Plan start **Caribou Refuge Habitat Texture (Pattern)** is below the desirable level for the caribou zone, as is achievement at the end of the 10-year period as measured with the OLT model. There is minimal harvesting within the caribou zone in this plan therefore results are not expected to change significantly – Minimal movement towards desirable ACHIEVED.

Forest Management Guide for Natural Disturbance Pattern Emulation (NDPE) Analyses

Landscape direction from the NDPE Guide was included in the 2012 FMP and was measured through use of the NDPE Tool model. (Note: This guide is intended to be replaced by the Landscape Guide, but the Landscape Guide has not been approved for implementation in this FMP.)

The *Forest Management Guide for Natural Disturbance Pattern Emulation (NDPE) (MNR, 2001)* standard for frequency of **planned clearcuts equal to or less than 260 ha** (80%) has been assessed at 76% of planned clearcuts under 260 hectares. This result is slightly lower than the 80% standard, but is acceptable to the Planning Team as it results from strategic landscape pattern direction and projected harvest allocations that balance consideration for all desired forest and benefits and operational challenges.

A **sliding scale assessment** was conducted on forest disturbances (required by NDPE guide) to evaluate the spatial separation of planned disturbances across the landscape. This analysis identifies the average distance between disturbances in each size class at Plan End with Harvest (2022) and measures how well like-sized disturbances are spread out over the landscape. The results of this sliding scale analysis project that the six size classes with planned disturbances (all disturbance classes up to 10,000 ha in size) are well distributed and have median distances that exceed the minimum target distances. Since there are no measured disturbances in the 5,000-10,000 ha or >10,000 ha) size classes, the median distances are recorded as 0 for these classes as a median distance cannot be calculated unless there are two points (Supp Doc N).

Spatial Analyses Conclusion – The spatial distribution of caribou habitat, marten core habitat, and landscape pattern (measured by OLT and NDPE Tool) is improved through implementation of the planned harvest allocations.

5.3 Social and Economic Assessment

The *Forest Management Planning Manual (2009)* requires that a Social and Economic Assessment (SEA) be prepared to identify the expected social and economic impacts of implementing the Long-term Management Direction (LTMD) proposed in the Forest Management Plan (FMP). The assessment examines how the quantity of timber supplied to the wood-processing facilities, and the silvicultural investment requirements for the proposed long-term management direction may affect the communities identified in the Social & Economic Description. The Social and Economic Assessment of timber volumes and silvicultural expenditures is based on a comparison of the planned levels for the 2004 FMP and the levels shown in the LTMD for the 2012 FMP. This assessment outlines the expected social and economic impacts associated with the proposed LTMD. The social and economic assessment is included in plan text Section 3.6.4.

The overall social and economic impacts of implementing the 2012 FMP as compared to the 2004 FMP are generally good. The social and economic assessment for this FMP indicates that current levels of social or economic benefits are projected to be generally maintained or increased for the 2012-2022 plan period, in comparison with the 2004-2009 FMP. The Planning Team confirmed that maintaining this level in this plan period did not negatively impact objective achievement or long-term sustainability of the Whiskey Jack Forest. Positive socio-economic benefits and positive objective achievement are maintained.

The implementation of the Long-term Management Direction should at least maintain the current plan's level of employment and employment income from the wood processing facilities and maintain the current job and net employment income. These gains represent direct positive social and economic impacts in the primary wood manufacturing facilities and will occur in communities that receive fibre from the Whiskey Jack Forest.

The impacts of forest management and operations on recreation and tourism are not dependant on the harvest level but rather how the specific value has been addressed. Some values benefit from increased access to previously un-accessed areas whereas others that rely on remoteness can be negatively impacted. The impacts of forest management on mining and mineral exploration and baitfish operations are mainly positive. Forest operations will directly affect certain traplines and not others depending on where harvest allocations are planned. These operations may have both a positive and negative impact to one or more trappers and their traplines. Bear management area (BMA) operators may also be affected by both the harvest operations and road access. Stakeholder involvement during plan development will allow consideration for other values and users to be incorporated in the FMP to minimize potential negative impacts from forest operations.

5.4 Prescriptions for the Protection of Values

Prescriptions for the protection of values from the potential impacts of forest operations have been included in the Area of Concern (AOC) Planning Documentation in Supplementary Documentation H and the operational prescriptions included in Table FMP-10. These prescriptions have been developed to prevent, minimize, or mitigate the impact to values associated with planned forest operations. Specific "compliance" indicators have been developed to ensure that values are being protected on the Whiskey Jack Forest. Compliance indicators are used to assess operational practices on the forest, to identify compliance issues and to determine training needs of forestry workers. Compliance indicators are also used to determine if operational practices are compromising the long-term sustainability of the forest, and implement a course of corrective action, where required. The Planning Team has developed compliance indicators to assess:

- Percent of forest operation inspections in non-compliance with management practices that prevent, minimize or mitigate site damage (by remedy type); and
- Percent of forest operations inspections in non-compliance with prescriptions developed for the protection of water quality and fish habitat (by remedy type).

The procedures that will be used to monitor the above-mentioned AOC prescriptions, as well as any other AOC prescriptions included in the plan are outlined in plan text Section 4.7.

5.5 Conclusion on the Sustainability of the FMP

Overall, based on the quantitative and qualitative objectives (Table FMP-9) that can be assessed during preparation of the forest management plan, there has been achievement in meeting or exceeding the desirable levels and associated targets for most indicators (forest condition, and goods and services). From a spatial perspective, the objectives related to landscape pattern (caribou habitat, distribution of landscape disturbance and clearcut sizes, marten core habitat) have been achieved or movement towards achievement has been demonstrated through projected implementation of the LTMD. The *Forest Management Guide for Natural Disturbance Pattern Emulation (MNR, 2001)* standard for frequency of planned clearcuts equal to or less than 260 ha (80%) is underachieved with 76% of planned clearcuts under 260 hectares in size. This result was acceptable given the initial landscape pattern, the strategic landscape objectives, public comments and operational considerations.

The social and economic assessment for this FMP indicates that current levels of social or economic benefits are projected to be maintained or increased for the 2012-2022 plan period, in comparison with the 2004-2024 FMP. The evaluation of the proposed operations for the 2012-2022 FMP indicates that they are consistent with those projected in the LTMD.

Overall, the assessment of objective achievement, the social and economic assessment and the Long-term Management Direction have all demonstrated that the 2012-2022 Forest Management Plan for the Whiskey Jack Forest has regard for plant life, animal life, water, soil, air, social and economic values, including recreational and heritage values. As a result, it can be concluded that this forest management plan provides for the sustainability of Ontario's Crown Forest on the Whiskey Jack Forest.

6.0 DOCUMENTATION

6.1 Supplementary Documentation

Supplementary Documentation accompanies this Forest Management Plan, and its contents are listed at the beginning of this plan with the Table of Contents.

6.2 Other Documentation

Some documentation was developed or referenced by the Planning Team during preparation of this forest management plan, but does not form part of the FMP.

The public correspondence related to the development of the plan is retained on file at the MNR Kenora District Office. The Aboriginal Background Information Reports for each Aboriginal community and Report on the Protection of Identified Aboriginal Values are also retained at the Kenora District MNR Office.

7.0 FOREST MANAGEMENT PLAN SUMMARY

The Forest Management Plan Summary is prepared as a separate document and is retained on file at the Kenora District MNR office in Kenora. The FMP Summary is available in English and French.

The FMP Summary files are as follows:

File Name:	Plan Component:
MU490_2012_FMP_P1_TXT_Sum.PDF	FMP Summary Text (English)
MU490_2012_FMP_P1_MAP_Sum_00.PDF	FMP Summary Map (English)
MU490_2012_FMP_P1_TXT_SumFR.PDF	FMP Summary Text (French)
MU490_2012_FMP_P1_MAP_SumFR_00.PDF	FMP Summary Map (French)

8.0 PLANNED OPERATIONS FOR THE SECOND FIVE-YEAR TERM

Prior to March 31, 2017, planned operations for the second five-year term will be prepared. The following forest management plan components will be completed at that time:

8.1 Introduction
8.2 Prescriptions for Operations
8.3 Harvest Operations
8.4 Renewal and Tending Operations
8.5 Roads
8.6 Expenditures
8.7 Monitoring and Assessment
8.8 Fire Prevention and Preparedness
8.9 Supplementary Documentation
8.10 Other Documentation
8.11 Planned Operations Summary

9.0 FOREST MANAGEMENT PLAN TABLES

The following is a listing of the tables required by the *Forest Management Planning Manual (2009)* included in this section:
(submitted in FMP file: MU490_2012_FMP_P1_TBL_Tables.PDF)

FMP-1	Management Unit Crown Land Summary
FMP-2	Description of Forest Units
FMP-3	Summary of Managed Crown Production Forest by Forest Unit
FMP-4	Silvicultural Ground Rules
FMP-5	Projected Forest Condition for the Crown Productive Forest
FMP-6	Projected Habitat for Species at Risk and Selected Wildlife Species
FMP-7	Projected Available Harvest Area by Forest Unit
FMP-8	Projected Available Harvest Volume by Species Group
FMP-9	Assessment of Objective Achievement
FMP-10	Operational Prescriptions for Areas of Concern
FMP-11	Planned Harvest Area
FMP-12	Planned Clearcuts > 260 Ha (5-Year)
FMP-13	Planned Harvest Volume by Species (10-Year)
FMP-14	Planned Harvest Volume and Wood Utilization (5-Year)
FMP-15	Planned Wood Utilization by Mill (5-Year)
FMP-16	Contingency Area: Harvest Area and Volume
FMP-17	Planned Renewal and Tending Operations
FMP-18	Road Construction and Use Management
FMP-19	Road Crossings, Landings and Aggregate Pits in Areas of Concern
FMP-20	Planned Expenditures (5-Year)
FMP-21	Area Planned for Assessment of Regeneration Success (10-Year)

9.0 FOREST MANAGEMENT PLAN TABLES

The following is a listing of the tables required by the *Forest Management Planning Manual (2009)*:

FMP-1	Management Unit Crown Land Summary
FMP-2	Description of Forest Units
FMP-3	Summary of Managed Crown Production Forest by Forest Unit
FMP-4	Silvicultural Ground Rules
FMP-5	Projected Forest Condition for the Crown Productive Forest
FMP-6	Projected Habitat for Species at Risk and Selected Wildlife Species
FMP-7	Projected Available Harvest Area by Forest Unit (10-Year)
FMP-8	Projected Available Harvest Volume by Species Group (10-Year)
FMP-9	Assessment of Objective Achievement
FMP-10	Operational Prescriptions for Areas of Concern
FMP-11	Planned Harvest Area
FMP-12	Planned Clearcuts > 260 Ha (5-Year)
FMP-13	Planned Harvest Volume by Species (10-Year)
FMP-14	Planned Harvest Volume and Wood Utilization (5-Year)
FMP-15	Planned Wood Utilization by Mill (5-Year)
FMP-16	Contingency Area: Harvest Area and Volume
FMP-17	Planned Renewal and Tending Operations
FMP-18	Road Construction and Use Management
FMP-19	Road Crossings, Landings and Aggregate Pits in Areas of Concern
FMP-20	Planned Expenditures (5-Year)
FMP-21	Area Planned for Assessment of Regeneration Success (10-Year)

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 to March 31, 2022

FMP-1 MANAGEMENT UNIT CROWN LAND SUMMARY

Land Ownership and Type	Land Ownership (Hectares)				FRI Fields Used for Classification	
	Crown		Patent	Total		
	Managed (Owner = 1)	Other * (Owner = 5,7)	Crown Timber (Owner = 2)		POLY_TYPE	DEVSTAGE
Unsurveyed	0	0	0	0	UNS

FMP-3 SUMMARY OF MANAGED CROWN PRODUCTIVE FOREST BY FOREST UNIT

Forest Unit	Age Class	Protection Forest (ha)	Production Forest		
			Unavailable (ha)	Stage of Management	Available (ha)
Total All Forest Units	1-20	667	225	clearcut	134,133
	21-40	7,542	314	clearcut	176,854
	41-60	1,132	462	clearcut	56,921
	61-80	5,613	1,444	clearcut	129,492
	81-100	8,840	2,129	clearcut	99,334
	101-120	2,900	1,154	clearcut	48,999
	121-140	1,047	261	clearcut	13,528
	141+	1,651	51	clearcut	7,789
Total All Forest Units		29,392	6,039		667,051
				Total Production Forest:	673,090
				Total Productive Forest:	702,482

NOTE: The above table reflects the base model inventory (Dec11_BMI_OPDEF) availability data.
* The available data includes 20,140 hectares of Crown Managed, DEVSTAGE LOWNAT area that has been classified as non-forest in the strategic modelling (SFMM) land base (see Analysis Package for rationale). This LOW area is split 20,036 ha available, 104 ha unavailable.
* Forested islands (3,123 ha) are included with Protection Forest (PF) in FMP-1 and SFMM modelling, but classified as unavailable in the Base Model Inventory and FMP-3.
* Estimated bypass, AOC reserves, Mgmt Res and inaccessible are classified as available in the BMI and FMP-3, but considered unavailable reserve in SFMM for strategic modelling purposes (33,417+76,265+1,389+124 = 109,692 ha)(Table FMP-1a).

The comparable sub-totals for this OWNERSHIP 1 Crown Managed forest table considering the reclassification of LOWNAT area, forested islands, estimated bypass/reserves for SFMM modelling are:

Protection Forest - 32,515 ha (includes forested islands, matches FMP-1).
Unavailable - 131,335 ha (includes unavailable (non-forest) LOWNAT area, estimated bypass/reserves/inaccessible).
Available - 538,618 (excl. unavail. LOWNAT and est. bypass/reserves, matches reconciliation of SFMM land base).

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 to March 31, 2022

Reconciliation of SFMM Initial Land Base to Tables FMP-1 and FMP-3.

SFMM Classification	Area in Hectares		Inventory Classification (OWNER, and POLYTYPE)
	SFMM Model	FMP-1 and FMP-3	
Available	538,619	667,051	OWNER = 1, POLYTYPE = FOR.
			Available breakdown from FMP-3.
Reserve (Unavailable)			Includes OWNER = 1, LOWNAT DEVSTAGE area (20,036 ha).
Slope-based Riparian	64,763		Estimated reserve areas in SFMM are classified as available in FMP-3.
Tourism	10,373		Estimated reserve areas in SFMM are classified as available in FMP-3.
Nests	1,129		Estimated reserve areas in SFMM are classified as available in FMP-3.
Pass	33,417		Estimated reserve areas in SFMM are classified as available in FMP-3.
Protf	34,149	34,149	FORMOD = PF, OWNER = 1, 5, 7 (excludes forested islands)
Forested Islands - Crown Managed	3,123		ACCESS1 = ISL, OWNER = 1
Forested Islands - Park		2,003	ACCESS1 = ISL, OWNER = 5, 7.
Parks	38,309	36,306	FORMOD = FOR, OWNER = 5 or 7 only. (includes forested islands in SFMM)
Management Reserve	1,389		
Access	124		POLYTYPE = FOR, ACCESS1=LUD, NAT, PEN. OWNER = 1.
		6,039	Unavailable in Table FMP-3, OWNER = 1
Reserve (Unavailable) Subtotal	186,776	78,496	(unavailable includes 104 ha LOWNAT and 3,123 ha Forested Islands).
Non-forest and Non-Productive			
OpMsk	33,594	33,594	POLYTYPE = OMS, OWNER = 1, 5, or 7.
TrMsk	22,070	22,070	POLYTYPE = TMS, OWNER = 1, 5, or 7.
BrsAld	26,761	26,761	POLYTYPE = BSH, OWNER = 1, 5, or 7.
Grass & Meadow	13	13	POLYTYPE = GRS, OWNER = 1, 5, or 7.
Rock	19,001	19,001	POLYTYPE = RCK, OWNER = 1, 5, or 7.
Agricultural Land	0	0	POLYTYPE = DAL, OWNER = 1, 5, or 7.
Water	203,040	203,040	POLYTYPE = WAT, OWNER = 1, 5, or 7.
UCL	3,489	3,489	POLYTYPE = UCL, RRW, or BFL, OWNER = 1, 5, or 7.
Older LOWNAT	20,140		OWNER=1 only.
Non-forested Islands ISL	0	0	POLYTYPE = RCK, ACCESS1 = ISL, OWNER = 1, 5, or 7.
Subtotal	328,108	307,967	
TOTAL SFMM AREA	1,053,501	1,053,515	Total Ownerships 1, 5, and 7.
TOTAL CROWN LAND BASE	**1,053,501**	**1,053,515**	10 ha variance due to rounding convention during SFMM area import. Acceptable.
Patent Land	0	0	Total Patent Ownership = 2 (not included in SFMM land base).
TOTAL LAND BASE OF THE FOREST	**1,053,501**	**1,053,515**	

Hierarchy for Classification of SFMM Initial Land Base: (unique sort - once an area is tagged, it is not retagged.)

Order:

1 **Patent** - Sort for non-Crown ownership 2, all land types. (not included in SFMM land base, but is included in land base reconciliation to Table FMP-1)
NOTE: Non-Crown ownerships 6, 8, 9, and Patent ownership 3, 4, all land types, are not included in SFMM land base and not included in Table FMP-1.

2 **RESERVE - ProtF** - Sort for Protection Forest

3 **NON-FOREST** - Sort for non-productive forest classes based on POLYTYPE, includes:

ISL POLYTYPE = RCK and ACCESS1 = ISL (sorted before rock is tagged)
LOW LOWNAT and LOWMGMT (team decision to consider Crown, managed, non-productive for SFMM modelling).
OMS Open Muskeg
TMS Treed Muskeg
BSH Brush & Alder
GRS Grass & Meadow
DAL Designated Agricultural Land
UCL UCL, PIT, RRW, BFL
WAT Water
RCK Rock

4 Sort for unavailable **RESERVE** classifications:

PARKS Productive Crown park land (ownership 5 and 7)
ISLND Forested islands (Ownership 1)
RIPAR Estimated slope-based Riparian reserve
TOURS Estimated Tourism Reserve
NESTS Estimated Nest Reserve
Access Classified actual areas with access issues.
MgRes Classified Management Reserves not otherwise classified as reserve (above).

5 **AVAIL** - Remainder of forest available for timber production
- Crown, managed ownership 1 only
- productive, forested land and not otherwise estimated to be reserved from harvest or non-forest.
(deferrals for large landscape patches and delay in availability of certain stands (harvest deferral) is applied to this AVAIL land base only.)

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 TO March 31, 2022

General Notes for the Silvicultural Ground Rules for the 2012-2022 Whiskey Jack Forest

Notes
1. Ecosites listed in the SGR are based on the Forest Ecosite Classification for vegetation and soils types for Terrestrial and Wetland Ecosites of Northwestern Ontario (Racey et al., May 1996). Ecosite classification will be confirmed prior to implementation of a silvicultural ground rule.
2. The most prominent ecosites that will receive the treatment are identified in **bold text.**
3. Regeneration Standard: a. These are the standards for determining regeneration success (e.g. acceptable species, the timeframes required, site occupancy). The standards of regeneration success are consistent with the development information associated with the desired future forest unit. b. FTG – Free-to-Grow - meaning the stand has met the indicated criteria and the regenerating crop is essentially healthy and free from competition. Stands are still monitored. c. Density – the use of density vs. stocking targets depends on the type of treatments employed. For treatments that uses extensive and basic, will receive regular free to grow, Large Scale Photography (LSP) or ocular survey and contain stocking. For areas treated intensively, will receive well-spaced free growing survey and will be density regulated.
4. Silvicultural System and Silvicultural Treatments: a. Silvicultural System – the Clearcut Silvicultural System is noted by the code “CC”. b. Silvicultural Treatments - For each silvicultural ground rule, the most common series of silvicultural and acceptable alternative treatments have been identified. Where a silvicultural treatment differs from the recommendations in the appropriate silvicultural guide, that treatment will be identified as an exception.
5. Harvest Method: Refers to the variant of the general silviculture system (e.g. conventional or strip clearcut, uniform shelterwood) as well as any reference to commercial thinning.
6. Logging Method: Describes the type of timber extraction, which is typically tree length.
7. Site Preparation: Describes the treatments that may be used to prepare harvested sites for renewal. Treatments may be used in combinations.
8. Regeneration: Describes the treatments that may be used to regenerate the site for renewal. Treatments may be used in combinations.
9. Tending: Describes the treatments used to control competition/enhance growth. Treatments may be used in combinations.
10. Site Occupancy: See monitoring program for regeneration success Supplementary Documentation F. A minimum of 80% site occupancy is the target.

Most Common Treatment Package	Conventional	Full Tree	Mechanical	Plant (1.8x1.8m Spacing)	None
Acceptable Alternative Treatments		Tree Length Cut to Length	None Manual Chemical		Cleaning-Chemical Ground Cleaning-Chemical Aerial Cleaning-Manual Cleaning-Mechanical

Exception to Silvicultural Guide to Managing for Black Spruce, Jack Pine and Aspen on Boreal Forest Ecosites in Ontario (OMNR, 1997);
NOTE: A list of rationales to the exceptions and conditions applicable to this Silvicultural Ground Rule can be found at the back of FMP-4.

Exceptions:	Conditions on Harvest:	Conditions on SIP:	Conditions on Regeneration:	Conditions on Cleaning:
ES12	ES12 ES13 ES14 ES26	ES12 ES13 ES14 ES26	N/A	N/A

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 TO March 31, 2022

List of Exceptions and Conditions to the Silvicultural Ground Rules for the 2012-2022 Whiskey Jack Forest

Exceptions
ES11: Full tree is Not Recommended where total soil depth (mineral and surface organic) is < 20 cm.
ES12: Full tree is Not Recommended where total soil depth (mineral and surface organic) is < 20 cm.
ES14: Artificial seeding is Not Recommended. This site is prone to draught which will limit the success of seeding.
ES21: Natural Regeneration Not Recommended for Sb or Pj . Advance Sb growth is not of sufficient or distribution to regenerate this site and Pj does not regenerate under a closed canopy.

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 TO March 31, 2022

List of Exceptions and Conditions to the Silvicultural Ground Rules for the 2012-2022 Whiskey Jack Forest

Conditions On Harvest
ES11: Full tree is permitted (Conditionally Recommended) where total soil depth exceeds 20 cm, provided that a winter harvest is employed or when other measures such as high floatation equipment are used to minimize disturbance of the organic layer. No restrictions apply on moderately deep to deep soils where mineral soil depth exceeds 30 cm and the thickness of the surface layer is > 5 cm.
ES12: Full tree is permitted (Conditionally Recommended) where total soil depth exceeds 20 cm, provided that a winter harvest is employed or when other measures such as high floatation equipment are used to minimize disturbance of the organic layer. No restrictions apply on moderately deep to deep soils where mineral soil depth exceeds 30 cm and the thickness of the surface layer is > 5 cm.
ES13: Full Tree Harvesting is Conditionally Recommended provided that “best practices” are used to minimize disturbance of the surface organic layer. Where surface organic thickness averages <5 cm, winter harvest and/or use of high flotation equipment should be considered to maintain the integrity of the surface organic layer.
ES14: Full-tree harvesting is Conditionally Recommended provided "best practices" are used to minimize disturbance and/or displacement of the surface organic layer.
ES15: Full tree harvesting is Conditionally Recommended provided "best practices" are used to minimize disturbance and/or displacement of the surface organic layer. Where surface organic thickness averages < 5cm, winter harvest and/or the use of high flotation equipment should be considered to maintain the integrity of the surface organic layer.
ES26: All logging methods are Conditionally Recommended. Fine textured soils are susceptible to rutting and compaction when saturated during the frost free season. Harvest on frozen ground or use low-impact equipment when soils are saturated.
ES31: All logging methods are Conditionally Recommended. Fine textured soils are susceptible to rutting and compaction when saturated during the frost free season. Harvest on frozen ground or use low-impact equipment when soils are saturated.
ES35: Logging is Conditionally Recommended. Harvest on frozen ground because organic soils are susceptible to rutting on fibric peatymor soils, low impact equipment may allow summer harvest.
ES36: Logging is Conditionally Recommended. Harvest on frozen ground because organic soils are susceptible to rutting on fibric peatymor soils, low impact equipment may allow summer harvest.
ES37: Logging is Conditionally Recommended. Harvest on frozen ground because organic soils are susceptible to rutting on fibric peatymor soils, low impact equipment may allow summer harvest.
ES38: Logging is Conditionally Recommended. Harvest on frozen ground because organic soils are susceptible to rutting on fibric peatymor soils, low impact equipment may allow summer harvest.

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 TO March 31, 2022

List of Exceptions and Conditions to the Silvicultural Ground Rules for the 2012-2022 Whiskey Jack Forest

Condition on Site Preparation (SIP)
ES11: Mechanical site preparation is Conditionally Recommended as sufficient seedbed may be created as a result of the harvest. Apply techniques that maintain a high percentage of intact forest floor to limit the loss of nutrients.
ES12: Mechanical site preparation is Conditionally Recommended as sufficient seedbed may be created as a result of the harvest. Apply techniques that maintain a high percentage of intact forest floor to limit the loss of nutrients.
ES13: Mechanical site preparation is Conditionally Recommended. Apply techniques that maintain a high percentage of intact forest floor to limit the loss of nutrients. A good distribution of mineral soil seedbeds created by mechanical site preparation will contribute to successful natural and/or direct seeding.
ES14: Mechanical site preparation is Conditionally Recommended provided techniques maintain a high percentage of intact forest floor to limit loss of nutrients.
ES15: Mechanical site preparation is Conditionally Recommended. Sufficient seedbed may be created as a result of the harvest. Apply techniques that maintain a high percentage of intact forest floor to limit nutrient loss.
ES21: Mechanical site preparation is Not Recommended for Po as scarification in cut Aspen stands where suckering has started there will be reduced growth in the replacement suckers.
ES26: Mechanical site preparation is Conditionally Recommended. Techniques, timing and sequencing of treatments should be carefully considered. Minimize mineral soil exposure on clays to reduce the incidence of soil baking/ frost heaving and to prevent increased competition from non-crop vegetation on a mixed mineral/organic microsite. Fine textured soils are susceptible to rutting and compaction when saturated during the frost free season.
ES31: Mechanical Site Preparation is Conditionally Recommended. Techniques, timing and sequencing of treatments should be carefully considered. Minimize mineral soil exposure on clays to reduce the incidence of soil baking and/or frost heaving, and to prevent increased competition from non-crop vegetation on a mixed mineral/organic microsite. Fine textured soils are susceptible to rutting and compaction when saturated during the frost free season.

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 TO March 31, 2022

List of Exceptions and Conditions to the Silvicultural Ground Rules for the 2012-2022 Whiskey Jack Forest

Conditions on Regeneration
ES21(1): Seeding Conditionally Recommended for Pj. Shelter seeding only. Good selection of seedbed microsites will contribute to success. Smothering seedbeds with hardwood litter will limit success. The distribution, abundance and vigour of competitive non-crop species will affect the survival of the seed origin Pj.
ES21(2): Artificial seeding is Conditionally Recommended. Shelter seeding only. Good selection of seedbed microsites will contribute to success. Smothering of seedbeds with hardwood litter will limit success. The distribution, abundance and vigour of competitive non-crop vegetation will affect the survival and growth of seed origin jack pine.
ES35: Seed-tree Harvest Method will be supplemented with leaving advanced growth.
ES36: Seed-tree Harvest Method will be supplemented with leaving advanced growth.
ES37: Seed-tree Harvest Method will be supplemented with leaving advanced growth.

NOTES: Data from Proposed Management Strategy 27d_OLTMS.
Area data reported for the beginning of each 20-year period.
Crown, managed LOWNAT and LOWMGMT area (20,140 ha) was classified as non-forest area in the strategic modellir (SFMM LTMD), but is classified as productive forest in Tables FMP-1 and 2.
Total productive forest area in Year 2012 is comparable to totals in Tables FMP-1 and FMP-2. SFMM land base reconciled 754,534 ha (14 ha lower than FMP-1 and FMP-2 due to rounding within SFMM model inputs).

Data derived from results of the SFMM Proposed Management Strategy 27d_OLTMS with regional calculations for defect and undersized volumes.

* Volumes for Other Conifer (Larch, Cedar) and Tolerant Hardwood (Black Ash) are reported but are not considered major species groups on the Whiskey Jack Forest.

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 to March 31, 2022

FMP-9 ASSESSMENT OF OBJECTIVE ACHIEVEMENT

SFMM data based on scenario 27d_OLTMS.cas

Management Objective:					CFSA Category:					Source:
Indicator / Measure(s)	Plan Start Level	Desirable Level	Timing of Assessment	Target	LTMD - Projected Achievement: Short-term (10 years)	Medium-term (20-70 years): Term when desirable level achieved and sustained:	Medium-term (20-70 years): Range of Values at achievement (or 20-70 year range of values if not achieved.)	Long-term (80-100 years): Term when desirable level achieved and sustained:	Long-term (80-100 years): Value at achievement or Year 100 value	Assessment
Management Objective:	**1. Landscape Pattern:** To emulate natural disturbance and landscape patterns characteristic of the management unit.				**CFSA Category:**	**Forest Diversity** - Natural Landscape Patterns				**Source:** 1a, 1b, 1c: Draft Landscape Guide 1b: NDPE Guide
Landscape Pattern **(1a) % of polygons with >60% mature and old forest**	**Percentage**	Landscape pattern consistent with OLT percentage projections for mature/old forest. **Min. Desirable %**	- Completion of proposed LTMD - Completion of Phase I Operational Planning - Year 10 Annual Report	Movement towards desirable level measured at Plan End 2022.	**Target: Percentage**	**Term**	**Percentage**	**Term**	**Percentage**	Spatial assessment showed that implementation of planned operations would result in a landscape pattern of mature and old forest moving towards the desirable level from plan start level. Target level **ACHIEVED** in this plan period.
Scale: 500 ha hexagon	27%	35%			29%	n/a	n/a	n/a	n/a	
Scale: 5,000 ha hexagon	18%	28%			24%	n/a	n/a	n/a	n/a	
(1b) Young forest patch size by size class. **Size Class:**	**Percentage**	Young forest landscape pattern consistent with OLT projections by size class. **Desirable %**	- Completion of proposed LTMD - Completion of Phase I Operational Planning - Year 10 Annual Report	Movement towards desirable level measured at Plan End 2022.	**Target: Percentage**	**Term**	**Percentage**	**Term**	**Percentage**	Spatial assessment of young forest by patch size shows movement towards the OLT desirable level in 6 of the 9 size classes. The 101-250 ha class increases in frequency whereas the template suggests a reduction. The 501-1,000 and 1,001-2,500 ha class frequencies decrease slightly at Plan End compared to higher desirable levels. Overall the movement toward the template frequency distribution is greater than the minor shortfalls in 3 classes. Target level is **ACHIEVED** in this plan period.
1 - 100 ha	63%	52%			60%	n/a	n/a	n/a	n/a	
101 - 250 ha	19%	15%			24%	n/a	n/a	n/a	n/a	
251 - 500 ha	7%	10%			9%	n/a	n/a	n/a	n/a	
501 - 1,000 ha	5%	8%			4%	n/a	n/a	n/a	n/a	
1,001 - 2,500 ha	4%	8%			2%	n/a	n/a	n/a	n/a	
2,501 - 5,000 ha	1%	4%			1.1%	n/a	n/a	n/a	n/a	
5,001 - 10,000 ha	1%	3%			1.3%	n/a	n/a	n/a	n/a	
10,000 - 20, 000 ha	0%	2%			0.2%	n/a	n/a	n/a	n/a	
> 20,000 ha	0%	1%			0.3%	n/a	n/a	n/a	n/a	
(1c) % of polygons with >60% mature and old conifer forest	**Percentage**	Landscape pattern consistent with OLT percentage projections for mature/old conifer forest. **Min. Desirable %**	- Completion of proposed LTMD - Completion of Phase I Operational Planning - Year 10 Annual Report	Movement towards desirable level measured at Plan End 2022.	**Target: Percentage**	**Term**	**Percentage**	**Term**	**Percentage**	Spatial assessment showed that implementation of planned operations would result in a landscape pattern of mature and old conifer forest moving marginally towards the desirable level from plan start level. The target level is marginally **ACHIEVED** in this plan period. Planned harvest is not negatively impacting achievement. More significant achievement will require aging of the forest over several plan periods.
Scale: 500 ha hexagon	4%	19%			6%	n/a	n/a	n/a	n/a	
Scale: 5,000 ha hexagon	1%	9%			1.3%	n/a	n/a	n/a	n/a	
Management Objective:	**2. Forest Composition:** To maintain or move towards a natural range of forest composition and age distribution.				**CFSA Category:**	**Forest Diversity** - Forest Structure and Composition - Distribution and Abundance of Forest Ecosystems				**Source:** 2a, 2d, 2e: Draft Landscape Guide 2b, 2c: FMPM
Area by OLT Forest Unit and Development Stage **(2a) Crown Productive Forest by Landscape Class:** **Landscape Class:**	**Hectares**	Achieve and maintain at or above the minimum of the lower interquartile hectare range (SRNV) for each Mate-Late landscape class as projected by OLT. **Minimum Desirable Ha.**	- Completion of proposed LTMD - Year 7 and Year 10 Annual Reports	Same as desirable level.	**Ha.**	**Target is Medium-term.** **Term**	**Ha.**	**Term**	**Ha.**	2 mature/late landscape classes achieves min. desirable and target levels at Plan Start. Remaining 2 ML classes are the smallest of ML classes and achieve and sustain desirable levels in medium-term (T4-T8) and sustain levels through long-term. Some achievement was increased to improve trends closer to OLT medians rather than minimum. Target levels **ACHIEVED** in the medium term indicator timeframe.
Mature/Late Balsam	8,361	8,706			8,119	T4	7,427 - 19,031	-	13,212	
Mature/Late Lowland	12,695	12,845			12,135	-	9,608 - 12,653	T8	12,850 - 12,884	
Mature/Late Hardwood	104,760	43,021			104,326	T1	43,100 - 104,760	-	49,208	
Mature/Late Conifer	182,885	178,461			189,168	T5	180,326 - 245,438	-	233,558	

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 to March 31, 2022

FMP-9 ASSESSMENT OF OBJECTIVE ACHIEVEMENT

SFMM data based on scenario 27d_OLTMS.cas

Management Objective:					CFSA Category:					Source:
Indicator / Measure(s)	Plan Start Level	Desirable Level	Timing of Assessment	Target	LTMD - Projected Achievement: Short-term (10 years)	Medium-term (20-70 years)		Long-term (80-100 years)		Assessment
(2b) Crown Productive Forest by Forest Unit:		Forest area consistent with OLT projections by forest unit and age grouping:	- Completion of proposed LTMD - Year 7 and Year 10 Annual Reports	Same as desirable level.		**Target is Medium-term.**				Min. desirable and target levels met for 19 of 24 forest unit/age groupings within this plan period (most with Plan Start conditions).
Forest Unit:	**Hectares**	**Minimum Desirable Ha.**			**Ha.**	**Term**	**Ha.**	**Term**	**Ha.**	
BFM - Young/Immature	18,788	1,948			17,267	-	2,674 - 16,568	-	3,844 - 4,232	Desirable and target levels are met and sustained for all forest unit/age groupings except as noted below: - Young BFM underachieved T13-14. - Young HMX underachieved T12-16. - Young OCL underachieves T1-4. - Young OTH underachieves T1-6. - Young PJM underachieves T1. - Mature PJD underachieves T1-5. - Mature PJM underachieves T3-6. - Mature POD underachieves T6-7. - Mature SBL underachieves T3-6. - Mature SPM underachieves T1-3. Target levels **ACHIEVED** in target timeframe (majority within this plan period). Overall desirable level achievement of area by forest unit and age grouping very good while managing for landscape class and old forest areas.
- Mature/Late	8,361	8,361			8,119	T4	9,531 - 19,031	-	13,212

OLD - PRW >140 years	457	457			688	T1	808 - 1,654	-	1,387	
(2d) Amount of red pine and white pine forest (all ages, PRW forest unit)	3,312 ha.	Maintain area of the PRW forest unit (minimum 3,312 ha.).		Same as desirable level.	**Target:** 3,500 ha.	3,495 - 4,126 ha.		3,923 - 4,121 ha.		Desirable and target levels **ACHIEVED** with Plan Start area. Additional red pine and white pine will be planted but not necessarily result in increased forest unit area.
(2e) Amount of upland pine and spruce forests (all ages, total of PJD, PJM, SPD, and SPM forest units)	403,400 ha.	Maintain minimum of 457,260 ha upland conifer as per OLT min. SRNV projection.		Movement towards desirable level during this plan period.	**Target:** 410,674 ha.	T7 457,770 ha.		466,121 - 483,176 ha.		Steady increase towards desirable level. Target level **ACHIEVED** in this plan period.

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 to March 31, 2022

FMP-9 ASSESSMENT OF OBJECTIVE ACHIEVEMENT

SFMM data based on scenario 27d_OLTMS.cas

Management Objective:					CFSA Category:				Source:
Indicator / Measure(s)	Plan Start Level	Desirable Level	Timing of Assessment	Target	LTMD - Projected Achievement: Short-term (10 years)	Medium-term (20-70 years)		Long-term (80-100 years)	Assessment
Management Objective:	**3. Wildlife Habitat:** To maintain forest function for wildlife habitat in the management unit.				**CFSA Category:**	**Forest Diversity** and **Provision of Forest Cover** - Habitat for animal life			**Source:** 3a, 3b, 3c: Draft Landscape Guide 3d: Marten Habitat Guide
(3a) Area of habitat for forest-dependent Species At Risk **Wildlife Species in caribou zone:**	**Plan Start Level (ha)**	Achieve and maintain min. OLT projected SRNV ha for caribou habitat (as below). **Minimum Desirable Ha.**	- Completion of proposed LTMD - Year 10 Annual Report	Move towards desirable level over next 30 years.	**Ha.**	**Target is Medium-term.** **Term**	**Ha.**	**Term**	**Ha.**	Caribou habitat generally increases from Plan Start to exceed min. desirable levels by Term 6 onwards. During this plan period, there is clean-up occurring in 4 caribou blocks which accounts for the short-term reduction in refuge and preferred winter habitat. Increase then projected from T3-6 to within SRNV levels to **ACHIEVE** target levels within the 30-year target timeframe.
Caribou - refuge	103,969	147,605			100,503	T6	154,830 - 156,352	-	150,000	
Caribou - winter used	45,055	26,809			45,782	T1	83,974 - 120,501	-	104,075	
Caribou - winter preferred	20,581	36,912			17,975	T5	54,271 - 60,933	-	44,972	
(3b) % of polygons with >60% caribou refuge habitat in caribou zone.	**Plan Start (%)**	Maintain min. OLT projected SRNV percentage for caribou refuge habitat pattern (as below). **Desirable %**		Move towards desirable level.	**Target: Percentage**	**Term**	**Percentage**	**Term**	**Percentage**	Spatial assessment shows 1% movement towards the desirable level for analysis at the 6,000 ha scale. The second analysis shows 1% movement away from the desirable level which is not considered significant. There is clean-up occurring in four caribou blocks which accounts for the reduction in refuge habitat at the 300 km2 scale. Overall target assessed as **ACHIEVED** in this plan period.
Scale: 6,000 ha hexagon	36%	87%			37%	n/a	n/a	n/a	n/a	
Scale: 30,000 ha hexagon	25%	92%			24%	n/a	n/a	n/a	n/a	
(3c) % of polygons with >60% caribou winter habitat in caribou zone.	**Plan Start (%)**	Maintain min. OLT projected SRNV percentage for caribou winter habitat pattern (as below). **Desirable %**		Move towards desirable level.	**Target: Percentage**	**Term**	**Percentage**	**Term**	**Percentage**	Spatial assessment shows movement towards desirable level for analysis at the 6,000 ha scale. Second analysis shows no movement away from the Plan Start 0% level (constant). Overall target assessed as **ACHIEVED** in this plan period.
Scale: 6,000 ha hexagon	0%	45%			4%	n/a	n/a	n/a	n/a	
Scale: 30,000 ha hexagon	0%	40%			0%	n/a	n/a	n/a	n/a	
(3d) Landscape pattern - interior, Marten Core Habitat	Year 2012: 4.9% of 676,469 ha. capable habitat in suitable conditions in core areas.	10-20% of capable Marten habitat area in suitable conditions in core areas of 3,000 to 5,000 ha.		10-20% of capable Marten habitat area in suitable conditions in core areas of greater than 1,000 ha moving towards the desirable level measured in 2072.	4.9% (same as Plan Start as is measured at 20 year term intervals)	**Target is Medium-term**: Over next 60 years, achievement is: 4.9% for Plan Start (2012), 8.6% for Year 20, 9.0% for Year 40, and 9.1% for Year 60. Preliminary assessment indicates that the min. target 10% should be available in 60-80 years.				Marten cores were developed to meet guideline levels and to incorporate the best concentrations of suitable habitat, spatially distributed across the forest for the next 60 years. The Whiskey Jack Forest currently lacks sufficient concentrations of conifer forest to meet the desirable level. The target level is expected to be **ACHIEVED** in 60-80 years based on preliminary assessment of projected suitable marten habitat.
Management Objective:	**4. Wood Supply:** To provide a predictable and continuous supply of wood products to the forest products industry from the management unit.				**CFSA Category:**	**Social and Economic** - Long-term harvest levels			**Source:** 4a, 4b: FMPM 4c: optional, Planning Team, previous FMPs	
Long-term projected available harvest area and volume, by species group **(4a) Long-term projected available harvest area**	**Average Ha/Year** 5,483 ha	Maintain an average total harvest area above 4,100 hectares per year.	- Completion of proposed LTMD	Same as desirable level.	Term 2: 4,431 ha/year.	4,117 - 4,775 ha/year.	**Target is Long-term: 4,111 - 4,601 ha/year.**		Long-term desirable level and target level for annual available harvest area **ACHIEVED.**	
(4b) Long-term projected available harvest volume by species group	**Annual Harvest Volume (m3)**	Achieve highest possible long-term harvest volumes while maintaining a balance of objective achievement reported by species group.	- Completion of proposed LTMD	Same as desirable level.	**m3/year**	**m3/year**	**Target is Long-term:**		Long-term desirable level and target level for annual available harvest volumes **ACHIEVED.** Sustainable, predictable harvest volumes projected. SPF and PO species groups were considered a higher priority than volume by other species groups or total volumes.

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 to March 31, 2022

FMP-9 ASSESSMENT OF OBJECTIVE ACHIEVEMENT

SFMM data based on scenario 27d_OLTMS.cas

Management Objective:					CFSA Category:					Source:
Indicator / Measure(s)	Plan Start Level	Desirable Level	Timing of Assessment	Target	LTMD - Projected Achievement: Short-term (10 years)	Medium-term (20-70 years)		Long-term (80-100 years)		Assessment
(4c) Short-term projected harvest volume per year	**Annual Harvest Volume (m3)** 574,600 m3	Maintain harvest volume (all species combined) at or above 510,000 m3 per year for this plan (2012-2022).	- Completion of proposed LTMD	Same as desirable level.	**Target:** 574,600 m3/yr	n/a	n/a	n/a	n/a	Term 1 desirable and target harvest volume levels were **ACHIEVED** in this plan period.
Management Objective:	**6. Aboriginal Involvement:** To work with local Aboriginal peoples, whose communities are situated in or adjacent to the management unit, to identify and implement forest operations (harvest, access, renewal, maintenance and protection) that will maintain or enhance social and economic benefits to Aboriginal peoples.				**CFSA Category:**	**Social and Economic** - Involvement in forest management planning				**Source:** 6a, 6b: FMPM
Opportunities for involvement provided to, and involvement of Aboriginal Communities in the plan development process. **(6a) Representation on the Planning Team**	n/a	Five Aboriginal Communities located in or adjacent to the WJF with representation on the planning team, measured during plan development.	- Draft Plan (FMP-9)	Same as desirable level.	**Target:** Five communities have identified representatives to the Planning Team.	n/a	n/a	n/a	n/a	Five communities assigned a representative to the planning team. Participation at planning team meetings and information centres varied based upon each representatives schedule and availability. Desirable and target levels **ACHIEVED** during the target timeframe of plan development.
(6b) Aboriginal Communities that contribute information to the planning process (e.g. to a tailored consultation process, Values Maps, the Aboriginal Background Information Report, Report on the Protection of Identified Aboriginal Values).	n/a	Five Aboriginal Communities located in or adjacent to the WJF that contribute information to the planning process, measured during plan development.	- Draft Plan (FMP-9)	Same as desirable level.	**Target:** Three communities contributed information to the planning process.	n/a	n/a	n/a	n/a	Three communities accepted the offer to review detailed operational plans at the LTMD stage and community information sessions were held. The Aboriginal Background reports were available for review by community members at the information sessions. Desirable and target levels **NOT ACHIEVED** during the target timeframe of plan development.
Management Objective:	**7. LCC Involvement:** To have the Local Citizens Committee effectively participate in the development of the FMP.				**CFSA Category:**	**Social and Economic** - Involvement in forest management planning				**Source:** 7a: FMPM
(7a) Local citizens committee's self-evaluation of its effectiveness in plan development.	n/a	LCC Effectiveness survey results indicate a minimum of 60-80% effectiveness in the development of the FMP.	- Draft Plan (FMP-9)	Same as desirable level.	**Target:** Overall result of the LCC survey was 82%.	n/a	n/a	n/a	n/a	**ACHIEVED**. Overall, the LCC members indicated a very good level of involvement and effectiveness during FMP development with 82% positive response.

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 to March 31, 2022

FMP-9 ASSESSMENT OF OBJECTIVE ACHIEVEMENT

SFMM data based on scenario 27d_OLTMS.cas

Management Objective:					CFSA Category:			Source:
Indicator / Measure(s)	Plan Start Level	Desirable Level	Timing of Assessment	Target	LTMD - Projected Achievement: Short-term (10 years)	Medium-term (20-70 years)	Long-term (80-100 years)	Assessment

The Following Indicators Are Measured After Implementation of the Forest Management Plan:

Management Objective:	3. Wildlife Habitat: To maintain forest function for wildlife habitat in the management unit.				CFSA Category: Silviculture, Forest Diversity, and Provision of Forest Cover - Habitat for animal life	Source: 3e, 3f: Endangered Species Act, CCP
(3e) % of conifer dominated forest units in the caribou zone. Forest Unit Proportion:		Maintain or increase percentage of specific conifer dominated forest units in the caribou zone.	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years). **FUTURE** assessment by forest unit based on actual harvest and forest inventory updates during plan period. Assessment: This indicator is calculated from an updated Base Model Inventory. In the caribou zone, total productive forest area of targeted conifer forest units (only PJD, PJM, SBL, SPD and SPM forest units) divided by the total productive area, expressed as a percentage. Information is reported by forest unit, but indicator is for combined total percentage of the targeted forest units in the caribou zone (not individually).	
PJD	33%					
PJM	11%					
SBL	3%					
SPD	21%					
SPM	7%					
Total for Targeted Forest Units:	75%					
(3f) % jack pine and spruce species composition by forest unit in the caribou zone. Proportion of PJ/SB/SW:		Maintain or increase percentage of jack pine and spruce species composition in the caribou zone.	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years) for reporting but assessment continues through long-term through future plan periods. **FUTURE** assessment by stand level conifer species composition based on actual harvest and forest inventory updates during plan period. Assessment: Forest composition to be derived using the Base Model Inventory with the species composition string parsed out. Indicator calculated for only PJD, PJM, SBL, SPD and SPM forest units within the caribou zone: the combined species composition percentage for jack pine, black spruce and white spruce (only) is calculated, based on the area weighted average tree species composition by forest unit.	
PJD	97%					
PJM	92%					
SBL	95%					
SPD	92%					
SPM	89%					

Management Objective:	4. Wood Supply: To provide a predictable and continuous supply of wood products to the forest products industry from the management unit.				CFSA Category: Social and Economic - Planned harvest levels - Community well-being	Source: 4e, 4f: FMPM
(4d) Actual harvest area, by forest unit (% of planned harvest area) **Forest Unit:**		Minimum % of the planned harvest area by forest unit actually harvested the 10-year plan period (2012-2022) based on FMP-11.	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years). **FUTURE** assessment based on actual harvest levels during plan period. NOTE: Planned harvest area includes internal areas to be left unharvested during operations (inoperable, residual, etc.) therefore the desired and target levels for actual harvest area reflect the anticipated reductions for unharvested areas for each forest unit.	
BFM	n/a	80 - 100%				
CMX	n/a	90 - 100%				
HMX	n/a	90 - 100%				
OCL	n/a	n/a (no AHA area)				
OTH	n/a	n/a (no AHA area)				
PJD	n/a	80 - 100%				
PJM	n/a	80 - 100%				
POD	n/a	90 - 100%				
PRW	n/a	80 - 100%				
SBL	n/a	80 - 100%				
SPD	n/a	80 - 100%				
SPM	n/a	80 - 100%				
(4e) Actual harvest volume, by species group (% of planned harvest volume) Volume Species Group:	n/a	% of the planned harvest volume by species group actually harvested during the 10-year plan period (2012-2022) based on FMP-13.	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years). **FUTURE** assessment based on actual harvest volumes during plan period.

Poplar		min. 90%				
White Birch		min. 80%				
Red Pine - White Pine		min. 80%				

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 to March 31, 2022

FMP-9 ASSESSMENT OF OBJECTIVE ACHIEVEMENT

SFMM data based on scenario 27d_OLTMS.cas

Management Objective:					CFSA Category:			Source:
Indicator / Measure(s)	Plan Start Level	Desirable Level	Timing of Assessment	Target	LTMD - Projected Achievement: Short-term (10 years)	Medium-term (20-70 years)	Long-term (80-100 years)	Assessment
Management Objective:	**5. Managed Crown Forest:** To provide continuous social benefits resulting from the managed Crown forest available for timber production on the management unit.				**CFSA Category:** Social and Economic - Harvest levels - Community well-being			**Source:** 5a: FMPM
(5a) Managed Crown forest available for timber production	572,035 ha.	Maintain a minimum of 570,000 ha of Managed, Crown forest available for timber production.	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Long-term (100 years). **FUTURE** assessment at completion of 10-year plan period based on updated Base Model Inventory based on updated Planning Inventory (e.g. actual depletions, non-productive areas, FTG survey results, etc.) and added forecasts and estimated reserves included for the BMI.			
Management Objective:	**8. Road Access:** To provide road-based access, land use and recreational opportunities through road maintenance and development of access to areas planned for harvest and renewal within the plan period.				**CFSA Category:** Social and Economic - Community well-being			**Source:** 8a: FMPM Endangered Species Act, CCP.
(8a) Kilometres of SFL road per square kilometre of Crown forest	**Non-caribou Zone:** 0.11 km SFL road per km2 productive forest	Maintain SFL primary and branch forest access road density in the non-caribou zone at a minimum of 0.11 km/km2 productive Crown area.	- Year 7 and Year 10 Annual Reports	Same as desirable level measured at Plan End 2022.	**FUTURE** assessment based on actual primary and branch road construction program and decommissioning measured after completion of 10-year plan period. (The degree to which individual roads contribute to this objective will be subject to MNR. District Land Use Guidelines and Fisheries Management Plan direction and the road decommisioning strategy).			
	Caribou Zone: 0.12 km SFL road per km2 productive forest	Maintain SFL primary and branch forest access road density in the caribou zone at a maximum of 0.13 km/km2 productive Crown area.						
Management Objective:	**9. Forest Renewal:** To successfully regenerate harvest areas to Free-Growing status in a manner that is consistent with the regeneration standards outlined in the Silvicultural Ground Rules.				**CFSA Category:** Silviculture			**Source:** 9a, 9b, 9c: FMPM
(9a) Regeneration Success: Percent of Harvested Forest Area Assessed as Free-Growing by Forest Unit	n/a	minimum of 95% of harvest area successfully regenerated to free-growing status within 10 years of harvest.	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years). **FUTURE** assessment based on actual renewal achievements during plan period. How to measure: - Identify Ha harvested by term from previous Annual Report and year 7/10 Annual Reports, identify Ha declared successfully regenerated by term and determine % success by Forest Unit, compare to target % by Forest Unit			
(9b) Silviculture Intensity: Planned and Actual Percent of Harvested Area Treated by Silvicultural Intensity	n/a	minimum of 80% of area treated by planned silvicultural treatment intensity for each 5-year plan term (2012-2017, 2017-2022).	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years). **FUTURE** assessment based on actual renewal achievements during plan period. How to measure: - Planned (target): Identify silvicultural intensity for planned harvest areas by term from composite plan inventory, express as percent of total harvest area - Actual: Identify Ha treated by silvicultural intensity from Annual reports and express as percent of total harvest area.			
(9c) Silvicultural Success: Planned and Actual Percent of Harvested Forest Area Assessed as Free-Growing and Successfully Regenerated to the Projected Forest Unit	n/a	70-100% of harvest area successfully regenerated to free-growing status and to the projected forest units within 10 years of harvest.	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years). **FUTURE** assessment based on actual renewal achievements during plan period. How to measure: - Planned (target): percentages used in strategic modelling by FU - Actual: Identify Ha harvested by term by FU from previous Annual Reports and year 7/10 Annual Reports, identify Ha declared successfully regenerated by term and FU and determine % of harvested area by Forest Unit, Compare to planned rates by FU.			
Management Objective:	**10. Forest Values:** To implement forestry operations in a manner that minimizes negative impacts on all identified resource users, and protects all identified values.				**CFSA Category:** Ecological Sustainability - Healthy forest ecosystems			**Source:** 10a: FMPM
(10a) % of forest operation inspections in non-compliance, by activity and remedy type (i.e. severity).	n/a	Maximum 5% of forest inspections reported in non-compliance reported for each 5-year plan term (2012-2017, 2017-2022).	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years). **FUTURE** assessment based on actual compliance levels during plan period.			

MANAGEMENT UNIT NAME: Whiskey Jack Forest
PLAN PERIOD: April 1, 2012 to March 31, 2022

FMP-9 ASSESSMENT OF OBJECTIVE ACHIEVEMENT

SFMM data based on scenario 27d_OLTMS.cas

Management Objective:					CFSA Category:			Source:
Indicator / Measure(s)	Plan Start Level	Desirable Level	Timing of Assessment	Target	LTMD - Projected Achievement: Short-term (10 years)	Medium-term (20-70 years)	Long-term (80-100 years)	Assessment
Management Objective:	**11. Soil and Water Resources:** To maintain productivity of soil function, and to protect water quality and fisheries habitat where forest management activities occur in the Forest.				**CFSA Category:**	**Ecological Sustainability** - Healthy forest ecosystems		**Source:** 11a, 11b: FMPM
(11a) % of forest operations inspections in non-conpliance with management practices that prevent, minimize or mitigate site damage (by remedy type)	n/a	Max. 5% of inspections related to prescriptions in the FMP that were developed using the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* reported as not in compliance.	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years). **FUTURE** assessment based on actual compliance levels during plan period.			
(11b) % of forest operations inspections in non-compliance with prescriptions developed for the protection of water quality and fish habitat (by remedy type)	n/a	Max. 5% of inspections related to water quality and fish habitat protection prescriptions not in compliance.	- Year 7 and Year 10 Annual Reports	Same as desirable level.	Target year is Short-term (10 years). **FUTURE** assessment based on actual compliance levels during plan period.

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value

List of AOCs in order of appearance in this table:

A01	Archaeological Potential Area
D01	Occupied black bear dens
D02	Occupied grey fox dens
D03	Occupied cougar dens
D04	Wolf dens
D05	Wolverine dens
M01	Mineral licks
N01	Bald eagle - primary nests - Identified Prior to Operations
N02	Bald eagle - alternate nests
N03	Bald eagle - inactive nests
N04	Bald Eagle Primary Nest - Discovered During Operations
ON01	Osprey - primary nests - Identified Prior to Operations
ON02	Osprey - alternate nests
ON03	Osprey - inactive nests
ON04	Primary Osprey Nest - Discovered During Operations
BH01	Active Great Blue Heron colonies
BH02	Inactive Great Blue Heron colonies
BG01	Active colonies of Bonaparte's gull
BS01	Active large colonies of bank swallows (≥100 pairs)
BS02	Barn Swallow Nests
HO01	Primary nests of great grey owl, northern goshawk, or red-shouldered hawk
HO02	Alternate nests of great grey owl, northern goshawk, or red-shouldered hawk
NO01	Stick nests occupied by barred owl, broad-winged hawk, common raven, Cooper's hawk, great horned owl, long-eared owl, merlin, red-tailed hawk, or sharp-shinned hawk.
NO02	Nests/ communal roosts in cavities occupied by American kestrel, barred owl, boreal owl, eastern screech-owl, great horned owl, northern hawk owl, northern saw-whet owl or chimney swift.
NO03	Ground nests occupied by northern harrier, short-eared owl, or turkey vulture
NO04	Whip-poor-will nest sites
NO05	Common nighthawk nest sites
NO06	Olive-sided flycatcher nest sites

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value
NO07	**Canada warbler nest sites**
NO08	**Bat Hibernacula** known to be suitable and to have been used at least once within the past 20 years by ≥ 50 **Little Brown Myotis** (Little Brown Bats) or ≥ 20 **Northern Myotis** (Northern long-eared bats)
PGP01	**FESC PGP G&Y Trial Plot**
PL01	**Patent Land**
RR01	**Railroad Right of Way**
NG01	**Natural Gas Transmission Pipeline**
HB01	**Highway Corridor Aesthetics**
LS01	**Tourism – Lac Seul Shoreline (Remoteness, aesthetics, fisheries, water quality, cultural heritage)**
TV01	**Tourism – Aesthetics Along Large High Volume Tourism Lakes, recognized canoe routes, recreational lakes**
TVgl	**Tourism- Gibi Lake**
TVnsl	**Tourism- North Star Lodge**
TVw	**Tourism – timing restriction**
TVwl	**Tourism – Wine Lake**
TVal	**Tourism – Aerobus Lake**
TVer	**Tourism – English River Waterway Park**
TVp	**Tourism - portage**
TVc	**Tourism - campsite**
WL01	**Large lakes, Medium lakes, Small lakes, Ponds - high or moderate potential sensitivity (HPS or MPS) to forest management operations**
WL02	**Ponds – low potential sensitivity (LPS) to forest management operations**
WS01	**Rivers, Stream segments -high or moderate potential sensitivity (HPS or MPS) to forest management operations**
WS02	**Stream segments -low potential sensitivity (LPS) to forest management operations**
WW01	**Wetlands occupied by breeding black terns, golden-winged warblers, least bitterns, or yellow rails**
WW02	**Woodland pools known to support flooded jellyskin**
FL01	**First Nation Reserve Land**
NE9	**Trumpeter Swan Nesting Site**
NE10	**Snapping Turtle nesting Site**

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
A01	**Archaeological Potential Area** Identified on the final archaeolgical potential area map Secondary Value (when water crossing is involved): Lakes, ponds, streams, rivers– high, moderate or low potential sensitivity (HPS, MPS, LPS) to forest management operations	Group	Forest Management Guide for Cultural Heritage Values (*MNR 2006)* pp. 33-35	No	Yes. See FMP-19	Yes	No aggregate extraction is permitted. No new aggregate pits are permitted.

Operational Prescription

Within each mapped area on operational maps one of the following will be done:

- a reserve

OR

- operations where the harvest, skidding, and renewal activities do not cause more than 5% mineral soil disturbance (on a weighted average basis) within the harvested portion of the area of concern within the block.
- Skid trails will minimize the skid distance out of the area of concern and sharp corners will be avoided.

OR

- Within blowdown areas the mineral soil disturbance (weighted average) may exceed 5% within the area of concern. Root mats are to be put back into place wherever possible,

OR

- If a Ministry of Culture Stage 2 archaeological assessment is completed, nothing is found and the recommendation is that no further archaeological works is required and Ministry of Culture has reviewed the report THEN regular operations can proceed in the assessed area. Copies of any archaeological assessment reports will be provided to the MNR area forester and provincial cultural heritage specialist.

If the protection measures for an area of archaeological potential are not complied with, operations must immediately cease within the area of concern and a Stage 2 archaeological assessment per Ministry of Culture's current standards and guidelines for consultant archaeologists shall occur.

If a cultural heritage value is discovered during operations (e.g. an arrowhead, cemetery, or old logging camp) then operations must immediately stop and the district MNR staff will be contacted as per the Forest Information Manual. The value class of the discovery will determine who of the following will be contacted: Ministry of Culture staff, the local Aboriginal community, Registrar of Cemeteries, and/or the provincial cultural heritage specialist. When the class of cultural heritage value is established, the appropriate protection measure(s) will be applied.

When human remains are discovered, work at the site must be suspended and the police notified. It is also appropriate to notify the MNR district staff. The police will investigate the report to determine if the human remains are of forensic interest or represent a burial site as defined by the *Cemeteries Act*. All involved parties must act to safeguard the location until the police attend the site, and to limit media contact or display.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
D01	**Occupied black bear dens**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010),* Pages 94-95.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Operational Prescription

- 100 m radius AOC centred on the den entrance.

Regular harvest, renewal, and tending operations are permitted within the AOC subject to timing restrictions during the denning period(see below).

October 15 to April 30 (Denning Period)

- Harvest, renewal, and tending operations involving heavy equipment are not permitted within the AOC.
- The only operations permitted during the first four weeks of the denning period (October 15 to November 15) are boundary marking and regeneration surveys with no ATV use. Harvest, renewal and tending operations that do not involve heavy equipment are permitted after November 15.

D02	**Occupied grey fox dens**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010),* Page 95.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Operational Prescription

- 100 m radius AOC centred on the den entrance.

April 15 to September 15 (Denning Period)
Harvest, renewal, and tending operations are not permitted within the AOC during the denning period.

September 16 to April 14 (Not Denning Period)
Regular harvest, renewal, and tending operations are permitted within the AOC outside the denning period and are subject to the general direction for the protection of dens of furbearing mammals (Plan text Section 4.2.2.2 Conditions on Regular Operations).

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
D03	**Occupied cougar dens**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010),* Page95-96.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Operational Prescription

- 200 m radius AOC centred on the den entrance.

Denning Period (see below)
Harvest, renewal, and tending operations are not permitted within the AOC during the denning period.

Kittens are typically born between April and September, but occupied dens may be located at any time of year. Thus, the denning period is potentially different for each occupied den encountered and is considered to extend for 8 weeks from the date an occupied den is located, or until a den is known to be no longer occupied.

Not Denning Period
Regular harvest, renewal, and tending operations are permitted within the AOC outside the denning period and are subject to the general direction for the protection of dens of furbearing mammals (Plan text Section 4.2.2.2 Conditions on Regular Operations).

D04	**Wolf dens**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010),* Pages 96-97.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Operational Prescription

- 200 m radius AOC centred on the den entrance.

0–100 m from den entrance
Harvest operations are not permitted.

If required, renewal and tending operations are allowed outside of the denning period (July 16-April 14) subject to wildlife trees and downed woody material requirements (plan text Section 4.2.2.2). Renewal and tending activities that reduce the mature forest to<60% relatively uniform canopy closure (canopy openings not to exceed individual tree crowns) are not permitted. All other renewal and tending operations are permitted.

101-200 m from den entrance, April 15-July 15 (Denning Period):
Harvest, renewal, and tending operations are not permitted.

101-200 m from den entrance, July 16-April 14 (Outside of Denning Period):
Harvest, renewal or tending operations permitted subject to residual pattern, wildlife trees and downed woody debris requirements (Plan text Section 4.2.2.2).

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
D05	**Wolverine dens**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010)* Page 127	No	No crossings or landings permitted in the AOC.	Yes	Yes
Operational Prescription • 4 km radius AOC centered on the den entrance. • No harvest, renewal and tending operations permitted within the AOC. • If a wolverine den is encountered during operations all operations will stop within a 4km radius AOC and the Kenora District Office MNR will be immediately notified of the presence of a wolverine den in proximity to forest operations. • No further harvest, renewal or tending activities are permitted within the AOC. • The FMP may be amended following the above by developing a new AOC in consultation with MNR biologists that includes a den site management plan for the specific location and in consideration of the following: o The specific dimensions of the wolverine den AOC; o Normally harvest, renewal and tending operations will be prohibited in the AOC, however, some operations may be permitted to meet ecological, social or economic objectives. Where operations will be permitted the AOC will outline the extent and timing of any harvest, renewal and tending operations; o Denning generally occurs between February and May when snow depth is usually at its greatest. • Reasonable efforts will be made to incorporate the AOC into a large block of unharvested and unroaded forest (i.e. marten core, caribou block).						
M01	**Mineral licks** (natural mineral licks known or encountered during operations. Excludes mineral licks created by salt accumulation along roadways)	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010),* Page 93.	No	No crossings or landings permitted in the AOC.	Yes	Yes
Operational Prescription • 120 m radius AOC measured from the edge of woody vegetation averaging at least 2 m tall and with ≥25% canopy cover. No harvest, renewal, or tending operations are permitted within the AOC.							
N01	**Bald eagle primary nests** (see definition below) **Identified Prior to Operations**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010),* Pages 64-66.	No	No	Yes	Yes
Bald Eagle Primary Nests (AOC N01) are nests known or suspected to have been occupied at least once within the past 5 years (i.e., active nests), unless the nest and all associated nests within the nesting area have been documented as unoccupied for ≥3 consecutive years, in which case the nest is considered **inactive** (see AOC N03). When ≥2 active nests occur in sufficiently close proximity to be considered part of the nesting area of an individual pair, the nest with the most recent known or suspected history of occupancy within this nesting area is the **primary nest** (AOC N01); the other active nest(s) is (are) considered **alternate nests** (AOC N02).							

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions

Operational Prescription

- 400 m radius AOC centred on primary nests.
- The critical breeding period for bald eagles is February 15 to August 31.

BALD EAGLE NEST IDENTIFIED PRIOR TO OPERATIONS:

0-200 m from primary nest

Critical breeding period and the nest is occupied:

- Harvest is not permitted within 200 m of a primary nest.
- No renewal and tending operations are permitted within 100 m of a primary nest.
- Only "low potential impact" renewal and tending activities (see Table FMP-10.1) are allowed 100-200 m from the nest in previously harvested areas.
- All renewal and tending operations within 100-200 metres of the nest are subject to wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2.
- Preferentially retain wildlife trees that may function as potential nest, perch or roost sites based on the following order of priority: 1) supercanopy trees, 2) veteran trees, 3) cavity trees, and 4) other live dominant or co-dominant trees that are windfirm. White pines, red pines, and poplars will be favoured when available.
- Renewal and tending operations that will leave a residual stand structure below the minimum described above are not permitted.

Critical breeding period and nest is not occupied, or outside of critical breeding period:

- Harvest is not permitted within 200 m of a primary nest.
- All renewal and tending operations are subject to wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2.
- Preferentially retain wildlife trees that may function as potential nest, perch or roost sites based on the following order of priority: 1) supercanopy trees, 2) veteran trees, 3) cavity trees, and 4) other live dominant or co-dominant trees that are windfirm. White pines, red pines, and poplars will be favoured when available.
- Renewal and tending operations that will leave a residual stand structure below the prescribed minimum (see text Section 4.2.2.2) are not permitted.

201-400 m from primary nest

Harvest, renewal and tending operations that will leave a residual stand structure below the minimum described below are not permitted.

Critical breeding period and the nest is occupied: Harvest and renewal and tending operations that are within the "high potential impact" category (see Table FMP-10.1) are not permitted within 201-400 m of occupied primary nests during the critical breeding period. Operations categorized in Table FMP-10.1 as "low potential impact" or "moderate potential impact" are allowed between 201-400 m of occupied primary nests during the critical breeding period subject to wildlife tree and downed woody material requirements outlined in FMP text Section 4.2.2.2.

Critical breeding period and nest is not occupied, or outside of critical breeding period: Harvest, renewal or tending operations are permitted subject to residual pattern (see note 2 above) and wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2. Preferentially retain wildlife trees that may function as potential nest, perch and roost sites based on the following order of priority: 1) supercanopy trees, 2) veteran trees, 3) cavity trees, and 4) other live dominant or co-dominant trees that are windfirm. White pines, red pines, and poplars will be favoured when available.

See AOC N04 for the area of concern prescription for bald eagle nests discovered during operations but after harvesting has occurred within 200 m of the nest.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
N02	**Bald eagle alternate nests** (see definition below)	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010),* Page 66.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Bald Eagle Alternate Nests (AOC N02) are nests known or suspected to have been occupied at least once within the past 5 years that are not primary nests (AOC N01), unless the nest and all associated nests within the nesting area have been documented as unoccupied for ≥3 consecutive years, in which case the nest is considered **inactive** (see AOC N03).

Operational Prescription
- 200 m radius AOC centred on alternate nests.

0-200 m from nest
No harvest is permitted. If harvest that retains <60% relatively uniform canopy closure occurs within 200m of an alternate nest prior to its discovery, an additional patch of unharvested forest equivalent to the area harvested will be retained, preferably attached to the remaining unharvested forest surrounding the nest (to provide a supply of potential nest and roost trees). Renewal and tending are permitted in previously harvested areas subject to wildlife tree and downed woody material requirements outlined in FMP text Section 4.2.2.2.

N03	**Bald eagle inactive nests** (see definition below)	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010),* Page 67.	No	Nonew crossings or landings permitted in the AOC, existing crossing 002.	Yes	Yes

Bald Eagle Inactive Nests (AOC N03) are nests not known or suspected to have been occupied at least once within the past 5 years, and primary and alternate nests within nesting areas where all nests within the nesting area have been documented as unoccupied for >=3 consecutive years.

Operational Prescription
- 100 m radius AOC centred on inactive nests.

0-100 m from nest
Harvest is not permitted in the AOC.
Renewal and tending are permitted in previously harvested areas subject to wildlife tree and downed woody material requirements outlined in FMP text Section 4.2.2.2.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
N04	**Bald Eagle Primary Nest Discovered During Operations**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010), Pages 64-66.*	No	No crossings or landings permitted in the AOC.	Yes	Yes

Operational Prescription

- 400 m radius AOC centred on primary nests.
- The critical breeding period for bald eagles is February 15 to August 31.

BALD EAGLE NEST DISCOVERED DURING OPERATIONS BUT AFTER HARVEST HAS OCCURRED WITHIN 200 METRES OF NEST:

0-200 m from primary nest

If harvesting operations are on-going, harvesting is to stop immediately and no further harvesting is permitted. Harvested trees remaining in the harvested area are not permitted to be removed during the critical breeding period. An additional patch of unharvested forest equivalent to the area harvested between 0-200 m from the nest is to be retained within 201-400 m of the nest. This patch will preferably be attached to the remaining unharvested forest.

If the nest is not occupied, or it is outside of the critical breeding period, renewal and tending activities are permitted as long as no standing trees are knocked over and the renewal and tending operations are subject to wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2.

If the nest is occupied and it is during the critical breeding period:

- No renewal and tending operations are permitted within 100 m of a primary nest.
- Only "low potential impact" renewal and tending activities (see Table FMP-10.1) are allowed 100-200 m from the nest in previously harvested areas.
- All renewal and tending operations within 100-200 metres of the nest are subject to wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2.

201-400 m from primary nest (*outside of additional patch described above*)

Harvest, renewal and tending operations that will leave a residual stand structure below the minimum described in Section 4.2.2.2 are not permitted.

Critical breeding period and the nest is occupied: Harvest and renewal and tending operations that are within the "high potential impact" category (see Table FMP-10.1) are not permitted within 201-400 m of occupied primary nests during the critical breeding period, Operations categorized in Table FMP-10.1 as "low potential impact" or "moderate potential impact" are allowed between 201-400 m of occupied primary nests during the critical breeding period subject to residual pattern (see Note 2 above) and wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2.

Critical breeding period and nest is not occupied, or outside of critical breeding period: Harvest, renewal or tending operations are permitted subject to residual pattern (see Note 2 above) and wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2. Preferentially retain wildlife trees that may function as potential nest, perch or roost sites based on the following order of priority: 1) supercanopy trees, 2) veteran trees, 3) cavity trees, and 4) other live dominant or co-dominant trees that are windfirm. White pines, red pines, and poplars will be favoured when available.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
ON01	**Osprey primary nests** (see definition below) **Identified Prior to Operations**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010)*, Pages 68-69.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Osprey Primary Nests (AOC ON01)are nests known or suspected to have been occupied at least once within the past 5 years (i.e., active nests), unless the nest and all associated nests within the nesting area have been documented as unoccupied for ≥3 consecutive years, in which case the nest is considered **inactive** (AOC ON03). When ≥2 active nests occur in sufficiently close proximity to be considered part of the nesting area of an individual pair, the nest with the most recent known or suspected history of occupancy within this nesting area is the **primary nest** (AOC ON01); the other active nest(s) is(are) considered **alternate nests** (AOC ON02).

Operational Prescription

- 300 m radius AOC centred on primary nests.
- The critical breeding period for osprey is April 15 to August 31.

OSPREY NEST IDENTIFIED PRIOR TO OPERATIONS:

0-150 m from nest
Harvest is not permitted at any time.
If the nest is not occupied, or it is outside of the critical breeding period:

- Renewal and tending activities are permitted in previously harvested areas subject to wildlife tree and downed woody material requirements outlined in FMP text Section 4.2.2.2.

If the nest is occupied and it is during the critical breeding period:

- Only "low potential impact" renewal and tending activities (see Table FMP-10.1) are allowed 75-150 m from the nest in previously harvested areas.
- All renewal and tending operations within 75-150 metres of the nest are subject to residual pattern (see Note 2 above) and wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2.

151-300 m from nest
Harvest, renewal and tending operations that will leave a residual stand structure below the minimum described below are not permitted.

Critical breeding period and nest is occupied: Harvest and renewal and tending operations that are within the "high potential impact" category (see Table FMP-10.1) are not permitted within 151-300 m of occupied primary nests during the critical breeding period, Renewal and tending operations categorized as "low potential impact" or "moderate potential impact" are allowed between 151-300 m of occupied primary nests during the critical breeding period subject to meeting wildlife trees and downed woody material requirements outlined in Section 4.2.2.2 of the FMP.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**

Operational Prescription

- 300 m radius AOC centred on primary nests.
- The critical breeding period for osprey is April 15 to August 31.

OSPREY NEST DISCOVERED DURING OPERATIONS BUT AFTER HARVEST HAS OCCURRED WITHIN 150 METRES OF NEST:

0-150 m from nest

If harvesting operations are on-going, harvesting is to stop immediately and no further harvesting is permitted. Harvested trees remaining in the harvested area are not permitted to be removed during the critical breeding period. An additional patch of unharvested forest equivalent to the area harvested between 0-150 m from the nest is to be retained within 151-300 m of the nest. This patch will preferably be attached to the remaining unharvested forest.

If the nest is not occupied, or it is outside of the critical breeding period:

- Renewal and tending activities are permitted in previously harvested areas subject to wildlife tree and downed woody material requirements outlined in FMP text Section 4.2.2.2.

If the nest is occupied and it is during the critical breeding period:

- Only "low potential impact" renewal and tending activities (see Table FMP-10.1) are allowed >75 metres from the nest in previously harvested areas.
- All renewal and tending operations are subject to wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2.

151-300 m from nest (*outside of additional patch described above*)

Harvest, renewal and tending operations that will leave a residual stand structure below the minimum described below are not permitted.

Critical breeding period and nest is occupied: Harvest and renewal and tending operations that are within the "high potential impact" category (see Table FMP-10.1) are not permitted within 151-300 m of occupied primary nests during the critical breeding period. Renewal and tending operations categorized as "low potential impact" or "moderate potential impact" are allowed between 151-300 m of occupied primary nests during the critical breeding period subject to meeting wildlife trees and downed woody material requirements outlined in Section 4.2.2.2 of the FMP.

Critical breeding period and nest is not occupied, or outside of critical breeding period:

Harvest, renewal and tending operations are permitted subject to residual pattern (see Note 2 above) and wildlife trees and downed woody material requirements outlined in Section 4.2.2.2 of the FMP. Preferentially retain wildlife trees that may function as potential nest, perch or roost sites based on the following order of priority: 1) supercanopy trees, 2) veteran trees, 3) cavity trees, and 4) other live dominant or co-dominant trees that are windfirm. White pines, red pines, and poplars will be favoured when available.

Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
BH01	**Active Great Blue Heron colonies** (see definition below)	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010),* Pages 73-74.	No	No new crossings or landings permitted in the AOC, existing crossing 001.	Yes	Yes

Active Great Blue Heron Colonies are defined as:

- Large heron colonies (≥4 occupied nests) known or suspected to have been occupied at least once within the past 10 years (unless documented as unoccupied for ≥5 years).
- Small heron colonies (<4 occupied nests) known or suspected to have been occupied at least once within the past 5 years (unless documented as unoccupied for ≥3 years).

Operational Prescription

- 300 m radius AOC measured from peripheral nests.
- The critical breeding period for great blue heron is April 1 to August 15.

<u>0-150 m from colony</u>

- No harvest is permitted.

Critical breeding period and nest is not occupied, or outside of critical breeding period:

- Renewal and tending activities are permitted in previously harvested areas subject to wildlife tree and downed woody material requirements outlined in FMP text Section 4.2.2.2.

Critical breeding period and the nest is occupied:

- Only "low potential impact" renewal and tending activities (see Table FMP-10.1) are allowed >75-150 metres from the nest in previously harvested areas.
- All renewal and tending operations within 75-150 metres of the nest are subject to wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2.

<u>151-300 m from colony</u>

- For large colonies - no harvest is permitted.
- For small colonies - harvest, renewal and tending operations that will leave a residual stand structure below the minimum described below are not permitted.

Critical breeding period and the nests are occupied:

- No harvest is permitted within 151-300 m of occupied nests during the critical breeding period..
- Renewal and tending operations that are within the "high potential impact" category (see Table FMP-10.1) are not permitted within 151-300 m of occupied nests during the critical breeding period.
- Renewal and tending operations categorized as "low potential impact" or "moderate potential impact" are allowed between 151-300 m of occupied nests during the

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions

insufficient to determine which nest in a nesting area has been most recently occupied the nest in the best condition is considered the primary nest.

Operational Prescription

- 400 m radius AOC centred on primary nests.
- The critical breeding period for great grey owl, northern goshawk and red-shouldered hawk is March 15 to July 15.

Harvest, renewal and tending operations that will leave a residual stand structure below the minimum (described below and in Section 4.2.2.2) are not permitted.

0-300 m from primary nest

Critical Breeding Period and the nest is occupied:

- No harvest is permitted. If harvest occurred prior to discovery of the nest, see below.
- Renewal and tending operations that are within the "high potential impact" category (see Table FMP-10.1) are not permitted within 200 m of occupied primary nests. Renewal and tending operations categorized as "moderate potential impact" are not allowed within 100 m of occupied primary nests.
- Renewal and tending operations categorized as "low potential impact" are not allowed within 50 m of occupied primary nests.
- Wildlife trees and downed woody material requirements outlined in Section 4.2.2.2 of the FMP apply.

Outside of Critical Breeding Period; or Critical Breeding Period and the nest is not occupied:

- No harvest is permitted within 50m of a primary nest. If harvest occurred prior to discovery of the nest, see below.
- All renewal and tending operations are subject to wildlife trees and downed woody material requirements outlined in FMP text Section 4.2.2.2.
- A total of 28 ha of *suitable nesting habitat* will be retained within the AOC. 7 ha of the 28 ha of *suitable nesting habitat* will be retained within 200 m of the primary nest; any harvest will follow the residual stand structure targets for creation of old growth forest conditions the remaining 21 ha of *suitable nesting habitat* may be located anywhere within the AOC.
    - *Suitable nesting habitat* will be retained as a contiguous patch that encompasses the primary nest.
    - *Suitable nesting habitat* will be retained that is classified as *preferred* based on the regional habitat matrices.
    - *Suitable nesting habitat* will be retained as a circular patch centred on the primary nest (300 m radius circle) if the primary nest occurs in a large uniform block of habitat. *Suitable nesting habitat* will be retained as an irregularly-shaped patch (contained within the 400 m AOC) if this configuration better encompasses primary and alternate nests as well as preferred habitat.

If some harvest occurs within 300 m of a primary nest prior to its discovery, or if there are notable amounts of area within 300 m of the nest that are not suitable nesting habitat:

- Any harvest that occurs within 300m of a nest prior to its discovery is to stop immediately upon discovery of the nest and no further harvest is permitted. Harvested trees remaining in the harvested area are not permitted to be removed within 200 metres of the nest from during the critical breeding period.
- The 0-300 m part of the AOC will be extended to a maximum of 400 m from the nest (in an irregular shape) for a total retention of 28 ha of suitable nesting habitat.
- If any of the harvest occurred within 50 m of a primary nest prior to its discovery, the primary nest will be retained in a 0.8 ha unharvested patch that is as nearly circular as possible (to minimize edge).

300 – 400 m from nest (or outside of the additional 28 ha area, as above):

- Harvest, renewal or tending operations are permitted subject to residual pattern, wildlife trees and downed woody material requirements outlined in FMP Section 4.2.2.2.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
HO02	**Alternate nests of great grey owl, northern goshawk, or red-shouldered hawk** (see definition below)	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010)*, Pages 80-81.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Alternate nests (AOC HO02) are defined as nests known or suspected to have been occupied at least once within the past 5 years that are not primary nests (AOC HO01) unless the nest and all associated nests within the nesting area have been documented as unoccupied for ≥3 consecutive years, in which case the nest is considered **inactive** (AOC HO03). Any nest in good repair within 400m of primary nest.

Operational Prescription

- 50 m radius AOC centred on alternate nests.

Harvest is not permitted within the AOC. If harvest occurred prior to discovery of the nest, see below.

If some harvest occurs within 50 m of an alternate nest prior to its discovery:

- Harvest is to stop immediately upon discovery of the nest and no further harvest is permitted.
- The alternate nest will be retained in a 0.8 ha unharvested patch that is as nearly circular as possible (to minimize edge).

In previously harvested areas or areas harvested prior to discovery of the nest renewal and tending operations that kill or knock down any trees are not permitted; all other renewal and tending operations are permitted.

NO01	**Stick nests occupied by barred owl, broad-winged hawk, common raven, Cooper's hawk, great horned owl, long eared owl, merlin or red-tailed hawk**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010)*, Page 82.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Operational Prescription

- 50-200 m radius AOC as mapped centred on the occupied nest based on species as shown in Table A below:

Table A

Species	Radius of AOC
(a) Barred owl	200 m
(b) Broad-winged hawk	100 m
(c) Cooper's hawk	100 m
(d) Great horned owl	100 m
(e) Long-eared owl	100 m
(f) Red-tailed hawk	100 m
(g) Common raven	50 m
(h) Merlin	50 m
(i) Sharp-shinned hawk	50 m

Management Unit Name: Whiskey Jack Forest [X] Phase 1 (Year 1-5)
Plan Period: April 1, 2012 to March 31, 2022 [ ] Phase 2 (Year 6-10)

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions

Regular harvest, renewal, and tending operations are permitted around nests subject to timing restrictions (see Table C below) and retention of the nest tree as shown in Table B below:

Table B

Species	Retain
(a) Barred owl (c) Cooper's hawk (d) Great horned owl (e) Long-eared owl (f) Red-tailed hawk (g) Common raven	The nest tree will be retained in an unharvested residual patch (≥20 m radius) if the nest is in good repair (may be counted as residual forest). If the nest is in poor repair, the nest tree will be retained as a wildlife tree.
(b) Broad-winged hawk (h) Merlin (i) Sharp-shinned hawk	The nest tree will be retained as a wildlife tree if the nest is in good repair or the nest tree contains a good fork.

0-200 m of *occupied* nests during Critical Breeding Period

Harvest, renewal, and tending operations are not permitted within 10-200 m of *occupied* nests during the *critical breeding period* based on species and potential impact of the operation. Table C below shows the distance from a nest that high impact, moderate impact, or low impact operations are not allowed within, if the nest is occupied during the critical breeding period. Refer to Supplementary Table 10.1 for an explanation of which operations are high, moderate, or low impact.

Table C

Species	Critical Breeding Period	High Impact Operations	Moderate Impact Operations	Low Impact Operations
(a) Barred owl	March 15 – July 15	200 m	100 m	50 m
(b) Broad-winged hawk	April 1 – July 31	100 m	50 m	25 m
(c) Cooper's hawk	April 1 – July 31	100 m	50 m	25 m
(d) Great horned owl	February 1 – May 31	100 m	50 m	25 m
(e) Long-eared owl	March 15 – July 15	100 m	50 m	25 m
(f) Red-tailed hawk	March 15 – July 15	100 m	50 m	25 m
(g) Common raven	February 15 – June 15	50 m	25 m	10 m
(h) Merlin	April 1 – July 31	50 m	25 m	10 m
(i) Sharp-shinned hawk	April 1 – July 31	50 m	25 m	10 m

If the nest is not occupied during the Critical Breeding Period:
No timing restrictions on operations apply. Refer to Table B that describes the area to be retained around the nest.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions

0-100 m of *occupied* nests/communal roosts during Critical Breeding Period

Harvest, renewal, and tending operations are not permitted within 0-100 m of *occupied* nests/communal roosts during the *critical breeding/roosting period* based on species and potential impact of the operation (see Table C below). Table C below shows the distance from a nest that high impact, moderate impact, or low impact operations are not allowed within, if the nest is occupied during the critical breeding period. Refer to Table FMP-10.1 for an explanation of which operations are high, moderate, or low impact.

Table C

Species	Critical Breeding Period	High Impact Operations	Moderate Impact Operations	Low Impact Operations
(a) Barred owl	March 15 - July 15	100 m	50 m	25 m
(b) Great horned owl	February 1 – May 31	50 m	25 m	10 m
(c) Northern hawk owl	March 15 - July 15	50 m	25 m	10 m
(d) Chimney swift	May 1 – September 30	50 m	25 m	10 m
(e) American kestrel	April 1 – July 31	25 m	10 m	0 m
(f) Boreal owl	April 1 – July 31	25 m	10 m	0 m
(g) Eastern screech-owl	March 15 – July 15	25 m	10 m	0 m
(h) Northern saw-whet owl	March 15 – July 15	25 m	10 m	0 m

If the nest is not occupied during the Critical Breeding Period
No timing restrictions on operations apply. Refer to Table B that describes the area to be retained around the nest.

NO03	**Ground nests occupied by northern harrier, short-eared owl, or turkey vulture**	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010)*, Pages 87-88.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Operational Prescription

50-150 m AOC as mapped based on species as shown in Table A below:

Table A

Species	Radius of AOC
(a) Turkey vulture	150 m
(b) Short-eared owl	100 m
(c) Northern harrier	50 m

Regular harvest, renewal, and tending operations are permitted with timing restrictions (see Table B below).
Harvest, renewal, and tending operations are not permitted within 10-150 m of *occupied* nests during the *critical breeding period* based on species and potential impact of the operation as shown in Table B below:

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

Species	**Critical Breeding Period**	**High Impact Operations**	**Moderate Impact Operations**	**Low Impact Operations**
(a) Turkey vulture	May 1 – August 31	150 m	75 m	40 m
(b) Short-eared owl	March 15 – July 15	100 m	50 m	25 m
(c) Northern harrier	April 1 – July 31	50 m	25 m	10 m

NO04	**Whip-poor-will Nesting Sites**	Group	Supplementary Documentation H AOC's	No	No crossings or landings permitted in the AOC.	Yes	No new aggregate pits are permitted.

Operational Prescription

When the habitat description under the ESA becomes available these conditions may be updated prior to plan approval if this is necessary to address the habitat description. If the habitat description becomes available after final plan approval, a plan amendment for this AOC may be submitted if necessary to address the habitat description.

- 200 m radius AOC centred on nesting sites identified in NRVIS or encountered by field operations. Upon discovery of a whip-poor-will nesting site, the local MNR biologist will be notified so that they can confirm the species using the nesting site.
- The critical breeding period for Whip-poor-will is May 1st to August 14th.
- The following operational prescription will be followed:
  - No forest harvest operations permitted within 200 m from the nesting site.
  - Site preparation, renewal and tending operations of previously harvested areas within the AOC are only permitted outside of the critical breeding period (August 15to April 30th).
  - Residual pattern, wildlife trees and downed woody material will be retained as prescribed in the FMP text Section 4.2.2.2.

NO05	**Common Nighthawk Nesting Sites**	Group	Supplementary Documentation H AOC's	No	No crossings or landings permitted in the AOC	Yes	No new aggregate pits are permitted.

Operational Prescription

When the habitat description under the ESA becomes available these conditions may be updated prior to plan approval if this is necessary to address the habitat description. If the habitat description becomes available after final plan approval, a plan amendment for this AOC may be submitted if necessary to address the habitat description.

• 200 m radius AOC centered on nesting sites identified in NRVIS or encountered by field operations. Upon discovery of a common nighthawk nesting site, the local MNR biologist will be notified so that they can confirm the species using the nesting site.
• The critical breeding period for Common Nighthawk is May 15th to August 15th.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**

	consideration of these activities in a PGP AOC: 1) selection or shelterwood harvest, 2) commercial thinning harvest, or 3) tending activities (e.g. herbicide application, pre-commercial thinning). • Forest Ecosystem Science Co-operative (Forest Co-op) PGPs may also be considered for clearcut harvest if three measurements have been conducted on a plot. Discussions with the Forest Co-op and MNR Regional Growth & Yield Specialists will determine the status of a Forest Co-op PGP and any clearcut harvest treatment. Permission to clearcut harvest a Forest Co-op PGP must be documented in writing by the Regional Growth & Yield Specialist and will be used for a separate AOC prescription to be developed and approved.						
PL01	**Patent Land**	Group	Supplementary Documentation H AOC's	No	No crossings or landings permitted in the AOC.	Yes	No new aggregate pits are permitted.
Operational Prescription • AOC width is 30 metres from the boundary of mapped patent land adjacent to allocated harvest blocks. Harvest operations are permitted subject to the procedure below being implemented in the following order: 1) If the property boundary had been previously established by a licenced surveyor and the boundary markers and monuments can be located then the harvest boundary will be established along the boundary markers and monuments. Regular harvest, renewal and tending operations are permitted in allocated blocks. 2) If there is an agreement with the neighbouring landowner regarding the placement of the limit of forest operations then the harvest boundary will be placed according to the agreement. Regular harvest, renewal and tending operations are permitted in allocated blocks subject to this agreement. 3) If neither 1) or 2) above apply, the harvest boundary will be established so that a buffer is put in between the mapped boundary and the harvest block. The size of the buffer will be no more than 30 metres wide, will be marked and will be determined by the forest operator's level of uncertainty regarding the true location of the property boundary. Regular harvest, renewal and tending operations are permitted outside of the marked reserve buffer.							
RR01	**Railroad Right of Way**	Group	Supplementary Documentation H AOC's	No	No crossings or landings permitted in the AOC.	Yes	No new aggregate pits are permitted.
Operational Prescription • 50 metre AOC from railway right of way. • Clear cut harvest to railway right of way within AOC, while leaving the 50 m AOC as a slash free zone. • All forest management activities permitted; however slash piles or chipper debris piles are to be removed. No slash piles or chipper debris piles are allowed to remain in landing for more than one year.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
WL01	Large lakes, Medium lakes, Small lakes, Ponds - high or moderate potential sensitivity (HPS or MPS) to forest management operations	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010)*, Pages 39-44.	No	No crossings or landings permitted in the AOC.	Yes	No aggregate pits are permitted.

Operational Prescription

For *large lakes, medium lakes, small lakes,* and *HPS* ponds, 30 to 90 m AOC as mapped based on slope as follows:

Slope (%)	Slope Angle (degrees)	Width of AOC
0 - 15	0 - 8.5	30 m
>15 - 30	8.6 – 16.7	50 m
>30 - 45	16.8 – 24.2	70 m
> 45	> 24.2	90 m.

For *MPS ponds*, 30 m AOC as mapped.

- The AOC is measured in the field from the edge of vegetation communities capable of providing an effective barrier to the movement of sediment. This will normally be those communities with >=25% canopy cover of trees, tall (>= 1 m high) woody shrubs such as alder or willow, or low (< 1 m high) woody evergreen shrubs such as Labrador tea or leatherleaf. For mapping purposes, the AOC may be measured from the edge of polygons identified as FOR, TMS, or BSH. If the inner edge of the AOC will be ≥300 m from the shoreline of the lake or pond when these criteria are used, an AOC is not required adjacent to those sections of shoreline, unless the intervening wetland is known to provide components of fish habitat for which there is a high species' dependence (e.g., spawning habitat).

- No harvest, renewal, or tending operations are permitted within the AOC that will result in damage to littoral zones or shorelines and associated stabilizing vegetation, or deposition of sediment within lakes or ponds. Operations specifically prohibited within the AOC include:
  - Machine travel within the inner 3 m of the AOC.
  - Felling of trees into lakes or ponds or the inner 3 m of the AOC. Trees accidentally felled into lakes or ponds will be left where they fall.
  - Excessive removal or damage of sapling-sized trees (< 10 cm dbh) and shrubs within the inner 3 m of the AOC.
  - Disturbance of the forest floor that leaves ruts or a significant area of exposed mineral soil within the inner 15 m of the AOC. Ruts and significant patches of exposed mineral soil will be promptly rehabilitated to prevent sediment from entering a water feature. Patches of mineral soil exposed by natural events are excluded.
  - Disturbance of the forest floor that disrupts hydrological function (i.e., impedes, accelerates, or diverts water movement) within recognizable ephemeral streams, springs, seeps, and other areas of groundwater discharge connected to lakes or ponds.

- Harvest is permitted within the AOC subject to the following conditions:
  - Areas within the AOC that can have harvest, renewal and tending operations (subject to all AOC conditions) will be mapped as a modified AOC.
  - Reserve areas within the AOC will also be mapped.
  - ≥ 50% of the area of the AOC (based on delineation of the AOC around the entire water feature both inside and outside the harvest area) associated with *small lakes, HPS ponds,* and *MPS ponds,*≥ 75% of the area of the AOC associated with *medium lakes,* and ≥ 90% of the area of the AOC associated with *large lakes* will be

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions

retained as forest that meets the definition of residual (see FMP text Section 4.2.2.2).
- The residual forest to be retained will be mapped as reserve (no harvest, renewal or tending permitted) (residual defined in FMP Section 4.2.2.2).
- When retaining residual shoreline forest, the inner 15 m will be mature forest with a relatively uniform canopy closure ≥60% (canopy openings not to exceed individual tree crowns) unless the adjacent harvest area outside the AOC meets the definition of residual forest.
- Conventional harvesting is permitted within the AOC only where the slope is ≤ 30%.
- For each ha of shoreline forest harvested that does not meet the definition of residual (e.g., conventionally harvested) 1 ha of residual shoreline forest will be retained that has not been harvested within 20 years.
- Within the AOC, direction for the retention of downed woody material as outlined in FMP text Section 4.2.2.2 will be followed.

- Some or all of the requirements for retention of residual forest within the AOC may be met by residual shoreline forest outside the harvest area, residual shoreline forest retained in overlapping AOCs, or residual shoreline forest retained in areas with steep slopes (>30%). Additional requirements for residual shoreline forest may be met by:
  - Retaining residual shoreline forest that meets the special habitat requirements of wildlife associated with lakes and ponds. For example,
    - Preferentially retaining residual shoreline forest adjacent to moose aquatic feeding areas (MAFAs), especially in specific areas (e.g., LLPs) identified for enhanced moose management.
    - Preferentially retaining residual shoreline forest where there is a high potential for ephemeral streams, springs, seeps, and other areas of groundwater discharge.
  - Retaining residual shoreline forest that maintains internal and external connectivity. To the extent practical and feasible within the AOC, a relatively continuous corridor (average width of gaps <50 m; maximum width of gaps <200 m) of residual forest at least 30 m wide will be retained along the length of lakes and ponds to connect special habitat features (e.g., osprey nests, MAFAs) associated with the lake or pond and link with residual forest on connected lakes, ponds, rivers, and streams.
  - Retaining residual shoreline forest to emulate natural patterns such as those created by wildfire. For example:
    - Preferentially retaining residual shoreline forest on the leeward side of a lake or pond.
    - Preferentially retaining residual shoreline forest comprised of less flammable forest types (e.g., hardwood, lowland conifer).
    - Preferentially retaining residual shoreline forest where there is an opportunity to incorporate it into a larger patch of residual forest.
  - Retaining residual shoreline forest that has the highest likelihood of being windfirm.

- Harvest, renewal, and tending operations will follow appropriate operating practices to minimize rutting, compaction, and mineral soil exposure that could lead to erosion and subsequent transport and deposition of sediment in lakes or ponds. Particularly,
  - Reasonable efforts (e.g. Pre-harvest skid trail planning) will be undertaken in order to avoid extraction trails crossing recognizable ephemeral streams, springs, seeps, and other areas of groundwater discharge when not solidly frozen. However if these features are required to be crossed, special care will be taken; temporary crossing structures that do not impede, accelerate, or divert water movement will be used when appropriate.

- Harvest, renewal, and tending operations will, to the extent practical and feasible, encourage perpetuation of the distinctive character of the shoreline forest while emulating natural disturbances and/or succession (unless conversion is required to meet other ecological objectives.)

- Within the inner 15 m of the AOC, at least 10 trees/100 m of shoreline spaced about 10 m apart will be retained, and identified (flagged) prior to harvesting, as a potential source of future aquatic coarse woody material. Living trees with the following characteristics will be preferentially retained:

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions

- At least 15 m tall (or the tallest of those available).
- Close to the shoreline (ideally within ½ the height of the tree).
- Leaning toward the shoreline.
- Coniferous supercanopy trees, scattered conifers, and veterans, especially large cedars, white pines, red pines, white spruces, and jack pines.
- Machine travel should be minimized within the inner 15 m of the AOC.
- Felled trees should not be piled within the inner 15 m of the AOC.

- Within the remainder of the AOC (beyond the inner 15 m), the general direction for retention of wildlife trees in as outlined in FMP text Section 4.2.2.2 will be followed. However, the focus will be on living trees with preferential retention of windfirm trees that provide the following special habitat features for wildlife:
  - Supercanopy trees of value to eagles and ospreys such as white pines, red pines, and poplars.
  - Large living hardwood trees with existing cavities or the potential to develop cavities.
  - Scattered veteran trees.

- No contamination of lakes or ponds by foreign materials is permitted. Specifically,
  - The use and storage of fuels will be carried out in accordance with the *Liquid Fuels Handling Code.*
  - No equipment maintenance (e.g., washing or changing oil) is permitted within 30 m of lakes or ponds.
  - Aerial application of pesticides for renewal, tending, or protection is permitted within the AOC but will follow spray buffer zones for *significant areas* or *sensitive areas* (as appropriate) as prescribed in the *Ontario Ministry of the Environment/Ontario Ministry of Natural Resources Buffer Zone Guidelines for Aerial Application of Pesticides in Crown Forests of Ontario (1992)*. Machine-based ground application of herbicides (e.g., air-blast sprayers mounted on skidders) is permitted within the AOC; spray buffer zones will be 30 m for *significant areas* and 60 m for *sensitive areas*. Hand-based ground application of herbicides (e.g., back-pack sprayers) is permitted within the AOC; spray buffer zones will be 3 m. All spray buffer zones will be measured from the inner boundary of the AOC.

WL02	Ponds – low potential sensitivity (LPS) to forest management operations	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010)*, Pages 44.	No	No new roads or landings permitted	Yes	No aggregate pits are permitted.

Operational Prescription
15 metre AOC as mapped

- No harvest, renewal, or tending operations are permitted that will result in damage to littoral zones or shorelines and associated stabilizing vegetation, or the deposition of sediment within ponds. Operations specifically prohibited include:
  - Machine travel within 3 m of ponds.
  - Excessive removal or damage of sapling-sized trees (<10 cm dbh) and shrubs within 3 m of ponds.
  - Felling of trees into ponds or within 3 m of ponds. Trees accidentally felled into ponds will be left where they fall.
  - Disturbance of the forest floor that leaves ruts or a significant area of exposed mineral soil within 15 m of ponds. Ruts and significant patches of exposed mineral soil will be promptly rehabilitated to prevent sediment from entering a pond. Patches of mineral soil exposed by natural events are excluded.

All spray buffer zones will be measured from the inner boundary of the AOC.

