of Proposed Operations	
No correspondence received	
Stage Four: Review of Draft Plan	
31-Oct-13	Received Earthroots comments on the 2012-2022 Whiskey Jack Draft FMP
1-Nov-13	Received email from Earthroots requesting data for the Draft Plan and the LTMD
05-Nov-13	Received email posing question regarding the Planned Wood Utilization by Mill (FMP-15) table from the Draft FMP
05-Nov-13	Email sent to Earthroots responding to request for large amounts of information on the 2012 Draft FMP
06-Nov-13	MNR responded to Earthroots November 5, 2013 request for digital information on the 2012-2022 FMP
26-Nov-13	Email from Earthroots regarding public input received during draft plan review and other questions related to planning
23-Dec-13	Responded to Earthroots email of November 26, 2013 providing all of the requested information.

2. **A detailed description, with supporting documentation, of how the issues raised in the IEA request:**
    a. **were addressed in the planning process; and**
    b. **will be addressed in the implementation of forest operations and/or through additional commitments.**

MOE determined that the following issues raised in the IEA request would be reviewed:

Issue 1 Harvest – Application of the clear cut silvicultural system on the area affected by the IEA request will disturb the soil causing naturally occurring mercury to become in flux and travel through the water system collecting in catchment areas already stressed with mercury, further exaggerating the existing mercury contamination issue in local waterways which may potentially affect human and ecosystem health and adversely impact Aboriginal and Treaty rights.

Issue 2 Harvest – MNR doesn't have the science and information base to support the development of prescriptions to mitigate the effect of mercury on terrestrial or aquatic ecosystems.

Issue 3 Harvest – FMP contains no requirements for ongoing monitoring of mercury levels in the area affected by the IEA request to determine if in fact approved forest operations once implemented would (further) elevate mercury levels in catchment areas.

Issue 4 Access – The construction of forest access roads on area affected by the IEA request will disturb the soil causing naturally occurring mercury to become in flux and travel through the water system collecting in downstream areas already stressed with mercury, further exaggerating the existing mercury contamination issue.

Issue 5 Consultation – MNR did not respond to comments submitted by the requestors on the mercury issue during the preparation of the FMP and the requestors have raised concerns about the failure to discharge the duty to consult in the development of this forest management plan.

Issues 1 to 4 deal with content of the FMP versus issue 5 which deals with the forest management planning process requirements. Therefore, issues 1 to 4 will be dealt with together and issue 5 will be dealt with separately.

Issues 1 to 4

During stages 1 through 3 of the planning process, issues 1 through 4 were not raised by the requesters. During Stage 4, the impact of clearcutting on mercury levels in piscivorous fish in local lakes and rivers was brought forward as one of a number of issues Earthroots had with the FMP. There was no corresponding mention of this issue in the response MNR received on the Draft FMP from GNFN. MNR responded to the issue brought forward by Earthroots indicating that MNR complied with the legislative, regulatory and policy requirements, including the approved forest management guides, which mitigate potential adverse effects on the environment. Through the implementation of the FMP, including the application of Area of Concern prescriptions, silvicultural ground rules, and best management practices for road construction activities, MNR will be further mitigating potential adverse effects on the environment. MNR has made no further commitments in the FMP to address the issues raised by the requesters.

Issue 5

In regards to the claim that MNR did not discharge its duty to consult during the development of the forest management plan, MNR followed the public and Aboriginal

consultation requirements outlined in the Forest EA approval and the FMPM as outlined below.

Aboriginal consultation for the 20012-2014 Whiskey Jack CP and the 2012-2022 Whiskey Jack FMP (Phase I) was undertaken in accordance with the requirements outlined in the 2009 Forest Management Planning Manual (FMPM):

1. Prior to the commencement of the formal public consultation process for the preparation of the 2012-202 Whiskey Jack FMP, the Kenora District Manager, in accordance with Part A, Section 4.4 of the FMPM, invited GNFN to discuss the development of a consultation approach for forest management planning with the community (i.e., customized consultation approach). GNFN declined the opportunity to develop a customized consultation approach.
2. The Kenora District Manager offered GNFN an opportunity to have a community representative sit on the FMP planning team and Local Citizens Committee (LCC). GNFN did not take the opportunity to become a member of the planning team or the LCC.
3. At each stage in the development of the CP and FMP notification letters were sent to GNFN to invite participation in the FMP process.
4. During the preparation of the 2012-2014 CP and the 2012-2022 FMP:
    a. the Kenora District Manager sought the involvement of GNFN to review and update the existing Aboriginal Background Information Report (ABIR), including the Aboriginal values maps; and
    b. The planning team produced a Report on Protection of Identified Aboriginal Values during the planning of operations as per the requirements of Part A, Section 4.6 of the FMPM

MNR responded to all comments submitted to the planning team during the preparation of the 2012-2014 CP and the 2012-2022 FMP in accordance with the requirements of the FMPM (Part A, Section 3.3.2.3). MNR did not receive any correspondence from GNFN, throughout the planning process, that there was a concern with the impact of clearcutting on mercury levels in piscivorous fish in local lakes and rivers. MNR did receive correspondence from Earthroots during Stage 4 of the planning process (i.e., Draft Plan Review) that they were concerned with, amongst many other concerns, with the impact of clearcutting on mercury levels in piscivorous fish in local lakes and rivers (Appendix A). MNR responded to these concern identified by Earthroots, indicating that MNR applied the direction in the approved forest management guides to mitigate potential adverse effects of forest management activities on the environment. (Appendix A).

In regards to the claim that MNR did not discharge its duty to consult during the development of these forest management plans, MNR followed the public and Aboriginal consultation requirements outlined in the Forest EA approval and the FMPM. Further, MNR has made substantial efforts to consult with GNFN on the specifics of the development of the 2012-2022 Whiskey Jack FMP and previous FMP plans (e.g., 2009 CP, 2012 CP). These efforts have been substantially rejected by GNFN. The duty to consult requirement is mandated under the Constitution Act, 1982 and as directed by case law, principally decisions rendered by the Supreme Court of Canada. It is also taken from this case law that First Nations cannot thwart the Crown's efforts to consult, such as refusing to participate in real and sincere efforts to consult. In regards to GNFN's assertion that "MNR did not discharge its duty to consult", with respect, the Ministry of the Environment has not been mandated to make a determination as to whether the MNR has met the burden of the Government's duty to consult.

In conclusion, the 2012-2014 CP and the 2012-2022 FMP for the Whiskey Jack Forest were prepared in accordance with the requirements of the FMPM.

3. Provide the web link to where a summary of Aboriginal involvement in the preparation of the FMP can be found.

The 2012-2022 Whiskey Jack FMP can be found on the Electronic FMP site at the following link:

http://www.efmp.lrc.gov.on.ca/eFMP/home.do

The summary of Aboriginal involvement has been retained at the Kenora District MNR office and its location is identified in Appendix C of the Supplementary Documentation. A copy of the summary can be found in the attachments to this letter.

Summary

The above documentation requested by MOE shows how MNR followed the *Forest Management Planning Manual - 2009* (FMPM) and engaged GNFN and Earthroots throughout the planning process. GNFN chose to remain on the periphery of forest management planning for the Whiskey Jack Forest by not participating on the planning team and rejecting offers to hold information centres at the community or engaging in face-to-face discussions. GNFN provided comments through the submission of letters at various stages throughout the planning process, and MNR responded to the concerns identified. The letters received from GNFN focused primarily on their rejection of the practice of "clearcutting" and their perception of elevated harvest levels. The application of the clearcut silvicultural system, as explained in MNRs responses to

GNFN, is the appropriate silvicultural system for the boreal forest, and ecosystem dominated by forest disturbance (eg. wildfire) and the planned harvest levels are in support of balanced objectives.