WS02	Stream segments - low potential sensitivity (LPS) to forest management operations	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010)*, Pages 53-54.	No	No crossings or landings permitted in the AOC.	Yes	Yes

Operational Prescription
This AOC code and AOC is applied to low potential sensitivity stream segments both mapped during the planning process and to those identified during plan implementation.

- 15 metre AOC as mapped.

- No harvest, renewal, or tending operations are permitted that will result in damage to stream channels or banks and stabilizing vegetation, or deposition of sediment within streams. Operations specifically prohibited include:
  - Machine travel within 3 m of the active channel (except at appropriate extraction trail crossings – refer to FMP-19)
  - Extraction trails may cross LPS streams. However, crossings will be minimized and operating practices will be followed that minimize rutting, compaction, and mineral soil exposure that could lead to erosion and subsequent transport and deposition of sediment in streams. Temporary crossing structures will be used when appropriate.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
	o Excessive removal or damage of sapling-sized trees (<10 cm dbh) and shrubs within 3 m of the active channel. o Felling of trees into streams or within 3 m of the active channel. Trees accidentally felled into streams will be left where they fall. o Disturbance of the forest floor which leaves ruts or a significant area of exposed mineral soil within 15 m of the active channel. Ruts and significant patches of exposed mineral soil will be promptly rehabilitated to prevent sediment from entering a water feature. Patches of mineral soil exposed by natural events are excluded. • No contamination of streams by foreign materials is permitted. Specifically, o The use and storage of fuels will be carried out in accordance with the *Liquid Fuels Handling Code.* o No equipment maintenance (e.g., washing or changing oil) is permitted within 15 metres of the active channel.						
WW01	**Wetlands occupied by breeding black terns, golden-winged warblers, least bitterns, or yellow rails** (see further description below)	Group	*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010)*, Pages 59-60, 125-126.	No	No new roads or landings permitted.	Yes	No new aggregate pits permitted.
	Description Delineated (mapped) habitat comprises the AOC. • Suitable habitat occupied by breeding black terns, golden-winged warblers, least bitterns, or yellow rails within the past 20 years (least bittern) or 10 years (black tern, golden-winged warbler, yellow rail) defined by either o suitable habitat occupied by breeding birds as delineated through field survey. o a 5 ha (least bittern), 10 ha (golden-winged warbler), 15 ha (yellow rail) or 20 ha (black tern) patch of suitable non-forested wetland habitat (or the entire wetland polygon if <5/10/15/20 ha) associated with individual *Element of Occurrence* observation points or other reliable sightings associated with breeding activity, or o as otherwise defined by an Endangered Species Act habitat description or habitat regulation. **Operational Prescription** Harvest, renewal and tending operations are permitted with the following conditions: • No harvest, renewal or tending operations are permitted that will result in significant damage to wetland vegetation or disruption of hydrological function. Operations specifically prohibited include: o Machine travel during the frost-free period within 3 m of those portions of the wetland dominated by open water or non-woody vegetation (i.e. vegetation communities with <25% canopy of trees, tall (>=1m high) woody shrubs such as alder or willow, or low (<1 m high) woody evergreen shrubs such as Labrador tea or leatherleaf. o Excessive removal or damage of sapling-sized trees (<10 cm dbh) and shrubs within 3 m of those portions of the wetland dominated by open water or non-woody vegetation. o Felling of trees during the frost-free period into, or within 3 m of those portions of the wetland dominated by open water or non-woody vegetation. Trees accidentally felled into those portions of the wetland dominated by open water or non-woody vegetation will be left where they fall. o Operation leaving ruts, a significant area of exposed mineral soil, or disrupt hydrological function within the wetland itself or with forest that is within 15 m of those portions of the wetland dominated by open water or non-woody vegetation. Ruts or significant patches of exposed mineral soil will be promptly rehabilitated. • No contamination of wetlands by foreign materials is permitted. Specifically: o The use and storage of fuels will be carried out in accordance with the *Liquid Fuels Handling Code.* o No equipment maintenance (e.g. washing or changing oil) is permitted within 15 m of non-forested wetlands.

Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

FMP-10 OPERATIONAL PRESCRIPTIONS FOR AREAS OF CONCERN

Note 1: Where the Road Crossings and Landings or Forestry Aggregate Pit conditions columns indicate "yes", additional information is provided in Table FMP-19.
Note 2: Residual pattern, wildlife trees and downed woody material requirements are detailed in the forest management plan in Section 4.2.2.2.
Note 3: Table FMP-10.1 Harvest, Renewal and Tending Activities and their Potential Impact is located at the end of Table FMP-10.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
WW02	**Woodland pools known to support flooded jellyskin**	Group	Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (p. 103-104)	No	No road crossings proposed	Yes	Yes

Operational Prescription

Delineated habitat comprises the AOC.

- Regular harvest, renewal and tending operations are permitted within the AOC with the following conditions:
  - Harvest, renewal and tending operations are not permitted within 30m of the high-water mark of woodland pools (see CRO-16) known to support Flooded Jellyskin. Trees will not be felled into this area, trees accidentally felled into this area will be left where they fall.
  - Direction for woodland pools will be applied to all other woodland pools (CROs Section 4.2.2.2) with a surface area ≥200m^2 (about a 15m diameter). In all forest units, all trees will be retained in and within 3m of pools and residual forest will be retained within 15m of pools.

AOC or AOC Group Identifier	Description of Natural Resource Feature, Land Use or Value	Group AOC	Source	Exception	Road Crossings and Landings		Forestry Aggregate Pit
					Primary or Branch Road Crossing/Landing Conditions	Operational Road/Landing Conditions	Conditions
FL01	**First Nation Reserve (Federal) Land**	Group	Supplementary Documentation H AOC's	No	No crossings or landings permitted in the AOC.	Yes	Yes

Operational Prescription

- AOC width is 30 metres from the boundary of mapped First Nation Reserve land adjacent to allocated harvest blocks.

Harvest operations are permitted subject to the procedure below being implemented in the following order:

1) If the property boundary had been previously established by a licenced surveyor and the boundary markers and monuments can be located then the harvest boundary will be established along the boundary markers and monuments. Regular harvest, renewal and tending operations are permitted in allocated blocks.
2) If there is an agreement with the First Nation regarding the placement of the limit of forest operations then the harvest boundary will be placed according to the agreement. Regular harvest, renewal and tending operations are permitted in allocated blocks subject to this agreement.
3) If neither 1) or 2) above apply, the harvest boundary will be established so that a buffer is put in between the mapped boundary and the harvest block. The First Nation Reserve boundary will be checked against information provided by both MNR and INAC. The more restrictive of the two boundaries will be used if agreement cannot be reached as to the proper boundary location. The size of the buffer will be no more than 30 metres wide, will be marked and will be determined by the forest operator's level of uncertainty regarding the true location of the property boundary. Regular harvest, renewal and tending operations are permitted outside of the marked reserve buffer.

Operational Prescription

Reserve Zone
Measured from the edge of the standing timber as mapped, 30 to 90 m AOC based on slope as follows:

Slope (%)	Slope Angle (degrees)	Width of AOC
0 - 15	0 - 8.5	30 m
>15 - 30	8.6 – 16.7	50 m
>30 - 45	16.8 – 24.2	70 m
> 45	> 24.2	90 m

No forest management operations are permitted within the reserve.

Modified Zone
Outside of the slope-based reserve, within a 120 metre modified operations zone, measured from the high water mark, where the following restrictions apply;
i. Harvesting, mechanical site preparation, and aerial spray operations are permittted between August 15th and April 15th,
ii. Tree planting is permitted but limited to one (1) crew of four (4) planters and ATV use is to be kept to a minimum. Tree caches are to be located as far from the nest as possible.

NE10	**Snapping Turtle Nesting Site** Secondary Values: Fish habitat, Water quality	Group		No	No road crossings proposed	Yes	Yes

Operational Prescription

Not applicable, conditions on roads, landings, forestry aggregate pits only.

Management Unit Name: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
Plan Period: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10)**

NOTES:

(1) Ministerial Conditional Commitment - As per Minister Donna Cansfield letter dated July 14, 2009, commiting to a temporary replacement of volume.

(2) As per Minister Donna Cansfield letter dated July 14, 2009, commiting to a temporary replacement of volume of 100,000 m3 Poplar.

(3) Minsterial Directive (20 years) - As per Minister Hampton letter to Prendiville Industries Ltd (Kenora Forest Products) dated November 16, 1994 (expires on March 31, 2014).

(4) 2007 Wood Supply Competitive Process Offer - Additional conifer volume conditionally offered to KFP through the 2007 Kenora area Wood Supply Competitive Process. This conditional offer was reconfirmed by Minister Gravelle in a letter dated October 18, 2011 regarding KFP's 2010 Wood Supply Competitive Process conditional offers.

(5) 2007 Wood Supply Competitive Process Offer - Conifer volume conditionally offered to Wincrief Forestry Products LP through the 2007 Kenora area Wood Supply Competitive Process. A Wood Supply Agreement for this volume is pending on resolution of Whiskey Jack Forest related issues (i.e., Grassy Narrows First Nation and Keewatin Lands issues).

(6) 2007 Wood Supply Competitive Process Offer - Conifer volume conditionally offered to 1358807 Ontario Ltd (D. Riffel Harvesting) through the 2007 Kenora area Wood Supply Competitive Process. A Wood Supply Agreement for this volume is pending on resolution of Whiskey Jack Forest related issues (i.e., Grassy Narrows First Nation and Keewatin Lands issues).

FMP-18 Road Construction and Use Management

Road or Road Network Identifier	Plan Start Length (km)	Planned Construction 10 Year	Planned Construction This Term	Use Management					
				Maintenance	Monitoring	Access Control		Future Use Management	
						Type	Year	Transfer Year	Management Intent

Summary of Use Management Strategies (UMS), as fully described in Supplementary Documentation G.

Road monitoring and maintenance will follow:

o Conditions for Water Crossings (Plan Text Section 4.7.4) and as documented in the AOC Supplementary Documentation G of this plan.

UMS-1

1. These roads and each associated right-of-way will receive maintenance, which will be carried out as required to maintain the road for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities). These roads will be maintained to minimize risk to road users and minimize the potential for environmental damage. Routine maintenance operations may include any one or combination of the following: summer grading, ditching, drainage, brush clearing with mechanical or chemical methods (e.g. application of chemical herbicides for vegetation control along road shoulders), gravelling, re-shaping of road bed, dust control measures, signage, snow plowing, sanding/salting and clearing existing right-of-ways including the harvest of merchantable trees as required. Maintenance may also include non-emergency repairs of existing water crossings to clean culverts, remove blockages caused by beavers, and to apply material (e.g. gravel, riprap) to mitigate or enhance long-term erosion protection around water crossings.

1. (cont.) For safety/engineering concerns minor road re-alignment and bypass construction may also be required for existing roads during the implementation of the FMP. This is permitted within the existing right-of-way, subject to the confirmation of values and the application of all applicable AOCs to the proposed work area. If an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied. In cases where new and/or replacement water crossings are required during the implementation of the FMP, the replacement of culverts are permitted subject to the following conditions; the values must be reviewed and updated for each location to ensure up-to-date values are considered, the applicable AOC must be applied to address any value impacted at the location (if an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied), and the planned water crossing replacements are identified and approved (with all applicable conditions on the construction, including preventative and mitigative measures) in the AWS for the year of construction.
1. (cont.) Emergency maintenance is defined as “road maintenance that required immediate attention to restore access and reduce the chance of personal injury, damage to equipment, inconvenience to road users and further road damage” (2009 FMPM). Emergency maintenance will be necessary where public safety and/or environmental damage have occurred unexpectedly. Emergency repairs can proceed immediately without MNR approval provided the emergency works are limited in scope to only what is necessary to address essential public safety concerns and restrict further environmental damage. All emergency actions will be reported to MNR as soon as practical and any further actions (e.g. restoration, reconstruction, abandonment) will be subject to normal planning approvals. Where sediment has been released into a watercourse, the Ministry of the Environment is to be informed.

1. (cont.) Where water crossings have been adversely impacted by unplanned events, water crossings may not be restored in a timely manner and remedial work may be limited to only eliminating or reducing safety hazards and/or interim measures to stop environmental damage. Access to areas impacted by unplanned events could be disrupted at any time and there is no obligation on the Crown or the Forest Industry to undertake repair work to restore infrastructure and access. However, all actions must be consistent with the Use Management Strategy for the road/road network. Situations could also arise where it is determined that a damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented.

2. While the road/road network is in use for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities), it will be monitored on an ongoing basis for safety or environmental concerns. Bridges used for ‘heavy truck hauls’ inspected at least once a year by a competent person (following the inspection guidelines in Appendix E of the Crown Land Bridge Management Guidelines or by a professional engineer). When the road/road network is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment approach with emphasis on the potential values which could be impacted (i.e. fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of aerial assessments of reforestation (e.g. FTG surveys). In addition, all staff and contractors (harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

UMS-2

o Same as UMS-1 with some access controls identified above.

UMS-3

o Same as UMS-1 with decommissioning requirements. The conditions for roads that are to be decommissioned and regenerated can be found in Section 4.5.8 of the Plan text. This decommissioning may involve the physical destruction and re-vegetation of the roadbed and the removal of high risk water crossings. All water crossings will be examined using MNR’s criteria for removal of water crossings (*Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* page 143-144) to determine whether decommissioning activities are appropriate based upon biological, water quality, engineering and safety factors. Water crossings planned for decommissioning will be identified in the applicable AWS, reviewed with respect to the Fisheries Act, and approved with any resulting conditions.

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

A. Primary Roads, Branch Roads and Landings

AOC Identifier	Road Identifier	Water Crossing	Planned or Existing		Acceptable Variations	
			Location	Conditions on Construction or Use	Location	Conditions on Construction or Use
A01				Existing Roads Use and maintenance of existing roads (i.e. previously disturbed right of ways) do not represent a new disturbance and therefore do not require archaeological assessment. Culvert replacement at an existing water crossing could result in a new disturbance as compared to the original culvert installation, in which case the significance of the disturbance must be assessed and an archaeological assessment may be required. Water crossing conditions found in AOC WS01, WS02 apply where applicable. If the protection measures for an area of archaeological potential are not complied with, operations must immediately cease within the area of concern and a Stage 2 archaeological assessment per Ministry of Culture's current standards and guidelines for consultant archaeologists shall occur. If a cultural heritage value is discovered during operations (e.g. an arrowhead, cemetery, or old logging camp) then operations must immediately stop and the district MNR staff will be contacted as per the Forest Information Manual. The value class of the discovery will determine who of the following will be contacted: Ministry of Culture staff, the local Aboriginal community, Registrar of Cemeteries, and/or the provincial cultural heritage specialist. When the class of cultural heritage value is established, the appropriate protection measure(s) will be applied and a plan amendment will be processed if required. When human remains are discovered, work at the site must be suspended and the police notified. It is also appropriate to notify the MNR district staff. The police will investigate the report to determine if the human remains are of forensic interest or represent a burial site as defined by the *Cemeteries Act*. All involved parties must act to safeguard the location until the police attend the site, and to limit media contact or display.		

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Years 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Years 6-10)**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

A. Primary Roads, Branch Roads and Landings

AOC Identifier	Road Identifier	Water Crossing	Planned or Existing		Acceptable Variations	
			Location	Conditions on Construction or Use	Location	Conditions on Construction or Use
WS01	April South Road, Bug Lake, Yellow Girl, Aesthetic Road, Witch Bay Road	Yes	AP-01, AP-02, YE-01, YE-02, BU-01, BU-02, AE-01, AE-02, AE-03, AE-04, WB-01, WB-02, WB-03, WB-04, WB-05, WB-06, WB-06, WB-07, WB-08, WB-09	<u>Design and Location</u> The preliminary location and conditions outlined in this area of concern for a water crossing will be confirmed or changed in the AWS. If the conditions or locations are changed, the change must be consistent with the FMP. The culvert or bridge opening size shall be determined by hydrologic and hydraulic analyses, in accordance with design procedures developed for Ontario use. A water crossing structure with a single span greater than 3 m is considered a bridge; design of all bridges will comply with the requirements in the *Crown Land Bridge Management Guidelines*. Selection of the type of water crossings structure, its location and its capacity to pass water and allow for the movement of fish, will consider: i. Possible negative effects on the form and function of the undisturbed natural channel and its floodplain; ii. The fish species present and the impact of the crossing structure on them, as required by the *Fisheries Act*, and iii. Whether the water crossing is over navigable waters. Avoid crossing in areas which affect known critical fish habitat, such as fish spawning, feeding, over-wintering, or nursery areas. Avoid steep banks or sites where actively slumping banks are evident. <u>Installation and maintenance</u> Those responsible for installation and maintenance will monitor operations and select operating practices, materials, and mitigation techniques at each water crossing to prevent the harmful alteration, disruption or destruction of fish habitat or the impairment of water quality. Harmful alteration, disruption, or destruction of fish habitat is not permitted without DFO approval.	Any location within 100 m mapped corridor/AOC with the exception of identified restricted area.	

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Years 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Years 6-10)**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

A. Primary Roads, Branch Roads and Landings

AOC Identifier	Road Identifier	Water Crossing	Planned or Existing		Acceptable Variations	
			Location	Conditions on Construction or Use	Location	Conditions on Construction or Use
				The installation of a water crossing will not result in the impediment of fish passage; mitigative techniques will be applied if the structure has the potential to impede or block fish migration or passage. Materials moved during construction, such as grubbed or earth fill material, will not be piled where they block drainage courses. At any time of year, the free movement of water and fish will not be blocked or otherwise impeded, except for brief periods during construction and as approved by MNR. The removal of stream boulders is generally not acceptable, except where necessary for installation of a crossing structure which retains a natural streambed (e.g., a bridge). Fill material required to build the road at the site of the crossing, below the high water level and within the floodplain of the water feature, will be erosion resistant and/or protected from erosion. Any exposed mineral soil between the height of land and the water crossing, or within 100 m of the water crossing, whichever is less, will be trimmed to a stable angle and be protected from erosion so sediment will not enter water. During construction and maintenance of a water crossing, contamination of a water feature by foreign materials such as lumber, nails, fuel, oil, or herbicides is not permitted (the crossing structure itself, including temporary crossings, can be in the water, if the approved design allows for this). Prevent sediment from entering the water features by using erosion and sediment control techniques. Blasting in or near water produces shock waves that can kill		

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Years 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Years 6-10)**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

A. Primary Roads, Branch Roads and Landings

AOC Identifier	Road Identifier	Water Crossing	Planned or Existing		Acceptable Variations	
			Location	Conditions on Construction or Use	Location	Conditions on Construction or Use
				fish and will normally be avoided. Blasting with a potential impact on fish or fish habitat will only be done following approval from DFO. Upon completion of a water crossing, any temporary fill, culverts, refuse, etc. will be removed from the construction area and properly disposed of in a satisfactory manner. After construction, on-site inspections will be made by the proponent to confirm these standards are being met. If using temporary winter-only crossings, materials other than ice and snow will be removed from the stream prior to spring break-up. Upon installation, each new water crossing will be incorporated into the approved program for monitoring roads and water crossings. These standards are applicable to previously installed water crossings when they are replaced or upgraded due to sub-standard safety, environmental, or operational reasons. Use techniques and materials appropriate for the conditions encountered at each water crossing, to minimize disturbance of a water feature and significantly reduce the potential for erosion and sedimentation. Ensure logs and brush which may need to be removed or trimmed at the crossing site do not enter the water feature. Grubbing of low vegetative cover between the height of land and a water crossing, or within 100 m of a water crossing, whichever is less, will be limited to that required to address engineering issues and safety concerns, such as the removal of hazards. When diverting and/or removing water for dry installations, chase away or trap and relocate live fish before completely		

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Years 1-5)**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

A. Primary Roads, Branch Roads and Landings

AOC Identifier	Road Identifier	Water Crossing	Planned or Existing		Acceptable Variations	
			Location	Conditions on Construction or Use	Location	Conditions on Construction or Use
				dewatering the area (note: permits may be required; consult the local MNR district office for further information). Apply mitigative techniques to provide for fish passage if there is potential to impede or block fish migration during installation of the crossing. Begin site stabilization and clean-up as soon as possible after the water crossing has been installed, including the removal of all diversions. Trim fill slopes to a stable angle, or use other mitigative stabilization techniques. A person should be able to walk up the slope without causing slumping and sliding of soil particles. When a temporary channel is no longer required, it should be stabilized to avoid long-term erosion. Construct and use fords during the driest time of the year but not during the restricted time of high risk to fish; ensure the ford does not restrict fish passage. Material used within the stream and on the banks to improve the crossing will be clean, non-erodable, and non-toxic to aquatic life. Install culverts on a straight section of stream. When installation of a culvert on a straight section of stream is not possible, minimize the change in stream morphology and impacts on fish habitat. <u>Conditions on Construction</u> No landings are permitted within the area of concern. Fill material placed to build the road below high water level within the floodplain of water body will be erosion resistant and/or protected from erosion. Materials moved during construction, such as grubbed or earth fill material, will not be piled where they block drainage courses.		

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Years 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Years 6-10)**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

A. Primary Roads, Branch Roads and Landings

AOC Identifier	Road Identifier	Water Crossing	Planned or Existing		Acceptable Variations	
			Location	Conditions on Construction or Use	Location	Conditions on Construction or Use
				Grubbing or stripping within the 100 metre width or to the height of land (whichever comes first) of the location of the crossing on both sides of the waterway will be kept to an absolute minimum required for construction and where required must be stabilized to prevent erosion. Any exposed mineral soil between the height of land and a water crossing, or within 100 m of a water crossing, whichever is less, will be trimmed to a stable angle of repose and be protected from erosion so sediment will not enter the water after construction. New roads that traverse the AOC will be planned to avoid areas with a high potential to contain ephemeral streams, springs, seeps and other areas of groundwater discharge. Crossings of recognizable ephemeral streams, springs, seeps, and other areas of groundwater discharge will consider the design principles in this AOC to minimize the risk of sediment delivery and disruption of hydrological function. <u>Right-of-way (ROW)</u> The right-of-way for the stream crossing will be cleared to a minimum width needed for construction to a maximum width of 20 metres for a distance from the stream within the AOC as per FMP-10: <u>Slope AOC width</u> 0 to 15% 30 metres >15 to 30% 50 metres >30 to 45% 70 metres >45%+ 90 metres <u>Timing Restriction</u> Construction operations that may enter a water feature or that may cause sediment to enter a water feature are not to occur during periods of fish spawning, incubation, or fry emergence, unless approved by MNR. The timing restrictions for operations where the following local fish species are present		

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Years 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Years 6-10)**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

A. Primary Roads, Branch Roads and Landings

AOC Identifier	Road Identifier	Water Crossing	Planned or Existing		Acceptable Variations	
			Location	Conditions on Construction or Use	Location	Conditions on Construction or Use
				are listed below: Walleye, Northern Pike, Lake Sturgeon: April 1st to June 15th. Muskellunge: May 1st to June 30th. Largemouth and Smallmouth Bass: May 15th to July 15th. Rainbow Trout or Unknown species: April 1st to July 15th. Lake Trout are present: Sept. 15th to May 15th. Brook Trout or Unknown species: Sept. 1st to June 15th. Lake Whitefish: Oct. 1st to May 15th. Lake Herring: Oct. 15th to May 15th. Some site conditions may require applying multiple timing restrictions. If warranted (i.e. late spring, no fish habitat) the MNR may vary timing dates based on local knowledge. The MNR will confirm at the AWS level all timing restriction conditions.		

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
A01		**Archaeological Potential Area:** Conditions on Location Operational roads are permitted in APAs with conditions below. Operational roads are to be minimized as much as possible in an APA. Conditions on Construction If there will be mineral soil disturbance within an APA then a Ministry of Culture's Stage 2 archaeological assessment is required and the report's recommendations followed. Regular operations can occur following the archaeological assessment where nothing has been found, the recommendation is that no further archaeological work is required, and the Ministry of Culture has reviewed the report. Use and maintenance of existing operational roads (i.e. previously disturbed right of ways) do not represent a new disturbance and therefore do not require archaeological assessment. Culvert replacement at an existing water crossing could result in a new disturbance as compared to the original culvert installation, in which case the significance of the disturbance must be assessed and an archaeological assessment may be required. An archaeological assessment is not required for operational roads that can be built with no mineral soil disturbance. Situations where operational roads can be constructed with no mineral soil disturbance might include: • Winter roads and landings constructed over packed snow and when the ground is frozen >20cm; • Water crossings constructed using snow, ice or a temporary bridge which do not require grubbing, filling or ditching, and only used while the ground is frozen >20cm • Minor alterations to the water course for culvert placement (e.g. removing a rock); and • Water crossings constructed using temporary bridges without in-ground footings. In winter, this provision applies to roads with approaches constructed using packed snow on frozen ground (>20cm). For other seasons, this provision applies to roads with approaches constructed using less than 2 metres of fill; the fill must be placed over geotextile, corduroy or brush mats; and there must be no grubbing or ditching. Water crossing conditions found in AOC WS01, WS02 apply where applicable. If the protection measures for an area of archaeological potential are not complied with, operations must immediately cease within the area of concern and a Stage 2 archaeological assessment per Ministry of Culture's current standards and guidelines for consultant archaeologists shall occur. If a cultural heritage value is discovered during operations (e.g. an arrowhead, cemetery, or old logging camp) then operations must immediately stop and the district MNR staff will be contacted as per the Forest Information Manual. The value class of the discovery will determine who of the following will be contacted: Ministry of Culture staff, the local Aboriginal community, Registrar of Cemeteries, and/or the provincial cultural heritage specialist. When the class of cultural heritage value is established, the appropriate protection measure(s) will be applied and a plan amendment will be processed if required. When human remains are discovered, work at the site must be suspended and the police notified. It is also appropriate to notify the MNR district staff. The police will investigate the report to determine if the human remains are of forensic interest or represent a burial site as defined by the *Cemeteries Act*. All involved parties must act to safeguard the location until the police attend the site, and to limit media contact or display.

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
D01		**Occupied Black Bear Den:** **Denning Period (October 15 to April 30):** • Road construction is not permitted within 100m of occupied dens. • Hauling and road maintenance operations are not permitted within 100 m of the den entrance, unless the road predates the den, is required for safety reasons or environmental protection.
D02		**Occupied Grey Fox Den:** **Denning Period (April 15 to September 15):** • Road construction is not permitted within100 m of the den entrance. • Hauling and road maintenance operations are not permitted within 50 m of the den unless the road predates the den, and is required for safety reasons or environmental protection. **Outside of the Denning Period (September 16 to April 14):** • No restrictions on road construction, maintenance or hauling operations.
D03		**Occupied Cougar Den:** **Denning Period:** • Road construction is not permitted within 200 m of the den entrance. • Hauling and road maintenance operations are not permitted within 100 m of the den unless the road predates the den, is required for safety reasons or environmental protection. **Note:** The*denning period* is potentially different for each occupied den encountered and is considered to extend for 8 weeks from the date an occupied den is located, or until a den is known to be no longer occupied. **Outside of the Denning Period:** • No restrictions on road construction, maintenance or hauling operations.
D04		**Wolf Den:** • New roads and landings are not permitted within the inner 100 m of the AOC. • Constructing of new roads and landings is not permitted within the outer 100m of the AOC unless it has been determined there is no other feasible alternative (e.g. terrain prevents road construction outside the AOC) in which case only one road is permitted and road will be built to the lowest standard necessary. • When roads are constructed within the AOC, temporary roads and/or water crossings will be used whenever practical and feasible to limit future access and disturbance (refer to AOC WS01 and WS02 for other conditions on water crossings that also apply). ***Denning Period* April 15 to July 15:**

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
		• Road construction is not permitted within 200 m of an occupied den during the *denning period*. • Hauling and road maintenance operations are not permitted within 100 m of an occupied den during the *denning period,* unless the road predates the den, is required for safety reasons or environmental protection.

D05		**Wolverine den:**
		• If a wolverine den is encountered all operations will stop within a 4km radius AOC and the Kenora District Office MNR will be immediately notified of the presence of a wolverine den in proximity to forest operations.
		• No further road/landing maintenance operations are permitted within the AOC.
		• Following the above the FMP may be amended by developing a new AOC, in consultation with MNR Biologists, with a den site management plan for a specific den site location that will include consideration of roads and landings in the AOC as follows:
		  • Denning generally occurs between February and May when snow depth is usually at its greatest;
		  • A Use Management Strategy for existing roads that will provide locally-appropriate measures to minimize road associated impacts on wolverines. This may include access controls while roads are in use and a decommissioning plan for roads following use.
		• Normally operational road construction will be prohibited in the AOC; however, some operations may be permitted to meet ecological, social or economic objectives. Where operations will be permitted the AOC will outline the extent and timing of any road/landing construction or maintenance operations.

M01		**Mineral licks:** • Operations associated with existing roads are permitted within the AOC. • New roads and landings are not permitted within the AOC.
N01		**Bald Eagle Primary Nest:** • New roads and landings are not permitted within 200 m of primary nests. • New roads and landings will not be constructed within 201-400 m of primary nests, unless no practical or feasible alternative locations exist (e.g. due to extremely rugged terrain in adjacent areas outside the AOC) in which case only one operational road or landing is permitted in the AOC. • When roads are constructed within the AOC, temporary roads and/or water crossings will be used whenever practical and feasible to limit future access and disturbance. See AOC WS01, WS02 for other conditions on water crossings that also apply when AOCs for aquatic features are crossed. • Operations associated with roads and landings are not permitted within 100-400 m of *occupied* nests during the *critical breeding period* (Feb. 15 – August 31) based on potential impact (see Table A, Table 19.1), unless required for safety reasons or environmental protection. • However, there is no timing restriction on hauling or low potential impact road maintenance operations (e.g., grading) if the road predates the nest. **Table A** **Potential Impacts** / **No operations within** High / 400 m Moderate / 200 m Low / 100 m

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
N02		**Bald Eagle Alternate Nest:** • New roads and landings are not permitted within 200 m of alternate nests. • No timing restriction on operations associated with roads and landings within the AOC.
N03		**Bald Eagle Inactive Nest:** • New roads and landings are not permitted within 100 m of inactive nests. • No timing restriction on operations associated with roads and landings within the AOC.
N04		**Bald Eagle Primary Nest Discovered During Operations But After Harvesting has Occurred within 200 metres of Nest:** • New roads and landings are not permitted within 200 m of primary nests. • New roads and landings will not be constructed within 201-400 m of primary nests, unless no practical or feasible alternative locations exist(e.g. due to extremely rugged terrain in adjacent areas outside the AOC) in which case only one operational road or landing is permitted in the AOC. • When roads are constructed within the AOC, temporary roads and/or water crossings will be used whenever practical and feasible to limit future access and disturbance. See AOC WS01, WS02 for other conditions on water crossings that also apply when AOCs for aquatic features are crossed. • Operations associated with roads and landings are not permitted within 100-400 m (see Table A, N01) of *occupied* nests during the *critical breeding period* (Feb. 15 – August 31) based on potential impact (see table FMP-19.1*),* unless required for safety reasons or environmental protection. • However, there is no timing restriction on hauling or low potential impact road maintenance operations (e.g., grading) if the road predates the nest.
ON01		**Osprey Primary Nest:** • New roads and landings are not permitted within 150 m of primary nests. • New roads and landings will not be constructed within 151-300 m of primary nests, unless no practical or feasible alternative locations exist(e.g. due to extremely rugged terrain in adjacent areas outside the AOC) in which case only one operational road or landing is permitted in the AOC. • When roads are constructed within the AOC, temporary roads and/or water crossings will be used whenever practical and feasible to limit future access and disturbance. See AOC WS01, WS02 for other conditions on water crossings that also apply when AOCs for aquatic features are crossed. • Operations associated with roads and landings are not permitted within 75-300 m of *occupied* nests during the *critical breeding period* (April 15 to August 31) based on potential impact (see Table A, Table 19.1), unless required for safety reasons or environmental protection. • However, there is no timing restriction on hauling or low potential impact road maintenance operations (e.g., grading) if the road predates the nest. **Table A** **Potential Impacts** / **No operations within** High / 300 m Moderate / 150 m Low / 75 m

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
ON02		**Osprey Alternate Nest:** • New roads and landings are not permitted within 150 m of alternate nests. • No timing restriction on operations associated with roads and landings within the AOC.
ON03		**Osprey Inactive Nest:** • New roads and landings are not permitted within 75 m of inactive nests. • No timing restriction on operations associated with roads and landings within the AOC.
ON04		**Primary Osprey Nest Discovered During Operations But After Harvesting has Occurred within 150 metres of Nest:** • New roads and landings are not permitted within 150 m of primary nests. • New roads and landings will not be constructed within 151-300 m of primary nests (see Table A, ON01), unless no practical or feasible alternative locations exist (i.e. due to extremely rugged terrain in adjacent areas outside the AOC in which case only one operational road or landing is permitted in the AOC). • When roads are constructed within the AOC, temporary roads and/or water crossings will be used whenever practical and feasible to limit future access and disturbance. See AOC WS01, WS02 for other conditions on water crossings that also apply when AOCs for aquatic features are crossed. • Operations associated with roads and landings are not permitted within 75-300 m of *occupied* nests during the *critical breeding period* (April 15 to August 31) based on potential impact (see table FMP-19.1) unless required for safety reasons or environmental protection. • However, there is no timing restriction on hauling or low potential impact road maintenance operations (e.g., grading) if the road predates the nest.
BH01		**Active Great Blue Heron Colonies:** • New roads and landings are not permitted within 150 m of colonies. • New roads and landings within 151-300 m of colonies (especially large colonies) are not permitted, unless no practical or feasible alternative locations exist (i.e. due to extremely rugged terrain in adjacent areas outside the AOC) in which case only one operational road or landing is permitted in the AOC. • When roads are constructed within the AOC, temporary roads and/or water crossings will be used whenever practical and feasible to limit future access and disturbance. See AOC WS01, WS02 for other conditions on water crossings that also apply when AOCs for aquatic features are crossed. Within residual forest, the width of the cleared corridor will be as narrow as practical and feasible, and will not exceed 20 m. • Operations associated with roads and landings are not permitted within 75-300 m of *occupied* nests (see Table A) within colonies during the *critical breeding period* (April 1 – Aug. 15) based on potential impact (see Table A, Table 19.1), unless required for safety reasons or environmental protection. • However, there is no timing restriction on hauling or low potential impact road maintenance operations (e.g., grading) if the road predates the colony. **Table A** **Potential Impacts** / **No operations within** High / 300 m Moderate / 150 m Low / 75 m

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
BH02		**Inactive Great Blue Heron Colonies:** • New landings are not permitted within the AOC. • New roads within the AOC are not permitted, unless no practical or feasible alternative locations exist (i.e. due to extremely rugged terrain in adjacent areas outside the AOC) in which case only one operational road is permitted in the AOC. • No timing restriction on operations associated with roads and landings within the AOC.
BG01		**Active colonies of Bonaparte's gull:** • New roads and landings are not permitted within 150 m of active colonies. • Operations associated with roads are not permitted within 40-150 m of *occupied* nests within colonies during the *critical breeding period* (May 1 to August 31)based on potential impact (see Table A, Table 19.1), unless required for safety reasons or environmental protection. • However, there is no timing restriction on hauling or low potential impact road maintenance operations (e.g., grading) if the road predates the colony. **Table A** **Potential Impacts** / **No operations within** High / 150 m Moderate / 75 m Low / 40 m
BS01		**Active large colonies of bank swallows (≥100 pairs)** • New roads and landings are not permitted within 50 m of active colonies. • Operations associated with roads and landings are not permitted within 10-50 m of occupied nests within colonies during the critical breeding period (May 1 – July 31)based on potential impact (see Table A, Table 19.1), unless required for safety reasons or environmental protection. • However, there is no timing restriction on hauling or low potential impact road maintenance operations (e.g., grading) if the road predates the colony. **Table A** **Potential Impacts** / **No operations within** High / 50 m Moderate / 25 m Low / 10 m
BS02		**Barn Swallow Nests** **The following is general guidance on protective prescriptions for barn swallow. Recognizing that unique situations and timing will arise and legislative conditions must be met, the Kenora District Biologist will be contacted upon the discovery of barn swallow nests on water crossing structures to ensure a nest management plan is in place. A FMP amendment will be required for any changes to the conditions for this AOC listed below.** The critical nesting period for Barn Swallow is May 1 – August 31.

MANAGEMENT UNIT NAME: Whiskey Jack Forest [X] **Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 [ ] **Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
		If water crossing work is being completed during the critical nesting period (May 1 – August 31): If barn swallow nesting activity is identified: • Scheduled work will be suspended and a record of the activity will be made and passed to the District Biologist including details of: o The name, site and type of activity proposed to occur on the nesting habitat, o A description of the structure, o The number, location and description of barn swallow nests located on the structure and the amount of area suitable for nesting on the structure. • An exclusion plan will be developed with the District Biologist and will include nest removal and habitat replacement plans. • The habitat replacement plan will be developed with the District Biologist whereby: o 1 artificial nest (cup) for every destroyed nest will be installed on new nesting habitat (kiosk) no further than 1000 m from the original site and no further than 500 m from foraging space (water/wetland). o New nesting habitat must provide suitable nesting conditions by: ▪ Providing horizontal ledges or rough vertical surfaces with a sheltered overhang. ▪ Providing surface areas suitable for nest attachment at a height that minimizes disturbance or chance of predation. ▪ Allowing barn swallow to enter and exit freely. ▪ Providing suitable area to accommodate spacing between nests. ▪ Being structurally sound and capable of providing habitat for at least 5 breeding seasons. o This must occur before the beginning of the active barn swallow season. If, despite all measures in place, barn swallow enter the structure to establish nests any part of the activity that would harm or harass barn swallow while nesting must be suspended until the end of the barn swallow active season. Monitoring of the artificial nesting habitat will occur for 3 critical nesting period seasons. Reports detailing the number, description and location of new nests created by barn swallow and an estimate of the number of barn swallow using the structure will be given to the District Biologist. **If water crossing work is being completed outside of the critical nesting period (September 1 – April 30):** If barn swallow nesting activity is identified and the structure is being altered but will still be available for nesting after work is completed: • 1 artificial nest (cup) for every destroyed nest will be installed on the structure that was the object of the activity or in any structure that exists within 1 kilometer if it provides conditions that are suitable for barn swallow nesting. If barn swallow nesting activity is identified and the structure is being removed, demolished, destroyed or will otherwise no long be available for barn swallow nesting: • A habitat replacement plan will be developed with the District Biologist whereby: o 1 artificial nest (cup) for every destroyed nest will be installed on new nesting habitat no further than 1000 m from the original site and no further than 500 m from foraging space (water/wetland) ▪ On a structure previously existing that is deemed suitable for barn swallow nesting OR,

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
		• Use of existing roads within the 100m AOC is permitted at anytime.

NO08		**Bat Hibernacula** known to be suitable and to have been used at least once within the past 20 years by ≥ 50 **Little Brown Myotis** (Little Brown Bats) or ≥ 20 **Northern Myotis** (Northern long-eared bats)
		• 200m radius AOC centred on the entrance to the hibernaculum.
		  • No new roads and landing permitted within the inner 100m of the AOC.
		  • Reasonable efforts will be made to avoid constructing new roads, landings within 101-200m of the AOC. (ie. construct only of there is no other feasible/possible alternative due to excessive terrain outside the AOC or safety reasons).
		  • When roads are constructed within the AOC, temporary roads and/or water crossings will be used whenever practical and feasible to limit future access and disturbance.
		  • Road construction is not permitted within the AOC during the hibernation and associated entrance and emergence periods (September 1-May 30)
		  • No hauling and road maintenance operations permitted within the inner 100m of the AOC during the hibernation and associated entrance and emergence periods (September 1-May 30) unless the road predates the hibernaculum or is required for safety reasons or environmental protection.

PL01		**Patent Land:** • Roads and landings are allowed in AOC up to the established harvest boundary with a maximum right of way width of 20m. No roads are permitted between the harvest boundary and the patent land without the permission of the patent land owner and will require a plan amendment.
RR01		**Railway Right of Way:** • Roads and landings are allowed in AOC up to the railway right of way. • No slash piles or chipper debris piles are allowed to remain in landing for more than one year.
NG01		**Natural Gas Transmission Pipeline:** • Roads and landing are allowed in AOC; however a TransCanada Pipeline representative must be contacted before operations begin. **Contact Information:** TransCanada Pipelines Lakewood Area Pipeline Technician Lakewood Area Manager Office # 807-548-4241Office # 807- 548-6025 Cell # 807-466-7212Cell # 807-466-7330
HB01		**Highway Corridor Aesthetics:** • Operational road crossings are allowed with a maximum right-of-way width of 20 m.

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
LS01		**Tourism – Lac Seul Shoreline (Remoteness, aesthetics, fisheries, water quality, cultural heritage)** • No roads within 240 m of shoreline • Roads between 241m and 650 m of shoreline will be decommissioned. • All roads within 650 m of shoreline will be regenerated within 3 years of harvest operations.
TV01		**Tourism – Aesthetics Along Large High Volume Tourism Lakes, recognized canoe routes, recreational lakes:** • No roads permitted in AOC.
TVgl		**Tourism – Gibi Lake** • Operational road construction permitted between Labour Day and Victoria Day only. No construction on weekends (Friday 5 p.m. and Sunday 6 p.m.) between Labour Day and Thanksgiving Day.
TVw		**Tourism – timing restriction** • Operational road construction and hauling permitted between November 1st and April 30th.
TVwl		**Tourism – timing restriction** • Operational road construction and hauling permitted between November 1st and April 30th.
TVal		**Tourism – Aerobus Lake** • Operational road construction permitted between November 1st and May 1stonly.
TVer		**Tourism – English River Waterway Park** • Operational roads and water crossings within 500 m of the park boundary are to be made impassable following harvest operations through the removal of water crossing structures, trenching of roads and/or placement of slash on the road way. All roads within 500 m of the park boundary must be regenerated, within 3 years of harvest operations, to prevent access.
TVp		**Tourism - portage** • The maximum right of way width is 25 metres, unless a wider right of way is required to maintain a safe line of sight distance to a maximum of 35 metres. • Grubbing or stripping of material within 100 metres or to the height of land, whichever is least, on both sides of the portage will be kept to an absolute minimum required for construction.
WL01		**Large lakes, Medium lakes, Small lakes, Ponds - high or moderate potential sensitivity (HPS or MPS) to forest management operations:** • No landings are permitted in the AOC. • No new roads are permitted in the AOC.
WL02		**Ponds – low potential sensitivity (LPS) to forest management operations:** • New roads will not be constructed within 15 m of LPS ponds unless there is no practical or feasible alternative (i.e. excessive steep terrain prohibits road construction) and the mitigative measures outlined in Section 4.5.7 'General Conditions on Road Planning, Construction and Maintenance, Landings, Aggregate Pits' are taken to minimize the risk of sediment entering ponds and disruption of hydrological function. • Landings are not permitted within 15 m of LPS ponds.

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
WS01		**Rivers, Stream segments - high or moderate potential sensitivity (HPS or MPS) to forest management operations:** New roads that are not associated with an approved river/stream crossing are not permitted within the AOC unless no practical or feasible alternative exists, appropriate mitigative measures are taken to minimize the risk of sediment entering rivers or streams, and the road, including specific location, is identified and justified through the FMP AOC planning process. Refer to Part A for conditions that also apply to this AOC. Conditions on Decommissioning Decommissioning of water crossings will only occur if they are consistent with the approved road use management strategy and are scheduled for decommissioning in the current Annual Work Schedule. The schedules for water crossing and road decommissioning will be coordinated. Decommissioning of the water crossing will be consistent with the vehicular traffic expected by the use management strategy for the road. If continued vehicle passage can be considered after removal of the crossing structure, ensure the crossing site is safe and erosion resistant (e.g. a ford). All water crossings on that road system will be assessed by the MNR based on the criteria in the Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales MNR 2010 in Section 5.1.2.3 Decommissioning and rehabilitation and will be decommissioned in an environmentally sound manner and approved by the MNR. The Annual Work Schedule will outline the necessary techniques required for decommissioning to prevent erosion and protect public safety based on the analysis of the above criteria. Techniques will be used appropriate for the conditions encountered at each crossing to minimize disturbance of the water feature and the potential for erosion and sedimentation during and after decommissioning. During decommissioning, workers will prevent contamination of a water feature by foreign materials such as lumber, nails, logs, brush, fuel or oil. Decommissioning and rehabilitation operations that may enter a water feature (i.e. in-water work) or that may potentially cause sediment to enter a water feature, are not to occur during periods of fish spawning, incubation or fry emergence (See Timing Restrictions in Part A above). The Proponent will monitor operations and mitigation techniques to prevent the harmful alteration, disruption, or destruction of fish habitat, the impairment of water quality, and problems related to fish passage. Fill material placed above the high water level within the floodplain of a water feature will be resistant and/or protected from erosion. Any exposed mineral soil between the height of land and the water crossing, or within 100 m of the water crossing, whichever is less, will be trimmed to a stable angle and be protected from erosion so sediment will not enter water. Upon completion of decommissioning, any temporary fill, culverts, refuse, etc. will be removed from the construction area and disposed of in a satisfactory manner. Following decommissioning, on-site inspections will be made by the Proponent to confirm the standards are being met. Problems are to be reported to MNR immediately. For decommissioned water crossings that have not been removed monitoring the water crossings will take place as per direction in Section 4.7.4.

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
WS02		**Stream segments - low potential sensitivity (LPS) to forest management operations:** New roads will not be located within 15 m of the active channel unless there is no feasible alternative and appropriate measures are taken to minimize and mitigate the risk of sediment entering streams and disruption of hydrological function. <u>Design and location of water crossings</u> The preliminary location and conditions outlined in this area of concern for a water crossing will be confirmed or changed in the AWS. If the conditions or locations are changed, the change must be consistent with the FMP. Avoid steep banks or sites where actively slumping banks are evident. <u>Installation and Maintenance</u> Those responsible for maintenance will monitor operations and select operating practices, materials, and mitigation techniques at each water crossing to prevent the harmful alteration, disruption or destruction of fish habitat or the impairment of water quality. Harmful alteration, disruption, or destruction of fish habitat is not permitted without DFO approval. The installation of a water crossing will not result in the impediment of fish passage; mitigative techniques will be applied if the structure has the potential to impede or block fish migration or passage. Materials moved during construction, such as grubbed or earth fill material, will not be piled where they block drainage courses. At any time of year, the free movement of water and fish will not be blocked or otherwise impeded, except for brief periods during construction and as approved by MNR. The removal of stream boulders is generally not acceptable, except where necessary for installation of a crossing structure which retains a natural streambed (e.g., a bridge). Fill material required to build the road at the site of the crossing, below the high water level and within the floodplain of the water feature, will be erosion resistant and/or protected from erosion. Any exposed mineral soil between the height of land and the water crossing, or within 100 m of the water crossing, whichever is less, will be trimmed to a stable angle and be protected from erosion so sediment will not enter water. During construction and maintenance of a water crossing, contamination of a water feature by foreign materials such as lumber, nails, fuel, oil, or herbicides is not permitted (the crossing structure itself, including temporary crossings, can be in the water, if the approved design allows for this). Prevent sediment from entering the water features by using erosion and sediment control techniques.

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
		Blasting in or near water produces shock waves that can kill fish and will normally be avoided. Blasting with a potential impact on fish or fish habitat will only be done following approval from DFO. Upon completion of a water crossing, any temporary fill, culverts, refuse, etc. will be removed from the construction area and properly disposed of in a satisfactory manner. If using temporary winter only crossings, materials other than ice & snow will be removed from the stream prior to spring break-up. After construction, on-site inspections will be made by the proponent to confirm these standards are being met. If using temporary winter-only crossings, materials other than ice and snow will be removed from the stream prior to spring break-up. Upon installation, each new water crossing will be incorporated into the approved program for monitoring roads and water crossings. These standards are applicable to previously installed water crossings when they are replaced or upgraded due to sub-standard safety, environmental, or operational reasons. Use techniques and materials appropriate for the conditions encountered at each water crossing, to minimize disturbance of a water feature and significantly reduce the potential for erosion and sedimentation. Ensure logs and brush which may need to be removed or trimmed at the crossing site do not enter the water feature. Grubbing of low vegetative cover between the height of land and a water crossing, or within 100 m of a water crossing, whichever is less, will be limited to that required to address engineering issues and safety concerns, such as the removal of hazards. When diverting and/or removing water for dry installations, chase away or trap and relocate live fish before completely dewatering the area (note: permits may be required; consult the local MNR district office for further information). Apply mitigative techniques to provide for fish passage if there is potential to impede or block fish migration during installation of the crossing. Begin site stabilization and clean-up as soon as possible after the water crossing has been installed, including the removal of all diversions. Trim fill slopes to a stable angle, or use other mitigative stabilization techniques. A person should be able to walk up the slope without causing slumping and sliding of soil particles. When a temporary channel is no longer required, it should be stabilized to avoid long-term erosion. Construct and use fords during the driest time of the year but not during the restricted time of high risk to fish; ensure the ford does not restrict fish passage. Material used within the stream and on the banks to improve the crossing will be clean, non-erodable, and non-toxic to aquatic life.

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
		Install culverts on a straight section of stream. When installation of a culvert on a straight section of stream is not possible, minimize the change in stream morphology and impacts on fish habitat. <u>Conditions on Construction</u> No landings are permitted within the area of concern. Fill material placed to build the road below high water level within the floodplain of waterbody will be erosion resistant and/or protected from erosion. Materials moved during construction, such as grubbed or earth fill material, will not be piled where they block drainage courses. Grubbing or stripping within the 100 metre width or to the height of land (whichever comes first) of the location of the crossing on both sides of the waterway will be kept to an absolute minimum required for construction and where required must be stabilized to prevent erosion. Any exposed mineral soil between the height of land and a water crossing, or within 100 m of a water crossing, whichever is less, will be trimmed to a stable angle of repose and be protected from erosion so sediment will not enter the water after construction. <u>Right-of-way (ROW)</u> The right-of-way for the stream crossing will be cleared to a minimum width needed for construction or to a maximum width of 20 metres for a distance of 15 metres from the stream. <u>Timing Restriction</u> Construction operations that may enter a water feature or that may cause sediment to enter a water feature are not to occur during periods of fish spawning, incubation, or fry emergence, unless approved by MNR. If warranted (i.e. late spring, no fish habitat) the MNR may vary timing dates based on local knowledge. The timing restrictions for operations where the following local fish species are present are listed below: Baitfish and Suckers: April 1st to June 15th. The MNR will confirm at the AWS level all timing restriction conditions. <u>Water Crossing structure</u> Type of crossing structure will be determined and approved in the AWS. <u>Conditions on Decommissioning</u> Decommissioning of water crossings will only occur if they are consistent with the approved road use management strategy and are scheduled for decommissioning in the current Annual Work Schedule. The schedules for water crossing and road decommissioning will be coordinated. Decommissioning of the water crossing will be consistent with the vehicular traffic expected by the use management strategy for the road. If continued vehicle passage can be considered after removal of the crossing structure, ensure the crossing site is safe and erosion resistant (e.g. a ford).

Upon completion of decommissioning, any temporary fill, culverts, refuse, etc. will be removed from the construction area and disposed of in a satisfactory manner. Following decommissioning, on-site inspections will be made by the Proponent to confirm the standards are being met. Problems are to be reported to MNR immediately.
WW01		**Wetlands occupied in the last 20 years by breeding black terns, golden-winged warblers, least bitterns, or yellow rails:** • No new all-weather roads or landings are permitted. • New winter roads are not permitted within the AOC unless there is no practical or feasible alternative, reasonable efforts will be made to mitigate potential impact on occupied habitat, and the road, including specific location, is identified, justified and approved through an FMP amendment. • Water drawdowns or other activities that significantly alter hydrological regime are not permitted. • Reasonable efforts (i.e. Pre-harvest skid trail planning) will be made to avoid crossing wetlands with extraction trails during the frost-free period. • During all seasons crossings will be minimized and will follow the appropriate operating practices in FMP Section 4.2.2.2 Conditions on Regular Operations for 'Wetlands mapped permanent non-forested' to minimize potential site damage and effects on hydrological function.

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

B. Operational Roads and Landings

AOC or AOC Group Identifier	Public Comment	Planned or Existing Conditions on Location, Construction or Use
WW02		**Wetlands known to support flooded jellyskin:** • New roads and landings are not permitted within 30m of the high-water mark of woodland pools known to support flooded jellyskin. • Direction for woodland pools (FMP Section 4.5.7) will be applied to all other woodland pools with a surface area ≥200m2 (about a 15m diameter). • New all-weather roads are not permitted within the AOC unless there is no other feasible/possible alternative due to excessive terrain or for safety reasons.
FL01		**First Nation Reserve Land** • No new roads planned to be constructed. • Where road already exists through the AOC, road is open for travel except for forestry purposes unless approved with local First Nation in writing.
NE10		**Snapping Turtle Nesting Sites:** On identified snapping turtle nests and nesting habitat as encountered in the field. Applies only to areas scheduled for road decommissioning and does not impact regular maintenance on active roads: • No road decommissioning, including water crossing work, during the nesting period (June 1 to Sept 30). • No landings permitted within 200m of the nesting habitat area.
PGP01		<u>75m radius AOC measured from PGP centre, squared off such that the final AOC is 150m by 150m</u> • No landings permitted in the AOC • An operational road may be constructed in the area between the 75m radius measured from the PGP centre and the squared off (150m x 150m) AOC boundary • If an operational road is constructed within the AOC outside of the 75m radius from the plot centre yet within the squared off AOC boundary, adjust the AOC boundary to follow the edge of the road right-of-way (i.e. do not extend the AOC to include area on the opposite side of the road to the PGP centre) • Neither the road right-of-way nor the road can infringe on the75m radius from the PGP centre • No bulldozing of trees or road construction debris into the 75m radius from the PGP centre <u>75m radius AOC measured from PGP centre and rectangular plot AOC</u> • No landings permitted in the AOC No operational roads permitted in the AOC

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

C. Forestry Aggregate Pits

AOC or AOC Group Identifier	Planned or Existing Conditions on Location, Construction or Use
A01	**Archeological Potential Area** • No aggregate extraction is permitted. • No new aggregate pits are permitted.
D01	**Occupied Black Bear Den:** • Aggregate extraction is not permitted within the 100 m AOC during the denning period October 15 to April 30.
D02	**Occupied Grey Fox Den:** • Aggregate extraction is not permitted within the 100 m AOC during the denning period April 15 – September 15.
D03	**Occupied Cougar Den:** • Aggregate extraction is not permitted within the 200 m AOC during the denning period. Note: **The** *denning period* is potentially different for each occupied den encountered and is considered to extend for 8 weeks from the date an occupied den is located, or until a den is known to be no longer occupied.
D04	**Wolf Den:** • New aggregate pits are not permitted within the inner 100 m of the AOC. • New aggregate pits will not be constructed within the outer 100 m of the AOC unless it has been determined there is no other feasible alternative (e.g. terrain prevents aggregate pit establishment outside the AOC) ***Denning Period* April 15 to July 15:** • Aggregate extraction is not permitted within 200 m of an occupied den during the *denning period*.
D05	**Wolverine Den:** • If a wolverine den is encountered during operations all operations will stop within a 4km radius AOC and the Kenora District Office MNR will be immediately notified of the presence of a wolverine den in proximity to forest operations. • No further aggregate pits permitted within the AOC. • Following the above the FMP may be amended in consultation with MNR Biologists by developing a new AOC with a den site management plan for a specific den site location that will outline the extent and timing of any aggregate operations.
M01	**Mineral licks:** • Operations associated with existing aggregate pits are permitted within the AOC. • New aggregate pits are not permitted within the AOC.

C. Forestry Aggregate Pits

AOC or AOC Group Identifier	Planned or Existing Conditions on Location, Construction or Use

NO01

Stick nests occupied by barred owl, broad-winged hawk, common raven, Cooper's hawk, great horned owl, long-eared owl, merlin, red-tailed hawk, or sharp-shinned hawk:

- New aggregate pits will not be constructed within 20 m of nests of the barred owl, Cooper's hawk, common raven, great horned owl, long-eared owl, and red-tailed hawk**.**
- New aggregate pits will not be permitted within 20 m of nests of the broad-winged hawk, merlin, and sharp-shinned hawk, unless no practical or feasible alternative locations exist(e.g. due to extremely rugged terrain in adjacent areas outside the AOC) in which case only one pit is permitted in the AOC.
- Operations associated with aggregate pits are not permitted within 10-200 m of *occupied* nests during the *critical breeding period* unless required for safety reasons or environmental protection (see Table A, Table 19.1).

Table A

Species	Critical Breeding Period	High Impact Operations	Moderate Impact Operations	Low Impact Operations
(a) Barred owl	March 15 – July 15	200 m	100 m	50 m
(b) Broad-winged hawk	April 1 – July 31	100 m	50 m	25 m
(c) Cooper's hawk	April 1 – July 31	100 m	50 m	25 m
(d) Great horned owl	February 1 – May 31	100 m	50 m	25 m
(e) Long-eared owl	March 15 – July 15	100 m	50 m	25 m
(f) Red-tailed hawk	March 15 – July 15	100 m	50 m	25 m
(g) Common raven	February 15 – June 15	50 m	25 m	10 m
(h) Merlin	April 1 – July 31	50 m	25 m	10 m
(i) Sharp-shinned hawk	April 1 – July 31	50 m	25 m	10 m

NO02

Nests/ communal roosts in cavities occupied by American kestrel, barred owl, boreal owl, eastern screech-owl, great horned owl, northern hawk owl, northern saw-whet owl, or chimney swift:

- New aggregate pits will not be constructed within 20 m of nests/communal roosts of the barred owl, great horned owl, or chimney swift**.**
- New aggregate pits within 20 m of nests of the American kestrel, boreal owl, eastern screech-owl, northern hawk owl, or northern saw-whet owl, unless no practical or feasible alternative locations exist(e.g. due to extremely rugged terrain in adjacent areas outside the AOC) in which case only one pit is permitted in the AOC.
- Operations associated with aggregate pits are not permitted within 0-100 m of *occupied* nests during the *critical breeding/roosting period* (See Table A, Table 19.1) unless required for safety reasons or environmental protection.

Table A

Species	Critical Breeding Period	High Impact Operations	Moderate Impact Operations	Low Impact Operations
(a) Barred owl	March 15 - July 15	100 m	50 m	25 m
(b) Great horned owl	February 1 – May 31	50 m	25 m	10 m
(c) Northern hawk	March 15 - July 15	50 m	25 m	10 m

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

C. Forestry Aggregate Pits

AOC or AOC Group Identifier	Planned or Existing Conditions on Location, Construction or Use

NO03

Ground nests occupied by northern harrier, short-eared owl, or turkey vulture:

- The *critical breeding period* for all of Ontario is defined as March 15 to July 15 for short-eared owl, April 1 to July 31 for northern harrier, and May 1 to August 31 for turkey vulture.
- Operations associated with aggregate pits are not permitted within 10-150 m of *occupied* nests during the *critical breeding period* (see Table A, Table 19.1) unless required for safety reasons or environmental protection.

Table A

		Distance from Nest (m) with Timing Restriction During Critical Breeding Period if Nest is *Occupied*		
Species	**Critical Breeding Period**	**High Impact Operations**	**Moderate Impact Operations**	**Low Impact Operations**
(a) Turkey vulture	May 1 – August 31	150 m	75 m	40 m
(b) Short-eared owl	March 15 – July 15	100 m	50 m	25 m
(c) Northern harrier	April 1 – July 31	50 m	25 m	10 m

NO04

Whip-poor-will Nesting Sites

- No new forestry aggregate pits are permitted in the AOC (radius 200 metres from nest)
- Operations associated with aggregate pits are not permitted within 200 m of nests during the *critical breeding period* (May 1 – August 14) unless required for safety reasons or environmental protection.

NO05

Common Nighthawk Nesting Sites

- No new forestry aggregate pits are permitted in the AOC (radius 200 metres from nest)
- Operations associated with aggregate pits are not permitted within 200 m of nests during the *critical breeding period* (May 15 – August 15) unless required for safety reasons or environmental protection.

NO06

Olive-sided flycatcher nesting sites

- No new forestry aggregate pits are permitted in the AOC (radius 100 metres from nest)
- Operations associated with aggregate pits are not permitted within 100 m of nests during the *critical breeding period* (May 1 – August 31) unless required for safety reasons or environmental protection.

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

C. Forestry Aggregate Pits

AOC or AOC Group Identifier	Planned or Existing Conditions on Location, Construction or Use
NO07	**Canada warbler nesting sites** • No new forestry aggregate pits are permitted in the AOC (radius 100 metres from nest) • Operations associated with aggregate pits are not permitted within 100 m of nests during the *critical breeding period* (May 15 – August 15) unless required for safety reasons or environmental protection.
NO08	**Bat Hibernacula** known to be suitable and to have been used at least once within the past 20 years by ≥ 50 **Little Brown Myotis** (Little Brown Bats) or ≥ 20 **Northern Myotis** (Northern long-eared bats) 200m radius AOC centred on the entrance to the hibernaculum. • No new aggregate pits permitted with the inner 100m of the AOC. • Reasonable efforts will be made to avoid constructing new aggregate pits within 101-200m of the AOC. (i.e. construct only of there is no other feasible/possible alternative due to excessive terrain outside the AOC or safety reasons). • Aggregate extraction is not permitted within the AOC during the hibernation and associated entrance and emergence periods (September 1-May 30)
PGP01	**FESC PGP Growth and Yield Trial Plot** • No new aggregate pits are permitted.
PL01	**Patent Land** • No new aggregate pits are permitted.
RR01	**Railroad Right of Way** • No new aggregate pits are permitted.
NG01	**Natural Gas Transmission Pipeline** • No new aggregate pits are permitted.
HB01	**Highway Corridor Aesthetics** • No new aggregate pits are permitted.
LS01	**Tourism – Lac Seul Shoreline (Remoteness, aesthetics, fisheries, water quality, cultural heritage)** • No aggregates permitted within 240 m of the shoreline.
TV01	**Tourism – Aesthetics Along Large High Volume Tourism Lakes, recognized canoe routes, recreational lakes:** • No aggregate pits are permitted in the AOC.
TVgl	**Tourism – Gibi Lake** • Aggregate extraction permitted between Labour Day and Victoria Day only. No aggregate extraction on weekends (Friday 5 p.m. and Sunday 6 p.m.) between Labour Day and Thanksgiving Day.

MANAGEMENT UNIT NAME: Whiskey Jack Forest **[X] Phase 1 (Year 1-5)**
PLAN PERIOD: April 1, 2012 to March 31, 2022 **[ ] Phase 2 (Year 6-10**

FMP-19 ROAD CROSSINGS, LANDINGS AND FORESTRY AGGREGATE PITS IN AREAS OF CONCERN

Note 1: Conditions on roads, landings and aggregate pits outside areas of concern are documented in FMP Text Section 4.5.7.
Note 2: Table FMP-19.1 Road Construction and Maintenance Activities and their Potential Impact are located at the end of Table FMP-19.

C. Forestry Aggregate Pits

AOC or AOC Group Identifier	Planned or Existing Conditions on Location, Construction or Use
TVw	**Tourism – timing restriction** • Aggregate extraction permitted between November 1st and April 30th.
TVwl	**Tourism – timing restriction** • Aggregate extraction permitted between November 1st and April 30th.
TVal	**Tourism – Aerobus Lake** • No activity in aggregate pits between May 15th and August 31st.
TVer	**Tourism – English River Waterway Park** • No new aggregate pits are permitted within 500 m of the park boundary
TVp	**Tourism – Portage Trails** • No new aggregate pits are permitted.
WL01	**Large lakes, Medium lakes, Small lakes, Ponds - high or moderate potential sensitivity (HPS or MPS) to forest management operations:** • No aggregate pits are permitted in the AOC.
WL02	**Ponds – low potential sensitivity (LPS) to forest management operations:** • Aggregate pits are not permitted within 15 m of ponds.
WS01	**Rivers, Stream segments - high or moderate potential sensitivity (HPS or MPS) to forest management operations:** • Aggregate pits are not permitted in the AOC.
WS02	**Stream segments - low potential sensitivity (LPS) to forest management operations:** • Aggregate pits are not permitted within 15 m of the active channel.
WW01	**Wetlands occupied by breeding black terns, golden-winged warblers, least bitterns, or yellow rails:** • New aggregate pits are not permitted within the AOC.
WW02	**Woodland pools known to support flooded jellyskin** • New aggregate pits are not permitted within 30 m of the high-water mark of woodland pools known to support the flooded jellyskin. • Direction for woodland pools (FMP Section 4.5.7) will be applied to all other woodland pools with a surface area of ≥200m^2. • No new aggregate pits permitted within the AOC.

This report is retained at the

Ministry of Natural Resources District Office in Kenora.

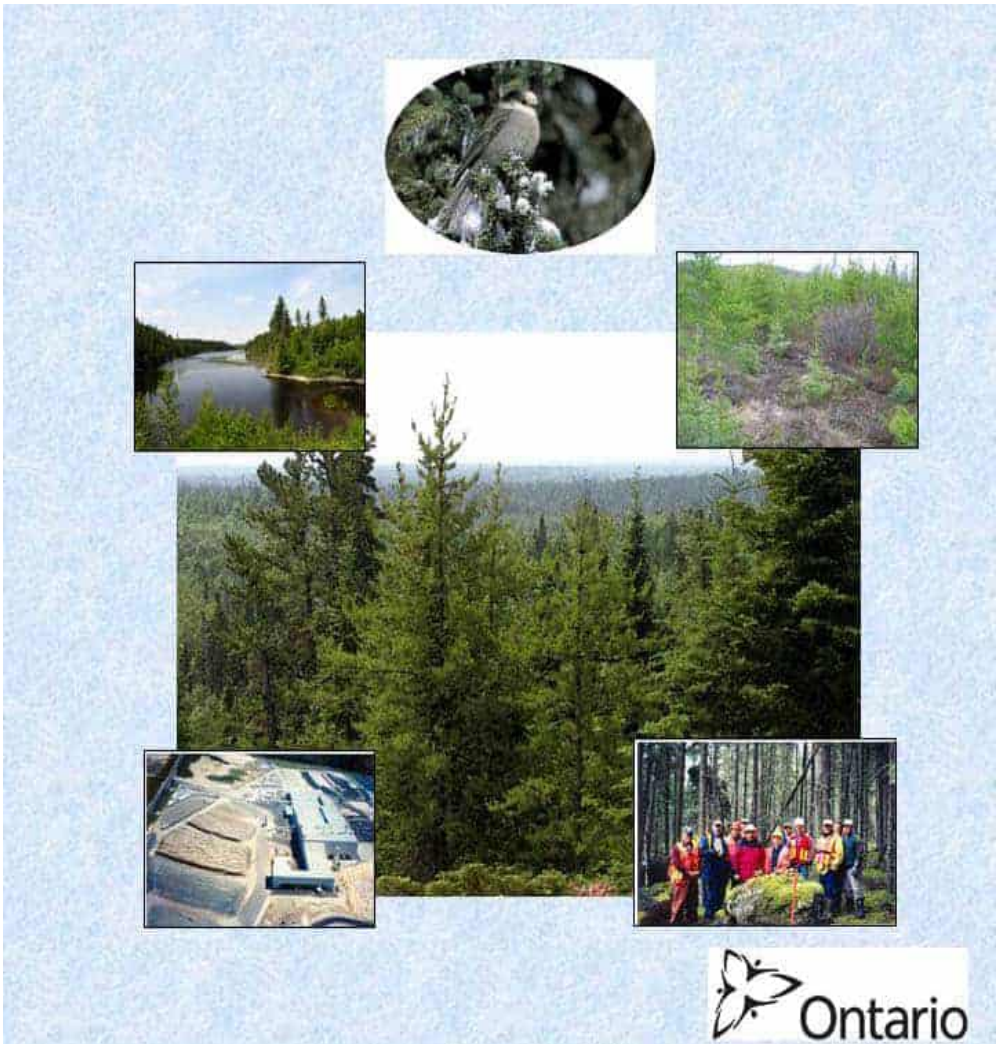
Supplementary Documentation D

2012-2022 Whiskey Jack Forest Management Plan

Social and Economic Information

Includes:
(i) Social and Economic Description (SED);
(ii) Demographic Profiles; and
(iii) Social and Economic Assessment (SEA).



Supplementary Documentation D - Social and Economic Information

Social and economic information in this supplementary document is organized into the following sections:

Part A: Social and Economic Description
- (a) communities that receive substantial amounts of timber, chips or other forest resources from the management unit, and communities that have substantial employment related to the forest industry;
- (b) forest resource-processing facilities; and
- (c) the primary uses and users of the forest.

Part B: Demographic Profiles

Part C: Socio-economic Assessment

Parts A and B have been updated to include current information for this 2012-2022 forest management plan.

A component of forest sustainability is the provision for the needs of individuals who receive benefits from the Whiskey Jack Forest. The Ministry of Natural Resources recognizes that activities within the Whiskey Jack Forest have significant impacts on the local economy, as well as the regional and provincial economies.

Demographic profiles for Whiskey Jack Forest have been produced and are included in this Supplementary Documentation. The socio-economic profile includes a description of the communities that receive substantial amounts of timber, chips or other forest products from the management unit, and communities that have substantial employment related to the forest industry; forest resource-processing facilities; and the primary uses and users of the forest.

Part A: Social and Economic Description

Communities

The Whiskey Jack Forest is located in the Kenora census district as defined in the 2006 Canada Census. A demographic profile was also produced specifically based on wood flow from the Whiskey Jack Forest to communities that have dependent wood processing mills. Crown wood fibre from the Whiskey Jack Forest went to mills in the following census districts in:

a) Kenora
b) Fort Frances
c) Chapple
d) Dryden
e) Sioux Lookout

Demographic profiles are generated by the Ministry of Natural Resources for this management plan with data derived from the standard Canada census. A summary profile, called the Demographic Profile for Wood Flow from FMU-Whiskey Jack Forest, is also produced for the affected area as a whole. The detailed profiles are included in Part B of this Supplementary Documentation.

Demographics and Migration

The following is a summary of the information found in the demographic profiles. These profiles provide information on population, labour force and community dependency on uses of the forest and are discussed below.

Kenora Census District:

i) Kenora Organized:
The total population for the Kenora district, from the 2006 census is 15,177 persons of which 51.2% are female and 48.8.% are male. Average individual income for this district is $31,069 with the average household income of $59,325. The employment rate in Kenora is 91.5% with 52.2% of the labour force being male and 47.8% is female. The portion of the local labour force engaged in the forest industry is 7.4%. This area had a high dependency on the pulp, paper and paperboard mills (16.8) followed by logging (14.6). Employment in Kenora is largest in the sales sector (30.6%). Trades and finance sectors employ 17.5% and 13.1% of the labour force respectively. Employment in the manufacturing sector is tied up in a relatively few number of businesses.

ii) Kenora Unorganized:
This is a subdivision of Kenora Census District and includes the township of Ear Falls, with a total population of 7,041 of which 51% are male and 49% female. The township of Ear Falls has an average population of 1,153. Average individual income for this subdivision is $28,504 with the average household income of $57,921. The employment rate is 68.9% with 55% of the labour force being male and 45% is female. The portion of the labour force that is engaged in forestry activity is 14% with heavy reliance on timber tract operations (76.3%).

Fort Frances Census District:

The total population for the Fort Frances district, from the 2006 census, is 8,103 persons of which 47.9% are male and 52.1% female. The general population trend for this district has been decreasing since 1981 census. Average individual income for this district is $30,443 with the average household income of $55,017. The employment rate in Fort Frances is 93% with 52.3% of the labour force being male and 47.7% female. The portion of the local labour force engaged in the forest industry is 17%. This area has a high dependency on the pulp and paper sector (48%) followed by the veneer, plywood sector (19% indexed to province). Employment in Fort Frances is largest in the forestry sector (14%).

Chapple Census District:

The total population for the Chapple district, west of Fort Frances, from the 2006 census, is 856 persons of which 50.9% are male and 49.1% female. The general population trend for this district has been decreasing since 1981 census. Average individual income for this district is $23,247 with the average household income of $50,563. The employment rate in the Chapple district is 100% with 55% of the labour force being male and 45% female. The portion of the local labour force engaged in the forest industry is 12%. This area has a high dependency on the logging sector (34%) followed by the sawmills and wood preservation sector (19% indexed to province). Employment in the Chapple area is largest in the forestry sector (13%).

Dryden Census District:

The total population for the Dryden district, from the 2006 census, is 8,195 persons of which 49.1% are male and 50.9% female. The general population trend for this district has been decreasing since the 1981 census. Average individual income for this district is $32,568 with the average household income of $62,625. The employment rate in Dryden is 67.5% with 54.3 % of the labour force being male and 45.7% is female. The portion of the local labour force engaged in the forest industry is 19.7%. This area has a high dependency on the pulp and paper sector (64 indexed to province). Employment in Dryden is largest in the sales sector (28.1%).

Sioux Lookout Census District:

The total population for the Sioux Lookout district, from the 2006 census, is 5,183 persons of which 49% are male and 51% female. The general population trend for this district has been stable since 1981 census. Average individual income for this district is $38,971 with the average household income of $79,374. The employment rate in the Sioux Lookout district is 96% with 50% of the labour force being male and 50% female. The portion of the local labour force engaged in the forest industry is 12%. This area has a high dependency on the sawmills and wood preservation sector (67%) followed by the logging sector (23% indexed to province). Employment in the Sioux Lookout district is largest in the forestry sector (10%).

Aboriginal Communities

A number of Aboriginal communities will also be directly affected by forest operations within the Whiskey Jack Forest. These include:

1. Asubpeeschoseewagong Netum Anishnabek First Nation (Grassy Narrows)
2. Naotkamegwanning First Nation No. 32A *(*Whitefish Bay)
3. Wabaseemoong Independent Nations (Whitedog)
4. Wabauskang First Nation No.21
5. Ochiichagwe'babigo'inning First Nation (Dalles)
6. Kenora Métis Council

Please refer to the Aboriginal demographics for these communities within Part B of this supplementary Documentation, as well as the Aboriginal Background Information Report (retained on file in the Kenora District MNR office) for additional details regarding the First Nation communities.

Industrial and non-Industrial Uses of the Forest

There are many resource-based activities that occur on the Whiskey Jack Forest, including forestry, recreation and tourism, mining, aggregate and hydro generation, trapping and bait-harvesting. Together, these activities form the social and economic environment that is affected by decisions made through the forest management planning process.

Timber

Timber Licences

The Whiskey Jack Forest is a Crown unit managed by the Ministry of Natural Resources, Kenora District. Wood supply Commitments in the now expired SFL document will be used as objectives in the development of the 2012 Whiskey Jack Forest Management Plan.

Background information for this section was obtained from TREES and *"An Economic Impact Analysis of the Northwestern Ontario Forest Sector (2006)",* This report provided projections about future trends for the industry on the Whiskey Jack Forest. The forestry report was prepared by B. Moazzami, Ph.D.in association with the Northwestern Ontario Forest Council (NOFC) for the year 2006. This information, provided by NOFC has been included in this plan as supplementary documentation; however, it has not been verified for accuracy, quality or completeness by the planning team. Due to the extent of the study area comprising of most of Northwestern Ontario it was decided to use the Kenora subregion in this report. The full details of this report are found Appendix 2.

The forestry industry is the predominant employer for 350 communities in Canada. Approximately 285 communities in Ontario are somewhat forest dependent. Seventy of these are considered moderately to highly dependent since more than 50% of their employment directly or indirectly depend on the forestry industry. Of the 285 communities, 32% or about 90 communities are in Northwestern Ontario.

Northwestern Ontario's forestry industry directly employed about 12,935 people in 2001. Average annual wages and salaries ranged from $22,275 for forestry services to $42,508 in forestry and logging and $57,345 in pulp and paper industries. The overall average annual wages and salaries in the forestry industry equalled $48,244.38 in 2001 compared to the average earnings of $31,362 in Northwestern Ontario. In other words, the average earnings in the forestry industry are 54% higher than the overall average earnings in Northwestern Ontario. Note that these wages and salaries do not include fringe benefits. With fringe benefits, the average compensation and benefits in Northwestern Ontario's forestry industry equalled $62,143.58 in 2001 dollars.

Community dependency on forestry employment in Kenora sub-regions is 19.8% with the regional average being 27%. Community dependency on forestry income according to the report was 25.5% and the regional average being 35%.

Wood Supply Commitments

As there is no SFL in the Whiskey Jack Forest; commitments found in the old SFL document will be used to analyze wood supply in strategic modelling. This document describes two types of wood supply commitments found in Paragraph 3.0 and appendix E. The SFL wording of those commitments follows:

"3.0 WOOD SUPPLY COMMITMENTS AND OVERLAPPING LICENCES"

3.1 The forest resources harvested pursuant to this licence are to provide a supply of forest resources to the existing forest resource processing facility of the Company

located at Kenora and Fort Frances, Ontario and to the beneficiaries of forest resource supply commitments identified in Appendix "E" hereto.

3.2 Subject to complying with the wood supply commitments described in Appendix "E" and the conditions in Appendix F, the Company shall be entitled to harvest and utilize the full available harvest described in the Forest Management Plan for the Whiskey Jack Forest.

APPENDIX "E" WOOD SUPPLY COMMITMENTS

The Company shall comply with the following wood supply commitments on the Whiskey Jack Forest:

1) To make available, through long term memorandum of agreement, hardwood veneer quality fibre (poplar), annually, to Columbia Forest Products Inc. for use in their core veneer mill to be constructed in Northwestern Ontario. This supply of hardwood veneer quality fibre is subject to the fulfillment of conditions as described in a letter dated March 31, 1995 from the Minister of Natural Resources to Mr. Harry Demorest, President and Chief Executive Officer of Columbia Forest Products Inc. The Company must provide a copy of the memorandum of agreement negotiated as a result of this condition of the SFL to the Ministry upon request.

2) To make available annually, through a long term memorandum of agreement, all aspen poplar and white birch non-veneer roundwood to Weyerhaeuser Company Limited for use in their laminated strand lumber mill located at Kenora, Ontario. This wood supply is consistent with a letter dated June 16, 1999 from the Minister of Natural Resources to Mr. Thomas H. Denig, President and CEO, Trus Joist MacMillan (now Weyerhaeuser Company Limited). The Company must provide a copy of the memorandum of agreement negotiated as a result of this condition of the SFL to the Ministry upon request.

3) To make available annually, through a long term memorandum of agreement, 133,000 cubic metres of jack pine, spruce, and balsam fir coniferous fibre material, to Kenora Forest Products Ltd. For use in their sawmill at Kenora, Ontario. This supply of coniferous fibre material is consistent with a letter dated November 16, 1994 from the Minister of Natural Resources to Maureen Prendiville, President of Prendiville Industries. The Company must provide a copy of the memorandum of agreement negotiated as a result of this condition of the SFL to the Ministry upon request.

In addition to these commitments wood is made available through overlapping licences to people wishing to harvest fuelwood from the forest or for small quantities of building logs (e.g. trapper cabins). The Ministry of Natural Resources and Abitibi work cooperatively to provide these small quantities of wood.

Harvest and Wood Utilization

Information in this report was provided by the Ministry of Natural Resources scaling and billing system (TREES). TREES provides detailed information regarding harvest (e.g. species, volumes) and utilization (e.g. mill destination). The information covers the nine-year period from 2004/05 to 2012/13 inclusive.

This information will be useful in determining an appropriate target for wood supply in the 2012/22 FMP. With recent closures of mills, demand for wood supply will have to be re-evaluated. Analysis regarding future demand or utilization from the forest will consider the SFL commitments and the current industrial capacity.

Over the nine year period, 2,391,486 cubic metres were harvested and utilized from the forest. The average annual volume harvested from the forest was 265,721 cubic metres of jack pine, spruce, poplar and white birch.

The majority of wood harvested was utilized at eighteen mills producing a variety of products including pulp, paper, lumber, composite boards, sawlogs and veneer.

Note: This red and white pine was originally identified as fuelwood in TREES but was utilized as sawlogs.
The data for this report includes both invoiced and undersize material which is consistent with the way volume is reported in the annual reports. The information is approximately equal to the annual report values. The Devlin sawmill closed in 2004. The Abitibi paper mill in Kenora closed in November 2005. One paper machine was closed at the Dryden mill in 2005.

1

Chips

The Kenora Forest Products in Kenora and Domtar Inc. in Ear Falls sawmills produces chips, both jack pine and spruce. The Domtar Inc. paper mill in Dryden used those chips in their process.

Facilities Utilizing Wood from the Forest

There are three facilities named in the SFL as beneficiaries of wood from the forest:

1. Abitibi-Consolidated (Kenora)

Number of Employees: Mill N/A
Woodlands N/A
Contractors N/A
Products: N/A
Ownership: N/A
Upgrades: N/A
Downtime: Closed November 2005

2. Trus Joist Weyerhaeuser (Kenora)

Number of Employees: Mill 214
Woodlands 6
Contractors 150
Products: Laminated Strand Lumber (LSL) used for concrete edge forms, beams, headers, flange stock, rim board, shear panels and wall framing (premium lumber).
Ownership: Weyerhaeuser (since 2001)
Upgrades: Construction began in October 2000 and began operations in October 2002. Combustor upgrades
Downtime: Temporary shutdown in January 2007, laid off 100 workers with 41 other jobs permanently lost. Currently operating 3 shifts/week.

3. Resolute Forest Products (Abitibi-Consolidated (Fort Frances))

Number of Employees: Mill - 720 salaried and hourly
Woodlands - 30 salaried
Contractors - 65 harvesting
- 25 silviculture
- 10 road construction
- 18 road maintenance

Products: Uncoated groundwood specialty paper and northern bleached softwood pulp
Ownership: Abitibi-Consolidated Company of Canada has developed through a series of acquisitions, divestitures and mergers over time. The key developments associated with the Fort Frances Mill are summarized as follows:

Abitibi-Consolidated Inc. was formed by the merger of Abitibi-Price and Stone-Consolidated in May 1997. Stone-Consolidated's assets included eight pulp and paper mills, including the Fort Frances and Kenora operations. On April 18, 2000

Abitibi-Consolidated Inc. announced that it had acquired Donohue Inc. The combined Company operations in Canada became Abitibi-Consolidated Company of Canada. Resolute was formed as merger of Abitibi and Bowater Inc. in 2010.

Upgrades: No significant changes in production capacity, but a significant change has occurred in the grade mix, as a result of the peroxide bleaching addition at the Fort Frances mill in 2001. As a result, Fort Frances now produces a higher proportion of Very High Brite (VHB) grades (those 75 brite and higher). In February 2009, the biomass boiler was accepting hog fuel and operating at full steam.

Downtime: The last significant downtime for the Fort Frances mill was in 1998, when a five-month shutdown resulted from a labour dispute. Although there has not been any significant downtime at the Fort Frances mill since 2000, market related down time at the Boise mill in International Falls, MN has caused the Fort Frances kraft mill to slow down the production of kraft pulp on a periodic basis. In 2013, Resolute laid off 240 staff due to curtailment of the kraft mill and one paper machine.

4. <u>Kenora Forest Products (Kenora) (currently closed)</u>

Number of Employees: Mill 109
Woodlands

Products: 2x4 and 2x6 kiln dried studs in 48'' to 104'' lengths for building purposes
1x4 rough green solid wood products in 48'' to 104'' lengths
Planer shavings, sawdust and bark used in Dryden, Wisconsin and Atikokan

Ownership: Prendiville (since 1994)

Upgrades: Production and recovery improvements

Downtime: Idled Indefinitely

5. <u>Devlin Timber (Kenora)</u>

The Devlin Timber sawmill ceased operations in 2004 due to a series of production, economic, and operational problems. In April of 2005 the assets of the mill were sold at a public auction. The mill is no longer in operation.

<u>A number of other facilities received wood from the forest during the 2004/2012 period. Significant users are listed below.</u>

6. <u>Mackenzie Forest Products (Hudson)</u>

Number of Employees: Mill 350
Woodlands 325

Products: Primarily 2x4 studs and some additional products such as 1x4 and 2x3 lumber.

Ownership: Buchanan Forest Group

Upgrades: Last major upgrade 1998 $20 million capital for a new DDM line (small diameter wood)

Downtime: Mill shutdown in September 2008.

7. Domtar Inc. (Dryden)

Number of Employees: Mill, woodlands, and contractors employ approximately 1,125 people
Products: Hardwood pulp and majority of softwood pulp used internally as feed stock for fine paper machine (720/fine paper). Mill complex contains two fine paper machines as well as converting facilities that convert paper rolls into cut sheets.
A sawmill operated on the site until 2004. Chips from the sawmill were used to supplement the roundwood in the Kraft papermaking process.
Ownership: Domtar Inc. has owned and operated Dryden pulp & paper mill since 2007.
Upgrades: Recent upgrades include construction of a new recovery boiler primarily to reduce emissions and odours. Project completed early in 2004 at a cost in excess of $250 million.
Downtime: No major downtime over past few years. Some idle time on paper machines due to soft markets.
In 2004 the sawmill was closed and operations were shifted to Ear Falls.
In 2005 one paper machine was closed. In November 2008, Domtar permanently shut down a paper machine affecting 195 employees.

8. EACOM Sawmill (Ear Falls) (currently **closed)**

Number of Employees:	Mill	189
	Woodlands	6
	Contractors	

Products: Stud Lumber Production
Ownership: EACOM has operated the facility since taking over from Domtar in 2010
Upgrades: Recent upgrades include new plant/equipment worth $1.6 million
Downtime: Idled since December 2009

9. Multiply/Levesque Plywood Limited (Nipigon) (operating as Columbia Forest Products) **MILL BURNT DOWN 2006, NOT REBUILT.**

10. Ainsworth Engineered Corp. (formerly Voyageur Panel Ltd.) (Barwick)

Number of Employees: Mill - 152
Products: Variety of value-added OSB products, including premium floor underlayment, rimboard and webstock, in addition to commodity structural sheathing panels.
Ownership: Ainsworth Engineered Corp. - mill purchased from Voyageur Panel Limited in May of 2004
Upgrades: None under new ownership.
Downtime: None under new ownership.

Notes for the volume and value table:

- Volume m3 is the invoiced volume.
- Undersize is the additional volume below the scaling manual minimum size.
- Undersize was free of Crown charges.
- Stumpage is the minimum Crown charge.
- Residual value fluctuates based on market conditions and the value of the product.
- Both are combined for the total stumpage charge.
- Renewal refers to contributions to the Forest Renewal Trust (FRT) account for the Whiskey Jack Forest.
- Future refers to the contribution to the Forest Futures Trust (FFT) account.

During the nine-year period, there were 115 licenses issued to individuals to collect fuel wood and an additional 5 licenses to harvest wood for other purposes (e.g trapping cabins).

Summary of Personal Use from the Whiskey Jack Forest
Nine Year period: 2004/05 to 2012/13

Personal Use	Volume m3	Undersize m3	Total Volume M3	Stumpage $	Residual $	Total Crown Charges	Renewal $	Future $	Total $
Fuelwood	2,093	0	2,093	$4,621	$0	$4,621	$231	$31	$4,883
Other	960	0	960	$3,619	$0	$3,619			$3,619
Total	3,053	0	3,053	$8,240	$0	$8,240	$231	$31	$8,502

Recreation and Tourism

Resource-based Tourism Industry

The tourism industry has been an important component in the Kenora area for a long time. Lodges and cottages were in operation by 1905. At that time the activities were based on hunting, fishing and canoeing opportunities. The Whiskey Jack Forest has attracted recreation-based tourism since the late 19th Century due to its variety of natural values. The area continues to be a desired recreational destination for canoeing, boating, fishing, hunting, hiking, snowmobiling, camping and cottaging for the following reasons:

- There are more interconnected lakes, rivers and portages.
- The rugged topography including cliffs, low wetlands, viewpoints and island-dotted lakes provide excellent scenery for summer and winter travelers.
- The area is traversed by numerous trails providing winter recreation opportunities by snowmobile, cross-country ski, or dog sled. In the summer, canoeist and hikers can access remote locations.
- There are numerous cultural heritage values including very old aboriginal heritage sites
- And more recent logging and mining heritage sites.

Background information for this section was obtained from the Crown Land Atlas and survey information was supplemented with data gathered from a number of other sources, specifically; MNR fishing and hunting licence files, tourist operator websites, the "*The Economic Impact of Tourism in Sunset Country, Ontario – Final Report (2003*) and the Lake of the Woods Economic Impact Study – Final Report (2003)". These last two reports provided projections about future trends for the industry on the Whiskey Jack Forest. The tourism report was prepared by Paul Kerr Forster in association with the Canadian Tourism Research Institute for the Northwestern Ontario Tourist Association (NOWATA) for the year 2001, expenditure or user days or travel distance for most of these activities. This information, provided by NOWATA has been included in this plan as supplementary documentation; however, it has not been verified for accuracy, quality or completeness by the planning team. Due to the extent of the study area comprising of most of Northwestern Ontario and Northern United States, it was decided to use the Kenora subregion in this report. The full details of this report are found Appendix 1.

There are 362 tourist operators in Kenora District and of that, of which 143 are associated with the Whiskey Jack Forest. There are 1,852 units available in the Whiskey Jack Forest. A "unit" is defined as any of the following: serviced hotel or motel room, serviced resort rooms, serviced cottages, serviced cabins, serviced outpost camps, housekeeping room, housekeeping suites, housekeeping cottages, housekeeping cabins, housekeeping outpost camps. The impact study reports that 54% of the operators have >= 10 units, 29% have between 11-19 units and 18% > 20 units. In 2001, the average revenue generated by each unit was $40,000. Of this, Retail and Guest services generated 25% of the revenue with Food and Beverage operations generated 11% of the total revenue. It is estimated that 500,000 people visited Kenora district in 2001 which was made up of travellers from Ontario (20%), other Canadian provinces (25%), United States (55%) and Others (1%).

The planning team sent out questionnaires to all the tourist operators registered within Kenora district as shown in Appendix 2. About 20% of the mail outs responded to the questionnaire which is considered a success. Of the respondents, 65% identified an average of 5 outpost camps, 20 beds, 25 employees and a minimum client volume of 200 people (mostly clients from the U.S.A. (75-100%)). The expectation is almost 90% will increase or like to increase the capacity of their lodges in the next 5 years.

The Sunset economic study reports that in 2001, 443 operators provided employment to 3,785 persons of which 1,221 were located in the Whiskey Jack Forest. The operator survey also indicated that there were 758 First Nations employed in Sunset Country of which 80% were seasonal or part time employees. Accommodation providers in Sunset Country employed 498 or 40% which were between 25-44 years old. The large variety of lakes and rivers, some of which are remote (17% boat access and 13% fly-in) while others are easily road accessible (62%), provide a wide range of angling opportunities. Whiskey Jack Forest has excellent natural lake trout lakes and walleye fishing is also popular in hundreds of small lakes along with larger lakes such as Lake of the Woods, Dryberry and Sydney Lakes.

The tourism expenditures in Kenora District, down into categories for both the amount spent and the amount retained in the District. This is useful in determining the retention rate of the tourism economic impact in the Study Region. According to the Ministry of Tourism & Recreation, overall, tourism in the Kenora Census Districts contributed just over $181 million in Gross Domestic Product in 2001, $109 million or 60% of which was retained in the District. It is estimated that tourism alone generated almost $80 million in taxes distributed to federal, provincial and municipal governments. Tourism creates almost 3,000 direct jobs in the Districts distributing close to $49 Million in direct wages and salaries. The total number of jobs created by tourism including direct, indirect and induced was 5,263 in 2001, with payroll earnings of just over $114 Million.

The Whiskey Jack Forest is comprised of five Wildlife Management Units (WMU); zones 3, 5, 6, 7B and 8. This represents a significant portion of these wildlife units that are utilized extensively for hunting and fishing. Hunting continues to be an important recreational activity in the Whiskey Jack Forest area. Big game is the primary activity although ruffed grouse, black bear, migratory waterfowl and snowshoe hare are also hunted. Hunting is either carried out adjacent to access roads created by the forest industry, by use of water based transportation to remote roadless areas, or by fly-in outfitters to backcountry locations. A large proportion of big game hunters are non-resident hunters who contribute to the local economy depending on how many local services they utilize. More than 90% of the bear hunters are non-residents. There are a wide variety of trails in the Whiskey Jack Forest that are used (depending on the nature of the activity and the Land Use designation) by hikers, cross country skiers, dog sledders, snowmobilers, and ATV operators. In addition to prepared trails, there are opportunities to travel on ungroomed areas such as snowshoeing along lakes and portages or snowmobiling along ungroomed lakes or unploughed roads.

Rushing River Provincial Park, and a few other private campgrounds along Highway 17 and Highway 71 corridor, provides camping opportunities. Approximately 65,000 people visit or use the many canoe routes around the park. Canoe trippers and anglers that are flown into backcountry sites use most of the remote sites. Many cottages were established after the railroad arrived in 1888 and made access to the Whiskey Jack Forest area easier. There are abundant cottages on Lake of the Woods are primarily located on the many islands on the lake, since shoreline development is limited. The building of what is now known as Hwy 17 made it easier to access additional lakes in the area.

The list of lodges on the Whiskey Jack Forest follows:

Mining, Aggregates and Hydro Generation

Mining

DESCRIPTION OF THE WHISKEY JACK FOREST MANAGEMENT UNIT

Overview of the Management Unit

The Whiskey Jack Forest Management Unit is located on the Precambrian Shield in northwestern Ontario. The Management Unit is underlain by rocks of the Superior Province contained within the Precambrian Shield. Rocks of the Superior Province are represented predominantly by granitic bedrock with substantial amounts of metavolcanic and meta-sedimentary rocks, generally termed greenstone.

The management unit's glacial geology was developed by advances of the Wisconsinan Sheet which started over 100,000 years ago and the subsequent glacial retreats which ended approximately 7,000 years ago.

Geology

There are geological features associated with two major eras of earth history visible within the management unit. The older is represented by the bedrock geology and the younger is expressed by surficial geological features. The bedrock in the area is a result of continent building processes which were active between approximately 2.7 and 1.1 billion years ago. Bedrock represents the solid foundation upon which the current landscape is set. The surficial geology is a result of erosion processes active since the continent-building activity. The last two million years saw glacial advances and retreats, which ended approximately 7,000 years ago. The glacial activity produced landforms by deposition and erosion of surface materials. The topography and landforms observed within the management unit are a result of the presence of both bedrock and surficial geological features and their interaction with environmental surface processes.

Bedrock Geology

The management unit is underlain by a diverse assemblage of rocks contained within the extensive Superior province. Within the boundaries of the management unit the Superior Province is further divided into the Wabigoon and Winnipeg River subprovinces. The Wabigoon subprovince is an east-trending belt made up of volcanic and sedimentary rocks that have been altered through exposure to heat and pressure, and subsequently intruded and surrounded by large bodies of granitic rocks. The volcanic rocks are prospective for base metal deposits; the volcanic and associated sedimentary rocks are prospective for gold deposits. The Winnipeg River subprovince makes up the northern portion of the management unit and is dominantly granitoid rocks with areas of highly metamorphosed and deformed volcanic and sedimentary rocks (OGS, 1991).

Surficial Geology

The Whiskey Jack Forest Management Unit consists of bedrock-controlled uplands, where the surficial sediment cover is commonly thin and consists of stony, sandy till. In the low-lying areas, there are significant areas of glaciolacustrine deposits related to Glacial Lake Agassiz interbedded with several layers of till of northeastern and northwestern provenance. Surficial deposits of granular resources occur primarily in the Rainy Lake-Lake of the Woods moraine and as buried ice-contact and subaqueous fan deposits (Bajc 2001).

Mining and Mineral Exploration

Historically, mining and mineral exploration have been an important activity in this management unit and historically gold, silver and copper were the predominant commodities mined. Currently there are four granite producers in operation which have been and continue to be a significant contributor to the economy of the area. The value of total granite production was not available at the time of writing. Historical metal production occurred within the management unit between 1893 and 1951 and totaled 68,513 ounces gold, 14,762 ounces silver and 1.89 million pounds of copper valued at $49.73 million CDN at current metal prices.

In addition to historical and current mineral production there are significant concentrations of gold, nickel, copper, silver and uranium contained within documented mineral deposits throughout the management unit. The total estimated value of metals contained within these deposits at current commodity prices is in excess of $158 million CDN.

There are an estimated 1,605 active mining claim units recorded throughout this management unit, as indicated on MNDM's CLAIMaps website (MNDM, 2006). These claims represent an investment in the management unit of approximately $400,000 CDN for claim staking, which directly relates to its mineral potential. In addition there is an estimated dollar expenditure of nearly $650,000 CDN per year related to mineral exploration work required to keep the claims in good standing. Current claim staking targets areas with potential for uranium, rare-metals, zinc and gold. Historically, several areas within the management unit have seen extensive staking and mineral exploration.

Aggregates

There are 12 aggregate sites located in the Whiskey Jack Forest, all operated by MNR.

Hydro

A number of hydro-electric facilities are located within or adjacent to the forest. These facilities are on the English River between Lac Seul and the Manitoba border and on the Winnipeg River between Lake of the Woods and the English River.

Two sites owned by Ontario Power Generation are located within the district:

1. Ear Falls

There are four power generating units at Ear Falls located on the English River at the outlet of Lac Seul. The first unit began operating in 1930.

Additional generating capacity is being developed at the Ear Falls GS by adding a new 12.5 MW generating unit capable of generating approximately 52 million kilowatt hours of hydroelectricity per year.

2. Manitou Falls

This facility is located on the English River where it enters Barnston Lake downstream of Ear Falls. There are five operating units located at this facility. Construction on this facility began in 1953.

Four additional sites are located within Kenora district and supply power to the area. Two of these are also owned by Ontario Power Generation and the other two (both in Kenora) are owned by Abitibi Consolidated.

3. Caribou Falls

Caribou Falls consist of three power generating units built in 1958 on the English River at the outlet of Umfreville Lake. The Caribou station was the third plant built along the English River which represented just a fraction of the widespread program undertaken to meet the challenge of expansion in mining and also pulp and paper industries.

4. Whitedog Falls

This facility consists of three power generating units built in 1958 on the Winnipeg River at Whitedog Falls.

5. Kenora Power House and Norman Dam

These generating stations are owned by Abitibi Consolidated. The Kenora Power House is located on the on the Winnipeg River in Kenora at the outlet of Lake of the Woods. The Norman Dam generating station is located on the Winnipeg River in Kenora.

Parks and Protected Areas

There are seven provincial parks or protected areas adjacent to or surrounded by the Whiskey Jack Forest. Parks in the management unit include the West English River, Eagle-Dogtooth, Tide Lake and the Maynard Lake Parks. The Pakwash Provincial Park is located adjacent to the northeast corner of the unit, Rushing River Provincial Park is located in the southern portion of the forest, and Woodland Caribou Provincial Park (and addition) is located in the northwest portion of the unit. All of these parks have either an Interim Management Statement or a park management plan that provides direction.

Parks and protected areas include Crown lands that are not available for forest management purposes. These areas include Provincial Parks and Conservation Reserves regulated under the *Provincial Parks and Conservation Reserves Act*. The Crown land areas where forest management cannot occur that lie in on or adjacent to the Forest are listed in Table 1. Some of the areas listed in this table lie entirely within the Whiskey Jack Forest, others are adjacent to, but outside of the forest (e.g., Pakwash and the pre-Ontario's Living Legacy portion of Woodland Caribou provincial parks), and portions of others lie both within and outside the boundaries of the forest (e.g., Eagle-Dogtooth).

Parks and protected areas lying within the boundaries of the Whiskey Jack Forest encompass a total of approximately 88,811hectares, of which 47,743 hectares is forested. This represents about 5% of the productive Crown land area of the forest.

For wildlife management purposes, park and conservation reserve areas on the Whiskey Jack Forest can be used in the establishment of core areas for marten habitat. Similarly, these areas can contribute to meeting 'old growth' targets but are not included in the determination of the available harvest area.

Provincial parks (and conservation reserves) provide places where people can enhance their health and well-being through enjoyment and recreational use of the outdoors, while developing a greater appreciation for Ontario's natural diversity. The following are important benefits and help to demonstrate how parks support our quality of life:

- Protection and contribution to ecological functions (air quality, water quality, flood control, soil stabilization),
- Biodiversity contributions (genetic material, protection of species at risk),
- Protection of resource integrity (some of the last green spaces left in the province),
- Health effects from use of parks (mental, physical, spiritual benefits),
- Worker productivity (healthy and happy workers tend to be more productive - a visit to a provincial park can contribute),

- Educational benefits (young and old learning about our environment),
- Scientific benefits (research in provincial parks),
- International responsibilities to protect natural settings, features and wildlife,
- Business location decisions (quality of life/business) and community cohesion.

Ontario Parks reports on the following indicators of economic impact:

- Value Added
- Provincial Gross Sales (or Provincial Gross Output)
- Wages & Salaries
- Provincial Person Years of Employment

Economic impacts are based on expenditures such as those made by the park on operations and capital improvements, as well as average visitor trip expenditures (camper and day visitor).

As well, the public and municipal officials should be aware that provincial parks help to make their communities attractive for business as well as for tourists and retirees. The retirement community brings in pension income, which is often indexed to inflation and is recession proof. Communities with attractive waterfronts, low crime, recreational activities and healthy environments are sought out by the retirement community. The park budget (operating and capital) represents a grant or transfer payment from the government to their community. Not all communities have this transfer. The community may also receive grants in lieu of taxes.

Following Table 1 is a description of the benefits that each provincial park provides. Conservation Reserves are included in Table 2.

Table 1 Parks and Protected Areas on (or adjacent to) the Whiskey Jack Forest

Name	CLUPA Reference ID*	Classification (Category)	Area (ha)**
West English River	P2345	Provincial Park (Waterway)	22,923
Tide Lake	P2614	Provincial Park (Nature Reserve)	51
Maynard Lake	P2698	Provincial Park (Nature Reserve)	25
Eagle-Dogtooth	P2363	Provincial Park (Waterway)	41,128
Rushing River	P2615	Provincial Park (Recreation)	340
Pakwash	P2528	Provincial Park (Recreation)	3,993
Woodland Caribou (existing)	P2370e	Provincial Park (Wilderness)	450,000
Woodland Caribou additions	P2370	Provincial Park (Wilderness)	30,442

* - MNR's Crown Land Use Planning Atlas (CLUPA) reference identification number
** - areas according to MNR's Crown Land Use Planning Atlas (CLUPA)

Woodland Caribou (P2370e), an operating wilderness class park of 450,000 hectares, was regulated in 1983. It protects representative earth and life science features of Site District 4S-1, such as the Eagle-Finlayson Moraine, prairie-boreal vegetation and habitat for Woodland Caribou, a threatened species. The park provides opportunities for backcountry canoeing, camping and outpost camp and main base lodge fishing. The park had 4799 camper-nights and 4799 days-use visitors in 2007. For 2005/06, the economic impact of Woodland Caribou Provincial Park was: Initial expenditure: $503,938; Value Added: $709,902; Wages and Salaries: $505,559; Person-years employment: 28. Only a portion of the Whiskey Jack Forest abuts Woodland Caribou, so the entire economic impact of the park does not affect the Forest.

Woodland Caribou recommended park additions (P2370) were established during Ontario's Living Legacy – Land Use Strategy. There are four additions to the existing park (Douglas Lake, Peisk Lake, Anchor Lake and Sydney Lake areas) although only Sydney Lake is within the FMU. The Sydney Lake addition includes a significant white elm site. A primary forest access road crossing between Rowdy and Sydney Lakes will be permitted as determined through previous forest management planning processes. This addition is in the most popular backcountry canoeing area of the park. It is unknown how much of the economic impact of Woodland Caribou Provincial Park (see above) can be assigned to the Sydney Lake recommended park addition.

Maynard Lake (P2698), a non-operating nature reserve class park of 25 hectares, was regulated in 1997. It consists of a peninsula with deep soils on the east shore of Maynard Lake. It provides representation/protection of an atypical old growth white pine stand (age class + 160 years) at the northern limit of the species range. It is surrounded by West English River Provincial Park on three sides. Camping, day-use, hunting and most other recreational activities are prohibited because of the classification of the park. The actual amount of use is unknown.

Tide Lake (P2614), a non-operating nature reserve class park of 51 hectares, was regulated in 1997. It consists of the peninsula between Ball and Tide lakes. The park provides representation/protection of an atypical old growth white pine stand (age class + 160 years) at the northern limit of the species' range. It is surrounded by West English River Provincial Park on three sides. Camping, day-use, hunting and most other recreational activities are prohibited because of the classification of the park. The actual amount of use is unknown.

West English River (P2345), a non-operating waterway class park of 22,923 hectares, was regulated in 2003. The area includes that portion of the English River from Barnston Lake to Tide Lake. The waterway contains old growth red and white pine at the northern extent of its range, wilderness environments and tourism attributes, and is an historic travel corridor. Two provincial nature reserves, Maynard Lake and Tide Lake, abut the park. Motor boating, canoeing, sport fishing, hunting and camping are popular activities, although the actual use is unknown.

Eagle-Dogtooth (P2363), a non-operating waterway class park of 41,128 hectares, was regulated in 2003. It provides a waterway linkage between Eagle Lake and nearby protected areas (e.g., Rushing River, Winnange). It is an important recreational waterway. The site contains regionally significant moraines, wetlands, pine forest ecosystems, eagles, waterfowl and is an important recreation and tourism area. Motor boating, canoeing, sport fishing, hunting and camping are popular activities, although the actual use is unknown.

Pakwash (P2528) is a staffed natural environment class provincial park of 3,993 hectares. The park was established in 1967 and was regulated in 1989 as a natural environment class Provincial Park. The park provides representation/protection of Site District 4S-2, specifically

the Hartman Moraine. Pakwash provides opportunities for car-camping and day-use. The park is operated through a partnership with Ear Falls 2000 Inc. The park had 8,523 camper-nights and 476 days-use visitors in 2007. For 2005/06, the economic impact of Pakwash Provincial Park was: Initial expenditure: $178,746; Value Added: $205,386; Wages and Salaries: $124,866; Person-years employment: 3.2. Only a portion of the Whiskey Jack Forest abuts Pakwash, so the entire economic impact of the park does not affect the Forest.

Rushing River (P2615), a staffed recreation class provincial park of 340 hectares was established in September 1958. Natural features include jack pine uplands, wetlands and a lush river valley. The park has a popular campground, day-use area and interpretive facilities/trails. The park had 47,804 camper-nights and 14,960 days-use visitors in 2007. For 2005/06, the economic impact of Rushing River Provincial Park was: Initial expenditure: $3,896,802; Value Added: $4,815,843; Wages and Salaries: $3,771,395; Person-years employment: 118.3. Only a portion of the Whiskey Jack Forest abuts Rushing River, so the entire economic impact of the park does not affect the Forest.

Disclaimer : This report provides background information on each protected area. The Area Profile section provides land use context and is built using thematic data, some of which is derived using GIS analysis. This report is based on the best available information at the time of report generation.

1

Other

Local residents use the forest for fuelwood cutting; primarily white birch and aspen.

Forest management activities can affect other forest resources in a variety of ways. Obvious affects include the loss of terrestrial habitat through road construction and forest removal. There may be short or long-term changes in ecosystem processes that may alter the regenerative course of the landscape and there may be adverse aesthetic impacts on people. There are also beneficial impacts, which include restoration of early successional habitat and improved access for hunters, trappers, anglers, naturalists and baitfish operators.

Summary of First Nation's Use of Other Resources

First Nation community members actively use portions of the Whiskey Jack Forest for many resource-based activities.

i) Fishing

Several First Nation communities hold commercial fishing licenses on Lake of the Woods and inland lakes. Lake of the Woods and surrounding lakes are used for subsistence fishing by community members.

Surrounding tourist lodges provide some employment opportunities for First Nation residents as guides in the sport fishery.

ii) Trapping

First Nation community individuals hold registered trap lines located all or partially within Kenora District.

iii) Wild rice

Wild rice is harvested annually be community members for personal use and re-sale from various lakes throughout the area.

iv) Cultural and Social, other Wildlife

Special sites within the forest are used for traditional cultural purposes such as fasting, vision quests and offerings. The specific location of these sites are known to community members, and the community is encouraged to participate in the forest management planning process to ensure these values are considered in proposed forest management activities.

Certain wildlife species, such as the bald eagle, have a cultural and social significance to First Nation people. The protection and management of these species and their habitats is important.

While the subsistence hunting, fishing, and gathering of resources from within the forest are an integral part of community existence, there are no accurate records of the level of such harvest. The harvest of deer, moose, waterfowl, rabbits and grouse provides an important source of food to community members.

Identified First Nation values for the Whiskey Jack Forest are confidential values and are retained on values maps on file in the Kenora District office.

Trapping

Trapping provides seasonal employment for 89 registered traplines in the Whiskey Jack Forest. Additionally, there are approximately 17 First Nation Community traplines located with the Whiskey Jack Forest. The expected average resources value per trapline is estimated at $2,440. Since all the trappers work out of their home it would not be appropriate to identify their names in this document The major fur bearing animals that are of economic importance are beaver, fox, muskrat, lynx, otter, mink, fisher, and marten. Registered trap lines cover the entire Whiskey Jack Forest as seen on the Values Map 4.4.

Baitfish

In 2009-2010, the Whiskey Jack Forest had licensed baitfish individuals of which all are camp operators operating in 95 harvest areas. Baitfish is consumed locally by the angling industry. Since the majority of baitfish operators' work as individuals out of their home, it would not be appropriate to identify their name in this document. The baitfish industry provides supplemental income to these people and complements the local angling industry.

Commercial Bear Management

There are approximately 124 commercial bear management areas on the forest operated by 76 tourist operators. All of these areas are accessible from the existing road network on the unit. The bear management areas are distributed throughout the unit except for the areas close to populated centres. Registered bear management areas cover all of the Whiskey Jack Forest as seen on the 2012 Values Map 4.4.

MNR Administration

Responsibility for forest management planning and day to day administration of the Whiskey Jack Forest (licencing, approvals etc.) lies with Kenora District. There are five staff positions in Kenora involved on a day to day basis with the Whiskey Jack Forest.

PART C: Social and Economic Assessment (SEA)

A component of forest sustainability is provision for the needs of the people who receive benefits from the forest. Decisions in a forest management plan have significant impacts on the local economy, as well as the regional and provincial economies. Therefore it is important to be knowledge about the social and economic impacts, which can result from decisions that are made in forest management plans.

The forest management planning process formally requires a socioeconomic impact assessment be prepared for the proposed management strategy. Socioeconomic impacts relate changes in production levels, and their associated expenditures patterns, to parameters of social concern. The most common socioeconomic indicators have been employment, wages, population and the like. But production activity also impacts other societal concerns: namely pollution, wealth effects and lifestyle issues.

As a result of achieving the forecasted timber volume (average planned volume in the Long-term management Direction) of 574,595 m^3 per year, which is within the -5% threshold of the last approved plan, a non-modeling analysis (NMA) was undertaken. The assumption is that this difference would not be large enough to significantly affect the stability of the dependent communities, forest mills or other stakeholders associated with the forest management unit (FMU).

Estimates of the annual harvest potential are derived by the Strategic Forest Management Model (SFMM) and are based upon a number of factors which define the management strategy. These are described and discussed elsewhere in the plan. Determining their impact depends on an assessment of the resulting production pattern in terms of product and location.

A number of events has occurred to reduce both the annual employment and estimated employment income since the 2004 FMP. The Abitibi Consolidated paper mill in Kenora in 2005 and the destruction by fire of the Multiply Plywood mill in Nipigon were the major ones reductions in processing capabilities. Implications were also felt in the reduction of wood deliveries to receiving facilities as per the Crown Roundwood Records. Assuming all other things being constant, the implementation of the Long-term Management Direction in the 2012 Whiskey Jack FMP will potentially maintain or increase the current job and net employment income. These gains represent direct social and economic impacts in the primary wood manufacturing facilities and will occur in communities that receive fiber from the Whiskey Jack Forest.

Recreation and Tourism

Non-Industrial Uses of the Forest –

a) Summary of First Nation Use of Other Resources

First Nation community members actively use portions of the Whiskey Jack Forest for many resource-based activities.

i) Fishing

Several First Nation communities hold commercial fishing licenses on Lake of the Woods and inland lakes. Lake of the Woods and surrounding lakes are used for subsistence fishing by community members.

Surrounding tourist lodges provide some employment opportunities for First Nation residents as guides in the sport fishery.

ii) Trapping

First Nation community individual hold registered trap lines located all or partially within Kenora District.

iii) Wild rice

Wild rice is harvested annually be community members for personal use and re-sale from various lakes throughout the area.

iv) Cultural and Social, other Wildlife

Special sites within the forest are used for traditional cultural purposes such as fasting, vision quests and offerings. The specific location of these sites are known to community members, and the community is encouraged to participate in the forest management planning process to ensure these values are considered in proposed forest management activities.

Certain wildlife species, such as the bald eagle, have a cultural and social significance to First Nation people. The protection and management of these species and their habitats is important.

While the subsistence hunting, fishing, and gathering of resources from within the forest are an integral part of community existence, there are no accurate records of the level of such harvest. The harvest of deer, moose, waterfowl, rabbits and grouse provides an important source of food to community members.

Identified First Nation values for the Whiskey Jack Forest are confidential values and are retained on values maps on file in the Kenora District office.

b) Resource Based Tourism Industry

The tourism industry has been an important component in the Kenora area for a long time. Lodges and cottages were in operation by 1905. At that time the activities were based on hunting, fishing and canoeing opportunities. The Whiskey Jack Forest has attracted recreation-based tourism since the late 19th Century due to its variety of natural values. The area continues to be a desired recreational destination for canoeing, boating, fishing, hunting, hiking, snowmobiling, camping and cottaging for the following reasons:

- There are more interconnected lakes, rivers and portages.
- The rugged topography including cliffs, low wetlands, viewpoints and island-dotted lakes provide excellent scenery for summer and winter travelers.
- The area is traversed by numerous trails providing winter recreation opportunities by snowmobile, cross-country ski, or dog sled. In the summer, canoeist and hikers can access remote locations.
- There are numerous cultural heritage values including very old aboriginal

heritage sites
- And more recent logging and mining heritage sites.

Background information for this section was obtained from the Crown Land Atlas and survey information was supplemented with data gathered from a number of other sources, specifically; MNR fishing and hunting licence files, tourist operator websites, the "*The Economic Impact of Tourism in Sunset Country, Ontario – Final Report (2003*) and the Lake of the Woods Economic Impact Study – Final Report (2003)". These last two reports provided projections about future trends for the industry on the Whiskey Jack Forest. The tourism report was prepared by Paul Kerr Forster in association with the Canadian Tourism Research Institute for the Northwestern Ontario Tourist Association (NOWATA) for the year 2001, expenditure or user days or travel distance for most of these activities. This information, provided by NOWATA has been included in this plan as supplementary documentation; however, it has not been verified for accuracy, quality or completeness by the planning team. Due to the extent of the study area comprising of most of Northwestern Ontario and Northern United States, it was decided to use the Kenora subregion in this report. The full details of this report is found in Appendix 1.

There are 362 tourist operators in Kenora District and of that, of which 143 are associated with the Whiskey Jack Forest. There are 1,852 units available in the Whiskey Jack Forest. A "unit" is defined as any of the following: serviced hotel or motel room, serviced resort rooms, serviced cottages, serviced cabins, serviced outpost camps, housekeeping room, housekeeping suites, housekeeping cottages, housekeeping cabins, housekeeping outpost camps. The impact study reports that 54% of the operators have >= 10 units, 29% have between 11-19 units and 18% > 20 units. In 2001, the average revenue generated by each unit was $40,000. Of this, Retail and Guest services generated 25% of the revenue with Food and Beverage operations generated 11% of the total revenue. It is estimated that 500,000 people visited Kenora district in 2001 which was made up of travellers from Ontario (20%), other Canadian provinces (25%), United States (55%) and Others (1%).

The planning team sent out questionnaires to all the tourist operators registered within Kenora district as shown in Appendix 2. About 20% of the mail outs responded to the questionnaire which is considered a success. Of the respondents, 65% identified an average of 5 outpost camps, 20 beds, 25 employees and a minimum client volume of 200 people (mostly clients from the U.S.A. (75-100%)). The expectation is almost 90% will increase or like to increase the capacity of their lodges in the next 5 years.

The Sunset economic study reports that in 2001, 443 operators provided employment to 3,785 persons of which 1,221 where located in the Whiskey Jack Forest. The operator survey also indicated that there were 758 First Nations employed in Sunset Country of which 80% were seasonal or part time employees. Accommodation providers in Sunset Country employed 498 or 40% which were between 25-44 years old. The large variety of lakes and rivers, some of which are remote (17% boat access and 13% flay in) while others are easily road accessible (62%), provide a wide range of angling opportunities. Whiskey Jack Forest has excellent natural lake trout lakes and walleye fishing is also popular in hundreds of small lakes along with larger lakes such as Lake of the Woods. Dryberry and Sydney Lakes.

The tourism expenditures in Kenora District, down into categories for both the amount spent and the amount retained in the District. This is useful in determining the retention

rate of the tourism economic impact in the Study Region. According to the Ministry of Tourism & Recreation, overall, tourism in the Kenora Census Districts contributed just over $181 million in Gross Domestic Product in 2001, $109 million or 60% of which was retained in the District. It is estimated that tourism alone generated almost $80 million in taxes distributed to federal, provincial and municipal governments. Tourism creates almost 3,000 direct jobs in the Districts distributing close to $49 Million in direct wages and salaries. The total number of jobs created by tourism including direct, indirect and induced was 5,263 in 2001, with payroll earnings of just over $114 Million.

The Whiskey Jack Forest is comprised of 5 Wildlife Management Units (WMU); zones 3, 5, 6, 7B and 8. This represents a significant portion of these wildlife units that are utilized extensively for hunting and fishing. Hunting continues to be an important recreational activity in the Whiskey Jack Forest area. Big game is the primary activity although ruffed grouse, black bear, migratory waterfowl and snowshoe hare are also hunted. Hunting is either carried out adjacent to access roads created by the forest industry, by use of water based transportation to remote roadless areas, or by fly-in outfitters to backcountry locations. A large proportion of big game hunters are non-resident hunters who contribute to the local economy depending on how many local services they utilize. More than 90% of the bear hunters are nonresidents. There are a wide variety of trails in the Whiskey Jack Forest that are used (depending on the nature of the activity and the Land Use designation) by hikers, cross country skiers, dog sledders, snowmobilers, and ATV operators. In addition to prepared trails, there are opportunities to travel on ungroomed areas such as snowshoeing along lakes and portages or snowmobiling along ungroomed lakes or unploughed roads.

Rushing River Provincial Park, and a few other private campgrounds along Hwy 17 and 71 corridors, provides camping opportunities. Approximately 65,000 people visit or use the many canoe routes around the park. Canoe trippers and anglers that are flown into backcountry sites use most of the remote sites. Many cottages were established after the railroad arrived in 1888 and made access to the Whiskey Jack Forest area easier. There are abundant cottages on Lake of the Woods are primarily located on the many islands on the lake, since shoreline development is limited. The building of what is now known as Hwy 17 made it easier to access additional lakes in the area.

When additional road access is proposed, road-based tourism could be enhanced, but at a cost to remote-based tourism. In contrast, when road closures are made, this could be beneficial to remote-based tourism, but a bane to road-based tourism.

In situations where road-based tourism occurs most often on a FMU, harvesting activities would probably have a positive impact, if they enhance road network for road-based tourism. Harvesting activities however, would have a negative impact to aesthetic beauty of the forests

One could argue that the opportunity cost of pursuing road-based tourism would be the foregone benefit of remote-based tourism, and aesthetic beauty of the forests.

If one values biodiversity the most in comparison to remote-based tourism and aesthetics beauty of the forests, then biodiversity would be the next best alternative (to road-based tourism). Along this line of reasoning, one can then say that the opportunity cost of establishing road-based tourism is the foregone benefit (or value if you may) of maintaining biodiversity.

Mining, Aggregates and Hydro Generation

Mining

Historically, mining and mineral exploration have been an important activity in this management unit and historically gold, silver and copper were the predominant commodities mined. Currently there are four granite producers in operation which have been and continue to be a significant contributor to the economy of the area. The value of total granite production was not available at the time of writing. Historical metal production occurred within the management unit between 1893 and 1951 and totalled 68,513 ounces gold, 14,762 ounces silver and 1.89 million pounds of copper valued at $49.73 million CDN at current metal prices.

In addition to historical and current mineral production there are significant concentrations of gold, nickel, copper, silver and uranium contained within documented mineral deposits throughout the management unit. The total estimated value of metals contained within these deposits at current commodity prices is in excess of $158 million CDN.

There are an estimated 1,605 active mining claim units recorded throughout this management unit, as indicated on MNDM's CLAIMaps website (MNDM, 2006). These claims represent an investment in the management unit of approximately $400,000 CDN for claim staking, which directly relates to its mineral potential. In addition there is an estimated dollar expenditure of nearly $650, 000 CDN per year related to mineral exploration work required to keep the claims in good standing. Current claim staking targets areas with potential for uranium, rare-metals, zinc and gold. Historically, several areas within the management unit have seen extensive staking and mineral exploration. There are no active mines located in the Whiskey Jack Forest.

When additional roads are built to increase access for mining exploration, a positive effect may result in increasing the profitability of mining companies. But this could have some deleterious effects on habitat protection.

With more roads, increased access for timber harvesting can clear areas for mining sampling and mapping, but potentially it would increase the chance or removing mining survey lines, and destruction of claim posts could occur. Timber harvesting however, would be beneficial to forest companies, but at the expense of reducing habitat protection.

Aggregates

There are 54 aggregate sites located in the Whiskey Jack Forest. Of these, Abitibi-Bowater Inc. operates 21 of those for forestry purposes.

Nelson Granite operates 7 sites in the production of bulk granite which is shipped to various processing facilities around the world. Granite production is approximately 16,000 metric tones annually. Full time employment is three.

The remaining 26 sites produce approximately 15,000 metric tonnes of sand and gravel annually. Employment is estimated at five.

Forest operations, such as timber harvesting, build forest roads that increase the chance of finding aggregates. More road network ultimately increases access to aggregates.

On the flip side, opening-up areas through additional road construction could have deleterious effect on remote-based non-timber activities and forest protection measures.

Hydro

A number of hydro electric facilities are located within or adjacent to the forest. These facilities are on the English River between Lac Seul and the Manitoba border and on the Winnipeg River between Lake of the Woods and the English River.

Two sites owned by Ontario Power Generation are located within the forest:

1. Ear Falls
There are four power generating units at Ear Falls located on the English River at the outlet of Lac Seul. The first unit began operating in 1930. Additional generating capacity is being developed at the Ear Falls GS by adding a new 12.5 MW generating unit capable of generating approximately 52 million kilowatt hours of hydroelectricity per year. It will create enough energy to service up to 4,000 homes and will create up to 20 new jobs.

2. Manitou Falls
This facility is located on the English River where it enters Barnston Lake downstream of Ear Falls. There are five operating units located at this facility. Construction on this facility began in 1953.

Four additional sites are located within Kenora district and supply power to the area. Two of these are also owned by Ontario Power Generation and the other two (both in Kenora) are owned by Abitibi Consolidated.

3. Caribou Falls
Caribou Falls consist of three power generating units built in 1958 on the English River at the outlet of Umfreville Lake. The Caribou station was the third plant built along the English River which represented just a fraction of the widespread program undertaken to meet the challenge of expansion in mining and also pulp and paper industries.

4. Whitedog Falls
This facility consists of three power generating units built in 1958 on the Winnipeg River at Whitedog Falls.

5. Kenora Power House and Norman Dam
These generating stations are owned by Abitibi Consolidated. The Kenora Power House is located on the on the Winnipeg River in Kenora at the outlet of Lake of the Woods. The Norman Dam generating station is located on the Winnipeg River in Kenora.

Some of the objectives of an FMU may specifically indicate whether hydro generation will be allowed in the area. Forest operations will usually allow for this kind of activity. Timber harvesting for example, will increase access for hydro generation, but will negatively impact the maintenance of habitat.

Other Uses:

Local residents use the forest for fuelwood cutting; primarily white birch and aspen.

Forest management activities can affect other forest resources in a variety of ways. Obvious affects include the loss of terrestrial habitat through road construction and forest removal. There may be short or long-term changes in eco system processes that may alter the regenerative course of the landscape and there may be adverse aesthetic impacts on people. There are also beneficial impacts, which include restoration of early successional habitat and improved access for hunters, trappers, anglers, naturalists and baitfish operators.

a) Fur Harvesting
Trapping provides seasonal employment for 89 registered traplines. Additionally, there are approximately 17 First Nation Community traplines located with the Whiskey Jack Forest. The expected average resources value per is trapline is estimated at $2,440. Since all the trappers work out of their home it would not be appropriate to identify their names in this document The major fur bearing animals that are of economic importance are beaver, fox, muskrat, lynx, otter, mink , fisher, and marten. Registered trap lines cover the entire Whiskey Jack Forest as seen on the Values Map 4.4.

b) Commercial Bear Management:
There are approximately 124 commercial bear management areas on the forest operated by 76 tourist operators. All of these areas are accessible from the existing road network on the unit. The bear management areas are distributed throughout the unit except for the areas close to populated centres. Registered bear management areas cover all of the Whiskey Jack Forest as seen on Values Map 4.4

c) Baitfish Operations
In 2009-2010, the Whiskey Jack Forest had licensed baitfish individuals of which all are camp operators operating in 95 harvest areas. Baitfish is consumed locally by the angling industry. Since the majority of baitfish operators' work as individuals out of their home, it would not be appropriate to identify their name in this document. The baitfish industry provides supplemental income to these people and complements the local angling industry.
.

<u>MNR Administration</u>

Responsibility for forest management planning and day to day administration of the forest (licensing, approvals etc.) lies with Kenora District. There are five staff positions in Kenora involved on a day to day basis with the Whiskey Jack Forest.

APPENDIX I: Detailed Procedures for Level II Sampling 18

APPENDIX II: Working Group Members 24

EXECUTIVE SUMMARY

In the silviculture guide for the Boreal Forest, full tree logging is listed as a 'not recommended' practice on shallow sites (ecosites 11 and 12) in Northwestern Ontario. The practice was designated as 'not recommended' because there is a lack of information to confirm whether or not the additional nutrient removal and soil disturbance associated with full tree harvesting would have a detrimental impact on the long term sustainability of forest management on these nutrient poor sites.

Many companies in Northwestern Ontario are using full tree logging equipment and are cautious about investing large amounts of capital into other logging systems (eg. tree length or shortwood logging systems). Therefore, to continue full tree harvest operations on these shallow sites, an approved monitoring program to assess the impact of this treatment is mandatory, in accordance with the 'exceptions' process of the Forest Management Planning Manual. A working group, comprised of Industry and OMNR stakeholders, in consultation with OMNR Boreal Science section, was formed to devise an appropriate monitoring procedure.

The proposed procedure includes two series of permanent sample plots. 'Level I' involves four case study sites that incorporate intensive monitoring procedures developed by CNFER's Stand Ecology Program to investigate long-term site productivity issues. These case study sites will be distributed across the Region to sample key soil textures and parent materials, and climatic conditions and patterns. Each case study site will have two blocks (high and low productivity areas within the ecosite), and three treatments (tree length and full tree logging and a no-cut control). Detailed sampling occurs prior to harvest, immediately post-harvest and five and ten years post-harvest for each of the treatments. An initial report is scheduled for year 5 post-harvest. A cost estimate has been prepared for the first three years of the program. As part of the cost of implementation, a Project Manager is required to coordinate site selection, plot establishment and data management for the initial three year period. The cooperators have proposed a cost sharing formula to reduce their individual implementation costs.

A second series of permanent sample plots (referred to as 'Level II' plots) will be established to address the variation of ES 11 and 12 sites across the Region, and to confirm that the results from Level I case studies are consistent with the range of normal operations. These plots follow a less intensive sampling methodology that is implemented by each SFL holder after harvest. The responsibility and cost for their establishment will be born by the respective SFL holder. An allocation matrix will be used to guide the location of these plots regionwide and ensure that the range of variability (ie. sites, operations) has been sampled. The aforementioned Project Manager will assist with site selection and data management. The implementation schedule proposes a maximum of 30 monitoring sites region wide for each of three years.

This document also outlines procedures for Companies to follow to identify shallow soil sites (maps and stand listings) in Annual Work Schedules and FMP's and track operations on these sites. A commitment is made to provide training to staff and contractors in identifying ecosites 11 and 12. 'Best management practices" to reduce both ground disturbance and nutrient loss are listed for use in developing Silvicultural Ground Rules and Forest Operation Prescriptions for shallow soil sites. Winter harvest remains the preferred option to reduce ground disturbance and nutrient losses on these sites.

1.0 INTRODUCTION

As the underpinning to all Forest Management Plans (FMP) prepared and approved in Ontario, the overall goal for Ontario's forests is: *... to ensure the long-term health of our forest ecosystems for the benefit of the local and global environments, while enabling present and future generations to meet their material and social needs* (OMNR 1995). Although a universal definition of "forest health" appears to be somewhat elusive, most definitions imply that forest health is a condition of the forest ecosystem which sustains complexity or diversity while still providing for human needs (Morris 1997). In turn, it has been recognized that forest management activities influence stand structure and function largely through the silvicultural treatments prescribed in the silvicultural ground rules and forest operation prescriptions (OMNR 1997a). These treatment packages refer to the range of acceptable treatments (*i.e.*, harvest, renewal, tending) for the appropriate forest unit (typically derived using FEC ecosites) which can be undertaken at various intervals throughout the life of a forest stand to achieve a desired future forest condition (OMNR 1996).

Many companies in Northwest Ontario are not presently equipped for tree-length or cut-to-length / shortwood logging (the recommended practices on ES11 and ES12s) and are cautious about investing large amounts of capital into such equipment. As such, there is a desire within the companies to harvest these shallow soil sites, utilizing full-tree harvesting equipment. To do so, and go against the recommended treatment package, companies must go through the "exception process" as detailed in the Forest Management Planning Manual. Part of the exceptions is to develop and implement an MNR acceptable monitoring program to assess a) the level of disturbance on and b) the recovery process of, the sites being harvested

The potential site hazards identified for harvesting and renewal activities on these ecosites include 1) susceptibility to nutrient loss (especially with soils < 5cm), 2) seasonal drought/desiccation, 3) erosion, and 4) rutting on the SS9 inclusions (OMNR 1997b). Based on these potential site hazards, the logging method of choice (*i.e.*, full-tree harvesting) on these ecosites prescribed in the proposed Silvicultural Treatment Packages for the ES11 and ES12 forest units in these upcoming management plans, is Not Recommended (NR) where total soil depth is less than 20cm and only conditionally recommended (CR) where soil depth exceeds 20cm provided that best practices are employed to minimize disturbance of the organic layer (OMNR 1997b). Linked to this recommendation, Archibald *et al*. (1997) suggested that forest units that have been identified as being sensitive to nutrient loss should be monitored to assess the "effectiveness" of the prescribed treatments. It should be emphasized that when approval is given to a practice in any FMP which has the NR designation in the silvicultural guide, monitoring is mandatory (A-133 of the FMP manual). In the case of monitoring soil quality, the physical site guideline (Archibald *et al*. 1997) falls short by not providing any quantitative measurements that could be used to monitor post-harvest recovery of these sites as indicators of potential impacts to soil quality and, ultimately, site productivity. In fact, this type of proposed monitoring program, and the associated sampling protocols, is rare across much of North America (Powers *et al*. 1998).

Soil quality is considered to be the ability of a specific kind of soil to function within its surroundings, support plant and animal productivity, maintain or enhance water and air quality, and support human health and habitation. Within this context, soil quality indicators are physical, chemical, and biological properties, processes, and characteristics that can be measured to monitor changes in the soil. In turn, soil quality standards are stated quantitative or qualitative threshold values for soil properties and conditions established to maintain or improve the suitability or productive potential of a soil. These threshold values, along with disturbed areal

extent limits are indicators of significant reduction in soil productivity. There are six key indicators/standards that should be monitored for the es11 or es12 ecosites: 1) soil compaction, 2) soil rutting and puddling, 3) soil displacement, 4) soil erosion, 5) soil organic matter retention and 6) soil nutrient reserves.

It should be recognized that these six standards apply to the cumulative effects of management practices over time. Overall, a large percentage of the activity area must be left in a condition of acceptable potential soil productivity following forest management activities (the U.S. standards suggest 85 %). If there are major site/slope differences within an activity area these can be evaluated separately. An activity area does not, however, include areas with dedicated uses such as permanent roads or dedicated trails.

As noted above, although some of these indicators are manifested at the time of harvest, others include parameters that are expected to change over time. Repeated measurements of these indicators must be done on appropriate time scales to provide a meaningful assessment of the potential impacts to soil quality.

The intent of the monitoring processes are either to confirm or change the "not recommended" status of full-tree harvesting on ES11/12 sites, as well as define acceptable threshold levels for the various soil quality indicators. This will be done by, utilizing a scientific approach on four case study sites (Level I monitoring) in conjunction with less intense monitoring on a subset of harvested ES12 sites from across the region (Level II). It is the combination of the Level I and Level II monitoring, in conjunction with the AWS documentation, which constitutes the whole monitoring program designed to fulfill the requirements of a regionally-based evaluation of the silvicultural recommendations.

2.0 LEVEL I SAMPLING

2.1 Site Selection

The ES12 (Black Spruce-Jack Pine: Very Shallow Soil), and ES11 (Red Pine-White Pine-Jack Pine: Very Shallow Soil) ecosites, are primarily located in the westerly portion of the region (*e.g.*, Fort Frances, Kenora). The soils on these ecosites, by their shallow nature (<20 cm), are highly variable in terms of depth and include the SS1 (Discontinuous Organic Mat on Bedrock) to the SS5 (Shallow-Moderately Deep / Sandy) soil types, with some inclusions of the SS9 (Shallow-Moderately Deep / Organic-Peaty Phase) soil type. The mineral soil is commonly overtopped by relatively thin fibrimor humus. The potential site hazards identified for harvesting and renewal activities on these ecosites include 1) susceptibility to nutrient loss (especially with soils <5cm, 2) seasonal drought/desiccation, 3) erosion, and 4) rutting on the SS9 inclusions (OMNR 1997b). These concerns are reinforced, with particular emphasis on the nutrient loss issue, in OMNR's Forest Management Guidelines for the Protection of the Physical Environment (Archibald *et al*. 1997).

The Northwest Ontario region covers a wide area of land from the Manitoba border in the west to Geraldton in the East. There are regional differences in the function of ecosystems due to factors such as general topography, soil texture and parent material, and climatic conditions and patterns. There are also differences in productivity within an ecosite beyond that of regional differences. These differences are a result of nutrient availability and rates of nutrient cycling of a particular site.

In order to address the regional and productivity differences of the ES12 sites in Northwest Ontario, four case study sites will be chosen for intensive study. Each of the four case study areas within the Northwest Region will be represented by two stands (ie. blocks) of different productivity levels. The following is a summary of the recommended structure of the Level I Monitoring Program.

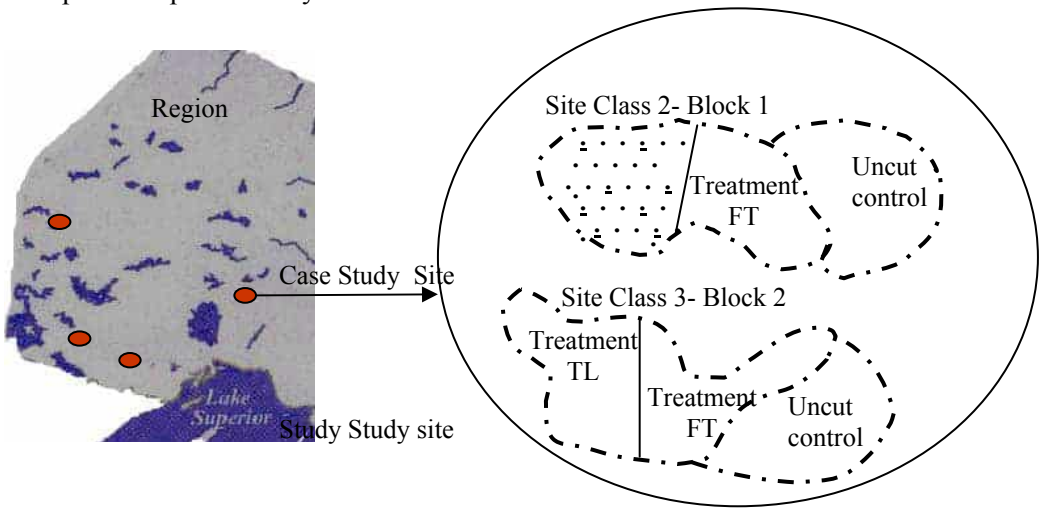
Case study sites:
1. Coarse textured tills on bedrock (North of Kenora)
2. Coarse to medium textured tills over greenstone
3. Fine soils on bedrock (Fort Frances)
4. Calcareous soils (Long Lac)

Blocks: Two blocks per case study = Eight blocks in total
1. high productivity
2. low productivity

Each block should be approximately 25 hectares in size to keep the treatments as operationally typical as possible.

Treatments: Each block is divided into three logging treatments, which will be completed during the snow-free period.
1. Tree length (R) approximately 10 ha
2. Full tree (NR) approximately 10 ha
3. Uncut (controls) approximately 5 ha

Plots: Thirty-six plots in each harvest treatment and 18 plots on the uncut (control) treatment are to be placed in systematically random location**s.** Twelve of the thirty six-plots (evenly distributed over the treatment) will be intensive plots where soil and vegetative nutrient concentrations will be collected. Each plot is marked with a GPS unit indicating its UTM position and elevation. The twelve intensive plots are permanently marked.



2.2 Pre-harvest Sampling:

The systematic layout (grid pattern) across each treatment provides a format where the site could be examined by layer. Modeling the stand in a 3-dimensional format, indicating nutrient pool quantities pre- and post-harvest will aid in assessing the effect of various treatments on the sites nutrient capital. Also, this format allows for a greater refinement of the variation

found on the ES12 sites. For example, the difference in nutrient capital between rock knobs and small deep soil inclusions could be shown.

Much of the concern with full-tree harvesting on these shallow sites deals with nutrient removals. Therefore, a full accounting of the nutrient capital and the compartments where those nutrients are found shall be done. Other indicators of possible soil degradation (compaction, rutting and erosion) must also be assessed in the monitoring system. The following important physical, chemical and biological properties of the sites shall be monitored on all 36 plots in a treatment unless otherwise indicated.

Physical

- Soil depth*, by horizon (include LFH layers if present)
- Field textures
- Bulk density*, particle density, total porosity, by horizon, recording the depth sample was taken (the 12 intensive plots only)
- Soil strength (by horizon, record depth) (the 12 intensive plots only)
- Coarse Fragment (cf) content (% by volume of horizon)*

* Essential for the determination of soil nutrient reserves.

Chemical

- Soil pH (distilled , Ca Cl_2)
- Soil sample retained for chemical determination (the 12 intensive plots only)
- Soil nutrient by horizon = concentration * soil volume *bulk density * (cf/100) (the 12 intensive plots only)

Biological

- Vegetation sampling
  - Tree
    - 7.5 meter radius plots
    - dbh and species on all free standing trees (live and dead)
    - status of tree (live or dead)
    - basal and dbh cores taken on 3 trees per species found in each of the 12 intensive plots
    - heights on cored trees
    - biomass samples of tree components for nutrient concentration analysis (N, P ,K, Ca, Mg) (two major species on the 12 intensive plots)
    - utilize existing regression equations (dbh to biomass by component)
    - use cores for proper age determination and calculating tree productivity.
  - Shrub
    - 2m x 2m-shrub plot taking percent cover
    - located within the tree plot
    - utilize an existing regression, % cover to biomass
    - existing nutrient data to determine nutrient capital
  - Herb
    - 1m x 1m herb plot within the shrub plot (percent cover)
    - utilize an existing regression equation , % cover to biomass
    - existing nutrient data to determine nutrient capital

- Moss
  - Percent cover: included in the herb plot
  - In addition, for each moss species encountered, a 225cm^2 - biomass plot (15cmX15cm) will be collected. These plots must have 100 percent cover of that particular moss species. (the 12 intensive plots only)
  - Moss biomass samples will be analyzed for nutrient concentrations (N, P ,K, Ca, Mg) (on the moss biomass samples described above)

- Coarse Woody Material
  - 3 Systematically random transects (2m X 7.5m) per treatment
  - All CWD greater than 2cm diameter is measured for:
    - distance along the transect
    - top, bottom and intersecting diameter
    - length of CWD
    - decay class (6 classes)
    - position (buried, partially buried, on surface, aerial)
    - samples of decay class and position combination taken for density determination and nutrient analysis (N, P ,K, Ca, Mg)

- Site Photographs (at each intensive plot)
  - Locate a tree of average diameter for that particular plot.
  - stretch a measuring tape 5 metres away from the tree and mark this as the camera position.
  - spray paint the stump of the tree with tree marking paint, tag the stump (very close to the base) with an aluminum tag facing the camera position
  - lean a metal meter stick, upright, against the tree facing the camera position
  - take two photos, one portrait and one landscape with the camera set a 28mm and the tree near the centre of the photo.

2.3 Harvest Treatments

Each case study site has two 25-hectare blocks where harvesting will take place. Three logging treatments will be employed on each block; 'full-tree' on 10 hectares, 'tree length' on 10 hectares and 'uncut' on the remaining 5 hectares of the block. Harvesting will be completed during the snow-free period. The time of year and soil condition should be noted at the time of harvest. The Project manager should be present for the actual harvest and should be on site for the change over of logging method (e.g. fulltree to tree-length).

Logging should be as operationally "normal" as possible. It is realized that equipment for tree-length harvesting under normal conditions may not be available so some simulation with roadside delimbers brought into the block and a careful redistribution of slash may be necessary. This will be done in consultation with the Project Manager, OMNR (Centre for Northern Forest Research (CNFER)), and company and contractor representatives.

2.4 Post-harvest Sampling

A temporal sampling schedule (0, 5 and 10 years post-harvest) will be adopted to estimate changes to the physical, chemical and biological properties measured as part of the pre-harvest measurements that result from the different harvest treatments.

Re-visitations to the pre-harvest plots shall be done on four separate occasions,
1) immediately after harvest (tØ),
2) after site preparation, if applicable,
3) five years post-harvest and
4) 10 years post harvest.

At each sampling period, the physical and chemical properties measured in the pre-harvest stand will be repeated. Sampling will be done within a three-meter radius of the pre-harvest plot locations.

In addition, an assessment of the six key indicators will be conducted in the following manner for all 36 plots in each treatment unless otherwise indicated**.**

- Soil Compaction
  - Measured as an increase of bulk density on the 12 intensive plots

- Soil Rutting and Puddling
  - Percent of plot area rutted and severity of rutting.

- Soil Displacement
  - Percent of plot area where soil displacement as a result of harvest occurred.

- Soil Erosion
  - Measure of slope, soil texture and exposed mineral soil within the plot.

- Soil Organic Matter Retention
  - Measure of soil organic matter depths and bulk density.

- Soil Nutrient Reserves
  - Residual biomass assessment (year 0) Slash
    - Similar to CWD plots without the diameter limits.
    - Count all slash intersecting a line transect to develop a relationship of slash count to mass.
    - Slash mass in a 2mx2m plot is weighed in the field
    - Samples collected and fresh weights, oven-dry weights and nutrient concentration determined.
  - Soil nutrient reserves (all four sampling periods)
    - As sampled in pre-harvest
  - Vegetation (after site prep, year 5 and year 10)
    - Assessment of vegetative recovery
      - → Seedling assessments, density, growth rates, foliar clipping for nutrient content
      - → Shrub, herb, moss percent covers.

In addition, at each sampling period, site photographs are to be taken at each pre-harvest photo site. Follow the same protocol as described in the pre-harvest section.

2.5 <u>Data Management and Associated Laboratory Work</u>

In both the pre- and post-harvest sampling times, there is a requirement to conduct laboratory work. This work involves preparing samples for nutrient analysis, properly handling samples for bulk density determination and data entry. Furthermore, the proper set up of a database is required to relate all pre- and post-harvest activities to the analytical results.

2.6 Cost Estimates

The cost estimate presented in the following table is for the establishment, monitoring, managing and analysis associated with one Level I case study site for the first 3 years of the program.

2.6.1 Costs per Case Study Site

Activity	Expenses	Cost $k
Site selection	1 wk travel for project manager	0.5
Site selection Total		**0.5**
Pre-harvest Sampling	Crew of 4 X 3 wks (650x4x3)	7.8
	Accommodations	3.0
	Field supplies	0.5
	Vehicle	0.6
Pre-harv Total		**11.9**
Associated Lab Work	2 people x 3 weeks	3.9
	Lab supplies	0.5
	Analytical chemistry - soils 150 samples x $30 = 4.5k - Veg 200 samples x $10 = 2.0 k	6.5
Pre-harv Lab Total		**10.9**
Harvest	Possible extra cost due to TL treatment	
Harvest Total		?
Post-Harvest (tØ field)	2 people x 2 wks (650 x 2 x 2)	2.6
	Accommodations	1.0
	Field supplies	0.2
	Vehicle	0.3
Post-Harvest field (tØ)		**4.1**
Post Harvest (tØ) lab	2 people x 1 wk	1.8
	Analytical chemistry (soil 150, veg 200)	6.6
Post-Harv. Lab (tØ)		**8.3**
Summary		
Total Establishment		**23.3**
Post-harvest (tØ)		**12.4**
Bottom Line per case study site		**35.7**

2.6.2 Project Coordination and Costs for Subsequent Assessments

In addition to the costs estimated in the preceding table, there will be a requirement for a **Project Manager at 40.0 k per year for 3 years**. This position would be responsible for, 1) site selection, 2) monitoring harvesting, 3) supervising Level I establishment, 4) post-harvest assessment, and 5) data management and synthesis of Level I & Level II projects.

Also not including in the above estimate is Year 5 and Year 10 sampling. Sampling at these periods is **estimated to be approximately 15.0K each sampling period per case study site**.

2.6.3 Cost Sharing Formula for Level I Monitoring

a) Seventy-five percent (75%) of the total cost for Level I monitoring will be split equally among the following cooperators:
- Bowater Pulp and Paper Canada Inc.
- Abitibi Consolidated Inc.
- Weyerhaeuser Canada Ltd.
- Domtar Forest Products
- Kimberly Clark Inc.
- Ontario Ministry of Natural Resources

b) Each cooperator's contribution to the remaining twenty-five percent (25%) of the total cost of Level I monitoring will be based on the amount of ecosite 11/12 scheduled for harvest in their current forest management plan, expressed as a percentage of the total amount of ecosite 11/12 scheduled for harvest in the current plans for all the Cooperators.

3.0 LEVEL II SAMPLING

Level II sampling is to provide an operational verification of the range of variability in full-tree harvest effects on specific parameters on ES11 and 12 sites. The data collected from this sampling procedure will tie into the Level I case study sites.

The design for Level II sampling will be modeled after the Field Manual for the Establishment of Forest Monitoring Permanent Sample Plots (Sumac Forest Information Services Ltd. draft version April, 2000). This design was chosen to provide the best utility of a sampling procedure, since the Level II PSP's may become Forest Growth and Yield Monitoring PSP's in future sampling periods. Appendix I includes the detailed procedures for Level II sampling.

Level II PSP's are proposed for a sub-sample of the ES 11/12 stands that are full tree logged. There is no requirement to sample tree-length logged areas.

The sampling intensity suggested is 30 clusters across the region in the planning year 2001/2002, with no more than 30 clusters in the 2 years following. At the time of submitting the annual work schedule, each S.F.L. will identify the areas of ES12 that are identified for harvest. A distribution of clusters will be determined based on an allocation matrix. At the completion of the first year of data collection, the Project Manager will synthesize the data to review how well the regional differences in ES11 and 12 were covered and evaluate the sample intensity for future periods. These differences should include the geographic range of shallow soils in the region, operational differences between SFL's, the frequency of ES 11/12 on a licenced area and the season of harvest.

4.0 LINKING LEVEL I and LEVEL II MONITORING

The sampling procedures conducted on the Level II sites are directly linked to the Level I experimental sites. The Level I experimental sites provide an opportunity to assess key site/soil types within the broad ES12 matrix. The Level II procedures allow a wider range of sites to be sampled to ensure or validate that the case study sites:

1) bridge the regional site variability of ES12 site types, and,
2) are within the range of normal operations.

The post-harvest /post-site preparation sampling for both levels are similar. The Level I sampling provides a greater detailed assessment of a particular site and is used to develop relationships (i.e. the relationship between slash intersects on transects to slash mass) where simpler and more efficient measurements can be made on the Level II sites.

It is the combination of the Level I and Level II monitoring, in conjunction with the AWS documentation (Section 5.0), which constitutes the entire program required to address the regional silviculture recommendation.

5.0 ANNUAL WORK SCHEDULE DOCUMENTATION

All ES 11 and ES 12 sites that are scheduled for operations in the Annual Work Schedule (AWS) will be handled as follows:

a) These sites will be clearly identified in the AWS (maps and stand listings). In the absence of an ecosite classification, surrogate information (e.g. stands designated as PFR) should be used to identify these sites in the inventory. Identification of these sites may require verification of the FRI designation through aerial photograph interpretation, aerial reconnaissance or field inspections prior to harvest. Mistyped stands (minimum size of 8 ha.) will be assigned to the correct ecosite and managed accordingly.

b) Operations on ES 11 and 12 will be in accordance with Best Management Practices (BMP's) as described in Section 6.0 of this document. Best Management Practices should be used for developing the Silviculture Ground Rules for shallow soil ecosites in the Forest Management Plan. They provide direction for formulating site-specific treatments when developing Forest Operation Prescriptions (FOP) during preparation of the Annual Work Schedule. When developing a FOP, actual site conditions are verified and the silviculture treatment to be used on that site is selected. At this point, additional details regarding the treatment packages (e.g. the application of BMP's) may be added (Archibald et al, 1997). Where feasible, best management practices will also be employed on inclusions of shallow soil conditions within stands typed to other ecosite types. The intent of these practices will be to minimize organic matter and soil disturbance, and reduce potential nutrient losses to the site.

c) Silviculture practices and assessments on ES 11 and ES 12 sites will be documented in accordance with the Silviculture Effectiveness Monitoring system, such that the results and effectiveness of treatments on these sites may be reported as required.

d) Companies that are cooperating with this comprehensive monitoring procedure may include the following statement in their AWS and, with slight wording adjustments, may amend the following statement to their Forest Management plans:

"Full tree logging on NWO ecosites 11 and 12, where total organic matter plus soil depth is less than 20 cm., is designated as a 'not recommended' practice in the silviculture guide for northwestern Ontario. This company is contributing to a comprehensive, region-wide initiative to monitor the impact of this treatment on these site conditions, as outlined in our forest management plan. As part of this monitoring program, these shallow soil sites have been identified in this Annual Work Schedule *(or Forest Management Plan)* and operations will be conducted in accordance with the best management practices approved for these site conditions."

6.0 BEST MANAGEMENT PRACTICES FOR ES 11/12 SHALLOW SOIL SITES

In addition to the Level I and II monitoring, Best Management Practices must be employed when harvesting stands that have been identified as Ecosite 11 or 12. "Best Management Practices are practices that are not considered part of normal operating procedures and are conducted specifically to prevent or minimize damage to the physical environment." (Archibald et al, 1997). The Best Management Practices included in the "Forest Management Guidelines for the Protection of the Physical Environment" (Archibald et al, 1997) are not considered the only management practices that may be "used to prevent, minimize or mitigate site damage." (Archibald et al, 1997). As a result, expanded lists of Best Management Practices are included in this section for consideration when planning or implementing operations on shallow soil sites.

All Ecosite 11 or 12 areas greater than 8 ha. must be identified in the Annual Work Schedule. It is recognized that significant shallow soil areas occur in stands typed to other ecosites. The sites which are most at risk (i.e. very shallow soils) are relatively easily identified. It is more difficult, however, to define the line where sites are marginally at risk, especially due to the variation in site conditions within each ecosite type. A 'conservative and adaptive approach' (Archibald et al, 1997) should be taken to managing these sites. The Best Management Practices selected for these sites must include practices that minimize the amount of site damage (i.e. ground disturbance and nutrient loss) occurring throughout the stand as a result of harvest and site preparation treatments.

The identification of these sites will be an important consideration during operator training, so that the best management practices may also be implemented on the small patches (< 8 ha.) of Ecosites 11 or 12 that have not been captured in the inventory. In order to minimize the potential for nutrient depletion from full-tree logging, the Best Management Practices listed in sections 6.1 and 6.2 are also recommended for these smaller shallow soil areas. Operational constraints will influence the extent to which these best management practices may be implemented on these smaller areas, but the overall goal will be to utilize practices that reduce ground disturbance and nutrient loss from the sites.

These Best Management Practices are to be considered in both planning and field implementation. The Silvicultural Ground Rules in the Forest Management Plan should address how these sites will be managed to prevent or minimize damage due to soil disturbance and nutrient loss. It may be appropriate to separate these sensitive sites into separate forest units for management purposes. (Archibald et al, 1997). The lists of Best Management Practices (Section 6.1 and 6.2) also provide direction for formulating site-specific treatments when developing Forest Operation Prescriptions (FOP) during preparation of the Annual Work Schedule. Operational design of activities (i.e. on-site planning), conducted at the field level, provides the

best opportunity for effectively implementing Best Management Practices. The level of detail associated with this planning level varies with the complexity of the forest conditions, and the type of forest operation being conducted (Archibald et al, 1997). Operator and field supervisor training are key to successful on-site implementation of Best Management Practices.

As mentioned, training will be a significant consideration for the implementation of these best management practices. Training, which will be carried out with MNR and forest industry staff, will focus on the identification of these sites and the proper application of best management practices. During the first year of the monitoring program (2001-2), each forest company will conduct a formal training session regarding best management practices for employees, contract staff and equipment operators involved with operations on ES 11 and ES 12 sites, and other shallow soil conditions. As required, each company will reinforce the implementation of best management practices on these sites through on-going discussions, annual reviews of practices, refresher training sessions, and regular inspections and reporting.

6.1 Minimize Ground Disturbance During Harvest and Renewal Activities:

Site disturbance associated with harvest and renewal activities should be minimized on shallow soil sites. All operations will be performed on shallow soil sites in such a manner and timing as to avoid widespread, continuous ground disturbance. Proper planning and timing of operations are key to avoiding extensive ground disturbance. These practices include:

- *Winter harvesting* of shallow soil sites is recommended, within operational constraints. Winter harvesting will conserve slightly more nutrients on site, and will help to reduce site damage such as erosion, compaction, or rutting. The use of winter harvesting does not preclude the use of other best management practices. Although winter harvesting is recommended, avoidance of excessive disturbance, and the implementation of other best management practices will minimize the impacts of summer logging on shallow soil sites.

- *Use high floatation (low impact) equipment* to maintain the integrity of the surface organic layer, and prevent rutting or compaction in the deeper soil inclusions. This is especially important during wet weather conditions when the organic layer or soil is saturated.

- *Minimize skid trails*, *landings* and roads on shallow soil sites, with an emphasis on creating the least amount of disturbance to the organic layer, and the protection of advanced regeneration. Whenever possible, non-productive areas such as rock outcrops shall be selected for landings or skid trails. Re-use skidways, rather than build extra landings. Avoid or minimize the amount of bulldozing required to create landings ***and roads*** on shallow soil sites. (e.g. backhoes may be used to build roads, avoiding the removal of soil from large areas).

- *Avoid harvesting and skidding on steep slopes* with shallow soils, since they will be susceptible to erosion (i.e. areas with only a discontinuous layer of organic material over bedrock). Clearcut practices may be modified to retain some trees adjacent to inoperable slopes. Modify skidding patterns on shallow soil slopes to reduce the risk of erosion (i.e. along the contour to the extent possible).

- *Silvicultural treatments that minimize ground disturbances should be favoured.* Natural regeneration, Careful Logging Around Advanced Growth (CLAAG), and artificial renewal treatments (i.e. aerial seeding, planting) that do not require mechanical site

preparation should be used, where appropriate. For example, planting without site preparation, through the thin LFH layer, or boot-screefing may be an alternative to mechanical site preparation. Planting with mini-plugs, or aerial seeding are viable renewal options for these sites, which tend to have low competition levels.

- *Mechanical site preparation should provide the minimum amount of mineral soil exposure* that is acceptable to meet silvicultural objectives *(e.g. if required for aerial seeding)*. Heavy mechanical site preparation (i.e. blading, heavy drags) will not be used on these sites. If mechanical site preparation is required, 'patch' type scarification is preferred. It is recognized that summer full-tree logging may result in adequate disturbance of the site for renewal purposes, thus eliminating the need for mechanical site preparation.

6.2 Avoid Practices That May Encourage Nutrient Loss from These Sites:

The following best management practices are recommended to prevent nutrient loss after full tree logging, with the emphasis on maintaining the nutrient capital stored on the sites:

- *Winter harvesting is recommended* to reduce nutrient loss from these sites. The use of winter harvesting does not preclude the use of other best management practices.

- *Careful Logging Around Advance Growth (CLAAG)* may be used as an operational harvest practice to improve the cycling and capture of nutrient capital.

- *Residual trees or snag trees should be left on site,* according to existing guidelines. Green hardwood trees should be favoured (particularly poplar), to improve nutrient cycling and the capture of nutrient capital. Residual trees should be left on areas susceptible to erosion.

- *Post-harvest prescriptions and renewal efforts* should be carried out as quickly as possible on shallow soil sites to encourage full site occupancy. This should also help to prevent problems with erosion and loss of nutrients.

- *Lower nutrient demanding species such as jack pine* should be matched to nutrient poor sites. The use of fast growing species is advisable to ensure rapid reforestation and reduce the erosion risk.

- *Chemical aerial tending* must be carefully assessed on shallow soil sites prone to nutrient depletion, since many of the competitive species on site act as nutrient sinks. This will maintain a diversity of tree and plant species on the site. Species such as alder, for example, are capable of fixing nitrogen in the soil, and should be retained. However, on some shallow sites, especially those with finer textured soils, aerial tending may be required to facilitate crop tree establishment, survival and growth.

- *Chemical site preparation* is generally not required, as these sites tend to be shrub and herb poor (i.e. low competition sites). However, on some shallow sites, especially those with finer textured soils, chemical site preparation may be required to facilitate crop tree establishment, survival and growth.

- *Prescribed Fire is* conditionally *recommended* due to potential loss of organic matter and nutrients. Low severity fires which remove less than 20% of the surface organic material are permissible**.**

7.0 REPORTING

7.1 Level I Monitoring:

The Project Manager is responsible for maintaining all files pertaining to the Level I permanent sample plots and developing the format for data management. All data and files will be kept at the Centre for Northern Forest Research (CNFER) within the Stand Ecology Program.
Establishment reports will be prepared for each of the Level I plots following the pre-harvest assessments and nutrient analyses. The report will include the following information:

- Locator maps and maps of plot layout
- The results of the physical, chemical and biological assessments, as outlined in section 2.2 of this document.
- Site photographs

At each of the **follow-up assessment periods** (i.e. "immediately**"** post-harvest, and "5 and 10 years" post-harvest), progress reports will be prepared which will include:

- Updated Site Photographs
- A summary of results of the current physical, chemical and biological assessments, as outlined in section 2.2 of this document.
- An assessment of the 'Six Key Indicators' (Section 1.0).

The Stand Ecology Program Leader at CNFER (or other suitably qualified individual) will complete the assessment of change in the six key indicators: Soil compaction, Soil Rutting and Puddling, Soil Displacement, Soil Erosion, Soil Organic Matter Retention, and Soil Nutrient Reserves.
In addition, at the year 5 and 10 assessments, the results of the Level II assessments will be compared to the Level I results, particularly with respect to the range of : post-harvest site disturbance (i.e. degree of rutting, MSE and soil displacement), amount of woody material on site post-harvest (i.e. residuals and snags, down woody material), and soil textures and fertility.

7.2 Level II Monitoring

SFL holders are responsible for the establishment and field assessment of Level II plots. Level II plots are key components of the Region wide monitoring proposal and are required to assess the relevance of Level I results. Therefore it is critical that the results of the Level II assessments be available in the centralized CNFER database.

When the Level II post-harvest assessment is complete, SFL holders will complete a computerized report in a standardized format (to be developed by the Project Manager using the outline in Appendix I of this document) and a copy will be sent to the Project Manager. The Project Manager will confirm the assignment of each plot to the allocation matrix and will be responsible for coordinating the analysis of nutrient samples.

If Post Site Preparation Sampling is required on the plot, the SFL holders will complete the field assessments and forward the information (see Section 3.0 of Appendix 1) to the Project Manager in a standardized format (to be developed).

7.3 Annual Work Schedules (AWS), Forest Management Plans (FMP), Annual Reports (AR) and Best Management Practices: Documentation

In order to be able to evaluate the extent to which these best management practices have been implemented over time, each SFL holder will be required to report on the implementation of Best

Management Practices in the text of their Annual Reports. The following information on ES 11/12 stands will be available to the Ministry of Natural Resources as supporting documentation:

- List of Stands and area harvested.
- Season of harvest.
- Details of the Forest Operation Prescription that was implemented for each stand.
- A summary of the renewal and tending treatments that have occurred on these sites (regeneration treatments, site preparation, and tending) and assessment results.

Each SFL holder is responsible for reporting the information outlined in Section 5.0 and Section 6.0 of this document. As indicated in these sections, the information pertaining to ES 11 and 12 stands will be reported in accordance with AWS, FMP and AR procedures outlined in the Forest Management Planning Manual.

8.0 OTHER OPPORTUNITIES: FURTHER INVESTIGATIONS AND ADDITIONAL FUNDING SUPPORT

Opportunities to link this monitoring program to further investigations of soil processes should be investigated. Soil quality monitoring is on the forefront of many North American jurisdictions, yet there has been very little work toward a comprehensive soil monitoring program. Opportunities may exist to establish partnerships with other jurisdictions to develop standards for measuring site degradation indicators.

The monitoring proposal outlined in this document involves static sampling of physical, chemical, and biological components of the ES11/12 sites. There are opportunities to investigate the processes that regulate the cycling of nutrients on these sites. More information on processes such as nutrient input through precipitation and weathering, decomposition rates, nitrogen mineralization rates, net forest water and litterfall aid in our understanding of how these systems function and ultimately recover from a specific disturbance.

Presently, the Centre for Northern Forest Ecosystem Research Stand Ecology Program (CNFER) is establishing a comprehensive plot network, using a chronosequence approach (stands of different ages developing on similar site/soil conditions). The intent here is to develop both wildfire and harvest chronosequences for different ecosites, including ES12, and compare stand development and important ecosystem processes to look for differences between these two modes of stand initiation/renewal. Further more, the data collected from these chronosequence sites will be used to calibrate and create ecological models. These models will be designed to look at the potential impacts of alternative silvicultural options on soil quality and ecosystem recovery.

The static samplings and process-oriented studies may generate interest in organizations involved in Criteria / Indicators, carbon sequestering or climate change work. These organizations may be able to provide some levels of funding. If these linkages are made, caution must be exercised to ensure that the integrity of the current monitoring system is not jeopardized.

Appendix I

ES11 and ES12 Soil Monitoring:
Detailed Procedures for Level II Sampling
(From: Field Manual for the Establishment of Forest Monitoring Permanent Sample Plots
(Sumac Forest Information Services Ltd.; draft April 2000))

Procedures:
The selected stands (greater than 8 ha) will have a cluster of three PSP's. Each PSP must be at least 70 m from the others in a cluster (center to center). Sampling will occur within the first year post-harvest and before site preparation.

1.0 PSP Location

Materials:
Candidate PSP pkg. (aerial photo, FRI data, main PSP info. form).
Unit road map. Locators map (blank).
Grease pencil. Ru ler.
Navigational protractor. Compass.
Hip chain.
Spray paint (orange and blue).
Flagging.

1.1 Locating The Tie Point:

Using the maps and candidate PSP package provided, locate a roadside tie point. The tie point should be a permanent and prominent feature i.e. road forks, bedrock outcrops.

1.2 Locating The PSP:

Managing body: PSP
PSP No._____
PSP Center Post

Upon completion of the PSP record the azimuth and distance (straight line) to the PSP from the roadside tie point. The tie point will be marked with a witness tree. A flag line is to be hung from the PSP to the witness tree. Ensure the witness tree is off the road right of way to avoid damage or removal during road maintenance.

Orange and blue bands painted at eye level identify the witness tree. The witness tree shall also bare the PSP number painted with tube paint below the coloured bands.

The Locator Map:

Map and describe the route to the PSP from a major permanent feature i.e. highway junction. Record the distance between each prominent feature (road junctions, bridges, and water crossings) that marks the route. Provide a distance beyond the PSP to a visible feature to indicate that the tie point has been passed.

This map need not be drawn to scale but should reflect the general direction of travel and have enough detail that person unfamiliar with the area can relocate the PSP with ease.

2.0 Main PSP Information Form

Location Information:

PSP No. – Record the PSP number.

The PSP is numbered as follows: Working circle – Year – Block number and Plot number i.e. 78-2000-606-1.

Working circles	Management Unit	Managing Body
4	English River Forest	Bowater
78	Black Sturgeon Forest	Bowater
12	Caribou Forest	Bowater
3	Brightsand Forest	Bowater
56	Dog River Matawin Forest	Bowater

Add in other Mgmt Units and interest groups

Ownership – Record *Managing Body*

Azimuth to PSP – Record azimuth to PSP from the witness tree.

Distance to PSP – Record distance to PSP from the witness tree.

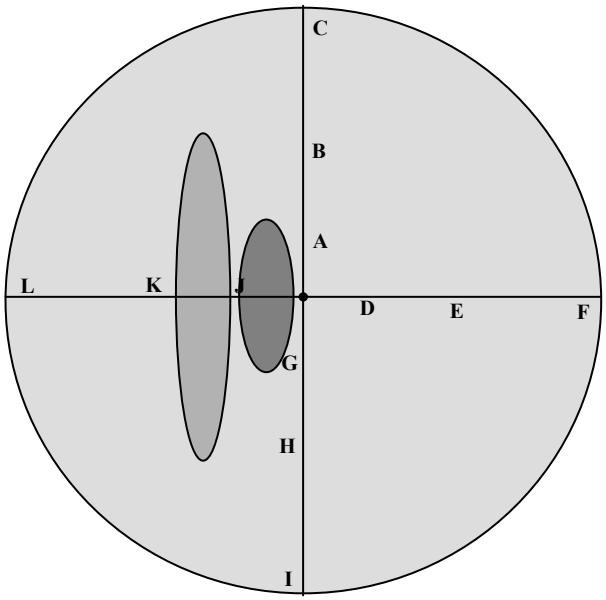
Declination – Record declination used.

Photo No. – Record aerial photo number.
Year - Flight Line - Roll – Photo Number.

Basemap / OBM No. – Record Basemap / OBM number.

Establishment Date – Record date of PSP establishment.
Year/ Month/ Day.

Crew 1 – Record the last name of tally person.
Crew 2 – Record last name of second crew person.



Plot Radius – Record 11.28 meters with four transects originating from the centre of the plot. The first transect bearing should be randomly selected and the other three at approximately 90^{o} intervals around the plot. Points are established along each transect at 2.82 m and at 5.64 m. These points will be labeled as A through L as per the accompanying diagram
To record general site conditions, take a **photo** along each transect line.

***Stand Information*:**

FRI Year – Record the FRI year.

FRI Stand No. – Record FRI stand number. Include stand suffix if applicable.
If unknown leave blank, until information is obtained. Note this occurrence on the Plot Package Checklist.

Stand Area ***– Record the stand area from FRI map or aerial photography provided***

Stand Disturbance – Record the stand disturbance code.
Harvest
Year:
Season:

**** Degree of Rutting:**
Heavy
Moderate
Light
Not evident
Definitions still required

Azimuths of transects
Azimuth A→C:
Azimuth D→F:
Azimuth G→I:
Azimuth J→K:

**** Map Exposed Bedrock**
Estimate pre-harvest condition

**** In the area without exposed bedrock**:
** Provide an ocular estimate of **MSE** (% of the area minus pre-harvest exposed bedrock)
** **Soil Displacement** as a result of harvest/SIP activities (% of area minus pre-harvest exposed bedrock)

(Note: items marked '' are re-assessed if a post Site Prep. Assessment is required)**

Main PSP information Form
Soils Information:
A soil pit is to be established at plot centre. The following information is to be collected.

A profile identifying the textural classes, depth to textural changes and depth to mottling is to be done for the primary site condition within the PSP. If there are other site conditions then location of the plot at this point should be reconsidered.

Sampling is required to Bedrock. Use a divot to determine the depths of the individual layers of the duff.

Scratch pits are allowable for the determination of bedrock. They are also helpful for the determination of mottling due to a fluctuating water table.

If the pore pattern remains the same throughout the profile a sample from the deepest section of the profile is to be bagged. Ensure a minimum of a fist size sample is collected. If there are multiple pore patterns present within the profile, samples of each are to be collected and properly labeled, PSP No., depth, and texture and sample number.

Depth From – Record the beginning depth of a textural change to the nearest cm.

Depth To – Record the ending depth of a textural change to the nearest cm.
All profiles are to end at bedrock.

Tex. / Tax. / Dec. – Record the texture class for each mineral horizon encountered. Record the proper taxonomic identifiers for each layer that makes up the duff layer.

Texture class is the nomenclature used in the Canadian System of Soils classification to describe the relationship between the base components of the soil, sand, silt and clay.

C – Clay	Si – Silt	vfS – Very Fine Sand
SC – Sandy Clay	SiS – Silty Sand	fS – Fine Sand
SCL – Sandy Clay Loam	SiL – Silt Loam	mS – Medium Sand
CL – Clay Loam	SiC – Silty Clay	cS – Coarse Sand
SiCL	– Silty Clay Loam	vcS – Very Coarse Sand
	L – Loam	
	SL – Sandy Loam (specify sand fraction)	
	LS – Loamy Sand (specify sand fraction)	

CF – Record the coarse fragments code.
1- <10% 2- 10-35% 3- >35%

Pore Pattern - Record the pore pattern for each mineral soil horizon and any bedrock horizon.
Pore patterns maybe found in the chart:

Depth to Mottles - Record the depth at which mottles begin. If none are found record 999.
Do not record a depth for hesitation or root mottles. Only mottles due to a fluctuating water table are to be recorded. Hesitation and roots mottles should be noted in the notes section.

Depth to Gley – Record the depth at which gley begins. If none is found record 999.

Bulk Density- Samples are taken from each horizon (including both organic and mineral) for Bulk Density determination.

Depth to Bedrock – Record the depth at which bedrock begins. If not encountered record 999.

Parent Material- Record the bedrock type, e.g. granitic, greenstone, calcareous …

Landform – Record the landform code.

1-	Outwash Plain	6-	End Moraine	11-	Rock Ridge	16-	Boulder Pavement
2-	Kame	7-	Lake Plain	12-	Spillway	17-	Other
3-	Esker	8-	Dune	13-	Drumlin		
4-	Terrace	9-	Delta	14-	Organic		
5-	Ground Moraine	10-	Beach	15-	Bedrock		

Mode – Record mode of deposition.

B-	Basal Till	G-	Glaciofluvial	O-	Organic
C-	Colluvial	L-	Lacustrine	R-	Rock
D-	Eolian	M-	Morainal		
F-	Fluvial	N-	Marine		

Slope Position – Record the slope position code.

1-	Crest	3-	Middle Slope	5-	Toe	7-	Level
2-	Upper slope	4-	Lower slope	6-	Depression	8-	Rolling/ Complex

Slope % – Record the average percent slope for the area of the PSP.

Aspect – **Record the azimuth for the direction the PSP is facing. If the site is complex record 999.**

Humus Form – Record the humus form code.

1-	Compact Mull	6-	Typical Moder		11-	Humimor
2-	Fine Mull	7-	Raw Moder		12-	Humic Peatymor
3-	Medium Mull	8-	Fibrimor	13	-	Mesic Peatymor
4-	Coarse Mull	9-	Humifibrimor		14-	Fibric Peatymor
5-	Mull like Moder	10-	Fibrihumimor		15-	Anmor (muck)

Effective Texture – Record the effective texture.
If soil is stratified (more than 1 pore pattern) determine effective texture. If one pore pattern is present record the texture of the dominant texture.

Moisture Regime – Record moisture regime. For Theta enter D.
In stratified mineral soils the moisture regime is to be calculated using the effective texture. Use the dominant texture for profiles with <60 cm mineral soil.

Do not use depth to hesitation mottles when calculating moisture regime. Following this determination, there is an allowance for moisture regime to be moved up one class, if warranted with the presence of hesitation mottles.

D-	Dry	3-	Very Fresh		7-	Moderately Wet
0-	Moderately Dry	4-	Moderately Moist		8-	Wet
1-	Moderately Fresh	5-	Moist	9	-	Very Wet
2-	Fresh	6 -	Very Moist			

Drainage Class – Record the drainage class code.
Use the effective texture.

Do not use depth to hesitation mottles when determining drainage class. Following this determination, there are allowances for drainage class to be moved up one class, if warranted with the presence of hesitation mottles.

1-	Very Rapid	4-	Moderately Well	7-	Very Poor
2-	Rapid	5-	Imperfect		
3-	Well	6-	Poor		

Texture Range – Record the texture range.
This is the broad grouping that is used to segregate out a range of textural classes. For example Coarse Loamy, Clayey, Sandy, etc.

Sandy – vcS, cS, mS, fS, vfS, LvcS, LcS, LmS, LfS
Coarse Loamy – LvfS, All SiS, SL, L
Silty – SiL, Si
Fine Loamy – SCL, CL, SiCL
Clayey – SC, SiC, C

S-Type – Record S-Type.
Use the C horizon of the soil auger for this purpose.

Nutrient Samples
At the end points of the four transects, soil cores are to be taken. For each organic and mineral horizon encountered, bag a sample of soil for nutrient analysis. These samples should be labeled as PSP number, ownership, horizon and point number (C, F, I or L)

Stump/residual and snag Inventory
Record the species and diameter at a height of 10cm of each stump, residual tree and snag in the PSP. Three dominant stumps should be aged to confirm the pre-harvest stand age. The diameter limit is 2cm minimum. The tally shall indicate whether it was a stump/ snag or residual tree.

Down Woody Material (4 transects)
Down Woody Material (DWD) is any woody material that is laying on the ground.

Measure the top, bottom and intersecting diameter, and the length of each piece of DWD that crosses the transects. Assign a decay class to each piece of DWD along the line. Minimum diameter = 2 cm. Determine species if possible, otherwise distinguish between hardwood and conifer.
Each transect is to have a 5m length assessed for DWD

Decay Class (Duval and Grigal, 1999)

0	Fresh Slash
1	Bark on, wood sound and round
2	Bark partially off, wood partially decayed but round
3	Bark mostly off, wood decayed and exterior friable, round to partially oval
4	No bark, wood very decayed and highly friable throughout, oval
5	No bark, wood sound and bleached

Fine Slash Count; (for each transect)
Record the count (by species) of each piece of DWD smaller than 2cm in diameter and belonging to decay class 0, that intersects the transect.

3.0 Post Site Preparation Sampling

Level II plots are to be established post-harvest, but prior to site preparation. If site preparation does occur, some parameters must be re-assessed to enable the impacts of full tree harvest and site preparation to be separated.

The following is the procedure to be used:
Re-locate the centre of each plot. Using the bedrock exposure map produced from the post-harvest sampling, provide an updated ocular estimate of 1) rutting severity, 2) mineral soil exposure and 3) mineral soil displacement using the same procedures followed in the first sampling.
In addition, record the following information and add it to the file for the site: 1) Year and Month of Site Prep., and 2) Type of Site Prep. equipment.

APPENDIX II

WORKING GROUP MEMBERS

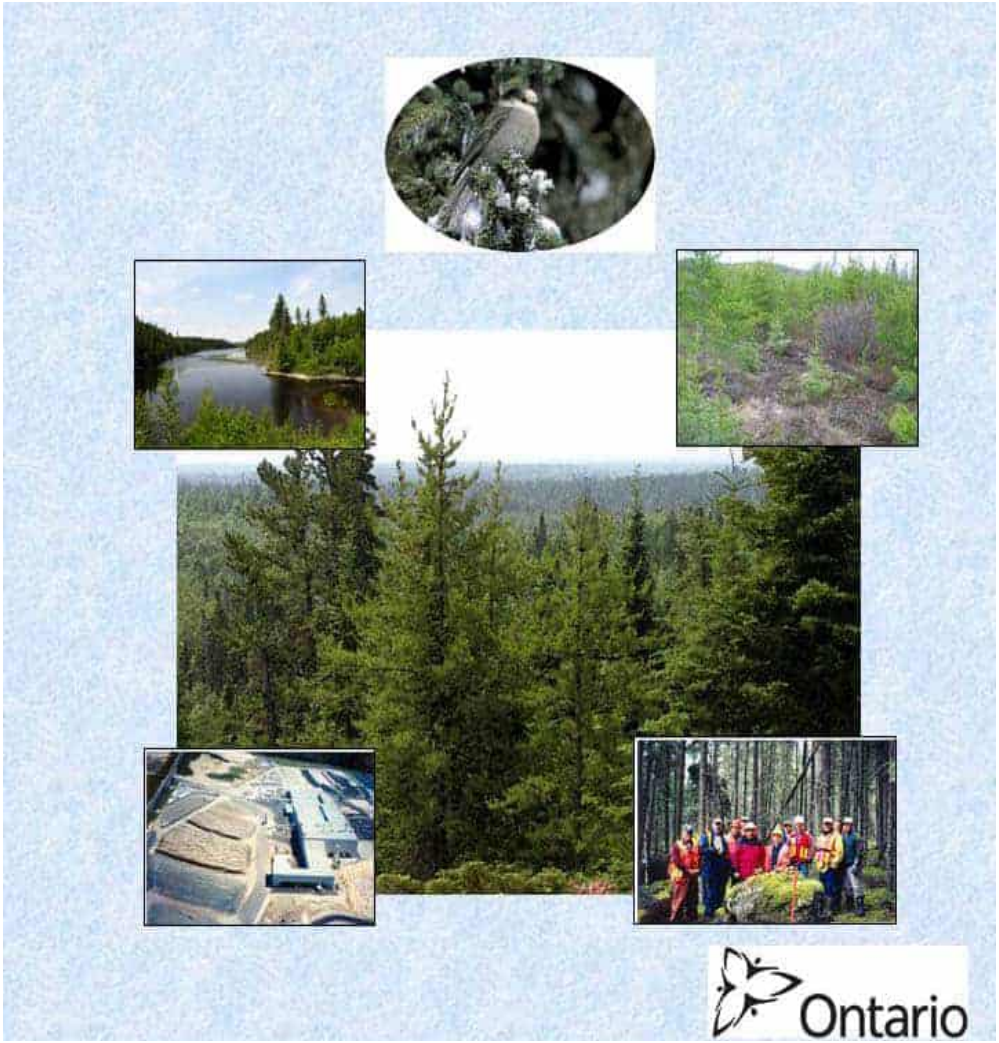
The following are the Industry and OMNR representatives assigned to the working group responsible for the development of this procedure:

- **Dave Archibald – Bowater Pulp and Paper Canada Inc.**
- **Steve Watson – Abitibi Consolidated Inc.**
- **David Salter – Weyerhaeuser Canada Ltd.**
- **Brian Campbell/Harry Pearce – Domtar Forest Products**
- **Ken Lennon – Kimberly Clark Inc.**
- **Richard Cameron – Red Lake Forest Management Company**
- **Dave Morris – OMNR, Centre for Northern Forest Research**
- **Dan Duckert – OMNR, Centre for Northern Forest Research**
- **Mike Dawe – OMNR, Kenora District**
- **Bob White – OMNR, Northwest Science and Technology**
- **Neil Stocker – OMNR, Provincial Silviculturist**
- **Ron Waito – OMNR, Northwest Regional Planning**

Supplementary Documentation F

2012-2022 Whiskey Jack Forest Management Plan

Monitoring Program for Regeneration Success



Pre-Free Growing Survey Methodology

Pre-free growing surveys are intended to determine the regeneration success of a given forest area and to identify any areas where regeneration is not adequate. Data collected can be used to determine the stocking of the area, species composition, and the extent of competing vegetation. This information provides a measure of how the stand is progressing towards its set objectives.

These surveys should be completed 2-5 years after harvesting or renewal treatments have been completed. This scheduling is designed to allow time for any remedial treatments to be completed and for their effects on the block to be seen before free to grow assessment. This timing should also allow seedlings to become established in the stand. Trees which were unsuccessful due to factors such as poor microsites would also be showing signs of stress by this point, allowing surveyors to easily identify seedlings unlikely to survive.

Plot Allocation

Plots 4m² in size, with a plot radius of 1.13 will be used to complete pre-free to grow surveys. This plot size will provide an adequate description of the survey area as the block being assessed contains smaller trees, meaning more trees can be captured in the plot. However, a plot density of **three** plots per hectare is needed in areas of higher variability in order to account for between plot variations and to provide an accurate description of the block. Blocks that are pure hardwood receive a plot density of one plot per hectare if they are uniform.

After the minimum plot number is established, plot locations should be determined systematically and mapped, with the grid size and pattern depending on the number of plots required. Plot spacing and line spacing should generally be kept similar in order to approximate a square layout pattern. The distance between survey lines and between the sample plots along the survey lines can be calculated using the following formula.

$$\text{Plot spacing (m)} \times \text{Line spacing (m)} = \frac{\text{Strata area (ha)} \times 10{,}000}{\text{Required min. number of plots}}$$

Once the desired survey line spacing is selected, calculate the required plot spacing (for the minimum number of plots) by substituting “line spacing”, “strata area (ha)”, and “required minimum number of plots” in the above formula and solving for “plot spacing”.

Mapping

The minimum number of plots required should be established on a map prior to going out to the field. Survey line locations should be tied into recognizable features on the ground, and distance and bearing information should also be included to facilitate mapping and navigation.

Data Collection

Before going into the field, a block header sheet should be filled out (Appendix 1). This provides the surveyor with background information for the block. The header sheet gives treatment types and dates, as well as the targets and standards for the block and should include the number of plots and plot spacing established in the previous step.

Plot Location

Follow the mapped survey lines and establish plots at the predetermined locations. The plot center should be flagged and GPS'd to aid in locating the plot in the future if necessary. If a plot lands in an area where a feature such as permanent water, or exposed bedrock composes over half of the plot, or if it lands in an un-harvested area, the plot should be moved and these features noted. Plots should be moved to a location halfway between two plots as near to the initial plot location as possible.

If a plot lands on a site where conditions resulting from forestry activities exist, such as equipment trails, puddle ruts, slash piles or wind throw, assess the plot normally and provide comments regarding site conditions on the tally sheet.

Tree Tally

After the plot is located, all trees in the plot are tallied by species and height class, and recorded in the Pre-free to grow tally sheet (Appendix 2).

Pre-free to grow surveys are completed after only 2 to 5 growing seasons, as a result there are no minimum heights required in order for a tree to be tallied during this survey. This time period does allow trees to become established in the stand. However, during seedling establishment, growth is not focused on the above ground portion of the tree, so heights will be lower resulting in several trees not being included in the tally because they do not meet height requirements when in reality they will grow and contribute to the stand given more time. Requiring trees to be a minimum height could result in a stratum not meeting stocking requirements or a fill plant being recommended when in reality there are several seedlings not captured in the surveys that will naturally fill in the spaces.

Dominant ground cover should also be recorded in the competing species column of the tally sheet (Appendix 2). Dominant ground cover is considered to be non-commercial vegetation such as shrubs and grasses which is competing with the seedlings. Dominant ground cover is recorded as the percentage of the plot that the species is covering, as well as the average height. This information will provide an indication of whether vegetation management is required in order to reduce competition and ensure the success of the crop species. Not all vegetation will compete with the seedlings to the same degree and therefore not all species of non-commercial vegetation will need to be treated.

Any health concerns or signs of stress such as drought or browsing should be noted during the survey. Dead seedlings or those not expected to recover from some stress should also be noted, but should not be included in the plot tally.

Determining Stocking

The percent stocking of a block is determined using survey results and the following formula. In order to be considered stocked, a plot must contain at least one crop tree. If a plot contains trees, but the species are not listed as desired or acceptable under the SGR for that stratum, the plot is considered to be not-stocked even though trees are present.

Stocking Formula

$$\frac{\text{\# of stocked plots}}{\text{total \# of plots}}$$

For example, if 72 "stocked" plots were recorded in a 30ha stratum which had 90 plots sampled, the stocking % would be as follows.

$$\frac{72}{90} = 80\% \text{ stocked}$$

In order for a plot to be measured it must be located on a site that is capable of supporting a tree. Areas that are flooded, located on bedrock or occur within an unmapped residual stand will not count towards the "total" number of plots. However, areas that are temporarily not capable of supporting trees, i.e. slash piles, operational roads, landings that do not occur on areas "permanently" incapable of supporting trees will be included in the total number of plots.

Determining Regeneration Status

The regeneration status of a stratum is determined as either Satisfactorily Regenerated (SR) or Not Satisfactorily Regenerated (NSR). This status is determined by comparing survey results with minimum standards determined by the silvicultural ground rule associated with the stratum. Determining whether a plot is satisfactorily regenerated or not satisfactorily regenerated is a function of plot size and the required minimum stocking level of the block.

The proportion of a hectare the plot composes determines the stocking factor of the plot.

1ha= 10,000m²
10,000 m²/ 4 m² = 2,500 meaning a 4 m² plot composes 1/2500 of a hectare.

For plots 4m² in size, the minimum stocking for each treatment (extensive, basic and intensive) as found in the SGRs (FMP-4) to be declared SR will depend on whether the stratum underwent extensive, basic or intensive treatments.

Treatment	Minimum Stocking Requirements
Extensive	70%
Basic	80%
Intensive	80%

The minimum number of stocked plots required in order to meet stocking standards can be found by multiplying the minimum average number of crop trees per plot by the total number of plots required in the stratum.

For Example, in a 30 hectare stratum, 90 plots are normally required in order to get a plot density of three plots per hectare (30ha x 3 plots/ha). The following are the minimum numbers of stocked plots required to meet stocking requirements under each silviculture intensity treatment.

Extensive 90 x 70% stocking= 63 stocked plots per block
Basic 90 x 80% stocking = 72 stocked plots per block
Intensive 90 x 80% stocking = 72 stocked plots per block

Survey Summary

After the survey is completed, a Pre-Free to Grow summary sheet should be completed based on the survey results (Appendix 3). This includes a summary of the total number of trees tallied by species and height class, which is then used to determine the current species composition and regeneration status of the stratum.

Based on these results, it can then be determined if the stratum is on its way to becoming a regeneration and silvicultural success. A stratum is considered a regeneration success when it meets stocking standards as found in its assigned SGR. A stratum is considered a silviculture success when it meets the species composition and desired forest unit found in its assigned SGR. The results of this survey will naturally alter by the time the stratum is assessed for Free Growing. However, this survey will determine if the desired species are present at the desired density in the stratum. If it is found that desired species are not present, or are in a low concentration in the stratum, a fill plant or other remedial actions can be completed to help the stand move towards the desired future forest condition.

Ocular Estimate Survey

Ocular estimate surveys will generally be conducted from the air via helicopter, with associated ground trothing for quality control. Some areas may be surveyed on the ground (e.g. not aerially assessed) depending on helicopter availability and road access.

This survey methodology is intended for use in stands where accurate estimates of stand conditions can be obtained through an ocular assessment, such as found in relatively pure species forest conditions like naturally regenerated poplar. This survey methodology is designed for strata that have undergone extensive or basic silviculture intensity treatments, where density regulation is not desired.

These surveys will be conducted by experienced forestry workers who will complete an ocular assessment of species composition, average height, stocking, and determination of free-to-grow status. Annual ground calibration surveys are conducted to ensure accuracy of observations. Previous on-the ground assessments following the pre-free to grow methodology found in Supplementary Documentation F will be used to determine suitability for ocular estimate strata and as a guide for species composition and stocking during the ocular estimate survey.

Silvicultural treatment polygons (based on silviculture records) are the initial survey polygons. These polygons may be stratified further based on differences in future forest unit, species distribution, site type, stocking, density or height.

Stocking is determined from the air for those areas where density regulation is not a criterion of regeneration standards. The ocular assessment will determine if the minimum stocking as identified in the Silvicultural Ground Rules (Table FMP-4) for extensively or basically treated areas is achieved across the harvested area. Determination of stocking will consider both the target and acceptable species. Stocking will provide a measure of the percent of the area within a harvest area occupied by target plus acceptable tree species to the acceptable limits identified in the SGRs. Balsam fir will only be used in determining stocking up to the limit specified in the appropriate SGR.

Site occupancy is also determined from the air for those areas where density regulation is not a criterion of regeneration standards. Site occupancy is assessed for density regulated stands using the Well-Spaced Free Growing Survey method (see Supplementary Documentation F). Site occupancy is assessed against a larger assessment area as compared to the stocking assessment area described above. The site occupancy assessment area includes all harvested areas, landings, slash and chip debris piles and roads that are to be renewed, excluding only those areas that did not originally support production forest (e.g. rock outcrops, natural wet areas) or elements such as residual wildlife trees or retained roads. Assessment areas with more than 20% gaps (16 m2 circular plot areas without a single target or acceptable tree species over 30 cm in height) would not be identified as free-to-grow.

Where stocking or site occupancy is not relatively uniform across an assessment area, the assessment area will be stratified to identify areas that are clearly above or below regeneration standards. Results will not be averaged over the whole assessment areas where results vary significantly within the assessment area. Portions of assessment areas that are clearly not adequately regenerated will either receive further renewal treatment to enhance stocking levels or will be monitored for natural ingress of target and acceptable species on those sites where ingress of desirable species is expected. Portions of assessment areas that are delineated as meeting regeneration standards will not require further regeneration treatment and will be declared free-to-grow.

Methodology for Large Scale Photography and Photo Interpretation

Schedule A

A1. BACKGROUND INFORMATION RELATING TO THE SERVICES

The Whiskey Jack Forest has approximately 22,000 hectares of backlog silviculture blocks that have not been declared Free Growing. These areas need to be assessed and declared Free to Grow so that they may be brought back into the working Forest Resources Inventory for the forest. As a result the MNR is contracting KBM Forestry to undertake Large Scale Digital 3-D Photography to be utilized in the interpretation and in determining a Free Growing status on approximately 2200 hectares of the backlog areas.

A2 Description of Services

1. MNR and KBM will work together during this process on the refinement and standardization of the photo interpretation methodology.
2. MNR will supply all shapefiles, depletion, acceptable species and silviculture information of the areas to be assessed.
3. The Contractor will utilize the supplied information to determine flight paths for large scale photography.
4. Large Scale Photography will be taken during leaf off conditions.
5. The resolution of the photography will be of sufficient size to determine species and height within a 16m2 plot.
6. The digital imagery will be processed and brought into the 3-D environment.
7. Calibration for photo interpretation – if available MNR will supply previous years Free Growing (FTG) survey results and shapefiles to Supplier. The Supplier will utilize this information to calibrate photo interpreters on stand characteristics. Calibration will be done prior to starting the remainder of the supply silviculture blocks.
8. Further ground sampling of the target stands may be require to provide interpreters with benchmark data.
9. Interpreters will use the imagery as well as available background information (e.g. pre-disturbance forest condition, depletion and silviculture records, ground data) to stratify the blocks into homogeneous polygons using the same stratification rules as the current forest resources inventories. Minimum strata size is 8 hectares for productive forest areas –and 2 hectares for unproductive or unique polygons. The entire depleted will be stratified in the assessment - roads, landings and harvested area. Areas related to non-productive land or elements such as residual wildlife stands, bypass or retained roads will not be included.
10. The Supplier will supply all digital imagery and will supply FTG information as per Forest Information Manual and Technical Specifications.

Interpretation Specifications

A random start grid pattern will be used to establish virtual plots. Intensity of plots will be two per hectare (square grid of just over 70 meters). At each intersection of the grid a virtual plot with a fixed size of 16m2 will be established. Using the elevation tool the 16m2 plot will be adjusted to ground level before interpreting each plot.

Minimum Free to Grow Heights

Unless otherwise stated in an SGR. The following FTG height standards will be utilized

Species	Height Class (m)
Sb, Sw, BF, Ce	>=0.8
Pj, Pr, Pw, La	>=1.0
Hardwoods	>=2.0

Plot Information

At the individual 16 m² plot the following information will be recorded:

Plot information - UTM location, stratum,

Total Trees – All trees species that meet the Minimum Free to Grow Heights will be recorded. Total trees will be used in to determine the effective density of the stand.

Effective density – a tally of all acceptable species (minimum free to grow height) and average height of each species is recorded.

Target or Acceptable Species– tally of target or acceptable species - 1 meter apart to a max of 4 trees or one per quadrate

Stocking - will be determined by dividing the total recorded stems of Target or Acceptable Species by 2500 stems per hectare. (Maximum number of stems based on 4 trees per plot in a 16m2 plot system).

Site Occupancy - This plot will also be used to assess site occupancy. The plots will be recorded as:

Productive - containing at least 1 target of acceptable tree as per minimum free to grow heights,
Void – previously productive area with no trees, including slash piles, roads and landings.
Naturally Unproductive – prior to disturbance. e.g. rock, natural wet areas, alder etc.

This data will be utilized to produce stand level information. ie. Species composition, stocking, total and acceptable tree density of trees meeting minimum height requirements, age (not interpreted), average height.

Data Entry

The individual plot data is recorded in a spreadsheet. The stratum data is summarized and the interpreted information is then entered into a geodatabase ensuring linkage to the polygons.

Quality control - a sub-sample of interpreter work is internally audited by the contractor to ensure consistent high quality results from image interpretation.

Delivery – include the geodatabase, rectified digital images of all project areas, stratification, digitized individual plot locations, and Tally Sheets for field verification. Geodatabase will also include all necessary fields required for a Forest Information Manual compliant Annual Report submission.

Determining Species Composition

Example of Survey Results:

a) Area of stratum: 20 hectare
b) Stand age: 10 years
c) Number of plots surveyed: 40 plots
d) Effective density for each species (that is, the total tally of stems (for each species) greater than or equal to the minimum heights, divided by the total number of productive plots x the expansion factor (625) = avg. stems/ hectare).

   Jack pine: 278 stems per hectare
   Black spruce: 1736 stems per hectare
   White Birch: 278 stems per hectare
   Aspen: 200 stems per hectare

e) Number of plots in which each species occurs;
   Jack pine: in 15 (of 40) plots
   Black spruce: in 30 plots
   White Birch: in 15 plots
   Aspen: in 10 plots

e) Number of voids: there were 4 plots with no measurable stems.

f) Number of Naturally Unproductive: 0

g) Total Productive Plots: Total plots – Naturally Unproductive – Voids = Productive Plots
   40 – 0 – 4 = 36 productive plots

H) Calculation:

Species	Effective Density (all stems per ha.)	Occurrence (% of occupied plots in which this species occurs)	Weighted Values	% Species Comp. based on weighted values
Jack pine	280	.42 (15/36)	118	7%
B. spruce	1700	.83 (30/36)	1411	84%
White Birch	280	.42 (15/36)	118	7%
Aspen	200	.27 (10/36)	54	2% (negligible)
Total	**2460**		**1701**	

Therefore, **interim species composition label for this stratum** is (after rounding): **Sb8PJ1BW1**

Site occupancy = 36/40 x 100 = 90 %
Site Density – 2460 stems per ha
Stocking: 1701 trees per hectare / 2500 = 68%

Regular Free to Grow Survey

This survey methodology is designed for strata that have undergone Extensive or Basic Silviculture Intensity treatments, where density regulation is not desired. It is used to measure the species composition, average height of desired species, stocking and to assess freedom from competition. The free to grow determination is based on stand structure and species competition at the time of assessment, but incorporates criteria designed to improve predictions that the trees remain free to grow over time.

This survey methodology is an adaptation from the Well-spaced Free-growing Regeneration Assessment Procedure for Ontario (White et al. 2005). The full reference is as follows: White, R.G., C.L. Bowling, W.J. Parton and W.D. Towill. 2005. Well-spaced free-growing regeneration assessment procedure for Ontario. Ont. Min. Natur. Resour. Northwest Sci. and Info., NWSI Tech. Manual TM-007. 38pp + appendices.

Plot Allocation

Free to grow surveys will be completed using plots sizes of 16m², with a plot radius of 2.26m. This plot size accounts for more within plot variation, which is important in heterogeneous blocks, and blocks where stocking is borderline. A plot density of **one** plot per hectare should provide sufficient coverage of an area, and account for any between plot variations.

After the minimum plot number is established, plot locations should be determined systematically and mapped, with the grid size and pattern depending on the number of plots required. Plot spacing and line spacing should generally be kept similar in order to approximate a square layout pattern. The distance between survey lines and between the sample plots along the survey lines can be calculated using the following formula.

$$\text{Plot spacing (m) x Line spacing (m) Required} = \frac{\text{Strata area (ha)} \times 10{,}000}{\text{min. number of plots}}$$

Once the desired survey line spacing is selected, calculate the required plot spacing (for the minimum number of plots) by substituting “line spacing”, “strata area (ha)”, and “required minimum number of plots” in the above formula and solving for “plot spacing”.

Mapping

The minimum number of plots required should be established on a map prior to going out to the field. Survey line locations should be tied into recognizable features on the ground, distance and bearing information should also be included to facilitate mapping and navigation.

Before going out into the field, a Survey Header Sheet (Appendix 1) should be filled out for each block. This document will include background information such as year of harvest, regeneration and vegetation management methods, as well as stocking standards for the block.

Data Collection

Plot Location

Follow the mapped survey lines and establish plots at predetermined locations. The plot should be flagged and GPS'd to aid in locating the plot in the future if necessary. If a plot lands in an area where a feature such as permanent water, or exposed bedrock composes over half of the plot, or if it lands in a bypass or un-harvested area, the plot should be moved and these features noted. Plots should be moved to a location halfway between two plots as near to the initial plot location as possible.

If a plot lands on a site where conditions resulting from forestry activities exist, such as equipment trails, puddle ruts, or slash piles, assess the plot normally and provide comments regarding site conditions on the tally sheet (Appendix 2).

Tree Tally

Tally all trees over 30cm tall by species and height class, both crop tree (desired and acceptable species) and non-crop tree species should be included. Trees below 30cm in height are not included in this tally as they generally do not contribute to the canopy of the future stand.

Identify a dominant crop tree (desired or acceptable species) as a starting point. A minimum inter tree distance of 2m is required to provide the trees with adequate growing space. The dominant crop trees selected are referred to as 'stocked' trees. The number of stocked trees in each plot should be recorded in the Regular Free to grow tally sheet (Appendix 2). Should tree distribution be clumped, the most dominant crop tree should be selected as the 'stocked' tree. At least one tree within the clump will survive to canopy closure, with the tree that is currently dominant having the best chances of out-competing the smaller crop trees. Disregard the other crop species within the clump as competition. These dominant or 'stocked' trees will be assessed for free to grow status.

When selecting a 'stocked' tree it is important to assess tree health and form as well as dominance. Trees that are suffering from temporary defects, such as an insect attack, but are otherwise healthy may be selected as a stocked tree. Trees which appear to be diseased or chlorotic should not be selected as these trees are unlikely to survive to maturity. Trees displaying poor stem form resulting from poor planting technique or smothering from grass or snow press should also not be selected. MNR free to grow criteria will be applied to the 'stocked' trees in each plot.

Free to Grow Evaluation

Stocked trees will be evaluated for free to grow status based on tree health, form, and non-crop tree competition. The flowchart included in Appendix 3 lists all of the criteria for a 'stocked' tree to be declared free to grow. The assessment aid is designed for use in the field and aims to aid surveyors in applying free to grow criteria to 'stocked' trees.

The free to grow assessment is carried out within a 1.2m radius around each 'stocked' tree. Competitor stems must be rooted within the cylinder or have a main stem growing vertically within the cylinder to be considered as competition (e.g. coppice birch stems). Competitor branches encroaching into the cylinder from outside are not assessed as competitors unless the 'stocked' tree is overtopped.

Any 'stocked' tree found under a closed canopy or being overtopped (i.e. a competitor's branch extends over the terminal of the 'stocked' tree) is not free to grow (Figure 1). Overtopping identifies potential for leader whipping, or growth loss due to excessive shading. This category does not apply to overstory trees left intentionally as part of the shelterwood silvicultural system or other retention guidelines.