The issue of methylmercury was raised by GNFN for the first and only time, prior to the IEA request, in an October 24th, 2013 letter to the Premier, coincident with the Stage 4 – Review of Draft Plan. Earthroots also identified methylmercury as a potential issue for the first time in a letter dated October 31st, 2013 during Stage 4 – Review of Draft Plan.

The planning process contemplated the issue of methylmercury through the application of the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* 2010 (SSG). The accompanying Background and Rationale document for the SSG clearly acknowledges the potential for forest management activities to mobilize mercury, it provides a comprehensive summary of available scientific literature on the topic, provides a clear rationale for guide direction and acknowledges the uncertainty associated with this direction. There are no claims that SSG direction and application of the SSG will mitigate or eliminate Hg mobilization.

The summary of Aboriginal involvement identifies how MNR followed the requirements identified within the FMPM pertaining to Aboriginal consultation.

In addition to the information requested by MOE, MNR has provided some additional information with regard to the additional efforts to work with GNFN on many aspects of forestry and forest management planning on the Whiskey Jack Forest.

MNR Science Review

As part of MNR's review of the IEA request submitted by Grassy Narrows First Nation and Earthroots, MNR sought input from MNR forest scientists. They reviewed the submission, and in particular the many scientific references throughout, to ensure they were valid and pertinent to the discussion. Subsequently, MNR's forest scientists prepared the following response to the IEA requester's submission.

Introduction:

The IEA requestors contend that the Whiskey Jack forest management plan "fails to adequately deal with the impacts of logging on mercury levels in boreal water and fish" and that the plan will "harm water quality, fish habitat, wildlife and the health of people who eat the fish". To support their concern the requestors present as evidence a number of research studies that have shown that forest disturbance (both forest management and fire) result in changes to mercury dynamics within watersheds which may increase the movement of terrestrial bound mercury into aquatic systems and may be associated with higher levels of mercury in aquatic organisms.

The requestors also argue that the forest management guidelines, provided in the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (the Stand and Site Guide or SSG), do not adequately address the issue of forest management impacts on mercury dynamics.

The IEA request is presented in 15 sections which address various related concerns. In the MNR science team's attempt to evaluate the scientific basis of the request and provide comments on current forest management policies and guidelines related to the issue, we have divided the sections into 4 general themes and we will address the scientific evidence and the interpretation of this evidence that is presented in themes A and B:

A) Concerns arising from research on mercury and forest management

1. Clearcutting Impacts Water Quality Through Mercury Contamination
2. Clearcutting Elevates Mercury Levels in Fish
3. Elevated Mercury Levels Impact Wildlife
11. Duration and Intensity of Impacts

B) Concerns associated with forest management policy (SSG)

7. Measures in the Logging Plan to Deal with the Mercury Problem
8. Stand and Site Guide Rationale on Mercury
9. Fundamental Problems with MNR Rationale
   - (i) Natural Disturbance Emulation Not Appropriate for Mercury Safety
   - (ii) Mitigation Science is Not Sufficiently Developed
   - (iii) Log Now, Test Later Approach.
12. Changes to Guidelines Are Likely to Make Mercury Problem Worse
   - (i) A. Logging to the Shoreline
   - (ii) Catchment Disturbance Thresholds Removed
13. Specific Deficiencies in MNR Mitigation Measures

C) Concerns arising from historical contamination

4. Fish in Grassy Narrows Have Critical Levels of Mercury
5. Mercury Impacts Human Health in Grassy Narrows

D) Concerns arising from the planning process (not directly linked to science/research)

6. Efforts to Raise the Mercury Issue
10. Delay and Hardship
14. Need for an Individual Environmental Assessment
15. Remedy Requested

A) Concerns arising from research on mercury and forest management

Mercury is a natural element that occurs in air, water, soil and biota in the boreal forest. Mercury, which exists in several inorganic, or elemental, forms (Hg) and as organic methylmercury (MeHg), alternates between forms and cycles among different components of the ecosystem as part of a complex biogeochemical process. Natural levels of mercury are spatially variable depending on geology, soil and forest characteristics; however, the global atmospheric pool of mercury has increased two to five fold over pre-industrial times (Linberg *et al.* 2007). There is clear evidence from a number of studies that forest management is one of a large number of factors that influence mercury dynamics within watersheds. In sections 1, 2, 3 and 11 the IEA requestors provide quotations from some of these studies to support their conclusions regarding the risk of mercury increases associated with forest management. The following is a review of these sections:

1. Clearcutting Impacts Water Quality Through Mercury Contamination

The requestors contend that forest management activities will result in an increase in Hg and MeHg in waterbodies in the area. As evidence to support this conclusion they present results from several studies conducted in Quebec, Sweden and Finland, much of which is summarized in a review paper by Bishop et al (2009).

MNR review:

- Increased mobilization of mercury within watersheds following forest disturbance has been documented in several studies done in Canada, Sweden and Finland.
- Disturbance impacts include increases in the concentration of Hg and MeHg in surface runoff (increased concentration) and increases in runoff, thereby increasing the movement of Hg even without concentration changes (transport or flux).
- Changes in Hg dynamics are highly variable among watersheds depending on a large number of factors, including watershed characteristics and the extent of disturbance. For example, Bishop et al (2009) show post-harvest Hg concentration response ranging from a 4 fold increase in a Finnish study to no increase found in a study done in Northwestern Ontario.
- Very little work is available which directly compares Hg mobilization between harvested and burned watersheds. Studies done in Quebec measured increases in dissolved organic carbon (DOC), to which Hg is bound in surface water runoff, following harvest under some conditions (large disturbance area within the watershed and a large watershed to lake area ratio) but not consistently (Carignan et al 2000).
- No research has been conducted to test the effectiveness of specific forest management planning or operational measures at mitigating increases in Hg

mobilization. Bishop et al (2009) provide some recommended practices which are similar to direction provided in the SSG (see discussion in theme B below).

Conclusion: There is strong evidence, based on a number of studies, that the rate of movement of Hg and MeHg from terrestrial to aquatic areas will increase following forest disturbance. There is not sufficient evidence to conclude that the magnitude of Hg response to forest management disturbance differs significantly from natural disturbance events in all cases; however, the mechanism of response is likely different. There is also no research available which tests the effectiveness of guidelines to mitigate changes in watershed Hg dynamics arising from forest disturbance.

2. Clearcutting Elevates Mercury Levels in Fish

The IEA requestors state that forest management activities in the Whiskey Jack forest will increase Hg inputs into aquatic systems which will harmfully alter fish habitat and result in an increase in MeHg levels in fish and other aquatic organisms. As evidence they present a number of quotes from Bishop et al (2009) as well as from Garcia and Carignan (2005). It should be noted that the Bishop et al (2009) paper is a review of previous research and all information presented on fish Hg levels come from a study by Garcia and Carignan (2000, 2005) so the evidence comes from a single study.