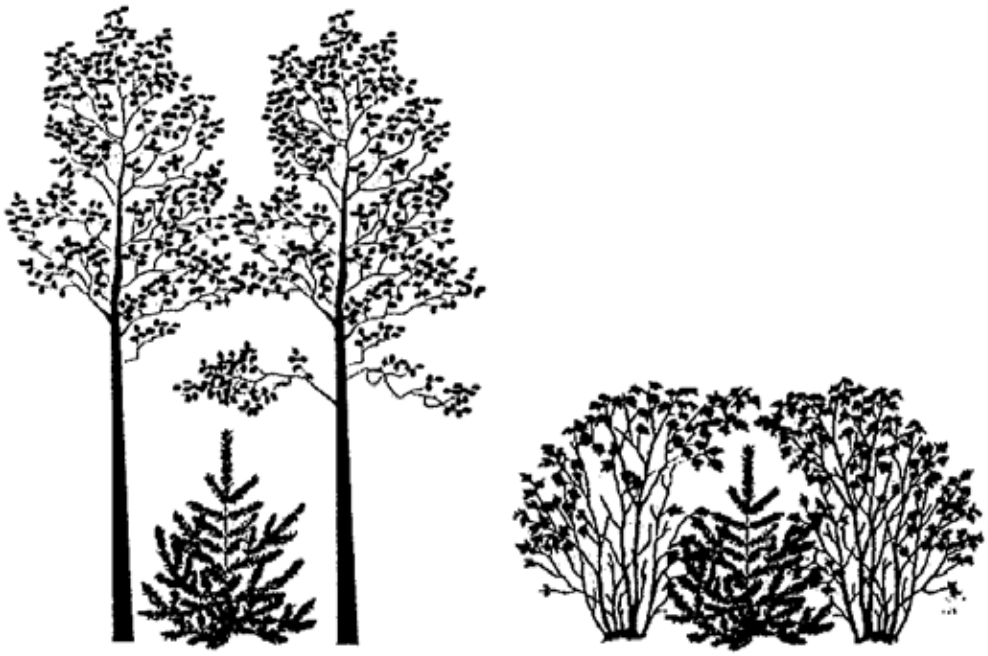

Figure 1: A 'stocked' tree underneath a closed canopy or overtopped cannot be considered free to grow

The competition relevant to the free to grow criteria is divided into brush and non-crop tree competition. At this stage of stand development, herbs, grasses, sedges, fireweed (*Epilobium angustifolium*), low-growing ericaceous shrubs [e.g. blueberries (*Vaccinium* spp.), Labrador tea (*Ledum Groenlandicum*), Laurels (*Kalmia* spp.), and bracken fern (*Pteridium aquilinum*)] are not considered competitors that would have an impact on the success of the selected crop trees. The species of brush and non-crop trees which are

considered competition for crop trees at this stage of development are found below (Table 1). Other species may be added to this table based on local conditions and knowledge.

Table 1: This table lists the species included as brush and tree competition for this free to grow assessment.

Shrub Competition	Tree Competition
Alders (*Alnus* spp.)	Poplar (*Populus* spp.)
Beaked Hazel (*Corylus cornuta*)	Birch (*Betula* spp.)
Cherries (*Prunus* spp.)	Red maple (*Acer rubrum*)
Dogwoods (*Cornus* spp.)	Sugar maple (*Acer saccharum*)
Elderberries (*Sambucus* spp.)	Ash (*Fraxinus* spp.)
Mountain Ash (*Sorbus* spp.)	Jack pine (*Pinus banksiana*)
Mountain Maple (*Acer spicatum*)	Larch (*Larix laricina*)
Raspberry/ Thimbleberry (*Rubus* spp.)	Eastern white cedar (*Thuja occidentalis*)
Serviceberry (*Amilanchier* spp.)	Balsam fir (*Abies blasamea*)
Striped maple (*Acer pensylvanicum*)	
Squashberry/ Highbush cranberry (*Viburnum* spp.)	
Willows (*Salix* spp.)	

Brush Competition

If the 'stocked' tree is greater than or equal to 1.5 times taller than the brush height, the tree is free to grow. For example, if the brush is 0.8m tall, the tree must be at least 1.5 x 0.8m = 1.2m tall to be considered free to grow (Figure 2). Table2 shows the minimum heights for crop trees to be declared free to grow when competing species with different heights are present.

Trees greater than 2.5m tall do not need to be evaluated for brush competition. Trees of this size are already well established in the stand and will not be significantly influenced by competition from brush species. Also, as long as the brush species is less than 1.7m in height, trees this size would be more than 1.5 times the size of the brush. Few of the brush species listed as competition in table 1 will exceed a height of 1.7m.

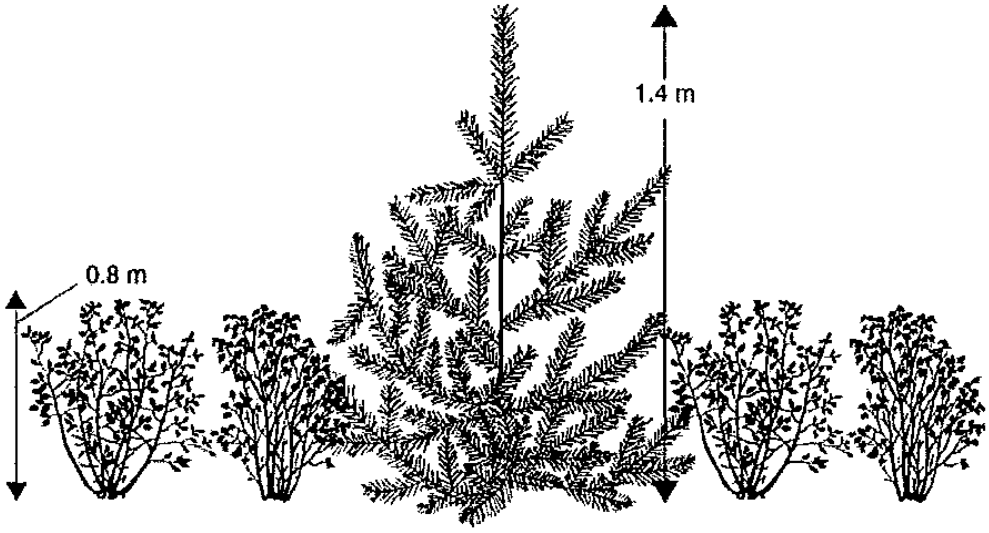

Figure 2: The free to grow tree is more than 1.5 times the height of the brush competition.

Table 2: Threshold height values for brush and tree competition (rounded up to the nearest 10cm). Brush and non-crop trees shorter than the heights listed are not considered competitors for determining free to grow status.

Height of Crop Tree (m)	Threshold Height of Competition	
	Brush (m)	Non-Crop Trees (m)
0.5	0.3	0.3
0.6	0.4	0.3
0.7	0.5	0.4
0.8	0.5	0.4
0.9	0.6	0.5
1.0	0.7	0.5
1.1	0.7	0.6
1.2	0.8	0.6
1.3	0.9	0.7
1.4	0.9	0.7
1.5	1.0	0.8
1.6	1.1	0.8
1.7	1.1	0.9
1.8	1.2	0.9
1.9	1.3	1.0
2.0	1.3	1.0
2.1	1.4	1.1
2.2	1.5	1.1
2.3	1.5	1.2
2.4	1.6	1.2
2.5	1.7	1.3

To quickly determine if the crop tree is free to grow from brush competition while in the field, measure the height of the brush stem and divide by 2 (round up the result to the nearest 10cm). Add this result (half the height of the brush stem) to the measured height of the brush stem. If this total is less than the height of the crop tree, then the crop tree is free to grow.

> **-e.g.** If a brush stem is 1.0m high, the crop tree must be at least 1.0 / 2 + 1.0 = 1.5m tall to be considered free to grow.

If the 'stocked' tree is less than 2.5m high and is not 1.5 times the brush height, the tree can still be declared free to grow if at least two quadrants within a1.2m radius of the tree are completely free of all brush and tree competition (Figure 3). When evaluating a plot for competition, there is no pre-determined direction for quadrant layout. They may be aligned in whichever way is most beneficial, and should be aligned so as to maximize the number of free to grow trees in a plot. For example, if quadrants can be aligned so competition is confined to one or two quadrants, allowing a 'stocked' tree to be declared free to grow, that is how the plot should be evaluated.

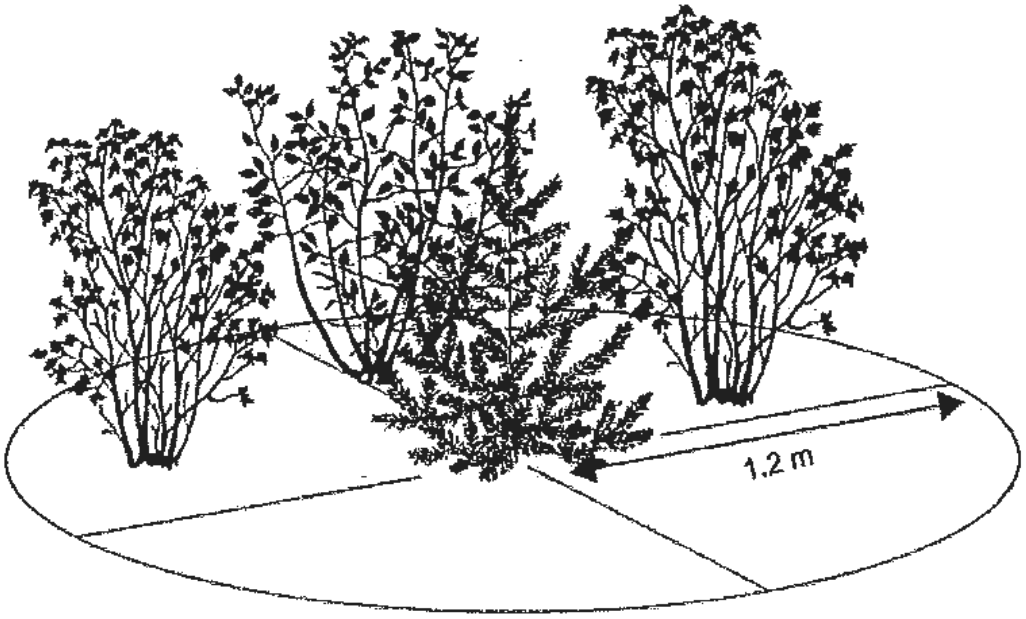

Figure 3: Although the tree is less than 1.5 times the brush height, the tree is free to grow since two quadrants are free of all competition exceeding the height criteria.

Tree Competition

Non-crop tree species considered to be competition for crop trees at this stage of stand development are found in Table 2. The criteria for determining if a 'stocked' tree is free to grow from non-crop tree competition are similar to the criteria used for brush competition. If a 'stocked' tree is not located underneath a closed canopy or overtopped

(i.e. a competitor's branch does not extend over the terminal of a 'stocked' tree) and competing tree stems are less than one-half the height of the 'stocked' tree then the 'stocked' tree is free to grow (Figure 4).

If the crop tree has growth rates equal to or faster than the competitor tree species (e.g. aspen or spruce crop trees with balsam fir competitors), it can be declared free to grow if the competing tree stems are less than or equal to the height of the 'stocked' trees, and all competition occurs in a maximum of two quadrants (Figure 5).

Figure 4: The free to grow tree is more than twice the height of the tree competition.

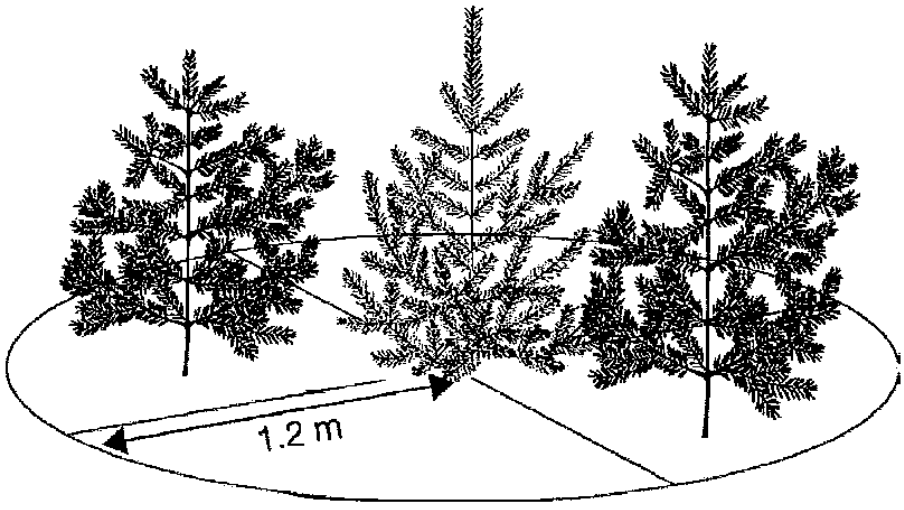

Figure 5: Crop trees with faster or similar growth rates than tree competitors are free to grow if the competing stems are less than or equal to the height of the 'stocked' tree and occur in a maximum of 2 quadrants.

When there are competing tree stems within a plot which are greater than one half the height of the 'stocked' tree, align the quadrants so the competition is confined to as few quadrants as possible. If all competition can be confined to only one quadrant the 'stocked' tree may still be declared free to grow (Figure 6).

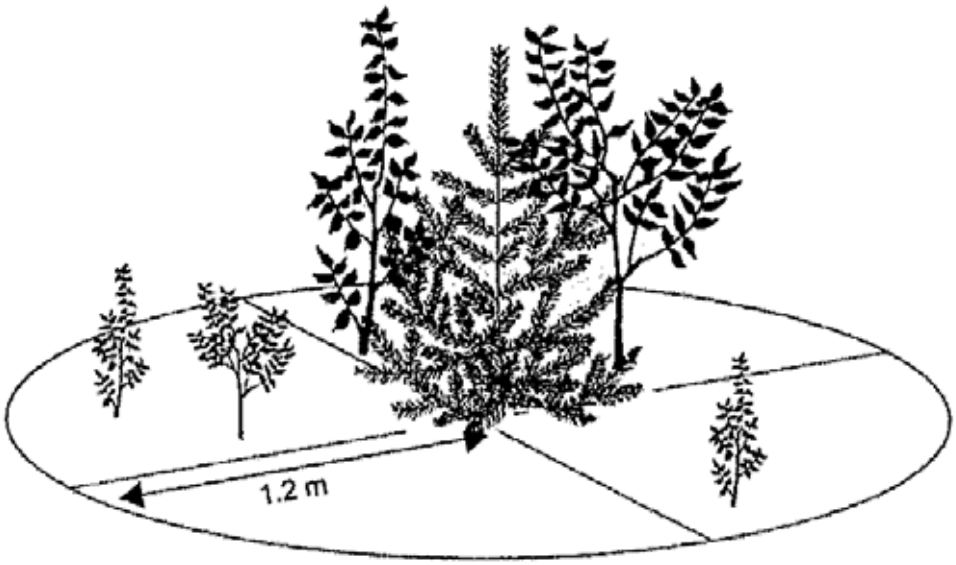

Figure 6: Although the tree competition is greater than one half the crop tree height, the crop tree is free to grow since the competition is confined to only one quadrant surrounding the tree.

Data Recording

The total number of trees over 30cm in height are recorded on the Regular Free to Grow Tally sheet by species and height class (Appendix 2).

In the "Number of Stocked Stems" column of the Regular Free to Grow tally sheet (Appendix 2), record the number of dominant trees of a crop species which have an inter-tree distance of 2m. As the trees found in these columns will be evaluated for free to grow status, the number in these columns may not be lower than the number found in the "Number of FG Stems" column.

In the competing species column of the tally sheet, record the average height and percent cover of each species of interest.

In the comments section, record forest health (insect and disease concerns). Record the plot as a VOID when no trees over 30cm tall are found in the plot. When a VOID is recorded, estimate the size of the opening by recording the approximate number of 16m² plots that would fit in the opening (e.g.: VOID – 2 plots). If the plot is recorded as a void, the number of stocked and free to grow trees is recorded as zero for use in calculations.

The mean canopy height of the plot should also be estimated and recorded. The height class tally gives an indication of the vertical stratification of the area; however, it only

gives a range of heights. Having an average canopy height will provide a more accurate representation of the stand.

Determining Regeneration Status

The regeneration status of a stratum is determined as either Satisfactorily Regenerated (SR) or Not Satisfactorily Regenerated (NSR). This status is determined by comparing survey results with minimum standard from the silvicultural ground rule associated with the stratum. Determining whether a plot is satisfactorily regenerated (SR) or not satisfactorily regenerated (NSR) is a function of plot size and the required minimum stocking for the block.

The proportion of a hectare the plot composes determines the stocking factor of the plot.

1ha= 10,000m²
10,000 m²/ 16 m² = 625 meaning a 16 m² plot composes 1/625 of a hectare.

The minimum stocking for each treatment (extensive, basic and intensive) as found in the SGRs determine the minimum number of free to grow trees to be found in each plot in order to meet stocking standards.

For plots 16m² in size, the minimum number of trees per plot required for the plot to be declared SR will depend on whether the stratum underwent extensive, basic or intensive treatments. The minimum number of trees per plot required to meet stocking requirements can be found by dividing the minimum stocking for each treatment by the stocking factor of 625 (Table 3)

.

Table 3: This table illustrates the minimum average number of free to grow trees per plot required to meet the stocking standards of each silviculture intensity treatment.

Treatment	Minimum Stocking Requirement (sph)	Minimum Average FG Trees per Plot
Extensive	1,750	2.8
Basic	1,850	3.0
Intensive	2,000	3.2

Assuming a plot density of one plot per hectare, the minimum number of stocked trees required in a stratum in order to meet stocking standards can be found by multiplying the minimum average number of free to grow trees per plot by the stratum area.

For Example for a 30 hectare stratum, the following are the minimum numbers of 'stocked' trees required for the stratum to meet stocking requirements.

Extensive 30 x 2.8 = 70 Free Growing trees
Basic 30 x 3.0 = 90 Free Growing trees
Intensive 30 x 3.2 = 96 Free Growing trees

Determining Stocking

The percent stocking of a stratum can be determined using survey results and the following formula.

Stocking Formula:

$$\frac{\text{Total \# of "stocked" trees}}{\text{4 x plots (ha)}} = \text{Stocking \%}$$

For example, if 84 "stocked" trees were recorded in a 30ha stratum which had 30 plots sampled, the stocking % would be as follows.

$$\frac{84}{4 \times 30} = 0.7 = 70\% \text{ stocked}$$

In order for a plot to be measured it must be located on a site that is capable of supporting a tree. Areas that are flooded, located on bedrock or occur within an unmapped residual stand will not count towards the "total" number of plots. However, areas that are temporarily not capable of supporting trees, i.e. slash piles, operational roads, landings that do not occur on areas "permanently" incapable of supporting trees will be included in the total number of plots.

Survey Summary

After the survey is completed, a Free to Grow Summary sheet should be completed based on survey results (Appendix 4).

This document includes a summary of the total number of trees tallied by species and height class, as well as the number of free to grow stems of each species, which is then used to determine the current species composition and regeneration status of the stratum.

Species composition should be determined using information from height classes 2 and 3. Selecting these trees will provide an accurate description of the current stand composition, as these trees are currently dominant in the stand. It will also provide an indication of what the stand will look like in the future, as trees currently dominant in the stratum are most likely to contribute to the canopy in the future. Trees in height class one will likely survive, however, most trees in this height class will be out competed by the larger trees before canopy closure.

Based on the survey summary, it should be decided if the stratum is a Regeneration Success and/or a Silvicultural success. A stratum is considered a regeneration success when it meets minimum stocking requirements as found in its assigned SGR. A stratum is declared a silvicultural success when it meets the desired species composition or forest unit based on the assigned SGR.

Well Spaced Free to Grow Survey

This survey methodology is designed for strata which have undergone Intensive Silviculture Intensity treatments, where density regulation is desired. It is used to measure the species composition, average height of desired species, stocking, stand density, and assess freedom from competition.

This survey will be completed with a systematic plot allocation method using 16m² plots with a density of one plot per hectare. Trees selected as well spaced and assessed for free to grow status will be chosen based on the MNR criteria.

This survey methodology is an adaptation from the Well-spaced Free-growing Regeneration Assessment Procedure for Ontario (White et al. 2005). The full reference is as follows: White, R.G., C.L. Bowling, W.J. Parton and W.D. Towill. 2005. Well-spaced free-growing regeneration assessment procedure for Ontario. Ont. Min. Natur. Resour. Northwest Sci. and Info., NWSI Tech. Manual TM-007. 38pp + appendices.

Plot Allocation

Surveys will be completed using plots sizes of 16m², with a plot radius of 2.26m. This plot size accounts for more within plot variation, which is important in heterogeneous blocks, and blocks where stocking is borderline. A plot density of one plot per hectare should provide sufficient coverage of an area, and account for any between plot variations.

After the minimum plot number is established, plot locations should be determined systematically and mapped, with the grid size and pattern depending on the number of plots required. Plot spacing and line spacing should generally be kept similar in order to approximate a square layout pattern. The distance between survey lines and between the sample plots along the survey lines can be calculated using the following formula.

$$\text{Plot spacing (m) Required} \times \text{Line spacing (m)} = \frac{\text{Strata area (ha)} \times 10{,}000}{\text{min. number of plots}}$$

Once the desired survey line spacing is selected, calculate the required plot spacing (for the minimum number of plots) by substituting “line spacing”, “strata area (ha)”, and “required minimum number of plots” in the above formula and solving for “plot spacing”.

Before going out into the field, a Survey Header Sheet (Appendix 1) should be filled out for each block. This document will include background information such as year of harvest, regeneration and vegetation management methods, as well as stocking standards for the block.

Mapping

The minimum number of plots required should be established on a map prior to going out to the field. Survey line locations should be tied into recognizable features on the ground, and distance and bearing information should also be included to facilitate mapping and navigation.

Data Collection

Plot Location

Follow the mapped survey lines and establish plots at predetermined locations. The plot should be flagged and GPS'ed to aid in locating the plot in the future if necessary. If a plot lands in an area where a feature such as permanent water, or exposed bedrock composes over half of the plot, or if it lands in a bypass or un-harvested area, the plot should be moved and these features noted. Plots should be moved to a location halfway between two plots, as near to the initial plot location as possible.

If a plot lands on a site where conditions resulting from forestry activities exist, such as equipment trails, puddle ruts, or slash piles, assess the plot normally and provide comments regarding site conditions on the tally sheet.

Tree Tally

Tally all trees over 30cm tall by species and height class, both crop tree (desired and acceptable species) and non-crop tree species should be included. Trees below 30cm in height are not included in this tally as they generally do not contribute to the canopy of the future stand.

Well Spaced Evaluation

The well spaced criteria are applied consecutively to crop trees (target and acceptable species) within the plot. A maximum of four well spaced crop trees can be tallied for each plot using this evaluation procedure. The flowchart included in Appendix 2 lists all of the criteria for a well spaced tree to be declared free to grow. The assessment aid is designed for use in the field and aims to aid surveyors in applying free to grow criteria to well spaced trees.

Procedure

Select and mark a prominent crop tree within the 16m² plot as the starting tree. A prominent tree is selected as a starting and ending point to avoid double counting trees. Prominent trees will be evaluated for well spaced status based on health, and crop-tree competition.

Tree Health

Careful attention must be paid to tree health and vigor when selecting well spaced trees. Trees that are suffering temporary defects (e.g. insect attack) but are otherwise healthy may be selected as well spaced trees. Trees with extensive chlorosis, trees that appear to be infected with disease, and trees that appear to be dying should not be selected as well spaced as it is unlikely they will survive to maturity. Trees displaying poor stem form resulting from poor planting technique or smothering from grass or snow press should also not be selected as a well spaced tree as trees with poor form are commercially undesirable.

Crop Tree Competition

An inter-tree distance of 1.8m is required in order for trees to be declared well spaced. If the tree under consideration has no other crop trees closer than 1.8m either inside or outside the plot, it is counted as a well spaced tree (i.e. all adjacent crop trees are at least 1.8m away)

If there is a crop tree (or trees) less than 1.2m away from the tree being considered, choose the most vigorous tree and continue well- spaced evaluation. With trees growing this close together, it is likely that one tree will out compete the others to become part of the future canopy, with the tree that is currently dominant having the best chance of out competing the smaller crop trees. The other trees within the 1.2m radius may be ignored entirely when continuing to assess the number of well spaced trees in the plot.

If there is another crop tree between 1.2m and 1.8m away from the crop tree being considered, tally the tree as well spaced if two quadrants within a 1.8m radius around the selected tree contain no crop trees more than half the height of the selected tree (Figure1). If a crop tree is less than half the height of the potential well spaced tree, it is not considered competition.

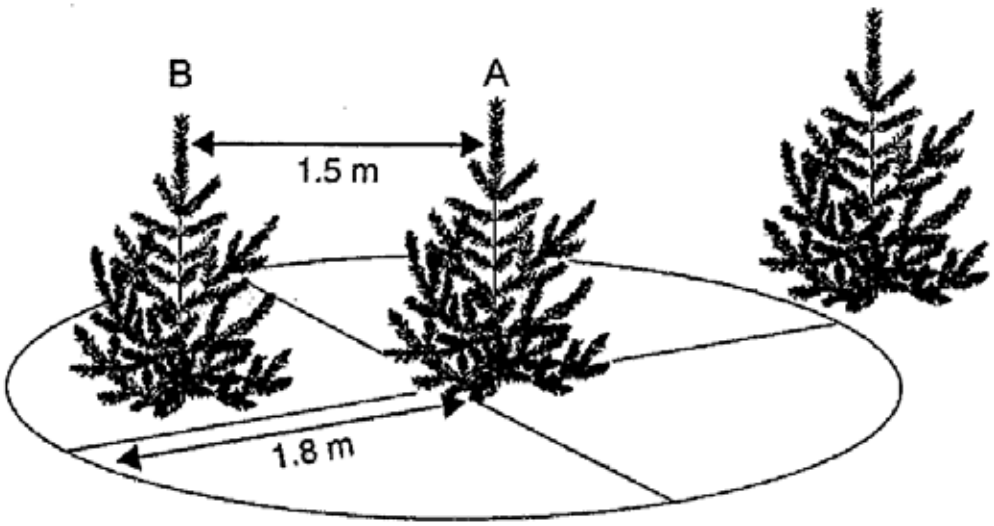

Figure 1: Tree A is well spaced even though tree B is less than 1.8m away because tree A still has at least two quadrants free of other crop trees.

Proceed systematically around the plot and select the next crop tree for evaluation. Record the total number of well spaced trees by species on the Well Spaced Free to Grow Tally Sheet (Appendix 2). A maximum of four well spaced trees may be tallied in each plot, in attempts to ensure each tree has adequate growing space.

Free to grow Evaluation

Well spaced trees will be evaluated for free to grow status based on tree health, form, and non-crop tree competition. A tree must be well spaced in order to be evaluated for free to grow status. The flowchart included in Appendix 4 lists all of the criteria for a well spaced tree to be declared free to grow. The assessment aid is designed for use in the field and aims to aid surveyors in correctly applying free to grow criteria to well spaced trees.

The free to grow assessment is carried out within a 1.2m radius around each well spaced tree. Competitor stems must be rooted within the cylinder or have a main stem growing vertically within the cylinder to be considered as competition (e.g. coppice birch stems). Competitor branches encroaching into the cylinder from outside are not assessed as competitors unless the well spaced tree is overtopped.

Any well spaced tree found under a closed canopy or being overtopped (i.e. a competitor's branch extends over the terminal of the well spaced tree) is not free to grow (Figure 2). Overtopping identifies potential for leader whipping, or growth loss due to excessive shading. This category does not apply to overstory trees left intentionally as part of the shelterwood silvicultural system or other retention guidelines.

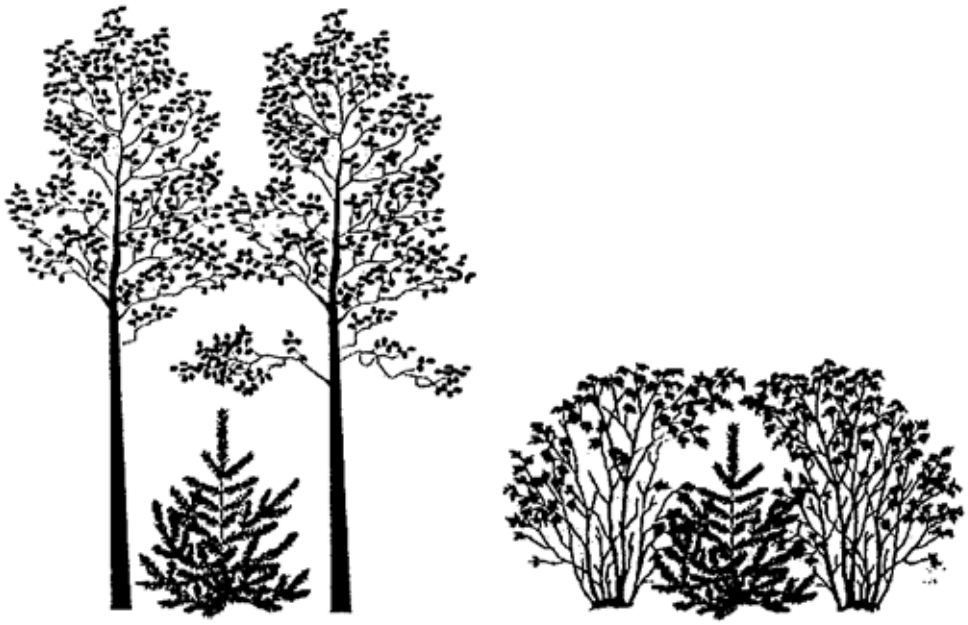

Figure 2: A well spaced tree underneath a closed canopy or overtopped cannot be considered free to grow

The competition relevant to the free to grow criteria is divided into brush and non-crop tree competition. At this stage of stand development, herbs, grasses, sedges, fireweed (*Epilobium angustifolium*), low-growing ericaceous shrubs [e.g. blueberries (*Vaccinium* spp.), Labrador tea (*Ledum Groenlandicum*), Laurels (*Kalmia* spp.), and bracken fern (*Pteridium aquilinum*)] are not considered competitors that would have an impact on the success of the selected crop trees. The species of brush and non-crop trees which are considered competition for crop trees at this stage of stand development are found below (Table 1). Other species may be added to this table based on local conditions and knowledge.

Table 1: This table lists the species included as brush and tree competition for this free to grow assessment.

Shrub Competition	Tree Competition
Alders (*Alnus* spp.)	Poplar (*Populus* spp.)
Beaked Hazel (*Corylus cornuta*)	Birch (*Betula* spp.)
Cherries (*Prunus* spp.)	Red maple (*Acer rubrum*)
Dogwoods (*Cornus* spp.)	Sugar maple (*Acer saccharum*)
Elderberries (*Sambucus* spp.)	Ash (*Fraxinus* spp.)
Mountain Ash (*Sorbus* spp.)	Jack pine (*Pinus banksiana*)
Mountain Maple (*Acer spicatum*)	Larch (*Larix laricina*)
Raspberry/ Thimbleberry (*Rubus* spp.)	Eastern white cedar (*Thuja occidentalis*)
Serviceberry (*Amilanchier* spp.)	Balsam fir (*Abies blasamea*)
Striped maple (*Acer pensylvanicum*)	
Squashberry/ Highbush cranberry (*Viburnum* spp.)	
Willows (*Salix* spp.)	

Brush Competition

If the well spaced tree is greater than or equal to 1.5 times the brush height, the tree is free to grow. For example, if the brush is 0.8m tall, the tree must be at least 1.5 x 0.8 = 1.2m tall to be considered free to grow (Figure 3).

Trees greater than 2.5m tall do not need to be evaluated for brush competition. Trees of this size are already well established in the stand and will not be greatly influenced by competition from brush species. Also, as long as the brush species is less than 1.7m in height, trees this size would be more than 1.5 times the size of the brush. Few of the brush species listed as competition in Table 1 will exceed a height of 1.7m. Table 2 shows the minimum heights for crop trees to be declared free to grow when competing species are present at different heights. For each crop-tree height listed, any brush or non-crop tree species below the heights listed are not considered competition. For example, for a 50cm crop tree, brush and non-crop tree species shorter than 30cms are not considered to be competition for the crop tree.

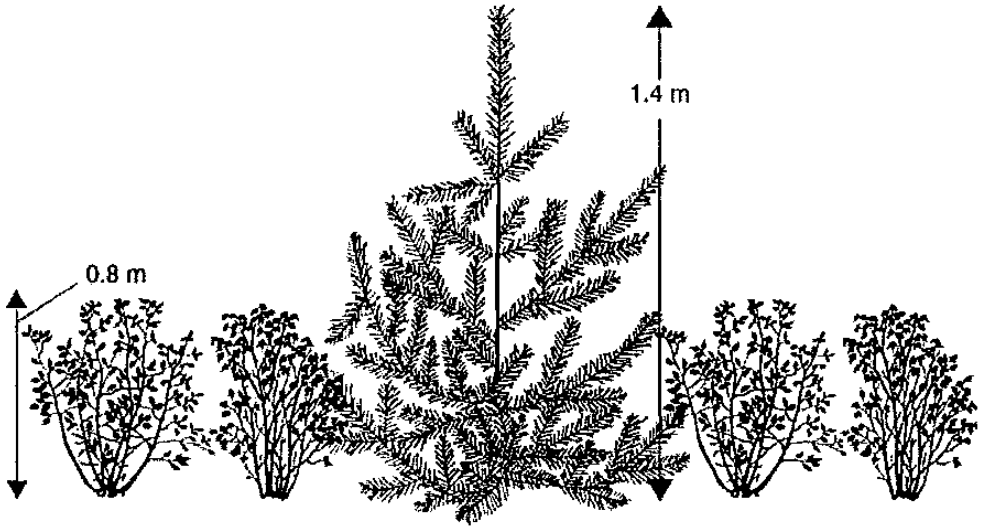

Figure 3: The free to grow tree is more than 1.5 times the height of the brush competition.

Table 2: Threshold height values for brush and tree competition (rounded up to the nearest 10cm). Brush and non-crop trees shorter than the heights listed are not considered competitors for determining free to grow status.

Height of Crop Tree (m)	Threshold Height of Competition	
	Brush (m)	Non-Crop Trees (m)
0.5	0.3	0.3
0.6	0.4	0.3
0.7	0.5	0.4
0.8	0.5	0.4
0.9	0.6	0.5
1.0	0.7	0.5
1.1	0.7	0.6
1.2	0.8	0.6
1.3	0.9	0.7
1.4	0.9	0.7
1.5	1.0	0.8
1.6	1.1	0.8
1.7	1.1	0.9
1.8	1.2	0.9
1.9	1.3	1.0
2.0	1.3	1.0
2.1	1.4	1.1
2.2	1.5	1.1
2.3	1.5	1.2
2.4	1.6	1.2
2.5	1.7	1.3

To quickly determine if a crop tree is free to grow from brush competition, measure the height of the brush stem and divide it by 2 (round up the result to the nearest 10cm). Add this result (half the height of the brush stem) to the measured height of the brush stem. If this total is less than the height of the crop tree, then the crop tree is free to grow.

> **- e.g.** If a brush stem is 1.0m high, the well spaced crop tree must be at least 1.0 / 2 + 1.0 = 1.5m tall to be considered free to grow.

If the well spaced tree is less than 2.5m high and is not 1.5 times the brush height, the tree can still be declared free to grow if at least two quadrants within a1.2m radius of the tree are completely free of all brush and tree competition (Figure 4). When evaluating a plot for competition, there is no pre-determined direction for the quadrants. They may be aligned in whichever way is most beneficial, which would be to maximize the number of free to grow trees in a plot. For example, if quadrants can be aligned so competition is confined to one or two quadrants, allowing a well spaced tree to be declared free to grow, that is how the plot should be evaluated.

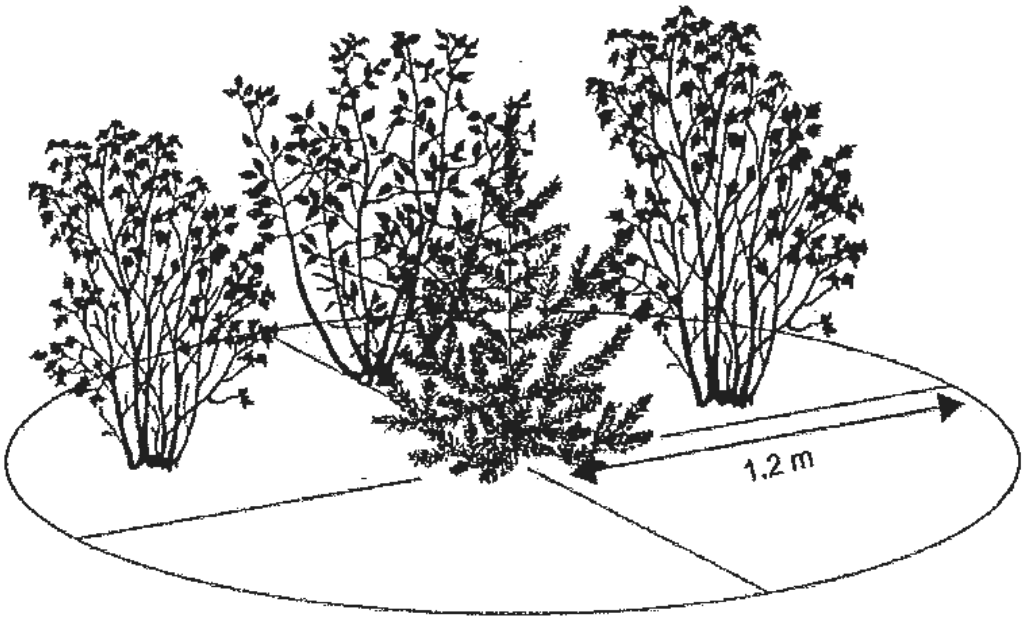

Figure 4: Although the tree is less than 1.5 times the brush height, the tree is free to grow since two quadrants are free of all competition exceeding the height criteria.

Tree Competition

Non-crop tree species considered to be competition at this stage of stand development are found in table 2. The criteria for determining if a well spaced tree is free to grow from non-crop tree competition are similar to the criteria used for brush competition. If a well spaced tree is not located underneath a closed canopy or overtopped (i.e. a competitor's branch does not extend over the terminal of a well spaced tree) and competing tree stems are less than one-half the height of the well spaced tree then the well spaced tree is free to grow (Figure 5).

If the crop tree has growth rates equal to or faster than the competitor tree species (e.g. aspen or spruce crop trees with balsam fir competitors), it can be declared free to grow if the competing tree stems are less than or equal to the height of the well spaced trees, and all competition occurs in a maximum of two quadrants (Figure 6).

Figure 5: The well spaced tree is more than twice the height of the tree competition and can be declared free to grow.

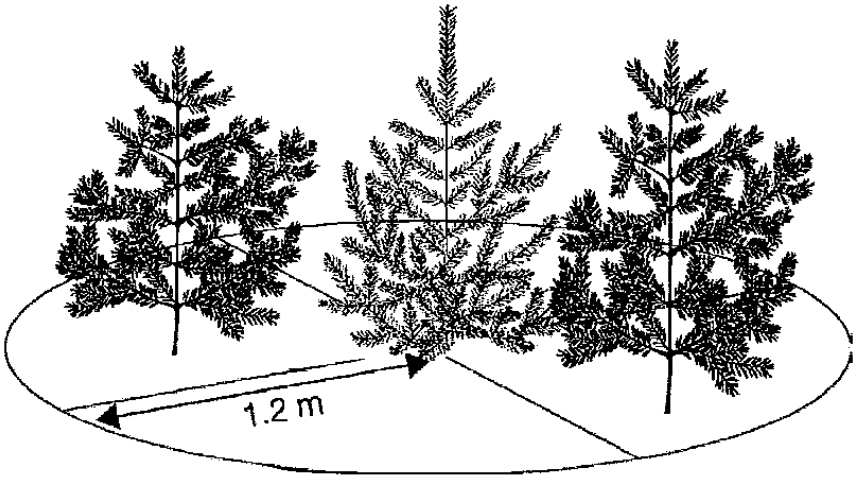

Figure 6: Crop trees with faster or similar growth rates than tree competitors are free to grow if the competing stems are less than or equal to the height of the well spaced tree and occur in a maximum of 2 quadrants.

When there are competing tree stems within a plot which are greater than one half the height of the well spaced tree, align the quadrants so the competition is confined to as few quadrants as possible. If all competition can be confined to only one quadrant the well spaced tree may be declared free to grow (Figure 7).

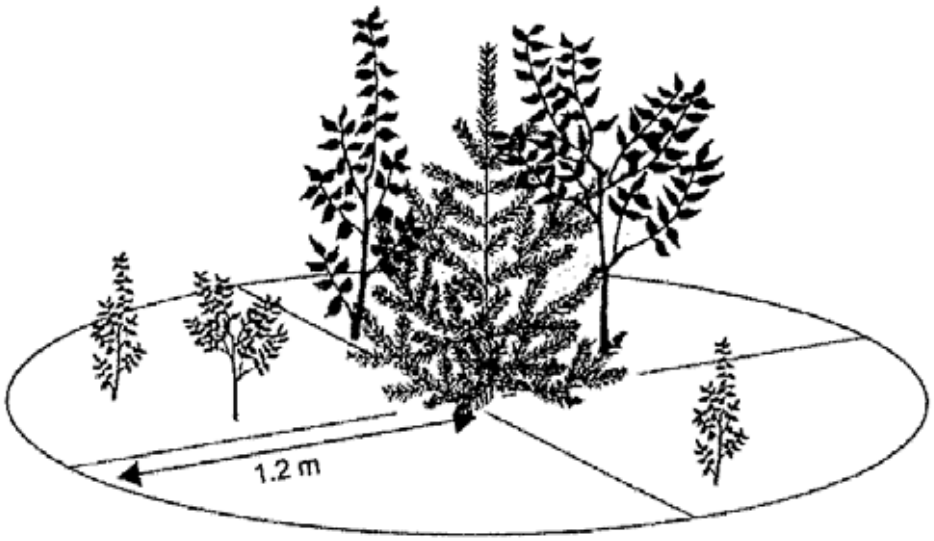

Figure 7: Although the crop tree is less than twice the height of the tree competition (i.e. the tree competition is greater than one half the tree height), the crop tree is free to grow since the competition is confined to only one quadrant surrounding the tree.

Data Recording

The total number of trees over 30cm in height are recorded on the Regular Free to Grow Tally sheet by species and height class Appendix 3).

In the "Number of WS Stems" column of the Well Spaced Free to Grow tally sheet (Appendix 3), record the number of stems which meet MNR well spaced criteria, up to a maximum of four trees per plot. As the trees found in these columns will be evaluated for free to grow status, the number in these columns may not be lower than the number found in the "Number of FG Stems" column.

In the competing species column of the tally sheet, record the average height and percent cover of each species of interest.

In the comments section, record forest health (insect and disease concerns). Record the plot as a VOID when no trees over 30cm tall are found in the plot. When a VOID is recorded, estimate the size of the opening by recording the approximate number of 16m² plots that would fit in the opening (e.g.: VOID – 2 plots). If the plot is recorded as a void, the number of well spaced and free to grow trees is recorded as zero for use in calculations.

The mean canopy height of the plot should also be estimated and recorded. The height class tally gives an indication of the vertical stratification of the area; however, it only gives a range of heights. Having an average canopy height will provide a more accurate representation of the stand.

Determining Regeneration Status

The regeneration status of a stratum is determined as either Satisfactorily Regenerated (SR) or Not Satisfactorily Regenerated (NSR). This status is determined by comparing survey results with minimum standard from the silvicultural ground rule associated with the stratum. Determining whether a plot is satisfactorily regenerated (SR) or not satisfactorily regenerated (NSR) is a function of plot size and the required minimum stocking for the block.

The proportion of a hectare the plot composes determines the stocking factor of the plot.

1ha= 10,000m²
10,000 m²/ 16 m² = 625 meaning a 16 m² plot composes 1/625 of a hectare.

The minimum stocking for each treatment (extensive, basic and intensive) as found in the SGRs determine the minimum number of free to grow trees to be found in each plot in order to meet stocking standards.

For plots 16m² in size, the minimum number of trees per plot required for the plot to be declared SR will depend on whether the stratum underwent extensive, basic or intensive treatments. The minimum number of trees per plot required to meet stocking requirements can be found by dividing the minimum stocking for each treatment by the stocking factor of 625 (Table 3).

Table 3: This table shoes the minimum average number of free to grow trees per plot required to meet the stocking standards of each silviculture intensity treatment.

Treatment	Minimum Stocking Requirement (sph)	Minimum Average FG Trees per Plot
Extensive	1,750	2.8
Basic	1,850	3.0
Intensive	2,000	3.2

Assuming a plot density of one plot per hectare, the minimum number of well spaced trees required in a stratum in order to meet stocking standards can be determined by multiplying the minimum average number of free to grow trees per plot by the stratum area.

For Example for a 30 hectare stratum, the following are the minimum numbers of trees required for the stratum to meet stocking requirements.

Extensive 30 x 2.8 = 84 trees
Basic 30 x 3.0 = 90 trees
Intensive 30 x 3.2 = 96 trees

Determining Stocking

The percent stocking of a stratum can be determined using survey results and the following formula.

Stocking Formula:

$$\frac{\text{Total \# of well spaced trees}}{\text{4 x plots (ha)}} = \text{Stocking \%}$$

For example, if 84 well spaced trees were recorded in a 30ha stratum which had 30 plots sampled, the stocking % would be as follows.

$$\frac{84}{4 \times 30} = 0.7 = 70\% \text{ stocked}$$

In order for a plot to be measured it must be located on a site that is capable of supporting a tree. Areas that are flooded, located on bedrock or occur within an unmapped residual stand will not count towards the "total" number of plots. However, areas that are temporarily not capable of supporting trees, i.e. slash piles, operational roads, landings that do not occur on areas "permanently" incapable of supporting trees will be included in the total number of plots.

Survey Summary

After the survey is completed, a Free to Grow Summary sheet should be filled out based on survey results (Appendix 5). This document includes a summary of the total number of trees tallied by species and height class, as well as the number of free to grow stems of each species, which is then used to determine the current species composition and regeneration status of the stratum.

Species composition should be determined using information from height classes 2 and 3. Selecting these trees will provide an accurate description of the current stand composition, as these trees are currently dominant in the stand. It will also provide an indication of what the stand will look like in the future, as trees currently dominant in the stratum are most likely to contribute to the canopy in the future. Trees in height class one will likely survive, however, most trees in this height class will be out competed by the larger trees before canopy closure.

Based on the survey summary, it should be decided if the stratum is a Regeneration Success and/or a Silvicultural success. A stratum is considered a regeneration success when it meets minimum stocking requirements as found in its assigned SGR. A stratum is declared a silvicultural success when it meets the desired species composition or forest unit based on the assigned SGR.

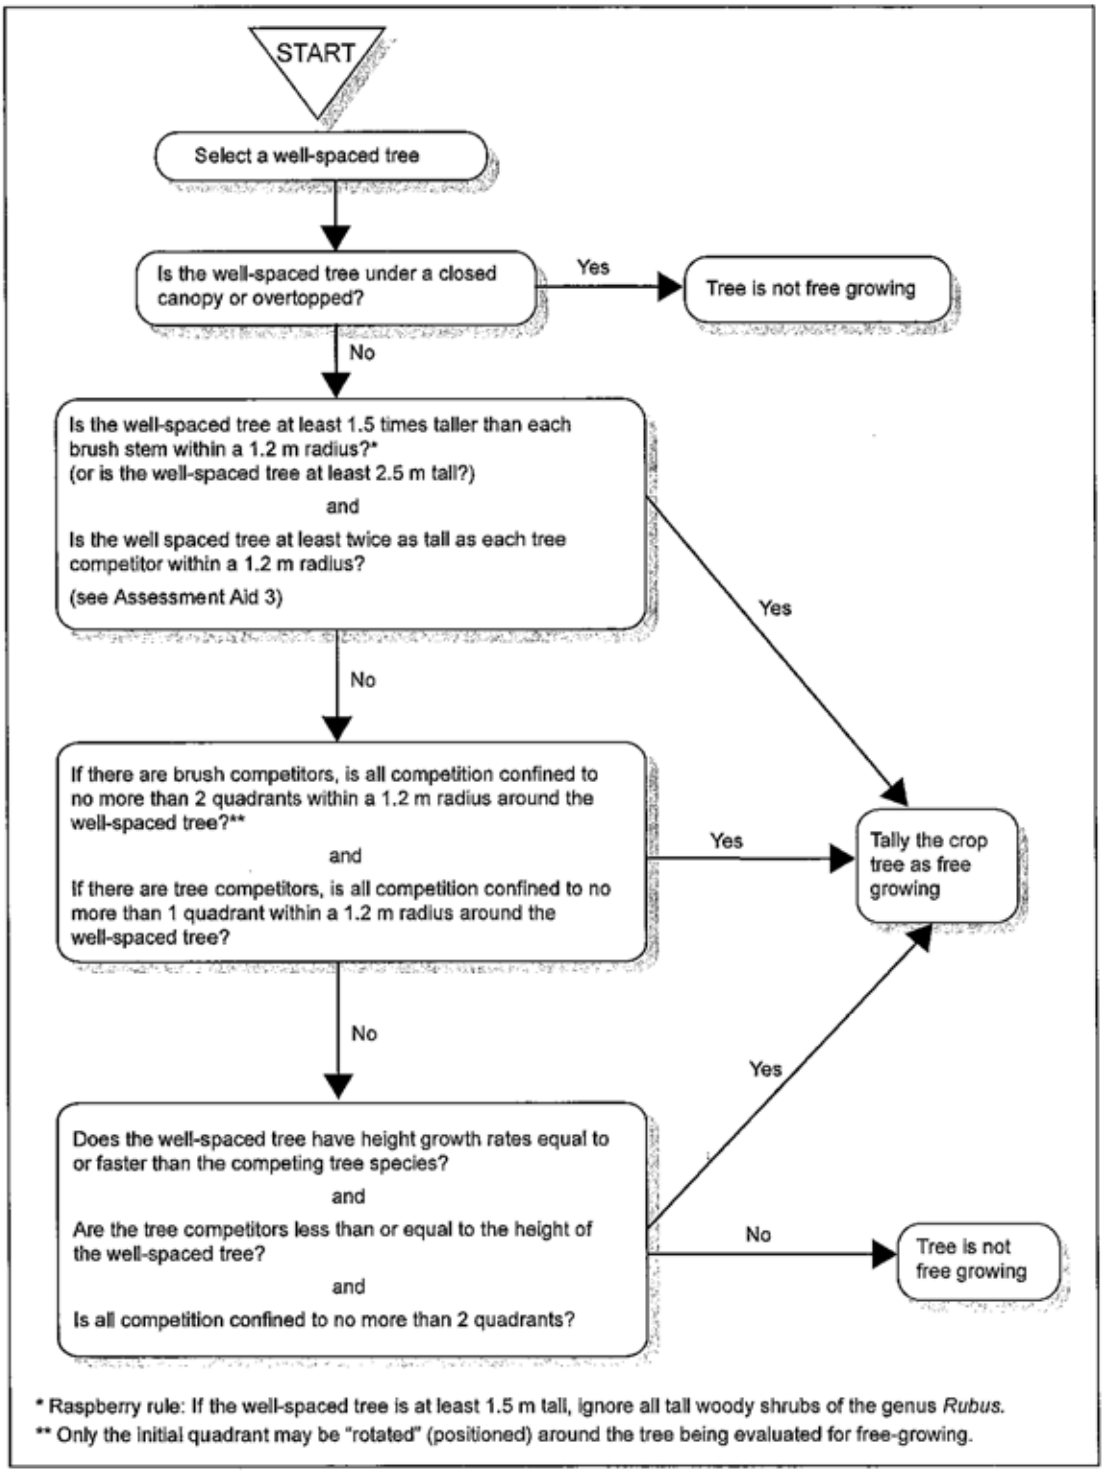
Stocking Formula: total # of well spaced trees/ 4x # plots(ha) = stocking %.

Appendix 4

Assessment Aid for Determining if a Well Spaced Tree is Free to Grow



START
Select a well-spaced tree
Is the well-spaced tree under a closed canopy or overtopped?
Yes
Tree is not free growing
No
Is the well-spaced tree at least 1.5 times taller than each brush stem within a 1.2 m radius?*
(or is the well-spaced tree at least 2.5 m tall?)
and
Is the well spaced tree at least twice as tall as each tree competitor within a 1.2 m radius?
(see Assessment Aid 3)
Yes
No
If there are brush competitors, is all competition confined to no more than 2 quadrants within a 1.2 m radius around the well-spaced tree?**
and
If there are tree competitors, is all competition confined to no more than 1 quadrant within a 1.2 m radius around the well-spaced tree?
Yes
Tally the crop tree as free growing
No
Yes
Does the well-spaced tree have height growth rates equal to or faster than the competing tree species?
and
Are the tree competitors less than or equal to the height of the well-spaced tree?
and
Is all competition confined to no more than 2 quadrants?
No
Tree is not free growing
* Raspberry rule: If the well-spaced tree is at least 1.5 m tall, ignore all tall woody shrubs of the genus Rubus.
** Only the initial quadrant may be "rotated" (positioned) around the tree being evaluated for free-growing.

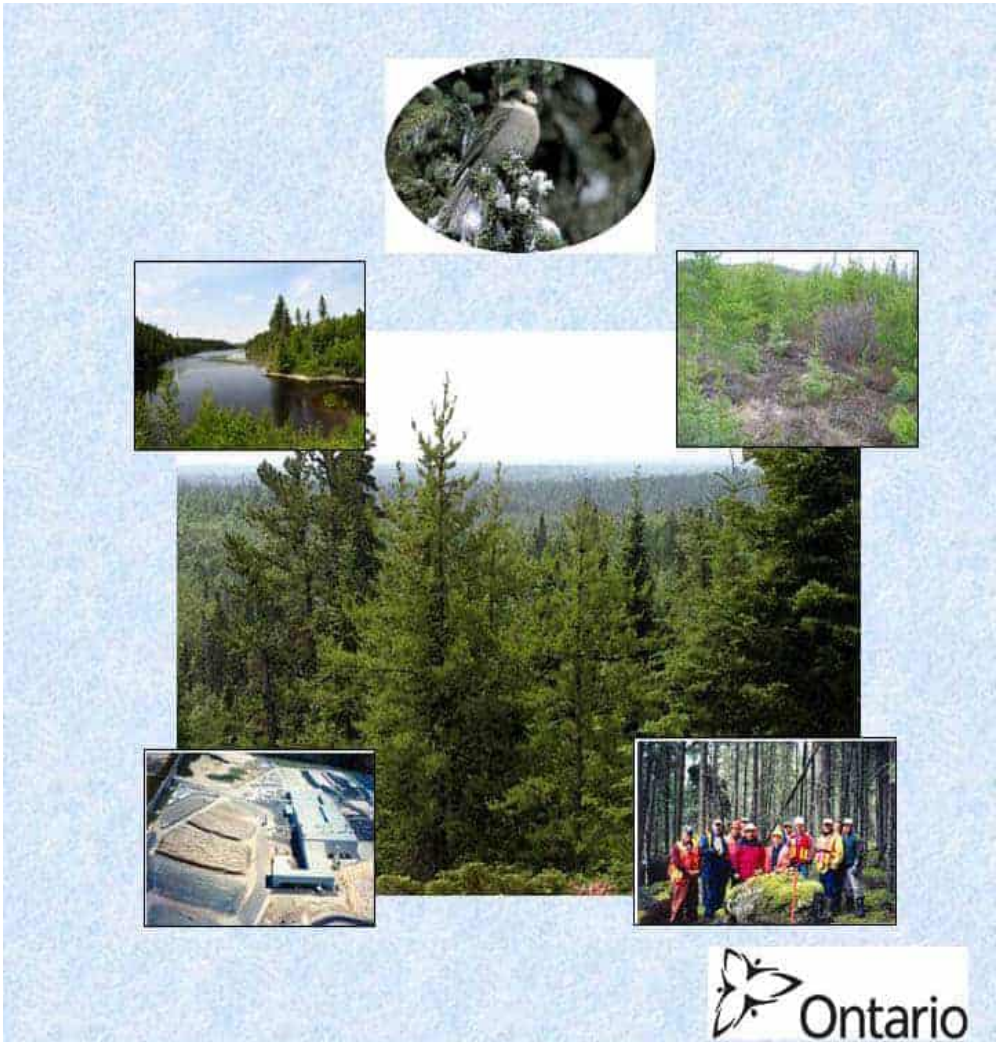
Supplementary Documentation G

2012-2022 Whiskey Jack Forest Management Plan

Roads Planning Documentation



ROADS SUPPLEMENTARY DOCUMENTATION FORM

ROAD NAME: Yellow Girl Bay Road (New Primary Road)

The Yellow Girl Bay Road is a new primary road, approximately 38 kilometers south of highway 17 junction with highway 71. This new road has a total road length of 8.2 km of which the first 3.2 km is reconstruction and the remaining length is new construction. This road provides access to a section of the southern part of the unit for forestry activities in the 2012-2014 as well as future plans. The road commences westerly off of the highway and proceeds near the Yellow Girl Bay Reserve 32B (Naotkamegwanning). (Basemaps 41548, 42548)

1. Alternative Corridors

In identifying a reasonable range of alternative corridors for analysis, the following was considered:

(a) Physical conditions, specific non-timber values and significant engineering or safety factors that may affect planning of the road corridor and the cost of construction of the road,

(b) Any other planning initiatives that deal with access in the area (e.g. Ontario's Crown Land Use Policy Atlas, management statement of conservation interest, park management plans, lake management plans, resource stewardship agreements), and

(c) Issues arising from public consultation regarding this primary road proposal.

Only one route is proposed due to the following:

- Corridor utilizes an existing road bed which will be reconstructed
- Provides for the most direct route in accessing future wood supplies and silviculture activities
- Location of lakes, topography and existing roads
- Provides for strategic access to southern portion of the management unit

2. Environmental Analysis of Alternative Corridors

a) Alternative Corridor (number) and Description: Yellow Girl Bay Road – Alternative 1(See Areas Selected for Operations Maps)

This proposed all weather primary road, approximately 8.15 km in length, commencing off of highway 71 approximately 38 km south of highway 17 and proceeds westerly near the Yellow Girl Bay Reserve 32B.

b) Environmental Analysis

i. Access to Areas Eligible for harvest, renewal and tending operations

Advantages

- Utilizes 3.2 km of existing operational roadbed for reconstruction to primary
- Observed to be the best location to build the road due to access limitations from lakes and waterways.
- Proposed road strategically develops future wood supply areas including a 60 year marten core deferral (Core # 23), as well as subsequent renewal and tending treatments.

Disadvantages

- None

Potential Effects on Non-Timber Values

Advantages

- Enhanced access for other forest users
- Provides for access to unoccupied Naotkamegwanning First Nations land for socioeconomic opportunities.

Disadvantages

- The proposed road requires two water crossings
- The proposed road will increase the amount of other users adjacent to the Reserve 32B.

Providing access to any remote Aboriginal communities which were previously inaccessible by road

- This corridor will not provide access to any remote Aboriginal communities that were not previously accessible by road.

ii) Use Management Strategy

(a) Maintenance provisions:

These roads and each associated right-of-way will receive maintenance, which will be carried out as required to maintain the road for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities). These roads will be maintained to minimize risk to road users and minimize the potential for environmental damage. Routine maintenance operations may include any one or combination of the following: summer grading, ditching, drainage, brush clearing with mechanical or chemical methods (e.g. application of chemical herbicides for vegetation control along road shoulders), gravelling, re-shaping of road bed, dust control measures, signage, snow plowing, sanding/salting and clearing existing right-of-ways including the harvest of merchantable trees as required. Maintenance may also include non-emergency repairs of existing water crossings to clean culverts, remove blockages caused by beavers, and to apply material (e.g. gravel, riprap) to mitigate or enhance long-term erosion protection around water crossings.

For safety/engineering concerns minor road re-alignment and bypass construction may also be required during the implementation of the FMP. This is permitted within the existing right-of-way, subject to the confirmation of values and the application of all applicable AOCs to the proposed work area. If an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied. In cases where new and/or replacement water crossings are required during the implementation of the FMP, the replacement of culverts are permitted subject to the following conditions; the values must be reviewed and updated for each location to ensure up-to-date values are considered, the applicable AOC must be applied to address any value impacted at the location (if an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied), and the planned water crossing replacements are identified and approved (with all applicable conditions on the construction, including preventative and mitigative measures) in the AWS for the year of construction company.

Emergency maintenance is defined as “road maintenance that required immediate attention to restore access and reduce the chance of personal injury, damage to equipment, inconvenience to road users and further road damage” (2009 FMPM). Emergency maintenance will be necessary where public safety and/or environmental damage have occurred unexpectedly. Emergency repairs can proceed immediately without MNR approval provided the emergency works are limited in scope to only what is necessary to address essential public safety concerns and restrict further environmental damage. All emergency actions will be reported to MNR as soon as practical and any further actions (e.g. restoration, reconstruction, abandonment) will be subject to normal planning approvals. Where sediment has been released into a watercourse, the Ministry of the Environment is to be informed.

Where water crossings have been adversely impacted by unplanned events, water crossings may not be restored in a timely manner and remedial work may be limited to only eliminating or reducing safety hazards and/or interim measures to stop environmental damage. Access to areas impacted by unplanned events could be disrupted at any time and there is no obligation on the Crown or the Forest Industry to undertake repair work to restore infrastructure and access. However, all actions must be consistent with the Use Management Strategy for the road/road network. Situations could also arise where it is determined that a damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented.

(b) Monitoring Provisions

While the road/road network is in use for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities), it will be monitored on an ongoing basis for safety or environmental concerns. Bridges used for ‘heavy truck hauls’ inspected at least once a year by a competent person (following the inspection guidelines in Appendix E of the Crown Land Bridge Management Guidelines or by a professional engineer). When the road/road network is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment approach with emphasis on the potential values which could be impacted (i.e. fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of aerial assessments of reforestation (e.g. FTG surveys). In addition, all staff and contractors (harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

c) Access provisions or restrictions which apply to the public and commercial resource users with the rationale for the restrictions:
- none

d) a statement if the intent of the sustainable forest licence is to transfer the responsibility for the road or road network to MNR in the next 20 years, and the operating year or
5-year term in which the transfer is intended to occur:
- There is no intent to transfer at this time.

e) where the sustainable forest licensee has indicated an intent to transfer responsibility, MNR will provide a preliminary indication of the management intent for the road or road network:

- There is no intent to transfer at this time.

f) where the sustainable forest licensee has indicated an intent to transfer responsibility during the five-year term and MNR's management intent is to not maintain the road for public use, the activities required prior to transfer, including potential removal of water crossings will be documented (e.g. decommissioning, signs):

- There is no intent to transfer at this time.

iii) Estimated Cost of Construction and Use Management

- Construction: $30,000 - $35,000 /km; plus two minor AOC WS01 water crossings at around $6,000 /per crossing; plus 20' bridge estimated to cost $20,000.
- Maintenance: $8,000 – $10,000 /km/yr

3. Summary of Public Comments:

- None received to-date.

4. Proposed Corridor:

a) Description: See Alternative 1

b) Rationale: Alternative 1 utilizes a segment of an existing road, develops future harvest and renewal activities, provides access to First Nations lands and is the most economical given the local terrain limitations.

c) Use Management Strategy: See Alternative 1

5. Summary of Public Comments:

None

6. Selected Corridor: See Proposed Corridor (Part 4)

Use Management Strategy:
No change to UMS

Summary of Public Comments:
Refer to Part 3

Use Management Strategy
See Alternative 1

ROADS SUPPLEMENTARY DOCUMENTATION FORM

ROAD NAME: Bug Lake Road

The Bug Lake Road is a primary road, approximately 25 kilometers south of highway 17 junction with highway 71. This new road has a total road length of 10 km of which all is reconstruction. This road provides access to a section of the southern part of the unit for forestry activities in the 2012-2022 FMP as well as future plans. The road commences westerly off of the highway and proceeds along the east shore of Bug Lake. (Basemaps 41548, 41549, 42549)

1. Alternative Corridors

In identifying a reasonable range of alternative corridors for analysis, the following was considered:

(a) Physical conditions, specific non-timber values and significant engineering or safety factors that may affect planning of the road corridor and the cost of construction of the road,

(b) Any other planning initiatives that deal with access in the area (e.g. Ontario's Crown Land Use Policy Atlas, management statement of conservation interest, park management plans, lake management plans, resource stewardship agreements), and

(c) Issues arising from public consultation regarding this primary road proposal.

Only one route is proposed due to the following:

- Corridor utilizes an existing road bed which will be reconstructed
- Provides for the most direct route in accessing future wood supplies and silviculture activities
- Location of lakes, topography and existing roads
- Provides for strategic access to southern portion of the management unit

2. Environmental Analysis of Alternative Corridors

a) Alternative Corridor (number) and Description: Bug Lake Road – Alternative 1(See Areas Selected for Operations Maps)

This proposed all weather primary road, approximately 10 km in length, commencing off of highway 71 approximately 25 km south of highway 17 and proceeds westerly along the east shore of Bug Lake.

b) Environmental Analysis

i. Access to Areas Eligible for harvest, renewal and tending operations

Advantages

- Utilizes 6 km of existing branch roadbed for reconstruction to primary
- Observed to be the best location to build the road due to access limitations from lakes and waterways.
- Proposed road strategically develops future wood supply areas including a 20 year marten core deferral (Core # 23), as well as subsequent renewal and tending treatments.

Disadvantages
- None

Potential Effects on Non-Timber Values

Advantages
- Enhanced access for other forest users

Disadvantages
- The proposed road requires one water crossing
- The proposed road will increase the amount of other users within the area.

Providing access to any remote Aboriginal communities which were previously inaccessible by road
- This corridor will not provide access to any remote Aboriginal communities that were not previously accessible by road.

ii) Use Management Strategy

(a) Maintenance provisions:

These roads and each associated right-of-way will receive maintenance, which will be carried out as required to maintain the road for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities). These roads will be maintained to minimize risk to road users and minimize the potential for environmental damage. Routine maintenance operations may include any one or combination of the following: summer grading, ditching, drainage, brush clearing with mechanical or chemical methods (e.g. application of chemical herbicides for vegetation control along road shoulders), gravelling, re-shaping of road bed, dust control measures, signage, snow plowing, sanding/salting and clearing existing right-of-ways including the harvest of merchantable trees as required. Maintenance may also include non-emergency repairs of existing water crossings to clean culverts, remove blockages caused by beavers, and to apply material (e.g. gravel, riprap) to mitigate or enhance long-term erosion protection around water crossings.

For safety/engineering concerns minor road re-alignment and bypass construction may also be required during the implementation of the FMP. This is permitted within the existing right-of-way, subject to the confirmation of values and the application of all applicable AOCs to the proposed work area. If an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied. In cases where new and/or replacement water crossings are required during the implementation of the FMP, the replacement of culverts are permitted subject to the following conditions; the values must be reviewed and updated for each location to ensure up-to-date values are considered, the applicable AOC must be applied to address any value impacted at the location (if an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied), and the planned water crossing replacements are identified and approved (with all applicable conditions on the construction, including preventative and mitigative measures) in the AWS for the year of construction company.

Emergency maintenance is defined as “road maintenance that required immediate attention to restore access and reduce the chance of personal injury, damage to equipment, inconvenience to road users and further road damage” (2009 FMPM). Emergency maintenance will be necessary where public safety and/or environmental damage have occurred unexpectedly. Emergency

repairs can proceed immediately without MNR approval provided the emergency works are limited in scope to only what is necessary to address essential public safety concerns and restrict further environmental damage. All emergency actions will be reported to MNR as soon as practical and any further actions (e.g. restoration, reconstruction, abandonment) will be subject to normal planning approvals. Where sediment has been released into a watercourse, the Ministry of the Environment is to be informed.

Where water crossings have been adversely impacted by unplanned events, water crossings may not be restored in a timely manner and remedial work may be limited to only eliminating or reducing safety hazards and/or interim measures to stop environmental damage. Access to areas impacted by unplanned events could be disrupted at any time and there is no obligation on the Crown or the Forest Industry to undertake repair work to restore infrastructure and access. However, all actions must be consistent with the Use Management Strategy for the road/road network. Situations could also arise where it is determined that a damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented.

(b) Monitoring Provisions

While the road/road network is in use for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities), it will be monitored on an ongoing basis for safety or environmental concerns. Bridges used for 'heavy truck hauls' inspected at least once a year by a competent person (following the inspection guidelines in Appendix E of the Crown Land Bridge Management Guidelines or by a professional engineer). When the road/road network is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment approach with emphasis on the potential values which could be impacted (i.e. fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of aerial assessments of reforestation (e.g. FTG surveys). In addition, all staff and contractors (harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

c) Access provisions or restrictions which apply to the public and commercial resource users with the rationale for the restrictions:

- none

d) a statement if the intent of the sustainable forest licence is to transfer the responsibility for the road or road network to MNR in the next 20 years, and the operating year or
5-year term in which the transfer is intended to occur:

- There is no intent to transfer at this time.

e) where the sustainable forest licensee has indicated an intent to transfer responsibility, MNR will provide a preliminary indication of the management intent for the road or road network:

- There is no intent to transfer at this time.

f) where the sustainable forest licensee has indicated an intent to transfer responsibility during the five-year term and MNR's management intent is to not maintain the road for public use, the activities required prior to transfer, including potential removal of water crossings will be documented (e.g. decommissioning, signs):

- There is no intent to transfer at this time.

iii) Estimated Cost of Construction and Use Management

- Construction: $30,000 - $35,000 /km plus two minor AOC water crossings at around $6,000 /per
- Maintenance: $8,000 – $10,000 /km/yr

3. Summary of Public Comments:

ROADS SUPPLEMENTARY DOCUMENTATION FORM

ROAD NAME: Witch Bay/ Loon Lake Road (New Primary Road)

The Witch Bay/Loon Lake Road is a primary road, approximately 12 kilometers south of highway 17 junction with highway 71. This new road has a total road length of 12 km of which all is reconstruction. This road provides access to a section of the southern part of the unit for forestry activities in the 2012-2022 FMP as well as future plans. The road commences westerly off of the highway and proceeds south following the power line and turns west towards Jadakin Lake. (Basemaps 41549, 41550)

1. Alternative Corridors

In identifying a reasonable range of alternative corridors for analysis, the following was considered:

(a) Physical conditions, specific non-timber values and significant engineering or safety factors that may affect planning of the road corridor and the cost of construction of the road,

(b) Any other planning initiatives that deal with access in the area (e.g. Ontario's Crown Land Use Policy Atlas, management statement of conservation interest, park management plans, lake management plans, resource stewardship agreements), and

(c) Issues arising from public consultation regarding this primary road proposal.

Only one route is proposed due to the following:

- Corridor utilizes an existing road bed which will be reconstructed
- Provides for the most direct route in accessing future wood supplies and silviculture activities
- Location of lakes, topography and existing roads
- Provides for strategic access to southern portion of the management unit

2. Environmental Analysis of Alternative Corridors

a) Alternative Corridor (number) and Description: Witch Bay/ Loon Lake Road – Alternative 1(See Areas Selected for Operations Maps)

This proposed all weather primary road, approximately 12 km in length, commencing off of highway 71 approximately 12 km south of highway 17 and proceeds southerly along the power line turning west towards Jadakin Lake.

b) Environmental Analysis

i. Access to Areas Eligible for harvest, renewal and tending operations

Advantages

- Utilizes 12 km of existing branch and operational roadbed for reconstruction to primary
- Observed to be the best location to build the road due to access limitations from lakes and waterways.
- Proposed road strategically develops future wood supply areas as well as subsequent renewal and tending treatments.

Disadvantages

- None

Potential Effects on Non-Timber Values

Advantages

- Enhanced access for other forest users

Disadvantages

- The proposed road requires one water crossing
- The proposed road will increase the amount of other users within the area.

Providing access to any remote Aboriginal communities which were previously inaccessible by road

- This corridor will not provide access to any remote Aboriginal communities that were not previously accessible by road.

ii) Use Management Strategy

(a) Maintenance provisions:

These roads and each associated right-of-way will receive maintenance, which will be carried out as required to maintain the road for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities). These roads will be maintained to minimize risk to road users and minimize the potential for environmental damage. Routine maintenance operations may include any one or combination of the following: summer grading, ditching, drainage, brush clearing with mechanical or chemical methods (e.g. application of chemical herbicides for vegetation control along road shoulders), gravelling, re-shaping of road bed, dust control measures, signage, snow plowing, sanding/salting and clearing existing right-of-ways including the harvest of merchantable trees as required. Maintenance may also include non-emergency repairs of existing water crossings to clean culverts, remove blockages caused by beavers, and to apply material (e.g. gravel, riprap) to mitigate or enhance long-term erosion protection around water crossings.

For safety/engineering concerns minor road re-alignment and bypass construction may also be required during the implementation of the FMP. This is permitted within the existing right-of-way, subject to the confirmation of values and the application of all applicable AOCs to the proposed work area. If an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied. In cases where new and/or replacement water crossings are required during the implementation of the FMP, the replacement of culverts are permitted subject to the following conditions; the values must be reviewed and updated for each location to ensure up-to-date values are considered, the applicable AOC must be applied to address any value impacted at the location (if an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied), and the planned water crossing replacements are identified and approved (with all applicable conditions on the construction, including preventative and mitigative measures) in the AWS for the year of construction company.

Emergency maintenance is defined as “road maintenance that required immediate attention to restore access and reduce the chance of personal injury, damage to equipment, inconvenience to road users and further road damage” (2009 FMPM). Emergency maintenance will be necessary where public safety and/or environmental damage have occurred unexpectedly. Emergency

repairs can proceed immediately without MNR approval provided the emergency works are limited in scope to only what is necessary to address essential public safety concerns and restrict further environmental damage. All emergency actions will be reported to MNR as soon as practical and any further actions (e.g. restoration, reconstruction, abandonment) will be subject to normal planning approvals. Where sediment has been released into a watercourse, the Ministry of the Environment is to be informed.

Where water crossings have been adversely impacted by unplanned events, water crossings may not be restored in a timely manner and remedial work may be limited to only eliminating or reducing safety hazards and/or interim measures to stop environmental damage. Access to areas impacted by unplanned events could be disrupted at any time and there is no obligation on the Crown or the Forest Industry to undertake repair work to restore infrastructure and access. However, all actions must be consistent with the Use Management Strategy for the road/road network. Situations could also arise where it is determined that a damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented.

(b) Monitoring Provisions

While the road/road network is in use for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities), it will be monitored on an ongoing basis for safety or environmental concerns. Bridges used for 'heavy truck hauls' inspected at least once a year by a competent person (following the inspection guidelines in Appendix E of the Crown Land Bridge Management Guidelines or by a professional engineer). When the road/road network is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment approach with emphasis on the potential values which could be impacted (i.e. fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of aerial assessments of reforestation (e.g. FTG surveys). In addition, all staff and contractors (harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

c) Access provisions or restrictions which apply to the public and commercial resource users with the rationale for the restrictions:

- none

d) a statement if the intent of the sustainable forest licence is to transfer the responsibility for the road or road network to MNR in the next 20 years, and the operating year or
5-year term in which the transfer is intended to occur:

- There is no intent to transfer at this time.

e) where the sustainable forest licensee has indicated an intent to transfer responsibility, MNR will provide a preliminary indication of the management intent for the road or road network:

- There is no intent to transfer at this time.

f) where the sustainable forest licensee has indicated an intent to transfer responsibility during the five-year term and MNR's management intent is to not maintain the road for public use, the activities required prior to transfer, including potential removal of water crossings will be documented (e.g. decommissioning, signs):

- There is no intent to transfer at this time.

iii) Estimated Cost of Construction and Use Management

- Construction: $30,000 - $35,000 /km plus two minor AOC water crossings at around $6,000 /per
- Maintenance: $8,000 – $10,000 /km/yr

3. Summary of Public Comments:

- None received to-date.

4. Proposed Corridor:

a) Description: See Alternative 1

b) Rationale: Alternative 1 utilizes a segment of an existing road, develops future harvest and renewal activities and is the most economical given the local terrain limitations.

c) Use Management Strategy: See Alternative 1

5. Summary of Public Comments:

None

6. Selected Corridor: See Proposed Corridor (Part 4)

7. Changes to a Confirmed Primary Road Corridor Road Use Management Strategy

Use Management Strategy:

No change to UMS

Summary of Public Comments:

Refer to Part 3

Use Management Strategy

See Alternative 1

ROADS SUPPLEMENTARY DOCUMENTATION FORM

B: Branch Road Corridors

ROAD NAME: April South and Aesthetic Branch Extension Roads (Branch Road)

1. Proposed Corridor

(a) April South (mapsheet 49555) and Aesthetic Branch Extension (mapsheets 40556, 41556) Roads (see Areas Selected for Operations Map)

These proposed road corridors are identified on the Index map and Areas Selected for Operations Maps. The April South road is located off the Ord road in the North east portion of the Whiskey Jack forest. The Aesthetic Branch Extension road is located off Highway 71 in the South west portion of the Whiskey Jack Forest. April South Road is an existing road that require reconstruction. The Aesthetic Branch Extension is new road construction off of the existing Aesthetic Road. The length of the roads can be found in table FMP-18.

(b) Rationale: The corridor was identified based on consideration of the following:

I. The degree to which the physical conditions, non-timber values (i.e. natural resource features, land uses and values, as identified on the values map for the MU) and significant engineering or safety factors in the area, act as constraints or provide opportunities, including possibilities for development of other resources.
II. Any Other Planning Initiatives that Deal with Access in the Area (i.e. Ontario's Crown Land Use Policy Atlas, management statement of conservation interest, park management plans, lake management plans, resource stewardship agreements)
III. Results of Consultation with Interested and Affected Persons and or Organizations.

Only one route is proposed due to the following:

- Corridors utilize an existing road beds
- Provides for the most direct route in accessing future harvest allocations and silviculture activities
- Location of lakes, topography and existing roads
- The roads currently exist and require minimal reconstruction efforts for hauling and safety requirements.

(c) Use Management Strategy

Proposed corridors share the following Use Management Strategy:

(a) Maintenance provisions:

These roads and each associated right-of-way will receive maintenance, which will be carried out as required to maintain the road for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities). These roads will be maintained to minimize risk to road users and minimize the potential for environmental damage. Routine maintenance operations may include any one or combination of the following: summer grading, ditching, drainage, brush

clearing with mechanical or chemical methods (e.g. application of chemical herbicides for vegetation control along road shoulders), gravelling, re-shaping of road bed, dust control measures, signage, snow plowing, sanding/salting and clearing existing right-of-ways including the harvest of merchantable trees as required. Maintenance may also include non-emergency repairs of existing water crossings to clean culverts, remove blockages caused by beavers, and to apply material (e.g. gravel, riprap) to mitigate or enhance long-term erosion protection around water crossings.

For safety/engineering concerns minor road re-alignment and bypass construction may also be required during the implementation of the CP. This is permitted within the existing right-of-way, subject to the confirmation of values and the application of all applicable AOCs to the proposed work area. If an appropriate AOC does not exist in the CP note that it will need to be amended into the CP and then applied. In cases where new and/or replacement water crossings are required during the implementation of the CP, the replacement of culverts are permitted subject to the following conditions; the values must be reviewed and updated for each location to ensure up-to-date values are considered, the applicable AOC must be applied to address any value impacted at the location (if an appropriate AOC does not exist in the CP note that it will need to be amended into the CP and then applied), and the planned water crossing replacements are identified and approved (with all applicable conditions on the construction, including preventative and mitigative measures) in the AWS for the year of construction company.

Emergency maintenance is defined as “road maintenance that required immediate attention to restore access and reduce the chance of personal injury, damage to equipment, inconvenience to road users and further road damage” (2009 FMPM). Emergency maintenance will be necessary where public safety and/or environmental damage have occurred unexpectedly. Emergency repairs can proceed immediately without MNR approval provided the emergency works are limited in scope to only what is necessary to address essential public safety concerns and restrict further environmental damage. All emergency actions will be reported to MNR as soon as practical and any further actions (e.g. restoration, reconstruction, abandonment) will be subject to normal planning approvals. Where sediment has been released into a watercourse, the Ministry of the Environment is to be informed.

Where water crossings have been adversely impacted by unplanned events, water crossings may not be restored in a timely manner and remedial work may be limited to only eliminating or reducing safety hazards and/or interim measures to stop environmental damage. Access to areas impacted by unplanned events could be disrupted at any time and there is no obligation on the Crown or the Forest Industry to undertake repair work to restore infrastructure and access. However, all actions must be consistent with the Use Management Strategy for the road/road network. Situations could also arise where it is determined that a damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented.

(b) Monitoring Provisions

While the road/road network is in use for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities), it will be monitored on an ongoing basis for safety or environmental concerns. Bridges used for ‘heavy truck hauls’ inspected at least once a year by a competent person (following the inspection guidelines in Appendix E of the Crown Land Bridge Management Guidelines or by a professional engineer). When the road/road network is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment

approach with emphasis on the potential values which could be impacted (i.e. fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of aerial assessments of reforestation (e.g. FTG surveys). In addition, all staff and contractors (harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

c) Access provisions or restrictions which apply to the public and commercial resource users with the rationale for the restrictions:

- none

d) a statement if the intent of the sustainable forest licence is to transfer the responsibility for the road or road network to MNR in the next 20 years, and the operating year or
5-year term in which the transfer is intended to occur:

- There is no intent to transfer at this time.

e) where the sustainable forest licensee has indicated an intent to transfer responsibility, MNR will provide a preliminary indication of the management intent for the road or road network:

- There is no intent to transfer at this time.

f) where the sustainable forest licensee has indicated an intent to transfer responsibility during the five-year term and MNR's management intent is to not maintain the road for public use, the activities required prior to transfer, including potential removal of water crossings will be documented (e.g. decommissioning, signs):

- There is no intent to transfer at this time.

2. Summary of Public Comments:

- None received to-date.

3. Selected Corridor: See Proposed Corridor

ROADS SUPPLEMENTARY DOCUMENTATION FORM

C. Operational Roads

OPERATIONAL ROAD BOUNDARY IDENTIFIER: ORBs listed in table FMP-18 with UMS-1:

ORB2, ORB4, ORB6, ORB8, ORB12, ORB14, ORB16, ORB18, ORB20, ORB22, ORB24, ORB26, ORB30, ORB32, ORB34, ORB36, ORB38, ORB40, ORB42, ORB44, ORB48, ORB52, ORB54, ORB56, ORB64, ORB66, ORB68, ORB70, ORB72, ORB74, ORB76, ORB78, ORB80, ORB82, ORB86, ORB88, ORB92, ORB98, ORB100, ORB102, ORB142, ORB136, ORB118, ORB202, ORB188, ORB200, ORB160, ORB166, ORB182, ORB180, ORB164, ORB126, ORB132, ORB112, ORB168, ORB106, ORB204, ORB210, ORB212, ORB214, ORB216, ORB218, ORB222, ORB228, ORB230, ORB234, ORB236, ORB238, ORB240, ORB242, ORB244, ORB248, ORB250, ORB254, ORB256, ORB262, ORB266, ORB268, ORB270, ORB272, ORB274, ORB276, ORB278, ORB282, ORB286, ORB288, ORB290, ORB292, ORB296, ORB298, ORB300, ORB304, ORB308, ORB312, ORB314, ORB316, ORB318, ORB332, ORB334, ORB336, ORB342, ORB348, ORB350, ORB352, ORB360, ORB364, ORB372, ORB374, ORB376, ORB378, ORB382, ORB386, ORB394, ORB396, ORB398, ORB400, ORB402, ORB404, ORB406, ORB410, ORB412, ORB414, ORB416, ORB418, ORB424, ORB426, ORB428, ORB460, ORB462, ORB466, ORB500, ORB502, ORB504, ORB508, ORB512, ORB516, ORB520, ORB522, ORB524, ORB526, ORB528, ORB530, ORB534, ORB540, ORB544, ORB546, ORB548, ORB550, ORB552, ORB554, ORB556, ORB560, ORB562, ORB564, ORB568, ORB582, ORB584, ORB586, ORB588, ORB592, ORB594, ORB598, ORB622, ORB640, ORB644, ORB646, ORB648, ORB656, ORB658, ORB662, ORB667, ORB666, ORB672, ORB676, ORB678, ORB680, ORB684, ORB686, ORB688, ORB690, ORB692, ORB694, ORB696, ORB698, ORB700, ORB702, ORB704, ORB710, ORB712, ORB714, ORB716, ORB718, ORB720, ORB722, ORB724, ORB730, ORB734, ORB736, ORB738, ORB740, ORB742, ORB744, ORB746, ORB748, ORB750, ORB752, ORB754, ORB756, ORB762, ORB766, ORB770, ORB774, ORB776, ORB778, ORB780, ORB782, ORB784, ORB786, ORB788, ORB794, ORB798, ORB808, ORB810, ORB390, ORB392, ORB388, ORB384, ORB533, ORB532, ORB510, ORB558, ORB536, ORB537, ORB206, ORB811, ORB812, ORB813, ORB814, ORB815, ORB816, ORB817, ORB819, ORB820, ORB821, ORB822, ORB823, ORB824, ORB825, ORB826, ORB827, ORB828, ORB830, ORB831, ORB832, ORB833, ORB176, ORB630

These operational road boundaries for which this road supplementary documentation applies are listed in table FMP -18 and are illustrated on the Areas Selected for Operations Maps.

1. Proposed Use Management Strategy for new Operational Roads / Networks

a) Maintenance Provisions

These roads and each associated right-of-way will receive maintenance, which will be carried out as required to maintain the road for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities). These roads will be maintained to minimize risk to road users and minimize the potential for environmental damage. Routine maintenance operations may include any one or combination of the following: summer grading, ditching, drainage, brush clearing with mechanical or chemical methods (e.g. application of chemical herbicides for vegetation control along road shoulders), gravelling, re-shaping of road bed, dust control measures, signage, snow plowing, sanding/salting and clearing existing right-of-ways including the harvest of merchantable trees as required. Maintenance may also include non-emergency

repairs of existing water crossings to clean culverts, remove blockages caused by beavers, and to apply material (e.g. gravel, riprap) to mitigate or enhance long-term erosion protection around water crossings.

For safety/engineering concerns minor road re-alignment and bypass construction may also be required for existing roads during the implementation of the FMP. This is permitted within the existing right-of-way, subject to the confirmation of values and the application of all applicable AOCs to the proposed work area. If an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied. In cases where new and/or replacement water crossings are required during the implementation of the FMP, the replacement of culverts are permitted subject to the following conditions; the values must be reviewed and updated for each location to ensure up-to-date values are considered, the applicable AOC must be applied to address any value impacted at the location (if an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied), and the planned water crossing replacements are identified and approved (with all applicable conditions on the construction, including preventative and mitigative measures) in the AWS for the year of construction.

Emergency maintenance is defined as “road maintenance that requires immediate attention to restore access and reduce the chance of personal injury, damage to equipment, inconvenience to road users and further road damage” (2009 FMPM). Emergency maintenance will be necessary where public safety and/or environmental damage have occurred unexpectedly. Emergency repairs can proceed immediately without MNR approval provided the emergency works are limited in scope to only what is necessary to address essential public safety concerns and restrict further environmental damage. All emergency actions will be reported to MNR as soon as practical and any further actions (e.g. restoration, reconstruction, abandonment) will be subject to normal planning approvals. Where sediment has been released into a watercourse, the Ministry of the Environment is to be informed.

Where water crossings have been adversely impacted by unplanned events, water crossings may not be restored in a timely manner and remedial work may be limited to only eliminating or reducing safety hazards and/or interim measures to stop environmental damage. Access to areas impacted by unplanned events could be disrupted at any time and there is no obligation on the Crown or the Forest Industry to undertake repair work to restore infrastructure and access. However, all actions must be consistent with the Use Management Strategy for the road/road network. Situations could also arise where it is determined that a damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented. However, all actions must be consistent with the UMS for the road / road network. Situations could also arise where it is determined that damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented.

Note that maintenance activities may be minimal as these operational roads are not intended for long term use. There is no expressed or implied commitment to maintain the entire existing road network for continuous general public access. There is no obligation on the Crown or the forest industry to undertake repair work to restore infrastructure and access beyond the requirements of forest management operations and/or terms of the use management strategy for the road.

b) Monitoring Provisions

While the road/road network is in use for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities), it will be monitored on an ongoing basis for safety or environmental concerns. Bridges used for ‘heavy truck hauls’ inspected at least once a year by

a competent person (following the inspection guidelines in Appendix E of the Crown Land Bridge Management Guidelines or by a professional engineer). When the road/road network is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment approach with emphasis on the potential values which could be impacted (i.e. fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of aerial assessments of reforestation (e.g. FTG surveys). In addition, all staff and contractors (harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

c) Access provisions or restrictions which apply to the public and commercial resource users with the rationale for the restrictions:

- N/A

d) a statement if the intent of the sustainable forest licence is to transfer the responsibility for the road or road network to MNR in the next 20 years, and the operating year or 5-year term in which the transfer is intended to occur:

- N/A

e) where the sustainable forest licensee has indicated an intent to transfer responsibility, MNR will provide a preliminary indication of the management intent for the road or road network:

- N/A

f) where the sustainable forest licensee has indicated an intent to transfer responsibility during the five-year term and MNR's management intent is to not maintain the road for public use, the activities required prior to transfer, including potential removal of water crossings will be documented (e.g. decommissioning, signs):

- N/A

2. Summary of Public Comments:

- None received

ROADS SUPPLEMENTARY DOCUMENTATION FORM

C. Operational Roads

OPERATIONAL ROAD BOUNDARY IDENTIFIER: ORBs listed in table FMP-18 with UMS-3:

ORB170, ORB172, ORB176, ORB168, ORB232, ORB764, ORB 320ER, ORB326ER, ORB332ER, ORB344ER, ORB622ER, ORB622ERa, ORB346ER, ORB448ER, ORB448ERa, ORB596ER, ORB600ER, ORB612ER, ORB660ER, ORB670ER

These operational road boundaries for which this road supplementary documentation applies are listed in table FMP -18 and are illustrated on the Areas Selected for Operations Maps.

1. Proposed Use Management Strategy for new Operational Roads / Networks

a) Maintenance Provisions

These roads and each associated right-of-way will receive maintenance, which will be carried out as required to maintain the road for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities). These roads will be maintained to minimize risk to road users and minimize the potential for environmental damage. Routine maintenance operations may include any one or combination of the following: summer grading, ditching, drainage, brush clearing with mechanical or chemical methods (e.g. application of chemical herbicides for vegetation control along road shoulders), gravelling, re-shaping of road bed, dust control measures, signage, snow plowing, sanding/salting and clearing existing right-of-ways including the harvest of merchantable trees as required. Maintenance may also include non-emergency repairs of existing water crossings to clean culverts, remove blockages caused by beavers, and to apply material (e.g. gravel, riprap) to mitigate or enhance long-term erosion protection around water crossings.

For safety/engineering concerns minor road re-alignment and bypass construction may also be required for existing roads during the implementation of the FMP. This is permitted within the existing right-of-way, subject to the confirmation of values and the application of all applicable AOCs to the proposed work area. If an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied. In cases where new and/or replacement water crossings are required during the implementation of the FMP, the replacement of culverts are permitted subject to the following conditions; the values must be reviewed and updated for each location to ensure up-to-date values are considered, the applicable AOC must be applied to address any value impacted at the location (if an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied), and the planned water crossing replacements are identified and approved (with all applicable conditions on the construction, including preventative and mitigative measures) in the AWS for the year of construction.

Emergency maintenance is defined as “road maintenance that requires immediate attention to restore access and reduce the chance of personal injury, damage to equipment, inconvenience to road users and further road damage” (2009 FMPM). Emergency maintenance will be necessary where public safety and/or environmental damage have occurred unexpectedly. Emergency repairs can proceed immediately without MNR approval provided the emergency works are limited in scope to only what is necessary to address essential public safety concerns and restrict

further environmental damage. All emergency actions will be reported to MNR as soon as practical and any further actions (e.g. restoration, reconstruction, abandonment) will be subject to normal planning approvals. Where sediment has been released into a watercourse, the Ministry of the Environment is to be informed.

Where water crossings have been adversely impacted by unplanned events, water crossings may not be restored in a timely manner and remedial work may be limited to only eliminating or reducing safety hazards and/or interim measures to stop environmental damage. Access to areas impacted by unplanned events could be disrupted at any time and there is no obligation on the Crown or the Forest Industry to undertake repair work to restore infrastructure and access. However, all actions must be consistent with the Use Management Strategy for the road/road network. Situations could also arise where it is determined that a damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented. However, all actions must be consistent with the UMS for the road / road network. Situations could also arise where it is determined that damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented.

Note that maintenance activities may be minimal as these operational roads are not intended for long term use. There is no expressed or implied commitment to maintain the entire existing road network for continuous general public access. There is no obligation on the Crown or the forest industry to undertake repair work to restore infrastructure and access beyond the requirements of forest management operations and/or terms of the use management strategy for the road.

b) Monitoring Provisions

While the road/road network is in use for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities), it will be monitored on an ongoing basis for safety or environmental concerns. Bridges used for 'heavy truck hauls' inspected at least once a year by a competent person (following the inspection guidelines in Appendix E of the Crown Land Bridge Management Guidelines or by a professional engineer). When the road/road network is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment approach with emphasis on the potential values which could be impacted (i.e. fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of aerial assessments of reforestation (e.g. FTG surveys). In addition, all staff and contractors (harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

c) Access provisions or restrictions which apply to the public and commercial resource users with the rationale for the restrictions:

- N/A

d) a statement if the intent of the sustainable forest licence is to transfer the responsibility for the road or road network to MNR in the next 20 years, and the operating year or 5-year term in which the transfer is intended to occur:

Between 2016 and 2022, these nineteen new road systems will be no longer required for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities) and therefore they are scheduled for transfer in the plan period. All water crossings on this road are scheduled for removal unless an interested third party is willing to become responsible for the road system.

e) where the sustainable forest licensee has indicated an intent to transfer responsibility, MNR will provide a preliminary indication of the management intent for the road or road network:

MNR's preliminary management intent is to not maintain the road for public use and to decommission the road (to make it impassable to vehicular traffic, enhance public safety and reduce environmental damage).

f) where the sustainable forest licensee has indicated an intent to transfer responsibility during the five-year term and MNR's management intent is to not maintain the road for public use, the activities required prior to transfer, including potential removal of water crossings will be documented (e.g. decommissioning, signs):

The conditions for roads that are to be decommissioned and regenerated can be found in Section 4.5.8 of the Plan text. This decommissioning may involve the physical destruction and re-vegetation of the roadbed and the removal of high risk water crossings. All water crossings will be examined using MNR's criteria for removal of water crossings (Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales guidelines page 143-144) to determine whether decommissioning activities are appropriate based upon biological, water quality, engineering and safety factors. Water crossings planned for decommissioning will be identified in the applicable AWS, reviewed with respect to the Fisheries Act, and approved with any resulting conditions.

2. Summary of Public Comments:

- None received

ROADS SUPPLEMENTARY DOCUMENTATION FORM

D. Existing Roads or Road Networks

ROAD OR ROAD NETWORK NAME/IDENTIFIER: Existing primary and branch road roads, or operational road networks following UMS-1 and have No Access Restrictions:

White Tail Road
Wilcox Road
Windfall Raod

The roads and road networks for which this road supplementary documentation applies are listed in table FMP -18 and are illustrated on the Areas Selected for Operations Maps and the Existing Road Inventory geospatial data MU490_12ERU00.E00 - Existing Road Use Management Strategy.

1. Proposed Use Management Strategy

(a) Maintenance provisions:

These roads and each associated right-of-way will receive maintenance, which will be carried out as required to maintain the road for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities). These roads will be maintained to minimize risk to road users and minimize the potential for environmental damage. Routine maintenance operations may include any one or combination of the following: summer grading, ditching, drainage, brush clearing with mechanical or chemical methods (e.g. application of chemical herbicides for vegetation control along road shoulders), gravelling, re-shaping of road bed, dust control measures, signage, snow plowing, sanding/salting and clearing existing right-of-ways including

the harvest of merchantable trees as required. Maintenance may also include non-emergency repairs of existing water crossings to clean culverts, remove blockages caused by beavers, and to apply material (e.g. gravel, riprap) to mitigate or enhance long-term erosion protection around water crossings.

For safety/engineering concerns minor road re-alignment and bypass construction may also be required during the implementation of the FMP. This is permitted within the existing right-of-way, subject to the confirmation of values and the application of all applicable AOCs to the proposed work area. If an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied. In cases where new and/or replacement water crossings are required during the implementation of the FMP, the replacement of culverts are permitted subject to the following conditions; the values must be reviewed and updated for each location to ensure up-to-date values are considered, the applicable AOC must be applied to address any value impacted at the location (if an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied), and the planned water crossing replacements are identified and approved (with all applicable conditions on the construction, including preventative and mitigative measures) in the AWS for the year of construction company.

Emergency maintenance is defined as “road maintenance that required immediate attention to restore access and reduce the chance of personal injury, damage to equipment, inconvenience to road users and further road damage” (2009 FMPM). Emergency maintenance will be necessary where public safety and/or environmental damage have occurred unexpectedly. Emergency repairs can proceed immediately without MNR approval provided the emergency works are limited in scope to only what is necessary to address essential public safety concerns and restrict further environmental damage. All emergency actions will be reported to MNR as soon as practical and any further actions (e.g. restoration, reconstruction, abandonment) will be subject to normal planning approvals. Where sediment has been released into a watercourse, the Ministry of the Environment is to be informed.

Where water crossings have been adversely impacted by unplanned events, water crossings may not be restored in a timely manner and remedial work may be limited to only eliminating or reducing safety hazards and/or interim measures to stop environmental damage. Access to areas impacted by unplanned events could be disrupted at any time and there is no obligation on the Crown or the Forest Industry to undertake repair work to restore infrastructure and access. However, all actions must be consistent with the Use Management Strategy for the road/road network. Situations could also arise where it is determined that a damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented.

(b) Monitoring Provisions

While the road/road network is in use for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities), it will be monitored on an ongoing basis for safety or environmental concerns. Bridges used for ‘heavy truck hauls’ inspected at least once a year by a competent person (following the inspection guidelines in Appendix E of the Crown Land Bridge Management Guidelines or by a professional engineer). When the road/road network is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment approach with emphasis on the potential values which could be impacted (i.e. fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of

aerial assessments of reforestation (e.g. FTG surveys). In addition, all staff and contractors (harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

c) Access provisions or restrictions which apply to the public and commercial resource users with the rationale for the restrictions:

- none

d) a statement if the intent of the sustainable forest licence is to transfer the responsibility for the road or road network to MNR in the next 20 years, and the operating year or 5-year term in which the transfer is intended to occur:

- There is no intent to transfer at this time.

e) where the sustainable forest licensee has indicated an intent to transfer responsibility, MNR will provide a preliminary indication of the management intent for the road or road network:

- There is no intent to transfer at this time.

f) where the sustainable forest licensee has indicated an intent to transfer responsibility during the five-year term and MNR's management intent is to not maintain the road for public use, the activities required prior to transfer, including potential removal of water crossings will be documented (e.g. decommissioning, signs):

- There is no intent to transfer at this time.

2. Summary of Public Comments:

- None received to-date.

3. Use Management Strategy:

- Refer to Part 1.

ROADS SUPPLEMENTARY DOCUMENTATION FORM

D. Existing Roads or Road Networks

ROAD OR ROAD NETWORK NAME/IDENTIFIER: Existing primary and branch road roads, or operational road networks following UMS-2 with existing access restrictions:

Primary and Branch Roads
Aesthetic Road
Lennan Road
Mac Lake Road
Sydney Lake Road
Tide Road
Unexpected Road

The roads and road networks for which this road supplementary documentation applies are listed in table FMP -18 along with the access control type and are illustrated on the Areas Selected for Operations Maps.