MNR review

- The study by Garcia and Carignan (2000,2005) which included 38 lakes (9 cut, 9 burned and 20 reference) is likely the most comprehensive study on the association between watershed disturbance and fish mercury levels.
- Fish in disturbed watersheds (cut and burned) had higher mercury levels than fish in undisturbed reference lakes
- Fish mercury levels were highly variable and were strongly positively correlated with fish size (fig 1) and fish trophic position (fig 4) (Garcia and Carignan 2005)
- Based on fig 4 (Garcia and Carignan 2005) more than 3 times more variability in fish mercury is associated with trophic position than with watershed disturbance and there is very little difference between fish mercury levels in cut and burned lakes when trophic position is controlled for.
- ‘The highest Hg concentrations were observed in fish from two partially burnt lakes’ (pg 690, Garcia and Carignan 2005). It appears that fire intensity (proportion of the watershed burned and the amount of organic layer burned) has a substantial impact on mercury dynamics in the watershed and the potential response of aquatic organisms.
- Through elevating DOC export from soils, an enhanced vector of Hg export to aquatic ecosystems occurs.

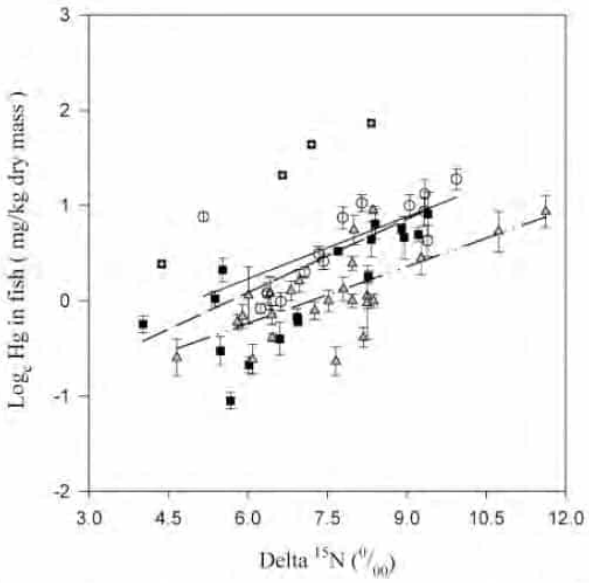

Fig. 4. Relationships between mercury (Hg) concentrations and fish $\delta^{15}N$ for reference lakes (triangles and dash-dot-dot line), and for lakes with cut (open circles and solid line) and burnt catchments (black and dotted squares for completely and partially burnt catchments, respectively, and dashed lines). Points represent fish of a standardized length from 62 populations. The $\delta^{15}N$ values are corrected for baseline variations. Error bars correspond to standard deviation.

From: Garcia and Carignan 2005

Conclusion: The comprehensive study of Quebec lakes provides evidence that fish in disturbed watersheds tend to have higher Hg concentrations than those in undisturbed watersheds. The study does not provide strong evidence that fish Hg concentrations consistently differ between burned and harvested watersheds. When trophic position is included in the analysis, fish Hg levels in harvested watersheds fall within the broader range of fish Hg levels in burned watersheds (fig 4, Garcia and Carignan 2005). This single study, despite being a very comprehensive, does not provide sufficient information to understand all the factors that influence fish Hg levels or how these factors may interact. Given the complexity of how disturbance impacts Hg dynamics and how aquatic systems may respond, it is unlikely that identical results would be seen in other regions of the boreal zone.

3. Elevated Mercury Levels Impact Wildlife

The IEA requestors express a concern that the mercury levels in a number of wildlife species, presumably those that consume fish, may increase if fish mercury levels increase. They provide evidence, primarily citing Environment Canada websites, which explains that mercury contamination can have negative impacts on the growth, development, behaviour and reproduction of wildlife species.

MNR review

- There is strong evidence that high body burdens of mercury may have toxic effects on certain wildlife species and lead to a number of health issues.
- Elemental mercury (Hg) in water and plants is not toxic to animals and is not stored in animal tissue; however, methylmercury (MeHg) is toxic and is stored and bioaccumulated in muscle and fat tissue. The main source of MeHg for terrestrial animals is the consumption of fish.
- We are unaware of any studies that directly examine the relationship between forest disturbance and wildlife Hg levels.

Conclusion: While it may be reasonable to assume that increases in fish Hg levels could lead to Hg increases in piscivorous wildlife species, the relationship between forest disturbance and fish Hg is not well understood (see section 2) and the further connection to wildlife is likely very complex and associated with a large number of interacting factors.

11. Duration and Intensity of Impacts

The requesters state on page 24 that “if further clearcutting is allowed without proven mitigation measures, and methyl mercury levels in local fish are elevated as a result, the impacts would likely be grave and long lasting.” They further contend that “the impacts of releasing mercury into the environment in Grassy Narrows through clearcut logging are likely to last at least a decade in fish, and at least one human lifespan beyond that in people”. They base their conclusions on data from studies conducted in (1) Ontario, Québec, Finland, and Sweden, much of which are summarized in studies by Bishop et al. (2009) and Garcia and Carignan (2005).

MNR review:

- The proponents state that “clearcutting has been found to increase MeHg bioaccumulation in boreal lakes by two to four fold, and sometimes as much as eight fold (Bishop et al., 2009)” (Page, 24). The further state that “As much as 37% of Hg in fish across a managed landscape would result from the increased Hg outputs associated with felling and thinning”. Bishop et al. (2009) actually calculated that forest harvesting may contribute 9 to 23% of MeHg fluxes from the soil following harvesting. They also made the point that many uncertainties existed in the calculations (e.g., small number of samples and a large range of impacts across studies).

- Few studies have been published regarding the effects of clearcut harvesting on fish MeHg concentrations. Those studies suggest that although MeHg concentrations in fish may increase following clearcut operations, it is generally limited to cases when soils are disturbed, and not to the harvesting of trees. This

was alluded to by Bishop et al. (2009), as well as reported in findings and discussions of other studies (Povari et al., 2003, Sørensen et al., 2009, Eklöf et al., 2012, 2013). Soil disturbance contributes to elevated fish concentrations in upland catchments via particulate matter (organic and mineral) transport from forest soils to streams and lakes. Whereas, soil disturbance of lowland (e.g., wetlands and riparian zones) catchments increase MeHg runoff to streams and lakes via enhanced dissolved organic carbon (DOC) transport. Therefore, no evidence exists contrary to the protection of soils from disturbance as described in the Stand and Site Guide as a mitigation measure minimizing forest harvesting operation effects on fish MeHg concentrations.

- The requesters further contend on pages 24 – 25 that "impacts of clearcutting on mercury have been found to persist for at least five years, with no known endpoint" and "the increased in Hg loading effect has also been observed to persist up to at least 5 years, and there are no examples so far of the logging effect having dissipated (Bishop et al., 2009)". In fact, Skyllberg et al. (2009) assessed stream MeHg concentration in Sweden by comparing 47 clearcut stands dominated by Norway spruce to 10 mature Norway spruce-dominated stands. They showed stream MeHg concentrations were elevated in stands 0 to 4 years after harvested, but no differences occurred in MeHg concentration in streams 4 to 10 years after harvested. Skyllberg et al. (2009) suggested these results were attributed to increased organic matter added by logging residue stimulating Hg methylating bacteria in the soil, and by 4 to 10 years, this effect dissipated.

- The Hg in fish higher in the food chain continued to increase several years after harvest (Garcia and Carignan 2000, 2005, as cited in Bishop et al., 2009 (Page 24).
  See response to section 2 for discussion of fish Hg response.