1. Proposed Use Management Strategy

a) Maintenance Provisions

These roads and each associated right-of-way will receive maintenance, which will be carried out as required to maintain the road for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities). These roads will be maintained to minimize risk to road users and minimize the potential for environmental damage. Routine maintenance operations may include any one or combination of the following: summer grading, ditching, drainage, brush clearing with mechanical or chemical methods (e.g. application of chemical herbicides for vegetation control along road shoulders), gravelling, re-shaping of road bed, dust control measures, signage, snow plowing, sanding/salting and clearing existing right-of-ways including the harvest of merchantable trees as required. Maintenance may also include non-emergency repairs of existing water crossings to clean culverts, remove blockages caused by beavers, and to apply material (e.g. gravel, riprap) to mitigate or enhance long-term erosion protection around water crossings.

For safety/engineering concerns minor road re-alignment and bypass construction may also be required for existing roads during the implementation of the FMP. This is permitted within the existing right-of-way, subject to the confirmation of values and the application of all applicable AOCs to the proposed work area. If an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied. In cases where new and/or replacement water crossings are required during the implementation of the FMP, the replacement of culverts are permitted subject to the following conditions; the values must be reviewed and updated for each location to ensure up-to-date values are considered, the applicable AOC must be applied to address any value impacted at the location (if an appropriate AOC does not exist in the FMP note that it will need to be amended into the FMP and then applied), and the planned water crossing replacements are identified and approved (with all applicable conditions on the construction, including preventative and mitigative measures) in the AWS for the year of construction.

Emergency maintenance is defined as “road maintenance that requires immediate attention to restore access and reduce the chance of personal injury, damage to equipment, inconvenience to road users and further road damage” (2009 FMPM). Emergency maintenance will be necessary

where public safety and/or environmental damage have occurred unexpectedly. Emergency repairs can proceed immediately without MNR approval provided the emergency works are limited in scope to only what is necessary to address essential public safety concerns and restrict further environmental damage. All emergency actions will be reported to MNR as soon as practical and any further actions (e.g. restoration, reconstruction, abandonment) will be subject to normal planning approvals. Where sediment has been released into a watercourse, the Ministry of the Environment is to be informed.

Where water crossings have been adversely impacted by unplanned events, water crossings may not be restored in a timely manner and remedial work may be limited to only eliminating or reducing safety hazards and/or interim measures to stop environmental damage. Access to areas impacted by unplanned events could be disrupted at any time and there is no obligation on the Crown or the Forest Industry to undertake repair work to restore infrastructure and access. However, all actions must be consistent with the Use Management Strategy for the road/road network. Situations could also arise where it is determined that a damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented. However, all actions must be consistent with the UMS for the road / road network. Situations could also arise where it is determined that damaged/deteriorating infrastructure is unsafe and continued use must be prohibited until a permanent solution is implemented.

Note that maintenance activities may be minimal as these operational roads are not intended for long term use. There is no expressed or implied commitment to maintain the entire existing road network for continuous general public access. There is no obligation on the Crown or the forest industry to undertake repair work to restore infrastructure and access beyond the requirements of forest management operations and/or terms of the use management strategy for the road.

b) Monitoring Provisions

While the road/road network is in use for forest management purposes (e.g. harvest, renewal, tending, transportation and hauling activities), it will be monitored on an ongoing basis for safety or environmental concerns. Bridges used for ‘heavy truck hauls’ inspected at least once a year by a competent person (following the inspection guidelines in Appendix E of the Crown Land Bridge Management Guidelines or by a professional engineer). When the road/road network is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment approach with emphasis on the potential values which could be impacted (i.e. fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of aerial assessments of reforestation (e.g. FTG surveys). In addition, all staff and contractors (harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

c) Access provisions or restrictions which apply to the public and commercial resource users with the rationale for the restrictions:

The following is an overview of the use management strategies for the Aesthetic, Lennan, Mac Lake, Sydney Lake, Tide and Unexpected Roads, and associated operational road networks:

- All roads will continue to be managed as closed or restricted travel roads under the *Public Lands Act* (Section 52).
- The road closure will be year round closures.
- Guidelines for issuing travel permits have been prepared for each road and will be administered by the Kenora District office.
- First Nations use of the above closed road systems will be a permitted activity and has been included in the above guidelines for issuing travel permits.

These road systems, as well as the branch and operational roads coming off of them, have restricted travel conditions to protect remote tourism and lake trout values. The travel restrictions for these roads have been in place for several FMP's:

Aesthetic Road: PLA sign
Lennan Road: PLA sign
Sydney Lake Road: PLA sign
Tide Road: PLA sign
Unexpected: PLA sign

The Mac Lake Road is travel restricted due to an MTO gate.

d) a statement if the intent of the sustainable forest licence is to transfer the responsibility for the road or road network to MNR in the next 20 years, and the operating year or 5-year term in which the transfer is intended to occur:

- N/A

e) where the sustainable forest licensee has indicated an intent to transfer responsibility, MNR will provide a preliminary indication of the management intent for the road or road network:

- N/A

f) where the sustainable forest licensee has indicated an intent to transfer responsibility during the five-year term and MNR's management intent is to not maintain the road for public use, the activities required prior to transfer, including potential removal of water crossings will be documented (e.g. decommissioning, signs):

- N/A

2. Summary of Public Comments:

- None received to-date.

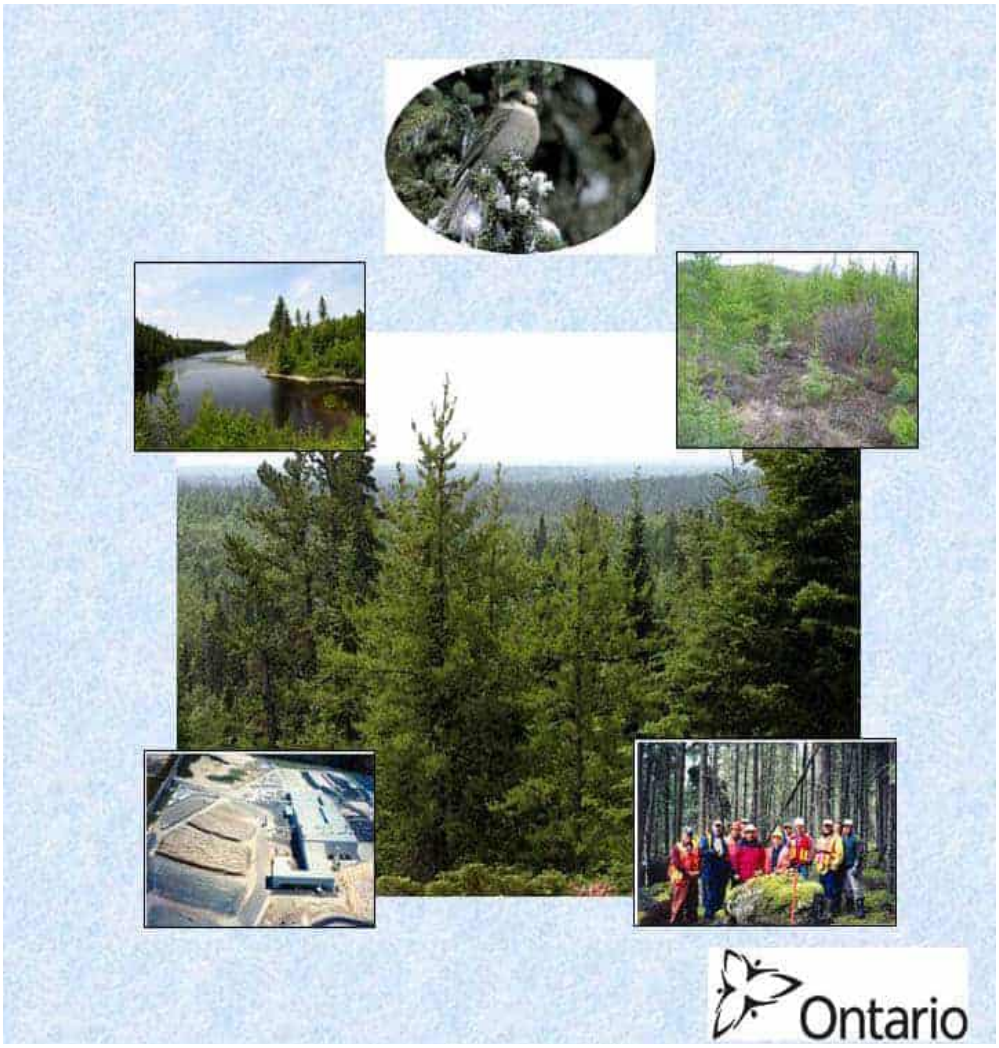
3. Use Management Strategy:

- Refer to Part 1.

Supplementary Documentation H

2012-2022 Whiskey Jack Forest Management Plan

Area of Concern (AOC) Planning Documentation



Management Unit Name: Whiskey Jack Forest
Plan Period: April 1, 2012 to March 31, 2022

Listing of Codes for Areas of Concern

(not all AOCs require supplementary documentation)

A01	Archaeological Potential Area
D01	Occupied black bear dens
D02	Occupied grey fox dens
D03	Occupied cougar dens
D04	Wolf dens
D05	Wolverine dens
M01	Mineral licks
N01	Bald eagle - primary nests - Identified Prior to Operations
N02	Bald eagle - alternate nests
N03	Bald eagle - inactive nests
N04	Bald Eagle Primary Nest - Discovered During Operations
ON01	Osprey - primary nests - Identified Prior to Operations
ON02	Osprey - alternate nests
ON03	Osprey - inactive nests
ON04	Primary Osprey Nest - Discovered During Operations
BH01	Active Great Blue Heron colonies
BH02	Inactive Great Blue Heron colonies
BG01	Active colonies of Bonaparte's gull
BS01	Active large colonies of bank swallows (≥100 pairs)
BS02	Barn Swallow Nests
HO01	Primary nests of great grey owl, northern goshawk, or red-shouldered hawk
HO02	Alternate nests of great grey owl, northern goshawk, or red-shouldered hawk
NO01	Stick nests occupied by barred owl, broad-winged hawk, common raven, Cooper's hawk, great horned owl, long-eared owl, merlin, red-tailed hawk, or sharp-shinned hawk.
NO02	Nests/ communal roosts in cavities occupied by American kestrel, barred owl, boreal owl, eastern screech-owl, great horned owl, northern hawk owl, northern saw-whet owl or chimney swift.
NO03	Ground nests occupied by northern harrier, short-eared owl, or turkey vulture
NO04	Whip-poor-will nest sites
NO05	Common nighthawk nest sites
NO06	Olive-sided flycatcher nest sites
NO07	Canada warbler nest sites
NO08	**Bat Hibernacula** known to be suitable and to have been used at least once within the past 20 years by ≥ 50 **Little Brown Myotis** (Little Brown Bats) or ≥ 20 **Northern Myotis** (Northern long-eared bats)
PGP01	FESC PGP G&Y Trial Plot
PL01	Patent Land
RR01	Railroad Right of Way
NG01	Natural Gas Transmission Pipeline
HB01	Highway Corridor Aesthetics
LS01	Tourism – Lac Seul Shoreline (Remoteness, aesthetics, fisheries, water quality, cultural heritage)
TV01	Tourism – Aesthetics Along Large High Volume Tourism Lakes, recognized canoe routes, recreational lakes
TVgl	Tourism- Gibi Lake
TVnsl	Tourism- North Star Lodge
TVw	Tourism – timing restriction
TVwl	Tourism – Wine Lake
TVal	Tourism – Aerobus Lake
TVer	Tourism – English River Waterway Park
TVp	Tourism - portage
TVc	Tourism - campsite
WL01	Large lakes, Medium lakes, Small lakes, Ponds - high or moderate potential sensitivity (HPS or MPS) to forest management operations
WL02	Ponds – low potential sensitivity (LPS) to forest management operations
WS01	Rivers, Stream segments -high or moderate potential sensitivity (HPS or MPS) to forest management operations
WS02	Stream segments -low potential sensitivity (LPS) to forest management operations
WW01	Wetlands occupied by breeding black terns, golden-winged warblers, least bitterns, or yellow rails
WW02	Woodland pools known to support flooded jellyskin
FL01	First Nation Reserve Land
NE9	Trumpeter Swan Nesting Site
NE10	Snapping Turtle Nesting Site

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: D05

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Wolverine Den.

(b) Dimensions of area of concern:
- 4 km radius AOC centered on the den entrance.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

- 4 km radius AOC centered on the den entrance.
- No harvest, renewal and tending operations permitted within the AOC.
- If a wolverine den is encountered during operations all operations will stop within a 4km radius AOC and the Kenora District Office MNR will be immediately notified of the presence of a wolverine den in proximity to forest operations.
- No further harvest, renewal or tending activities are permitted within the AOC.
- The FMP may be amended following the above by developing a new AOC in consultation with MNR biologists that includes a den site management plan for the specific location and in consideration of the following:
  - The specific dimensions of the wolverine den AOC;
  - Normally harvest, renewal and tending operations will be prohibited in the AOC, however, some operations may be permitted to meet ecological, social or economic objectives. Where operations will be permitted the AOC will outline the extent and timing of any harvest, renewal and tending operations;
  - Denning generally occurs between February and May when snow depth is usually at its greatest.
- Reasonable efforts will be made to incorporate the AOC into a large block of unharvested and unroaded forest (ie. marten core or caribou block).

(c) Environmental Analysis:

(i) Potential effects: This prescription provides protection for wolverine dens by utilizing a reserve area and prohibiting continued forestry operations near the den.

(ii) Advantages/disadvantages: The prescription protects wolverine dens while permitting some level of forest operations on the forest management unit. There are no known disadvantages to den sites by applying this prescription.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: Only 1 alternative has been proposed in order to follow *the Forest Management Guide for Conserving Biodiversity at the Stand and Site Guide Scales* while documenting the option to amend the plan at a further date if a specific wolverine den site is located.

Wolverines have low reproductive potential and are sensitive to human disturbance, especially with respect to den site selection. Natal and maternal dens are selected, in part, to avoid humans and predators during the denning and kit-rearing periods. Human contact may cause females to abandon den sites; dens are typically located a considerable distance from roads and human infrastructure. The operational prescription for this AOC is based on all of these premises.

(c) Exception: No

3. Summary of Public Comments

None.

4. Selected Prescription

See Alternative 1.

C: Conditions on Operational Roads

No operational roads allowed in AOC. AOC supplementary documentation is not required for Conditions on Operational Roads.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: NO04

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Whip-poor-will nesting site.

(b) Dimensions of area of concern:
- 200 m radius AOC centered on nesting site. The critical breeding period for whip-poor-will is May 1st to August 14th.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) Alternative identifier/number: 1

(b) Description of proposed operational prescription:

When the habitat description under the ESA becomes available these conditions may be updated prior to plan approval if this is necessary to address the habitat description. If the habitat description becomes available after final plan approval, a plan amendment for this AOC may be submitted if necessary to address the habitat description.

• 200 m radius AOC centred on nesting sites identified in NRVIS or encountered by field operations. Upon discovery of a whip-poor-will nesting site, the local MNR biologist will be notified so that they can confirm the species using the nesting site.
• The critical breeding period for Whip-poor-will is May 1st to August 14th.
• The following operational prescription will be followed:
  - No forest harvest operations permitted within 200 m from the nesting site.
  - Site preparation, renewal and tending operations of previously harvested areas within the AOC are only permitted outside of the critical breeding period (August 15th to April 30th).
  - Residual pattern, wildlife trees and downed woody material will be retained as prescribed in the FMP text Section 4.2.2.2.

(c) Environmental Analysis:

i) Potential effects: There is the potential to impact the nesting site through operations occurring in the area, prior to the discovery of the nesting site.
ii) Advantages of the alternative operational prescription: The prescription provides protection for known nesting sites, as well as nesting sites discovered during operations.
iii) Disadvantages of the alternative operational prescription: There are no disadvantages to applying this prescription.

2. Proposed Operational Prescription

(a) Description: Same as Alternative 1.

(b) Rationale: Whip-poor-will is designated as a threatened species under the Endangered Species Act (ESA). This prescription was developed to address habitat protection for this species as there is currently

no guideline or habitat description available for Whip-poor-will. The prescription was developed through consultation with the MNR Species at Risk (SAR) biologist based on the best available knowledge at this time. Whip-poor-will is a territorial bird that exhibits high site fidelity. While they are known to forage up to 500 metres from a nesting territory, their typical home range is confined to 400 metres and within this area they defended a smaller territory from 3 to 11 hectares (average 5). They require a landscape that provides both forest canopy for nesting and open areas for feeding. In a managed forest setting harvest is required to maintain long term habitat supply. One study found that densities of Whip-poor-will were twice as high in areas where open clear-cut habitats were immediately available in the landscape as compared to mature forest only and further that Whip-poor-will rarely ranged more than 200 metres from adjacent forest edge. Given these habitat requirements, the MNR SAR biologist has recommended that a 200 metre AOC be considered in forest management until such time that a habitat description in support of the ESA is available. Whip-poor-will does not create a nest as it lays its eggs on leaf matter. The male whip-poor-will investigates intruders near-by "hovering in place with its body nearly vertical and its tail spread wide to show off the broad white tips of the tail feathers". This makes finding the nesting site very difficult. As a result, the prescription has added the statement that the local MNR biologist or SAR biologist will be notified so that they can confirm the location of the nesting site and species using the nesting site. When the habitat description under the ESA becomes available this prescription may be updated via a plan amendment if necessary to address the ESA habitat description. The critical breeding period for whip-poor-will is May 1st to August 14th, therefore existing forestry related land use activities adjacent to the nesting area is restricted at this time. These include conditions on aggregate extraction and road use.

(c) Exception: No.

3. Summary of Public Comments

None.

4. Selected Prescription

Alternative 1.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC NO04 in Table FMP-19.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: NO05

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Common Nighthawk nesting site.

(b) Dimensions of area of concern:

- 200 m radius AOC centered on nesting site.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) Alternative identifier/number: 1

(b) Description of proposed operational prescription:

When the habitat description under the ESA becomes available these conditions may be updated prior to plan approval if this is necessary to address the habitat description. If the habitat description becomes available after final plan approval, a plan amendment for this AOC may be submitted if necessary to address the habitat description.

• 200 m radius AOC centered on nesting sites identified in NRVIS or encountered by field operations. Upon discovery of a common nighthawk nesting site, the local MNR biologist will be notified so that they can confirm the species using the nesting site.
• The critical breeding period for Common Nighthawk is May 15th to August 15th.
• The following operational prescription will be followed:
  - No forest harvest operations permitted within 200 m from the nesting site.
  - Site preparation, renewal and tending operations of previously harvested areas within the AOC are only permitted outside of the critical breeding period (August 16th to May 14th).
  - Residual pattern, wildlife trees and downed woody material will be retained as prescribed in the FMP text Section 4.2.2.2.

(c) Environmental Analysis:

i) Potential effects: There is the potential to impact the nesting site through operations occurring in the area, prior to the discovery of the nesting site.
ii) Advantages of the alternative operational prescription: The prescription provides protection for known nesting sites, as well as nesting sites discovered during operations.
iii) Disadvantages of the alternative operational prescription: There are no disadvantages to applying this prescription.

2. Proposed Operational Prescription

(a) Description: Same as Alternative 1.

(b) Rationale: Common Nighthawk is designated as a special concern species under the Endangered Species Act (ESA). This prescription was developed to address habitat protection for this species as

there is currently no guideline or habitat description available for Common Nighthawk. The prescription was developed through consultation with the MNR Species at Risk (SAR) biologist based on the best available knowledge at this time. Finding common nighthawk nesting sites can be difficult. As a result, the prescription has added the statement that the local MNR biologist or SAR biologist will be notified so that they can confirm the location of the nesting site and species using the nesting site. When the habitat description under the ESA becomes available this prescription may be updated via a plan amendment if necessary to address the ESA habitat description. The critical breeding period for common nighthawk is May 15th to August 15th, therefore existing forestry related land use activities adjacent to the nesting area is restricted at this time. These include conditions on aggregate extraction and road use.

(c) Exception: No.

3. Summary of Public Comments

None.

4. Selected Prescription

Alternative 1.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC NO05 in Table FMP-19.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: NO06

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Olive-sided flycatcher nesting site.

(b) Dimensions of area of concern:

- 100 m radius AOC centered on nesting site.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) Alternative identifier/number: 1

(b) Description of proposed operational prescription:

When the habitat description under the ESA becomes available these conditions may be updated prior to plan approval if this is necessary to address the habitat description. If the habitat description becomes available after final plan approval, a plan amendment for this AOC may be submitted if necessary to address the habitat description.

• 100 m radius AOC centered on nesting sites identified in NRVIS or encountered by field operations. Upon discovery of an olive-sided flycatcher nesting site, the local MNR biologist will be notified so that they can confirm the species using the nesting site.
• The critical breeding period for olive-sided flycatcher is May 1st to August 31st.
• The following operational prescription will be followed:
  - No forest harvest operations permitted within 100 m from the nesting site.
  - Site preparation, renewal and tending operations of previously harvested areas within the AOC are only permitted outside of the critical breeding period (September 1st to April 30th).
  - Residual pattern, wildlife trees and downed woody material will be retained as prescribed in the FMP text Section 4.2.2.2.

(c) Environmental Analysis:

i) Potential effects: There is the potential to impact the nesting site through operations occurring in the area, prior to the discovery of the nesting site.
ii) Advantages of the alternative operational prescription: The prescription provides protection for known nesting sites, as well as nesting sites discovered during operations.
iii) Disadvantages of the alternative operational prescription: There are no disadvantages to applying this prescription.

2. Proposed Operational Prescription

(a) Description: Same as Alternative 1.

(b) Rationale: Olive-sided flycatcher is designated as a special concern species under the Endangered Species Act (ESA) and threatened under the Species At Risk Act (SARA). This prescription was developed to address habitat protection for this species as there is currently no guideline or habitat description available for Olive-sided flycatcher. The prescription was developed through consultation with the MNR Species at Risk (SAR) biologist based on the best available knowledge at this time. Finding olive-sided flycatcher nesting sites can be difficult. As a result, the prescription has added the statement that the local MNR biologist or SAR biologist will be notified so that they can confirm the location of the nesting site and species using the nesting site. When the habitat description under the ESA becomes available this prescription may be updated via a plan amendment if necessary to address the ESA habitat description. The critical breeding period for olive sided flycatcher is May 1st to August 31st, therefore existing forestry related land use activities adjacent to the nesting area is restricted at this time. These include conditions on aggregate extraction and road use.

(c) Exception: No.

3. Summary of Public Comments

None.

4. Selected Prescription

Alternative 1.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC NO06 in Table FMP-19.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: NO07

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Canada warbler nesting site.

(b) Dimensions of area of concern:

- 100 m radius AOC centered on nesting site.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) Alternative identifier/number: 1

(b) Description of proposed operational prescription:

When the habitat description under the ESA becomes available these conditions may be updated prior to plan approval if this is necessary to address the habitat description. If the habitat description becomes available after final plan approval, a plan amendment for this AOC may be submitted if necessary to address the habitat description.

• 100 m radius AOC centered on nesting sites identified in NRVIS or encountered by field operations. Upon discovery of a Canada warbler nesting site, the local MNR biologist will be notified so that they can confirm the species using the nesting site.
• The critical breeding period for Canada warbler is May 15th to August 15th.
• The following operational prescription will be followed:
  - No forest harvest operations permitted within 100 m from the nesting site.
  - Site preparation, renewal and tending operations of previously harvested areas within the AOC are only permitted outside of the critical breeding period (August 16th to May 14th).
  - Residual pattern, wildlife trees and downed woody material will be retained as prescribed in the FMP text Section 4.2.2.2.

(c) Environmental Analysis:

i) Potential effects: There is the potential to impact the nesting site through operations occurring in the area, prior to the discovery of the nesting site.
ii) Advantages of the alternative operational prescription: The prescription provides protection for known nesting sites, as well as nesting sites discovered during operations.
iii) Disadvantages of the alternative operational prescription: There are no disadvantages to applying this prescription.

2. Proposed Operational Prescription

(a) Description: Same as Alternative 1.

(b) Rationale: Canada warbler is designated as a special concern species under the Endangered Species Act (ESA). This prescription was developed to address habitat protection for this species as there is currently no guideline or habitat description available for Canada warbler. The prescription was developed through consultation with the MNR Species at Risk (SAR) biologist based on the best available knowledge at this time. Finding Canada warbler nesting sites can be difficult. As a result, the prescription has added the statement that the local MNR biologist or SAR biologist will be notified so that they can confirm the location of the nesting site and species using the nesting site. When the habitat description under the ESA becomes available this prescription may be updated via a plan amendment if necessary to address the ESA habitat description. As Canada warbler are some of the last song birds to arrive in the spring and first to leave in late summer, the critical breeding period for Canada warbler has been defined as May 15th to August 15th. Existing forestry related land use activities adjacent to the nesting area is restricted at this time. These include conditions on aggregate extraction and road use.

(c) Exception: No.

3. Summary of Public Comments

None.

4. Selected Prescription

Alternative 1.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC NO07 in Table FMP-19.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: PGP01

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
Provincial Forest Growth & Yield Research Plots: Permanent Growth Plot (PGP)

A PGP is a 400m2 circular plot, 11.28m in radius.

Historic PGPs (i.e. Beckwith & Roebellen, Andison) may be rectangular in nature.

(b) Dimensions of area of concern:
Circular plot:
75m radius measured from the PGP centre, squared off such that the final AOC is 150m by 150m

OR

75m radius measured from the PGP centre

Rectangular plot:
65m measured from each boundary (side) of the PGP

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

Circular plot:

No harvest, renewal or tending within a 75m radius measured from the PGP centre, squared off such that the final reserve is 150m by 150m (2.25ha). As required of FMP-19 adjust the AOC boundary to follow the edge of the road right-of-way if a road is permitted outside of the 75m radius from the plot centre yet within the squared off AOC boundary (i.e. do not extend the AOC to include area on the opposite side of the road to the PGP centre).

OR

No harvest, renewal or tending within a 75m radius measured from the PGP centre (1.77ha)

Rectangular plot:

No harvest, renewal or tending 65m from each boundary (side) of the PGP.

A separate AOC must be developed and approved for any harvest, renewal or tending activities within a PGP AOC.

- The Growth & Yield Program may permit some forest management activities within a PGP AOC, such as partial harvest, renewal or tending operations, in order to monitor the impact of these activities. Discussions with the MNR Regional Growth & Yield Specialist will determine where and when this may occur. Permission to carry out such activities must be documented in writing by the Regional Growth & Yield Specialist and will be used for a separate AOC prescription to be developed and approved.
- If the following forest management activities are planned in the area adjacent to a PGP AOC, contact the MNR Regional Growth & Yield Specialist for consideration of these activities in a PGP AOC:
  1) selection or shelterwood harvest,
  2) commercial thinning harvest, or
  3) tending activities (e.g. herbicide application, pre-commercial thinning).
- Forest Ecosystem Science Co-operative (Forest Co-op) PGPs may also be considered for clearcut harvest if three measurements have been conducted on a plot. Discussions with the Forest Co-op and MNR Regional Growth & Yield Specialists will determine the status of a Forest Co-op PGP and any clearcut harvest treatment. Permission to clearcut harvest a Forest Co-op PGP must be documented in writing by the Regional Growth & Yield Specialist and will be used for a separate AOC prescription to be developed and approved.

(c) Environmental Analysis:

(i) identification of the potential environmental effects of specific forest management operations on the natural resource feature(s), land use(s) or value(s) in the area of concern:

Growth and yield is an empirical (i.e. based on data) branch of forest science that attempts to understand and predict the growth, composition and productivity of forest stands through time. This objective is accomplished through a consistent and continuous cycle of data collection, analysis and interpretation, and is most efficiently implemented through the use of long-term monitoring plots. An accurate and efficient method of determining growth and yield is with Permanent Sample Plots (PSPs) and Permanent Growth Plots (PGPs).

The Ontario Forest Growth and Yield Program establishes and monitors a network of PSPs and PGPs in managed and natural forests across the province. These plots have a broad ecosystem focus and serve as a benchmark network for provincial level information needs. Permanent plots serve a vital role in forest monitoring and modeling forests, as growth (including stand dynamics) can be estimated directly from repeated measurements of various ecosystem elements. To ensure the integrity of the permanent growth and yield plot network, the Forest Growth & Yield Program protects PGPs from vandalism, trespassing, logging and other types of human-caused damage.

(ii) assessment of the advantages and disadvantages of the alternative operational prescription in preventing, minimizing or mitigating those potential effects:

A harvest, renewal and tending reserve on the PGP will ensure that the existing structure and integrity of the plot at the stand and tree level is maintained. Maintaining the forested conditions around the plot provides a forest buffer that minimizes the potential effects of adjacent harvest, renewal or tending operations on the Permanent Growth Plot. Also, by providing an adequate buffer around the plot, blow down of trees in the buffer zone adjacent to the harvest area will have a minimal impact on the plot.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: The proposed operational prescription has been developed with input from the MNR Provincial Growth & Yield Program and the Forest Ecosystem Science

Co-operative Growth & Yield Science Unit. This AOC prescription utilizes the direction provided in the *OMNR Growth and Yield PSP and PGP Reference Manual 2009*, the *Forest Co-op Field Manual for the Location & Measurement of Permanent Growth Plots 2009*, and is recommended by the MNR Regional Growth and Yield Specialists. The proposed operational prescription will protect the investment of the MNR and Forest Co-op in the establishment and monitoring of provincial growth and yield permanent growth plots.

(c) Exception: N/A

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC PGP01 in Table FMP-19.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: PL01

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Patent land.

(b) Dimensions of area of concern:
- 30 m from the boundary of mapped patent/federal land adjacent to allocated harvest blocks.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

- AOC width is 30 metres from the boundary of mapped patent land adjacent to allocated harvest blocks.

  Harvest operations are permitted subject to the procedure below being implemented in the following order:

  1) If the property boundary had been previously established by a licenced surveyor and the boundary markers and monuments can be located then the harvest boundary will be established along the boundary markers and monuments. Regular harvest, renewal and tending operations are permitted in allocated blocks.
  2) If there is an agreement with the neighbouring landowner regarding the placement of the limit of forest operations then the harvest boundary will be placed according to the agreement. Regular harvest, renewal and tending operations are permitted in allocated blocks subject to this agreement.
  3) If neither 1) or 2) above apply, the harvest boundary will be established so that a buffer is put in between the mapped boundary and the harvest block. The size of the buffer will be no more than 30 metres wide, will be marked and will be determined by the forest operator's level of uncertainty regarding the true location of the property boundary. Regular harvest, renewal and tending operations are permitted outside of the marked reserve buffer.

(c) Environmental Analysis:

(iii) Potential effects: The prescription will protect the boundary of the private land by providing a buffer between the cutover and the property line, to ensure that no trespasses onto private land occur. The prescription will protect the value while also optimizing fibre extraction.

(iv) Advantages/disadvantages: Protects the property boundary. Provides a margin for error, and a moderate aesthetic buffer. Adjacent landowner may see some cutover areas behind the buffer.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: This prescription provides a reasonable buffer to ensure that no trespasses onto private land occur, while minimizing fibre loss to the forest industry.

(c) Exception: No

3. Summary of Public Comments

There were a no public comments received.

4. Selected Prescription

See Alternative 1.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC PL01 in Table FMP-19.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: FL01

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- First Nation Reserve (federal) land.

(b) Dimensions of area of concern:
- 30 m from the boundary of mapped First Nation Reserve land adjacent to allocated harvest blocks.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

- AOC width is 30 metres from the boundary of mapped First Nation Reserve land adjacent to allocated harvest blocks.

  Harvest operations are permitted subject to the procedure below being implemented in the following order:

  1) If the property boundary had been previously established by a licenced surveyor and the boundary markers and monuments can be located then the harvest boundary will be established along the boundary markers and monuments. Regular harvest, renewal and tending operations are permitted in allocated blocks.
  2) If there is an agreement with the First Nation Community regarding the placement of the limit of forest operations then the harvest boundary will be placed according to the agreement. Regular harvest, renewal and tending operations are permitted in allocated blocks subject to this agreement.
  3) If neither 1) or 2) above apply, the harvest boundary will be established so that a buffer is put in between the mapped boundary and the harvest block. The First Nation Reserve boundary will be checked against information provided by both MNR and INAC. The more restrictive of the two boundaries will be used if agreement cannot be reached as to the proper boundary location. The size of the buffer will be no more than 30 metres wide. Regular harvest, renewal and tending operations are permitted outside of the marked reserve buffer.

(c) Environmental Analysis:

(i) Potential effects: The prescription will protect the boundary of the federal land by providing a buffer between the cutover and the property line, to ensure that no trespasses onto federal land occur. The prescription will protect the value while also optimizing fibre extraction.

(ii) Advantages/disadvantages: Protects the property boundary. Provides a margin for error, and a moderate aesthetic buffer.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: This prescription provides a reasonable buffer to ensure that no trespasses onto federal land occur, while minimizing fibre loss to the forest industry.

(c) Exception: No

3. Summary of Public Comments

None received.

4. Selected Prescription

See Alternative 1.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC FL01 in Table FMP-19.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: RR01

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Railroad Right of Way

(b) Dimensions of area of concern:
- AOC width is 50 metres from the railroad right of way.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) Alternative identifier/number: 1

(b) Description of proposed operational prescription:

- Clear cut harvest to railway right of way within AOC, while leaving the 50 m AOC as a slash free zone. All forest management activities permitted; however slash piles or chipper debris piles are to be removed. No slash piles or chipper debris piles are allowed to remain in landing for more than one year.

(c) Environmental Analysis:

i) Potential effects: Reduction in fire hazard along railway right of ways.

ii) Advantages/disadvantages: Ensuring there is no slash within 50m of the railway right of way and allowing the area to regenerate to hardwoods will reduce potential fire hazard.

(a) Alternative identifier/number: 2

(b) Description of proposed operational prescription:

50 metre reserve from railway right of way.

(c) Environmental Analysis:
i) Potential effects: Increased fire hazard along railway from trees in reserve as they mature, die and fall over.
ii) Advantages/disadvantages: Reserved trees will reduce blowing and drifting snow on the railway in the winter. Retained trees will provide habitat that may cause more animals to browse and travel along the railway, leading to increased animal mortality through collisions with trains.

2. Proposed Operational Prescription

(a) Description: Same as Alternative 1.

(b) Rationale: The proposed prescription provides for the full recovery of merchantable timber and provides for a level of protection from railway caused fires.

(c) Exception: No.

3. Summary of Public Comments

None.

4. Selected Prescription

See Alternative 1.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC RR01 in Table FMP-19.

Summary of Public Comments:

No comments received.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: NG01

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Natural Gas Transmission Pipeline

(b) Dimensions of area of concern:
- AOC width is 30 metres from the pipeline right-of-way.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription: 30 metre AOC from natural gas transmission pipeline right-of-way. All forest management activities are permitted; however a representative from TransCanada pipelines is required to be notified before operations begin. TransCanada Pipelines will mark the pipeline outside edge of right-of-way to ensure that the proper location is identified.

Contact Information:
TransCanada Pipelines:
Lakewood Area Pipeline Technician, Lakewood Area Manager
Office # 807-548-4241Office # 807- 548-6025
Cell # 807-466-7212Cell # 807-466-7330

(c) Environmental Analysis:

i) Potential effects: A reduction of the potential of unauthorized travel within the pipeline right-of-way.

ii) Advantages/disadvantages: Ensuring the pipeline right-of-way is properly marked will reduce the likelihood of damage or explosion of the pipeline due to forestry operations.

(a) **Alternative identifier/number: 2**

(b) Description of proposed operational prescription: 30 metre reserve from natural gas pipeline right of way.

(c) Environmental Analysis:

i) Potential effects: Increased fire hazard along right of way from trees in reserve as they mature, die and fall over.

ii) Advantages/disadvantages: Loss of merchantable timber.

2. **Proposed Operational Prescription**

(a) Description: **Same as Alternative 1.**

(b) Rationale: The proposed prescription provides for the full recovery of merchantable timber and provides for a level of protection from unauthorized travel within the pipeline right of way.

(c) Exception: No

3. Summary of Public Comments
None.

4. Selected Prescription
See Alternative 1.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC NG01 in Table FMP-19.

Summary of Public Comments:
No comments received.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: HB01

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Highway corridor aesthetics.

(b) Dimensions of area of concern:
iii. 60 metre AOC from highway right-of way (as mapped).

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

- Harvest operations are permitted in the AOC only when adjacent forest/cutover is a minimum of 2 metres tall.
- Regular renewal and tending operations as per SGRs are permitted.

(c) Environmental Analysis:

(i) Potential effects: Protection of viewscape as seen from the highway and prevention of blowing and drifting snow.

(ii) Advantages/disadvantages: Harvesting of timber using the methods described above permits recovery of the merchantable timber while retaining the aesthetics and functional aspects of the AOC buffer.

(a) **Alternative identifier/number: 2**

(b) Description of proposed operational prescription:
Clearcut harvest of 60-metre AOC to highway right of way.

(c) Environmental Analysis:

(i) Potential effects: Aesthetics from the highway will be less pleasing to the traveling public.

(ii) Advantages/disadvantages: Harvesting to the highway edge allows capture of all merchantable timber however no protection is provided for the viewscape or from blowing or drifting snow.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: The proposed prescription provides the best balance between recovery of merchantable timber and the long term protection of highway viewscape and the prevention of blowing and drifting snow on the highway.

(c) Exception: No

3. Summary of Public Comments
None received.

4. Selected Prescription
See Alternative 1.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC HB01 in Table FMP-19.

Summary of Public Comments
No comments received.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: TV01

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Tourism aesthetics along large, high volume tourism lakes, recognized canoe routes, recreational lakes.

(b) Dimensions of area of concern:
- 90 metre AOC.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

For *large lakes, medium lakes, small lakes, HPS* ponds, *rivers* and *HPS* streams associated with identified canoe routes, 30 to 90 m AOC based on slope as follows measured from the edge of standing timber along the shoreline:

Slope (%)	Slope Angle (degrees)	Width of AOC
0 – 15	0 - 8.5	30 m
>15 - 30	8.6 – 16.7	50 m
>30 - 45	16.8 – 24.2	70 m
> 45	> 24.2	90 m

No harvest, renewal and tending operations are permitted within the AOC.

(c) Environmental Analysis:

(iii) Potential effects: increased visual buffer from water.

(iv) Advantages/disadvantages: As the AOC is measured from the standing timber it will protect lakes, pond, river, and stream values and maintain aesthetically pleasing shoreline vistas for the public.

(a) **Alternative identifier/number: 2**

(b) Description of proposed operational prescription:

- Apply a 90-metre AOC measured from the edge of the standing timber along the shoreline.
- No harvest, renewal and tending operations are permitted within the AOC.

(c) Environmental Analysis:

(i) Potential effects: Large reserve of standing timber reduces visibility of harvested areas and provides protection for lakes, pond, river, and stream values.

(ii) Advantages/disadvantages: A reserve wider than that proposed in alternative 1 will exceed that required to protect the water bodies however will reduce the visibility of areas that would otherwise be seen in alternative 1. Potentially an over protection of aesthetics, lakes, pond, river, and stream values as it is not a slope dependent AOC and the entire AOC is reserve. Does not provide environmental benefits of young forest adjacent to shoreline. May result in decreasing aesthetic value in future as trees get old and fall down, as opposed to having young healthy forest adjacent to shoreline.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 2.**

(b) Rationale: Ensuring that the AOC is measured from the standing timber will maintain aesthetically pleasing shoreline vistas for the public. Prescription meets or exceeds requirements for protection of lakes, rivers, ponds, and stream values as required of the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales, 2010*.

(c) Exception: No

3. Summary of Public Comments

General support of the additional harvest reserves.

4. Selected Prescription

See Alternative 2.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads. Refer to AOC TV01 in Table FMP-19.

Summary of Public Comments

No comments received.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: TVw

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Tourism-timing restriction.

(b) Dimensions of area of concern:
- As mapped, boundaries of blocks 12.130, 12.131, 12.181, 12.498, 12.503, 12.513, 12.339, 12.333, 12.884, 12.162, 12.158, 12.160

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

Seasonal restriction on harvest, and mechanical site preparation operations between May 1 and October 31. No restrictions of timing of low-noise renewal activities. All operations are permitted between November 1 and April 30th.

(c) Environmental Analysis:

(i) Potential effects: Will maintain sense of remoteness.

(ii) Advantages/disadvantages: This prescription maintains the sense of remoteness. No disadvantage to the identified values however, the prescription limits the flexibility of harvest operations.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: Seasonal harvest restriction was the only prescription that addressed the identified values therefore only one option was developed. The prescription allows for timber extraction while ensuring that the sense of remoteness is maintained.

(c) Exception: No

3. Summary of Public Comments

Comments were supportive of the seasonal harvest restriction. Comments were received from mainly tourist establishments expressing concern with summer harvesting and its effect on their business.

4. Selected Prescription

See Alternative 1.

C: Conditions on Operational Roads

Refer to AOC TVw in Table FMP-19.

Summary of Public Comments

None received.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: TVwl

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Tourism – Wine Lake

(b) Dimensions of area of concern:
- As mapped, boundaries of blocks 12.354

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:
No harvest or mechanical site preparation operations between May 1 and October 31. No restrictions on timing of low-noise renewal activities. All operations are permitted between November 1 and April 30th. A 200 m no-harvest reserve as mapped along top end of Wabauskang Lake and river leading into Wine Lake. Wine Lake Camp owners are to be notified prior to harvest.

(c) Environmental Analysis:

(iii) Potential effects: Will maintain sense of remoteness.

(iv) Advantages/disadvantages: This prescription maintains the sense of remoteness. No disadvantage to the identified values however, the prescription limits the flexibility of harvest operations.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: Seasonal harvest restriction and 200 m no harvest reserve was the only prescription that addressed the tourism sense of remoteness therefore only one option was developed. Prescription developed with affected tourism operator. The prescription allows for timber extraction while ensuring that the sense of remoteness is maintained.

(c) Exception: No

3. Summary of Public Comments

Prescription developed with affected tourism operation.

4. Selected Prescription
See Alternative 1.

C: Conditions on Operational Roads

Refer to AOC TVwl in Table FMP-19.

Summary of Public Comments

None Received

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: TVgl

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Tourism – Gibi Lake

(b) Dimensions of area of concern:
- As mapped, boundaries of blocks 12.168 and 12.170.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

60 meters no-harvest reserve from Witch Bay road. No harvest and mechanical site preparation operations are permitted between Victoria Day and Labour Day holidays. No restrictions of timing of low-noise renewal activities. All operations are permitted between Labour Day (September) and Victoria Day (May) with the exception of no weekend operations permitted between Labour Day and Thanksgiving (Friday 5 p.m. to Sunday 6 p.m.).

(c) Environmental Analysis:

(v) Potential effects: Will maintain sense of remoteness.

(vi) Advantages/disadvantages: This prescription maintains the sense of remoteness. No disadvantage to the identified values however, the prescription limits the flexibility of harvest operations.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: Seasonal harvest restriction was the only prescription that addressed the identified values therefore only one option was developed. Prescription developed with affected stakeholders. The prescription allows for timber extraction while ensuring that the sense of remoteness is maintained.

(c) Exception: No

3. Summary of Public Comments
None received

4. Selected Prescription
See Alternative 1.

C: Conditions on Operational Roads

Refer to AOC TVgl in Table FMP-19.

Summary of Public Comments
None received

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: TVer

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Tourism – English River Waterway Park

(b) Dimensions of area of concern:
- As mapped, 500 m from park boundary.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

Within 500 m of the park boundary, no harvest will occur between April 1 and September 30.

(c) Environmental Analysis:

(i) Potential effects: Will maintain sense of remoteness.

(ii) Advantages/disadvantages: This prescription maintains the sense of remoteness. No disadvantage to the identified values however, the prescription limits the flexibility of harvest operations.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: The prescription allows for timber extraction while ensuring that the sense of remoteness is maintained. Prescription developed with Park Ontario.

(c) Exception: No

3. Summary of Public Comments
None received.

4. Selected Prescription
See Alternative 1.

C: Conditions on Operational Roads

Refer to AOC TVer in Table FMP-19.

Summary of Public Comments
None Recieved

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: **TVal**

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Tourism – Aerobus Lake

(b) Dimensions of area of concern:
- As mapped, boundaries of blocks 04.389.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

No harvest or mechanical site preparation operations between May 1 and October 31. No restrictions of timing of low-noise renewal activities. All operations are permitted between November 1 and April 30th.

(c) Environmental Analysis:

(iii) Potential effects: Will maintain sense of remoteness.

(iv) Advantages/disadvantages: This prescription maintains the sense of remoteness. No disadvantage to the identified values however, the prescription limits the flexibility of harvest operations.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: Seasonal harvest restriction was the only prescription that addressed the identified values therefore only one option was developed. The prescription allows for timber extraction while ensuring that the sense of remoteness is maintained. This prescription is consistent with a previous Resource Stewardship Agreement in place prior to the Whiskey Jack Forest reverting to a Crown management unit.

(c) Exception: No

3. Summary of Public Comments
None received

4. Selected Prescription
See Alternative 1.

C: Conditions on Operational Roads

Refer to AOC TVal in Table FMP-19.

Summary of Public Comments

None received

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: TVp

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Tourism – identified portage trails

(b) Dimensions of area of concern:
- As mapped.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

No harvest, renewal or tending permitted in the AOC.

Measured from the edge of the identified portage as mapped, 30 to 90 m AOC based on slope as follows:

Slope (%)	Slope Angle (degrees)	Width of AOC
0 - 15	0 - 8.5	30 m
>15 - 30	8.6 – 16.7	50 m
>30 - 45	16.8 – 24.2	70 m
> 45	> 24.2	90 m

(c) Environmental Analysis:

(i) Potential effects: Will maintain sense of remoteness. Operations crossing trails may damage the portage trail and create conflicts with other forest users.

(ii) Advantages/disadvantages: This prescription maintains the sense of remoteness and protection of the value. No disadvantage to the identified value.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: This prescription provides protection for the identified value and acknowledges the importance of trails on the forest to other forest users.

(c) Exception: No

3. Summary of Public Comments
None.

4. Selected Prescription
See Alternative 1.

C: Conditions on Operational Roads

Refer to AOC TVp in Table FMP-19.

Summary of Public Comments
None.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: TVc

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)
- Tourism – campsites

(b) Dimensions of area of concern:
- As mapped.

B: Operational Prescription

1. Environmental Analysis of Alternative Operational Prescriptions

(a) **Alternative identifier/number: 1**

(b) Description of proposed operational prescription:

- 70 metre reserve from campsite centre.
- No harvest, renewal or tending operations permitted.

(c) Environmental Analysis:

(i) Potential effects: Operations near campsites may create damage and create conflicts with other forest users. Implementation of prescription will maintain sense of remoteness.

(ii) Advantages/disadvantages: This prescription will prevent damage to campsites and conflicts with other forest users, and will maintain a sense of remoteness. No disadvantage to the identified values.

2. Proposed Operational Prescription

(a) Description: **Same as Alternative 1.**

(b) Rationale: This prescription provides protection for the identified value and acknowledges the importance of campsites on the forest to other forest users.

(c) Exception: No

3. Summary of Public Comments
None.

4. Selected Prescription
See Alternative 1.

C: Conditions on Operational Roads

No operational roads proposed.

D: Primary or Branch Road Crossing

No primary or branch roads proposed.

E: Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: NE9

2. Description of Natural Resource Feature, Land Use or Value:

a) Description:
Trumpeter Swan Nesting Site

Secondary Values
Fish habitat
Water Quality

b) Dimensions of AOC:
120 metres.

B. Operational Prescription:

1. Environmental Analysis of Alternative Operational Prescriptions:

a) Alternative identifier/number: 1

b) Description of proposed operational prescription:

Reserve Zone

Measured from the edge of the standing timber as mapped, 30 to 90 m AOC based on slope as follows:

Slope (%)	Slope Angle (degrees)	Width of AOC
0 - 15	0 - 8.5	30 m
>15 - 30	8.6 – 16.7	50 m
>30 - 45	16.8 – 24.2	70 m
> 45	> 24.2	90 m

No forest management operations are permitted within the reserve.

Modified Zone
Outside of the slope-based reserve, a 120 metre modified operations zone, measured from the high water mark, where the following restrictions apply;

i. Harvesting, mechanical site preparation, and aerial spray operations are permittted between August 15th and April 15th,
ii. Tree planting is permitted but limited to one (1) crew of four (4) planters and ATV use is to be kept to a minimum. Tree caches are to be located as far from the nest as possible.

c) Environmental analysis:
This prescription will protect the nesting site and ensure the birds are not disturbed during the nesting period.

2. Proposed Operational Prescription:

a) Description:
See alternative # 1 above

b) Rationale:

- There is no forest management guide for trumpeter swan nesting sites. Prescription meets or exceeds requirements for protection of lakes, rivers, ponds, and stream values as required of the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales, 2010*.
- Harvest, mechanical site preparation and aerial herbicide spray operations within the modified operations zone will be conducted outside of the nesting season as to avoid disturbing the nest. The maintenance of a minimum 30 metre reserve around the nesting site and maintaining residual trees in the modified operations zone will contribute towards mitigation of changes to the landscape created by clearcut harvesting by reducing the visual impact of the cutover area as seen from the nest. Conditions on the number of tree planters will minimize disturbance to the nesting birds and contribute towards mitigation of changes to the landscape created by clearcut harvesting.

Only one alternative was documented for this AOC because:

- The prescription is based on a similar prescription used in previous Forest Management Plans. There was no known negative effect on the swans.

c) Exception:
No

3. Summary of Public Comments:
No comments received

4. Selected Prescription:
See alternative # 1 above.

C. Conditions on Operational Roads

Not applicable – none permitted.

D: Primary or Branch Road Crossing

Not applicable – none proposed in AOC.

E. Monitoring Program

Not applicable.

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: LS01

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)

- Lac Seul Shoreline (Remoteness, aesthetics, fisheries, water quality, cultural heritage)

(b) Dimensions of area of concern:

- 650m from the shoreline of Lac Seul

B: Operational Prescription

a) Description:
No timber harvested within 120 meters of the shoreline of Lac Seul. No conditions on harvest, renewal or tending between 121 – 650 m from the shoreline; conditions on roads only, refer to table FMP-19.

b) Rationale:
A General Use Area has been identified around Lac Seul. The prescription matches the policy direction from the Lac Seul Lake Management Plan (Section 5.0, Page 11).

c) Exception:
No

3. Summary of public comments:

No public comments have been received to date.

C: Conditions on Operational Roads
Refer to FMP-19.

Summary of Public Comments
No public comments have been received to date.

D: Primary or Branch Road Crossing

Not applicable – none proposed

E: Monitoring Program

Not Applicable

This supplementary documentation is organized into five parts for each individual or group Area of Concern:

A: Area of Concern Description
B: Operational Prescription
C: Conditions on Operational Roads
D: Primary and Branch Road Crossings
E: Monitoring Program

A: Area of Concern Description

1. Area of Concern (AOC) Identifier: WS01

2. Description of Natural Resource Feature, Land Use or Value:

(a) Description of natural resource feature (s), land use(s) or value(s)

- Rivers, stream segments – high or moderate potential sensitivity (HPS or MPS) to forest management operations identified prior to plan approval.

(b) Dimensions of area of concern:

- For *rivers* and *HPS* streams, 30 to 90 m AOC based on slope as follows:

Slope (%)	Slope Angle (degrees)	Width of AOC
0 - 15	0 - 8.5	30 m
>15 - 30	8.6 – 16.7	50 m
>30 - 45	16.8 – 24.2	70 m
> 45	> 24.2	90 m

For *MPS streams*, 30 m AOC as mapped.

B: Operational Prescription

AOC supplementary documentation is not required for the operational prescription.
Refer to AOC WS01 in Table FMP-10.

C: Conditions on Operational Roads

AOC supplementary documentation is not required for Conditions on Operational Roads.
Refer to AOC WS01 in Table FMP-19.

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

April South Road – AP-01

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

AP-01 is an existing crossing that may need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The April South Road is located to utilize an existing road, however the water crossing location may need upgrading. In addition to utilizing the existing road location, lakes and other impeding factors within or adjacent to the road corridor make this AOC crossing unavoidable. There are no other known values impacted by these crossings. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

April South Road – AP-02

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

AP-02 is an existing crossing that may need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The April South Road is located to utilize an existing road, however the water crossing location may need to be upgraded. In addition to utilizing the existing road location, lakes and other impeding factors within or adjacent to the road corridor make this AOC crossing unavoidable. There are no other known values impacted by these crossings. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Yellow Girl Road – YE-01

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

YE-01 is a new crossing proposed as part of the construction of the new primary road listed above. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The crossing is located on a flat section with approximately 1% grade and good cobble located in the area to minimize erosion of the site. This location represents the best alternative available within the corridor as other locations will require more than one crossing or to be located across swamp or flood plain areas. There are no other known values impacted by these crossings. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Yellow Girl Road – YE-02

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

YE-02 is a new crossing proposed as part of the construction of the new primary road listed above. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The crossing is located in a narrow section of a swampy area that has a relatively defined channel in comparison to many areas around this location. This location represents the best alternative available within the corridor. There are no other known values impacted by these crossings. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Bug Lake Road – BU-01

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

BU-01 is an existing crossing that will need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The water crossing location is on the existing road location. The re-use of this location will minimize disruption of other areas along the stream. There are no other known values impacted by this crossing although it is in an area of high potential cultural heritage, by re-using the existing location there is no opportunity to damage any potential cultural heritage. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Bug Lake Road – BU-02

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

BU-02 is an existing crossing that will need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The water crossing location is on the existing road location. The re-use of this location will minimize disruption of other areas along the stream. There are no other known values impacted by this crossing. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Aesthetic Road – AE-01

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

AE-01 is an existing crossing that will need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The water crossing location is on the existing road location. The re-use of this location will minimize disruption of other areas along the stream. There are no other known values impacted by this crossing although it is in an area of high potential cultural heritage, by re-using the existing location there is no opportunity to damage any potential cultural heritage. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Aesthetic Road – AE-02

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

AE-02 is an existing crossing that will need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The water crossing location is on the existing road location. The re-use of this location will minimize disruption of other areas along the stream. There are no other known values impacted by this crossing although it is in an area of high potential cultural heritage, by re-using the existing location there is no opportunity to damage any potential cultural heritage. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Aesthetic Road – AE-03

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

AE-03 is an existing crossing that will need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The water crossing location is on the existing road location. The re-use of this location will minimize disruption of other areas along the stream. There are no other known values impacted by this crossing although it is in an area of high potential cultural heritage, by re-using the existing location there is no opportunity to damage any potential cultural heritage. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Aesthetic Road – AE-04

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

AE-04 is an existing crossing that will need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The water crossing location is on the existing road location. The re-use of this location will minimize disruption of other areas along the stream. There are no other known values impacted by this crossing although it is in an area of high potential cultural heritage, by re-using the existing location there is no opportunity to damage any potential cultural heritage. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Witch Bay Road – WB-05

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

WB-05 is an existing crossing that may need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The water crossing location is on the existing road location. The re-use of this location will minimize disruption of other areas along the stream. There are no other known values impacted by this crossing although it is in an area of high potential cultural heritage, by re-using the existing location there is no opportunity to damage any potential cultural heritage. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Witch Bay Road – WB-06

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

WB-06 is an existing crossing that may need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The water crossing location is on the existing road location. The re-use of this location will minimize disruption of other areas along the stream. There are no other known values impacted by this crossing although it is in an area of high potential cultural heritage, by re-using the existing location there is no opportunity to damage any potential cultural heritage. No interested or affected persons or organizations have provided comments on these AOC crossings.

Refer to FMP-19 for preventative and mitigative measures appropriate for the aforementioned AOC crossings.

2. Summary of Public Comments

None.

3. Selected Crossing Location

See Proposed Crossing Location

D: Primary or Branch Road Crossing

ROAD NAME IDENTIFIER:

Witch Bay Road – WB-07

1. Proposed Crossing Location

(a) Identification of the 100m metre wide location (i.e. individual AOC identifier) for the road

WB-07 is an existing crossing that may need to be re-built in this plan. For each crossing, the 100 m location is shown on the Areas Selected for Operations Maps. There is no variation from the proposed crossing.

A complete listing of the road name, water crossing numbers and the conditions on the construction or use is presented in table FMP-19 under WSO1.

(b) Rationale for the crossing location

The water crossing location is on the existing road location. The re-use of this location will minimize disruption of other areas along the stream. There are no other known values impacted by this crossing although it is in an area of high potential cultural heritage, by re-using the existing location there is no opportunity to damage any potential cultural heritage. Supplementary Documentation I

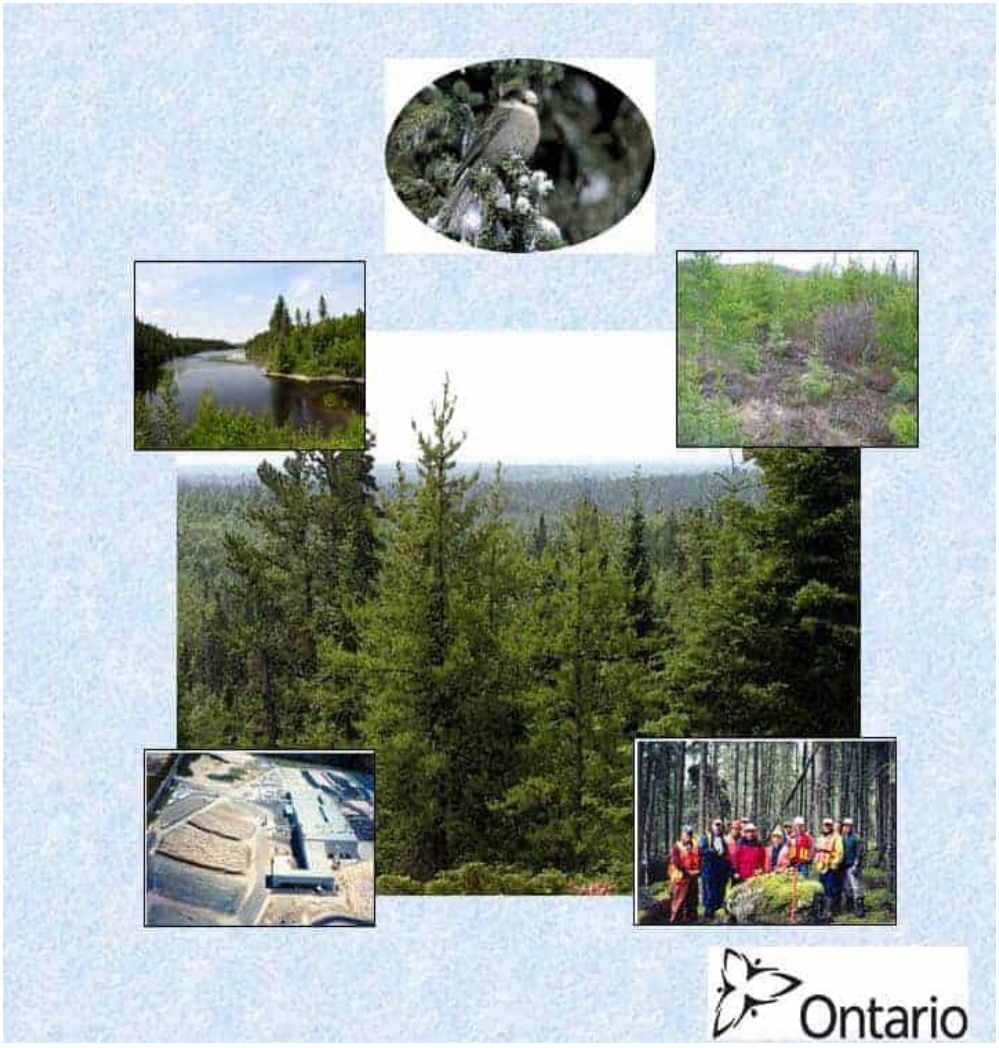
2012-2022 Whiskey Jack Forest Management Plan

Summary of Public Consultation

Includes:
(i) a summary of each stage of consultation.
(ii) a summary of all comments received and the consideration of those comments; and
(iii) a summary of issue resolution.



Summary of Public Consultation for the Whiskey Jack Forest 2012-22 FMP

Mail Out

Invitation to Participate

A letter to affiliations including approximately 800 stakeholders and 545 property owners was sent on January 29, 2010. This letter advised the stakeholders that planning for the 2012-2022 Whiskey Jack Forest Management Plan was about to begin. It invited stakeholders to provide input and views on desired benefits and contributions to background information and values.

LTMD

A letter to affiliations including approximately 800 stakeholders and 545 property owners was sent out on December 14, 2011 to all known stakeholders advising of LTMD

(See Contingency Plan Consultation for communications during hiatus between 2010-2013)

Stage 3

A letter to affiliations including approximately 800 stakeholders and 545 property owners was sent on January 31, 2013. This letter invited stakeholders to the 'Proposed Operations' Information Centre for the 2012-2022 Whiskey Jack Forest Management Plan to be held March 4 to 7th in Kenora, Sioux Narrows, Red Lake and Ear Falls.

Draft Plan

A letter to affiliations including approximately 800 stakeholders and 545 property owners was sent on July 30, 2013. This letter invited stakeholders to Information Centres for the 2012-2022 Whiskey Jack Forest Draft Management Plan to be held September 3 to 6th in Kenora, Sioux Narrows, Red Lake and Ear Falls.

Communication

Invitation to Participate

Newspapers advertisements were placed in the following editions with the dates provided:

Kenora Daily Miner and News	February 2, 2010
Sioux Lookout Wawatay News	February 18, 2010
Lake of the Woods Enterprise	February 6, 2010
Dryden Observer	February 10, 2010
Red Lake Northern Sun News	February 3, 2010

(See Contingency Plan Consultation for communications during hiatus between 2010-13)

LTMD

EBR Posting Approved November 22, 2011 (Withdrawn)
EBR Posting Approved December 24, 2011

Notices were published in local newspapers

Kenora Daily Miner and News	December 14, 2011
Lake of the Woods Enterprise	December 17, 2011
Dryden Observer	December 21, 2011
Sioux Lookout Wawatay News	December 22, 2011

Stage 3

Newspaper advertisments were placed in the following editions:

Kenora Daily Miner and News	January 29, 2013
Kenora Lake of the Woods Enterprise	January 28, 2013
Northern Sun News	February 2, 2013
Dryden Observer	February 2, 2013
Sioux Lookout Wawatay News	February 14, 2013

Draft Plan

Newspaper Advertisements were placed in the following informing of dates of the Information Centres.

Kenora Daily Miner and News	August 2, 2013
Kenora Lake of the Woods Enterprise	August 1, 2013

Information Centres were held as follows:

Sioux Narrows – September 4, 2013 – 0 members of public attended
Red Lake - September 4, 2013- 6 members of public attended
Ear Falls – September 5, 2013 – 10 members of public attended
Kenora – September 6, 2013 – 4 members of public attended.

First Nations Communications
Invitation to Participate
Letters were sent from the District Manager to the current chief of each First Nations Community in both the Whiskey Jack and the Kenora Forest Management Units as an Invitation to Participate in the 2012-2022 Plans. The letter mentions the possibility of combining forest units as well as the need for an Aboriginal Task Team.

Only one response was received through the Minister's Office. A response from the Ministers Office was sent out June 22, 2010

LTMD
Registered Letter was sent to communities and Metis Council on December 14, 2011 inviting review and comment on the Long Term Management Direction for the Whiskey Jack Forest. One community requested a open house in early 2012.

(See Contingency Plan Consultation for communications during hiatus)

Stage 3
Letters were sent January 14, 2013 from the District Manager to the Resource Mangers of First Nations Communities to inform that Planning is starting for the WJFFMP 2012-2022. Please advise if council would like a session brought to their community.

On January 31, 2013, a follow up letter was sent from the District Manager to Chiefs within the WJF and the Metis Council announcing the MNR et al intentions to hold public information centres on the progress to date in the preparation of the FMP for the WJF.

Draft Plan

.

On July 30, 2013, a detailed information package and letter was sent to Chiefs within the WJF and to the Kenora Metis Council regarding the upcoming information centres for the Draft Plan.

Summary of remaining responses:

Invitation to Participate

Environmental Agency	2 requests to be added to mailing list
Miscellaneous	Public member questioned Biodiversity, Historic forest condition Marten and Old Growth and WJF Independent Audit
Private Land Owners	7 responses, 4 of which requested additions/changes to mailing list.
Utilities/Pipelines	1 response concerning work around pipelines
Tourist Operators	4 responses from initial mail out

LTMD

Municipalities	one municipality questioned whether there would be activity within their municipal boundary.
Rec/Special Interest Group	series of communications regarding canoe routes and AOC's between one group.
LCC	email sent to LCC members on December 14, 2011. Met via Con Call with Red Lake LCC on January 11, 2012.
Forestry	Three forest industries sent letters of support to the Minister regarding the LTMD for the WJF.
Cottager/Private Land	two cottagers or their representatives requested information on this stage.
Environmental	One representative from an environmental group has maintained communications throughout the planning process.

Stage 3

Trapper	requested map of trapline area
Cottager/Private Land	Notice sent to Lake of the Woods Area News
Special Interest Group	referred to confusion of dates on EBR. Noted that AOC's are Now added to canoe routes.
LCC	Presentation made to Red Lake LCC on Feb 5/13. Also Kenora LCC member requested copies of OP maps.
Tourist Operator	Two operators responding (also several during contingency plan). Wanted maps and information on operations.

Draft Plan

Correspondence received to date during the Draft Plan stage are as follows.

First Nations	– follow up emails to communities regarding hosting information centres.
Cottager/Private Land	– one detailed submission requesting further information and stressing concerns.
Environmental Groups	– two large email campaigns, one consists of 680 emails to Premier and cc'd to forester regarding harvesting in Grassy Narrows area and one consisting of 1048 emails from Amnesty International focusing on 'Free Prior and Informed Consent' to forester and cc'd to Premier.
Tourist Operator	– one tourist operator requested maps and will be identifying Bear Bait areas.

Resource Based Tourism Mailout

Invitation to Participate

A follow-up to the initial invitation was sent out to tourist outfitters with interests within the Whiskey Jack Forest. A standardized set of questions were asked. Out of 163 tourist outfitters contacted, there were 8 responses.

Summary of Consultation
Whiskey Jack Forest 2012-2022 FMP

Invitation to Participate	Date	Comment	Response
Notices sent to Mail List.			
Notice sent to Media List			
Newspaper clippings			
attached organizational maillist			
attached private land and requests to be included list			
Shoal Lake Watershed list			
Registered Letters to FN communities.			
Wilderness Lodge	05-May-09	had concerns with CP and wanted to review maps.	explained that review period had expired but that the AWS would be coming up soon and once completed he would be notified through the regular channels.
Big North Lodge and Outposts	02-Mar-10	Re: remote tourism values. Recommends a formula for determining value.	Steve Duda discussed at LCC
Crowrock Lodge and outposts	23-Mar-10	wants to be kept informed on activities near Rowdy lake and boat cache lakes.	Spoke with lodge owner. Company noted that RSA was sent to him as well.
BMA holder	30-Apr-10	called J. Superovich/B. Ranta re concern over bear dens being destroyed during fmp operations	staff discussed concerns with BMA holder.
Wine Lake Camps	25-May-10	camp owner provided maps and reports of wildlife and fisheries values near his camp	Management Forester to provide response
Pickerel Creek Camp and Outpost	09-Dec-10	concerns with Aerobus an Deer Lake Roads.	Management Forester assured lodge owner that he would keep him informed of any work that is planned on these two road systems. Also suggested setting up a meeting.
Wine Lake Camps	08-Feb-11	in response to email from K.P., lodge owner voices concerns over portages between Wabaskang Lake and Anishishabi River. Wants to retain solitude for guests	Management Forester responded that they have a talk to discuss concerns.
Crowrock Lodge and outposts	11-Feb-11	Interested in areas around Rowdy Lake and the Western Penninsula	KMU Forester emailed a response and forwarded the email to Kurt Pochailo for WJF information.
Anishinabi Lodge	15-Feb-11	concerned that the Windfall and Deer Lake Roads were going to be connected.	Management Forester assured lodge owner that there is no current plan to join these two roads.
Nestor Fall Fly-In Outpost	18-Mar-11	operater concerned with values in area around Lount Lake, including timing and roads.	Management Forester promised to draft an AOC prescription that would take his concerns into account and send it to him to look over.
Big North Lodge and Outposts	08-Feb-11	1.Wondered if the RTV formula that was proposed and accepted last winter is now incorporated into the FMP. 3. Understood that RTV was to be incorporated, not to be pulled out for discussion as need arose. 5. Operator responded that this should be discussed again in March 2011.	2.MNR responded 'no' as there has been no discussion as yet with individual operators. 4. correct that it was accepted in principle. Discussed on April 23 that it may be inappropriate to carte blanche apply this formula to all tourism facilities…

Report of the Kenora Local Citizen's Committee (KLCC)
Whiskey Jack Forest 2012-2022 Forest Management Plan
April 2009 – September 2012

INTRODUCTION

This report is prepared in accordance with the Forest Management Planning Manual for Ontario's Crown Forests (2009). The intent of the report is to summarize the activities of this committee and to document key issues and interests.

The Kenora Local Citizens Committee (KLCC) is an advisory committee to the District Manager of the Kenora District Ministry of Natural Resources. The committee consists of individuals from the surrounding communities with diverse interests and backgrounds. The current membership includes:

Member	Affiliation
Clarke Anderson – Chair	Kenora Trapper's Council
David Anderson	Independent
Wayne Bruce	LOWDPOA
Dave Canfield	City of Kenora
Karen Cederwall	Independent
Henry Dribnenky	LOWDPOA (Alternate)
Rod McKay	Forest Industry
Alasdair Mowat	Mineral Exploration
Dale Munro	Forest Industry (Alternate)
Alex Rheault	Tourism
Pat Rheault	Tourism (Alternate)
Mark Scott	Independent Loggers
Sandra Triskle	Kenora Métis Council
Floyd Triskle	Kenora Métis Council (Alternate)

The area covered by this local citizens committee is the Kenora District, which includes all of the Kenora Forest and the majority of the Whiskey Jack Forest. The remainder of the Whiskey Jack Forest lies within the Red Lake District and as a result, the Red Lake Resource Management Committee also plays an advisory role.

The Kenora Forest and the Whiskey Jack Forest are both on the 2012-2022 planning schedule and, in order to increase efficiencies, the KLCC serves as the Local Citizens Committee for both forests. Throughout the period covered by this report, many KLCC meetings included discussion and information about both the Kenora and Whiskey Jack Forests. When the Kenora Forest 2012-2022 Forest Management Plan (FMP) was completed, planning continued on the Whiskey Jack 2012-2022 Forest Management Plan. This KLCC Activity Report has been prepared for the 2012-2022 Whiskey Jack FMP, but may include some discussions on forest management planning in general, and the Kenora Forest 2012-2022 FMP.

At monthly KLCC meetings, members reviewed the Whiskey Jack Forest components as presented, and received FMP updates and status reports regularly from the Planning Team. The KLCC has participated in several Forest Management Planning activities.

ACTIVITIES

- KLCC representatives: W. Bruce was nominated as KLCC representative on the Planning Teams for the Whiskey Jack and Kenora Forests.

- The KLCC representative participated in almost all of the Planning Team meetings for the Whiskey Jack Forest FMP.

- There were 43 total KLCC meetings from April 2009 to June 2013..

May 26, 2009	*October 12, 2010*	*January 24, 2012*
July 7, 2009	*November 4, 2010*	*February 8, 2012*
August 5, 2009	*December 7, 2010*	*March 27, 2012*
September 14, 2009	*December 21, 2010*	*May 1, 2012*
December 1, 2009	*January 25, 2011*	*May 24, 2012*
January 19, 2010	*February 28, 2011*	*June 14, 2012*
February 2, 2010	*April 12, 2011*	*August 14, 2012*
March 2, 2010	*May 10, 2011*	*October 30, 2012*
March 30, 2010	*June 21, 2011*	*January 9, 2013*
April 27, 2010	*July 19, 2011*	*February 28, 2013*
May 18, 2010	*August 23, 2011*	*May 9, 2013*
June 23, 2010	*September 20, 2011*	*June 3, 2013*
August 30, 2010	*November 7, 2011*	*August 28, 2013*
September, 20, 2010	*December 6, 2011*	*October 9, 2013*
		November 12, 2013

- At monthly KLCC meetings, members reviewed both the Kenora Forest FMP and Whiskey Jack FMP components as presented and received planning updates from Planning Team members.

- KLCC members reviewed and made recommendations on amendments.

TRAINING

2009 *April* - Forest Management Training in Kenora
K. Cederwall in attendance.

November - Long Term Management Direction Training in Kenora
H. Dribnenky, D. Anderson, and R. McKay in attendance.

2010 *September* - Operational Planning/Changes
H. Dribnenky in attendance.

2011 *April* – LCC Training Modules – option for all KLCC members to complete online.

ACKNOWLEDGEMENTS

The KLCC would like to acknowledge all of the effort that both Henry Dribnenky and Stephen Duda put into this current FMP, as well as forest management planning in Kenora District in general, and thank them for all of their hard work.

KLCC MEETING DISCUSSIONS AND INFORMATION SHARING

This section includes a summary of the topics and issues raised and discussed at KLCC meetings during the time period covered by this report. Some topics are specific to the Whiskey Jack Forest, while others are pertinent to both the Whiskey Jack and Kenora Forests.

Inventories

Independent Forest Audit

The Whiskey Jack 2009 independent forest audit was discussed by the KLCC at several meetings (5+). The committee requested and received presentations from the auditors and was provided a short text version of the audit, as well as copies of the final report on two separate occasions. Early on, the KLCC noted that silviculture was of particular interest and expressed skepticism that audit findings would have any beneficial influence in the current FMP process. Some KLCC members were of the impression that audit findings would be watered down before being finalized and in essence, MNR and Industry would 'pull the wool over the public's eyes'. Other concerns include questions about who has liability for silviculture shortfalls, roads abandonment, and slash pile maintenance associated with the previous Sustainable Forest Licence. The KLCC is also concerned about whether the public received value for money invested in respect of silviculture and if funding would be available to address audit findings associated with silviculture shortfalls. The KLCC documented these concerns in a November 9, 2010 letter to the District Manager and the MNR formally responded to these concerns in a letter to the KLCC dated March 16, 2011. Additionally, the MNR provided information to the KLCC on how two of the audit recommendations have been addressed in the silviculture strategy for the 2012-2022 Whiskey Jack Forest FMP.

SFMM (Strategic Forest Management Model), Volume Discrepancies

SFMM and the discrepancies between planned and actual harvest volumes has been a long standing concern for the KLCC. Much discussion has occurred at KLCC meetings throughout the time period covered by this report and many concerns have been expressed about SFMM. It is the impression of many committee members that plan authors can, and do, change the numbers that are entered into the SFMM program until SFMM provides them with the desired answer. Additionally, many on the KLCC cannot understand why forest managers plan to harvest at one level when they know that traditionally the actual harvest is only a fraction of this level (e.g. plan to harvest 5,000ha/yr vs. actual harvest is 1,200ha/yr). At several KLCC meetings, representatives from MNR and Industry made presentations with the intent to explain the SFMM program and the planning rationale for annual harvest allocations; however these topics continue to be unclear and are still concerning to the KLCC.

Age Class Substitution

The KLCC has expressed concerns about age class substitution during the planning process and how it affects the long term sustainability of the forest. A committee member noted that age class substitution has been a problem in the past and is concerned about the trend to continue this practice. MNR provided the rationale for age class substitution on the Whiskey Jack Forest and explained it was an accepted planning tool within the FMP manual.

Climate Change

Climate change was discussed and the MNR explained that all management plans must include text referencing climate change. The KLCC expressed its concern with how climate change will affect the local forest and suggested that a climate change adaptation option should be included in the upcoming plans.

Internal KLCC Workings

Recruitment

The lack of First Nation representation on the KLCC has been discussed at several meetings (Grassy Narrows specifically and all First Nations in general). Early during the period covered by this report (spring/summer of 2009) a general letter of invitation was sent from the MNR to many area stakeholders and communities including First Nations and Métis. The Kenora Métis Council responded and is now represented on the KLCC but no response was received from First Nation communities. Later in the process (Feb 28, 2011) an additional letter was sent from the KLCC to all First Nation communities. One community indicated interest as a result of this letter, however they did not follow-up with attendance at a meeting. The KLCC continues to have no First Nation representation and this is a concern for several members.

Communication

The KLCC has expressed concerns on numerous occasions that MNR is not communicating all information to them that they should. On one occasion, a committee member noted that any issues that MNR discusses with industry should also be brought forward to the KLCC for information purposes. In another meeting, the KLCC expressed their opinion that historically they had been well informed about amendments to FMP's, but that recently they had the perception that they were not always being consulted. The forest managers for both the Kenora and Whiskey Jack Forests explained that although one amendment had not been presented to the committee (apologies provided), and two others had been presented after being classified as administrative, all other amendments had been presented to the committee. It was speculated by the MNR that the KLCC may have had the perception that they were not being informed of amendments because there had been an extended period of time without amendments (one full year). The KLCC also expressed concerns that the MNR is not providing a summary of compliance activities consistently. The MNR responded to this at the following meeting by providing a summary of the previous year's compliance activity for both forests while noting that there was minimal compliance activity because there had been minimal forest management activity.

Other Users

Grassy Narrows Mediation

The KLCC expressed on many occasions their extreme frustration with Justice Iacobucci's mediation talks with Grassy Narrows. The talks themselves were not of concern but the process in general was. The KLCC was extremely frustrated with the lack of communication about how the talks were proceeding and asked on many occasions for the MNR to arrange a meeting/conference call with Justice Iacobucci. The MNR was not able to schedule this meeting and has explained that this was due to Justice Iacobucci's busy schedule and the confidentiality of the talks themselves. Of equal concern for the KLCC was the length of time that the mediation talks took as well as the perceived extravagance of the meeting locations. On many occasions committee members questioned why the talks were occurring in Toronto and Winnipeg and not in Kenora or Grassy Narrows.

Resource Based Tourism

Early in the planning process a committee member provided the MNR with a tourism valuation formula to recognize resource based tourism values within an FMP. This formula was accepted in principle by the KLCC pending MNR review. The MNR explained to the committee that they believe the formula can be a tool to provide to resource based tourism outfitters for their use in developing Resource Stewardship Agreements.

Forest Management

Optimum Use of Wood Harvested

Several of the committee members have expressed concerns about the optimum end use of the wood being harvested. Committee members have heard that in some cases harvested wood was being used by mills to burn for energy (hog fuel) instead of for conventional purposes (sawlogs/pulp). In the opinion of the KLCC, this is not the proper end-use of forest resources. It has also been the concern of the KLCC that harvesting of conifer continues on the Whiskey Jack Forest while there are no local mills to utilize the wood (e.g. Kenora Forest Products). Instead this conifer is being utilized by the pulp mill in Dryden. It's the opinion of some KLCC that this conifer should not be harvested until local mills reopen; however other members did not agree and were happy that the wood was being utilized and providing employment. Some members of the KLCC are also concerned that prime, sawlog grade conifer stands are being harvested and utilized to produce pulp. In the KLCC's opinion these stands should not be targeted until the local mill reopens and in the interim mixed species stands should be harvested.

Pure Species Management

The KLCC has concerns about forest management direction to convert many mixed species stands to pure species stands. Foresters from both forests explained that it is the current opinion that forest stands prior to European settlement were pure species, and it is the desire to return to this condition. The committee expressed skepticism that this was true and inquired what effect conversion to pure conifer would have on wildlife such as moose and deer. One member expressed his

opinion that mixed species stands were part of the landscape in his childhood and in his opinion, are part of the natural condition.

Harvesting to Shoreline

Forest managers have described to the KLCC the forest management option to harvest to the shoreline in certain cases. They have explained the rationale and reiterated that it would only be considered in non-contentious and environmentally safe situations. However, the KLCC continues to have concerns about how harvesting to shoreline will affect fisheries, shoreline erosion, waterbodies, and their plant and wildlife communities.

Roads

Density of Roads

A member of the KLCC has expressed concerns about the number of roads that 'crisscross the forest' thereby detracting from the remote tourism value. The MNR, SFL and another member of the KLCC all explained that the forest industry needs to build a certain amount of roads to access harvest areas. Sometimes it is necessary to go around swamps, creeks, rock, etc. Roads must also be built to accommodate the weight of loaded pulp trucks, allow them to pass each other and turn around in certain spots. Due to the costs associated with road building and gravel hauling, the forest industry does not build more road than is actually needed.

PERSONAL OBSERVATIONS OF INDIVIDUAL KLCC MEMBERS

This section includes issues and opinions expressed by individual committee members. The individual comments may, or may not, reflect the collective opinion of the committee; however, all comments have been included in this report with full committee support.

Inventory

Inventory and Allowable Harvest Calculations

- There is concern that the inventory used for computer modeling does not represent the inventory on the ground. More ground-truthing is necessary. When harvesting, the estimated yield should be compared to the actual yield. The forest inventory should then be adjusted to the actual results. There is no measure of the accuracy of the inventory. This does not give a comfort level for those on the KLCC that doubt the accuracy.

- The KLCC has also heard how changes in the silvicultural ground rules and the assessment of silvicultural success will be modified in the 2012 plan, partly in response to auditor concerns. One outstanding concern that was raised by the auditor and the KLCC has to do with the inventory used in the 2012 plan. The auditor was concerned about how regeneration surveys and surveys of natural disturbances have been reflected in the inventory. The auditor questions the accuracy of some 112,000 ha of barren and scatter/regeneration surveys. The audit recommendation is that the results of those surveys must be reviewed to ensure that the inventory reflects the current forest condition. Errors in an area that size, roughly 15% of the productive land base, could have significant impact on descriptions of the current forest and consequently, the future forest and all plan objectives that project changes in forest condition.

Independent Forest Audit

- The Whiskey Jack FMP must incorporate the 2009 audit findings and recommendations.

- The committee has asked for details from the MNR in response to the 2009 Whiskey Jack audit. The LCC sent a letter to the MNR with a number of questions. The letter was sent on November 6, 2010 and it took MNR until March 16, 2011 to respond.
- The MNR prepares audit action plans based on audit report recommendations. These action plans are not made available to the LCC on a timely basis.

Sustainability and Accountability

- Sustainability should be determined prior to an audit. As illustrated by the Whiskey Jack audit in which the silviculture was badly mismanaged and the damage was not detected until the audit. By then corrective action in some cases is too late. There is no accountability or evident consequences if the forest is mismanaged. Again the Whiskey Jack Forest is an example of this allegation. Sustainability should be determined through Annual Reports, past Forest Operations Reports, etc. (from past experience). Using the Whiskey Jack Forest as an example, sustainability was only determined as a result of an audit which occurs many years later. The test for sustainability needs to be more transparent.

- In spite of indications of problems, there have been no meaningful discussions regarding forest inventory, miles of abandoned roads, & major disturbances within cut blocks. It appears that it is "business as usual", in spite of many indications that current practices are unsustainable.

SFMM

- The inputs and assumptions that are put into the SFMM model are suspect and are not transparent to the KLCC. The concern is that the inventory should represent the inventory on the ground. Inputs and assumptions are tweaked until the objectives are met for the LTMD. The model is run multiple times until the objectives and the targets are achievable or there is an explanation why not. The process must be more transparent.

- When the management plan has an objective, it seems to me the SFMM, age classes and inventories are tweaked and stretched to meet an unrealistic target.

- The short term impacts of age class substitution relative to the age class structure resulting from the strategic model must be explained.

- Members of the LCC have expressed concerns about the strategic models. I share those concerns. We've heard that the models are complex, not easily interpreted for non-users, and there is uncertainty about inputs and inventory, etc.

  Independent Forest Audits have reported that there is a trend toward forest conversion from conifer to hardwood or various types of hardwood/conifer mixed wood. This trend is evident in any analysis of past and present forest inventories. There is no question in my mind that forest management, namely logging, has caused changes in forest conditions that cannot be reversed through management as we see it in the current management plans. As it is, with government scientists predicting a progressively warmer and drier environment through time I think it is highly likely we will see more, not less, forest conversion to hardwood/mixed woods.

  The FMP doesn't consider climate change and for this and other reasons I think it doesn't really reflect past and likely future changes in forest cover.

  I would like to see a different approach to development of the strategic model. Move away from the unsustainable objective to produce wood and focus on the ecology of the forest, the historic logging pattern, and trends in changes in forest cover. Projections of silvicultural success have been adjusted to reflect results of recent regeneration surveys but I don't think that goes far enough. At a minimum, the model should include estimations of most likely changes in forest cover under climate conditions predicted in the climate change model. I think it's reasonable to think that long term forest composition and structure forecasts are still too optimistic in a forest that has already been significantly modified from the natural condition.

  The Racey/Towill report discusses a number of issues related to warmer/drier climate conditions that could be used to explore potential changes in forest cover.
  - longer and more severe fire seasons
  - earlier increased damage from windstorms
  - increases in insect infestation
  - encroachment by non-native plant species
  - lower productivity from typical silvicultural practices

Climate Change

- Forest Management Planning should include recommended methods to adapt our forest for climate change and mitigate our losses. Thus far FMPs are totally silent on the issues and the potential long term impact of climate change. An available computer model should be used to measure the carbon sink now and compare the net carbon sink after the Proposed Management Strategy is chosen.

- The KLCC has raised the question of climate change and why it isn't considered as an influencing factor in terms of the future forest condition in the development of current and past management plans. In the June 2005 KLCC Report, the KLCC said that computer modeling is necessary to predict 'what if' scenarios and the impacts of climate change on the sustainability of the forest.[1]

  Six years later, and we have yet to hear how forest managers are adapting plans in the event that predictions about climate change are right. Climate change is important to the Province of Ontario[2] and in fact the Province has developed the models that could be used to describe changes in forest condition resulting from various climate change scenarios.[3] The MNR Science Unit in Northwestern Ontario developed models specific to the Northwest Region that show changes in species distribution resulting from various climate change scenarios.[4] In that report, they show that in the worst case scenario, black spruce will no longer be a 'native' species by 2071 when climate change is taken into consideration. Similar changes are predicted for jack pine.

Recommendation: To consider the likely outcomes resulting from climate change, at a minimum the plan should:

a) Include a comprehensive assessment of the most likely climate change scenarios, using MNR science as the base.
b) Include measures to adapt to the predicted changes through silviculture.
c) Develop a future forest condition reflective of the changes predicted through climate change.
d) Adjust plan objectives and planned operations to be more reflective of the changes predicted as a result of climate change.

- In my opinion climate change is the most significant threat facing the global environment and lack of discussion about climate change in the plan is, in my opinion, a disappointing oversight. Climate changes predicted by MNR scientists will affect future forest conditions regardless of efforts of planners to manage the forest. Rather than focus on wood supply the plan should focus on adaptation and mitigation strategies as described in the Province of Ontario climate change policy. I think the record shows that the planning team spent part of one meeting two years ago on the climate change issue but decided to ignore it. At a minimum the planning team might have assigned someone to investigate the work done by Government of Ontario scientists to provide some perspective to the team (and the LCC) to be included in the FMP(s). The planning manual lists climate change as one of the topics that may be considered in development of the LTMD.

  I accept the conclusions of government scientists predicting changes in climate and forest cover. According to the science, we will see climate changes in time frames of less than 60-70 years, well within the 160 year planning horizon. The FMP predicts changes in forest conditions between 2012 and 2172 based on current climate conditions. I don't think the management strategy in the FMP is particularly reliable under those circumstances and I can't agree with a management strategy that disregards the scientific conclusions around climate change.

  The following is a list of some of the climate change sites available from the Province of Ontario that cover a wide range of climate change issues. The Province has a number of websites dedicated to reports on science and policy across all Ministries. The Ministry of Natural Resources has websites more specifically directed at forests and climate change as well as a 'tool' that allows the user to visual changes in climate over the next 100 years or so.

Clearly, the Province of Ontario has no reservations concerning the reality of climate change and the impacts climate change will have on our environment, including forests and forest management. Climate change is real, it is happening and there will be significant changes in our forests, particularly the Boreal forest, as the climate warms and becomes drier.

Internal KLCC Workings

Recruitment

- We have always had a problem attracting regular First Nation representation despite the repeated efforts and invitations from the MNR and sitting KLCC members.

- Most of us have trouble finding an alternate or a replacement if we want to retire. One reason often given to me is the KLCC advice and input is not given serious consideration. I have sometimes felt that the DM and the regional director ignore us as 'pesky gnats'.

Communication

- Members, from time to time, request things from the MNR (maps, copies, etc) to be brought to a meeting without bringing the request up for a vote as an action item.

- MNR personnel often have to take flack over things that are beyond their control.

- There is no communication between the Ontario Government's MNR and MNDM departments. Regarding our local Kenora MNR District office, copies of all meeting reports and maps should be forwarded to the regional MNDM's regional office in Thunder Bay. After processing, the pertinent information should be distributed to other stakeholders with concerns in the Kenora area.

Other Users

Aboriginal

- The issue between Grassy Narrows and the MNR continues and will continue to raise questions about the effectiveness of this entire process.

- After years of paying an extremely high priced facilitator and providing honorariums and cost-free trips (to several big cities) for dozens of 'negotiators', the blockade at Grassy Narrows remains in place and there are no near-by forest operations. Thousands of cords of harvested timber were stranded to rot in the forests beyond the blockade. The Segise Bridge has been washed out and, until harvesting is resumed, there are no resources available to repair the bridge on this logging road. Until it is once again passable, there is no short-cut for the community members to reach the Red Lake Road. I know that the local MNR office has little power to alter what is going on but I just had to vent my frustration over what I have heard is a constantly changing list of demands(?) and the seemingly insincere desire to come to an agreement. It seems to me, and to a lot of people I've talked to, that this situation has become a 'cash cow' for people involved.

- The LCC has been interested in the progress of the Grassy Narrows negotiations and the development of the Whiskey Jack LTMD. The LTMD is well advanced but the negotiations are on going. It isn't clear what aspects of the negotiations or the process agreement were considered in the development of the LTMD.

Forest Management

Wood Supply, Utilization

- There should be clarification of the wood supply objectives including volumes, species, products and destinations.

- The KLCC has asked about wood supply and how wood is being utilized in the current plan and where harvested wood will go in the upcoming FMP. The information available says that the wood supply targets for the Whiskey Jack plan are based on supply commitments from previous plans. In my opinion, these wood commitments are out of date and do not reflect the reality of the current forest industry. With the exception of the hardwood commitments to Weyerhaeuser there is no current local demand for any fibre from these forests, yet the target volumes are higher than ever, even when there were paper mill and sawmill operations.

  When I asked the question about wood supply commitments, I was told simply that allocations would be 'as per the FMPM'. In my opinion the MNR has no idea what the true wood supply is and where it might go.

  The problem with this approach is that these 'commitments' become the target in the arithmetic model. The target drives everything that follows, namely achievement of non-timber objectives. In my opinion, that isn't 'forest management' so much as it is 'supply management'.

  We hear others talking about Bill 151 and their belief that new legislation will open up Ontario's forests to export. We hear about the emerging use of forest resources for biofibre/biofuel.

  With these issues in mind and with the substantial volumes still forecast from the Whiskey Jack Forest, the KLCC has reason to be concerned about transparency in the planning process, especially regarding planned wood utilization.

  Recommendation: MNR should clarify wood utilization and provide realistic estimates of mill volumes and provide rationale for planned utilization considering volume estimates much higher than historic harvest levels.

- The MNR has approved a facility licence for a new facility in Kenora that plans to produce utility poles. The facility has been granted a wood supply (9,000 cubic metres) from the Kenora Forest through a Ministerial Directive. A similar volume has been directed from the Whiskey Jack Forest for a total of 18,000 cubic metres.

  Utility poles can be manufactured from jack pine or red pine; however red pine is clearly preferred. Red pine is also relatively scarce in the forest as a result of decades of harvesting and for the most part is found as scattered individuals, on islands or locked up in riparian reserves. The KLCC asked if a wood supply analysis was done before the license was issued and was told that confirmation of the wood supply was the responsibility of the proponent.

  It isn't clear if the Whiskey Jack FMP has considered a strategy to provide material for this new facility. In my opinion, from a social and economic perspective, it doesn't make a lot of sense to encourage investment in a facility reliant upon a reasonably specialized wood supply without confirming there is a long term sustainable supply.

  Recommendation: A wood supply study is required.

Pure Species Management, Protection of Local Interests

- Nearby pure, young conifer stands are made available in the plan when KFP is not in operation. To harvest conifer in mixed stands and turn them into the desired pure conifer stands is one thing, but I feel nearby pure conifer blocks should be preserved for now.

- It must be taken into account that there are very few large blocks of harvestable timber available and a few of them should be managed for future local needs.

- More conifer is targeted in the FMP than can be used locally at present.

- The KLCC heard presentations about the planning process from both planning teams about the planning process and how forest management will lead to a desired forest condition sometime in the future. The KLCC was told that the strategic plan is based on an understanding of the natural forest condition and that forest management is supposed to lead from

the current forest condition to a point where the forest resembles whatever is defined as the natural forest. The KLCC has heard that logging certain forest types and implementing strategic silvicultural strategies will over time lead to a forest that resembles the natural forest. All the arithmetic presented by the planning team seeks to demonstrate how that will be achieved.

I'm not convinced that proposed operations are consistent with that outcome. The KLCC hears from some that the current situation, heavily weighted to mixedwoods and hardwoods, may be the natural forest but we also hear that the natural forest would be more pure conifer and less hardwood. We also see that silvicultural strategies seem to be leaning toward low cost investments, which will not promote the pure conifer conditions.

This is confusing and leads to inconsistencies in planning. If the goal is to maintain the current forest condition then it may be completely acceptable to keep silviculture investments low and promote hardwood/mixedwood conditions. If the goal is to move toward purer conifer conditions, then there has to be a commitment to higher cost silvicultural strategies, which doesn't seem to be the case.

Independent audits for the Dryden and Whiskey Jack forest management units also indicate that harvesting has led to an increase in forest conversion from conifer (the type of tree that dominates the Boreal Forest landscape) to hardwoods such as aspen. This is very problematic from both a forest industry perspective as well as a wildlife habitat perspective, as many Boreal species are dependent on habitat that is made up primarily of conifer forests.[5]

Silviculture, Silviculture Ground Rules

- Current (5-10 year) harvest areas/volumes are calculated largely on the theory that silviculture today (harvest, renewal, tending and protection) will create a certain forest condition with specific species and harvest yields. Essentially the theory says that volume and species composition improves over time through silviculture and therefore more area can be cut today.

  The problem with the theory is that if the silviculture fails, if assumptions are overly optimistic or if in fact there is insufficient investment, then the theory collapses. The future forest does not materialize and forecast/current harvest levels are too high. As we learned from the audits, the current track in both the Kenora and Whiskey Jack Forest is toward more mixedwoods and less conifer. That forest condition will not produce the forecast yields and therefore current harvest levels, based on future returns, are too high.

  If we factor in the predicted changes in forest cover from climate change, the forecasts of future yields, forest condition and forest composition become unrealistic.

- The Whiskey Jack Forest long term silvicultural strategy talks about increasing pure species conditions, especially conifer, consistent with the natural forest condition. The KLCC has asked for information regarding silvicultural ground rules, but to date we haven't had an opportunity to discuss strategic silvicultural planning. The KLCC doesn't have the tools or knowledge to understand how the ground rules and their implementation during the plan term will contribute to the desired forest condition. The high proportion of natural regeneration in the Whiskey Jack suggests to me that silvicultural investments are not high enough to move toward the desired forest in a timely manner.

  These concerns have been discussed in previous independent forest audits.

  We concluded that the investment in conifer renewal is being jeopardized by a lack of adequate monitoring and tending on these ecosites. While the sites will eventually become mixedwood forest units (with a component of conifer), the objective of maintaining higher conifer stocking levels within these stands will not likely be achieved without further silvicultural interventions (i.e. infill planting, seeding, tending, etc.).[6]

  Silviculture practices, including a lack of tending of artificially regenerated areas, are leading to reduced stocking of conifer and an increased component of hardwood on the Forest. This trend does not support the management intention of maintaining a conifer dominated forest, as set out in the 2004-2024 Whiskey Jack Forest FMP.[7]

[6] Kenora Independent Forest Audit 2003/08 pg 41
[7] Whiskey Jack Independent Forest Audit 2004/09 pg iii

Recommendation: The MNR should assess and report on the ground rules and provide rationale describing how the ground rules as presented will provide the results required to achieve the future forest condition.

Roads

Density

- Word games are sometimes used to disguise what is really meant, for example new all-weather roads are not being accurately described as such.

- There are too many roads that crisscross the forest.

Decommissioning and Liability

- The MNR is too committed to decommissioning of roads and trails in Ontario because of the liability concerns. Question: "How many successful liability suits have been filed against the government; particularly, the MNR"? If the MNR and government are that concerned, they should put warning labels on all issued licenses; example, timber harvesting, minnow trapping, trapping, hunting, fishing, boating, camping, prospecting; et cetera. The "Warning Label" should read: "To enter Ontario Forests and water ways by means of water craft, foot or other means is at your own risk". The Government has already established legal precedence by labeling tobacco and alcohol products. The roads and trails have been paid for directly and indirectly by the Ontario tax payer, at great expense, both in construction and decommissioning and in several cases the same roads have been reconstructed with future decommissioning.

Mining and Agriculture

- The Provincial Government's MNR does not think outside the box! The roads and trails are constructed for timber purposes and timber purposes only. Any other resource activity is an annoyance. These road systems offer other opportunities in opening up resource development of mining and agriculture.

- Agriculture has been overlooked! Without going into a lengthy discussion on increasing food costs with dimensioning food supply with increasing food demand, the government has to look at agricultural development within the non-productive forest areas; examples are Quebec, Manitoba. Road access through these areas creates economic opportunities for First Nations. Included in this agriculture package are road /trail access to small lakes/ponds suitable for hydroponics development-floating rafts. In both cases, these land and water areas will provide vegetable and berry production for domestic consumption and financial income. The floating hydroponic platforms will provide shade for fish, which will increase fish harvesting production.

Whiskey Jack Forest – Red Lake Resource Management Committee participation

- March 2, 2009 meeting of the Red Lake Resource Management Committee (RLRMC): Committee approved a motion to endorse the Whiskey Jack Forest Contingency Plan.
- June 1, 2009 meeting of the RLRMC: Trevor Park provided an update on the Whiskey Jack Forest Contingency Plan/AWS.
- October 5, 2009 meeting of the RLRMC: Dave New and Laurent Tetreault provided an update on the IFA for the Whiskey Jack Forest, which took place in September 2009.
- February 1, 2010 meeting of the RLRMC: Conference call and PowerPoint presentations by Steve Duda and Abby Anderson on "Desired Forest and Benefits" for Whiskey Jack and Kenora Forests and a Desired Forest and Benefits Questionnaire.

  Rod Seabrook of KBM (phone-in and PowerPoint Presentation) provided a discussion on the findings of the IFA on the Whiskey Jack Forest that was conducted in September 2009.
- April 12, 2010 meeting of the RLRMC: Gregg Lloyd, Red lake MNR representative to the Whiskey Jack FMP planning team, provided an update and a handout regarding a major amendment proposal to the current Whiskey Jack Forest FMP.

  Trevor invited any RLRMC members to attend the Planning Team meeting on May 17, 2010.