- The requesters contend on pages 25 – 26 that logging is likely to (1) further elevate mercury in fish in previously contaminated lakes due to increasing methylation rates of newly added mercury and stored mercury in lake sediments, (2) prolong the length of time for which fish in previously contaminated lakes remain unsafe to eat, (3) elevate mercury levels in fish in marginally safe lakes above safety limit, and (4) elevate mercury levels in fish in currently safe lakes above the safety limit.

  Skyllberg et al. (2009) reported that 17% of MeHg in streams came from methylation of stored mercury, while 73% arose from methylation of newly added mercury from logging debris and that TOC (total organic carbon in non-filtered water samples) and its structure did not differ between streams draining clearcut and mature forest catchments. Furthermore, Neff et al. (2012) conducted an intensive study of lake mercury levels in the English-Wabigoon River system. They examined long-term (1970 – 2010) monitoring data to assess temporal

trends in mercury in walleye, northern pike, and lake-whitefish in 4 lakes along a chain of lakes occurring from closest to furthest locations from a paper mill source (approximately 10 tonnes Hg input between 1962 and 1970); Clay, Ball, Separation, and Tetu Lakes, respectively. Neff et al. (2012) found that for all lakes and fish species, mercury declined by 35 to 94% through time, although walleye and northern pike mercury concentrations were above (Clay Lake) or near (Ball and Separation Lakes) the human consumption guideline of 0.5 µg g-1 of fish tissue. Additionally, the authors summarized mercury concentrations of walleye (45 cm length) and northern pike (50 cm length) based on 143 and 123 locations in northwestern Ontario. Neff et al., (2012) reported median values near the 0.5 µg g-1 guideline for walleye (25th – 75th percentiles = 0.38 and 0.75 µg g-1, respectively) and median of 0.38 (25th – 75th percentiles = 0.25 and 0.60 µg g-1, respectively) for northern pike.

Most rapid declines in fish mercury concentrations occurred between 1970 and 1985; however declines slowed from the late 1980s to 2010. Contributions to the slower declines are many and include (1) the lakes approaching baseline values prior to mercury contamination, (2) climate change enhancement of (a) area burned and severity of soil organic matter and mercury combustion or (b) extended drought followed by intense precipitation events, (3) catchment cover types and the wetland-to-lake ratio, and (4) connectivity of wetlands, streams, rivers, and lakes in a drainage basin.

- The proponents also suggest on pages 25 – 26 that “clearcutting leads to higher DOC compared to reference lakes and burned lakes (Garcia and Carignan, 2005), stimulating bacterial methylation, decreasing photo-oxidation of MeHg to Hg^{2+}, and possibly decreasing photo-reduction of Hg^{2+} to gaseous mercury. Those processes were suggested to elevate mercury levels in fish.

  Research has shown in the temperate and boreal regions of North America (Couture et al., 2012) and Europe (Laudon et al., 2013) that climate change is the primary cause of elevated DOC concentrations in lakes. Moreover, although studies (e.g., Haines et al., 1994; Sellers et al., 1996) suggest elevated DOC concentrations may inhibit photo-oxidation of MeHg and reduction of Hg^{2+} to gaseous mercury these results are far from universal. For example, although DOC is an important transport vector for Hg^{2+} and MeHg, this DOC is highly recalcitrant (e.g., low bacterial degradability). Whereas bacterial methylation is dependent upon the presence of easily degradable DOC concentrations (as well as electron acceptors such as sulphate); thus increasing DOC-Hg transport from soil to lakes does not necessarily translate into greater rates of mercury-methylation.

Conclusion: For forest harvesting to further exacerbate walleye and northern pike mercury concentrations in lakes situated in the English-Wabigoon River System, any mercury input to upstream catchments will need to traverse a myriad of interconnected

wetlands, streams, and lakes within the river system. However, we are aware of no published studies addressing potentially elevated long-range mercury transport in large drainage basins. In terms of MeHg (and assuming it is elevated in headwater catchments), some of it would be removed from the water column of lakes through (1) MeHg photo-oxidation to Hg^{2+} and its subsequent reduction to gaseous mercury and loss to the atmosphere or (2) settling of DOC- and particulate matter-bonded mercury from the water column to the sediments as water moves downstream. While much variation occurs in the photo-oxidation rates of MeHg to Hg^{2+} and its reduction to gaseous mercury, the current scientific evidence indicates that protecting soils from disturbance during harvesting operations as spelled out in the Stand and Site Guide will minimize total and methyl mercury loading from soils to streams and lakes in a catchment. Furthermore, it can be reasonably argued that any MeHg-containing water resulting from harvesting in headwater catchments will be diluted prior to reaching the English and Wabigoon Rivers and their connected lakes, thereby contributing little to mercury concentrations in the river system's lakes.

B) Concerns associated with forest management policy (SSG)

Direction in the SSG was based on a thorough review of existing literature, and discussions with and review by ecological researchers, practitioners, policy makers, stakeholders, and members of the public to ensure that direction would be effective in meeting ecological objectives, while also being feasible to implement and socially palatable. *'In all cases, the direction in the Stand and Site Guide represents a series of predictions or hypotheses. Those with a high degree of uncertainty have been identified as a high priority for testing through an effectiveness monitoring program (see Section 7). The results of this monitoring program, along with other sources of information, will be used during periodic reviews of the Stand and Site Guide to help determine when the guide needs to be revised'* (SSG section 1.3.5, pg 5). The SSG therefore represents a summary of the best available direction to meet MNR's objectives and legislative requirements for sustainable forest management and incorporates an adaptive management approach to evaluate and improve direction in areas of uncertainty.

Section 1.3 of the SSG summarizes the guide's approach to conserving forest biodiversity using guidance characterized as coarse and fine filters. This direction is based on the principles of the *Crown Forest Sustainability Act, 1994* (CFSA) which a key piece of legislation regulating forest management. Specifically the CFSA states:

> *The long term health and vigor of Crown forests should be provided for by using forest practices that, within the limits of silvicultural requirements, emulate natural disturbances and landscape patterns* [coarse filter] *while minimizing adverse effects on plant life, animal life, water, soil, air and social and economic values, including recreational values and heritage values* [fine filters] (CFSA s. 2(3)2).

The coarse filter approach to the emulation of natural disturbance and landscape patterns is intended to maintain the natural diversity of forest condition and ecological processes in order to conserve forest biodiversity and is a legal requirement under the CFSA. The coarse filter is not intended as a specific mitigation measure but rather an approach to maintain the state of all elements of the forest ecosystem within a natural range. Fine filter direction is included when there is evidence that additional mitigation measures will improve the protection of specific values.

During the development of the SSG, MNR did an extensive review of the body of scientific literature examining the relationship between forest disturbance and mercury dynamics. A summary of this review and the resulting decision on guide direction are provided in the SSG Background and Rationale document (pg 23-25) which is included as an appendix in the IEA request. The key points from the review were:

- The potential for forest management activities to result in mobilization of terrestrial mercury into aquatic systems is well documented and a serious concern.
- The nature and magnitude of changes in mercury dynamics within a watershed following disturbance are complex and related to a number of interacting factors including area disturbed, changes to hydrology, the amount and type of wetland in the area and soil disturbance.
- There is limited information on the potential for fish Hg levels to be influenced by harvest disturbance but the best available evidence shows that fish in lakes with disturbed watersheds had higher mercury levels than those in undisturbed watersheds and that the range of Hg levels in fish in harvested watersheds was within the range of those in burned watersheds (Garcia and Carignan 2000, 2005).
- There is a high degree of uncertainty regarding Hg response to forest management and the issue should be a high priority area for guide effectiveness monitoring.