  Discussion took place surrounding Desired Forest and Benefits to the Whitefeather Forest; some ideas transferable to the Whiskey Jack Forest.
- May 3, 2010 meeting of the RLRMC: Committee informed about Whiskey Jack Information Center for Major Amendment (Red Lake Rec. Centre: Wed. May 5 from 4-8 p.m. and Ear Falls Legion: May 6 from 4-8 p.m.).
- May 17, 2010 meeting of Whiskey Jack Planning Team: Laurent Tetreault attended as RLRMC rep.
- May 18, 2010 Desired Forest and Benefits meeting of KLCC: Laurent Tetreault attended as RLRMC rep.
- October 4, 2010 meeting of the RLRMC: Steve Duda, project manager for the Whiskey Jack FMP attended meeting and provided a presentation on Long Term Management Direction.
- November 4, 2010 meeting of RLRMC: Laurent Tetreault updated the group on intended harvest areas.
- December 6, 2010 meeting of RLRMC: Laurent Tetreault indicated that the next meeting of the Whiskey Jack FMP Planning team would be held on December 7, 2010 in Kenora.
- January 10, 2011 meeting of RLRMC: Laurent Tetreault provided an update, focusing on recent activities concerning bridge installation at Caribou Falls.
- February 7, 2011 meeting of the RLRMC: Steve Duda reviewed the Whiskey Jack LTMD and asked the RLRMC if they had any problems or issues with the current round of forest management planning. He also asked the RLRMC to consider what kind of protocol they feel should be put in place to coordinate the RLRMC and the KLCC.
- January 9, 2012 meeting of RLRMC: Steve Duda, via teleconference, gave the group an update on the stage of planning and anticipated next steps for the Whiskey Jack Forest.
- February 4, 2013 meeting of RLRMC: Hassan Mohamed, via teleconference, gave the group an update on Stage 3 of planning and the associated Information Centres.
- October 7, 2013 meeting of RLRMC: Shawn Stevenson, via teleconference, gave the group an update on Stage 4 of planning and the associated Information Centres.

Problems and Issues

There were no problems or issues identified that were specific to the Whiskey Jack Forest 2012-2022 FMP.

KLCC Effectiveness – WHISKEY JACK FOREST

As part of the Local Citizens Committee report for the draft plan phase of the Whiskey Jack Forest 2012-2022 Forest Management Plan, the KLCC were asked to complete an Effectiveness Survey. The survey consisted of 20 statements and the committee was asked to rank their agreement to the statements from 0 to 5 (0 = disagree, 5 = agree). The target set by the planning team for this objective is that the "LCC effectiveness survey results indicate a minimum of 60% effectiveness in the development of the FMP".

The overall effectiveness of the committee structure was determined by analysing all responses to all questions of the LCC Effectiveness Survey. Ten committee members completed and submitted the survey. The results of the survey are as follows:

	Question Number																				
KLCC Member	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**	**13**	**14**	**15**	**16**	**17**	**18**	**19**	**20**	***Avg. (%)***
1	3	5	5	3	4	5	2	3	2	1	1	N/A	N/A	2	3	4	2	1	2	3	57
2	4	4	3	4	4	4	4	4	3	4	3	4	4	5	4	5	5	4	4	5	81
3	5	5	4	5	5	5	5	5	5	4	4	4	3	5	5	4	4	5	5	5	92
4	4	4	4	3	4	4	5	5	5	4	4	5	4	5	2	5	4	5	5	3	84
5	5	5	4	5	4	5	5	5	4	4	4	5	4	2	4	4	5	5	4	4	87
6	5	4	4	5	5	4	5	4	5	4	4	5	5	5	4	4	4	4	5	4	89
7	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	5	100
8	2	2	2	3	2	4	4	3	2	2	2	2	5	5	4	5	4	2	2	4	61
9	4	4	3	4	4	5	4	5	3	2	3	4	4	4	4	4	4	4	4	4	77
10	5	4	3	4	5	5	5	5	5	3	4	5	4	5	5	4	5	4	5	4	89
Total	42	42	37	41	42	46	44	44	39	33	34	39	38	43	40	44	42	39	41	41	817
Avg/Ques.	4.2	4.2	3.7	4.1	4.2	4.6	4.4	4.4	3.9	3.3	3.4	4.3	4.2	4.3	4.0	4.4	4.2	3.9	4.1	4.1	4.1
																				%	**82.0**

The responses to survey questions were analysed and combined to arrive at the following assessments.

When asked how informed the KLCC members felt they were on the process and contents of the FMP, the overall average of the five questions in this section was 4.1/5 (82%).

The questions that assessed how involved the KLCC members felt they were in the development of the FMP resulted in an overall average of 4.3/5 (87%).

When asked how influential KLCC members felt they were in terms of decisions made during FMP development, the average response of the two questions in this section was 3.35 (67%).

The questions that assessed how well KLCC members felt they and other members represented their stakeholders resulted in an overall average of 4.1/5 (82%).

Overall, members believed that the KLCC functioned quite well, with an average response of 4.1/5 (82%).

The results of this analysis indicate that, in general, the KLCC ranks the committee's overall effectiveness at 4.1/5 (82%).

The committee's general agreement or disagreement with the forest management plan

The Kenora LCC is in general agreement with the Whiskey Jack Forest FMP. However, all KLCC members have expressed some level of reservation with one or more specific aspects of the plan.

WHISKEY JACK FOREST
2012-2022 FOREST MANAGEMENT PLAN
Local Citizen's Committee Effectiveness Survey

Public participation is integral to the forest management planning process. In addition to the consultation opportunities for the general public, Local Citizen's Committees (LCCs) participate directly in the forest management planning process. The completion of an LCC self-evaluation can help forest managers assess the effectiveness of the committee in the development of the forest management plan (FMP).

One of the Whiskey Jack Forest 2012-2022 FMP objectives is that the Kenora LCC completes a self-evaluation of its effectiveness in plan development. The target set by the planning team for this objective is that the LCC effectiveness survey results indicate a minimum of 60% effectiveness in the development of the FMP.

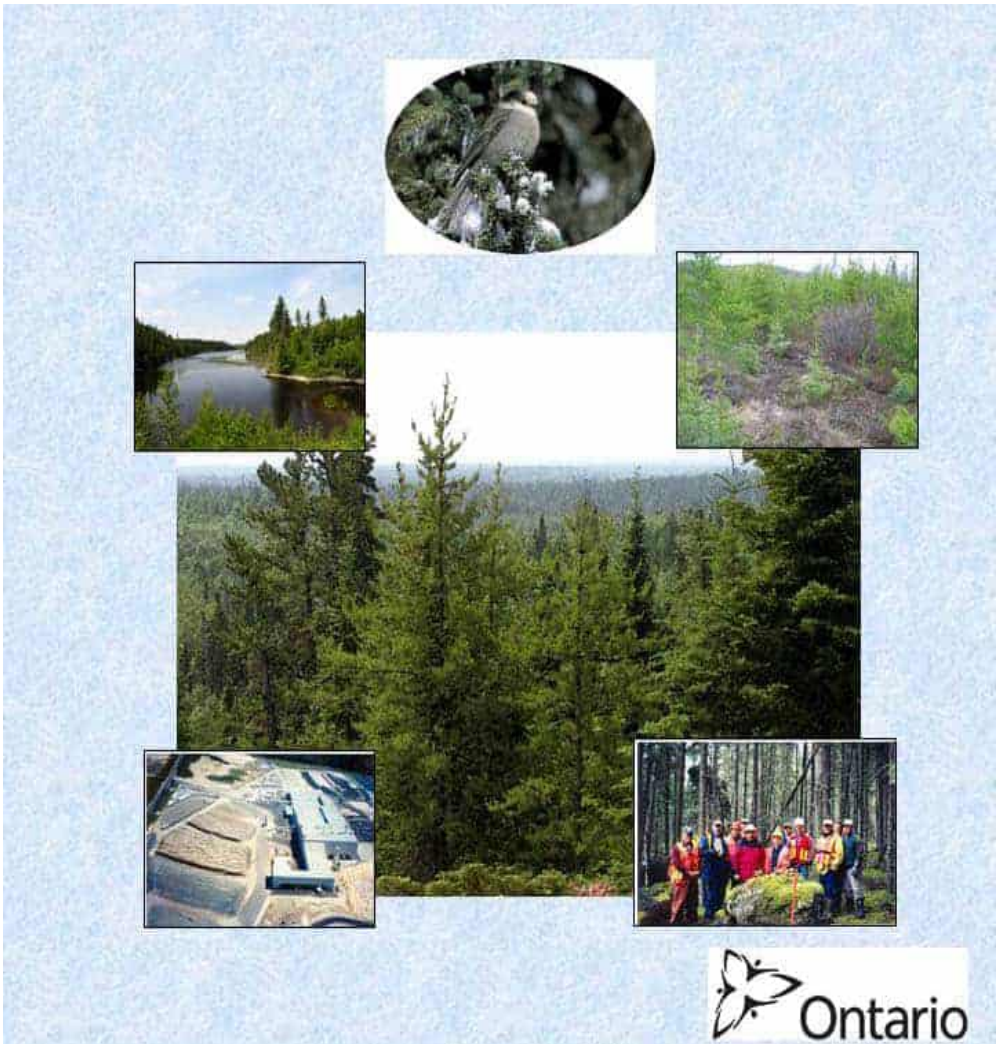
Considering *specifically* the development of the *Whiskey Jack Forest 2012-2022 FMP*, each LCC member is asked to respond to the following 20 questions by circling the appropriate number/ranking. You are not required to provide your name. If you have additional comments, please provide them at the end of the questionnaire. Thank you in advance for taking the time to complete this survey. If you have questions, please contact Abby Anderson at 468-2556 or abby.anderson@ontario.ca.

QUESTIONS	**RANKED RESPONSE**				
INFORMED – these questions assess how informed you as a local citizens committee member believes you were/are on the process and contents of the forest management plan.	**disagree**	←		→	**agree**
1. Adequate training opportunities & information was given to me to assist me in understanding the FMP process	**1**	**2**	**3**	**4**	**5**
2. I have an adequate understanding of the FMP process	**1**	**2**	**3**	**4**	**5**
3. I have an adequate understanding of the contents of the FMP	**1**	**2**	**3**	**4**	**5**
4. Sufficient & accurate information was provided to me to enable me to make informed decisions	**1**	**2**	**3**	**4**	**5**
5. Planning team members assisted me, as necessary, to understand the FMP	**1**	**2**	**3**	**4**	**5**
INVOLVED – these question assess how involved you believe you were in the development of the forest management plan	**disagree**	←		→	**agree**
6. I attended organized LCC functions & events (regular scheduled meetings, information centres, field tours) related to forest management planning	**1**	**2**	**3**	**4**	**5**
7. I have been given adequate opportunity to voice my opinions within the LCC	**1**	**2**	**3**	**4**	**5**
8. I have been a regular participant in LCC discussions	**1**	**2**	**3**	**4**	**5**
9. I feel that the planning team considered all viewpoints in developing the FMP	**1**	**2**	**3**	**4**	**5**
INFLUENTIAL- these questions assess how influential you as a local citizens committee member believed you were in terms of decisions made during the development of the FMP	**disagree**	←		→	**agree**
10. The LCC is effective at influencing decisions made in the FMP	**1**	**2**	**3**	**4**	**5**
11. I feel that the forest management planning team considered my input/viewpoint in forming their decisions	**1**	**2**	**3**	**4**	**5**
REPRESENTATIVE – these question assess your beliefs as to whether you were a representative of your stakeholders (i.e.: interest groups and organizations), and your views on how other LCC members represented their respective stakeholders.	**disagree**	←		→	**agree**
12. I was able to represent the views of my stakeholders as a member of the LCC	**1**	**2**	**3**	**4**	**5**
13. I actively engaged my stakeholders in discussions about the FMP	**1**	**2**	**3**	**4**	**5**
14. The LCC contains a broad cross-section of stakeholders	**1**	**2**	**3**	**4**	**5**
15. I feel that other members on the LCC accurately reflected their stakeholder viewpoints	**1**	**2**	**3**	**4**	**5**
16. Other LCC members were regular attendees of committee meetings & related functions	**1**	**2**	**3**	**4**	**5**
FUNCTIONING – these questions assess how well you as a local citizens committee member believed that your committee functioned	**disagree**	←		→	**agree**
17. The LCC worked toward consensus decisions	**1**	**2**	**3**	**4**	**5**
18. The LCC committee members respected & considered others' viewpoints	**1**	**2**	**3**	**4**	**5**
19. All LCC members participated in discussions & decisions	**1**	**2**	**3**	**4**	**5**
20. LCC meetings & functions were well-organized & well-run	**1**	**2**	**3**	**4**	**5**

Supplementary Documentation K

2012-2022 Whiskey Jack Forest Management Plan

Final List of Required Alterations, and a List of Major Changes from the Draft to Final Contingency Plans



Final List of Required Alterations - Whiskey Jack Forest
2012 - 2022 Whiskey Jack Forest Management Plan

For the 2012 Whiskey Jack Forest Management Plan, I am certifying the required alterations relating to manipulation of the forest cover.

Ian Pyke, R.P.F.
Kenora Forest Area Forester
MNR Kenora District

58275	lil anderson	1	N/A	N/A	N/A	MEA DEA	Required	6.2 (f) Areas Selected of Operations Maps	DEA and MEA areas developed by the Management Biologist for the Kenora District and those developed by the Area Biologist for the WJF do not jive where there is overlap. The shapefiles must be adjusted to reflect entire district MEA and DEA in a consistent manner.
58284	lil anderson	1	N/A	N/A	39557	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Crown land disposition and commercial outpost camp on pennisula of Brown Bear Lake (12.622) is not readily apparent on operational map. Ensure this value is recognized.
58537	abby anderson	1	85	21	N/A	N/A	Required	2.2.1 Overview of Social and Economic Context	Change to "Wabaseemoong Independent Nations (Whitedog)"
58541	lil anderson	1	N/A	N/A	40549	N/A	Required	8.10 (f) Areas Selected of Operations Maps	Tidy up the operational road boundary on block 12.347 so that it doesn't cross private land
59412	Cathy Cavalier	1	112	Nov-28	N/A	3.2.8 IFAs	Required	3.2 Management Considerations	line 11 needs rest of sentence; line 17 last line should come out is is N/A to water crossings (which are AOCs); lines 24-28 do not appear to be relevant as topic is about pit 'rehabilitation', double check if these other sections actually have anything about this; also line 27 'Lands' should be 'Landings'
59413	Cathy Cavalier	1	126	34-35	N/A	N/A	Required	3.4 Desired Forest and Benefits	revise 'category 14 pits' to 'forestry aggregate pits'

59414	Cathy Cavalier	1	132	N/A	N/A	N/A	Required	3.4 Desired Forest and Benefits	RSA & value of tourism industry: refers to implementing mandatory RSA process, RSA contact made, MNR participating in RSA discussions; this needs to be revised/briefly explained to reflect that there are technically no RSAs given is a Crown unit, as per page 77; also does not seem appropriate to include a person's name in this table e.g. revise to 'LCC Tourism Industry contact'
59300	Fred Zroback	1	16	N/A	N/A	N002	Required	FMP-10: Operational Prescriptions for AOCs	Chimney Swift missing from species list.
59304	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (m) Statement of Environmental Values (SEV) consideration document	Page 1: 2nd bullet at end of 1st sentence add wording such as 'Some of these guides include: Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales, Forest Management Guide for Natural Disturbance Pattern Emulation, Forest Management Guideline for the Provision of Marten Habitat, Management Guidelines for Forestry and Resource-Based Tourism, and Forest Management Guide for Cultural Heritage Values.'; 4th bullet change 'Contingency Plan' to 'FMP'. Page 2 1st paragraph end add 'or request for an individual environmental assessment'; 6th bullet revise roads guide to 'Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales'. Page 3 add whether or not Aboriginal community consultation approaches were developed & if so very briefly what they were; please resubmit to reviewer in advance of plan resubmission
59354	Fred Zroback	1	27	N/A	N/A	AOC WL01 - Bullet point 7	Required	FMP-10: Operational Prescriptions for AOCs	info to be added to the first sentence; (after .....retained): and marked (flagged) prior to harvesting .....as a potential source of future aquatic coarse woody material.
59389	Cathy Cavalier	1	N/A	N/A	N/A	2.1.3.2.2 Rare Species	Required	2.1.3.2 Fish and Wildlife Inventories	Rare Species: For each of these species, in consultation with SAR and regional biologist, provide explanation in this section [e.g. add a new column at right of table] as to why there is not a specific AOC prescription [e.g. covered by another AOC, etc] or cross reference to/develop AOC prescription (or species specific CROs if determined appropriate). Page 70 lines 33-37 should be revised to cover species that might be discovered but not identified in this plan. Please provide documentation to reviewer in advance of plan resubmission for advice/review

59391	Cathy Cavalier	1	53-67	N/A	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	In reviewing this section in conjunction with table 6 on page 53 there seems to be a number of species that require AOCs; for example there is an AOC for eastern cougar with no known locations yet no AOC for barn swallow, flooded jellyskin, olive-sided flycatcher, Canada warbler, common nighthawk, rusty blackbird, snapping turtle; review all species in consultation with SAR and regional biologist and develop needed AOC prescriptions; other recent NWR plans can be checked for examples
59397	Cathy Cavalier	1	54	30-31	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	'If avoidance is not possible and disturbance is likely, an ESA permit may be sought in consultation with the MNR SAR biologist' does not seem correct to be included, since AOC D03 already approves conditions underwhich operations are permitted; consult with SAR biologist/reviewer
59401	Cathy Cavalier	1	63	47	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	include AOC #[D04] similar to how other species with AOCs have been done
59403	Cathy Cavalier	1	66	48-49	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	Stand & Site Guide should not be referenced because it does not provide prescription for common nighthawk; other plans are developing prescription developed by planning team, consult with SAR biologist
59404	Cathy Cavalier	1	67	17	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	Rusty blackbird: text refers to Dryden Forest, revise to what is relevant to Whiskey Jack Forest (page 53 identifies has potential to be on WJ)
59405	Cathy Cavalier	1	53	N/A	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	table 6: forest context should be worded in a way to include applicable AOC ID where there is one; woodland caribou says 'AOC prescriptions applied to calving/nursery areas' however there are no prescriptions in this plan = revise/update; showy goldenrod include this parcel is not subject to forest management [as noted on page 62]; lake sturgeon state whether or not there are any water crossings & if any what AOC; bats add brief wording why no AOC
59406	Cathy Cavalier	1	65	N/A	N/A	23-25	Required	2.1.3.1 Inventories and Information for Species at Risk	olive-sided flycatcher, Canada warbler: AOCs, not CROs, are required for SAR - consult with SAR biologist to develop prescription developed by planning team, examples from other NWR plans are available
59407	Cathy Cavalier	1	67	50	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	snapping turtle: add that would need to be addressed by an AOC, consult with SAR biologist, examples are available from NWR plans e.g. conditions on roads

59408	Cathy Cavalier	1	75	35	N/A	N/A	Required	2.1.3.3 Natural Resource Features, Land Uses and Values	'conditions on regular operations' needs to be removed because does not apply to AOCs in a general sense i.e. they are conditions on 'regular operations'; CROs are already covered starting at line 44
59410	Cathy Cavalier	1	107	23-31	N/A	3.2.4 Species at Risk	Required	3.2 Management Considerations	line 23 remove reference to CROs as all SAR are covered by AOCs; lines 28-30 refer to grey fox dens and yellow rails but these species are not listed in section 2.1.3.1/table 6 as SAR; need to update paragraph for additional AOCs as a result of ID#59391 & related comments on section 2.1.3.1
59418	Cathy Cavalier	1	221	30-35	N/A	N/A	Required	4.2.1 Operational Prescriptions for AOCs	text is contrary to previous paragraph AOC prescription in FMP-10 from Stand & Site Guide which does not require den site management plan and only allows operations outlined in the AOC i.e. outside denning period; remove paragraph and if changes to FMP-10 are needed make changes there; if varies from SSG may require format of prescription developed by planning team (i.e. sup doc); advise/provide to reviewer in advance of plan resubmission
59420	Cathy Cavalier	1	226	46	N/A	N/A	Required	4.2.2.1 Silvicultural Ground Rules	aerial seeding of jack pine shows ES 14 as well as ES 21, but ES 14 is not shown on exceptions page or page 285; fix whichever is in error so all match
59423	Cathy Cavalier	1	246	37-43	N/A	N/A	Required	4.3.1 Harvest Areas	line 37 is about mapped residual but line 42 says there were no mapped residual, clarify
59424	Cathy Cavalier	1	264	25-32	N/A	N/A	Required	4.5.5 Existing Roads	revise contingency plan references to this FMP instead
59432	Chris Schaefer	1	V	N/A	N/A	N/A	Required	Figure B-3: Forest Management Plan Contributors	Note that Hilary Gignac is back in her home position as the regional species at risk biologist, so Hilary should be noted along with Lori in the regional/provincial advisors list and add Hilary to the plan reviewer list on page vi. Add Brian Campbell in as another Forest Industry Liaison as he will be leading the review and add Brian to the plan reviewer list on page vi. Also, add in the regional analyst (Rob Bowen and/or Scott Hole) as an advisor, as they participated in the LTMD development and they will be reviewing the plan.
59441	hassan mohamed	1	245	1	N/A	N/A	Required	4.3.1 Harvest Areas	Please correct the POD numbers in the chart.
59456	Angus Carr	1	N/A	N/A	N/A	N/A	Required	6.2 (i) Information products (coverages)	PRP Coverage seems incorrect. The "RESID" attribute contains only NULL values, and the polygons seem larger than a residual polygon should be. Modify the layer according to FIM Tech Spec.

59460	Darryl Pajunen	0	N/A	N/A	N/A	Values map PDF	Required	6.2 (c) Values Maps	The MU490_2012_FMPDP_P1_MAP_ValFish_00.pdf exceeds 25MB. This map should be reduced to less than 25MB in size.
59461	Darryl Pajunen	0	N/A	N/A	N/A	E00 Submission file	Required	6.2 (i) Information products (coverages)	The MU490_12PRC00.e00: ACC_REM field is empty and needs to be populated.
59466	Jennifer Hughes	1	291	49	N/A	N/A	Required	4.8 Fire Prevention and Preparedness	4.8.1.2 Operational Modifications Line 49 - Any wildfires will be reported immediately to the MNR District Fire Management Headquarters. Add telephone # 548-5837 or 310-FIRE (3473)
59467	Jennifer Hughes	1	293	N/A	N/A	Section 4	Required	4.8 Fire Prevention and Preparedness	4.8.2.1 Trained and Capable, and Limited Operators Section 4 Training - How often will re-fresher training occurr and who will deliver it? (usually 3 years) Need to specify timeframe
59475	sarah mckenzie	1	285	PAR. 3	N/A	DCHS	Required	6.1 (u) Other Supplementary Documentation	Tracts listed available for harvest on this page are 6,7,8,9. In the description of each tract 10 is also listed as being available for the first ten years.
59476	sarah mckenzie	1	287	PAR. 1	N/A	Assessment of Obj. Caribou	Required	6.1 (u) Other Supplementary Documentation	"There is no planned harvesting (with the exception of some initial clean-up of mature wood in the southern section of the caribou zone) for the next 30 years." - Should be 60 years as previously stated in this section.
59477	sarah mckenzie	1	290	2	N/A	Marten	Required	6.1 (u) Other Supplementary Documentation	Says KMU not WJFMU
59478	Chris Schaefer	1	15	1	N/A	N/A	Required	1.0 INTRODUCTION	The date MU boundary was established and a description of any change is required to be included in this section (B-14, ln 11)
59479	sarah mckenzie	1	60	26	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	Edit NO4
59480	sarah mckenzie	1	67	18	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	Reference to Dryden Forest
59481	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	Table headings need to match FMPM, right now 'description of Natural Resource Feature...' is across top but only belongs as 2nd column header; source Stand & Site Guide 'year' needs to be 2010 instead of 2009 [final guide is dated March 18, 2010]; also sup doc 6.7 is referenced in some AOCs as source, however, seems needs to be sup doc H instead
59482	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	Nest and water AOCs have cross references to section 4.2.2.2 but include the 'CP' throughout, need to check all and remove this reference

59484	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	N02 & ON02 alternate nests after 'No harvest is permitted' add 'If harvest that retains <60% relatively uniform canopy closure occurs within ___ m of an alternate nest prior to its discovery, an additional patch of unharvested forest equivalent to the area harvested will be retained, preferably attached to the remaining unharvested forest surrounding the nest (to provide a supply of potential nest and roost trees).', as per Stand & Site Guide
59485	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-3: Summary of Managed Crown Productive Forest by Forest Unit	The unavailable column in the table should add up to the 109,692 as identified in the footnote. The corresponding available production forest in the table would then add up to 538,618, not 667,051.
59486	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	HO02 alternate nest at end of definition add 'Any nest in good repair within 400m of primary nest' as per Stand & Site Guide page 80
59487	Chris Schaefer	1	29	3	N/A	N/A	Required	2.1.2.1 Forest Units	Discussion is warranted regarding the lack of supply in the 41-60 age class as this gap is common across all confer dominated FUs.
59488	Chris Schaefer	1	36	16	N/A	N/A	Required	2.1.2.1 Forest Units	Text contradicts earlier text on pg 27, ln 40 which states species increases (not FU increases) are desired.
59490	sarah mckenzie	1	82	24	N/A	N/A	Required	2.1.3.3 Natural Resource Features, Land Uses and Values	speaks to agreements with the SFL.
59492	sarah mckenzie	1	84	10	N/A	N/A	Required	2.1.3.3 Natural Resource Features, Land Uses and Values	Road decommissioning would also occur as a wildlife management strategy (caribou).
59499	Chris Schaefer	1	37	41	N/A	N/A	Required	2.1.2.2 Forest Landscape Classes	While there is a discussion on the implications of the current landscape pattern, it has not been provided for the landscape classes. Please add this discussion or refer the reader to where it is discussed (compare to simulated ranges).
59500	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOCs NO01, NO02, NO03 combine various species with different AOC dimensions & timing restrictions (and prescriptions) such that if AOC identifier was on a map it could not be determined what from FMP-10 would apply; therefore revise to more separate AOCs e.g. NO01-1, NO01-2, etc or separate within e.g. NO01a, NO01b, etc. reviewer has examples of both available to easily facilitate this change

59502	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC NO01 description of value revise 'Stick nests of barred owl...' to 'Stick nests occupied by barred owl...' as per Stand & Site Guide page 82; this AOC only covers occupied nests, unoccupied are covered by CROs therefore 'of' is incorrect; adjust list of AOCs as well
59503	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC NO02 description of value revise 'occupied by or previously used by' to 'occupied by' as per Stand & Site Guide page 85; this AOC only covers occupied nests, unoccupied are covered by CROs therefore 'previously used by' is incorrect; adjust list of AOCs as well
59504	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC N04 201-400 from nest critical breeding period: 2nd line 'within 400m' needs revision to 'within 201-400m'
59505	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC TVgi: revise to state what 'seasonal restriction' is in 2nd sentence i.e. should this wording be replaced by 'No'; remove duplication about Labour Day & Thanksgiving Day
59508	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC TVer last sentence belongs in FMP-19 instead as is conditions on roads
59513	Chris Schaefer	1	58	22	N/A	N/A	Required	2.1.3.1 Inventories and Information for Species at Risk	Both this paragraph and the end of the following paragraph need to be updated to reflect recent changes. Please work with your district and regional SAR Biologist on this wording.
59522	sarah mckenzie	1	106	44	N/A	N/A	Required	3.2 Management Considerations	Car10 is described as being available for harvest in Supp Doc N, 06-09 are only listed here.
59536	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC WS02 LPS streams remove 1st paragraph as LPS streams need to have an AOC as per direction provided by forests branch in July 2012; also revise AOC list
59539	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	FL01 #2 last sentence 'subject to this agreement' reads like agreement approves what happens rather than MNR; revise instead to state what is approved e.g. is the following correct 'Regular harvest, renewal and tending opeations are permitted in allocated blocks outside of the placement of the limit on forest operations outlined in the agreement'
59541	sarah mckenzie	1	112	11	N/A	N/A	Required	3.2 Management Considerations	Line should be finished. Same comment as before -road decommissioning should also be considered as a wildlife management strategy in the caribou zone.

59542	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC NE9 modified zone description overlaps with reserve zone, revise wording such as 'Outside of the reserve, within 120 metres measured from the high water mark, the following operations are permitted with restrictions as outlined:'; add whether or not there are conditions on operational roads/landings and forestry aggregate pits
59562	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	Part A AOC WS01 page 5 add missing Stand & Site Guide page 137 1st standard 'The installation of a water crossing will not result in the impediment of fish passage; mitigative techniques will be applied if the structure has the potential to impede or block fish migration or passage.'; page 9 last paragraph refers to 'both timining restrictions', it is unclear what 'both' means; 1st guideline on top of page 53 of Stand & Site Guide needs to be included
59563	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	Part B AOC A01 2nd heading 'where roads are approved in an APA' needs to be removed as above point already says they are approved subject to these conditions below
59564	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	Part B AOC D01 1st bullet remove 'unless the road predates the den and is required for safety reasons or environmental protection' as is not part of this standard in Stand & Site Guide page 95
59577	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC H003: remove this AOC from Table and from list, it is already correctly a CRO in plan text as required of Stand & Site Guide page 81
59578	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	Part B & Part C all AOCs with more than one species providing a distance range of no operations and cross reference to FMP 19.1: need instead to list what impacts apply to what distance or add a cross reference to FMP-10 if they are listed there e.g. AOC NO01 shows a cross reference
59579	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	Part B AOC HO01: 1st bullet states 'or within the 7 ha patch of suitable habitat retained within 200m' as noted in Stand & Site Guide, however, FMP-10 was not done showing this (instead it has no operations within 200m); therefore it does not seem correct to refer to this 7 ha patch; review compared to how FMP-10 was done; also refers to 'reasonable efforts' however does not explain like in all other AOCs, therefore recommend adding e.g. 'unless no practical or feasible alternative locations exist (i.e. due to...)'

59580	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	Part B & Part C AOC HO03 remove AOC, as is already correctly a CRO as per Stand & Site Guide page 81
59581	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	AOC NO03 Part B: 1st point lists timing but then 2nd bullet refers to FMP-10, should just be done once
59582	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC PGP01 operational roads should be showing none permitted instead of 'yes'
59583	Chris Schaefer	1	77	10	N/A	N/A	Required	2.1.3.3 Natural Resource Features, Land Uses and Values	I am unable to find the required FMPM statement in this section of the plan. Please add the required statement. See FMPM B-18, ln 26-30.
59584	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	AOC PL01 Part B: add will require a plan amendment at end of 2nd sentence, since plan needs to state whether or not roads are approved by MNR i.e. landowner does not 'approve'; 2nd point needs to be removed and made part of 1st sentence by adding 'with a maximum right of way width of 20m' at end of sentence; any conditions between harvest boundary & patent land would be determined at time of plan amendment in consideration of landowner permission
59585	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	AOC LS01 and TVer both need to include that roads will be reclaimed and regenerated and include when this will be done(as per regional direction)
59586	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	AOC WS01 Part B: 1st condition before design & location needs to incorporate Stand & Site Guide page 52 1st road guideline 'New roads that are not associated with an approved 'river/stream' crossing are not permitted within the AOC unless...'; then heading 'design and location' should include 'of water crossings'; should instead be cross referencing to conditions in Part A and indicate any other condition that varies as they are same AOC/same SSG requirements [& same review comments as Part A] i.e. 'Refer to Part A for conditions that also apply to this AOC. ' Then include decommissioning conditions unless there is something else that varies; page 22 reference to 'SFL Holder' in 1st & 2nd paragraphs needs to be removed & replaced e.g. SSG refers to 'the proponent'

59597	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	AOC WS02 Part B: 1st condition before design & location needs to incorporate Stand & Site Guide page 54 last road guideline 'New roads will not be located within 15 m of the active channel unless...'; then heading 'design and location' should include 'of water crossings'; should instead be cross referencing to conditions in Part A and indicate any other condition that varies as they are same SSG requirements [& same review comments as Part A] i.e. 'Refer to Part A for conditions that also apply to this AOC other than timing restriction____, etc. Refer to Part B for decommissioning provisions that also apply to this AOC.' page 25 reference to 'SFL Holder' in last 2 paragraphs needs to be removed & replaced e.g. SSG refers to 'the proponent'
59599	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	AOC WW01 last condition is referring to CRO section 4.2.2.2 for wetlands; SSG page 60 is referring to section 5.2 of SSG - have a look at these sections & add cross reference to those relevant sections in the plan CROs
59600	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	AOC BS01 Part C states 'subject to timing restrictions (see below)' however need to add restrictions to next point
59601	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	AOC NO01, NO02 Part C: last bullet timing restriction needs revision as does not apply to all nests; also NO02 includes 'chimney swift' however is missing from Part B and FMP-10, revise whichever is in error so all match
59604	Cathy Cavalier	1	239	N/A	N/A	N/A	Required	4.2.2.2 Conditions on Regular Operations	salvage - all Stand & Site Guide standards & guidelines on page 160 with respect to salvage need to be included, not just those that refer to wildlife trees/downed woody material
59605	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	4.2.2.2 Conditions on Regular Operations	Erosion: Stand & Site Guide 'Guidelines' on page 152 need to be included; note these conditions are not only for shallow soils
59606	sarah mckenzie	1	145	17	N/A	N/A	Required	3.5 Objectives and Indicators	The ESA is provincial and SARA is federal.
59607	Cathy Cavalier	1	271	N/A	N/A	section 4.5.7	Required	4.5 Roads	Furbearing mammal dens enduring features: no road construction (of existing roads) and no aggregate extraction needs revision to be about 'occupied dens'; hauling and road maintenance 'within 20 m of the den entrance' should be 'within 20 m of occupied dens' to match Stand & Site Guide page 98

59612	Cathy Cavalier	1	233	N/A	N/A	N/A	Required	4.2.2.2 Conditions on Regular Operations	maintenance of S1, S2, S3: remove condition as is missing actual required conditions on operations; Stand & Site Guide page 13 guideline is about vegetation 'communities' only, if MNR has identified any then add CROs specific to those communities; there are already general statements in plan text page 54 and 70; refer to related ID comments on plan text section 2.1.3.2.2 rare species and section 2.1.3.2 SAR
59614	Cathy Cavalier	1	271	N/A	N/A	section 4.5.7	Required	4.5 Roads	inactive great grey owl...nest: 1st bullet states 'new' will not be constructed, however, Stand & Site Guide refers to 'reasonable efforts' e.g. 'unless no practical or feasible alternative...'; just checking if this should be revised as version incorrectly shown as an AOC in FMP-19 is done this way (related ID#59580 says to remove AOC from table as is supposed to be a CRO)
59617	Chris Schaefer	1	107	1	N/A	N/A	Required	3.2 Management Considerations	Text will need to be updated to reflect regulation changes for SAR (caribou)
59618	Chris Schaefer	1	112	15	N/A	N/A	Required	3.2 Management Considerations	Also include FMP-18 and the associated road SupDocs as monitoring of the road and water crossings is covered as a component of the UMS.
59620	Cathy Cavalier	1	272	N/A	N/A	section 4.5.7	Required	4.5 Roads	1st & 3rd text box say new roads... will not be constructed, however Stand & Site Guide page 84 & 87 refers to reasonable efforts to avoid (e.g. terrain...) for these nests; checking to see if what was shown was intentional or whether SSG requirement was missed
59622	Cathy Cavalier	1	233	N/A	N/A	N/A	Required	4.2.2.2 Conditions on Regular Operations	last text box includes text about nest trees if a safety risk, however, this is not in Stand & Site Guide page 87, just checking if this was meant to be included or was included by mistake
59623	Cathy Cavalier	1	234	N/A	N/A	N/A	Required	4.2.2.2 Conditions on Regular Operations	2nd text box includes chimney swift, but noticed was missing from roads page 272, not sure which is in error, fix so both match
59625	Cathy Cavalier	1	273	N/A	N/A	section 4.5.7	Required	4.5 Roads	Rich lowland dominated forest & Wetlands: 'when practical and feasible' needs revision to 'reasonable efforts will be made to' to match Stand & Site Guide page 59 & 60 and what this means should be shown e.g. terrain...; definition of reasonable efforts is in SSG page 209, 'practical & feasible' are specifically not used
59626	Chris Schaefer	1	114	7	N/A	N/A	Required	3.3 Base Model	Please ensure all components of the required statement is reflected in this section, or just copy the entire statement from the FMPM (B20, ln 25-28) into your text.

59627	Cathy Cavalier	1	235	N/A	N/A	N/A	Required	4.2.2.2 Conditions on Regular Operations	Ponds, streams: remove from CROs as LPS are required to be AOCs as per July 2012 direction previously sent via forests branch
59628	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC WL02 description of value remove 'identified prior to plan approval' and remove 1st paragraph under operational prescription; LPS ponds are required to be AOCs as per direction provided by forests branch in July 2012; also revise list of AOCs
59629	Cathy Cavalier	1	270	N/A	N/A	section 4.5.7	Required	4.5 Roads	general road conditions: 13th & 14th bullets about debris should be part of loss of productive land section instead where seems to be covered; 16th point 'SFL holder' needs revision; Stand & Site Guide page 131 last guideline [engineering safety considerations] and page 132 [have a monitoring program] need to be added, including cross reference to where monitoring program is in plan
59630	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC PGP01: more information from prescription provided through G&Y program needs to be used in particular rationale & disadvantages/advantages are inadequate i.e. saying prescription was provided does not provide information required; also prescription 'No harvest or new roads in AOC until third measurement has taken place (10 years post-establishment)' is not in FMP-10, both need to be the same; as well this cannot be included without all related information from G&Y program prescription; operational prescriptions do not include 'roads', remove this reference; operational roads remove 2nd statement about not needing sup doc, since no roads are permitted
59631	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	Remember to make changes in AOC sup doc for any related changes in FMP-10/FMP-19 so all match
59634	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC FL01 refers to 'federal land' throughout but this is not used in FMP-10 at all (uses First Nation Reserve', revise so terminology is consistent, correct whichever is in error
59635	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC RR01 prescription needs last sentence of prescription in FMP-10 added, unless table is in error
59636	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC NG01 prescription contact information as per FMP-10 needs to be added, since sup doc is supposed to be source of what goes in FMP-10

59637	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	TV01: alt 1 values are not those described in values above & environmental analysis does not match either; proposed alt 2 does not match FMP-10 which only refers to large lakes with tourism values but environmental analysis & rationale refers to different values; revise sup doc throughout to be consistent with/cover all values identified and update FMP-10 to match; operational roads should not be referring to FMP-19 since FMP-10 says no roads/landings are permitted
59638	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC TVw blocks listed in dimension do not match FMP-10; remove reference to roads/hauling from prescription for H, R, T, as belongs in FMP-19 only
59639	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC TVai public comments refers to previous RSA, however, instead this belongs as part of rationale and in FMP-19 remove 'yes' from public comments since sup doc says there are none; similarly TVgl & TVwi where public comments says was developed with tourism outfitter this belongs as part of rationale; if there are actually public comments on file then make note of that & if none remove 'yes' from FMP-19
59640	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC TVnsi part B 1-4 needs to be removed, just note conditions on roads only; what is shown now is about roads but part B is only completed for prescriptions for H, R, T; since there are no public comments this sup doc does not seem to be needed & remove reference in FMP-19 but recommend add '(application of previously negotiated RSA)' after 'conditions on roads only' in FMP-10
59641	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC LS01 values do not match FMP-10, revise whichever is in error so both match
59642	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC TVp requires AOC sup doc, FMP-10 identifies as source but could not find it
59643	Cathy Cavalier	1	N/A	N/A	N/A	N/A	Required	6.1 (h) AOC SupDoc	AOC WS01 Part D revise incorrect references to contingency plan
59650	Brian Campbell	2	N/A	N/A	N/A	Table FMP-15	Required	4.3.6 Wood Utilization	For Table FMP-15: The Commitment types, volumes and associated footnotes for Weyerhaeuser need to be adjusted based on more recent Ministerial conditional commitments. The Commitment types, volumes and associated footnotes for Kenora Forest Products need to be adjusted based on the recent Wood Supply Competitve Process offers. Please contact Brian Campbell 807-475-1450 brian.campbell2@ontario.ca, to discuss proposed changes to the table

59651	Brian Campbell	1	255	1 TO 28	N/A	N/A	Required	4.3.6 Wood Utilization	For Section 4.3.6: Plan text may have to be adjusted based on changes to Table FMP-15 Please contact Brian Campbell 807-475-1450 brian.campbell2@ontario.ca, to discuss proposed changes to the text.
59654	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-9: Assessment of Objective Achievement	For objective 8a the text states 0.13 (pg 155) as a maximum limit while the table does not provide this maximum. The 'maintain or decrease' from a current level of 0.12 would not permit 0.13.
59655	Chris Schaefer	1	155	24	N/A	N/A	Required	3.5 Objectives and Indicators	For objective 8a the text states 0.13 (pg 155) as a maximum limit while FMP-9 does not provide this maximum. The 'maintain or decrease' from a current level of 0.12 would not permit 0.13. Please reconcile.
59657	Chris Schaefer	1	182	14	N/A	N/A	Required	3.6.2 Selection of Areas for Harvest	53470.5 is identified as the planned harvest area (10-year) in FMP-11
59660	Chris Schaefer	1	187	13	N/A	N/A	Required	3.6.2 Selection of Areas for Harvest	Please confirm the 7% extent of the harvest substitution into younger age classes. In Table 22 only 11,921 ha should have been allocated in all age classes below the age of 80, while the 10-year allocations under the age of 80 were 22,795 ha. Also confirm the paragraph on page 189, ln 32 and correct the 10-year planned harvest area as reported in FMP-11 & table 22 (53,471 ha)
59661	Chris Schaefer	1	184	32	N/A	N/A	Required	3.6.2 Selection of Areas for Harvest	I suggest that text be included to identify the legal direction for planning of allocations within this area, in addition to more details on the scheduling approach taken. I suggest the text express the overall balance between terms within the overall FN areas/zones (or by each zone) so that the balancing strategy is clear to the reader. In addition, the influence of the Aboriginal community input on this criteria is warranted (B-23, ln 8).
59663	Chris Schaefer	1	191	1	N/A	N/A	Required	3.6.3 Assessment of Objective Achievement	Provide a text block in this section regarding the efforts and analysis undertaken to balance objectives (B-23, ln 20), or refer the reader to where this is covered.
59664	Chris Schaefer	1	219	2	N/A	N/A	Required	4.1 Introduction	Introduction needs to also describe the operations that have been planned, for both 5-year terms (B-24, ln 6).
59665	Chris Schaefer	1	225	15	N/A	N/A	Required	4.2.2.1 Silvicultural Ground Rules	Please verify this statement as I understand Large Scale Photography (LSP) is also proposed to evaluate FTG achievement for some intensive stands.
59666	Chris Schaefer	1	226	10	N/A	N/A	Required	4.2.2.1 Silvicultural Ground Rules	Note that the SGR are also required to be identified (portrayed) on the maps (B-26, ln 23), not just the coverages (B26, ln 12). Please adjust this paragraph.

59668	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	6.2 (f) Areas Selected of Operations Maps	SGRs need to be portrayed for the harvest areas. Since you have the present FU identified on the map for each harvest stand, I suggest that you add a simple lookup table in the legend with FU/SGR so that the link is provided on the map product. Also, note that the SGRs also need to portrayed for the renewal and tending areas.
59669	sarah mckenzie	1	3	N/A	N/A	N/A	Required	FMP-9: Assessment of Objective Achievement	3e and 3f are not reported in table but are specified in text
59670	Chris Schaefer	1	232	N/A	N/A	loss of productive land	Required	4.2.2.2 Conditions on Regular Operations	The text block on 'chip debris' needs to be edited to incorporate the actual treatment practices as outlined on page 249, while removing the reference to burning of chipper debris piles (as this practice is currently restricted). Any final treatment options that identify windrowing and piling of chip debris on productive land must be limited in application (extraordinary circumstances). Please discuss approach with this reviewer prior to final plan submission.
59671	sarah mckenzie	1	158	27	N/A	N/A	Required	3.5 Objectives and Indicators	Reference to 'the company'.
59676	Chris Schaefer	1	247	30	N/A	N/A	Required	4.3.1 Harvest Areas	Text conflicts with pg 247 ln 18 & pg 246, ln 42. Is mapped residual shown on the operations maps?
59677	Chris Schaefer	1	249	1	N/A	N/A	Required	4.3.1 Harvest Areas	As noted in alteration 59670 this entire section needs to be incorporate into the associated CRO for the productive landbase. Any direction for the treatment of the actual landing surface itself needs to be incorporated in 4.5.7.
59679	Chris Schaefer	1	254	44	N/A	N/A	Required	4.3.6 Wood Utilization	The text regarding the renewal of biofibre areas needs to refer the appropriate CRO for the piles and the CORLAP for the landing areas. This will eliminate conflicting direction.
59680	sarah mckenzie	1	182	45	N/A	N/A	Required	3.6.2 Selection of Areas for Harvest	Car10 was identified in Supp Doc N as being available for harvest - was it considered in the decision criteria?
59681	sarah mckenzie	1	188	27	N/A	N/A	Required	3.6.2 Selection of Areas for Harvest	80ha was listed as the min (economically feasible) block size above but says 70ha here.
59683	Gregg Lloyd	1	VI	5	N/A	N/A	Required	Figure B-3: Forest Management Plan Contributors	Please include inforatmion on the Red Lake LCC and their general agreement or disagreement or at least the involvement in the planning.
59687	Gregg Lloyd	1	19	27	N/A	N/A	Required	2.1.1 Current Forest Condition	Please give further details on what the company surrendered (SFL) and either why or a bit of history on this.
59688	Gregg Lloyd	1	19	25	N/A	N/A	Required	2.1.1 Current Forest Condition	Using "manipulation" makes it sound like you are fudging the inventory. Please describe this as the coverage that would require the least amount of update information in order to be usable for planning purposes or something to that extent.

59689	Gregg Lloyd	1	19	33	N/A	N/A	Required	2.1.1 Current Forest Condition	The land base expanded by 7000 due to reduced road ROW buffering? More explanation is required to defend this amount of increase in the size please.
59692	sarah mckenzie	1	189	34	N/A	N/A	Required	3.6.2 Selection of Areas for Harvest	typo on age classes older than LTMD projectsion (1,5900 ha)
59693	Cathy Cavalier	1	266	46	N/A	section 4.5.7	Required	4.5 Roads	'applies to conditions on new' needs to be 'applies to conditions on new and existing'
59694	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-17: Planned Renewal and Tending Operations	Plan text (pg 258) states approximately 16ha slash pile burning per year but the table shows far more for the 5-year and 10-year numbers. Please correct, and ensure only the pile area is reported.
59695	Chris Schaefer	1	261	21	N/A	N/A	Required	4.5.1 Primary and Branch Roads	FMP-18 shows 3 new primary roads (Yellow Girl, Bug L., Witch Bay/Loon Lake) while the text only notes one. Please correct.
59696	Chris Schaefer	1	261	39	N/A	N/A	Required	4.5.1 Primary and Branch Roads	FMP-18 shows Bug L.& Aesthetic roads as new branch roads while the text only notes a different road. Please correct.
59697	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-18: Road Construction and Use Management	Note that the text discussion regarding the 3 new primary and 2 new branch roads on page 261 does not correspond with the table. Please correct.
59698	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-18: Road Construction and Use Management	At the top of the footnotes a couple of the points need to be removed, as the monitoring and maintenance will follow the direction in the plan.
59699	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-18: Road Construction and Use Management	Please document the actual decommissioning provisions in the footnote to the table (UMS-3). The clause needs to, at a minimum, address the activities required prior to transfer and the potential removal of water crossings for roads scheduled for transfer in the 5-year term (B-33, ln 4-6).
59700	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-18: Road Construction and Use Management	The last clause in the footnotes needs to be edited or removed. As noted in the generic unplanned events footnote, the actions must be consistent with the UMS for the road and as such there is an obligation for your principle access roads that are used by the public. I suggest this extra text be removed, leaving only the generic text block.
59701	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-18: Road Construction and Use Management	There are no existing operational roads identified in the table. These roads (from the SupDoc) need to be listed with the UMS.

59702	Chris Schaefer	1	264	17	N/A	N/A	Required	4.5.5 Existing Roads	Please update this section to reflect what is shown in FMP-18. From the table it appears that there are no existing operational roads identified in the table and the ORBs are to cover both existing and new operational roads within the ORB. However, note that the UMS must then be applicable to each and every new and existing operational road within the ORB. You have 5 ORBs identified for transfer and decommissioning during this term (new and existing roads?). You will likely need to break out existing operational roads in these networks if it is only these roads that are to be transferred and decommissioned. Please discuss this with this reviewer.
59703	Chris Schaefer	1	262	1	N/A	N/A	Required	8.5.1.1 Operational Roads	Please update this text as you only have 'networks' shown in FMP-18, the construction is identified for the 5-year term, and you have identifed 5 networks identified for transfer and decommissioning in the 5-year term (all new and existing operational roads in these ORBs?). You will likely need to break out existing operational roads in these networks if it is only these roads that are to be transferred and decommissioned. Please discuss this with this reviewer.
59704	Chris Schaefer	1	264	17	N/A	N/A	Required	4.5.5 Existing Roads	If you have Provincial Parks or Conservation Reserve crossings please build in text to discuss the approvals required for maintenance on the road segments under the Act (PPCRA).
59706	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	4.5.6 Conditions on Forestry Aggregate Pits	Please edit this section as an aggregate extraction area is not needed to establish a forestry aggregate pit in most cases. It is only required where the pit is to be established outside of the criteria as you noted on page 265 ln 36-44.
59711	lil anderson	1	N/A	N/A	40549	N/A	Required	6.2 (f) Areas Selected of Operations Maps	clean up boundary of proposed road corridor where it enters on private land on block 12.347.
59712	lil anderson	1	N/A	N/A	41549	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Harvest block shown right up to trappers cabin on RTA KE109. Block 12.355. Recommend a buffer on cabin and/or discussion with trapper.
59714	lil anderson	1	N/A	N/A	41552	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Blk 12.998 (contingency) is along a popular canoe/recreational and tourism system. Can we see a TV buffer put on the rapids and portage between Mitchell Pond and Balne Lake (Mitchell on map) Heavy clays (winter harvest?)in this area could also lead to siltation into major spawning area at rapids if not sufficiently buffered.

59716	lil anderson	1	N/A	N/A	N/A	N/A	Required	8.10 (f) Areas Selected of Operations Maps	Road corridor accessing Blk 12.325 passes between two bald eagle nests which are not shown on map and crosses a portage which will need to remain open and unblocked for public use. Apply aoc's for nests and portage.
59719	lil anderson	1	N/A	N/A	41558	N/A	Required	8.10 (f) Areas Selected of Operations Maps	There is a trumpeter swan nest in proposed road corridor to blk 12.651 that requires protection. Draw downs of water in this system while doing road work or culvert maintenance during breeding/nursery stage will put the young at risk.
59720	lil anderson	1	N/A	N/A	42559	N/A	Required	6.2 (f) Areas Selected of Operations Maps	There is an LUP remote outpost on the N. shore of Gordie Lake missing from values. Outpost had moved from a southern location in 2009, but value had not been updated. Owned by Pickerel Creek Outfitter. Blk 12.685 will impact it.
59722	lil anderson	1	N/A	N/A	42554	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Buffer required for trap cabin on Everett (Cox) Lake block 12.278.
59724	Chris Schaefer	1	287	42	N/A	N/A	Required	4.7.3 Assessment of Regeneration Success	Text should be discussing the 10-year term and the projected 16.223 ha proposed for assessment.
59725	Chris Schaefer	1	295	35	N/A	N/A	Required	4.9 Comparison of Proposed Operations	As noted in alteration 59660 you have considerable substitution (20%) into wood under the age of 80 (than was projected in SFMM) and this needs to be discussed. The paragraph will need to be adjusted.
59726	Ian Pyke	1	N/A	N/A	N/A	N/A	Required	FMP-18: Road Construction and Use Management	On page 2 of FMP-18, please put in a total and subtotal in the 10 year construction column.
59727	Chris Schaefer	1	N/A	N/A	N/A	figure 47	Required	4.9 Comparison of Proposed Operations	Please verify the reporting of the final test age classes, given that 10,000 ha of addition 60-80 year old wood was substituted into in term 1. This variance between the planed OPS and the LTMD should be visible in this chart.
59728	Chris Schaefer	1	209	18	N/A	N/A	Required	3.6.3 Assessment of Objective Achievement	Please confirm the number of indicators that did not achieve the Desired Level during the plan period while achieving the Target Level after 10-years.
59729	Chris Schaefer	1	309	3	N/A	N/A	Required	5.0 DETERMINATION OF SUSTAINABILITY	Please confirm the number of indicators that did not achieve the Desired Level during the plan period while achieving the Target Level after 10-years. I also suggest that the assessment notes cover all indicators that were not achieved during the plan period (add 1c, 2c, 2e, 6a)
59730	scott lockhart	1	87	41	N/A	N/A	Required	2.2.2 Summary of Demographic Profiles	remove 'by'
59731	scott lockhart	1	88	1	N/A	N/A	Required	Figure B-1A: Title, Certification and Approval Page	change 'Whiskey Jack' to 'Kenora'

59732	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	6.1 (l) Planning team's terms of reference	Please place a statement on the TOR approval page identifying where the original is retained if the signed approval page is not being included. Also note that the attached May 28, 2012 addendum deals with the CP and needs to be removed and replaced with the one for the FMP, if applicable.
59733	Julie Sullivan	1	N/A	N/A	N/A	N/A	Required	8.10 (f) Areas Selected of Operations Maps	The WCPP park additions are shown on the values map, but not the operational scale maps. This was pointed out at the Proposed Operations stage.
59734	scott lockhart	1	88	20	N/A	N/A	Required	2.2.2 Summary of Demographic Profiles	Lake of the Woods, the 'second largest inland lake in Ontario'
59735	Julie Sullivan	1	N/A	N/A	N/A	N/A	Required	8.10 (f) Areas Selected of Operations Maps	There is phase 2 harvest adjacent the south shore of Sydney L. There is no AOC prescription addressing harvest or access in this block. In the 2004-09 FMP where there were ops proposed north of Sydney L we asked for: harvesting to occur between Oct 1 and Mar 31 to protect tourism values, and all roads within 500 m of the park boundary be regenerated to prevent future unauthorized access. Similar is needed on the south shore of Sydney Lake. This was requested at the proposed operations stage.
59736	scott lockhart	1	86	6	N/A	N/A	Required	2.2.2 Summary of Demographic Profiles	'Fort' Frances
59737	Julie Sullivan	1	N/A	N/A	N/A	N/A	Required	Figure B-1A: Title, Certification and Approval Page	AOC "TVer" (Tourism – English River Waterway Park) applied to SOME blocks adjacent this park. The locations where it has been applied are all okay based on location of tourism facilities and canoe routes. However the AOC Supp Doc for TVer and Table FMP-19 (Road Crossings, Landings and Forestry Aggregate Pits in Areas of Concern) have conflicting info about roads within TVer. The road condition in AOC supp doc is "All roads within 500 m of park boundary must be regenerated to prevent access". FMP-19 says: "Operational roads and water crossings within 200 m of the park boundary are to be made passable following harvest operations through the removal of the water crossing structures, trenching of roads and/or placement of slash on the road way." The distances and conditions should be the same in both locations; 500 m is preferable.

59738	Julie Sullivan	1	N/A	N/A	N/A	N/A	Required	FMP-18: Road Construction and Use Management	Table FMP-18 (Road Construction and Use Management) indicates that there are NO access restrictions on Windfall Road leading to West English River Provincial Park. This is a problem. The Proposed Operations stage included Road Supp doc for Windfall Road, which indicated access restrictions which applied to public and commercial resource users : Access to West English River Provincial park is prohibited from this road." This supp doc is not included in the draft plan.
59739	Julie Sullivan	1	N/A	N/A	N/A	N/A	Required	FMP-18: Road Construction and Use Management	Conifer and Fly roads accessing north/west side of West English River Provincial Park (north shore Unexpected L and west shore Wilcox Lake) do not appear to have any access restrictions on them. Table FMP-18 indicates that these roads have NO access restrictions. Access restrictions are needed similar to what is on Windfall Road.
59740	Julie Sullivan	1	N/A	N/A	N/A	N/A	Required	Figure B-1A: Title, Certification and Approval Page	A few blocks of phase 1 and 2 harvest adjacent Rushing River, near entrance adjacent block on west side of highway. See BM41550, block 12.339. There is no AOC for aesthetics, noise, or access. No AOC prescription for timing restrictions applied. This needs to be addressed because noise carries and industrial noise is much different than Hwy noise.
59741	Julie Sullivan	1	N/A	N/A	43550	N/A	Required	8.9 (f) AOC SupDoc	A few blocks of phase 1 and 2 harvest adjacent Eagle-Dogtooth. Blocks around Ethelma/Highwind lakes (12.162, 12.158, 12.160) have a timing restriction (Seasonal restriction on harvest and mechanical site preparation operations between May 1 and Oct 31. No restriction on other low-noise renewal activities. All operations permitted between Nov 1 and April 30.). Some Operational Road Blocks (ORB) (170, 172) in the area are scheduled for decommissioning in 2016. AOC is shown on maps, but stands are not listed in supplementary documentation for AOC "TVw". Need to add stands to supp doc.

59742	Julie Sullivan	1	N/A	N/A	42550	N/A	Required	8.10 (f) Areas Selected of Operations Maps	There is no AOC on harvest or access on block 12.333 / ORB 168 east of Kilvert Lake (Eagle-Dogtooth PRovincial Park). At the Proposed Operations stage we asked that the follwowing prescription be applied: "Seasonal restriction on harvest and mechanical site preparation operations between May 1 and Oct 31. No restriction on other low-noise renewal activities. All operations permitted between Nov 1 and April 30.)" This was not done. The prescription should also be applied to block 12.884.
59743	Julie Sullivan	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	This relates to FMP-10, FMP-18 and AOC supp doc. There is no Road Supplementary documentation for Highwind Road. There was a conference call with district and regional staff about this. The district didn't want to include this Crown-responsibility road in the FMP and would rather deal with it via work permits. Part of the outcome was that operations in block 12.160 /ORB 176 and 178 (not adjacent park) would be carried out via an operational road in winter to ensure no change in condition of Highwind Road or change in accessibility to park beyond this area (i.e. to Hillock L). The maps show this, but Table FMP-10 needs to have block 12.160 added to AOC TVw. Maps show the operational road blocks but do not indicate that operations will be carried out in winter. Table FMP-18 does not indicate that road will only be used in winter; it only indicates that roads will be decommissioned in 2016. Road Supplementary Documentation for these operational roads does not indicate that operations will be carried out in winter only. This concern was raised at proposed operations stage.
59745	scott lockhart	1	89	29	N/A	N/A	Required	2.2.2 Summary of Demographic Profiles	remove 'off' (Jones Road, also known as Highway 671)
59746	scott lockhart	1	89	39	N/A	N/A	Required	2.2.2 Summary of Demographic Profiles	what is the difference between '185 private dwellings and 185 households'?
59748	scott lockhart	1	90	10	N/A	N/A	Required	2.2.2 Summary of Demographic Profiles	change 'Whitefish Bay No. 32C' to 'Sabaskong Bay No. 32C'
59749	scott lockhart	1	90	13	N/A	N/A	Required	2.2.2 Summary of Demographic Profiles	change 'Sabaskong Bay No. 32A' to 'Whitefish Bay No. 32A'
59750	scott lockhart	1	90	29	N/A	N/A	Required	2.2.2 Summary of Demographic Profiles	The community profiles for Wabaseemoong and Dalles do not include as much info as the other FN communities. This info should be available
59753	Ian Pyke	1	227	30, 31	N/A	N/A	Required	4.2.2.1 Silvicultural Ground Rules	Please revise the sentence starting at the end of line 29 to "Actual ES 11 and 12 areas will be identified on the AWS maps."

59756	Julie Sullivan	1	N/A	N/A	42550	N/A	Required	8.10 (f) Areas Selected of Operations Maps	The park superintendent for Eagle-Dogtooth Provincial Park has had ongoing discussions about reomoving a water crossing on an operational road south of Gale Lake at the park boundary (near block 12.884 on the operations map where it says “WS01” on the left side of the purple area, and the road/crossing is just south of that). There is no specific time frame of when this work should or can be completed, but since the company is harvesting in that area and will have machinery there, the water crossing removal could be done whenever the block is harvested.
59757	scott lockhart	1	219	N/A	N/A	N/A	Required	Figure B-1A: Title, Certification and Approval Page	change top header to '4.0 Planned Operations'
59764	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-4: Silvicultural Ground Rules	Please review the renewal standards (acceptable species limits) for Intensive and Basic PJD, Intensive and Basic PJM, and Intensive SPD as the resulting forest condition (yield curves) are 100% Pj+Sb while these SGRs would permit up to 30% other species (and up to 20% Po+Bw). These standards should be tighter.
59766	brenda skene	1	N/A	N/A	40548	N/A	Required	8.10 (f) Areas Selected of Operations Maps	There is a patented property (BR54) on the SW corner of phase 2 block 12.349 that was not identified on the FMP maps. The property is located within a shoreline reserve but may require more buffer. Patented land reference is 104823. Location has been marked on the hard copy maps.
59767	sarah mckenzie	1	4	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	Den prescriptions for furbearing mammals (enduring and transitory features) missing from FMP-10.
59768	brenda skene	1	N/A	N/A	45555	N/A	Required	8.10 (f) Areas Selected of Operations Maps	There is an LUP (LUP 56) very close to the S end of phase 2 block 12.373 that has not been identified on the FMP map. Location is marked on the hard copy map.
59769	sarah mckenzie	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC for bat hibernacula - should add the SSG (see s.4.2, Table 4.2l, p.99) prescription now that bats have been included on the SAR list.
59773	brenda skene	1	N/A	N/A	48560	N/A	Required	6.2 (f) Areas Selected of Operations Maps	There is a disposition identified in CLAIMaps that may be patented property not identified on FMP map. The dispositions are located in the NE end of phase 1 block 12.360 within the Lac Seul shorline AOC. The area is in the Red Lake district and the nature of the disposition will have to verified by RL district. Location of dispositions marked on hard copy of map. There is also a road to the disposition that runs through the operational area of block 12.360.

59774	sarah mckenzie	1	16	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	Chimney Swift missing from NO02
59776	sarah mckenzie	1	16	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	Should have an AOC for Flooded Jellyskin (S. 4.3, Table 4.3a, p.103 SSG)
59777	Chris Schaefer	1	N/A	N/A	N/A	UMS-3	Required	6.1 (g) Road SupDoc	For your operational road SupDoc using UMS-3 clause C) needs to be updated (pg 3, ln 1) as it is dealing with 5 ORBs (not 5 roads) and the timeframe is 2016 not the CP 2012-2014 (pg 3, ln 3). In addition, more detail is required to outline the actual decommissioning provisions to be applied to these roads to address the Regional Direction (recover productive landbase) in clause F). If this detail is covered in the 4.5.8 section of the main text please note this in the SupDoc and the FMP-18 footnotes for UMS-3 (but be aware that this text states that the preliminary provisions including regeneration conditions and timelines are documented for the roads ... in the SupDoc? (pg 274, ln 9). Also look through the other provisions in 4.5.8 closely and ensure that they all apply (progressive rehab, 5-years).
59781	sarah mckenzie	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	AOC for wolverine dens missing.
59782	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	6.1 (g) Road SupDoc	Ensure all applicable primary and branch road SupDocs are included in the draft plan. FMP-18, the associated 4.5 plan text, and the Road SupDoc all identify different new primary and branch roads for planned construction during this 5-year term. A SupDoc is required for each new planned Primary or Branch road.
59783	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-18: Road Construction and Use Management	Ensure the plan start length (0) and 10-year planned construction length are included for the primary and branch roads that are scheduled for construction during the 5-year term. Some are blank.
59784	John Myshrall	1	N/A	N/A	N/A	N/A	Required	4.3.1 Harvest Areas	"The company" change to Forest Manager
59786	John Myshrall	1	N/A	N/A	47557	N/A	Required	6.2 (c) Values Maps	Patent area's missing. Trap cabin should be at landing area 475980 5578010
59787	John Myshrall	1	N/A	N/A	47560	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Blk 12.751 * indicated on map Nest site? no associated AOC Many maps with this ie 48559
59788	John Myshrall	1	N/A	N/A	49557	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Water crossing in wrong location Blk 12.192
59789	John Myshrall	1	N/A	N/A	50559	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Blk 12.963 Stream labeled WS02-WS01-Wso2 again. Should be Wso2-Wso1
59790	John Myshrall	1	N/A	N/A	50556	N/A	Required	6.2 (c) Values Maps	Patent layers missing Angood lake area again.
59791	John Myshrall	1	N/A	N/A	39556	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Islands in English river id as LUP, none exist same as 39557
59792	sarah mckenzie	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	Please consider adding the row of titles to the aggregate/roads columns on at least the top AOC.

59793	John Myshrall	1	N/A	N/A	40550	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Roads layer incorrect label- Label storm bay rd
59794	John Myshrall	1	N/A	N/A	41554	N/A	Required	6.2 (f) Areas Selected of Operations Maps	blk 12.260 Orb should be around patent not encompass patent.
59795	John Myshrall	1	N/A	N/A	42549	N/A	Required	6.2 (f) Areas Selected of Operations Maps	blk 12.194 Gelley lake Landfill not identified.
59797	Gregg Lloyd	1	20	38	N/A	N/A	Required	2.1.1 Current Forest Condition	The text shows the total area as 1,063,446 but this is not shown in table 1, are there ownership types that are not being shown in the table? Please ensure these numbers match or explain why they don't.
59798	Todd Skene	1	N/A	N/A	N/A	Maps	Required	8.10 (h) Other Maps	Show Modified AOC (hatching) in Harvest Blocks 12.354, 12.352
59799	Gregg Lloyd	1	21	5	N/A	N/A	Required	2.1.1 Current Forest Condition	Please insert Park Addition into the text.
59801	Gregg Lloyd	1	25	1	N/A	N/A	Required	2.1.2.1 Forest Units	Please provide a description of the FU that are listed on the page or the link to table 2.
59805	Gregg Lloyd	1	27	37-42	N/A	N/A	Required	2.1.2.1 Forest Units	Please explain why the decision has been made to increase the amount of conifer and pine on the unit.
59808	Gregg Lloyd	1	34	1	N/A	N/A	Required	2.1.2.1 Forest Units	The total for the first eight FU equal 96% and the last four equal 2.8%, for a total of 98.8. I"m assuming the remaining 1.2% is rounding but this needs to be shown, especially as you are showing the FU that are less than 1%.
59809	Gregg Lloyd	1	53	9	N/A	Table 6	Required	2.1.3 Forest Resources	Whip-poor-will context is citing the Dixie Lake Road which is not in the Whiskey Jack forest. Either expand title to identify it is a regional context or limit examples to WJ forest.
59812	Rob Bowen	1	1	1	N/A	SFMM Data File	Required	8.9 Supplementary Documentation	The SFMM data file submitted with the draft plan is missing the last few runs, including the final LTMD. Please provide the data file with all the required runs.
59814	Gregg Lloyd	1	78	8	N/A	N/A	Required	2.1.3 Forest Resources	Please indicate if the MNR operates any of these pits as they are managing the unit and if not where the MNR gets the material for road building.
59815	Gregg Lloyd	1	80	20	N/A	N/A	Required	2.1.3.3 Natural Resource Features, Land Uses and Values	Pakwash park is no longer run by Ear Falls 2000 but rather Friends of Pakwash. Please correct.
59816	Gregg Lloyd	1	84	11	N/A	N/A	Required	2.0 MANAGEMENT UNIT DESCRIPTION	Please indicate that roads may be decommissioned for caribou concerns regardless of whether a third party is interested in maintaining the road.
59817	Todd Skene	1	219-223	N/A	N/A	Header	Required	4.0 PLANNED OPERATIONS	Header needs to be changed to 4.0 Planned Operations Page 219 to 223
59819	Gregg Lloyd	1	112	11	N/A	N/A	Required	3.0 DEVELOPMENT OF THE LTMD	Please complete sentence.
59821	sarah mckenzie	1	24	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	"New roads will not be located within 15m of the active channel unless there is no feasible alternative...." (S. 4.1, p.54 SSG) missing from LPS streams.
59822	Gregg Lloyd	1	118	25	N/A	N/A	Required	3.0 DEVELOPMENT OF THE LTMD	Please explain why this was deleted as an objective or explain how it was incorporated into other objectives.

59824	Todd Skene	1	244	14	N/A	Figure 40	Required	4.3.1 Harvest Areas	Change "Comparison of 10-Year Harvest Area by Forest Unit" to "Comparison of 10-Year Harvest Area by Age Class"
59825	Gregg Lloyd	1	122	43	N/A	N/A	Required	3.0 DEVELOPMENT OF THE LTMD	Was there no objective target to limit the increase of mixwood areas for long term FU targets or for wildlife concerns through silviculture? Please explain how this relates to this objective as this may relate negatively to your target of achieving the lowest cost per metre. (I.e. more spray to limit deciduous species will increase cost).
59826	Gregg Lloyd	1	128	1	N/A	N/A	Required	3.0 DEVELOPMENT OF THE LTMD	Forest composition and structure.... Not sure what note in red means at the end of input, please explain further or remove.
59827	Gregg Lloyd	1	131	1	N/A	N/A	Required	3.0 DEVELOPMENT OF THE LTMD	* are used throughout table that might be indicating a foot note, but no footnote is shown. Please remove * or indicate footnote.
59828	Gregg Lloyd	1	178	2	N/A	Figure 31	Required	3.0 DEVELOPMENT OF THE LTMD	Please explain why PJD is the largest FU on the unit with almost 1/4 of the area but it appears that POD and HMX are the largest FU's being harvested.
59832	Gregg Lloyd	1	199	2	N/A	Table 30	Required	3.0 DEVELOPMENT OF THE LTMD	You have indicated that OLT wasn't used for this FU, so why is it necessary to show it in the table? Having the numbers there just confuses the reader and leads to concerns about the validity of the assumptions for the OLT.
59835	Gregg Lloyd	1	212	17-26	N/A	N/A	Required	3.0 DEVELOPMENT OF THE LTMD	The harvest level is similar to the previous plan so please explain further as to why the spending is dropping 46%. This is in light of your objectives to decrease the amount of mix-woods on the unit and provide habitat for caribou. Appears that extensive treatments are being favoured due to budget constraints rather than the other objectives in the plan.
59838	brenda skene	1	121	8	N/A	N/A	Required	3.4 Desired Forest and Benefits	insert (MEA) after Moose Emphasis Area
59840	brenda skene	1	259	27, 30	N/A	N/A	Required	4.4.2 Renewal Support	The Seed Collection Forecast and the Planting Stock Forecast tables are mislabled or the tables are misplaced (take your pick)
59844	sarah mckenzie	1	230	LLP	N/A	N/A	Required	4.2.2.2 Conditions on Regular Operations	MEA description syas that there are no harvest blocks in the Moose Emphasis Areas - old CP text?
59848	Todd Skene	1	280	45-46	N/A	N/A	Required	4.7.1 Forest Operations Inspections	Todd Skene also is designated to review nad approve FOIP inspections.
59849	Todd Skene	1	281	06-Jul	N/A	N/A	Required	4.7.1 Forest Operations Inspections	Naotcrief Resource Management Inc. is no longer an existign company.
59850	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-4: Silvicultural Ground Rules	I add this alteration, so that the standards can be altered after draft plan, if desired. The use of density and stocking needs to be reviewed as it may be better to express these standards differently, so that the LSP method currently being tested on the forest can be directly linked to the standards.

59852	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	6.2 (f) Areas Selected of Operations Maps	SGR's need to be portrayed for harvest & R/T areas on you operational scale maps. For harvest suggest adding a relationship table (FU=Preliminary SGR) in the legend. For R/T since this has only been shown at a landscape scale, something more creative will be required (as the FU and ecosite information is only shown on the OPS scale maps).
59853	Todd Skene	1	286	24-30	N/A	N/A	Required	4.7.3 Assessment of Regeneration Success	Need to add to bullet points the use of LArge Scale Photoraghy and photo interpretation.
59854	Chris Schaefer	1	N/A	N/A	41549	Loon Lk Rd corridor	Required	6.2 (f) Areas Selected of Operations Maps	The reconstruction of this road is being planned as a new road, including the apparent reconstruction within an N01 value. I see that the corridor excludes the core so this should be OK, as I expect that the AOC does not permit new roads in this zone. However, I am not seeing a crossing location to the west of this value in WS01, or the outer zone of N01 (and I do not think you are going all the way around to the east). Once a 100 m crossing is confirmed, please undertake any necessary updates to the AOC SupDoc, Road SupDoc, FMP-10 and FMP-19.
59855	Gregg Lloyd	1	227	13	N/A	N/A	Required	4.0 PLANNED OPERATIONS	Please indicate if this is the only exception to the SGR in the plan and if not, briefly explain what the others are.
59856	Gregg Lloyd	1	228	1	N/A	biofibre	Required	4.0 PLANNED OPERATIONS	This paragraph leads the reader to think that slash piles are not available for chipping into biofibre, is that the intent? Further to this, any full tree chipping operation will be chipping and using some of the branches from the trees, is this considered part of the harvested tree? Please provide further clarification in this section so it is clear what is allowed to be used and what is not.
59857	Gregg Lloyd	1	228	1	N/A	Downed woody material	Required	4.0 PLANNED OPERATIONS	The last bullet seems to indicate that site prep can't occur. Please clarify, in text, exactly what you are referring to here, please.
59858	Gregg Lloyd	1	228	1	N/A	Erosion	Required	4.0 PLANNED OPERATIONS	2nd bullet point is too wishy-washy. Please replace "where possible" with something more definite or give qualifications on when this can occur.
59859	Gregg Lloyd	1	229	1	N/A	Erosion	Required	4.0 PLANNED OPERATIONS	1st bullet - please define what an extreme slop would be.
59860	Gregg Lloyd	1	229	1	N/A	Erosion	Required	4.0 PLANNED OPERATIONS	4th bullet: Please clarify that only steep slopes (i.e. slopes great than x%) will require this treatment.

59863	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	I note that you are planning to reconstruct the Bug Lk and Witch Bay road through an APA area (BM41549). While FMP-10 identifies the crossing by this new road, FMP-19 is missing the crossing construction conditions for primary and branch roads crossing AOC A01, and the basemap is missing the 100 m wide crossing location of this value.
59864	Chris Schaefer	1	N/A	N/A	41549	N/A	Required	6.2 (f) Areas Selected of Operations Maps	I note that you are planning to reconstruct the Bug Lk and Witch Bay road through an APA area (BM41549). While FMP-10 identifies the crossing by this new road, FMP-19 is missing the crossing construction conditions for primary and branch roads crossing AOC A01, and the basemap is missing the 100 m wide crossing location of this value.
59865	sarah mckenzie	1	N/A	N/A	N/A	N/A	Required	6.2 (h) Other Maps	MAFA's are missing on the maps - noticed specifically in the MEA.
59866	sarah mckenzie	1	N/A	N/A	N/A	N/A	Required	8.10 (f) Areas Selected of Operations Maps	Residual in the MEA should be mapped out to address low residual zones in harvest blocks.
59868	brenda skene	1	N/A	N/A	N/A	Sup Doc H	Required	List of Supplementary Documentation	Remove the reference to the CP on page 1 - B: Operational Perscription, (b) Description of proposed operational perscription, last bullet
59869	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	FMP-19: Road Crossings, Landings, and Forestry Aggregate Pits in AOCs	Note that the listing at the front of the table will need to be updated to reflect primary/branch road crossing of A01. There may be others but the OPS maps show Bug lake and Witch Bay crossing A01.
59871	Chris Schaefer	1	N/A	N/A	N/A	N/A	Required	6.2 (f) Areas Selected of Operations Maps	In my spot check I did not see a map product identifying the roads to be decommissioned or roads with UMS changes, or access controls ... nor did I see these identified in the standard OPS legend block. This is needed.
59872	Todd Skene	1	N/A	N/A	N/A	N/A	Required	FMP-4: Silvicultural Ground Rules	CAn you add a PJD and PJM BAS1 to PRW.
59873	Todd Skene	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	The column headers are missing in each AOC Table. When indicating yes or no within a column the reader does not know what the questions is.
59874	Todd Skene	1	N/A	N/A	N/A	N/A	Required	FMP-4: Silvicultural Ground Rules	The AOC Operation Prescriptions quite often refer to the CP. Should be changede to FMP
59875	Todd Skene	1	N/A	N/A	N/A	N/A	Required	FMP-15: Planned Wood Utilization by Mill	Add a foot note stating why there is a shortfall in the poplar supply.

59876	Gregg Lloyd	1	231	2	N/A	loss of productive land	Required	4.0 PLANNED OPERATIONS	You indicate that ALL chipper debris will be taken back, which is economically impossible and should cause compliance issues immediately with operations. You have six options for dealing with chipper debris but one needs to be the preferred method. (I've since found this on page 249 so please reference this section or elaborate here) Also, when will the discussions happen with the forest manager, why not have them now and figure out what the preferred method will be and list it here and then it will be enforceable with operators. Currently, chipper piles are not allowed to be burnt, so please re-word this section to remove or down play this operation. You also say that all chipped pads will be recorded in the AWS, is this really feasible? Please clarify.
59877	sarah mckenzie	1	N/A	N/A	N/A	N/A	Required	8.10 (f) Areas Selected of Operations Maps	Some nest AOC's are showing inconsistent buffers to labels. Example: Map 44558 Block 12.931 the NO1 nest sizes and buffers are smaller than the NO1's adjacent.
59878	Gregg Lloyd	1	239	1	N/A	Wildlife trees	Required	4.0 PLANNED OPERATIONS	Should consider putting a max limit on the amount of snags allowed in the cutover.
59879	Gregg Lloyd	1	239	1	N/A	Wildlife trees	Required	4.0 PLANNED OPERATIONS	Please explain what will happen if a stand is harvested that does not have 25cm DBH trees.
59880	Gregg Lloyd	1	239	1	N/A	Wildlife trees	Required	4.0 PLANNED OPERATIONS	Please explain how operator will know when he is allowed to stub a stand. I.e. how will he know if the tree is required to be a seed source. When will this direction be given?
59881	Todd Skene	1	N/A	N/A	N/A	SUP DOC F	Required	List of Supplementary Documentation	Withni SUP DOC F - there should be soem discussion around teh use of Large Scale Photo Interpretation.
59883	Gregg Lloyd	1	241	26	N/A	N/A	Required	4.0 PLANNED OPERATIONS	Please add a cover all statement that indicates that if these operations were to be required on the unit an amendment would occur to the FMP where affected stakeholders would be consulted.
59884	Gregg Lloyd	1	249	23	N/A	N/A	Required	4.0 PLANNED OPERATIONS	Please give more details on pilot project for burning chip piles.
59885	Todd Skene	1	4	N/A	N/A	N/A	Required	List of Supplementary Documentation	SUP DOC G - Roads Planning Documentation Section 2 iii) Estimated Cost of Construction and Use Management - needs to include th installation of a 20' bridge.
59886	lil anderson	1	N/A	N/A	42548	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Municipal Sewage Lagoon located in proposed road corridor for blk. 12-204. Realign proposed road corridor to exclude area.
59887	lil anderson	1	N/A	N/A	42558	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Provincially tracked species indicated in blocks 12.568 and 12.675 and 674.

59888	lil anderson	1	N/A	N/A	43548	N/A	Required	6.2 (f) Areas Selected of Operations Maps	NNE side of Blk 12.184 is on patented land that is not shown on map.
59889	lil anderson	1	N/A	N/A	43558	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Trapping cabin at ORB 336 or blk 12.540 should be recognized as value and buffered.
59890	lil anderson	1	N/A	N/A	45555	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Block 12.273 has patented land and lodge within its boundaries. realign block boundaries outside of patented land.
59891	lil anderson	1	N/A	N/A	47559	N/A	Required	6.2 (f) Areas Selected of Operations Maps	Osprey nest on south edge of Block 12.366 (Red Lake District) is in proposed corridor.
59892	lil anderson	1	N/A	N/A	48557	N/A	Required	6.2 (f) Areas Selected of Operations Maps	There is no buffer on lodge and patented land in block 12.772
59893	lil anderson	1	N/A	N/A	N/A	N/A	Required	6.2 (c) Values Maps	Patented land on Land Value Map would be more visable if it too was 'boxed'. Otherwise it appears that small pieces are missing from map, ie. Havik Lake, North side of Silver, Keys, etc. while small lup's are very noticable.
59896	Gregg Lloyd	1	256	10	N/A	N/A	Required	4.0 PLANNED OPERATIONS	Please discuss the snow damage that occurred on the unit last October and if this will potentially be harvested.
59897	Rob Bowen	1	136	1	N/A	N/A	Required	3.5 Objectives and Indicators	Somewhere in this section there should be a reference to the section of the Analsysis Package with the inputs, results and conclusions of the development of the managment objectives and scoping investigations (FMPM B-21 L9-11).
59898	Rob Bowen	1	143	30-32	N/A	N/A	Required	3.5 Objectives and Indicators	This sentence seems to contradict itslef. If OLT did not adequately capture PRW area (not enough?) then how can it grossly overestimate PRW area?? Perhaps it is just in how the sentence is worded? Please correct or clarify this statement.
59900	sarah mckenzie	1	240	N/A	N/A	N/A	Required	4.2.2.2 Conditions on Regular Operations	CRO's missing for barn swallow and snapping turtle
59901	sarah mckenzie	1	230	N/A	N/A	N/A	Required	4.2.2.2 Conditions on Regular Operations	LLP DEA's list 9 blocks planned - is this from the CP?
59902	Rob Bowen	1	150	40	N/A	N/A	Required	3.5 Objectives and Indicators	I would not think it is fair to say the total volume in the long-term is 520,000 in the LTMD. You certainly achieve more than 510,000 in Term 1 (~575,000), but the long-term would be better characterized as between 450,000 and 500,000. The LTMD only ever exceeds 500,000 in one term (T10) after T2. So, "the current harvest level could be sustained through the long-term at 520,000 m3" seems like a stretch. Please fix the paragraph.

59903	brenda skene	1	N/A	N/A	several	N/A	Required	6.2 (f) Areas Selected of Operations Maps	There is a gas line running through blocks, or the operational area of blocks, on several basemaps. This utility line is not shown on the FMP map. Gas line is active, North & Central Gas Corp. EAS #59 (easement). Basemaps and phase 1 blocks affected: 48555 12.308, 48556 12.306, 48557 12.112, 49558 12.340 12.344. Possible blocks in Red Lake district that may be affected (red lake to verify): 48560 12.362 12.360
59904	Rob Bowen	1	150	19	N/A	N/A	Required	Figure B-1A: Title, Certification and Approval Page	SPF from the LTMD is pretty consistently 340,000 m3 (only four terms are higher). So, please re-characterize this sentence to emphasize the 340,000 level, with a few terms higher (as much as 400,000). Feel free to choose appropriate words, but put the emphasis on the 340,000 level being achieved.
59905	Rob Bowen	1	150	20	N/A	N/A	Required	3.5 Objectives and Indicators	Po volume from the LTMD is 90,000 to 100,000 in the long-term (with one term hitting 113,000). The sentence in the text states a long-term range of 90,000 to 150,000. Please correct.
59906	Gregg Lloyd	1	259	14	N/A	N/A	Required	4.0 PLANNED OPERATIONS	Please explain why there is no tree improvement at all planned for the next ten years on the unit.
59907	brenda skene	1	N/A	N/A	41554	N/A	Required	6.2 (f) Areas Selected of Operations Maps	There is a 'Ballast Pit' identified in phase 1 block 12.254 on the lands control maps and in CLAIMaps, no evidence of disturbance on 2009 imagery. Will need to verify with Janet F to determine protection required (if any)
59908	brenda skene	1	N/A	N/A	43561	N/A	Required	6.2 (f) Areas Selected of Operations Maps	There is a alienation identified in CLAIMaps WKRL 93/94 in phase 1 block 12.488 in the Red Lake District area. May be an aggregate permit (quarry). No evidence of disturbance on 2009 imagery. Needs to be verified by Red Lake district and/or Provincial Mining Recorder
59909	Gregg Lloyd	1	262	25	N/A	N/A	Required	4.0 PLANNED OPERATIONS	As this is a Crown unit, aren't the roads all MNR roads anyway? Please clarify why you are discussing MNR transfer.
59910	Gregg Lloyd	1	276	15	N/A	N/A	Required	4.0 PLANNED OPERATIONS	Please mention that all compliance inspections are required to be completed by a certified compliance inspector.
59911	lil anderson	1	N/A	N/A	48559	N/A	Required	6.2 (f) Areas Selected of Operations Maps	There is patented land at north side of Wabaskang Lake that should have buffer RFD 247,187,

59914	Rob Bowen	1	126	Jan-25	N/A	N/A	Required	3.4 Desired Forest and Benefits	You should refer to the indicators as coming from the "Science and Information in support of Ontario's Forest Management Guides for Landscapes", rather than the draft guide ...the draft guide can't give direction (and it's certainly not coming out before this plan is approved...). Throughout the rest of the plan text you have been good about referring to OLT or the science package rather the guide that is not approved. Please adjust the paragraph to maintain the context, but make sure it is the science package you are drawing the indicators from.
59916	Rob Bowen	1	162	48-51	N/A	N/A	Required	3.6 Long-Term Management Direction	OLT does not represent PRW well. So, go with no decrease. However, argument here (continued on top of next page) doesn't seem to quite make sense. I thought OLT under-estimated PRW, not the other way around? Please contact me to make sure we are both on the same wave-lenght on the facts, and to discuss a potential adjustment to this piece of text.
59918	lil anderson	1	N/A	N/A	46558	N/A	Required	6.2 (f) Areas Selected of Operations Maps	It would appear that company is not using the most up to date water layer, as Anishinabi Lake is not showing as a cool water lake. Values map shows correct thermal value.
59919	Rob Bowen	1	184	1	N/A	N/A	Required	3.6.2 Selection of Areas for Harvest	In the list of criteria for harvest area selection, there is no mention of ESA listed species and specifically caribou (the caribou mosaic). Please add something about how the caribou mosaic may have been a selection criteria (or not!).
59920	Rob Bowen	1	184	1	N/A	N/A	Required	3.6.2 Selection of Areas for Harvest	You need to make some comments on how the criteria reflect the strategic modelling (FMPM B-22, L31-33).
59921	Rob Bowen	1	N/A	N/A	N/A	N/A	Required	FMP-11: Planned Harvest Area	The available harvest area numbers (...the numbers from the model) are missing from the table (greyed out!). The footnote indicates where they numbers come from, but they are not in the table. Please provide.
59922	Glen Hooper	1	246	1	N/A	N/A	Required	4.3.1 Harvest Areas	RE 4.3.1.1 Stand Level Residual in Harvest Areas: Please add reference that the residual requirement does not apply in your caribou emphasis area, which is the area covered by the DCHS. (wildlife tree requirements still apply, but not the patch sized residual).

59923	Rob Bowen	1	187	21	N/A	N/A	Required	3.6.2 Selection of Areas for Harvest	I am generally not too concerned with the level of subsitution and the rationales provided. However, the SPD in the available was about 45% less than 100 years old, but in the allocations 82% is less than 100 years old. This one stands out a bit and requires some specific mention within the rationales that follow the tables (not necessarily it's own sub-topic, just some specific highlighting).
59924	Rob Bowen	1	204	4	N/A	N/A	Required	3.6.3 Assessment of Objective Achievement	The statement that the SPF volume is projected to remain over 450,000 m3 is incorrect (I think that would be the Total volume?). Please correct discussion to reflect the SPF numbers.
59925	Rob Bowen	1	207	1	N/A	N/A	Required	3.6.3 Assessment of Objective Achievement	In the discussion of the indicators to be assessed during plan implementation (3.6.3.7...?), there should be some discussion of how the planned activities will contribute to the overall objective achievement (FMPM B-23, L28-30).
59926	Rob Bowen	1	299	10	N/A	N/A	Required	4.9 Comparison of Proposed Operations	The pdf supplied does not appear to document the same "Final_Test" run that was included with the SFMM data file? The pdf appears to agree with the plan text, but the provided SFMM run. Please verify and correct the appropriate documentation or data file.
59927	Rob Bowen	1	N/A	N/A	N/A	N/A	Required	FMP-9: Assessment of Objective Achievement	Forest Composition medium term projected numbers for Mature/Late Balsam don't seem to agree with the model projection ...perhaps just a typo?? Please correct.
59928	Angus Carr	1	N/A	N/A	N/A	N/A	Required	6.2 (i) Information products (coverages)	PRP Layer contains areas not in the PHR layer. The layer is not the raw output of the EFRT. Include only areas where mapped residual (SSG 3.2.2.2) is required.
59931	Glen Hooper	1	N/A	N/A	N/A	N/A	Required	FMP-10: Operational Prescriptions for AOCs	FMP-10 AOC's: Canoe route portages and campsites need an AOC, because they are a value and are nmappable. CRO's on roads is not enough for this value. The good news is that an AOC for both canoe route portages and campsites have recently been developed on Resolute Plans for Phase 2. This one can be borrowed as-is See Caribou FMP Phase-2 for latest approved version. If you need to discuss, please contact GH for details, thanks.

Summary of Major Changes between Draft and Final Plans

The *Forest Management Planning Manual (2009)* requires that a list of major changes to the draft forest management plan be prepared and be included in the supplementary documentation of the final FMP.

There were no major changes required to the draft plan during preparation of final forest management plan.

The changes and revisions included in the final plan were of a minor nature and did not change the Long-term Management Direction or the majority of the planned operations. Minor changes included:

- Minor revisions to planned harvest areas to address public comments and to address no harvest portions of areas of concern associated with newly identified values.
- Area of concern (AOC) prescriptions added to address protection for additional Species At Risk.
- Revised portions of the plan text and supplementary documentation as per required, suggested and editorial review comments. No changes were made to the long-term strategic management direction.

Preparation of the

2012 to 2022
FOREST MANAGEMENT PLAN

for the
Whiskey Jack Forest

This Terms of Reference meets the requirements of the Forest Management Planning Manual (2009) and the Forest Information Manual (FIM). As Plan Author, I am committed to my role in ensuring that this Forest Management Plan (FMP) is produced on schedule as described in this Terms of Reference and in compliance with all relevant legislation.

1.0 INTRODUCTION

This Terms of Reference in conjunction with the associated project plan will guide Phase I planning efforts to prepare the Whiskey Jack Forest Management Plan (FMP) for the ten-year period from April 1, 2012 to March 31, 2022 including detailed operational planning for the first five-year term April 1, 2012 to March 31, 2017. Prior to the start of Phase II planning, the Terms of Reference and Project Plan will be reviewed and updated.

2.0 ORGANIZATION FOR PLANNING

This section provides the organizational structures established to ensure the timely completion of the FMP. Those structures include the steering committee, Planning Team, plan advisors and plan reviewers. More detailed descriptions of roles and responsibilities for these groups including any Task Teams set up to facilitate production of the FMP, can be found in the associated project plan.

2.1 Steering Committee

List of Steering Committee Members:

Steering Committee Member Name	Organization and Title	Role
Andrew Applejohn	MNR District Manager	Leader
Shawn Stevenson	Area Supervisor	Member
Kevin Ride, R.P.F.	Representative of Regional Director	Member

2.2 Planning Team

List of Planning Team Members

Planning Team Member Name	Representing	Role
Kurt Pochailo, R.P.F.	MNR	Area Forester/Plan Author
Stephen Duda	MNR	Planning & Information Management Supervisor/ Planning Team Chair (strategic) /Project Manager
Shawn Stevenson	MNR	Area Supervisor/Planning Team Chair (operational)
Hassan Mohamed, R.P.F.	MNR	Resource Analyst
Mary Duda	MNR	Area Biologist
Abby Anderson, R.P.F.	MNR	District Planner

Planning Team Member Name	Representing	Role
Henry Dribnenky	Kenora LCC	LCC Representative
Laurent Tetreault	Red Lake LCC	LCC Representative
Dale Munro, R.P.F.	Kenora Forest Products	Industry Representative - Receiving Facility
Bob Boyce, R.P.F.	Weyerhaeuser	Industry Representative - Receiving Facility
Norm Hissa	MNR	Aboriginal Community Liaison
Greg Lloyd, R.P.F.	MNR	MNR Forester (Red Lake District)
Debora Henry	Ochiichagwe'babigo'inning (Dalles) First Nation	Aboriginal Community Representative
Joel Henley	Kenora Métis Council	Aboriginal Representative
Doug Riffel	Wabauskang First Nation	Aboriginal Community Representative
Marvin McDonald	Wabaseemoong Independent Nations	Aboriginal Community Representative
Conrad Tom	Naotkamegwanning (Whitefish Bay) First Nation	Aboriginal Community Representative
TBA	Grassy Narrows First Nation (Asubpeeschoseewagong Netum Anishinabek)	Aboriginal Community Representative

2.3 Key Advisors and Support

The following identifies those individuals who will act as Key Plan advisors and Support.

Support/Key Advisor Name	Representing	Role
Jason Suprovich	MNR	Logistics and forestry support
Lil Anderson	MNR	Communications support
Gerry Simmons	MNR	GIS support
Todd Skene	MNR	Operational Support
Shannon Rawn, R.P.F.	Forest Resource Licence Holder	Wincrief/Naotcrief Support
Matt Yeo	Ontario Parks – Parks Superintendent	Operational Support

2.4 Other Plan Advisors

District MNR Advisors:	
Walt Lesenke	Fire Management
MNR Regional/Provincial Advisors:	
Kevin Ride, R.P.F.	A/Senior Forest Management Planner
Chris Schaefer, R.P.F.	Forest Mgmt. Planning Specialist
Rob Bowen, R.P.F.	Regional Analyst
Darren Elder	A/Regional Planning Biologist
Angus Carr	Regional Planning Analyst
Cathy Cavalier, R.P.F.	Forest Program Specialist
Jenn Chikoski	A/Species at Risk Biologist
Garnet Beemer	Regional Analyst Information Specialist
Evan Simpson	Senior Planner
Renee Carrière	Cultural Heritage Specialist
John Stephens	Provincial Planning Economist
Bill Taylor	Native Liaison Officer
Ontario Parks Advisors:	
Julie Sullivan	Senior Park Planner
Matt Yeo	Park Superintendent
Ron Leekam	Natural Heritage Specialist
MNR Science Advisors:	
Bob White	Science Advisor
Colin Bowling	Science Advisor
Other Provincial Advisors:	
Ministry of Northern Development, Mines and Forests:	
Hugh Lockwood	Regional Land Use Geologist
Andreas Lichtblau	Resident Geologist
Pat Corbett / Mike Davis	Forest Industry Liaison
Mark Vermette	Northern Development Officer
Frank Bastone	Tourism Consultant
Ministry of Citizenship and Culture:	
Paige Campbell/Andrew Hinshelwood	Regional Archaeologist

2.5 Plan Reviewers

List of Plan Reviewers

Plan Reviewer Name	**Position**
Greg Lloyd, R.P.F.	MNR Area Forester (Red Lake)
Hassan Mohamed, R.P.F.	Resource Analyst
Stephen Duda	Planning and Information Management Supervisor, Planning Team Chair and Project Manager
Shawn Stevenson	Area Supervisor
Mary Duda	Biologist
Abby Anderson, R.P.F.	District Planner

Plan Reviewer Name	Position
Norm Hissa	Aboriginal Community Liaison
Todd Skene	IRM Technical Specialist
Fred Zroback	Area Technician
Kevin Ride, R.P.F.	Senior Forest Management Planner (Acting)
Chris Schaefer, R.P.F.	Forest Mgmt. Planning Specialist
Rob Bowen, R.P.F.	Regional Analyst
Angus Carr	Regional Planning Analyst
Garnet Beemer	Regional Analyst Information Specialist
Cathy Cavalier, R.P.F.	Forest Program Specialist
Julie Sullivan	Senior Park Planner
Ron Leekam	Natural Heritage Specialist
Jenn Chikoski	A/SAR Biologist
Darren Elder	A/Regional Biologist

2.6 Operation of the Planning Team

Planning Team Meetings

- Meetings will be monthly (more frequently if required).
- Stephen Duda will chair.
- Agenda items are submitted to the chair prior to distribution of the agenda by the Chair.
- Meeting protocols:
    - All members will have an opportunity to express their views.
    - Members will be respectful of other members or visitors.
    - Discussions should remain focused on the topic at hand.
    - The Chair will control the speaking order, to ensure that all Planning Team members have an opportunity to participate in the discussions.
- Standing Agenda items will include a schedule update, updates from active Task Teams, correspondence received and discussions held with stakeholders and Aboriginal Planning Team member items for discussion.
- Freedom of Information and Protection of Privacy Act (FIPPA) will apply such that other than Planning Team members' names, personal information will not appear in the minutes.
- Discussion items not on the agenda, or beyond the scope of the FMP, will be discussed as time permits or scheduled for a separate meeting.

The Planning Team will also be available to meet to discuss issues with stakeholders directly affected by proposed operations. This will provide an opportunity to engage in discussions that will initiate the process for resolution of any conflicts. Where major issues arise, a separate process of stakeholder meetings may be required.

Decision Process:

Whenever possible, decisions by consensus.

- To seek consensus:
  - All members will be provided with the necessary opportunity to fully express their viewpoints, and will be expected to provide input.
  - All members will be respectful of the opinions of other members and will give their input full consideration.
  - The chair will periodically poll the group to determine if there is a progression toward consensus and to focus discussion on any significant difference of opinion.
  - Differences of opinion will be thoroughly discussed with an emphasis placed on,
    - Attempting to understand conflicting viewpoints;
    - Clarifying any misinterpretations and focusing discussions on specifics; and
    - Seeking to identify modifications that will move toward a mutually acceptable solution.
- If a consensus cannot be attained, the issue may be forwarded to the Steering Committee for advice or action.
- The Decision Making Process may involve The Process Streamlining Test (PST) for considering the need for additional plan content or products. The PST is comprised of the following questions:
  1. What is the objective of the requirement (for additional plan content/products)?
  2. Is the requirement necessary to meet the objective?
  3. Is the requirement as simple, cost effective and efficient as it can be?
  4. What alternatives or change will lead to a positive response to the above?

3.0 PLAN PRODUCTION, REVIEW AND APPROVAL

3.1 Schedule for Plan Production

See Appendix 2 of the Project Plan for a schedule of plan production which details the plan component/requirements as per the FMPM.

3.2 Key Plan Production Deliverables and Associated Issues

Issues and challenges exist for the development of this FMP. The following issues have the potential to impact the plan production schedule. Where appropriate, Task Teams have been established and advisors have been identified to address these issues.

Furthermore, there has been recognition of the unique challenges to forest management planning in the Kenora District at the Regional and District level. Efficiencies to planning are expected by coordinating planning efforts between the Kenora and Whiskey Jack Forests, taking advantage of much of the previous planning effort which was part of the Planning for the 2009 Whiskey Jack Forest (strategic inputs and outputs) where possible, and assuming similar on the Kenora Forest. As well, there is Regional commitment to support these planning processes with the appropriate staff and resources necessary to meet the challenges of these planning processes.

- SFL transfer.
- Maintaining consistency and timelines between Kenora and Whiskey Jack FMPs.
- Landscape Guide approval and implementation.
- Stand and Site Guide implementation.
- Caribou Conservation Plan implementation.
- Resources currently available within MNR and SFL holder to achieve the planning schedule.
- The current planning schedule has been compressed to meet the required timelines in order to achieve an April 1, 2012 implementation target date.

For a listing of key plan production deliverables refer to the production schedule of the Project Plan.

3.3 Additional Plan Products

The Aboriginal Task Team may produce supplemental documentation for inclusion with the FMP which outlines the process as perceived by the First Nation and recognized Aboriginal Communities. Aboriginal topics/items brought forward in the planning process and how they were considered and/or other information that the Task Team and Planning Team feel is relevant to the plan productions or products thereof.

During plan production, the Planning Team may be asked (by a Planning Team member or external to the Planning Team) to include an additional plan product in the FMP. The Planning Team will consider inclusion of these additional products using the decision making process identified above in 2.5. The decision on the request for additional plan product/ content will be documented in the minutes to the Planning Team meeting (or some other agreed upon forum).

3.4 Analysis Tools

The FIM requires that all information systems (analytical models and tools) used in the development of the FMP are identified. Specifically, the plan project plan must identify the timelines for the provision of information prepared for each information system (inputs) and the results generated by each information system (outputs). The schedule must identify the critical stages in plan production where inputs and outputs/ results from the various information systems must be verified and accepted by the Planning Team. The schedule for plan production must also account for the interactive nature and integration of information between dependent information since results produced from one analytical tool are often inputs to another analytical model. The schedule must identify, for each information system, the following: when the input information will be provided to the Planning Team members for verification and acceptance; when the information inputs must be verified and accepted; and when the results produced from the various information systems must be verified and accepted by the appropriate Planning Team members and the MNR. The Planning Team members involved with each analysis tool are identified in the Project Plan in section 2.2 Task Teams.

1. Strategic Forest Management Model (SFMM)
SFMM is based on linear programming techniques and is used to model timber production capabilities of a forest for various levels of management intensity. The model is designed to be compatible with information currently available in Ontario. The model is also used to model wildlife habitat abundance for a range of species. SFMM version 3.5 will be used.

2. Stand and Site Coarse Filter Residual Tool
Evaluates the amount of residual forest at 50 and 500 ha scales and identifies areas where additional residual may be required.

3. Ontario Landscape Tool (OLT)
OLT is a tool to quantify landscape conditions and comparison with simulated range of natural variation. Specifically, the purpose of the tool is to: assign young forest classes to forest inventories; assign forest unit age class groupings to forest inventories; calculate old growth values from forest inventories; calculate frequency histograms of current and planned young forest pattern to allow comparisons with the landscape guide range; calculate landscape signature of current and planned texture of the mature forest matrix to allow comparisons with the landscape guide range. This tool measures both songbirds and wildlife indicator species, such as moose, marten, fisher, etc.

4. The Heritage Assessment Tool (HAT)
The HAT model is designed to identify high potential Cultural Heritage sites across the forest. A review of the proposed areas of operations by the MNR provincial archaeologist, Plan Author and Planning Team will subsequently refine the high potential areas.

5. Ontario Forest Analyst (OFA)
This program is designed to assist in applying the "Forest Management Guidelines for the Conservation of Woodland Caribou". It contains a caribou habitat classification query set, based on the guidelines, which identifies both preferred and useable habitat.

6. Socio-Economic Impact Model (SEIM)
SEIM is used to specify financial details of natural resource based projects and will produce an economic, social and environmental analysis. This model will may be used to detect relative socio-economic impacts among optional management alternative between the current level of operations and the proposed management strategy.

7. *Ontario Marten Analyst 2 (OMA2)
This tool has been developed in the Northwest Region to classify the landbase into "capable" forest types and "suitable" habitat. Suitable habitat can then be modelled through time, based on the current forest condition. OMA2 contains a "core builder" tool where the user can create various core habitat area scenarios and generate core habitat statistics.

8. *Natural Disturbance Pattern Emulation Guide Tool (NDPEGtool)
Is a GIS tool (ArcView based) designed to estimate forest disturbance perimeter, estimate residual (insular and peninsular) within forest disturbances, estimate planned clear cut.

Note: The Forest Management Guide for Landscapes has not yet been formally approved for implementation into 2012 plans. It is understood that the tools listed above will be used in the preparation of the 2012 FMPs and that the intent of the Forest Management Guide for Landscapes will be followed based upon the assumption that this Guide is soon to be approved with the expectation that 2012 FMP's will be prepared following its direction.

** In the event the landscape guide is not approved, these tools will be used to replace the OLT.*

3.5 Draft and Approved Forest Management Plan Distribution

The Plan Author will submit the plans in electronic format (via the Forest Information Portal) as described by the Forest Information Manual FMP Technical Specification and the FMPM 2009.

4.0 COMMUNICATIONS PLAN

4.1 General

The Forest Management Planning Manual (FMPM) identifies the need for a Communications Plan to ensure all interested parties are involved with, and are aware of formal opportunities to comment on all aspects of the development of the FMP. MNR is responsible for the preparation and delivery of the Communications Plan.

4.2 Internal Communications

The Planning Team will hold meetings and record/distribute minutes of these meetings to the appropriate groups. The Planning Team chair will maintain frequent communications with team members to assess progress and share information.

4.3 Communications with the Local Citizens Committee

The Local Citizens Committee (LCC) will be kept informed and updated with respect to the plan production through regular updates at LCC meetings. Individual issues or concerns that arise during the preparation of the plan may also be brought to the LCC for discussion and advice.

Copies of FMP Planning Team meeting minutes will be provided to LCC members and discussed at regularly scheduled LCC meetings.

4.4 Communications with Plan Advisors

Plan Advisors will be contacted to provide advice and assistance within their area of expertise during the development of the FMP. Advisors will also be available to review specific plan components in advance of Progress Checkpoints and/or key milestone dates. Planning Team minutes will be provided to the Forest Management Planning Specialist to keep the MNR Regional Plan Advisors informed as to plan developments.

Where other Agencies or Ministries have determined they have specific interests that should be addressed in the FMP, the Advisors for those organizations will be contacted when those interests are to be discussed by the Planning Team. Every attempt will be made to provide the Advisors with sufficient lead-time to arrange to attend specific Planning Team meetings if they wish. These Advisors will also be provided copies of all Planning Team minutes in order to stay current with planning developments.

4.5 Consultation Schedule

The schedule for consultation is included in the Project Plan (Appendix 2).

4.6 Public Notices

External notification throughout the planning process will occur primarily through direct mailings, local newspaper ads, and *Environmental Bill of Rights* (EBR) information notices through the Environmental Registry. Other notification methods may include e-mail, web postings etc. The required public notices for each stage of the planning process will be developed/arranged by the Planning Team and posted/organized by the MNR.

Supplementary notices, approximately one week prior to the scheduled date of information centres, may be issued by MNR, in consultation with the LCC and the Planning Team as a reminder to the public of their opportunity to participate.

An updated EBR information notice will be placed on the EBR Registry, at each stage of consultation.

Summary of Notices for Each Stage of Consultation

Note: Consultation timelines as prescribed in the FMPM will commence with the public postings that are placed in the local Kenora media (i.e. *Kenora Daily Miner and News*, *Lake of the Woods Enterprise*; whichever is first available to the public)

Notice Type	Remarks
Mailed	Whiskey Jack Forest mail-out
Newspaper	Notices to be placed in the following newspapers: *Kenora Daily Miner and News, Lake of the Woods Enterprise*, *Northern Sun News*, *Dryden Observer*, *Wawatay News*
EBR Notice	Information Notice on the Environmental Registry

4.7 Aboriginal Community Notices

If a customized consultation approach has not been agreed to with an Aboriginal community, a direct written notice will be provided to the Aboriginal Community in English, and upon request, in the Aboriginal language specified by the Community for each notice required for the FMP. A media notice will also be placed in the *Wawatay News*. The Aboriginal Communities to be provided direct written notice are:

- Ochiichagwe'babigo'inning First Nation (Dalles)
- Wabauskang First Nation
- Wabaseemoong Independent Nations
- Naotkamegwanning First Nation (Whitefish Bay)
- Grassy Narrows First Nation (Asubpeeschoseewagong Netum Anishinabek)
- Kenora Métis Council

4.8 Summary of Input and Confidentiality

Input will be acknowledged and brought to the Planning Team for response. The Planning Team will evaluate and analyse input during meetings to determine how the input could be considered in the development of the FMP. MNR, or the Plan Author, will respond in writing, in a timely way, to all written comments and submissions received from any person or organization during the preparation of the FMP. This requirement will also apply to all verbal comments if a written response has been requested.

After each stage of consultation, a summary of input received and response provided will be produced. This summary will form an Appendix to both the draft and final FMP but will not include names or address of people providing input into the FMP. Normally, the names and addresses of persons who provide input will be added to the mailing list unless advised not to.

Notices will identify that comments will become part of the public record, but that under the *Freedom of Information and Protection of Privacy Act*, personal information will remain confidential unless prior consent is obtained.

5.0 MNR FUNDING REQUIREMENTS

Summary Description of MNR Funding Requirements	**Fiscal Year (April 1 to March 31)**			
	2009/2010	**2010/2011**	**2011/2012**	**Total**
Public and Aboriginal Consultation Funding Requirements	15.0	25.0	25.0	65.0
Customized Aboriginal Consultation Funding Requirements - estimated on basis of 5 Aboriginal communities involved with Planning Team and anticipated efforts with Grassy Narrows First Nation.	15.0	20.0	20.0	55.0
Total	30.0	45.0	45.0	120.0

6.0 RECORD OF CHANGES TO TERMS OF REFERENCE

Changes to the terms of reference will be recorded and approved as necessary during the planning process, and included as an addendum.

Addendum 1

CHANGES TO TERMS OF REFERENCE
Draft Plan Stage

Some minor changes to the Terms of Reference were made to reflect the additional task of preparing the 2012 – 2014 Contingency Plan and 2012-2022 Forest Management Plan. These changes are noted below in blue.

1.0 INTRODUCTION

This Terms of Reference in conjunction with the associated project plan will guide Phase I planning efforts to prepare the Whiskey Jack Forest Management Plan (FMP) for the ten-year period from April 1, 2012 to March 31, 2022 including detailed operational planning for the first five-year term April 1, 2012 to March 31, 2017. Prior to the start of Phase II planning, the Terms of Reference and Project Plan will be reviewed and updated.

2.0 ORGANIZATION FOR PLANNING

This section provides the organizational structures established to ensure the timely completion of the FMP. Those structures include the steering committee, Planning Team, plan advisors and plan reviewers. More detailed descriptions of roles and responsibilities for these groups including any Task Teams set up to facilitate production of the FMP, can be found in the associated project plan.

2.1 Steering Committee

List of Steering Committee Members:

Steering Committee Member Name	Organization and Title	Role
~~Andrew Applejohn~~ Deb Weedon	MNR District Manager	Leader
Shawn Stevenson	Area Supervisor	Member
Kevin Ride, R.P.F.	Representative of Regional Director	Member

At Draft plan stage no significant changes were required to the Terms of Reference. Most notable were the name changes associated with changes to individual roles/responsibility changes (e.g. no longer in the position). Therefore the following wording will be added to the Terms of Reference through this addendum…

Within the Terms of Reference individual names are provided as guidance only at the start of the planning process. Throughout the planning process it is understood that specific roles of individuals will change, new people will become involved and others

will no longer. Specific roles, responsibilities, approvals, memberships, etc should only be considered as assigned to the position or representation listed. Generally speaking individual names outside of the Planning Team members have been included in the development of the Terms of Reference as reference only.

Despite the above, the List of Planning Team Members and Key Advisors / Support staff active at Draft Plan stage include:

2.2 Planning Team

List of Planning Team Members

Planning Team Member Name	**Representing**	**Role**
Kurt Pochailo, R.P.F.	MNR	Area Forester/Plan Author
Stephen Duda	MNR	Planning & Information Management Supervisor/ Planning Team Chair ~~(strategic)~~ /Project Manager
Shawn Stevenson	MNR	Area Supervisor~~/Planning Team Chair (operational)~~
Hassan Mohamed, R.P.F.	MNR	Resource Analyst
Mary Duda	MNR	Area Biologist
Abby Anderson, R.P.F.	MNR	District Planner
Henry Dribnenky	Kenora LCC	LCC Representative
~~Laurent Tetreault~~ Dutchie Lowman	Red Lake LCC	LCC Representative
Dale Munro, R.P.F.	Kenora Forest Products	Industry Representative - Receiving Facility
~~Bob Boyce, R.P.F.~~ Matt Wilkie	Weyerhaeuser	Industry Representative - Receiving Facility
~~Norm Hissa~~ Scott Lockhart	MNR	Aboriginal Community Liaison
TBA	MNR	MNR Forester (Red Lake District)
Debora Henry	Ochiichagwe'babigo'inning (Dalles) First Nation	Aboriginal Community Representative
Joel Henley	Kenora Métis Council	Aboriginal Representative

Planning Team Member Name	Representing	Role
Doug Riffel	Wabauskang First Nation	Aboriginal Community Representative
TBA	Wabaseemoong Independent Nations	Aboriginal Community Representative
~~Conrad Tom~~ Alex Tom	Naotkamegwanning (Whitefish Bay) First Nation	Aboriginal Community Representative
TBA	Grassy Narrows First Nation (Asubpeeschoseewagong Netum Anishinabek)	Aboriginal Community Representative
Susan Jarvis, R.P.F.	Forest Concepts	Planning Contractor
Bob Boyce, R.P.F.	Miisun	Planning Contractor

2.3 Key Advisors and Support

The following identifies those individuals who will act as Key Plan advisors and Support.

Support/Key Advisor Name	Representing	Role
~~Jason Suprovich~~	~~MNR~~	~~Logistics and forestry support~~
Lil Anderson	MNR	Communications support
~~Gerry Simmons~~ Darryl Pajunen	MNR	GIS support
Todd Skene	MNR	Operational Support
Shannon Rawn, R.P.F.	Forest Resource Licence Holder	Wincrief/Naotcrief Support
Donna Puls	Miisun	Planning Contractor
Matt Yeo	Ontario Parks – Parks Superintendent	Operational Support

Approved

Addendum 1 to the Terms of Reference for the Preparation of the 2012-2022 Whiskey Jack Forest Management Plan

_____ _____

Deb Weedon
District Manager
Kenora District

Date

The original signed version of this page is retained at the MNR Kenora district office in Kenora.

Addendum 2

CHANGES TO TERMS OF REFERENCE
Final Plan Stage

Some minor changes to the Terms of Reference were made to reflect the additional task of the preparing the 2012 – 2022 Whiskey Jack Forest Management Plan. These changes are noted below in blue.

1.0 INTRODUCTION

This Terms of Reference in conjunction with the associated project plan will guide Phase I planning efforts to prepare the Whiskey Jack Forest Management Plan (FMP) for the ten-year period from April 1, 2012 to March 31, 2022 including detailed operational planning for the first five-year term April 1, 2012 to March 31, 2017. Prior to the start of Phase II planning, the Terms of Reference and Project Plan will be reviewed and updated.

2.0 ORGANIZATION FOR PLANNING

This section provides the organizational structures established to ensure the timely completion of the FMP. Those structures include the steering committee, Planning Team, plan advisors and plan reviewers. More detailed descriptions of roles and responsibilities for these groups including any Task Teams set up to facilitate production of the FMP, can be found in the associated project plan.

2.1 Steering Committee

2.2 Planning Team

List of Planning Team Members

Planning Team Member Name	Representing	Role
Kurt Pochailo, R.P.F.	MNR	Area Forester/Plan Author
~~Stephen Duda~~ Hassan Mohamed, R.P.F.	MNR	A/Planning & Information Management Supervisor/ Planning Team Chair ~~(strategic)~~ /Project Manager/ Resource Analyst
Shawn Stevenson	MNR	Area Supervisor~~/Planning Team Chair (operational)~~
~~Hassan Mohamed, R.P.F.~~	~~MNR~~	~~Resource Analyst~~

Planning Team Member Name	Representing	Role
~~Mary Duda~~ Sarah McKenzie	MNR	~~Area~~ Management Biologist
Abby Anderson, R.P.F.	MNR	District Planner
~~Henry Dribnenky~~ Wayne Bruce	Kenora LCC	LCC Representative
Dutchie Lowman	Red Lake LCC	LCC Representative
Dale Munro, R.P.F.	Kenora Forest Products	Industry Representative - Receiving Facility
Matt Wilkie	Weyerhaeuser	Industry Representative - Receiving Facility
Scott Lockhart	MNR	Aboriginal Community Liaison
Greg Lloyd R.P.F.	MNR	MNR Forester (Red Lake District)
~~Debora Henry~~ TBA	Ochiichagwe'babigo'inning (Dalles) First Nation	Aboriginal Community Representative
Joel Henley	Kenora Métis Council	Aboriginal Representative
Doug Riffel	Wabauskang First Nation	Aboriginal Community Representative
TBA	Wabaseemoong Independent Nations	Aboriginal Community Representative
Alex Tom	Naotkamegwanning (Whitefish Bay) First Nation	Aboriginal Community Representative
TBA	Grassy Narrows First Nation (Asubpeeschoseewagong Netum Anishinabek)	Aboriginal Community Representative
Susan Jarvis, R.P.F.	Forest Concepts	Planning Contractor
~~Bob Boyce, R.P.F.~~ Shannon Rawn, R.P.F.	Miisun	Planning Contractor

2.3 Key Advisors and Support

The following identifies those individuals who will act as Key Plan advisors and Support.

Support/Key Advisor Name	Representing	Role

Support/Key Advisor Name	Representing	Role
Lil Anderson	MNR	Communications support
Darryl Pajunen	MNR	GIS support
Todd Skene	MNR	Operational Support
~~Shannon Rawn, R.P.F.~~	~~Forest Resource Licence Holder~~	~~Wincrief/Naotcrief Support~~
Donna Puls	Miisun	Planning Contractor
Matt Yeo	Ontario Parks – Parks Superintendent	Operational Support

2.4 Other Plan Advisors

District MNR Advisors:	
Jennifer Hughes ~~Walt Lesenke~~	Fire Management
MNR Regional/Provincial Advisors:	
Kevin Ride, R.P.F.	Regional Forest Resources Supervisor ~~A/Senior Forest Management Planner~~
Chris Schaefer, R.P.F.	Forest Mgmt. Planning Specialist
Rob Bowen, R.P.F.	Regional Analyst
Glen Hooper ~~Darren Elder~~	~~A/~~Regional Planning Biologist
Angus Carr	Regional Planning Analyst
Cathy Cavalier, R.P.F.	Forest Program Specialist
Hilary Gignac ~~Jenn Chikoski~~	~~A/~~Species at Risk Biologist
Garnet Beemer	Regional Analyst Information Specialist
Evan Simpson	Senior Planner
Renee Carrière	Cultural Heritage Specialist
John Stephens	Provincial Planning Economist
Bill Taylor	Native Liaison Officer
Ontario Parks Advisors:	
Julie Sullivan	Senior Park Planner
Matt Yeo	Park Superintendent
Ron Leekam	Natural Heritage Specialist
MNR Science Advisors:	
Bob White	Science Advisor
Colin Bowling	Science Advisor
Other Provincial Advisors:	
Ministry of Northern Development, Mines and Forests:	
Hugh Lockwood	Regional Land Use Geologist
Andreas Lichtblau	Resident Geologist
Pat Corbett / Mike Davis	Forest Industry Liaison
Mark Vermette	Northern Development Officer

Frank Bastone	Tourism Consultant
Ministry of Citizenship and Culture:	
Paige Campbell/Andrew Hinshelwood	Regional Archaeologist

2.5 Plan Reviewers

List of Plan Reviewers

Plan Reviewer Name	Position
Greg Lloyd, R.P.F.	MNR Area Forester (Red Lake)
Hassan Mohamed, R.P.F.	A/Planning and Information Management Supervisor, Planning Team Chair and Project Manager/ Resource Analyst
Shawn Stevenson	Area Supervisor
Sarah McKenzie	Management Biologist
Abby Anderson, R.P.F.	District Planner
Scott Lockhart	Aboriginal Community Liaison
Todd Skene	IRM Technical Specialist
Fred Zroback	Area Technician
Kevin Ride, R.P.F.	Regional Forest Resources Supervisor
Chris Schaefer, R.P.F.	Forest Mgmt. Planning Specialist
Rob Bowen, R.P.F.	Regional Analyst
Angus Carr	Regional Planning Analyst
Garnet Beemer	Regional Analyst Information Specialist
Cathy Cavalier, R.P.F.	Forest Program Specialist
Julie Sullivan	Senior Park Planner
Ron Leekam	Natural Heritage Specialist
Hilary Gignac	SAR Biologist
Glen Hopper	Regional Biologist
Brian Campbell, R.P.F.	Forest Industry Liaison Officer

Approved

Addendum 2 to the Terms of Reference for the Preparation of the 2012-2022 Whiskey Jack Forest Management Plan

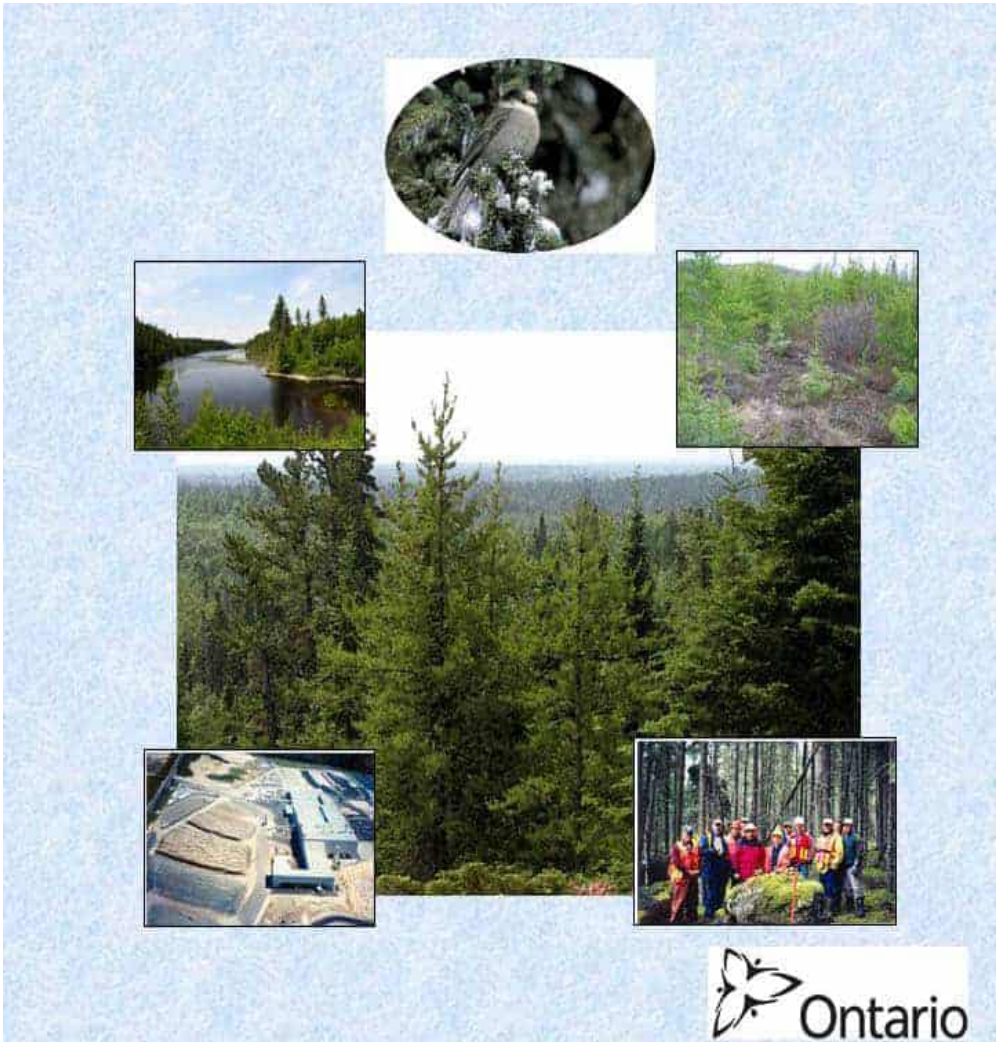
Supplementary Documentation M

2012-2022 Whiskey Jack Forest Management Plan

Statement of Environmental Values (SEV)



Consideration of MNR's Statement of Environmental Values for the Whiskey Jack Forest 2012 - 2022 Forest Management Plan

Description of Proposal

The Whiskey Jack Forest is over 11,000 square kilometres in area and is located in Northwest Region of Ontario. The major community within the unit is Kenora. Approximately 99% of the management unit is Crown land. It is located within the Kenora and Red Lake Districts of the Ontario Ministry of Natural Resources (MNR). The Whiskey Jack Forest is situated within the Boreal Forest. Tree species common to the forest include Jack Pine and Black Spruce with significant amounts of Poplar, Balsam Fir, and White Birch. Smaller amounts of White Spruce, Red and White Pine and Eastern White Cedar are scattered components of mixedwood stands.

The Whiskey Jack Forest has been a Crown Management Unit since Abitibi Company of Canada surrendered the Sustainable Forest Licence in August 2009. The Whiskey Jack Forest primarily supplies fibre to the Weyerhaeuser iLevel mill in Kenora, with other receiving mills being the, Domtar mill in Dryden and the Kenora Forest Products mill in Kenora. The anticipated dates that the Forest Management Plan (FMP) will be in effect are for the 10-year period of April 1, 2012 to March 31, 2022.

1. Each of the following principles of resource stewardship as outlined in MNR's Statement of Environmental Values, 2008 have been considered in the context of this proposal. The following describes how these principles have been applied:

- **A sound understanding of natural and ecological systems and how our actions affect them is key to achieving sustainability.**
  Through preparation of the FMP in accordance with the Forest Management Planning Manual (FMPM) the plan incorporates indicators of sustainability. The Natural Disturbance Template for the Whiskey Jack Forest provides the basis for establishing landscape pattern targets. The FMPM and the Forest Management Guide for Natural Disturbance Pattern Emulation (NDPEG) both require the FMP to examine landscape pattern based on the frequency distribution of disturbances (clear cuts and wildfires) by size class. The template incorporates expressions of landscape processes which serve as measurable indicators for forest sustainability.

- **As our understanding of the way the natural world works and how our actions affect it is often incomplete, MNR staff should exercise caution and special concern for natural values in the face of such uncertainty.**
  The plan makes use of the appropriate existing guides for the protection of values (e.g. water quality, fish habitat, caribou habitat, moose habitat, marten habitat, and raptors). These guides take into account data gaps and provide the basis for adaptive management. Some of these guides include: Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales, Forest Management Guide for Natural Disturbance Pattern Emulation, Forest Management Guideline for the Provision of Marten Habitat, Management Guidelines for Forestry and Resource-Based Tourism, and Forest Management Guide for Cultural Heritage Values.

- **The finite capacity of our natural systems should be recognized in planning and allocation decisions.**
  This plan recognizes forests have natural limits in terms of their capacity to produce timber and, by extension, specific types of wildlife habitat. This is incorporated into the plan by using the Strategic Forest Management Model (SFMM) computer modelling tool which outputs an "available harvest area" based on the social, environmental and economic inputs provided by the planning team. This optimization model solves by selecting silvicultural prescriptions to renew harvested areas to meet desired future forest conditions and objectives. Determining the most effective treatment will require consideration and understanding of the site. This plan has also incorporated the results of a "Bounds of Natural Variation" analyses and spatial analysis of landscape features, processes, and habitat.

- **Natural resources should be properly valued to provide a fair return to Ontarians and to reflect their ecological, social and economic contributions.**
  Determination of rates charged for Crown timber is not a component of an FMP. The continued provision of sustainable timber resources through this FMP provides economic value to Ontarians. Social, economic and ecological value of other forest resources (habitat, tourism, etc.) has been recognized and is considered in this

FMP. Strategies and prescriptions have been developed to ensure continued contributions of non-timber resources to the province of Ontario.

- **Participation in resource management by all those who share an interest is a necessary ingredient, particularly in support of communities who must balance economic diversity with other needs. Those affected by proposed changes must have access to information and opportunities to provide input to decisions that affect their lives.**
  The plan's public consultation and Aboriginal involvement process provided opportunities for the public to access information and become involved with planning of the forest operations. MNR played a major role on the planning team including being the author of the plan. Other planning team members included representatives from 5 local First Nations and the Kenora Métis Council. Members from the Kenora Local Citizens Committee (KLCC) and the Red Lake Advisory Committee (RLAC) also had representation on the planning team and were both used as a forum for plan development and meaningful input. Decisions proposed during the planning process can be appealed through an issue resolution process or request for an individual environmental assessment.

- **Applied research and sharing of scientific and technological knowledge and innovative technologies must be fostered to support the sustainable development of natural resources.**
  The plan used existing models [Ontario Marten Analyst 2 (OMA2), SFMM], a Geographic Information System, satellite imagery, and science based guides to assist in determination of resource sustainability.

- **An ecosystem approach to managing our natural resources enables a holistic perspective of social, economic and ecological aspects and provides the context for integrated resource management.**
- **In order to achieve sustainable development, environmental protection must be an integral part of the development process and cannot be considered in isolation.**
- **From both a sound business and environmental perspective, it is less costly and more effective to anticipate and prevent negative environmental impacts before undertaking new activities than it is to correct environmental problems after the fact.**
  To the extent possible, the Whiskey Jack Forest 2012 FMP has adopted strategies that support an integrated approach to management and recognizes the impact of forestry activities on the entire ecosystem. The plan recognizes that in some areas no harvesting should be allowed and in other areas normal forest harvesting activities need to be modified to prevent or mitigate impacts on forest ecosystems or other known values. Area of Concern (AOC) prescriptions to guide operations have been used to maintain the integrity of these values.

  Planning was done by a multidisciplinary team charged with the responsibility of ensuring decisions took into consideration all known forest values. Use of the model SFMM and a qualitative social and economic description analysis was used to evaluate management objectives and strategies in order to provide for the best mix of social and economic benefits. Similarly, SFMM, the NDPEG tool as well as the OMA2 model were used to model the effects of various objectives and strategies on wildlife habitat.

- **The planning for and management of natural resources should strive for continuous improvement and effectiveness through adaptive management of natural resources.**
  This plan implements most recent policy, information sources, science, and analysis tools developed through continuous learning. Ontario's FMP process requires evaluation of current and previous FMPs and the assessment of achievement of objectives, including analysis of effectiveness of LCCs.

- **Rehabilitating degraded environments is an important aspect of resource stewardship**.
  Identification of forest structure and composition, and habitat issues and concerns, and development of strategies to address these concerns are key elements of this FMP. The plan makes use of appropriate existing guides and computer models to evaluate strategies and develop management prescriptions that promote healthy ecosystems, sites, and natural populations (such as NDPEG, Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales, SFMM, and OMA2).

2. Opportunities for Consultation: how in the context of this proposal MNR provided for

- **An open and consultative process when making decisions that might significantly affect the environment; and**
- **Opportunities for involvement of Aboriginal people whose interests may be affected by decisions that might significantly affect the environment.**

Formal Public Consultation

In accordance with provisions of the 2009 FMPM, formal public consultation has occurred at four stages during preparation and review of this FMP: Invitation to Participate, Review of Long Term Management Direction (30 days), Information Centre – Review of Proposed Operations (60 days), and Information Centre – Review of Draft Plan (60 days). Public Inspection of the Approved Plan (30 days) will occur following plan approval. Direct written notice is provided to individuals and organizations at each stage of the planning process as required of the FMPM. Individuals and organizations may request to be added to this list, which is updated at each stage. Public notice is provided through advertisements in local newspapers. All comments and submissions received from public consultation to date have been considered as part of the decision-making process by MNR. A written response has been provided to written comments and submissions, and upon request, to all verbal comments. All comments and submissions are part of the public record. There is an opportunity during the FMP process to seek resolution of issues with the plan author, the MNR District Manager or the MNR Regional Director. During the 30-day inspection period for the approved plan any person may make a written request to the Director of Environmental Assessment and Approvals Branch, Ministry of the Environment, for an individual environmental assessment of specific proposed forest management activities in the FMP. A response to a request for an individual environmental assessment will normally be provided after the completion of the 30-day inspection period.

Opportunities for Involvement of Aboriginal People

Representatives of the Kenora Metis Council were members of the LCC and representatives of Kenora Metis Council, Wabaseemoong Independent Nations, Natokamegwanning (Whitefish Bay) First Nation, Ochiichagwe'babigo'inning (Dalles) First Nation, and Wabauskang First Nation were members of the planning team. This participation provided for an integral role in plan preparation.

Each Aboriginal community in or adjacent to the Whiskey Jack Forest was provided with the opportunity to develop a consultation approach for forest management planning. There were no formal consultation approaches developed, but Natokamegwanning (Whitefish Bay) First Nation, Ochiichagwe'babigo'inning (Dalles) First Nation, and Wabauskang First Nation all took the opportunity to have the Plan Author and other planning team members come to the communities to discuss the planning process and discuss the 2012-2022 FMP.

Early in the planning process the Aboriginal Background Information Report was prepared. This report documents Aboriginal use of the natural resources on the Whiskey Jack Forest, forest management related problems and issues for those Aboriginal communities, Aboriginal values, and a summary of negotiations between MNR and Aboriginal communities. The Report on the Protection of Identified Aboriginal Values was prepared following operational planning. This report documents proposed operations and road corridors of interest to the community, Aboriginal and other values, a discussion of the AOC prescriptions for Aboriginal values and a discussion of how Aboriginal use of the forest has been addressed in the plan. A Summary of Aboriginal Involvement in the production of the FMP has also been prepared and included in the FMP.

3. Additional Information: any other considerations of MNR's SEV in the context of this proposal

The MNR has taken into account social, economic and other considerations. These have been integrated with the purposes of the EBR. The broad objective of forest management on Crown land in Ontario and in this plan is to provide for the wise use of forest resources, which is sustainable over the long term. The planning process and related guides see that environmental, ecological, social and economic values are identified and measures are taken to protect, conserve or enhance these values. A strategy of adaptive management allows new science findings to be incorporated into the FMP. Harvesting activities are planned within the context of silvicultural systems and the sustainability of the resource is addressed through the use of computer modelling and professional knowledge to determine appropriate allocation levels. Sites that may be affected by operations, including cultural heritage values,

are protected by AOC prescriptions. The health of the forest is maintained through regeneration activities and landscape diversity strategies. The public's right to a healthy environment is protected through the planning process, which requires identification of environmental values and prevention or mitigation of potential damage to those values. This right is further protected through mandatory reporting of accomplishments, and associated compliance and effectiveness monitoring. These monitoring efforts will ensure the FMP is followed and future planning strategies are modified as required.

Other considerations have been addressed by following the Class Environmental Assessment for Timber Management on Crown Lands in Ontario, as extended and amended by MNR's Class Environmental Assessment Approval for Forest Management on Crown Lands in Ontario (MNR-71 as amended by MNR-71/2) and adhering to the Crown Forest Sustainability Act (1994) in preparation of the FMP. This process requires the integration of social, economic, ecological considerations through use of the FMPM for Ontario's Crown Forests (2009) in preparation of the FMP.

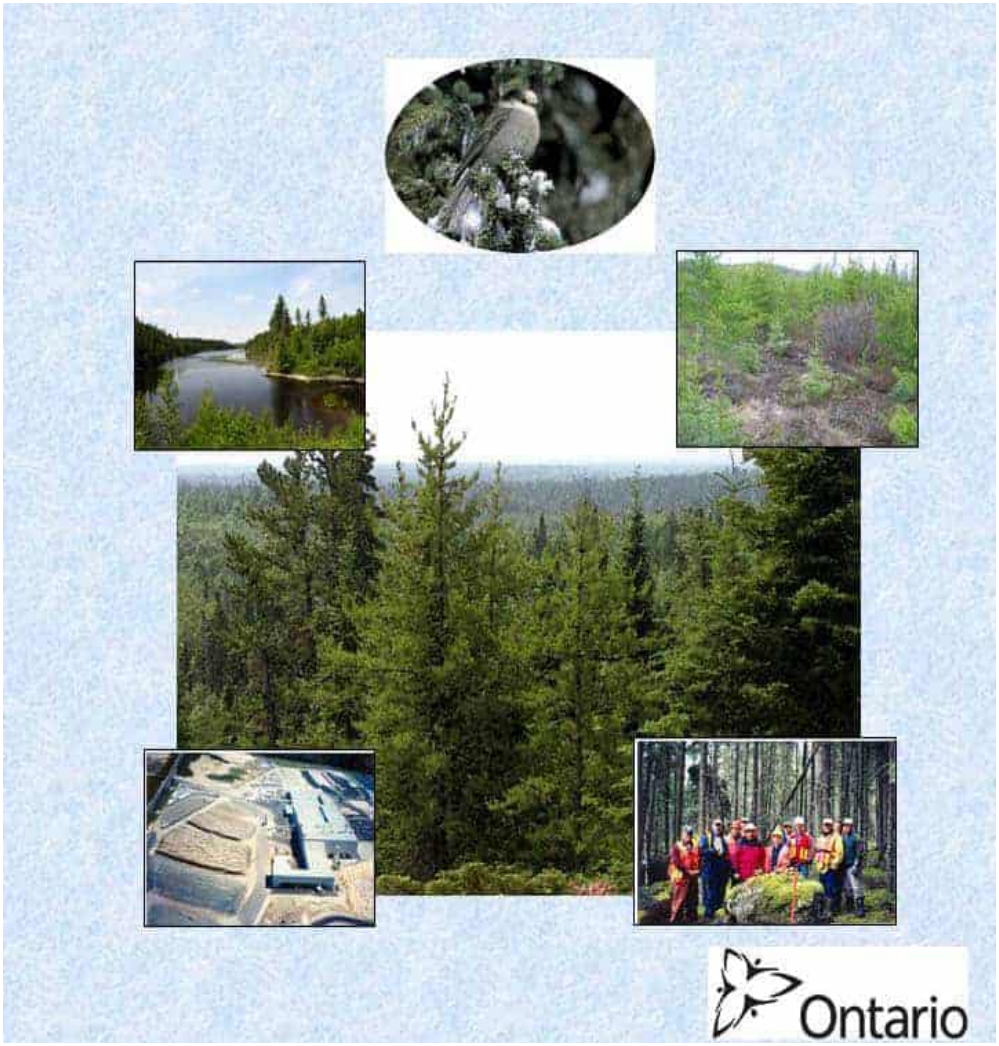
Part B – Marten Habitat Management
Part C – Landscape Pattern (OLT and NDPE indicators)



Supplementary Documentation N – Spatial Analysis Reports
Part A – Caribou Habitat Management

WHISKEY JACK FOREST MANAGEMENT PLAN 2012-2022 WOODLAND CARIBOU MANAGEMENT STRATEGY

This document is intended to provide an update on the current status of woodland caribou on the Whiskey Jack Forest in addition to providing the results of habitat modeling that was used to predict the availability of suitable habitat into the future. The intent of these recommendations is to ensure the provision of suitable habitat for the long-term maintenance of woodland caribou use on the Whiskey Jack Forest.

The Caribou Conservation Plan (CPP) has been developed to meet the requirements under subsection 11(8) of the Endangered Species Act (ESA) 2007 to identify and prioritize the actions the government intends to take in response to the final Recovery Strategy for Woodland Caribou (forest-dwelling, boreal population) in Ontario. The CPP provides direction to manage the quality, quantity and location of caribou habitat in the area of continuous extent of caribou occurrence. In accordance with the CPP, the Whiskey Jack Forest Management Plan will use a variety of tools to provide for caribou habitat, including silviculture, scheduling of harvesting and deferrals, science-based modeling, precautionary planning in the face of natural uncertainty such as wildfire, and a dynamic caribou habitat schedule. This document will outline the planning decisions made to best provide for an uninterrupted supply of year-round caribou habitat within the limits of natural forest variability, recognizing the influence of both forest harvesting and wildfire.

The Whiskey Jack FMP also requires the effective renewal of caribou habitat through a number of silvicultural initiatives, including

- a caribou-based objective for silviculture to be included in all forest management plans within the geographic distribution of caribou;
- use of the Silvicultural Effectiveness Monitoring and Independent Forest Audit programs to assess the effectiveness of forest renewal for caribou, provide recommendations for improvements, and monitor how successfully logged areas are tracking toward a suitable future habitat condition, before any long-term deferrals are made available for harvest;

Preliminary ranges across the area of southern caribou distribution (within and immediately adjacent to areas licensed for forest management) have been identified for the *Caribou Conservation Plan* (Figure 1), based upon the following criteria (in priority order):

- Animal survey data – movements, distribution, and evidence of shared geography;
- Habitat functions and behavioural responses; and
- Predominant risk factors.

Boundaries will be refined on a criteria-based approach as new scientific and management information and Aboriginal Traditional Knowledge become available, as part of the adaptive management process.

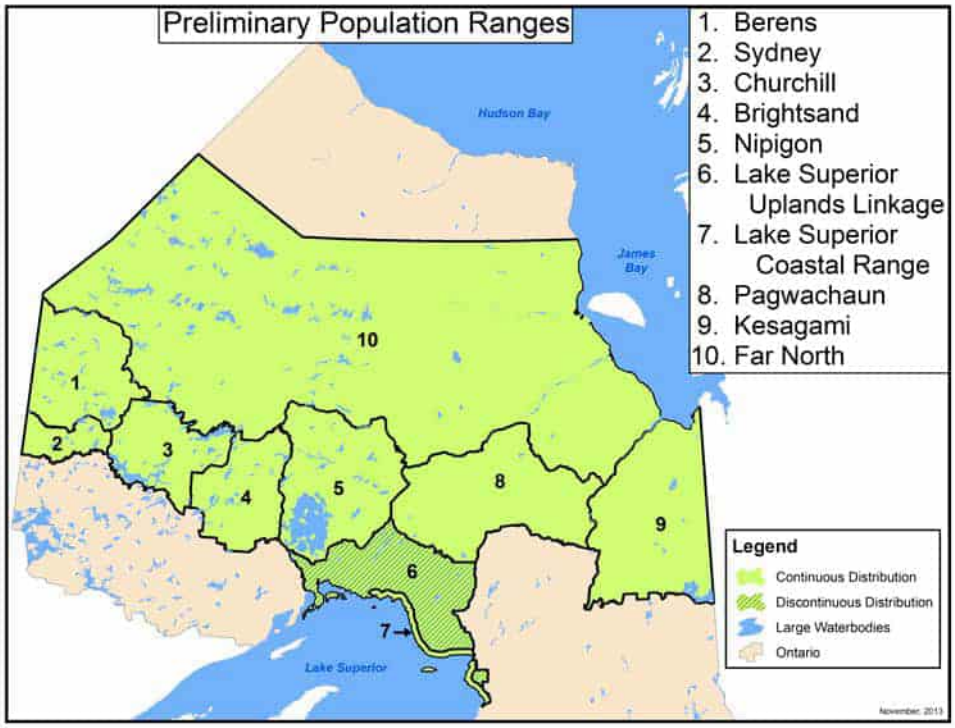


Figure 1. Preliminary delineation of local Woodland Caribou populations ranges along the southern edge of the Provincial extent of occurrence (OMNR, 2009)

Woodland Caribou Populations on the Whiskey Jack Forest

Historical records indicate that caribou distribution on the Whiskey Jack Forest has remained relatively static since the 1960's. The exception to this is the loss of an isolated group of caribou occupying the Cliff Lake area (southwest of Perrault Falls). The Cliff Lake caribou herd declined rapidly during the 1970's and was essentially gone by 1980. Brouseau (1978) attributed the loss of this caribou herd to the effects of logging which started in the area south of Cliff Lake in 1972. The disappearance of the Cliff Lake caribou herd is not unique in Ontario and is indicative of a larger range recession for this species. Surveys throughout the last five years have identified caribou occupancy west of Sydney Lake on the Kenora Forest Management Unit. On March 14, 2008 fourteen caribou were located in the area west of Medicine Stone Lake in the Whiskey Jack Forest. This area is currently the only area of mature forest on the Whiskey Jack that is suitable caribou habitat and has been maintained on the landscape primarily for its historical use by caribou for calving. The 2008 survey indicates, for the first time since the most recent harvesting in the 1999 FMP that caribou occupancy persists in this area.

Woodland Caribou Habitat Management on the Whiskey Jack Forest

In the 1999-2004 FMP most of the eligible harvest area, in the northern portion of the forest that historically supported caribou, was harvested (Figure 2). This area was subsequently deferred for 100 years in the 2004-2009 FMP. During preliminary planning of the 2009 FMP, which was never finalized, a more formal caribou mosaic was developed in conjunction with the approved Forest Management Guidelines for the Conservation of Woodland Caribou: a Landscape Approach (1999). This resulted in the identification of an expanded area for caribou management consideration based on both the existing, and long-term potential caribou habitat. This analysis product was used to develop the area identified as the southern caribou distribution which is currently identified in the CPP (Figure 1), and will be used as a basis for caribou habitat management in the 2012-2022 FMP (Figure 2).

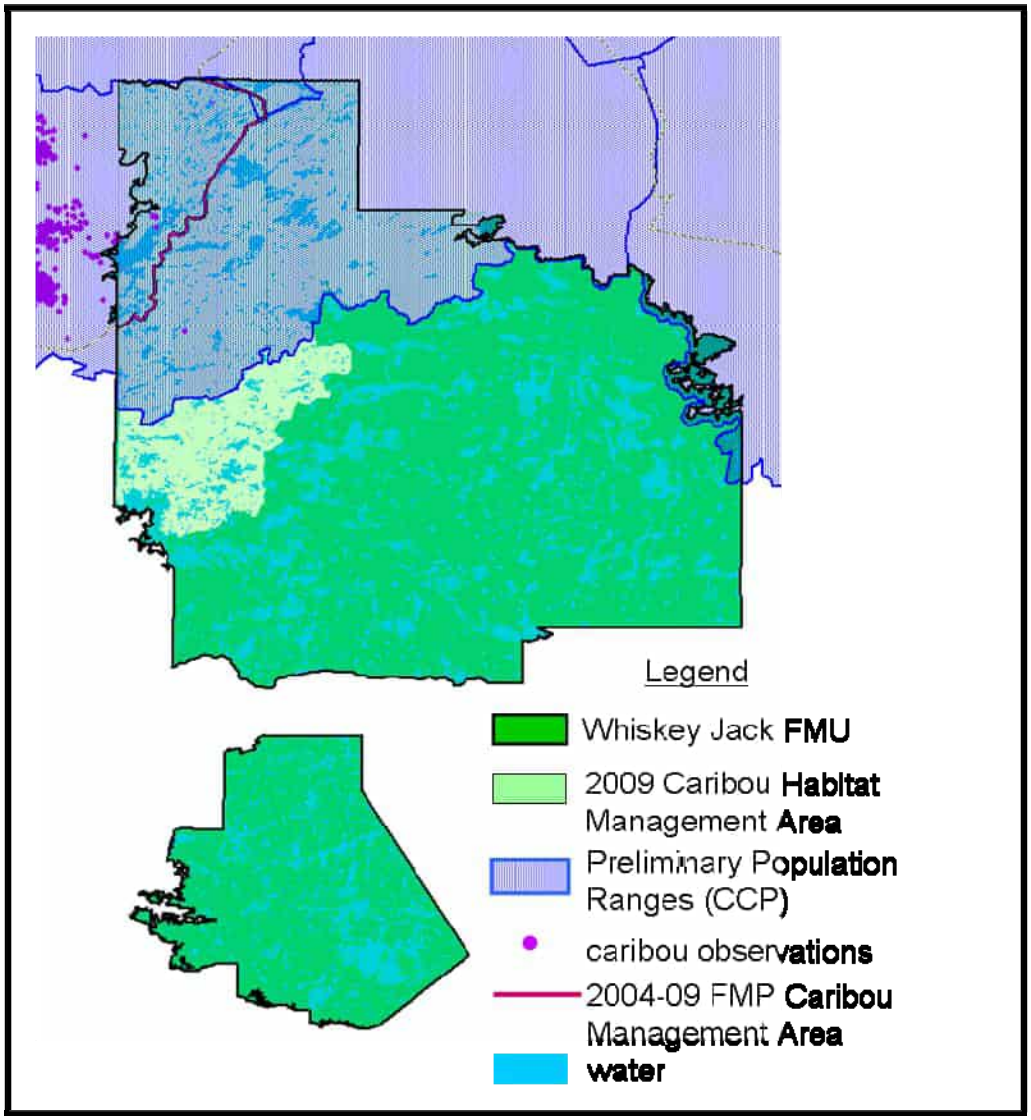

Figure 2. Location of historical and current caribou management areas and animal occurrences on the Whiskey Jack FMU.

Caribou Habitat Capability and Suitability/ Identification of Habitat Tracts

Woodland caribou use habitat differently in various parts of their range. Their range usually includes some habitat that supplies abundant arboreal or terrestrial lichens. Caribou winter range typically includes open coniferous forest with abundant ground cover of reindeer lichens (*Cladina* spp.). Arboreal lichens are generally a secondary food source, but may be locally important (Schaefer and Pruitt 1991, Darby and Pruitt 1984).

Cladina lichen cover tends to be low in younger fire-origin stands, gradually building to approach pre-disturbance levels by a minimum age of approximately 40 years (Schaefer and Pruitt 1991, Harris 1996), although in many stands lichen cover may continue to accumulate to 60 to 80 years. Caribou will start to use these areas once they have self-thinned and continue until the lichen crop declines as the gaps in the canopy close with understory trees (Schaefer and Pruitt 1991, at approximately 100 years.

Caribou are most common in areas where alternate prey and wolf (*Canis lupus*) densities tend to be low (Seip 1992, Cumming 1992, Cumming *et al.* 1996). These are typically large areas dominated by mature coniferous forest and sometimes open peatland complexes where deciduous browse and edge habitat are minimal. Caribou habitat in the boreal forest has been shaped primarily by fire. Fire size in the boreal forest is variable, with fires ranging in size from less than 0.1 ha to more than 1,000,000 ha. Winter habitat quality changes with age. Habitat starts to become available in the 40 to 60 years age range. Habitat tracts in the 60 to 80 year range can be counted on to provide winter habitat and tracts greater than 80 years of age can be considered as prime habitat.

Habitat Tract Analysis

Caribou habitat on the Whiskey Jack forest was identified by identifying areas that are current and/or potential future caribou habitat. Areas were identified if they had ecosites which have a relatively higher probability of providing suitable caribou habitat as specified in the "woodland caribou habitat suitability matrix for northwestern Ontario. This product was used as the basis for identifying "Ecosite Tracts" which represent current and future caribou habitat at a landscape scale on the WJ FMU (Figure 3). The 'Ecosite Tracts' were subdivided into 'Age Class Tracts' representing areas with forest cover of relatively similar ages (Figure 3.). The 'Age Class Tracts' were then subsequently subdivided into "Species Tracts" representing differences with respect to operationally feasibility and potential eligible timing for harvest in the mosaic (Figure 3). These final eleven tracts formed that basis of the habitat tracts/sub-units which will be scheduled for disturbance for the next 100 years in a manner which would best provide suitable habitat for the long-term maintenance of woodland caribou on the Whiskey Jack Forest (Figure 3, Figure 4)

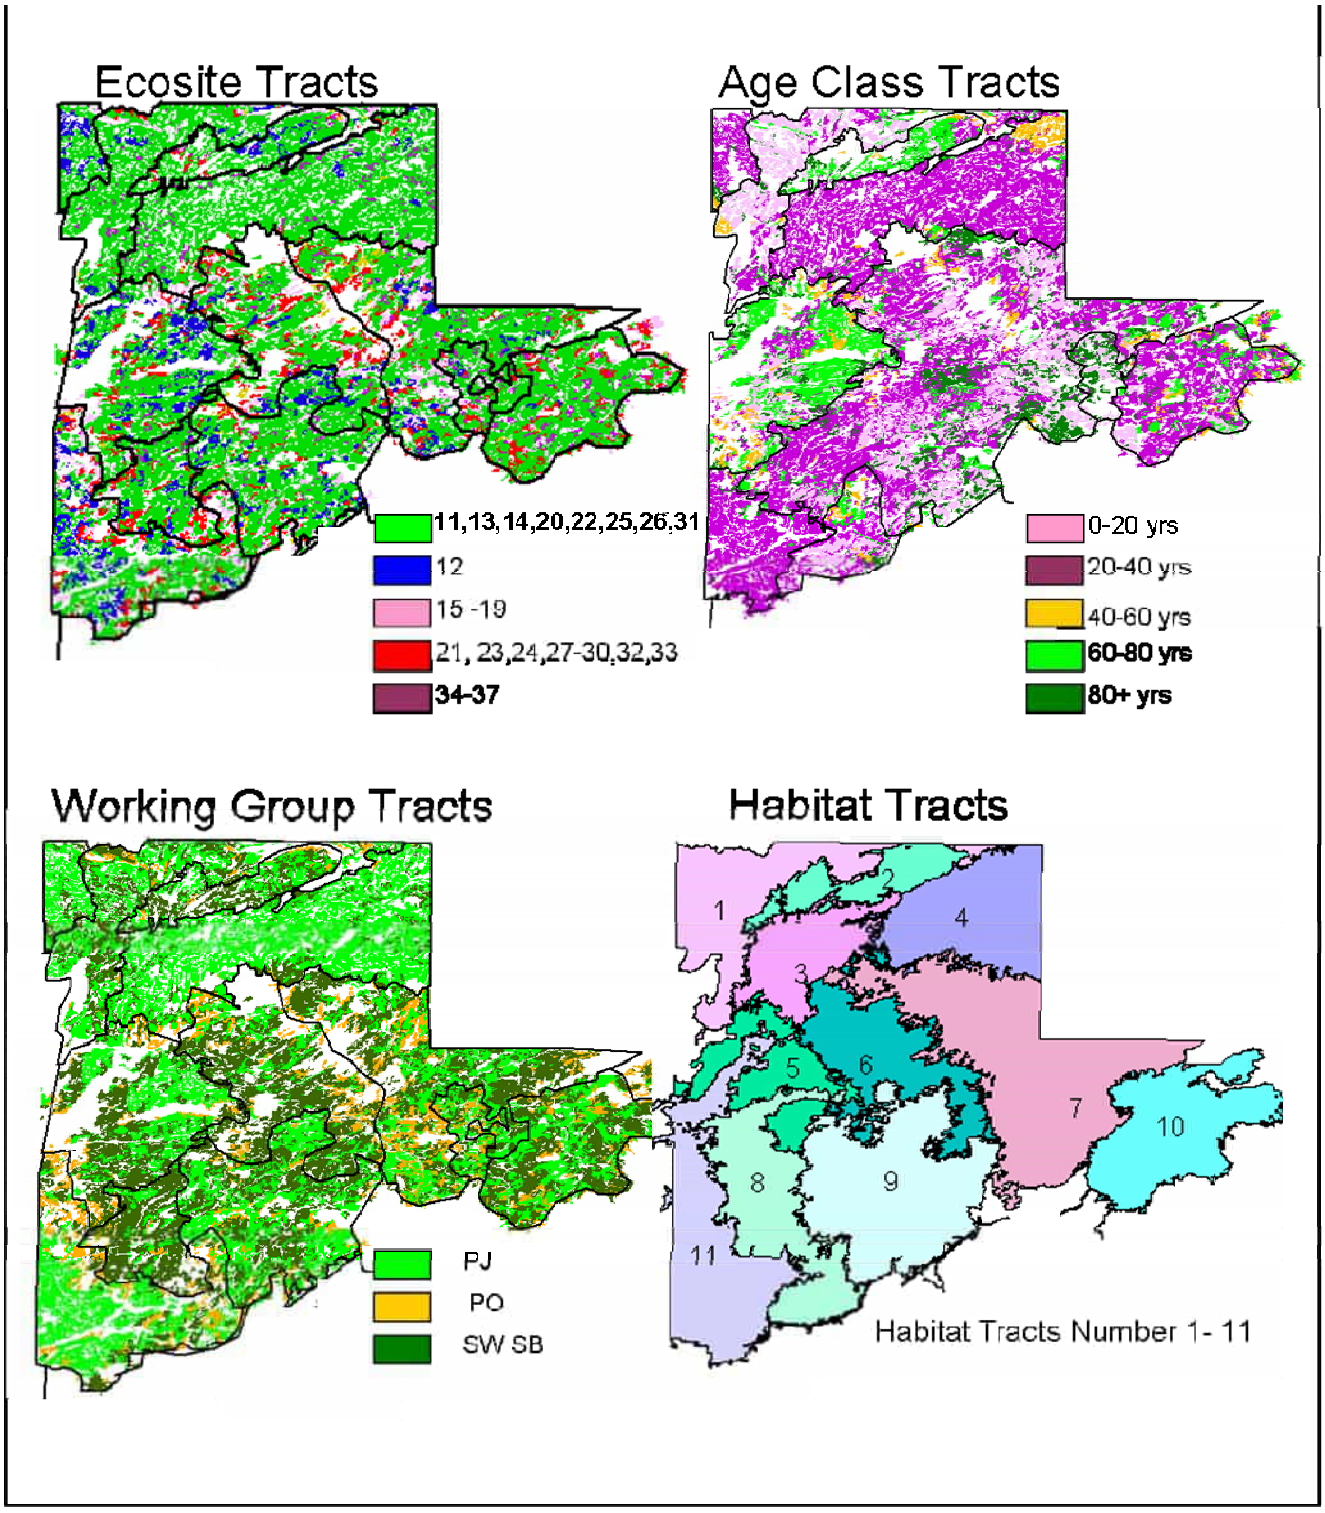

Figure 3: Caribou Habitat Analysis, Whiskey Jack FMU, FMP 2012-2022

Habitat Tract Descriptions

Habitat Tract 1	Comprised of ecosites 12, 13, 14, 20 and 22. A large portion of this tract was harvested, seeded and/or planted in the last 10 years, and is currently dominated by 10 year old conifer forest. This tract also consists of a large 1988 burn which is currently regenerating as 20 year old pure jack pine and spruce. This young habitat tract is capable of producing high quality caribou habitat in approximately 40-60 years.
Habitat Tract 2	Comprised of ecosites 12, 13, 20, 22, 31 and 35. A large portion of this tract is 60-80 years old and consists of pure jack pine and spruce stands. In March 2008, 14 caribou were observed in this tract confirming its current suitability for caribou. This tract contains confirmed caribou nursery and rearing areas. There is a portion of this tract that was harvested in 1997/98 and is currently 10 year old conifer.
Habitat Tract 3	Comprised primarily of ecosites 13, 14 and 35. This tract is a 1983 burn with regeneration dominated by jack pine. This tract is projected to have suitable caribou habitat by approximately 2062.
Habitat Tract 4	Comprised of ecosites 11, 13, and 14. A large portion of this tract was harvest in the last 10 years was seeded/planted and is currently approximately 10 year conifer dominated area. This tract also consists of a large 1988 burn which is currently 20 year old pure stands of jack pine and spruce. This young habitat tract is capable of producing high quality caribou habitat in approximately 40 years.
Habitat Tract 5	Comprised of ecosites 11, 12, and 13. A large portion of this tract is a result of a 1937 burn and is currently 73 year old jack pine. A small portion of this tract burnt in 1978. This tract should be capable of supporting caribou within the 10 years.
.	
Habitat Tract 6	Comprised of ecosites 12, 13, 14, 19, 20 and 22 this is a more heterogeneous tract composition than the more northern tracts. Harvesting has taken place throughout this tract resulting in a younger forest 0-40 years of age with comfier dominated stands mixed with jack pine and spruce. This tract is similar to Tract 7 with a larger portion of the tract having a spruce working group. Due to it's current age heterogeneity, this tract this tract has been scheduled to allow harvesting in the first ten years of the plan to permit further defragmentation of the area. This will provide for the production of a more uniform aged patch of large conifer forest which is predicted to be capable for supporting caribou in 2062.

Habitat Tract 7	Comprised of ecosites 12, 13, 14, 19, 20 and 22 this is a more heterogeneous tract composition than the more northern tracts. Harvesting has taken place throughout this tract resulting in a younger forest 0-40 years of age with comfier dominated stands mixed with jack pine and spruce. This tract is similar to Tract 6 with a larger portion of the tract having a jack pine working group. Poplar leading stands are in the more productive ecosites along the waterways throughout this tract. Due to it's current age heterogeneity, this tract this tract has been scheduled to allow harvesting in the first ten years of the plan to permit further defragmentation of the area. This will provide for the production of a more uniform aged patch of large conifer forest which is predicted to be capable for supporting caribou in 2072.
Habitat Tract 8	Comprised of ecosites 12, 13, 14, 20 and 22. Significant harvesting has taken place within this tract generating a 1-40 year conifer dominated forest with a predominance of the spruce working group. Due to it's current age heterogeneity, this tract this tract has been scheduled to allow harvesting in the first ten years of the plan to permit further defragmentation of the area. This will provide for the production of a more uniform aged patch of large conifer forest which is predicted to be capable for supporting caribou in 2062.
Habitat Tract 9	Comprised of ecosites 12, 13, 14, 20 and 21. Significant harvesting has taken place within this tract generating a 0-40 year conifer dominated forest with a predominance of the spruce and jack pine working groups. Due to it's current age heterogeneity, this tract this tract has been scheduled to allow harvesting in the first ten years of the plan to permit further defragmentation of the area. This will provide for the production of a more uniform aged patch of large conifer forest which is predicted to be capable for supporting caribou in 2062.
Habitat Tract 10	Comprised of ecosites 13, 14, 20, 21, 22 31, and 35. Significant harvesting has taken place within this tract generating a 20-40 year conifer dominated forest with a predominance of the jack pine and spruce working groups. Due to it's current age heterogeneity, this tract has been scheduled to allow harvesting in the first ten years of the plan to permit further defragmentation of the area. This will provide for the production of a more uniform aged patch of large conifer forest which is predicted to be capable for supporting caribou in 2062.
Habitat Tract 11	Comprised of ecosites 12, 13, 14. This tract is a result of a 1983 burn and is currently 27 year old jack pine. This young habitat

tract has is capable of producing high quality caribou habitat in 2062.

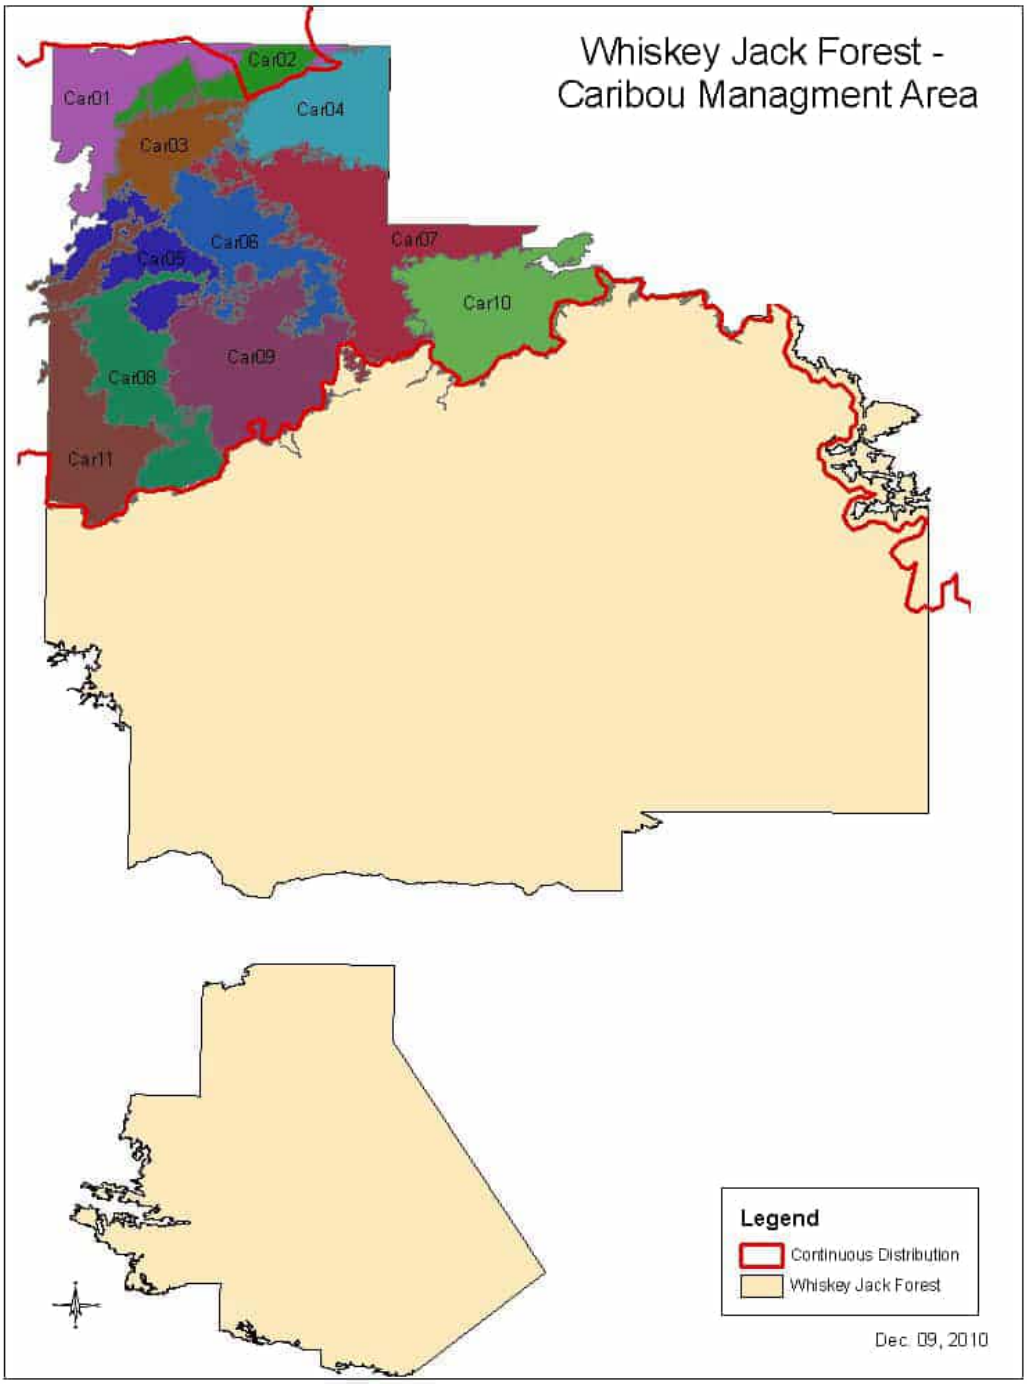

Figure 4. Caribou Habitat Tracts

Caribou Dynamic Habitat Schedule

The Caribou Dynamic Habitat Schedule is intended to provide strategic direction to the areas and timing of harvest in order to fulfill long-term caribou habitat needs. The delineation of tracts of forest land across the landscape is based on the potential winter habitat, estimated knowledge of habitat requirements, soils, age class and tree species. The habitat schedule represents large areas of conifer dominated landscape that provide refuge habitat from predation, tracts of terrestrial lichen, and winter habitat for the caribou. The habitat tracts stratify the forest into areas available for harvest in 10 years periods, and areas that are set aside for one or more 10 year periods.

The habitat tracts were used to plan a series of disturbances (harvest areas) on the landscape in order to:

i) maintain a current habitat supply,
ii) ensure a continuous supply of large areas containing winter (40-120 years old) or summer habitat, and
iii) account for existing distribution of caribou and alternate future habitat.

The proposed Caribou Dynamic Habitat Schedule is illustrated in the Figure 4, which displays the caribou habitat supply through time in 10 year terms. Terms where no changes in supply occurred were omitted from Figure 4. In general, there is no harvest scheduled in the entire caribou management area for 50 years. The exception to this is Tracts 6, 7, 8, 9 and 10 which are open to clean-up harvest for Term 1 and then closed to all harvesting for 60 years. Allowing harvest in these four tracts is based on the high degree of fragmentation that currently exists in this area. Cleaning up these areas will result in further defragmentation of the tracts and provide a more even aged forest in the future. In addition, this clean up activity contributes to fulfilling volume objectives in areas where there are currently no caribou.

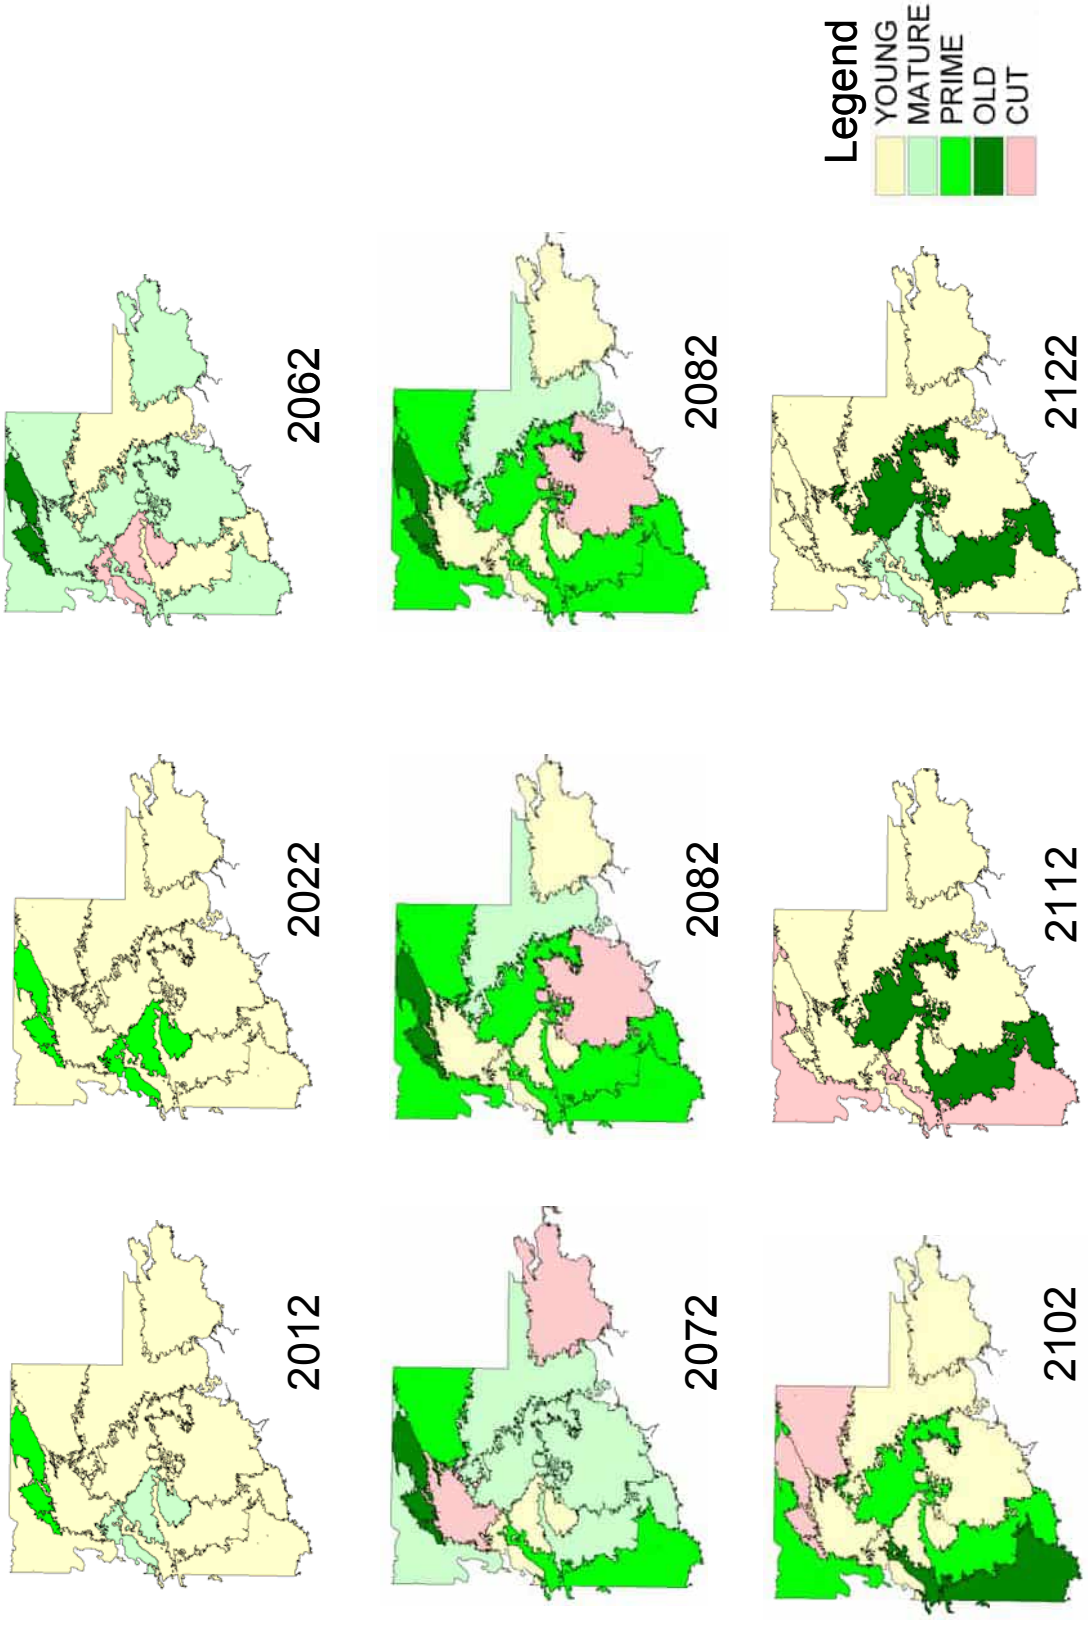

Figure 4. Caribou Dynamic Habitat Schedule 2012-2122

Assessment of Objective Achievement

The objective for caribou habitat is to maintain the landscape in a suitable supply of an interconnected arrangement of on-line habitat tracts/mosaic blocks through time. The desired level is to maintain at least 40-50% of the landscape in tracts/mosaic blocks that are at least 60 years of age (all forest units). The target is based on the best case scenario resulting from the dynamic habitat schedule that has been developed for the Whiskey Jack FMP (Table 1). Table 1 indicated that for the initial thirty years of the plan the amount of interconnected caribou habitat is significantly lower that the desired level. This is a result of the current age classes that exists on the forest, however it still represents the best possible scenario available to meet the long-term caribou habitat objectives. There is no planned harvesting (with the exception of some initial clean-up of mature wood in the southern section of the caribou zone) for the next 60 years. At this time much of the forest starts to become suitable for caribou.

Table 1. Results of Assessment of Objective Achievement

Year	Desired Level (ha)	Target (ha)	Desired Level (%)	Target (ha)
2012	102,317	23,065	40	9
2022	102,317	23,065	40	9
2042	102,317	23,065	40	9
2062	102,317	174,625	40	70
2082	102,317	158,897	40	62
2102	102,317	92,935	40	36
2122	102,317	58,183	40	22

WHISKEYJACK FOREST MANAGEMENT UNIT
MARTEN HABITAT ANALYSIS

INTRODUCTION

The marten (*Martes amer*icana) is a small furbearing animal in the weasel family that is commonly found in Ontario's boreal forest. Marten prefer habitat comprised of large contiguous areas of mature coniferous forest especially those with complex physical structures near the ground. Although the marten is a predatory animal whose diet consists mainly of rodents and small animals such as rabbit, it is also known to feed extensively on vegetation such as berries, nuts and seeds.

Natural resource sustainability is an integral component of forest management planning. The marten was elevated to the status of a "provincially featured species" in the mid 1990's. In 1994 the Crown Forest Sustainability Act (CFSA) and the Class Environmental Assessment (EA) Board for Timber Management set forth requirements for the sustainable resource management. In an April 1994 decision the EA Board set forth terms and conditions for which the development and implementation of the marten guidelines were mandated. In 1995 the Forest Operations and Silviculture Manual (OMNR 1995) listed the marten guidelines to be considered in the preparation and implementation of forest management plans in the boreal regions of Ontario. In 1996 the Forest Management Guidelines for the Provision of Marten Habitat were developed to ensure that there are large, relatively unfragmented core habitat areas maintained on the landscape that consist mostly of mature conifer dominated stands. Secondly, the provision for marten habitat supplies habitat for other species that are associated with the mature and over mature forest, cavity trees and downed and woody debris (Watt et al. 1996, Elkie, Hooper, Carr and Rempel, 1996)

In accordance with the CFSA and the EA terms and conditions, the Whiskey Jack Forest Management Unit (WJFMU) planning team have applied the marten guidelines in the Whiskey Jack Forest Management Plan. This report documents the development and analysis of the WJFMU marten core habitat areas. Twenty-five cores will be identified for the three twenty year planning periods beginning April 1, 2012, and ending March 31, 2072. Associated rationale for the location, size and deferral periods will also be provided in the analysis of the cores.

RECOMMENDED MARTEN GUIDELINES

The EA Board decision to elevate the marten to a featured species for the boreal forest was made to maintain large contiguous areas of mature to over mature coniferous forest. The habitat of the marten is representative of such forest types and it is one of the most demanding species to occupy mature and over mature coniferous forest.

The Forest Management Guidelines for the Provision of Marten Habitat (1996) breaks down the criteria for marten habitat at the landscape and stand levels as follows:

Landscape Level

1. Maintain 10-20 percent of the forest[1], which has the capability to produce marten in suitable conditions.
2. Suitable conditions are achieved where stands have the following characteristics:
   - The composition of the overstory is greater than 40% in spruce, fir or cedar. Mixed composition is preferred over pure stands
   - Canopy closure of conifer is preferred over pure stands.
   - Found within preferred Northwest Forest Ecosite Classes (NWFEC) site and vegetation types (those rated as ""good" or "fair").
     GOOD-6, 7, 14, 15, 16, 19, 20, 21, 24, 25, 31
     FAIR-1, 4, 8, 9, 10, 11, 22, 32, 33, 34
     POOR-2, 3, 5, 12, 13, 17, 18, 23, 26, 27, 28, 29, 30, 35, 36, 37, 38
   - Are at least 15m in height (approximately 80 years old). Uneven canopies are preferred.[2]
3. Suitable marten habitat should be arranged in "core habitat areas" between 30 and 50 km^2 (3000 to 5000 ha) in size. A minimum of 75% of core habitat should be comprised of suitable stands.[3]
4. Partial harvesting can occur in as much as 30% of the core habitat provided it retains 50% of the original conifer basal area and crown closure of at least 50%.
5. Riparian reserves and other unharvested forest should connect core area. While connection need not be contiguous, gaps of open habitat more that 1-2 km across should be avoided.

Stand Level

Maintenance of suitable marten habitat at the stand level, which was previously found in the marten guide, has been replaced by direction now provided by the Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (2009); (the 'Stand & Site Guide). Direction in the Stand & Site Guide that pertains to marten habitat is specific to the silvicultural system or stage of management used during harvest operations. Additional direction on managing downed woody material is also provided by the Stand & Site Guide.

[1] OMNR Regional direction has clarified that the 10-20% target is measured as suitable marten habitat in functioning (50% suitable and/or minimum 1000 ha suitable) marten core areas.

In brief, the following general direction will apply to most areas where forest operations occur on the Whiskey Jack Forest (i.e., where clearcut silviculture is practised):

1. an average of ≥ 25 stems/ha (referred to as wildlife trees) will be retained during harvest operations; of which an average of ≥ 10 will be large stems or large stubs/ha with at least five large living trees on each ha;
2. wildlife trees that fall to the ground become downed woody material and will be left on site; and
3. downed woody material present prior to harvest will be left on site.

More detailed direction on wildlife tree retention and management of downed woody material with respect to silvicultural systems/stage of management, types of trees (e.g., species) to be retained, number of trees, dispersion of trees, and operational considerations during renewal and tending are provided in the Stand & Site Guide.

METHODS

Ontario Marten Analyst and Forest Resource Inventory

The development of the marten habitat cores areas began by identifying existing capable and suitable habitat. ArcView was the tool used to identify, analyze and portray the marten habitat and the cores. The Ontario Marten Analyst (OMA), an ArcView application, was used to help in the identification of marten habitat.

OMA requires the following stand information in order to classify marten habitat over the next sixty years:

- Height
- Species composition
- Site Class
- Year of Origin (age)
- Stocking

The forest polygon coverage of the WJFMU forest resource inventory (FRI), consisting of forecasted depletions up to April 1, 2012, was used for the analysis of marten habitat. This FRI planning inventory is the same as that used in the Strategic Forest Management Model (SFMM).

Habitat Classification

The required FRI fields were selected for year of origin, height, site class, stocking and species composition. From this information new fields for the selected attributes were created and populated. Among the new fields created are the fields for all tree species (working groups) that would be contained in the species composition. These species fields were populated with values associated with the percentage of each species composition string.

The queries for habitat classification are presented in Appendix A, and resulted in the addition of fourteen new fields that contain the base information on habitat capability, suitability, and the cores.

IDENTIFICATION AND SELECTION OF CORES

Benchmark Scenario

When all fields describing capability and suitability of stands through time are fully populated and saved to the Marten FRI coverage, an analysis of the spatial distribution of the suitable stands can be completed. A ‘benchmark scenario’ was developed to determine the maximum level of suitable marten habitat that the Whiskey Jack forest was capable of supplying over the next sixty years. Core areas were chosen from concentrations of suitable habitat by viewing suitability of stands on 20 year time horizons and sixty year suitability maps. Areas of habitat concentrations for each period were identified on a habitat suitability map. Using the core builder tool in OMA, suitable stands were selected and assigned to a core. A new core was created from each large concentration area. Unsuitable stands were also selected and assigned to cores to maintain connectivity between suitable stands within a core.

Preliminary core areas were reviewed to determine if the minimum recommended core area guidelines were met. Statistics were generated to identify the suitability and size for each core over time. Cores which were not 50% suitable or a minimum of 1000 ha suitable during a particular time period were considered 'non-functioning', and did not contribute to the landscape statistics for that respective term. OMA's statistical tools provide data for 20 years terms. .

RESULTS

Landscape

A total of 753,707.4 ha of the Whiskey Jack Forest was classified. Of this 676,468.7 ha of the unit area is capable of producing marten habitat. Based on this total capable area, the 10% minimum objective for marten habitat is 67,646.9 ha and the 20% goal is 135,293.7 ha (TABLE 1).

TABLE 1: Marten Habitat Classification: Landbase Summary

Total Area Classified (Capable & Non-capable) (ha)	753,707.4
Total Amount of Capable Forest (ha)	676,468.7
Total Amount of Non-Capable Forest (ha)	77,238.7
Proportion of Landbase that is Capable (%)	89.8
Minimum 10% Objective (ha)	67,646.9
20% Objective (ha)	135,293.7

A total of 25 marten cores were identified in the benchmark scenario Figure 1. The current forest condition (2012) provided for 38,592.20 ha of suitable habitat in marten cores, representing 5.70% of the total capable area. It is expected that the deferral of these 25 cores for the next 60 years, providing there is no natural disturbance, will provide for an increase of suitable marten habitat to 62,811.10 ha (9.29 % capable) by 2069 (Figure 1, Table 2). While this scenario does not meet the 10-20% marten habitat objectives, it does represent the best case scenario for the WJFMU.

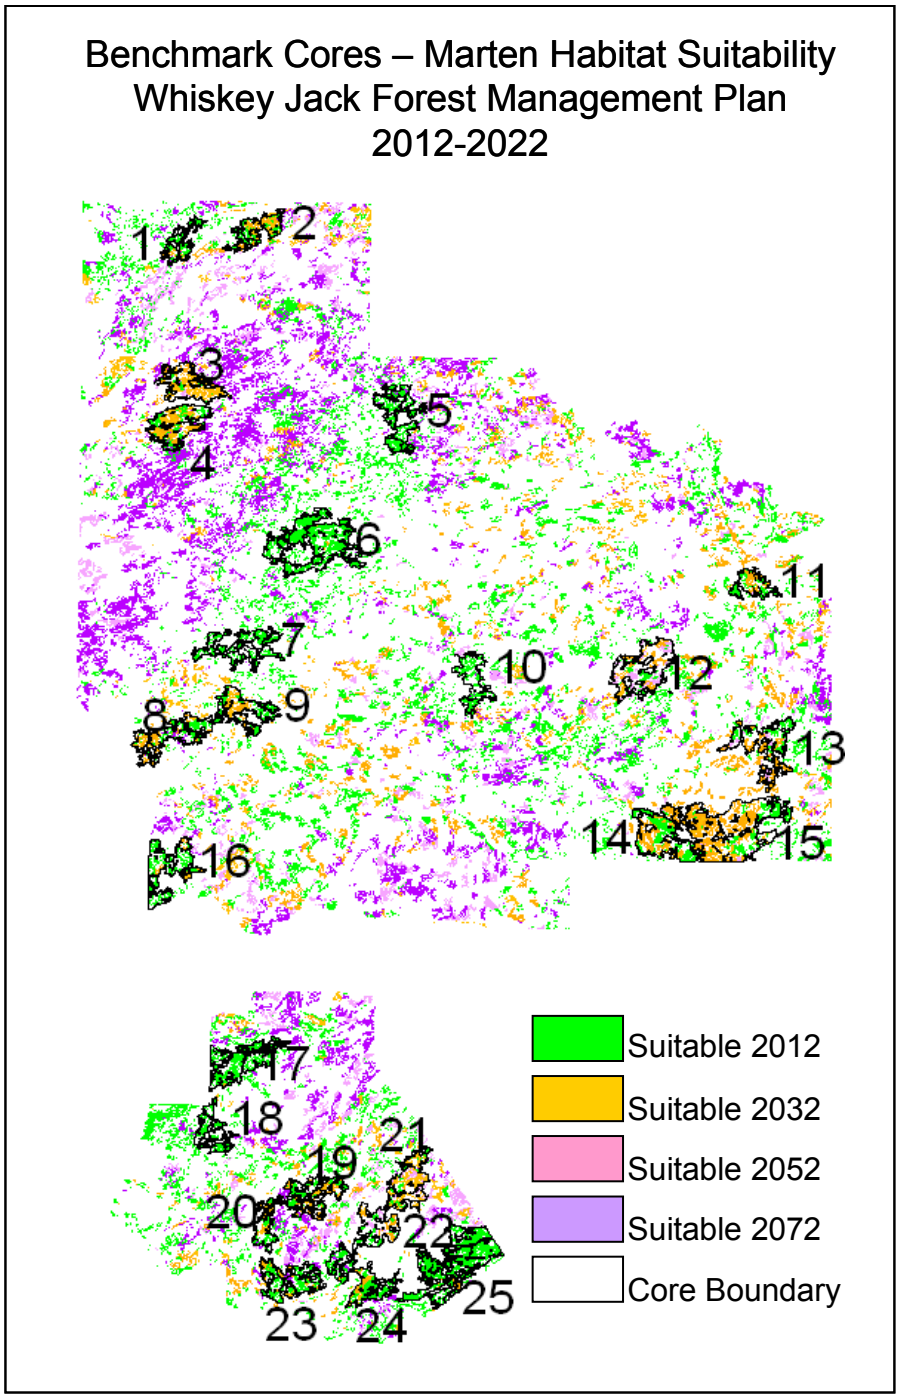

FIGURE 1; Whiskey Jack Forest Management Unit, Suitable Marten Habitat in Cores, Benchmark Scenario

DISCUSSION

Benchmark Scenario

The Benchmark Scenario was completed in order to amalgamate concentrations of suitable marten habitat into core areas. Ideally the task team would provide spatial and temporal management recommendations of these areas in consideration of the 10-20% marten habitat objective. In some cases this may have resulted in the selection of the highest quality cores for deferral, or cores being released from deferral once adjacent cores started to provide adequate suitable habitat. However, with a benchmark scenario which does not meet the 10-20% marten habitat objective, and our inability to predict where any natural disturbance may occur in the next sixty years such opportunities did not present themselves and resulted in the need to maintain all 25 cores throughout the sixty years in the benchmark scenario.

TABLE 2: Bench Mark Scenario: Suitable Habitat Summary

TERM	Total Amount of Suitable Area (ha)	% Capable
2012	33,172	4.9
2032	58,428	8.6
2052	60,871	9.0
2072	31,676	9.1

Having relatively small amounts of suitable habitat available on a landscape which is highly fragmented by water, provided limited opportunities with respect to the spatial and temporal management of the cores. It also resulted in the creation of a number of cores which may not meet the recommended criteria, but remain a relative valuable component of marten habitat on the WJFMU. The individual core statistics for each term are presented in Appendix B. While the benchmark scenario does not allow the WJFMU to meet the minimum 10% marten objective, it provides for the maximum amount of marten habitat possible on the WJFMU for the next sixty years.

PART C – Spatial Analysis: Landscape Pattern

A. Developing Simulated Range of Natural Variation 2012 Whiskey Jack Forest FMP

1.0 Introduction

The Simulated Range of Natural Variation (SRNV) provides the basis for establishing landscape pattern targets for the FMP. The Forest Management Planning Manual (FMPM), and Science Packages of the Landscape Guide both require the FMP to examine landscape pattern. The SRNV developed in this plan will provide targets based on natural fire history, disturbance succession and weather patterns to assess how proposed areas selected for operations will influence the landscape pattern on the Whiskey Jack Forest and to determine whether the proposed plan will create a pattern consistent with Simulated Range of Natural Variation.

2.0 Methodology

Please refer to the Science Packages for methodology and calibration used in developing the SRNV. The Boreal Forest Landscape Dynamics Simulator (BFOLDS), a grid-based, spatially explicit model that contains a simulation module for Crown-fire regimes (FSM) and a vegetation transition module (VTM) was used to estimate ranges of variation in the Boreal Forest Region. BFOLDS simulates the fire regime and fire induced forest cover dynamics at broad spatial and temporal scales (>10 million hectares and >300 year), but uses a relatively fine spatial scale for some processes (1- hectare spatial resolution). BFOLDS is a modelling tool developed specifically for modeling stand initiating fire, succession and post fire transitions in the Boreal Forest Region of Ontario.

The first consideration in the development of a SRNV is the "study area" or the geographic extent to which historic data will be used to represent the management unit. The basis for this selection is the ecological planning units (eco- districts) associated with Ontario's Ecological Land Classification (Crins et al). The analysis for the Whiskey Jack Forest was based on the ecological regions in which it is situated. This includes eco-regions 3S and 4S.

The selection of a "study area" based on certain ELC eco-districts ensures that the areas chosen to be representative of the management unit have similar climatic and edaphic conditions and thus provide a reasonable basis in which to examine pre-industrial condition data for the Whiskey Jack Forest.

Once the selection of the geographic extent was completed, the descriptions of information sources including the SRNV, historical survey records (Pre-Industrial Condition), and, current ecological databases (e.g. FRI, remote sensing, growth and yield plots) was prepared by the Ministry of Natural Resources Regional Planning Unit and provided to the Whiskey Jack Forest Planning Team.

2.1 Method of Comparing Simulated Range of Natural Variation to Harvesting

Boreal Forest Landscape Simulation model data used in the development of the Simulated Range of Natural Variation (SRNV comes from Ontario Landscape Tool (OLT)).

The assessment of disturbance perimeter is completed using the computer analysis OLT. This tool generates the measurable values as described above. Three scenarios are run through the tool:

Scenario 1: Plan Start 2012 Plan Start
Scenario 2: Plan End 2022 Plan End without harvesting.
Scenario 3: Plan End 2022 Plan End with planned harvest areas for 2012 to 2022.

Scenario 1 and 2 use the approved base model inventory to determine existing (Scenario 1) and future disturbance patterns. The base model inventory is simply aged by 10 years to identify changes in pattern assuming no new disturbances to 2022 (Scenario 2). Scenario 3 uses the 10-year planned harvest areas for operations from the planning coverages to update the inventory. Forest description attributes are updated to reflect depleted age, height, year of origin, stocking and year of depletion. Stand composition was not updated for forecasted silviculture treatments or for expected future forest condition. Forest composition is assumed to stay the same and there are no changes for forest succession included.

2.2 Ontario Landscape Tool Analysis

One of the key directions in the 2009 Forest Management Plan Manual (FMPM) is to develop an FMP with the best available science and information, new legislation, regulation and policy, and changes to forest conditions and land base (FMPM A-29). The expectation was to utilize the Forest Management Guides for Boreal Landscapes (hereafter called the Landscape Guide) in development of the 2012 Whiskey Jack FMP. Since the landscape guide was not approved for implementation during the development of this FMP, regional advice has been to utilize the draft Landscape Guide science package as a reference for the estimated natural forest condition. The science packages used in the development and prepared for the support of the landscape guide were prepared by science teams.

The **goal** of the landscape guide is to provide direction to forest managers on how to meet the objective of conserving biodiversity in an effective and efficient manner through landscape-level approaches, thereby contributing to the achievement of forest sustainability in an effective and efficient manner. The direction identifies and helps to set landscape mosaic goals and targets for forest composition (forest tree species groups and age classes) and structure (pattern) in forest management plans.

Landscape guide indicators measured the Whiskey Jack Forest Management Plan is the landscape pattern indicators. The indicators measured by running the Ontario Landscape Tool (OLT) are:

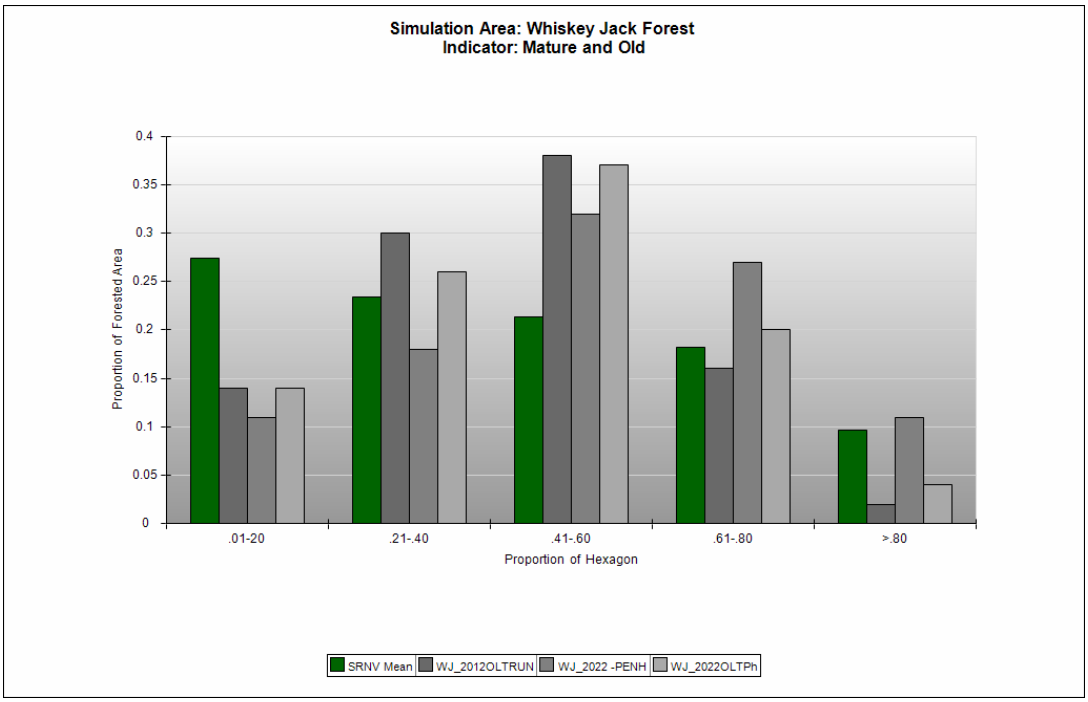
- Indicator 1a - Mature and old forest
- Indicator 1b - Young Forest Patch Size

- Indicator 1c - Mature and Old conifer forest
- Indicators 3b and 3c - Landscape level caribou refuge and winter habitat pattern.

Please refer to the science packages embedded in OLT for a full detail of methodology and result interpretation. The results are provided in Table FMP-9.

Indicator 1a - Mature and Old Forest

Mature and old forest indicator is used to provide habitat for certain song birds and wildlife habitat that requires this seral stage. The SRNV for this indicator is compared to the Plan Start, Plan End no harvest and Plan End with harvest and is depicted below:



Two scales were used to measure this indicator. 500 and 5,000 hectare hexagons are draped on the planning inventory. The measurement is done for 60-80% and 80%+ concentrations added together. For the 500 hectare hexagon analysis, the plan start is at 24% moving to 27% at plan end. The SRNV for the 500 ha scale analysis of this indicator is 35%, therefore the change from plan start to end shows movement towards the SRNV. For the 5,000 hectare hexagon analysis, the plan start is at 18% moving to 24% by plan end. The SRNV for the 5,000 ha analysis of this indicator is 28 %, therefore the change during this plan period shows movement towards the SRNV.

Indicator 1b - Young Forest Patch Size

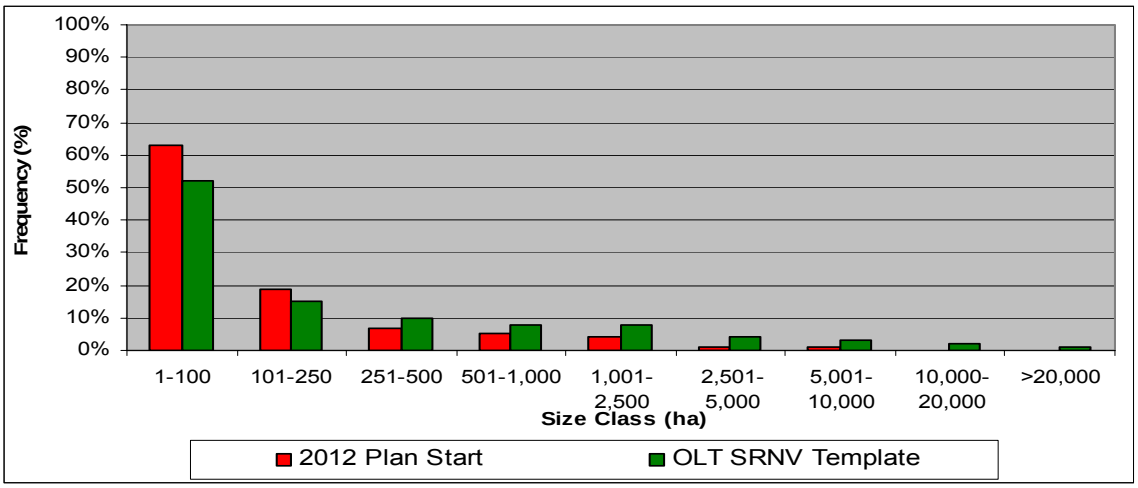
Patches deal with the *extent* of the homogeneous forest types that make up the landscape mosaic. Patch size can influence the availability of habitat conditions. From the Simulated Range of Natural Variation (SRNV) work done for the Whiskey Jack Forest, young forest patch is classified the forest into stands less than 36 years old. A 7 hectare hexagon fabric is draped onto the classified surface and estimates the amount of young forest within each hexagon. The proportion of young forest is estimated based on the total area of forest within each hexagon. For hexagons that have less than 50% forest in them the hexagon is considered as 0. A hexagon is considered to be young if it has 50% or greater young forest in it. Patch size is then estimated based on the adjacency of hexagons classes as young.

OLT produces both a map and a histogram of the result. The histogram is a frequency distribution representing the proportion of patches (relative to the total number of patches) in various size classes. The resulting SRNV estimated natural landscape pattern for young forest is used as the "Template" of the natural forest landscape pattern for the Whiskey Jack Forest. The SRNV template is illustrated in the following subsection.

Comparison of Plan Start Young Forest Frequency to SRNV

The young forest frequency by size class of the land base at Plan Start 2012 was compared to the SRNV template for the management unit to determine a baseline distribution of young forest patch size at the start of this planning period. Figure 1 shows the relationship of the current young forest patch size frequency compared to the SRNV. Significant differences are observed in the smaller young forest size patch frequencies where the SRNV developed for the Whiskey Jack Forest suggests there would naturally be significantly less small disturbances (1-100 and 101-250 ha), and more large disturbances (> 250 ha) than is evident at 2012. This larger proportion of smaller young forest patch at 2012 is a result of past forest management, unprecedented natural disturbance and harvesting practices on the Whiskey Jack Forest, and is typical of the management units in the Northwest Region. Management direction in the last 10 years has been moving to larger harvest blocks to emulate natural disturbance pattern more closely. It will take the implementation of several forest management plans with larger harvest area patches to reverse the legacy of small disturbance patches on the Whiskey Jack Forest.

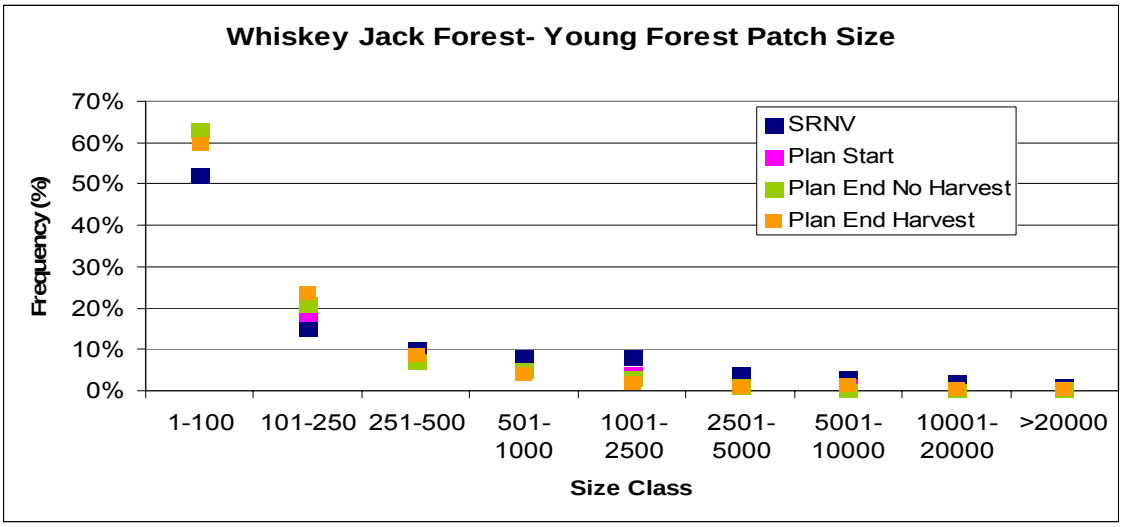
Figure 1 Frequency Distribution of Young Forest by Size Class - 2012 vs SRNV



Given this Plan Start information, the planning team decided to look at the current (Plan Start 2012) and future disturbance patterns (Plan End 2022 with no harvest, and also analyze landscape pattern at Plan End 2022 with planned harvest depletions) on the Whiskey Jack Forest and compare them to the SRNV.