Because there are no studies which identify or evaluate mitigation measures to minimize mercury mobilization following disturbance there are no mitigation measures specific to mercury in the SSG. The guide does provide direction to minimize site disturbance, sediment transport and hydrologic disruption (listed on pg 24 of the SSG Background and Rationale) all of which may be associated with increased mercury mobilization. In a review paper published following the release of the SSG, Bishop et al (2009) conclude that “An understanding of the processes controlling the output of Hg from catchments to surface waters, and subsequent bioaccumulation, is not sufficiently developed to confidently recommend ameliorative measures for forestry” (pg 378). They do offer some suggested practices, which include minimizing site disturbance and hydrological disruption and protecting wetlands. Direction in the SSG is entirely consistent with the recommendations of Bishop et al (2009).

The IEA request raises a few specific concerns about the SSG which suggest that they have misinterpreted the direction in the guide:

- In section 8 the requestors interpret the SSG rationale on mercury as stating “1. Logging is essentially equivalent to fire so attempts to emulate fire will eliminate Hg impacts”. The SSG does not suggest that emulation of natural disturbance patterns will eliminate Hg impacts. The emulation of natural disturbance patterns within watersheds is expected to result in watershed scale hydrologic changes that are within the range that would occur as a result of natural disturbance processes. The SSG provides additional direction to minimize site disturbance associated with harvest and road construction, particularly in areas that are expected to have higher soil moisture levels. The SSG acknowledges that Hg dynamics will likely change within the watershed as a result of any type of forest disturbance and that further research and monitoring is required to refine direction in the guide.

- In section 9 the requestors state that “logging and forest fire have nearly opposite impacts on mercury” (pg. 16). This statement is demonstrably false as all the literature they cite as evidence shows that Hg is mobilized and/or bioaccumulated following both fire and harvest disturbance. The mechanism and magnitude of Hg response almost certainly differs between burned and harvested watersheds but all of the studies cited found some level of Hg response following disturbance by fire. Fire intensity is likely an important factor that influences Hg response with high intensity fires volatilizing Hg bound in the organic soil layer and low intensity fires leaving this layer undisturbed and Hg subsequently being mobilized as water tables rise and surface runoff increases. In their study of fish Hg levels, Garcia and Carignan (2000, 2005) found the highest Hg levels in fish from watersheds impacted by low intensity fires and lower Hg levels in fish from watersheds with high intensity fires. Fish Hg levels in harvested watersheds fell within this range (Garcia and Carignan, 2000, 2005). (Note that the requestors appear to use fire size and fire intensity interchangeably when in fact these measure different things)

Conclusion: The Stand and Site Guide and accompanying Background and Rationale document clearly acknowledge the potential for forest management activities to mobilize mercury, provide a comprehensive summary of available scientific literature on the topic, provide a clear rationale for guide direction and acknowledge the uncertainty associated with this direction. There are no claims that SSG direction will mitigate or eliminate Hg mobilization.

Supplemental Information:

Outline of recently completed, ongoing, and proposed MNR research activities addressing identified science gaps with respect to total and methyl-mercury dynamics in forested watersheds.

As noted in section B (Concerns associated with forest management policy – SSG) of MNR's response to the current IEA request, and highlighted in the SSG Background and Rationale document there remains a high degree of uncertainty regarding Hg response to forest management activities. As such, MNR views this as a high priority area for guide effectiveness monitoring and research. It is anticipated that results from MNR's ongoing research efforts will be a valuable source of new scientific knowledge that will be used during the required periodic reviews of the SSG as part of the adaptive management approach to evaluate and improve direction in the guide with respect to minimizing the adverse effects of Hg mobilization and subsequent bioaccumulation.

As has been clearly highlighted in MNR's response to the IEA request of the Whiskey Jack FMP, total and methyl mercury export from terrestrial to aquatic ecosystems, and their accumulation through trophic levels in the latter are controlled by a myriad of interacting processes, including disturbance type and intensity, inherent site conditions, atmospheric mercury deposition, and climate change. These interacting factors contribute further to the high variability in mercury dynamics within forested watersheds. As such, MNR is supporting a number of research projects that are well-positioned to address critical science gaps associated with terrestrial and aquatic mercury dynamics, many of which have been part of multi-institutional (provincial ministries, federal , and academic) partnerships. The summary below provides brief overviews of research projects that are: (1) examining patterns in fish mercury bioaccumulation, (2) evaluating the levels of mercury runoff from forest and wetland soils to aquatic systems, (3) mercury research conducted by other provincial and federal agencies, some of which include MNR as partners, and (4) a proposed synthesis of land use effects (e.g., mining, hydroelectric, and forest management activites) on watershed Hg cycling and export..

1. **Fish mercury bioaccumulation**
   A. MNR research lead: Dr. Tom Johnston, Research Scientist, Aquatic Research and Monitoring Section
      1) Ongoing efforts to update fish mercury information, both in the near north and far north, to improve consumption guidelines and assist with community-based land-use planning.
      2) Determine temporal changes in fish mercury bioaccumulation, 1970s to present. These efforts are largely focused in the near north but does include some work in the far north as well. This project was the basis for Rex Tang's MSc thesis and has already been published (Tang et al. 2013. Sci. Tot. Environ.). Additional work is targeting additional lakes to provide

better geographic coverage for the analysis, and considering to repeat the analysis over shorter (more recent) timeframes.

3) Assess the relative importance of food web position and growth rate in shaping interspecific variability in piscivore mercury concentrations. This project is targeting lakes that have co-habiting populations of lake trout, burbot, walleye, and northern pike. This will allow us to control, to some extent, the between-lake variability when making interspecific comparisons.
4) Determine the spatial variation in fish mercury concentrations from headwaters to James Bay in the Attawapiskat River drainage basin (Lescord PhD project, started 2013). This project is restricted to the far north and looks at mercury dynamics following a river continuum framework. The PhD candiate will compare how mercury moves through the food web at various points along the continuum from the headwater lakes of the shield, to the main stem river of the lowlands.
5) Determine the roles of physical-chemical limnology and food web structure in shaping fish mercury patterns in lakes across a climatic gradient (Sumner MSc project, started 2013). The MSc student will examine lakes across the near north and far north, comparing the role of climate (inferred from latitude or GDD) with the role of other factors. She may include some landscape factors (e.g., area or vegetation cover of drainage basin) in the analysis.

B. MNR research lead: Dr. Rob Mackereth, Research Scientist, Centre for Northern Forest Ecosystem Research
    1) Ongoing monitoring of mercury in small stream biota to evaluate the association between the rate of bioaccumulation and biomagnification of mercury and stream characteristics, including catchment disturbance. Sampling of periphyton, benthic invertebrates and fish have been conducted in watersheds having different forest management histories. Results to date show that mercury is present in all stream biota and tends to be higher in small streams compared to large. We have found no differences in fish mercury levels based on forest management activities in the watershed. Fish and invertebrate mercury concentrations tend to be associated with local conditions including pH, conductivity, stream gradient and temperature. Future work will focus on measuring fish and invertebrate mercury levels in streams within burned watersheds.

2. Mercury runoff from forest and wetland soils to aquatic systems

A. MNR research lead: Dr. Rob Mackereth, Research Scientist, Centre for Northern Forest Ecosystem Research
    1) The Escape Lake experimental watershed study was initiated to evaluate the impacts of forest management activity on the hydrologic connectivity between terrestrial and aquatic habitats and to observe the catchment scale hydrologic (groundwater levels, surface water flow, water chemistry)

and soil chemistry response. Beginning in March 2003, the watershed was surveyed (high resolution DEM, vegetation plots, soil pits) instrumented (wells and pizometers in wetland and along 3 experimental and 1 reference hillslope transect, resin bag transects) and monitored for 1.5 years. Experimental clearcut harvesting was carried out in June 2004, and included harvesting merchantable trees within the prescribed 30m buffer. Water quality constituents examined include major cations (Ca^{2+}, Mg^{2+}, K^{+}, Na^{+}) and anions (SO_4^{2-}, Cl^{-}), nutrients (NO^{3-}, NH^{4+}, TN, ortho-P, TP), TSS, turbidity, DOC, SRSI and metals (Al, Fe, Mn, Cu, Cd, Pb, Zn, Ni and MeHg and THg). Mercury concentration in ground and surface waters did not increase; however, following harvest, catchment water yield approximately doubled relative to pre-harvest resulting in an increase in Hg flux.

2) The associations between watershed and lake scale characteristics with THg in piscivorous fish were examined as part of an MSc research project (Victoria Danco). ArcGIS was used to delineate the waterbody catchment area and extract waterbody catchment characteristics for 243 of northern Ontario's lakes. Walleye (*Sander vitreus,* n= 121 lakes), lake trout (*Salvelinus namaycush,* n= 60 lakes), brook trout (*Salvelinus fontinalis*, n= 18 lakes), northern pike (*Esox lucius,* n =107 lakes), smallmouth bass (*Micropterus dolomieu*, n = 37 lakes), and burbot (*Lota lota,* n= 4 lakes) populations were standardized to the mean length of the populations by using power-series regressions. Multivariate analysis (non-metric multidimensional scaling) and univariate analysis were used to determine the associations between total mercury concentrations in fish and watershed scale and lake scale variables. Watershed and lake chemistry characteristics poorly described the variability in THg concentrations. Forest harvesting and natural disturbance were not associated with fish mercury concentrations.

B. MNR research lead: Dr. Jim McLaughlin, Research Scientist, Forest Research and Monitoring Section

1) Climate change effects on total and methyl mercury runoff from peatlands. Intact peat monoliths were collected in 2012 from peatland located near White River and transported to the University of Western Ontario BIOTON, where we are exposing the cores to varying atmospheric-CO_2 concentrations, air temperature, and water table levels in a replicated experiment. Preliminary results point to low water table followed by rewetting of the peat through precipitation significantly elevated MeHg in runoff water compared to other treatments. Our PhD student (Catherine Dielman, started in 2013) is currently testing the relationships among climate change, plant vegetation, peat decomposition, Hg release, and its transport in conjunction with DOC flux.

2) On April 4 2014, the NSERC-Research Tools and Infrastructure funding program awarded us (University of Western Ontario, lead institute) a grant

to establish a field-based experimental system for the evaluation of the effects of elevated temperature and elevated atmospheric carbon dioxide (CO_2) on total and methyl mercury runoff peatlands.

3) Establishing baseline conditions for Far North peat total mercury storage. This project is ongoing, where peat samples are collected and analyzed for total mercury concentration, bulk density, and peat depth to mineral sediment recorded. The data will then be used to scale peat mercury levels to peatland area of the Far North.
4) Establishing baseline conditions for forest soil mercury storage. This project is also currently ongoing, where organic (e.g., forest floor) and mineral soil samples collected at selected locations are analyzed for total mercury and bulk density, and soil horizon thickness. These will then be used to scale total mercury levels by forest cover types in the Far North and Managed forest.

3. Other provincial and federal mercury research and monitoring studies

A. Ontario Ministry of the Environment
   1) Monitoring Results for Mercury in Ontario's Water in the Great Lakes, northern Ontario lakes, and the English-Wabigoon River System.
   2) Ontario Ministry of Environment commitment to fund the Experimental Lakes Area (ELA), which is one of the world's premier watershed-based studies on forest, wetland, and aquatic mercury cycling and transport research in the boreal forest. Past research has involved the Department of Fisheries and Oceans.

B. Canadian Network for Aquatic Ecosystem Services
   1) This national research network supported by NSERC's Strategic Network Grants program, which encourages large-scale, multidisciplinary, collaborative research projects that could improve Canada's economy, society and environment within the next decade. The network is a consortium of approximately 30 researchers from 11 universities, government, and industrial partners. The Attawapiskat River Basin is one of the intensive study locations.
   2) Provincial (MOE and MNR) and federal (Department of Fisheries and Oceans and Canadian Forest Service) are network partners, whose research and monitoring staff are working with Ontario universities (University of Western Ontario, University of Toronto, and Laurentian University), and those across Canada, to establish baseline conditions of aquatic mercury levels and understanding mercury transport (and methylation) mechanisms from terrestrial to aquatic ecosystems.

C. Environment Canada
   1) Canadian Environmental Sustainability Indicators tracks the emissions of mercury to the air. The data used to calculate these indicators are taken from the Air Pollutant Emission Summaries and Trends and the National

Pollutant Release Inventory (NPRI), Canada's legislated, publicly accessible inventory of pollutant releases. National and regional emissions of mercury are provided, with emissions broken down by source.

4. Synthesis of land use (e.g., mining, hydroelectric, forest harvesting and regeneration) effects on watershed total and methyl mercury cycling and export

A. Draft outline for synthesis
   1. Mercury atmospheric deposition amounts and trends.
   2. Forest and peatland mercury cycling and runoff to aquatic ecosystems.
   3. Mercury methylation and demethylation processes.
   4. Mercury turnover rates in litter and soil.
   5. Watershed hydrology and mercury fluxes.
   6. Aquatic mercury cycling and fluxes.
   7. Land use activities (e.g., forest harvesting, hydroelectric, mining activities) and their cumulative effects on aquatic mercury levels.

It is anticipated that this synthesis effort will be a key science product that will help guide the development of future research efforts to continue targeting important science/knowledge gaps with respect to Hg dynamics and response to land use activities.

Additional Forestry Discussions with Grassy Narrows First Nation

It is very important to note, that in addition to the consultation requirements addressed during the preparation of the 2012-2014 Whiskey Jack CP, and the 2012-2022 Whiskey Jack FMP, MNR has been actively involved in improving the relationship with GNFN for many years. Various representatives of MNR including the local District Manager, Regional Director and Assistant Deputy Minister's, have engaged in direct face-to-face efforts to hear and understand Grassy Narrows's community leadership and its members' views on forestry. Preparation of the 2009-2019 ten (10) year Forest Management Plan was delayed numerous times using interim FMPs called contingency plans (CP). These plans, the 2009-2012 CP and the 2012-2014 CP, were used to demonstrate MNR's commitment to the relationship by enabling ongoing discussions with GNFN. The result was that the development of a full and complete forest management plan, as per the Crown Forest Sustainability Act, was delayed for 5 years.

The following is a brief summary of the additional discussions undertaken by MNR with GNFN that are outside of the forest management planning process, that demonstrate MNR's ongoing commitment to build a sound relationship with GNFN:

- Grassy Narrows First Nation (GNFN), MNR, Abitibi and Indian and Northern Affairs Canada (INAC) have been in forestry discussions, individually or as a group, at various times, since at least 2004. In March 2004, focused discussions were initiated in response to road blockades organized by members of GNFN and their sympathizers. These discussions sought to understand and respond to GNFN grievances around forestry activities on the Whiskey Jack Forest.
- MNR, Abitibi and INAC indicated throughout the talks that they were prepared to discuss GNFN grievances on a practical basis, i.e., measures to address concerns

about how forestry was conducted, not rewriting the provincial forestry legislation or considering assertions for jurisdictional control of the GNFN traditional lands. The parties met on numerous occasions throughout 2004 and 2005 and exchanged a series of Interim Measures documents including a final joint offer that responded substantively to GNFN demands for enhanced consultation and involvement in forest management planning and increased economic benefits from forestry activities.

- The Interim Measures included annual funding for three years for capacity, infrastructure and community support as well as economic benefits in the form of preferential contracting and employment and annual wood allocation valued at approximately $2.5 million. Grassy Narrows First Nation has not responded or accepted these interim measures to date.
- Grassy Narrows has repeatedly rejected recent offers and has indicated that all future land use activities on their "homeland" will be directed by a culturally and ecosystem-based plan to be prepared independently by GNFN.
- GNFN has indicated that they will no longer react to "clearcut plans" of others nor are they able to remove existing blockades, release downed wood behind the blockades or enter into any agreement that would guarantee no further disruption of forestry operations.
- In 2008 Grassy Narrows First Nation and MNR signed a Memorandum of Understanding, which is referred to as the “Process Agreement”, to explore numerous aspects of forestry in the Whiskey Jack Forest as part of a multi-year process. The Honorable Justice Frank Iacobucci mediated the discussions between GNFN and MNR that led to the development and signing of the Process Agreement.
- During that time Grassy Narrows has received significant provincial funding and has worked with MNR on various working groups on matters related to forestry practices (i.e. new area of concern prescriptions, harvest block design, harvesting systems, etc.) and traditional values and use studies. These forestry practices were to be tested in the 115,000 hectare Pilot Project Area that was identified and agreed to by GNFN as part of the Process Agreement.Between 2009 and 2014 MNR deferred the completion of a new forest management plan to allow for Grassy Narrows to apply these practices; unfortunately little progress has been made during that time.
- This Process Agreement was twice mediated by the Honorable Justice Frank Iacobucci without resolving the lack of commitment by GNFN to achieving the practical measures identified in the agreement (e.g., traditional use study, forest management prescriptions to protect identified aboriginal values, etc.) or those identified in the mediated settlements (e.g., concurrent limited harvesting and concurrent forest management planning).
- The Process Agreement is still in effect though its focus has shifted from achieving the practical measures outlined in the document to discussing GNFN’s role in a new forest tenure relationship for the Whiskey Jack Forest. GNFN has expressed interest in being part of the new forest tenure on the Whiskey Jack Forest
- In 2012, MNR initiated detailed discussions with Grassy Narrows on the basis of their potential involvement in establishing a new forest tenure arrangement for the Whiskey Jack Forest.

- In 2013, MNR begun discussions with nine First Nation communities, including Grassy Narrows First Nation, to explore transition to an enhanced sustainable forest licence (ESFL) for the Whiskey Jack Forest and give First Nations communities a greater say in the resource management.
- Since 2004, Kenora District MNR staff have engaged the communities leadership, Chief and Council, on matters relating to economic development opportunities for the community and the opportunities to be afforded to the community by participating in the forest economy (e.g., tree planting, brush saw tending contracts, slash pile burning, etc.) and forest management planning.
- Since 2004 the issue of mercury or methyl mercury release through forest practises was not brought up as an issue critical to the community, until the IEA Request was filed by GNFN/ Earthroots.

Communications

Invitation to Participate
Letters were sent on February 2, 2010 from the District Manager to the current Chief of each First Nations Community in both the Whiskey Jack and the Kenora Forest Management Units as an Invitation to Participate in the 2012-2022 Plans. The letter mentions the possibility of combining forest units as well as the need for an Aboriginal Task Team.

Only one response was received through the Minister's Office. A response from the Ministers Office was sent out June 22, 2010

LTMD
Registered Letter was sent to communities and Metis Council on December 14, 2011 inviting review and comment on the Long Term Management Direction for the Whiskey Jack Forest. One community requested an open house in early 2012.

(See Contingency Plan Consultation for communications during hiatus)

Stage 3
Letters were sent January 14, 2013 from the District Manager to the Chiefs of each First Nation Community identified above, to inform that Planning is starting for the WJ FMP 2012-2022. Please advise if Chief and Council would like a session brought to their community.

On January 31, 2013, a follow-up letter was sent from the District Manager to Chiefs within the WJF and the Metis Council announcing the MNR et al intentions to hold public information centres on the progress to date in the preparation of the FMP for the WJF.

Draft Plan
On July 30, 2013, a detailed information package and letter was sent to Chiefs within the WJF and to the Kenora Metis Council regarding the upcoming information centres for the Draft Plan. This letter invited the communities to Information Centres for the 2012-2022 Whiskey Jack Forest Draft Management Plan to be held September 3 to 6th in Kenora, Sioux Narrows, Red Lake and Ear Falls. The option to have an information centre at individual communities was presented.

Final Plan
On December 23, 2013 letters were sent from the District Manager to the Chiefs of each First Nation Community identified above, to invite them to inspect the Approved 2012-2022 Whiskey Jack FMP. The Final Plan was available for inspection between December 23rd, 2013 and January 22nd, 2014.

Newspaper Communications
Invitation to Participate
Newspapers advertisements were placed in the following editions with the dates provided:

Kenora Daily Miner and News	February 2, 2010
Sioux Lookout Wawatay News	February 18, 2010
Lake of the Woods Enterprise	February 6, 2010
Dryden Observer	February 10, 2010
Red Lake Northern Sun News	February 3, 2010

(See Contingency Plan Consultation for communications during hiatus between 2010-13)

LTMD
EBR Posting Approved November 22, 2011 (Withdrawn)
EBR Posting Approved December 24, 2011

Notices were published in local newspapers

Kenora Daily Miner and News	December 14, 2011
Lake of the Woods Enterprise	December 17, 2011
Dryden Observer	December 21, 2011
Sioux Lookout Wawatay News	December 22, 2011

Stage 3
Newspaper advertisements were placed in the following editions:

Kenora Daily Miner and News	January 29, 2013
Kenora Lake of the Woods Enterprise	January 28, 2013

Re: Appeal of disclosure from the Ministry of the Environment and Climate Change
A-2015-00157

Please accept this letter of appeal of the Ministry of the Environment and Climate Change's ("MOECC") disclosure decision, file no. A-2015-00157. This letter provides details about the grounds for appeal and the possible resolution of this appeal. Full submissions will follow at a later date.

The Appeal Form dated October 28, 2015, the appellant's request letter dated January 7, 2015, the MOECC's decision letters dated September 8, 2015 and September 25, 2015, a copy of the envelope with the postmark date of the disclosure package of September 29, 2015, and a cheque for $25.00 are enclosed.

Request for Information under the *Freedom of Information and Protection of Privacy Act*

This appeal relates to the following request for disclosure from the MOECC, dated January 7, 2015:

1. All records contained in the confidential MOECC file for the Whiskey Jack 2012-2022 Forest Management Plan project. We do not require any documents that were submitted by Earthroots. Please list any documents in the file that have already been provided to Earthroots, but copies are not required.

2. Any other records which the MOECC relied on in making the decision on the request for individual environmental assessment of the Whiskey Jack 2012-2022 Forest Management Plan submitted by Grassy Narrows and Earthroots.

Background

This request for information relates to Earthroots and Grassy Narrows First Nation's ("GNFN") application to the MOECC for an Individual Environmental Assessment ("IEA") of the Whiskey Jack Forest Management Plan 2012-2022. The MOECC denied the request for an IEA. Earthroots and GNFN made the IEA request so that the MOECC could assess through the IEA whether clearcut logging authorized under the Forest Management Plan would release mercury into the watersheds of the English-Wabigoon river system, which is part of the traditional territory of GNFN. Earthroots and GNFN are concerned that this mercury will contaminate the fish in the river system, increasing the risk of serious harm to wildlife and humans consuming fish from that river system.

Request for Review

Reasonable Search – All documents responsive to the request must be disclosed

We request that the MOECC confirm that there are no other documents responsive to this disclosure request.

All notes from all meetings or phone calls relating to the IEA request, including meetings between MOECC and the appellant, and MOECC and the Ministry of Natural Resources and Forestry ("MNRF"), should be disclosed. For example, there was a meeting between the appellants and MOECC on March 27, 2014. No notes from that meeting have been disclosed. The appellants submitted documents at that time and there is no mention of those documents in the disclosure package.

Improper application of subsection 13(1) of the Freedom of Information and Protection of Privacy Act

The MOECC has improperly applied section 13 of the *Freedom of Information and Protection of Privacy Act,* RSO 1990, c F31 *("FIPPA")*. Disclosure of these documents serves the purposes of the *FIPPA* regime under section 1.

The following documents are properly classified under subsection 13(2) of *FIPPA* and should be disclosed. There is also a compelling public interest in their disclosure pursuant to sections 11(1) and 23 of *FIPPA* based on the very serious health and environmental issues arising from the MOECC's decision not to order an IEA. These documents would shed light on the operations of government and allow the public to understand the IEA decision-making process.

- 1- The following documents should be disclosed:

  (a) WhiskeyJackIEA review1 1.docx (attachment referred to on page 188)
  (b) WhiskeyJackIEA MOE review1 1.docx (attachment referred to on page 198)

(c) A MOECC document that examines the "potential methyl mercury impacts of forestry activities" (record referred to on page 238)
(d) July IEA Clarification to MOE.pdf (attachment referred to on pages 245,268)
(e) Whiskey Jack IEA MNR Science Comment July 2014 (attachment referred to on pages 245,268)

These documents should be disclosed in their entirety. Earthroots and GNFN put forward scientific evidence that clearcut logging will cause further mercury contamination of the English-Wabigoon water system, which will result in very serious health impacts for members of GNFN. These documents consist of background and factual information.

It is also in the public interest for the full extent of the MOECC's review of the IEA request to be made public. There has been a significant public interest in the MOECC's decision and there are very serious health and environmental issues at stake.

- 2- At page 236 of the disclosure package, Ms. Fletcher identified external experts on the issue of methyl mercury and forestry. This is factual information and should be disclosed. This information should also be disclosed pursuant to section 23 of *FIPPA,* because it is in the public interest to understand the full extent of the review performed by MOECC. This information would shed light on the government's decision-making process.

- 3-There are several documents, and redacted portions of documents, which relate to discussions between MOECC and MNRF during the decision-making process. GNFN and Earthroots were not previously aware of these discussions or of the extent of communication between the ministries. These documents are not properly classified under subsection 13(1) and should be disclosed to allow the public to assess the rigour and fairness of MOECC's IEA process. Disclosure of these documents would shed light on the government's decision-making process.

  This request relates to the following documents:

  - The two attachments, Appendix 1 and Appendix 6, referred to in the email at page 557 of the disclosure package, should be disclosed.

  - At page 576 of the disclosure package, an email between John Sullivan, MNRF, and Devon Wills, MOECC, refers to comments by Mr. Sullivan on Appendix 1 and Appendix 6. The two attachments should be disclosed.

  - Paul Glassford attached a document entitled 2014 02 24 Appendix 1 MNR Final.docx to an email dated February 25, 2014 between MNRF and Devon Wills at MOECC, at page 598 of the disclosure package. The attachment should be disclosed.

- At page 620, Paul Glassford, MNRF sent a document entitled Document 1.docx to Devon Wills. The email notes that the document relates to the "mercury issue". It is unclear whether this document has been disclosed. If it has, MOECC may refer us to the document in the disclosure package. If not, we ask that the document be disclosed.

- At page 1531, Harley Berlin, MOECC, noted that the review process for IEA requests is a "process we have worked with MNRF on". The redacted portion of this email should be disclosed.

- 4- Drafts of the decision and drafts of the conditions attached to the decision should be disclosed. These documents are not properly classified under subsection 13(1). Because of the significant health and environmental implications of the decision, there is a strong public interest in understanding the basis for the MOECC's decision. This disclosure will also shed light on the MOECC's decision-making process. This request relates to the following documents:

  (a) The drafts of Appendix 1 and Appendix 6, referred to at pages 1618 and 1659
  (b) The draft of the decision note referred to at page 1044 and redacted at page 1045 of the disclosure package, and
  (c) The draft conditions being considered at pages 1063 and 1549-1550 of the disclosure package.

- 5- The attached Whiskey_Jack_2014_AWS.pdf documents, at page 1899 of the disclosure package, relates to the Annual Work Schedule for the Whiskey Jack Forest. Section 13 does not apply to this document and it should be disclosed. If this document has already been disclosed, MOECC may refer us to the document.

The appeal related to these documents could be resolved if these documents, and any other related documents, were disclosed in their entirety pursuant to sections 1, 11(1), 13(1), 13(2) and 23 of *FIPPA*.

Documents that cannot be identified

It is not possible to definitively identify several documents which have been withheld pursuant to section 13 of *FIPPA*. We are therefore unable to assess whether section 13 was properly applied to these documents or whether they should be disclosed under subsection 13(2), or sections 11(1) and 23 of *FIPPA*. This appeal relates to the following documents:

- The document at pages 5-14 of the disclosure package

- The document at pages 16-19 of the disclosure package

- The document at pages 874-883 of the disclosure package
- The document at pages 1011-1014 of the disclosure package
- The document at pages 1069-1071 of the disclosure package
- The document at pages 1076-1078 of the disclosure package
- The document at pages 1554-1571 of the disclosure package
- The document at pages 1874-1879 of the disclosure package

There are other fully redacted documents within the disclosure package that can likely be identified from the surrounding documents, but we ask that they be reviewed and disclosed if appropriate.

The application of subsection 13(1) to these records may be resolved by the MOECC providing clear information that identifies the date, author, recipients, copied parties and subject of the documents and an explanation of its application of subsection 13(1) to the records.

It is our position that these records should be released under subsection 13(2), or sections 11(1) and 23 of *FIPPA*. If those sections are found not to apply, the MOECC should ensure that the documents are released to the extent possible under subsection 10(2) of *FIPPA*.

Redaction – "Consultation not Necessary"

We are unaware of any justification for the redaction at page 806, which is classified as "Consultation not Necessary". We ask that this segment of the email be disclosed.

Thank you for your consideration of this matter. Should you require any further information, please feel free to contact me. Please note that full submissions on these issues will follow at a later date.

Yours truly,