A total of 10 years of planned harvest allocations have been included for assessment to see how much movement towards the SRNV is projected to be achieved through implementation of the forest management plan. The results are presented below.

Figure 2 Frequency Distribution of Young Forest by Size Class



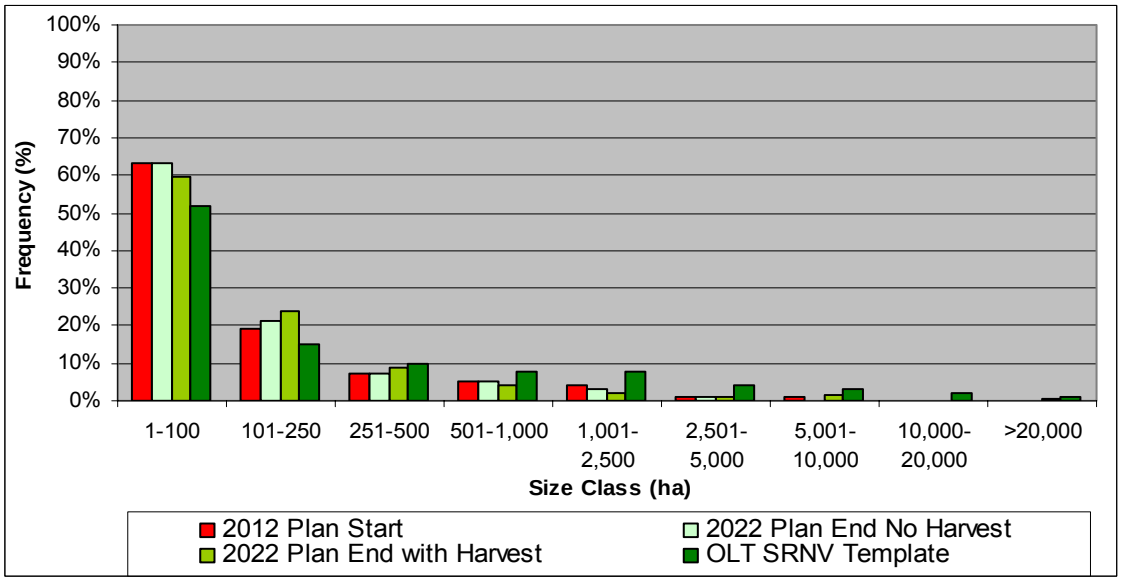


Table 1 Frequency Distribution of Young Forest by Size Class

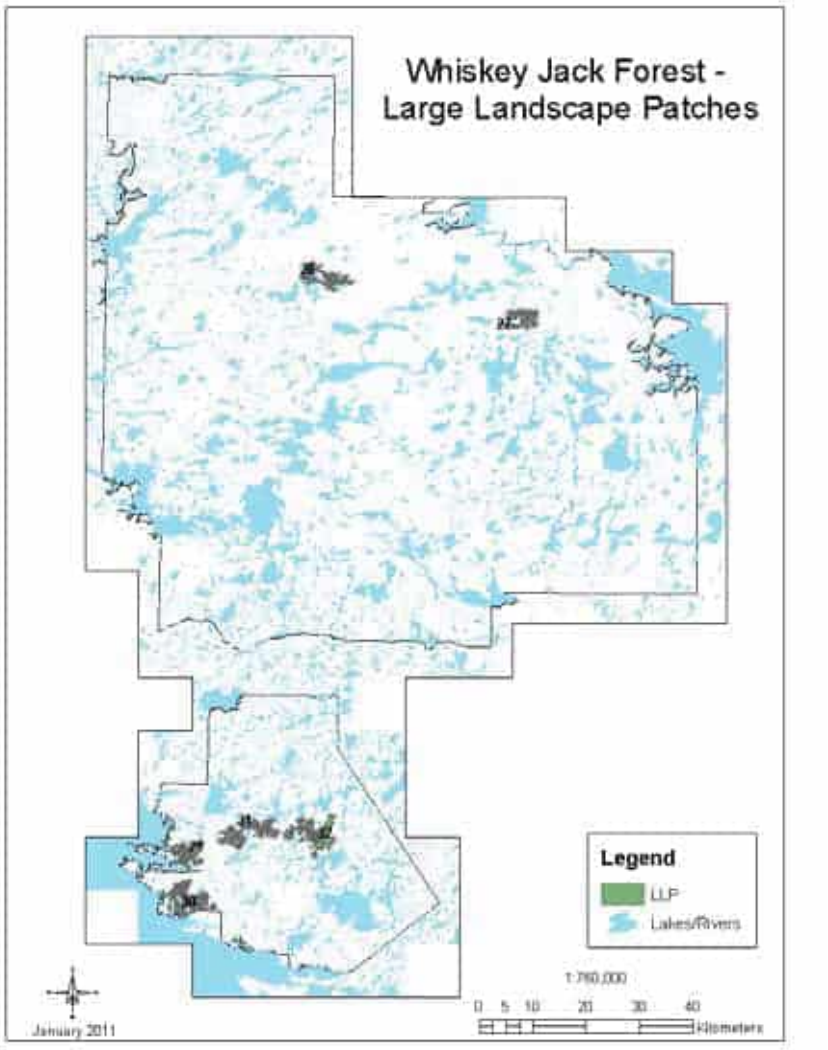
	As a Percent				Assessment
Size Class (ha)	2012 Plan Start	2022 Plan End No Harvest	2022 Plan End with Harvest	OLT SRNV Template	Assessment of Movement Towards Natural SRNV Template
1-100	63%	63%	60%	52%	Movement towards
101-250	19%	21%	24%	15%	Movement away
251-500	7%	7%	9%	10%	Movement towards
501-1,000	5%	5%	4%	8%	Minor movement away
1,001-2,500	4%	3%	2%	8%	Minor movement away
2,501-5,000	1.0%	1.0%	1.1%	4.0%	Towards - but no significant change
5,001-10,000	1.0%	0.0%	1.3%	3.0%	Towards - but no significant change
10,000-20,000	0.0%	0.0%	0.2%	2.0%	Towards - but no significant change
>20,000	0.0%	0.2%	0.3%	1.0%	Towards - but no significant change
Total					

Six of nine young forest patch size classes project movement from Plan Start distribution towards the Simulated Range of Natural Variation (SRNV) through implementation of planned harvest areas for this plan period. Four of these size classes that show movement towards the SRNV do not change significantly from the Plan Start frequency. Three size classes project movement away from the SRNV at the end of this plan period. The 101-250 ha class increases in frequency from 19% to 24% whereas the template suggests a reduction to 15%. The 501-1,000 and 1,001-2,500 ha class frequencies decrease slightly at Plan End compared to higher desirable levels, but only change by 1-2%. Overall assessment is that the target level for this indicator is achieved, as the movement toward the template frequency distribution is greater than the minor shortfalls in 3 classes.

Indicator 1c - Mature and old Conifer Forest

This indicator is intended to influence the supply and arrang ement of mature and older conifer-dominated forest across the Whiskey Jack Forest. The conifer dominated forest is composed of PJD, PJM, SPD and SPM. In ad dition to the marten cores, large la ndscape patches (LLP) which are >500 hectares were selected from OLT output and deferred in the strategic model for 40 years. This will provide future habitat for coarse filter wildlife such as marten. The map shows the location of the LLP in the Whiskey Jack Forest.

Two scales were used to measure this indicator. A 500 and 5,000 hectare hexagon is draped on the planning inventory. The measurement is done for 60-80% and 80%+ concentrations added together. For the 500 hectare hexagon, the plan start is at 4% moving to 6% at plan end. The SRNV for this indicator is 19 % showing move ment towards the SRNV. For the 5,000 hectare hexagon, the plan start is a t 1% movin g to 1.3%. The SRNV f or this indicator is 9% showing movement towards the SRNV. The re sults show movement towards SRNV from plan start.



Indicators 3b and 3c - Landscape Level Caribou Habitat Pattern

Using the caribou habitat dynamics area, part of the Whiskey Jack Forest inventory was clipped and the caribou management zone was run through OLT. The intent of this analysis is to compare the Plan Start and End results with the estimated SRNV provided by MNR. There is little harvesting activity happening on the caribou zone of the Whiskey Jack Forest and the results show movement towards the SRNV for both the caribou refuge habitat pattern and caribou winter habitat pattern.

Two scales were used to measure this indicator. A 6,000 and 30,000 hectare hexagon is draped on the planning inventory. The measurement is done for 60-80% and 80%+ concentrations added together.

For the caribou refuge habitat, the 6,000 hectare hexagon, the plan start is at 36% moving to 37% at plan end. The SRNV for this indicator is 87% showing movement through plan implementation towards the SRNV. For the 30,000 hectare hexagon, the plan start is at 25% moving to 24%. The SRNV for this indicator at this scale is 92%, therefore implementation of planned harvest projects minor (1%) movement away from the SRNV. Spatial assessment of caribou refuge habitat pattern shows 1% movement towards the desirable level for analysis of caribou refuge habitat at the 6,000 ha scale and 1% movement away from the desirable level at the 30,000 ha scale which is not considered significant. There is clean-up occurring in four caribou blocks which accounts for the reduction in refuge habitat at the 300 km2 scale. Overall assessed as ACHIEVED.

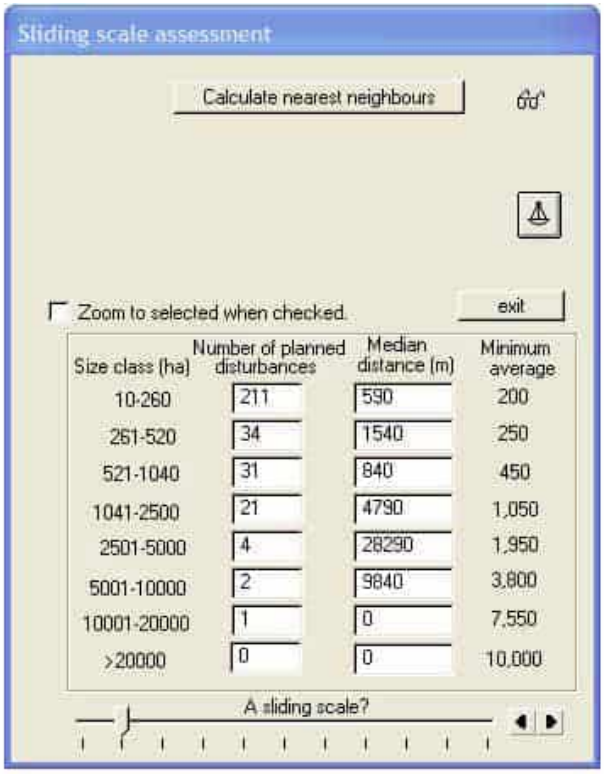
For the caribou winter habitat, the 6,000 hectare hexagon, the plan start is at 0% moving to 4% at plan end. The SRNV for this indicator is 45% therefore implementation of the planned harvest is projected to move caribou winter habitat pattern towards the SRNV. For the 30,000 hectare hexagon, the plan start is at 0%, remaining at 0% after implementation of the planned harvest. The SRNV for this indicator is 40%, therefore at this scale, there is no movement towards or away from the SRNV. Spatial assessment shows movement towards the desirable level for analysis at the 6,000 ha scale. The second analysis shows no movement away from the Plan Start 0% level (constant). Overall assessed as ACHIEVED.

Sliding Scale Assessment

A sliding scale assessment was conducted on forest disturbances to evaluate the spatial separation of planned disturbances across the landscape. This analysis identifies the average distance between disturbances in each size class at Plan End with Harvest (2022) and measures how well like-sized disturbances are spread out over the landscape.

The goal of the Sliding Scale Assessment is to have the median distance for each size class greater than the minimum average target distance for the size class. The sliding scale assessment is based on the product from the NDPE tool. The following figure shows the minimum average distance required between like-sized disturbances, with the number of disturbances and the median distance between them.

Figure 1 Sliding Scale Assessment



Size class (ha)	Number of planned disturbances	Median distance (m)	Minimum average
10-260	211	590	200
261-520	34	1540	250
521-1040	31	840	450
1041-2500	21	4790	1,050
2501-5000	4	28290	1,950
5001-10000	2	9840	3,800
10001-20000	1	0	7,550
>20000	0	0	10,000

The results of this sliding scale analysis project that the six size classes with planned disturbances (all disturbance classes up to 10,000 ha in size) are well distributed and have median distances that exceed the minimum target distances. Since there are no measured disturbances in the >20,000 ha size class and only one disturbance in the 10,001-20,000 ha size class, the median distances are recorded as 0 for these two classes as a median distances cannot be calculated unless there are two points in the size class.

Planned Harvest Disturbances by Size Class

The planned harvest disturbance analysis considers areas disturbed by harvest activities within a 20 year analysis window as does the disturbance analyses. However for this planned harvest disturbance analysis, only five years of planned harvest is considered therefore Plan End for the planned harvest disturbance analysis is five years after Plan Start (2017) for Phase I planning of the 2012 forest management plan. Planned harvest disturbances include all planned harvest area for the five year plan term and any "old" harvest areas less than or equal to 15 years old within 200 metres of the "new" cut area. Each "planned harvest disturbance" must be separated by 200 metres of forest greater than or equal to 3 metres in height and 30% stocking or greater than 20 years old in order not to be part of the same planned harvest disturbance. Planned harvest disturbances do not include any area naturally disturbed (unlike the disturbance analysis that does include natural disturbances).

According to the (NDPE guide), 80% (in the *Forest Management Guide for Natural Disturbance Pattern Emulation* Boreal Forest) of planned harvest disturbances (referenced as planned clearcuts in the guide) determined by frequency should be less than 260 hectares in size. The guide also states that, although less than 80-90% of fires are smaller than 260 hectares, this direction recognizes the public sensitivity concerning large harvest disturbances.

This analysis identified planned harvest disturbances projected to be present in 2017, the end of the first five-year term of the plan. In the assessment of the "80 % under 260 hectares" standard, the assessment has identified 76% of planned harvest disturbances to be equal to or under 260 hectares in size, leaving 24% of planned harvest disturbances greater than 260 ha. This result is acceptable to the Planning Team as it is close to the target level and exceeds the result of 2004 FMP which was 60% under 260 hectares and 40% of planned harvest disturbances greater than 260 ha. There are spatial constraints to the allocations that contribute to not meeting the standard, in this case the Planning Team placed an emphasis on meeting the landscape-level habitat supply of marten and Woodland Caribou.

Planned harvest disturbances range from 2 to 7,904 hectares in size, with an average of 302 hectares. It should be noted that planned harvest disturbances contain both new and older harvest areas (up to 20 years old). For those planned harvest disturbances over 260 hectares (average size 964 ha), the average size of "new cut" in these planned harvest disturbances is 533 hectares (55% of gross planned harvest disturbance area).

Each planned harvest disturbance that exceeds 260 hectares is identified in Table FMP-12. These planned harvest disturbances over 260 hectares will provide large landscape patches for forest diversity and wildlife habitat in the future and contribute to a range of disturbance sizes on the forest which emulates a more natural disturbance pattern than if all planned harvest disturbances were the same size. These planned harvest disturbances result from the consolidation of eligible new cut harvest area adjacent to harvest areas from the past 20 years, or the allocation of a concentration of eligible harvest area in this plan period.

6.0 Base Model Inventory and Base Model **26**

6.1 Development of the Base Model Inventory 26
6.1.1 Management Decision Information 27
6.1.1.1 Managed / Unmanaged Indicator (MANAGED) 27
6.1.1.2 Stand Type (TYPE) 27
6.1.1.3 MNR Code (MNRCODE) 27
6.1.1.4 Stand Age (AGE) 27
6.1.1.5 Silviculture System (SILVSYS) 27
6.1.1.6 Stage of Management (MGMTSTG) 27
6.1.1.7 Source of Silviculture Intensity (SISRC) 27
6.1.1.8 Availability Indicator (AVAIL) 28
6.2 Development of the Base Model 30
6.2.1 Land Base Assumptions 31
6.2.1.1 Other SFMM Land Base Information 33
6.2.2 Forest Dynamics Assumptions 35
6.2.2.1 Natural Succession 35
6.2.2.2 Natural Rehabilitation of Non-forest to Forest 38
6.2.2.3 Natural Disturbances 39
6.2.2.4 Growth and Yield in Even-age Forest 44
6.2.2.5 Timber Product Proportions in Even-aged Forest 44

6.2.2.6 Wildlife Habitat Classification 44
6.2.3 Strategic Silvicultural Options 45
6.2.3.1 Clearcut Harvest Operability Ranges 45
6.2.3.2 Clearcut Growing Stock Volumes Left Unharvested 46
6.2.3.3 Clearcut Post-Renewal Forest Succession and Costs 51
6.2.3.4 Stumpage Values and Timber Harvesting Costs 53
6.2.3.5 Areas Reserved from Harvesting 54
6.2.3.6 Conversion of Harvested Areas to Non-Forest Land 57
6.2.3.7 Strategic (Biological) Forest Renewal Limits by Proportion 57
6.2.3.8 Mid-rotation Tending and Non-forest Rehabilitation Options 59
6.2.4 Correlation to the Simulated Range of Natural Variation (SRNV) 60
6.2.5 Base Model and LTMD Management Options 64
6.2.5.1 Silvicultural Budgets, Distribution and Discount Rates 64
6.2.5.2 Stability of Forest Unit Areas 64
6.2.5.3 Age Class Area Limits by Forest Unit Group and Age Class Group 64
6.2.5.4 Age Class Proportion Limits by Forest Unit (Old Forest Area) 65
6.2.5.5 Growing Stock Targets 65
6.2.5.6 Timber Volume Species Group Definitions & Harvest Flow Policies 68
6.2.5.7 Sub-Unit Harvest and Renewal Operability Timing 69
6.2.5.8 Stability of Harvest Areas (Area Regulation) 70
6.2.5.9 Harvest Area Limits by Forest Unit 70
6.2.5.10 Forest Renewal Limits by Proportion (Biological Limits and Management Decisions) 71
6.2.5.11 Mid-rotation Tending Limits and Partial Harvest Options 73
6.2.5.12 Timber Values 73
6.2.5.13 Execution Control Options 73
6.3 Documentation of the Base Model Inventory and Base Model Checkpoint 74

7.0 Documentation of SFMM Model Results 74

PART 4: MANAGEMENT OBJECTIVES 75

8.0 Introduction 75

8.1 Review of Objectives from the 2004 FMP 75
8.2 Consideration of Background Information and MNR Guides 83
8.3 Summary of Scoping Investigations 90
8.4 Documentation of the Management Objectives Checkpoint 94

PART 5: PROPOSED LONG-TERM MANAGEMENT DIRECTION 95

9.0 Introduction 95

9.1 Management Objective Representation and Interpretation of Results in the Analysis 95
9.2 Summary of Development of the Long-term Management Direction 97
9.3 Long-term Management Direction Documentation 107
9.4 Documentation of Proposed LTMD Checkpoint 107

APPENDICES 108

Appendix 1 Yield Curves 108
Appendix 2 Summary of Investigation and LTMD Development Results 134
Appendix 3 Summary of Long-term Management Direction Results 205

1.0 Introduction

The Analysis Package is used to document the information, assumptions and decisions made during the strategic analysis conducted to support the development of the Long-term Management Direction (LTMD) for the Whiskey Jack Forest 2012-2022 Forest Management Plan. The Analysis Package consists of text, tables, maps and other information prepared by the Sustainable Forest Licence holder, the Ontario Ministry of Natural Resources, (Kenora District).

2.0 Analytical Tools

The following tools were used during the development of the management strategy for the 2012-2022 Forest Management Plan for the Whiskey Jack Forest:

Strategic Forest Management Model (SFMM)

SFMM is based on linear programming techniques and is used to model timber production capabilities of a forest for various levels of management intensity. The model is designed to be compatible with information currently available in Ontario. The model is also used to non-spatially model wildlife habitat abundance for a range of species. SFMM version 3.5 Build 2010.04.23 was used with AIMMS solver version 3.8.4.10433.

The Strategic Forest Management Model (SFMM) was used as the primary analysis tool for the strategic analysis. This tool is used to track the entire Whiskey Jack Forest land base through time, and produce projections of changes to the forest structure and composition for 160 years into the future. SFMM also allows for the evaluation of forested areas and their contribution to forest diversity, socio-economic benefits including timber production, old forest and wildlife habitat through time.

Ontario Landscape Tool (OLT)

Ontario's Landscape Tool contains science and information that was used in the development of Ontario's Landscape Guides. OLT provides a direct link to the science and information packages which contain inputs, rationale, simulation results and several tools which can be used when writing a forest management plan or when interested from a science perspective in testing model inputs, assumptions and results. OLT version 3.0.3827 loaded with the updated forest inventory was used for this FMP.

OLT was used as a source of direction for the setting of desirable levels for landscape level forest composition and age structure, caribou habitat and landscape texture and pattern indicators in the forest management plan.

Ontario Marten Analyst 2 (OMA-2)

This tool has been developed in the Northwest Region to classify the land base into "capable" forest types and "suitable" habitat for marten. Suitable habitat can then be modelled through time, based on the current forest condition. OMA-2 contains a "core builder" tool where the user can create various core habitat area scenarios and generate marten core habitat statistics.

Natural Disturbance Pattern Emulation Guide Tool (NDPEG Tool)
Is a GIS tool (ArcView based) designed to estimate forest disturbance perimeter, estimate residual (insular and peninsular) within forest disturbances, estimate planned clear cut and assess a sliding scale of goodness of fit, using the definitions in the NDPEG Guide.

ArcGIS Spatial Analyst
The ArcGIS based computer model was used to determine estimated slope based riparian reserve widths. Data was used to determine estimated reserve percentages for the SFMM modelling inputs and for preliminary area of concern reserves for operational planning.

3.0 Progress Checkpoints

A summary of the key production tasks and responsibilities is found in the Terms of Reference and Project plan for the 2012-2022 Whiskey Jack Forest Management Plan. The Terms of Reference and Project Plan identify the roles and responsibilities for developing the above-mentioned analytical models, data compilation, update, classification, and conducting the analysis required under the *Forest Management Planning Manual for Ontario's Crown Forests (2009).*

Progress checkpoints are key steps in the development of the Long-Term Management Direction of a forest management plan. The progress checkpoints are:

(A) Planning Inventory (approved February 2, 2010);
(B) Current Forest Condition (approved January 19, 2011);
(C) Base Model Inventory and Base Model (approved October 8, 2010);
(D) Management Objectives (approved January 13, 2011);
(E) Proposed Long-term Management Direction (approved March 9, 2011); and
(F) Preliminary Endorsement of Long-term Management Direction.

Development and decisions related to the completion of the above progress checkpoints are detailed in the following parts of the Analysis Package.

PART 1: PLANNING INVENTORY

4.0 Development of the Planning Inventory

The planning inventory for the management unit provides information required for forest management planning, including forest modelling, habitat modelling and forest diversity analyses. The planning inventory contains updated Forest Resource Inventory information as a result of forest management activities and natural disturbances. The planning inventory also contains expected (forecast) changes, based on anticipated harvest for the remainder of the term of the current forest management plan.

The detailed technical requirements, responsibility and timing for production and submission of the planning inventory are described in the *Forest Information Manual (2009)* and *FIM Forest Management Planning Technical Specifications (November 2009)*. Under these specifications, the planning inventory is made up of two different pieces, the planning composite and the forecasted depletions. The planning inventory reflects forest inventory updated with most up to date depletions and silviculture information, but does not include depleting forecasted depletions to the 2012 plan start. The forecast depletions coverage consists of those depletions from the last actual reported depletions (2008/2009 Annual Report) to the end of the 2012 FMP not yet depleted and recorded.

The Crown forest portion of the management unit is the land base used for decision-making in the forest management plan. For forest management planning purposes, the Crown forest is categorized as areas managed for timber production and other areas. Other areas include provincial parks and conservation reserves, and areas that have been designated through legal or policy means, or a land use decision, as unavailable for timber production. The areas managed for timber production include all remaining Crown forest lands. The total area of Crown forest on the management unit can contribute to the achievement of non-timber objectives in the forest management plan.

The planning composite was developed based on the 2004 Whiskey Jack FMP planning collection inventory. The Inventory Task Team considered the 2004 PCOL inventory as the most up to date inventory information available and would require the least amount of manipulation to be updated for the 2012 FMP production. The following is a summary of update process to create the planning inventory.

<u>Data Source</u>

The Whiskey Jack FRI updates history is:

1997: Last full FRI – new photos and interpretation

2003: Information converted from UTM Zone 15 NAD 27 datum to UTM Zone 15 NAD 83 datum

2006: Historical information related to natural and harvest depletions updated, ownership and roads base coverages updated

2009: As part of the surrender conditions, Abitibi Bowater Inc. updates the forest polygon coverage to include actual harvest depletion, silviculture and Free-To-Grow information from April 1, 2004 to March 31, 2009. MNR created a seamless coverage from this inventory.

The composite planning inventory was assembled using the following methodology:

1. Incorporated hydro corridor, railway bed and ownership with buffer distances depicted below.
2. Incorporated roads by creating new road buffers.

The Base Model Inventory was assembled using the following methodology:

3. Created a Forecast Depletion layer from the approved 2009-2012 Contingency Plan. Estimated depletions were given a YRDEP of 2012.
4. This was merged with the MU wide AOC reserves to create the Base Model Inventory (BMI). The BMI layer was utilized for FMP-3 and SFMM initial land base.

Base Feature	Last Update	Comments
Water	January 1, 2009	Used FRI water which came from OBM
Wetlands		No Provincial significant wetland identified
Streams (permanent feature)	January 27, 2010	- Buffered 15m
Streams (Intermittent feature)	January 27, 2010	- Buffered 1.5m
MU Boundary	January 29, 2010	Used NRVIS data
Ownership and Land Tenure	January 27, 2010	Used NRVIS data
Parks and Reserves	January 27, 2010	Used NRVIS data
Railways	December 12, 2009	Buffered 20m
Utility Line	December 15, 2009	Buffered 20m
Roads	July 12, 2005	- Primary roads were buffered 20m - Branch roads were buffered 10m

B&S area is now classified as a variety of “Below Regeneration Standards” classes as per FIM. This area has reduced slightly from the 2004 FMP – mainly because the B&S area in the 2004 FMP was artificially inflated due to the 1991 blow down and forecast depletion inventory update estimates (i.e. clearcut forest unit stands were depleted to B&S when not all of these ended up being cut and those that were cut often did not become B&S).

The overall Crown land base decreased by 103 ha as a result of boundary adjustment to match the management unit metes and bounds. As a result of the major inventory update undertaken in 2005, the production landbase increased by 7,012 ha. These are some area that was shifted to protection forest and a decrease in unclassified land (road right-of-way buffering).

Area summaries in all tables reflect the base model inventory (after the union on the planning inventory and the forecast depletions). This usually results in an over estimation of "recent disturbance" and "below regeneration standards" area due to the full depletion of all forecast clearcut forest unit stands.

Planning Inventory File: mu490_2012_inv_p1.zip, containing:
Mu490_12pcm00.e00
Mu490_12fdp00.e00

4.1 Documentation of the Planning Inventory Checkpoint

Progress Checkpoint #1 approval of the Planning Inventory was received on February 2, 2010.

----- Original Message -----
From: Mohamed, Hassan (MNR)
To: Susan Jarvis
Sent: Wednesday, September 29, 2010 9:40 AM
Subject: RE: KF and WJ Progress checkpoint #1 and #2 approval?

We (Matt and I) could not load the inventory in the portal so neither of us has notification. But the Kenora Forest PI was approved by the District on: mu644_2012_inv_p1.zip, modified 1/25/2010. The Whiskey Jack Forest was approved on February 2, 2010.

Hassan

PART 2: CURRENT FOREST CONDITION

5.0 Current Forest Condition

The planning inventory products are combined and updated with forest classification information to produce the base model inventory, in accordance with the requirements of the *Forest Information Manual*. The base model inventory and landscape level information are used to describe the current forest condition. The following sub-sections describe the development of the various forest condition classifications.

5.1 Forest Units

The Forest Management Planning Manual (FMPM) defines forest units as: "aggregates of forest stands which normally have similar species composition; develop in a similar manner (both naturally and in response to silvicultural treatments); and are managed under the same silvicultural system."

Two types of forest unit classifications are used in the current FMP. Both types of forest units have a specific purpose in the analysis of the Whiskey Jack Forest. The Northwest Region Standard forest units are used as a standard classification that can be compared to other forest and for the classification of landscape classes, old forest and wildlife habitat. The second set of forest units are the planned forest units. These classes are similar to the standard forest units, but reflect a more local characterization. The planned forest units will be the primary classification for the planning process. They will be used in the development of the modelling inputs, allocations and annual operations until the next FMP.

5.1.1 Regional Standard Forest Units (SFU)

The standard forest units are developed regionally to reflect the different forest conditions found across the province and the different forest types. The Northwest region is dominated by Boreal Forest with a minor portion of Great Lakes - St. Lawrence Forest and Carolinian Forest. Therefore, the dominant forest types reflect conifer forest types such as spruce, jack pine and balsam fir, and hardwood forests are dominated by aspen and white birch and mixedwood. The Northwest Region standard forest units cover these forest types and try to include some regional ecosite considerations.

Standard forest units were developed to allow forest planning teams across the Boreal part of Northwest Region to work with a common set of forest cover descriptions that were consistent for a number of reasons:

1. To allow forest planning across the region to use a consistent description of forest cover.
2. To ensure a close match of forest units to ecosites.
3. To allow science, planning and industry to develop a common set of parameters for modelling:
    a) yield curves
    b) post-disturbance succession rules
    c) natural succession (old age) rules
    d) maintenance of biodiversity

e) Landscape Guide Classes

4. To ensure all forest plans maintain a consistent base set of principles for their forest units:
   a) remove rare and unique forest units first
   b) pure forest units at 70%+, mixed forest units at 40-60%
   c) separate upland conifer into rich (spruce-fir) versus poor (spruce-pine) communities
   d) separate upland mixedwoods into rich (Ecosite 28) versus poor (Ecosite 13) communities
5. To create a direct relationship between units of forest management and units of habitat.
6. To allow for a consistent "roll-up" of forest cover descriptions to higher planning levels.
7. To allow for a simple assignment of higher-order targets to each FMP.

The Northwest Region standard forest units are presented in Table 1.

Table 1 Northwest Regional Standard Forest Units

Standard Forest Unit	Descriptions	SQL Query (SFUs assigned based on specific sort order. Query copied from MIST version 2.0)
PwDom	White Pine Dominant	PW >= 40
PrDom	Red Pine Dominant	PR >= 70
PrwMx	Red and White Pine Mixedwood	PW + PR >= 40
UplCe	Cedar Dominant Uplands	CE >= 20 And (ECOSITE1 Like 'NW17%')
OCLow	Other Conifer Lowlands (Ce/La)	((CE + LA >= 50) Or (WG = 'Ce' Or WG = 'La')) And PR + PW + PJ + SW + BW < 10
SbLow	Black Spruce Lowlands	(ECOSITE1 Like 'NW34%' And PR + PW + PJ + SW + BF <= 20) Or (ECOSITE1 Like 'NW35%' Or ECOSITE1 Like 'NW36%' Or ECOSITE1 Like 'NW37%') Or (ECOSITE1 Like 'NW38%' And (WG = 'Sx' Or WG = 'Sb' Or WG = 'Ce' Or WG = 'Sb' Or WG = 'Ce' Or WG = 'La'))
SbSha	Shallow Spruce Dominated Uplands	SB >= 70 And PO + BW <= 20 And (ECOSITE1 Like 'NW12%' Or ECOSITE1 Like 'NW11%')
SbDee	Productive Spruce Dominant Uplands	SB >= 70 And PO + BW <= 20
PjSha	Shallow Jack Pine Dominated Uplands	((PJ >= 70 And PO + BW <= 20) Or (PJ >= 50 And PO + BW <= 20 And AGE >= 120)) And (ECOSITE1 Like 'NW12%' Or ECOSITE1 Like 'NW11%')
PjDee	Productive Jack Pine Dominated Uplands	(PJ >= 70 And PO + BW <= 20) Or (PJ >= 50 And PO + BW <= 20 And AGE >= 120) Or (PJ >= 70 And (ECOSITE1 Like 'NW13%' Or ECOSITE1 Like 'NW14%'))
PoSha	Shallow Aspen Dominated Uplands	PO >= 70 And (ECOSITE1 Like 'NW12%' Or ECOSITE1 Like 'NW11%')
PoDee	Productive Aspen Dominated Uplands	PO >= 70
BwSha	Birch Dominated Shallow Soils	BW >= 60 And BW + PO >= 70 And (ECOSITE1 Like 'NW12%' Or ECOSITE1 Like 'NW11%')
BwDom	Productive White Birch Dominated	BW >= 60 And BW + PO >= 70

Standard Forest Unit	Descriptions	SQL Query (SFUs assigned based on specific sort order. Query copied from MIST version 2.0)
OthHd	Tolerant Hardwoods	TOL >= 30
SbMx1	Spruce Dominant Conifer Mixedwoods	PR + SB + PJ + SW + BF >= 70 And BF <= 10 And PO + BW <= 20 And (SB + SW) > PJ
PjMx1	Jack Pine Dominant Conifer Mixedwoods	PR + SB + PJ + SW + BF >= 70 And BF <= 10 And PO + BW <= 20 And PJ >= (SB + SW)

General Ecosite Relationships for Standard Forest Units

PwDom - white-pine dominated stands (white pine > 40%)
- suitable for management using shelterwood or patch clearcut
- primary ecosites: 11, 24, 18
- secondary ecosite: 15

PrDom - pure red pine (red pine > 70%)
- developed to capture pure stands, usually as a result of plantations
- primary ecosites: 15
- secondary ecosite: 11, 18

PrwMx - white and/or red pine in the overstorey
- might be suitable for shelterwood, often clearcut and regenerated to more pine
- primary ecosites: 15, 18
- secondary ecosite: 11, 24

UplCe - White cedar
- primary ecosite: 17

OCLow - lowland conifer, mixture of black spruce, larch and cedar
- primary ecosites: 36, 37

SBLow - lowland pure black spruce, or black spruce dominated conifer lowland
- primary ecosites: 35, 36
- secondary ecosite: 37

SbSha - black spruce pure upland (Shallow Soil)
- does not contain white spruce or cedar
- primary ecosites: 12

SbDee - black spruce pure upland (Deep Soil)
- does not contain white spruce or cedar
- primary ecosites: 20, 22, 26
- secondary ecosite: 21, 31

PjSha - pure jack pine, usually on shallow soil
- primary ecosite:12

PjDee - pure jack pine, usually on fresh sandy
- primary ecosite: 13, 20, 25
- secondary ecosites: 21, 14

PoSha - pure poplar on shallow soil
- primary ecosites: 12
- secondary ecosites: 19, 29

PoDee - pure poplar and poplar-dominated hardwood mix
- primary ecosites: 29, 19
- secondary ecosites: 33, 16, 28

BwSha - pure white birch on shallow or poor soils
- primary ecosite: 12

BwDom - pure white birch and white birch dominated hardwood mix
- primary ecosite: 19, 29
- secondary ecosites: 16, 33

OthHd - transitional (GLSL/Boreal) Forest Unit in most cases
- in transitional areas, mostly soft maple, otherwise black ash
- primary ecosites: 30, 38
- secondary ecosite: 33

SbMx1 - black spruce dominated mixed conifer
- will contain white spruce (and often cedar)
- primary ecosites: 21, 20, 26
- secondary ecosites: 12, 22, 14, 13

PjMx1 - jack pine dominated mixed conifer on sandy soils
- primary ecosite: 20, 12, 21, 13
- secondary ecosites: 25, 14

BfPur - Balsam fir dominated (balsam fir > 70%)
- primary ecosites: 21, 27
- secondary ecosite: 14

BfMx1 - balsam fir dominated mixed conifer
- primary ecosite: 14, 20, 21, 26, 27
- secondary ecosites: 12, 22

HrDom - hardwood dominated (>70%)
- primary ecosites: 19, 29
- secondary ecosites: 33, 28

HrMw - hardwood dominated (>70%)
- primary ecosites: 19, 21, 29
- secondary ecosites: 28

ConMx - Conifer dominated mixedwood
- primary ecosites: 21, 27, 12
- secondary ecosites: 14, 26

The correlation between the site and forest unit is depicted in the edaphic grid below and in Table 2:

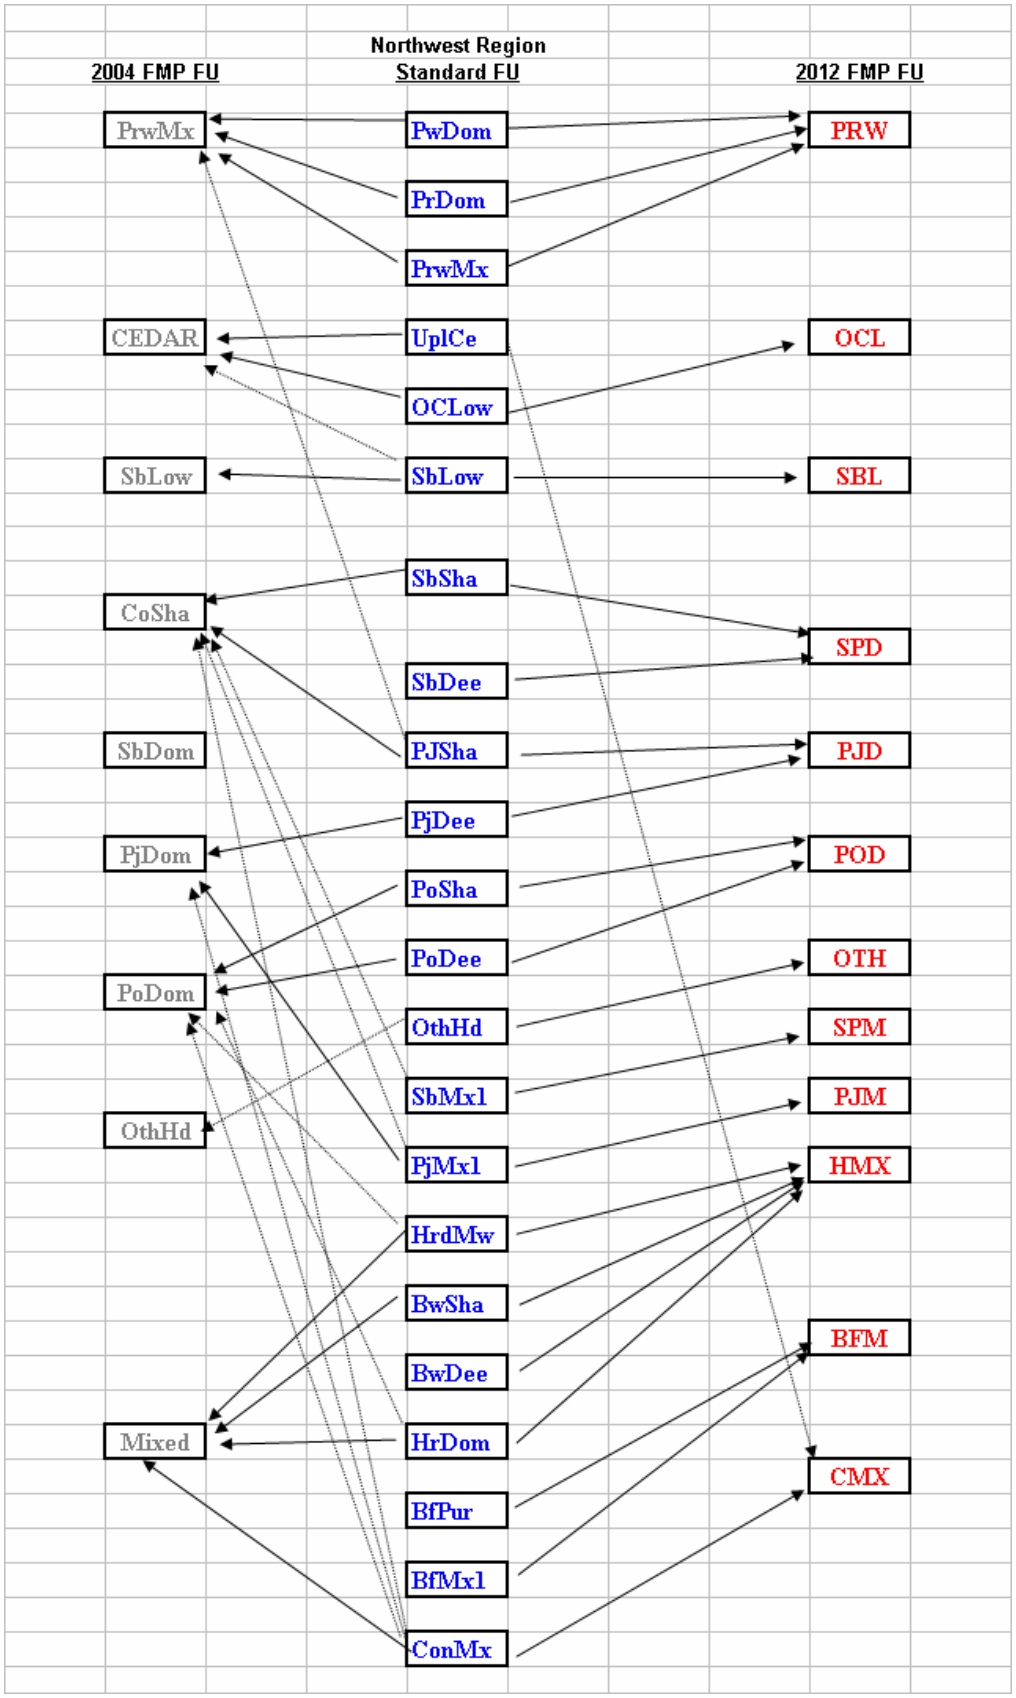
5.1.2 Plan Forest Units (PLANFU)

The first step in the development of plan forest units for this 2012 FMP was agreement that it was a cooperative process with the Kenora Forest 2012-2022 Planning Team and that both forest management plans would be prepared using the same forest unit definitions. Preparing 2012 plans for these adjacent forests utilizing the same forest units was considered a key objective as identical forest units would streamline future planning if there was a potential land base amalgamation and identical forest units would streamline future reporting of forest management activities. Another consideration was that by utilizing the same suite of forest units, there were some efficiencies to be realized in plan development for the 2012 plans (e.g. strategic modelling inputs, plan documentation, etc.). While development of forest units was a joint process between two planning teams, both teams separately demonstrated the appropriateness of the final PLANFUs to each of the two individual management units.

The Forest Resource Inventory parameters used for the development of these forest units were species composition, stocking, site class, age and ecosite (for shallow and wet soils). A number of adjustments were made to the Whiskey Jack Forest 2004 FMP forest units to be more consistent with the Northwest Region Standard Forest Units. With only very minor exceptions, each standard forest unit fit into a single PLANFU. The relationship between standard forest units and plan forest units are documented in Figure 2 below. This strong correlation between PLANFUs and SFUs was important since many forest diversity and forest condition desirable levels and targets were based on science developed for the Ontario Landscape Tool, which utilized inputs documented primarily by standard forest units. Better correlation in forest units to SFUs allowed better analysis of projections to Ontario Landscape Tool Simulated Ranges of Natural Variation (SRNV)(Section 6.2.4).

A number of Regional Standard Forest Units were amalgamated to create the 2012-2022 Whiskey Jack Plan Forest Unit. Major ones are the **UplCe** was lumped into **CMX** since **UplCe** is on a much more productive site than **OCLow**, and only makes up 3,545 ha , **HrDom, HrdMw, BwDom and BwSha** was lumped to create **HMX, BfPur** was lumped with **BfMx1** to create **BFM, PrDom, PwDom and PrPrMx** was lumped to create **PRW.** These areas were lumped because they represent small area as shown in Table 2.

Figure 2 Correlation Between 2004 and 2012 FMP Planned Forest Units



The PLANFU forest units are summarized in Table 3 and are consistent with Table FMP-2. These PLANFU descriptions were used to classify stands in the planning inventory.

Table 3 Whiskey Jack Forest 2012-2022 FMP Forest Units

Planned Forest Unit Code	Name	Ecosites (descending order of NW ES occurrence, only areas >100 ha)	FRI Parameters & Criteria (Script to be applied in specific sort order)
PRW	Red Pine and White Pine Mixedwood	11, 18, 15, 24.	SORT ORDER 1: PW+PR >= 40
CMX	Conifer Mixedwood	12, 21, 11, 17, 18, 27, 26, 14, 25, 29, 22, 32, 15, 20, 19, 24.	SORT ORDER 2: CE>=20 And (ECOSITE1 Like 'NW17*') SORT ORDER 13: SB+PJ+BF+SW+CE+PW+PR+LA+HE>=50

5.1.3 Forest Landscape Classes

The *Forest Management Guide for Landscapes* (Landscape Guide) was still being drafted and was not required to be applied to forest management plans in the Boreal Forest at the time of preparation of this 2012 Whiskey Jack Forest FMP. However, the information on biodiversity indicators and the simulated ranges of natural variation for these biodiversity indicators was considered the best available science by the Planning Team and regional advisors. Therefore a management objective indicator related to landscape class area was included in this 2012 FMP in Table FMP-9. This approach was endorsed by the Planning Team and LCC and was consistent with regional and provincial FMP training provided to 2012 FMP Planning Teams.

The following excerpt discussing landscape classes is from the draft *Forest Management Guide for Landscapes (MNR, 2008)*:

> *"A landscape provides habitat for a mixture of wildlife species, each with its own preferences for combinations of vegetation types, seral stages, patch sizes and configurations. It would be impossible to assess landscapes for each species of wildlife individually within the context of a forest management plan therefore the landscape guide uses a classification of landscapes according to our understanding of how forests function as habitat (as codified through wildlife habitat matrices (e.g., Holloway et al. 2004)). Landscape classes for both the Boreal Forest and the Great Lakes – St. Lawrence Forest are based on a cluster analysis of the preferred habitat types (forest units and seral stages) used by a range of wildlife."*

The amount of area by landscape class is a non-spatial measure of the area, in hectares, of the landscape classified into landscape classes. Seven landscape classes have been developed for assessment in the Northwest Region. These landscape classes incorporate forest type attributes, age and to a limited degree site (e.g. upland / lowland designation for conifer forests).

The assessment of area by landscape class is new for 2012 FMP Planning Teams and has not been included in forest management plans for the Whiskey Jack Forest previously. Landscape classes are measured during strategic modelling analysis and areas are not tagged within the Base Model Inventory. Areas by landscape class have been incorporated into the Ontario Landscape Tool (OLT) to approximate the best estimate of the simulated range of natural variation for the Whiskey Jack Forest. The planning team compared the Plan Start 2012 landscape class areas to the OLT suggested natural range in area and determined an

appropriate landscape class objective indicator and desirable levels during development of the Long-term Management Direction.

The seven landscape classes are described in **Table 5** with reference added for which plan forest units are included in each landscape class (subject to age criteria included in Table 6).

Table 5 Northwest Region Landscape Classes

(excerpt from Ontario Landscape Tool Science and Information Package A with PLANFU column added)

Landscape Class	Northwest Region 3W, 4S, 4W, 3S Landscape Guide Forest Unit	Development Stages	Corresponding Plan Forest Units (PLANFUs)
1 - Presapling & Sapling	All	Pre-sapling, Sapling	All
2 - Immature Conifer	BfDom, ConMX, PjDee, PjMx1, PrwMx, SbDee &SbMx1	Immature	BFM, CMX, OCL, PJD, PJM, PRW, SBL, SPD, SPM.
3 - Immature Hardwood	BwDom, HrdMw, HrDom, OthHd, PoDee,	Immature	HMX, POD, OTH
4 – Mature & Late Balsam Fir	BfDOM	Mature, Late	BFM
5 – Mature & Late Lowland Conifer	OcLow, SbLow	Mature, Late	OCL, SBL.
6 – Mature & Late Hardwood & Mixed	BwDom, HrdMw, HrDom, PoDee	Mature, Late	HMX, POD, OTH
7 – Mature & Late Upland Conifer & Mixed	ConMx, PjDee, PjMx1, PrwMx, SbDee & SbMx1	Mature, Late	CMX, PJD, PJM, PRW, SPD, SPM.

5.2 Management Decision Information

5.2.1 Management Zones (SMZ, OMZ)

In the development of the long-term management direction, the planning team chose to partition the management unit into management zones. A management zone is a geographical area within a management unit that provides spatial context to the long-term management direction, and may influence strategic analysis, and operational planning. Two types of management zones, strategic and operational, were used to represent spatial considerations. Strategic management zones represent areas with distinct ecological characteristics, landscape biodiversity requirements or forest-level harvest and retention considerations. Strategic management zones are identified in the SMZ field of the spatial PCM inventory information, and operational management zones are identified in the OMZ field.

The Planning Team recognized the area of caribou habitat management as a strategic management zone. The Planning Team decided to consider deer and moose management areas at the operational level and did not classify related areas as strategic management zones.

These management zones are described in more detail below:

Strategic Management Zones

Patch patterns which simulate those believed to occur naturally from fire, blowdown, insects and disease, in conjunction with use of the appropriate wildlife and silvicultural guidelines, should ensure the broad range of habitats needed for all of the wildlife species found in the Whiskey Jack Forest. Population monitoring (in Ontario, but not necessarily in the Whiskey Jack Forest) will be required to help assess some of the assumptions being made with respect to the present and future habitats used by wildlife in Ontario forests.

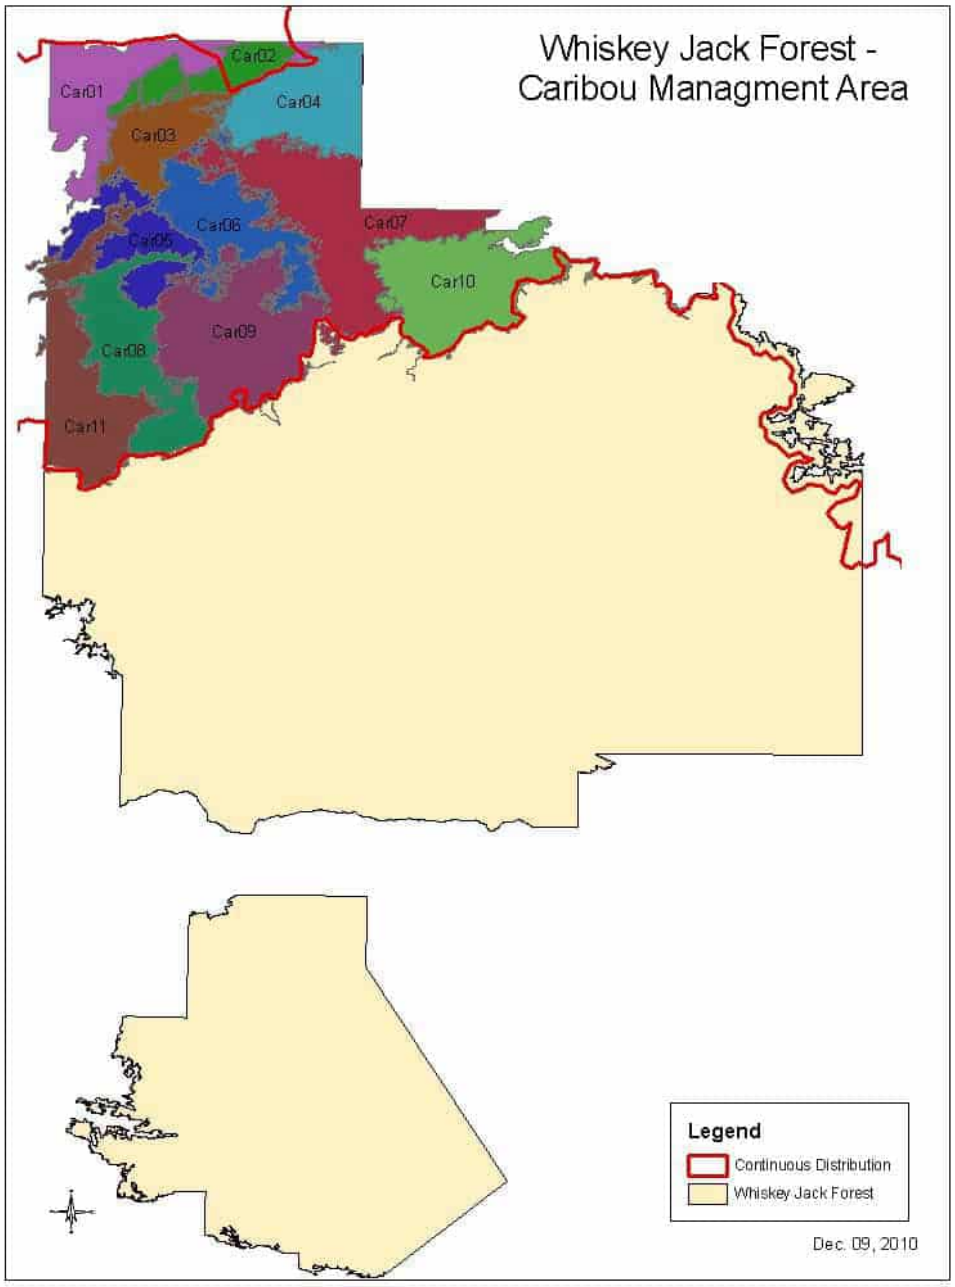
Currently, MNR's delineation of the area of continuous range occupancy for woodland caribou is the primary division of the management zone for caribou (strategic zone) and the rest of the management unit being managed primarily for marten (strategic), moose (operational) and deer (operational).

For strategic purposes in this 2012 FMP, it was agreed to continue to implement the existing 2004 FMP sub-management units which represented the caribou habitat mosaic blocks where caribou habitat management was the primary consideration. The caribou zone and the caribou mosaic blocks within the caribou zone are shown in Figure 3. Caribou dynamic habitat schedule blocks (caribou blocks Car01 through to Car11) are strategic management zones and are identified in the SMZ field of the spatial PCM inventory information.

The *Forest Management Guidelines for the Provision of Marten Habitat (MNR, 1996)* was applied to the Whiskey Jack Forest for this plan. Spatial analysis was conducted for marten with additional habitat definitions of capable and suitable included. The intent of the marten guideline is to provide large contiguous areas of mature conifer-dominated forest as habitat. The strategic landscape level application of the guidelines directed planning teams to develop core areas of suitable marten habitat in 3,000 to 5,000 hectare blocks to be deferred from harvesting. The planning team applied the strategic landscape level section of the marten guidelines on 25 relatively large contiguous areas (marten core habitat areas or large, landscape patches) of Crown land on Whiskey Jack Forest (

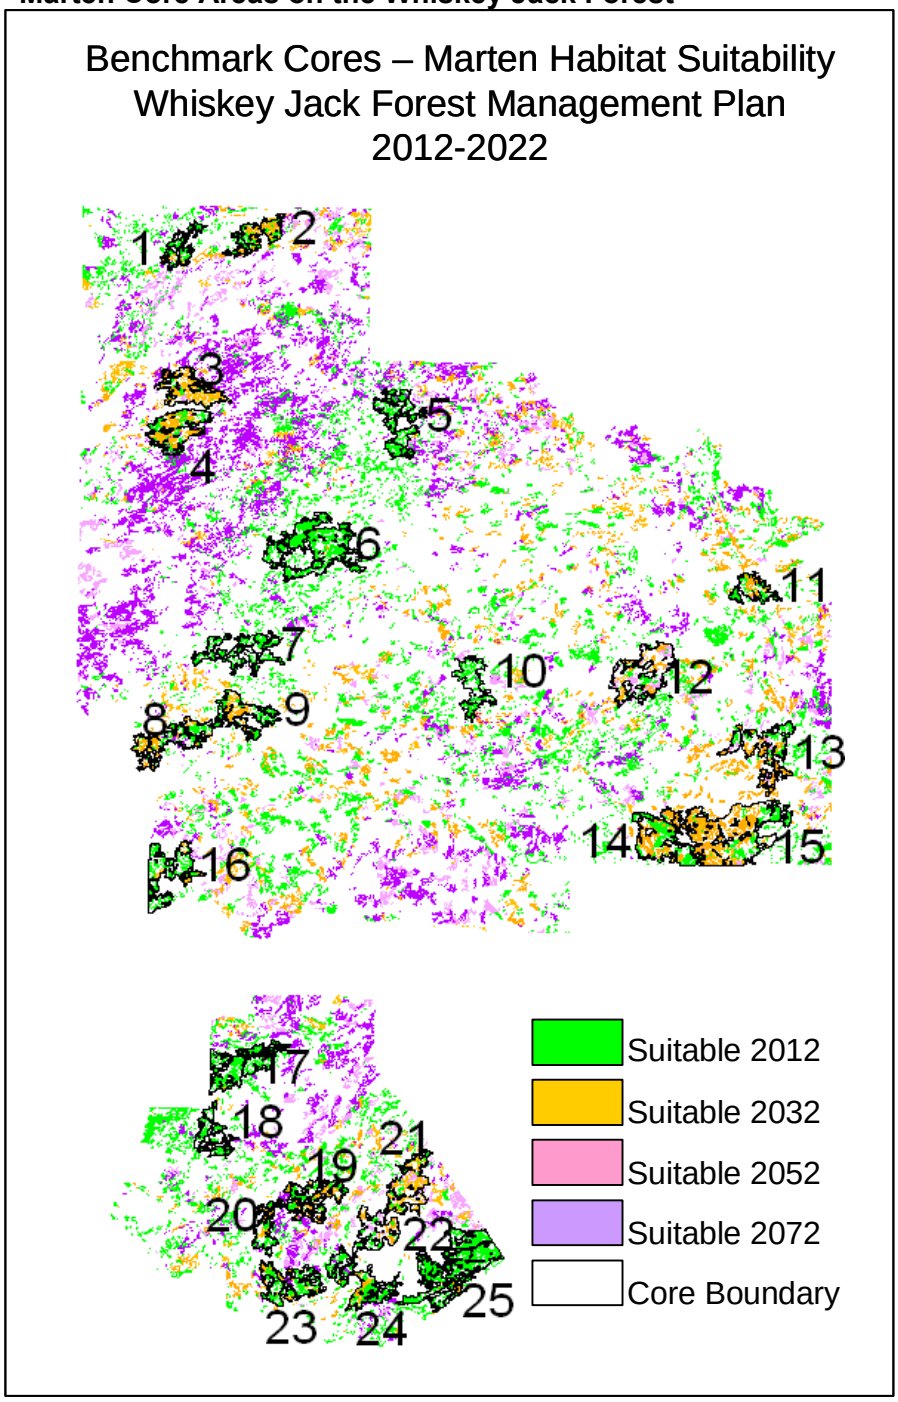
Figure **4**). Marten core areas outside of the caribou management zone are strategic management zones and are identified in the SMZ field of the spatial PCM inventory information. The caribou blocks are the primary SMZ in the caribou management zone, therefore marten cores in the caribou zones Car01 to Car11 are not identified in the SMZ field of the PCM inventory.

Figure 3 Caribou Habitat Management Zone on the Whiskey Jack Forest



Detailed spatial habitat analysis is documented in Supplementary Documentation N – Spatial Analyses: Caribou Habitat.

Figure 4 Marten Core Areas on the Whiskey Jack Forest



Detailed spatial habitat analysis is documented in Supplementary Documentation N – Spatial Analyses: Marten Habitat.

5.2.2 Sub-management Units (SUBMU)

The management unit was classified into sub-management units to recognize the areas within the caribou management zone that have defined dynamic caribou habitat schedules.

5.2.3 Silviculture Intensity (SI)

Silviculture Intensity (SI) indicates a term in forest modelling to provide an indicator of productivity and the expected growth and development pattern and applies only to even-aged forest stands that are managed under the clear-cut silvicultural system.

The Strategic Task Team started by reviewing the previous plan SI by forest unit to determine if they were consistent with current thinking or needed to be update based on operations and silvicultural regeneration standards. The team used a strategy to identify silviculture intensity by defining the objective of the SI and then determining how to represent it in the inventory and modelling. The intent was also to be consistent with the Silvicultural Ground Rules (SGRs)(Table FMP-4). The forest condition objectives for each silviculture Intensity are declared in Table 7 Silvicultural Intensities which represents the Strategic Task Team's decision on how to classify the managed forest stands by silvicultural intensity.

Silvicultural intensities are used to represent both present and future forest conditions.

***Present*:** All stands in current forest except those classified as treated (seeding, plantations) in the inventory.(>30 years of age).

***Extensive*:** Current and Future forest: all areas renewed naturally or with low-cost silviculture. (Current forest that does meet present stocking condition, may or may not be managed)

***Basic1*:** Current forest: all stands that received seed or low density planting in the inventory, that are not density regulated. Future forest: all areas renewed with moderate silvicultural investment (seeding or plantation/natural combination).

***Intensive1*:** Current forest: all stands identified as plantations (including spaced-seeded areas) in the inventory. Future forest: all areas renewed with higher silvicultural investment or resulting in a density regulated forest.

***Basic2*:** Not Used.

***Intensive2*:** Not Used. Can be utilized to reflect a second density regulated condition in addition to Intensive1 (i.e. different average species composition with density regulation).

Assumptions used to Define Silvicultural Intensities in Base Model Inventory:

Silvicultural Intensity (SI) classification is based on forest unit species definition, stocking, DEVSTAGE and age.

Stands must meet forest unit species composition definitions.

Sort for Present intensity stands first, then sort for the highest valid silvicultural intensity followed by classification downwards to Basic and Extensive.

Stocking = site occupancy.

1 Table 7 Silvicultural Intensities

	Silvicultural Intensity					
Forest Unit	**Present**	**Extensive**	**Basic1**	**Intensive1**	**Basic2**	**Intensive2**
BFM	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED, FTGNAT	All NEWNAT. All stands less than 30 years old not already tagged with higher intensity. (<66%)	(FTGPLANT, FTGSEED, or THINPRE) (>=75%)	Not used	Not used	Not used
CMX	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED,FTGNAT	All NEWNAT. All stands less than 30 years old not already tagged with higher intensity. (<70%)	(FTGPLANT, FTGSEED, or THINPRE) (>=70% and <80%) or >110%.	(FTGPLANT, FTGSEED, or THINPRE). (>=80% and <=110%)	Not Used	Not Used
HMX	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, FTGNAT, NEWPLANT, NEWSEED and any stands < 30 years old with stocking >= 70%.	All stands less than 30 years old and stocking <70% The extensive curve will be the same as the present curve	Not used	Not used	Not used	Not used
OCL	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED	All stands less than 30 years old, not tagged as Present.	Not used	Not used	Not used	Not used
OTH	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED	All stands less than 30 years old. -(<75%)	Not used	Not used	Not used	Not used
PJD	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED, FTGNAT	All NEWNAT. All stands less than 30 years old not already tagged with higher intensity. (<80%)	(FTGPLANT, FTGSEED, or THINPRE). (>=80% and <90%)	(FTGPLANT, FTGSEED, or THINPRE) where stocking (>=90% and <=110%)	Not used	Not used
PJM	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED, FTGNAT	All NEWNAT. All stands less than 30 years old not already tagged with higher intensity. (<70%)	(FTGPLANT, FTGSEED, or THINPRE) (>=70% and <80%) or >110%.	(FTGPLANT, FTGSEED, or THINPRE) where stocking (>=80% and <=110%)		
POD	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED	All stands less than 30 years old. (<80%) The extensive curve will be the same as the present curve	Not used	Not used	Not used	Not used
PRW	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED, FTGNAT	All NEWNAT. All stands less than 30 years old not already tagged with higher intensity. (<60%)	(FTGPLANT, FTGSEED, or THINPRE) (>=60% and <80%) or >110%.	(FTGPLANT, FTGSEED, or THINPRE) where stocking >=80 and <=110% **and Pr >= 70%.**	Not used	Not used

	Silvicultural Intensity					
Forest Unit	**Present**	**Extensive**	**Basic1**	**Intensive1**	**Basic2**	**Intensive2**
SBL	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED, FTGNAT	All NEWNAT. All stands less than 30 years old not already tagged with higher intensity. (<70% and >110%)	(FTGPLANT, FTGSEED, or THINPRE) where stocking >=70% and <=110%	Not used	Not used	Not used
SPD	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED, FTGNAT	All NEWNAT. All stands less than 30 years old not already tagged with higher intensity. (<70%)	(FTGPLANT, FTGSEED, or THINPRE) (>=70% and <80%) and >110%.	(FTGPLANT, FTGSEED, or THINPRE) where stocking >=80 and <=110%.	Not used	Not used
SPM	Average species composition and stocking from inventory for stands >= 30 years old and any DEPNAT, NEWPLANT, NEWSEED, FTGNAT	All NEWNAT. All stands less than 30 years old not already tagged with higher intensity. (<70%)	(FTGPLANT, FTGSEED, or THINPRE) (>=70% and <80%) or >110%.	(FTGPLANT, FTGSEED, or THINPRE) where stocking (>=80% and <=110%)		

Note: All NEWPLANT, NEWSEED will be PRESENT.

5.3 Documentation of the Current Forest Condition Checkpoint

Progress Checkpoint #2 approval of the Current Forest Condition was received on January 19, 2011.

From: Hole, Scott (MNR)
To: Duda, Steve (MNR) ; Mohamed, Hassan (MNR) ; Pochailo, Kurt (MNR) ; Susan Jarvis
Cc: Salter, David (MNR) ; Ride, Kevin (MNR)
Sent: Wednesday, January 19, 2011 8:57 AM
Subject: Current Forest Condition checkpoint

All:

I have received confirmation from the Regional advisors that the materials submitted for the Current Forest Condition Checkpoint satisfy the requirements of the Forest Management Planning Manual.

Provided the rest of the advisors and planning team members agree, the checkpoint can be considered passed.

Scott Hole, R.P.F.
Resource Analyst
Northwest Region Planning Unit
p. 807-475-1444
f. 807-473-3023

PART 3: BASE MODEL INVENTORY and BASE MODEL

6.0 Base Model Inventory and Base Model

The Strategic Forest Management Model (SFMM) was used as the primary analysis tool for the strategic analysis. This tool is used to track the entire Whiskey Jack Forest land base through time, and produce projections of changes to the forest structure and composition for 160 years into the future. SFMM also allows for the evaluation of forested areas and their contribution to forest diversity, timber production, old forest area and wildlife habitat through time.

The first step in the strategic analysis for the management plan was development of a base model inventory used for the initial forest land base within the Strategic Forest Management Model. Secondly, a suite of SFMM modelling inputs for natural forest dynamics, silvicultural options and management options were developed that would provide structure to the projected natural and human-influenced changes projected within the SFMM model. The base model serves as the common starting point for development of the long-term management direction.

6.1 Development of the Base Model Inventory

The *Forest Information Manual Forest Management Planning Technical Specifications,* Nov. 2009, Section 4.1.9.1 gives the following description and direction towards creating a base model inventory.

> *"The base model inventory is a union of the planning composite and the forecast depletions into one spatial data layer. This layer provides the necessary information to generate the inputs for spatial and non-spatial models required for strategic modelling in the long-term management direction."*
>
> "The tabular attributes associated with the base model inventory will be the same as those of the planning composite. This process requires that forest stand description information be updated to reflect the estimated result of activities planned for the remainder of the current plan term – this is a best approximation. Forest Classification attributes, as identified in the planning composite coverage polygon attribute table, will be populated for forest polygons."

The Base Model Inventory for the Whiskey Jack Forest was created through updating information in the Forest Classification Fields in the Approved Planning Inventory (Planning Composite and Forecast Depletion Layer (MU490_12PCM00 & MU490_12FDP00) and then creating a union of these two layers. What follows is a description of how each Forest Inventory and Classification attribute was updated.

Forecast Depletions - The forecast depletion coverage was prepared based on the Forest Management Planning Technical Specification (2009) requirement. The coverage contains projected harvest allocations from the 2004-2012 Whiskey Jack Forest FMP not yet declared harvested through annual reports for the Whiskey Jack Forest, and the draft (not from an approved Annual Report yet) actual depletions from 2009-2010. The LTMD task team reviewed the forecast depletions and agreed that this was the best estimate based on current information.

6.1.1 Management Decision Information

6.1.1.1 Managed / Unmanaged Indicator (MANAGED)

This attribute applies to Crown forest area only and indicates whether or not there is a legal or land use planning decision which prevents the land from being managed for timber. The classification is as follows:

- Ownership (OWNER) = 1 ---------- Managed
- OWNER = 5 or 7 ---------- Unmanaged.
- OWNER = 2, 3, 4, 6 or 9 ---------- Null.

6.1.1.2 Stand Type (TYPE)

The TYPE attribute was populated with standard historical stand type data.

6.1.1.3 MNR Code (MNRCODE)

The MNRCODE attribute was populated with standard historical values.

6.1.1.4 Stand Age (AGE)

This attribute indicates the average age of the dominant and co-dominant trees based on the working group species in a forest stand at the start of the new plan term (2012). This was calculated from the difference between the plan start (2012) and the YRORG value.

6.1.1.5 Silviculture System (SILVSYS)

This attribute indicates the Silvicultural System for forest stands that have been identified as available for timber production in the AVAIL attribute. The main harvest method for the Whiskey Jack Forest is clearcut harvest. At current time there are not plans on performing shelterwood or selection harvest in the area. It was agreed that all available forest stands would be designated as “CC” (Clearcut).

6.1.1.6 Stage of Management (MGMTSTG)

This attribute indicates the next harvest or cut treatment that is scheduled to occur in a productive forest stand being managed for timber production (AVAIL=A). The main harvest method for the Whiskey Jack Forest is clearcut harvest. Therefore, by default the only available management stage under the clearcut harvest system is “CLEARCUT”. It was agreed to populate this attribute with “CLEARCUT”.

6.1.1.7 Source of Silviculture Intensity (SISRC)

The source of silviculture intensity attribute indicates how the silviculture intensity (Section 4.1.2.6) values was determined. For this FMP, the values of SI were calculated based on inventory attribute information. This type of classification is represented by “ASSIGNED” value. Therefore, the majority of the SISRC was classified as “ASSIGNED”. For those stand that may have had actual survey results information available, there was the potential to classify the SI with a value that best represented the yield curve and SI criteria. However, most of the survey information that has been gather over the past few years has either not been analyzed to generate the SI value or lacks the required information to assign the individual stand SI as is defined for the 2012 FMP. Therefore, at this time no stands were updated with survey information for SI. The decision was to classify all stands as “ASSIGNED”.

6.1.1.8 Availability Indicator (AVAIL)

The availability indicator identifies which portions of the managed Crown production forest are available for timber production or not. The availability of forest is based on several pieces of information such as access, land use designation, physical operability limitation and managed decisions. Those MANAGED Crown land stands that are deemed unavailable are considered as reserves for the modeling purposes. An additional attribute field (RESERVE) was added to the inventory information to classify the unmanaged forest into different reserve types. A summary of the classification for Available and Reserves are include in the following table.

Table 8 Summary of Crown Forest Availability and Reserve Types

SFMM Reserve Code	Reserve Query for Inventory	Availability	Reserve
Protection Forest	FORMOD = "PF"	U	Protf
Parks and Protected Areas	OWNER = "5" or "7"	U	Parks
Islands	Access1 = "ISL"	U	Islnd

Once the Base Model Inventory was created the following modifications were made to enhance the strategic modelling:

6.1.1.8.1 Slope-based Reserves

Slope based shoreline reserves were added to all lakes, rivers and streams. Reserve widths were based on slope calculated through MNR's digital terrain model and widths were applied as follows:

Slope%	Reserve Width
0-15	30 m reserve
16-30	50 m reserve
31-45	70 m reserve
>45	90 m reserve

Reserves were applied from the treed edge (polytype FOR, TMS, RCK, BSH) to simulate the guidelines direction that the reserve will be measured from the edge of vegetation communities capable of providing a effective barrier to the movement of sediment such as alders, willows, labrador tea and leatherleaf. There was discussion regarding whether or not to use standing timber as the start of the reserve width, however this was considered an overestimate of the amount of reserves. This is taking into consideration that the new Stand and Site Guide allows for harvesting of a portion of the shoreline reserves and operationally shoreline reserves along rivers and streams are usually measured from woody shrubs and not from standing timber. These reserves were then intersected with the inventory, and each stand was analyzed to determine the amount of area in reserve. This area was then added as additional attribute in the inventory (no stands were harmed in the making of this inventory).

Reserve widths will be reviewed and adjusted during operational planning to ensure proper reserve widths as measured from the woody shrub line as directed in the Stand and Site Guide.

6.1.1.8.2 Tourism Reserves

It was recognized that high usage lakes will require larger reserves than what is necessary to protect the environment as generally there arises concerns from the public and the tourism industry that the aesthetics of the lake will be reduced if harvesting is adjacent to the shoreline. In order to portray this concern Tourism reserves of 90m width were placed on lakes that, based on past experience, would require reserves wider than the water quality buffers for social reasons. This includes virtually all lakes with cottages or resource based tourism operation accommodations. As per the water quality reserves (6.1.1.8.1), the area of reserve in each stand was calculated and updated in the inventory.

6.1.1.8.3 Nest Reserves

All stick nests currently identified on MNR's NRVIS layer were buffered using the new Stand and Site Guide direction with the following reserves:

Eagle: 200m reserve
Osprey: 150 m reserve
Blue Heron: 300 m reserve

As per the water quality reserves (6.1.1.8.1), the area of reserve in each stand was calculated and updated in the inventory.

6.1.1.8.4 Harvest Reserves and Deferrals

The Whiskey Jack Forest is a fragmented forest with a long history of harvesting. It was observed that there are numerous areas where there is merchantable wood adjacent to recently harvested areas; however the area is too small to be allocated as harvest area on its own. In order to ensure that SFMM does not overestimate available harvest area it was decided to defer the harvest of these smaller older (>70 years old) forest stands until the adjacent recently harvested areas would become eligible for harvest. The classification was done manually by spatially identifying the operational eligible areas and comparing adjacent stand information. A new attribute field (OP_DEF) was created to identify these areas in the inventory. A total of 7,823 ha were deferred for 40 years (net area not already tagged as reserve area) and an additional 33,417 ha were classified as unavailable reserve area type PASS and were not expected to be available in the future.

6.2 Development of the Base Model

The use of the SFMM model requires that land base, forest dynamics, silvicultural options, and management constraints and targets data be entered into the model. Within the four categories, the following items are required:

i) **Land Base Definition (Section 6.2.1)**: forest unit descriptions, listing of areas available and unavailable for timber production (by forest unit and age class), and non-forested land type descriptions. Land base data for unmanaged land within the management unit (e.g. Crown land parks and exclusions) is entered to facilitate the analysis of wildlife habitat and biodiversity. Islands and site class 4 sites are categorized as "reserve". Riparian reserves were estimated in the land base for strategic modelling purposes and were included as a "reserve" category. Non-Crown land (i.e. patent land) is not entered into the SFMM land base and does not contribute to wildlife habitat or forest diversity indices because the company does not have any control over activities on this patent land.

ii) **Forest Dynamics Information (Section 6.2.2)**: rates of natural succession from one forest type to another, rates of natural succession of non-forested land types to forested, forest development information (yield curves) for natural forest development and various silvicultural treatments.

iii) **Silvicultural Options (Section 6.2.3)**: harvest operability ranges, stumpage values, allowances for reserve prescriptions and unharvested volumes within harvest areas, conversion of harvested areas to non-forested land, forest renewal options, post-renewal forest succession rates, commercial thinning and tending treatment options, and active non-forest rehabilitation treatments options.

iv) **Management Objectives and Targets (Section 6.2.5)**: silvicultural budgets, stability of forest units, desired future forest condition, minimum landscape class and old forest area targets, minimum growing stock, species group definitions, harvest flow policies, harvest volume targets, stability and limits of harvest area, forest renewal limits, mid-rotation tending limits, non-forest rehabilitation limits, seedling availability and distribution limits.

Land base classifications have already been described in Analysis Package Sections 5.1 to 5.3 and Section 6.1. A summary of other base model inputs, data sources, and other model assumptions developed for the 2012 Whiskey Jack FMP by the planning team follows in Sections 6.2.1 to 6.2.5 of this Analysis Package.

6.2.1 Land Base Assumptions

Although the Planning Composite identified most areas that were not available for harvesting due to access, peninsula etc. further area was deemed as unharvestable, such as inoperable or had some management consideration, and then classified as Access or Management Reserve, and Unavailable. These areas were classified in the Base Model Inventory based on a spatial review of the inventory and were manually updated (described in Section 6.1.1).

In order to help with the classification and input of the inventory information into the modelling and for use in analysis, additional inventory attribute were included in the BMI. These attribute include individual species fields, three different age class attributes, standard forest unit and the plan forest unit from the 2004 FMP.

The individual tree species fields reflect the tree species contained in the Species Composition (SPCOMP) attribute. Each tree species attribute contains the percent composition included in the species string for that species. These attributes were included for ease of analysis of forest composition and is used in several modelling utility tool such as Ontario Marten Analyst 2.

The three age class attributes reflect a 20-year age class, a 10-year age class and a SFMM 10-year model input age class. The two regular age class attributes are used in the production of FMP tables and ease of use for operations and summarizing data. The SFMM age class will be used to directly input the inventory land base into the SFMM model. All the age classes reflect the age at plan start (2012).

This attribute is used to create sub management units such as ecological zones, watershed zones, wilderness zones, industrial working circles etc. Sub management units were used in the 2004 FMP for caribou management subunits, and to recognize the varied management considerations for the historic working circle areas. This approach was continued in the 2012 FMP.

For previous forest management plans, strategic modelling included inputs for wildlife habitat units and seral stages. These inputs were not used for this 2012 FMP as the forest condition (including various conditions providing varied wildlife habitat) was included and considered using different model inputs.

After the Base Model Inventory is completed and accepted for use, the various land base classifications are sorted to ensure the initial land base is entered correctly into the Strategic Forest Management Model (SFMM) for use in investigations and developing a Long-term Management Direction for the Whiskey Jack Forest. This SFMM initial land base was reconciled to Tables FMP-1 and FMP-3 (Table 9).

Table 9 Reconciliation of SFMM Initial Land Base to Tables FMP-1 and FMP-3

SFMM Classification	Area in Hectares		Inventory Classification (OWNER, and POLYTYPE)
	SFMM Model	FMP-1 and FMP-3	
Available	538,619	667,051	OWNER = 1, POLYTYPE = FOR.
			Available breakdown from FMP-3.
Reserve (Unavailable)			Includes OWNER = 1, LOWNAT DEVSTAGE area (20,036 ha).
Slope-based Riparian	64,763		Estimated reserve areas in SFMM are classified as available in FMP-3.
Tourism	10,373		Estimated reserve areas in SFMM are classified as available in FMP-3.
Nests	1,129		Estimated reserve areas in SFMM are classified as available in FMP-3.
Pass	33,417		Estimated reserve areas in SFMM are classified as available in FMP-3.
Protf	34,149	34,149	FORMOD = PF, OWNER = 1, 5, 7 (excludes forested islands)
Forested Islands - Crown Managed	3,123		ACCESS1 = ISL, OWNER = 1
Forested Islands - Park		2,003	ACCESS1 = ISL, OWNER = 5, 7.
Parks	38,309	36,306	FORMOD = FOR, OWNER = 5 or 7 only. (includes forested islands in SFMM)
Management Reserve	1,389		
Access	124		POLYTYPE = FOR, ACCESS1=LUD, NAT, PEN. OWNER = 1.
		6,039	Unavailable in Table FMP-3, OWNER = 1
Reserve (Unavailable) Subtotal	186,776	78,496	(unavailable includes 104 ha LOWNAT and 3,123 ha Forested Islands).
Non-forest and Non-Productive			
OpMsk	33,594	33,594	POLYTYPE = OMS, OWNER = 1, 5, or 7.
TrMsk	22,070	22,070	POLYTYPE = TMS, OWNER = 1, 5, or 7.
BrsAld	26,761	26,761	POLYTYPE = BSH, OWNER = 1, 5, or 7.
Grass & Meadow	13	13	POLYTYPE = GRS, OWNER = 1, 5, or 7.
Rock	19,001	19,001	POLYTYPE = RCK, OWNER = 1, 5, or 7.
Agricultural Land	0	0	POLYTYPE = DAL, OWNER = 1, 5, or 7.
Water	203,040	203,040	POLYTYPE = WAT, OWNER = 1, 5, or 7.
UCL	3,489	3,489	POLYTYPE = UCL, RRW, or BFL, OWNER = 1, 5, or 7.
Older LOWNAT	20,140		OWNER=1 only.
Non-forested Islands ISL	0	0	POLYTYPE = RCK, ACCESS1 = ISL, OWNER = 1, 5, or 7.
Subtotal	328,108	307,967	
TOTAL SFMM AREA	1,053,501	1,053,515	Total Ownerships 1, 5, and 7.
TOTAL CROWN LAND BASE	**1,053,501**	**1,053,515**	10 ha variance due to rounding convention during SFMM area import. Acceptable.
Patent Land	0	0	Total Patent Ownership = 2 (not included in SFMM land base).
TOTAL LAND BASE OF THE FOREST	**1,053,501**	**1,053,515**	

Hierarchy for Classification of SFMM Initial Land Base: (unique sort - once an area is tagged, it is not retagged.)

Order:

1 **Patent** - Sort for non-Crown ownership 2, all land types. (not included in SFMM land base, but is included in land base reconciliation to Table FMP-1)
NOTE: Non-Crown ownerships 6, 8, 9, and Patent ownership 3, 4, all land types, are not included in SFMM land base and not included in Table FMP-1.

2 **RESERVE - ProtF** - Sort for Protection Forest

3 **NON-FOREST** - Sort for non-productive forest classes based on POLYTYPE, includes:

ISL POLYTYPE = RCK and ACCESS1 = ISL (sorted before rock is tagged)
LOW LOWNAT and LOWMGMT (team decision to consider Crown, managed, non-productive for SFMM modelling).
OMS Open Muskeg
TMS Treed Muskeg
BSH Brush & Alder
GRS Grass & Meadow
DAL Designated Agricultural Land
UCL UCL, PIT, RRW, BFL
WAT Water
RCK Rock

4 Sort for unavailable **RESERVE** classifications:

PARKS Productive Crown park land (ownership 5 and 7)
ISLND Forested islands (Ownership 1)
RIPAR Estimated slope-based Riparian reserve
TOURS Estimated Tourism Reserve
NESTS Estimated Nest Reserve
Access Classified actual areas with access issues.
MgRes Classified Management Reserves not otherwise classified as reserve (above).

5 **AVAIL** - Remainder of forest available for timber production
- Crown, managed ownership 1 only
- productive, forested land and not otherwise estimated to be reserved from harvest or non-forest.
(deferrals for large landscape patches and delay in availability of certain stands (harvest deferral) is applied to this AVAIL land base only.)

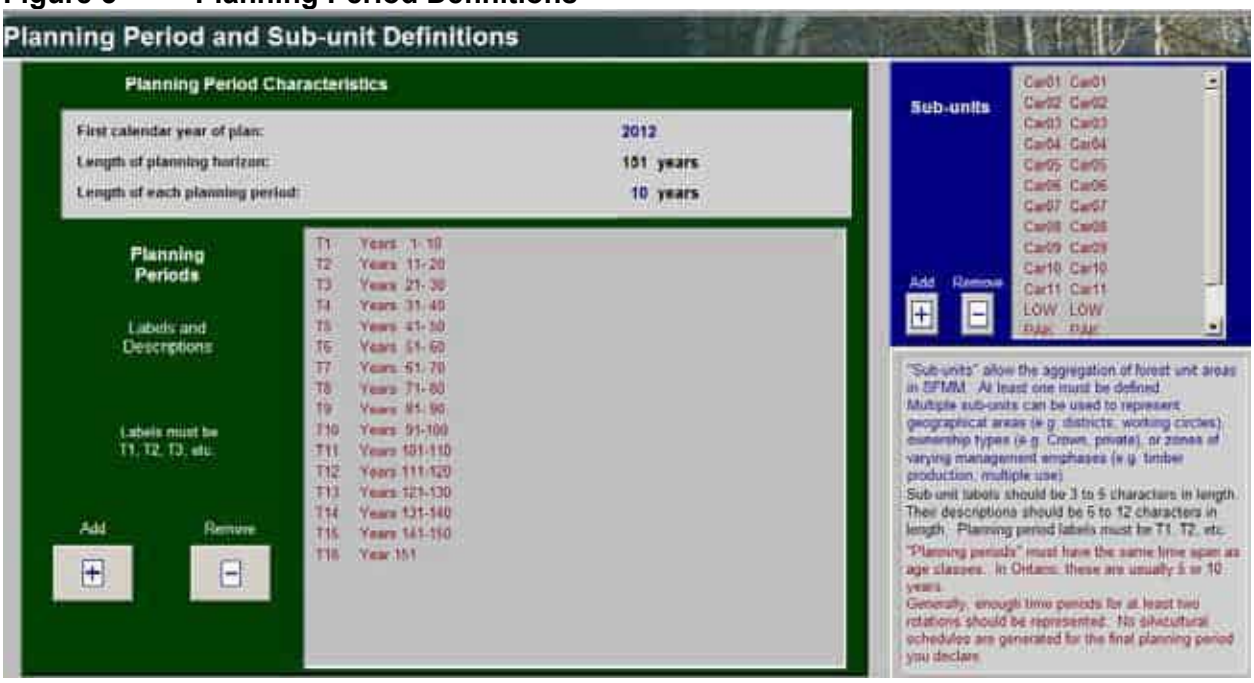
2

6.2.1.1 Other SFMM Land Base Information

6.2.1.1.1 Planning Period Definition

Ten-year terms were used for modelling which correspond with the 10-year period of this forest management plan (Figure 5). One 10-year annual available harvest area would apply to the full 10-year FMP. Ten-year terms were also suitable for other applications (dynamic caribou habitat schedule, and marten core area and operational deferrals). Ten-year terms were also used for the modelling for the 2001 and 2004 FMPs.

Figure 5 Planning Period Definitions



6.2.1.1.2 Estimated Riparian Reserves

Estimated riparian reserve area was included in the initial SFMM land base and was not included in the planning inventory (Section 4.0) but was used to refine AVAILABILITY in the Base Model Inventory (Section 4.1.1.8.1 Slope based Reserves). The estimated riparian reserve is not a management decision, but rather an estimate of a reduction to the available forest land base to better strategically modelling what is expected to occur during implementation of forest management plans. Estimated riparian reserves were derived from a computer based terrain analysis tool to use actual slope information to vary the projected reserve widths around waterbodies. This estimate of riparian reserve was intended to account for reserve area adjacent to water bodies based on actual percentage slopes. The degree of slope of the shoreline of the water body was used to determine the width of reserve suggested by the Stand and Site Guide. Riparian reserve area estimates calculated through the use of GIS spatial analysis were included in the modelling as “reserve” area by forest unit, age class and silvicultural intensity affected. This detailed estimate for modelling purposes reflects the “best information available” to the Planning Team and shows improvement in modelling assumptions since the 2004 FMP.

6.2.1.1.3 Provincial Landscape Classes

The assessment of area by landscape class is new for 2012 FMP Planning Teams and has not been included in forest management plans for the Whiskey Jack Forest previously. Landscape classes are measured during strategic modelling analysis (based on forest unit and age class) and areas are not tagged within the Base Model Inventory.

In order to assess non-spatial area by landscape class, inputs into the Strategic Forest Management Model (SFMM) were needed to allow the classification of the future forest into landscape classes (projected 10-160 years in the future during development of the Long-term Management Direction). This measurement of Plan Start 2012 areas by landscape class and comparison to future projected area by landscape class gave the Planning Team another tool to measure forest condition and regulate change in order to improve sustainability of the forest. The analysis of landscape class area through time is consistent with information projected by the Ontario Landscape Tool which was used for the setting of desirable levels for forest condition management objective indicators.

The representation of landscape class area was incorporated into SFMM through the use of additional "tree species" as a proxy for the additional landscape class areas. In order to measure the projected landscape class areas, SFMM inputs related to the landscape class were added to the growth and yield curves to count the hectares in each landscape class. Unharvested volume percentages were also refined ensure that projected harvest volumes were accurate and were not inflated due to the additional proxy tree species (count of hectares within landscape classes). Specific inputs for landscape class areas are included in the yield curves embedded in the SFMM input file.

6.2.1.1.4 Old Forest Area

As was discussed for landscape class area above, the area of old forest by groupings was included in the SFMM modelling to facilitate the projection and analysis of old forest area through time. Again, as with landscape class area, the area of old forest was accomplished through the tagging of "tree species" within the yield curves which are simply counters for area of old forest based on the forest unit and age class of the SFMM land base. Specific inputs for old forest areas are included in the yield curves embedded in the SFMM input file.

6.2.2 Forest Dynamics Assumptions

Assumptions pertaining to old-age natural forest succession and natural disturbances were also incorporated into the base SFMM model. Natural forest disturbance rates included in the base model reflected that fire suppression would be conducted should fires start on the Whiskey Jack Forest. The assumptions used are included in the SFMM Base Model and summarized in this Analysis Package.

6.2.2.1 Natural Succession

Natural succession patterns portray how certain forest types tend to succeed to other forest types once they reach a certain age, without intervention from catastrophic natural disturbances or harvesting. These transition rules are portrayed in strategic modelling as succession pathways.

Multiple succession entries are required to capture the dynamic nature of forests. Not all forest unit stands succeed at the same age. Multiple entries are also required to ensure that the full land base in a given forest unit eventually succeeds to younger age classes (and in some cases other forest units) in accordance with SFMM conventions for ageing and succeeding the forest.

The main assumptions for the development of the natural succession rules is succession occurs at the points where the species composition no longer meets the description of the forest unit. That is the main transition point between one forest unit to another. A second assumption is that the Present silviculture represents both naturally disturbed and successional forest conditions whereas Extensive, Basic1 and Intensive1 reflect silviculturally treated forest conditions. This mean all other silviculture intensities naturally succeed to a Present forest condition. The third natural succession assumption within each specific forest unit was based on gap phase and sub canopy dynamics. Succession to a lower age class occurs where overstory stocking in a forest unit is no longer the dominant forest type. At that point sub canopy composition and age class are assigned.

Natural succession inputs for this 2012 FMP originated with the baseline natural succession inputs used in the BFOLDS model (Boreal Forest Landscape Dynamics Simulator) which are prorated for the standard forest units of the forest inventory. These BFOLDS forest dynamics inputs form part of the science package developed to support the Ontario Landscape Tool (OLT) which is considered the best available science for landscape level forest composition and pattern simulations. Use of the BFOLDS natural succession inputs was considered important for this FMP as many of the forest composition targets included in the long-term management direction were derived from this same forest dynamic information. By using similar forest dynamics assumptions for each forest unit, the strategic LTMD modelling would be using the same underlying natural succession rules.

The natural succession rules for each forest unit and silvicultural intensity was checked to ensure all of the current stands were caught by a succession rule and that no areas were able to slip through and continue to age beyond a reasonable age for the forest unit. The succession rules were also checked and refined as necessary to ensure that any volume change resulting from application of the succession rule was reasonable and would not result in major volume gains or losses.

A delay of one 10-year term was included in the natural succession base model inputs. The inventory was already updated to 2012 therefore there was no need to apply natural succession rules in the strategic modelling to Term 1. Natural succession was included in the Base Model and not adjusted for any subsequent investigations.

Documentation of natural succession patterns by forest unit used for all SFMM investigations is detailed below (same for all subunits) and included electronically in investigation files in provided to MNR for plan review and approval.

6.2.2.2 Natural Rehabilitation of Non-forest to Forest

Some areas of low stocking, previously classified as Barren and Scattered (B&S) were assessed prior to this FMP. Where appropriate these areas were reclassified as productive forest. The remaining low stocking stands within the inventory are either naturally burnt areas or a form of permanent B&S. These areas were classified in the planning inventory with the development stage (DEVSTAGE) of LOWNAT. Therefore, no values for natural rehabilitation of non-forest to forest were included in the SFMM modelling.

Natural rehabilitation of roads and landing was accounted for in the proportions of area converted to non-forest (Silvicultural Option - accumulating roads and landings). Operational roads and landings would in most cases be actively rehabilitated after harvesting. For the most part, primary and branch roads would not be abandoned during this FMP. Therefore, no natural rehabilitation of roads and landing were included in the model.

6.2.2.3 Natural Disturbances

Resource managers need to understand the implication of forest disturbance specifically fire, windthrow and insect damage so that they can gain insight into natural forest development. Natural events such as forest fires and insect infestations are important elements of forest dynamics and are an important consideration to enable the accurate prediction of the future forest condition. Fire regimes vary across regions and climates and greatly affect forest stand composition and structure.

The Natural Disturbance Cycles and Succession screen allows you to specify an average natural disturbance cycle for each forest unit, and the succession rules that describe how disturbed areas succeed to new forest types. SFMM assigns areas naturally disturbed to the youngest age class of the future (post-disturbance) forest units with a silvicultural intensity of Present.

6.2.2.3.1 Fire Cycles

Natural disturbance rates portray expected annual rates of catastrophic disturbances such as fire, blow down, and lethal insect infestations. Two rates of natural disturbance were utilized in development of the SFMM Base Model. The first rate depicted a "cycle rate" of forest disturbance by forest unit that the forest would sustain without human intervention (without fire suppression called "Pre-suppression") as determined by the MNR historical records and base line data from the BFOLDs simulated fire cycle inputs incorporated into the Ontario Landscape Tool (OLT) model. This Natural Scenario is not an investigation, but rather is a run used to ensure that the forest dynamics within the Base Model are calibrated similarly to the projections in the OLT Model, that also includes pre-suppression fire cycles.

The second rate of natural disturbance is an average annual rate of disturbance based on MNR historical records of natural disturbance under fire suppression strategy (called "Suppression"). These rates for various management units were summarized by the MNR. The Fresch report and NW Forestry Forum bulletin entitled *Forest Fire Disturbance: Factors for Modelling and Mapping Procedures (2001)* were used to determine the suppression fire cycle.

The fire cycle analysis estimated a natural pre-suppression fire cycle for the Whiskey Jack Forest of 60 to 200 years depending on the forest unit for the natural scenario calibration run (average of 81 years) – data from MNR information (regional estimates).

Suppression fire cycle from Forestry Forum technical paper with 299 years for the Whiskey Jack Forest (used 299 years, same as 2004 FMP). Forest unit transitions based on Northwest Region Bounds of Natural Variation science data and forest unit definitions. The impacts of disturbance rates and resulting forest unit transitions were tested on their own and in combination with other natural succession rules. The planning team evaluated the future forest condition in all scenarios and made refinements where necessary to ensure reasonable calibration with the OLT model.

6.2.2.3.2 Post Natural Disturbance Forest Unit Transitions

Forest unit transitions after natural disturbance were primarily based on natural disturbance inputs to the BFOLDs model as used in the OLT Model, based on the area weighted average of standard forest units and eco-districts located on the forest. This information was considered the best available information and allowed for a successful calibration between the natural scenario and the OLT model. Natural succession assumptions are reasonably consistent with the inputs used for the 2004 FMP strategic modelling.

Forest unit transitions resulting from fire disturbance were consistent for all of the investigations. Natural disturbance inputs are summarized in Table 10 below.

Table 10 Natural Disturbance Cycles and Succession

Forest Unit	Pre-Suppression Fire Cycle (yrs)	Suppression Fire Cycle (yrs)	Proportion Succeeding to Forest Unit after Disturbance:

6.2.2.4 Growth and Yield in Even-age Forest

Each forest unit has a distinct yield curve for the "Present" forest condition (i.e., natural origin), and additional yield curves to reflect post-harvest stand development based on varying levels of silviculture investment or management intensity (Extensive, Basic1 and Intensive 1).

The main assumption used in the development of the curves, is that all points in time, the curves species composition is consistent with the forest unit definition. At any point where the composition of the yield curve suggest the composition no longer meet the forest unit definition, the final point of succession is established. This is consistent for all forest units at all intensities.

Most yield curves for this FMP (all except OCL, OTH, and PRW) were designed by Dr. Margaret Penner and modified by the planning team to account for management strategies, consistency with the planning inventory and timber utilization standards. The planning team's modification to the yield curves developed by Margaret Penner included changing average species composition by silviculture intensity, stand stocking and site index. Weighted averages were derived from the planning inventory. The planning inventory was refined only to use stands that were Free to Grow and were not site class 4. All other stands either had an estimated stand description or were protected from harvesting.

Yield curves for OCL, OTH and PRW were derived from area weighted forest inventory information imported into the MIST program (Modelling and Inventory Support Tool). Their derivation was similar to those for the other, larger forest units as the MIST program was provincially developed using Margaret Penner's growth and yield calculations.

Yield curves development and yield curves for each forest unit and silviculture intensity can be found in Appendix 1.

6.2.2.5 Timber Product Proportions in Even-aged Forest

The following tree species were included in the strategic modelling:

14 Boreal tree species. Product "ALL" only used.

PW	"White Pine"		41	LA	"Larch"
PR	"Red Pine"		42	HE	"Hemlock"
PJ	"Jack Pine"		43	PO	"Poplar"
SB	"Black Spruce"		44	BW	"White Birch"
SW	"White Spruce"		45	MH	"Maple"
BF	"Balsam Fir"		46	UH	"Upland Hardwood"
CE	"Cedar"		47	LH	"Lowland Hardwood"

6.2.2.6 Wildlife Habitat Classification

In previous plans, wildlife habitat units and the regional wildlife matrixes used in the SFMM modelling were based on regional definitions and values. With the inclusion of landscape class areas and specific inputs to relate to caribou habitat, the use of these inputs in the strategic modelling was not required for this FMP.

Therefore wildlife habitat units, wildlife habitat seral stages, the wildlife habitat suitability matrix, selected wildlife species (other than Species At Risk), the correlation of forest unit area to wildlife habitat units and the non-forest land to wildlife habitat units proportions were not used in the SFMM modelling.

6.2.3 Strategic Silvicultural Options

Silvicultural Options are used to specify the silvicultural strategies (i.e. renewal and tending treatments) appropriate for the forest. There are options for harvesting, renewal, tending and partial harvesting, and active non-forest rehabilitation treatments, such as afforestation.

6.2.3.1 Clearcut Harvest Operability Ranges

Harvest operability ranges define the youngest and oldest ages that may be considered eligible for harvest. These ranges are constant through the planning period. Projected available harvest areas and volumes are sensitive to these operability limits. Narrow operability limits can produce misleadingly reduced long-term wood supply estimates because a high proportion of stands tend to pass through these ages without a stand growing up to replace them for long periods of time. Operability limits are therefore set fairly wide. A lower operability limit of 50 years does not necessarily imply a rotation age of 50 years for that forest type; rather, it means that more forest area can be considered for harvesting during times of projected timber shortages, and that some stands over the age of 50 can be considered within the mix of older ages harvested. Lower operability limits are likely to exist for the more intensive silvicultural intensities. One reason for performing more intensive renewal and tending treatments is to prepare stands for potential harvesting sooner than they would be under less intensive regimes. Thus more intensively managed areas should be eligible for harvest at younger age, or as a minimum, contain higher value products at the same time as harvest would occur in less intensively managed stands.

Lower operability ages generally correspond to 80 cubic metres per hectares harvest volumes. These minimum volume requirements were related to yield curves for each forest unit and silviculture intensity to determine the minimum operability age limits for the SFMM modelling. Some adjustment to lower operability ages were done to improve product piece size or to facilitate clean-up of BFM areas.

The upper operability limit used is generally infinite. This is not to say that a forest type is eligible for harvest infinitely. It does indicate that the forest type is deemed to be operable until the age at which it naturally succeeds (through old age), as defined in the natural succession pattern for a given forest type in SFMM. The difference between the lower operability limit in the operability age table and the age of forest succession define a window of harvest operability. Operability ranges used in modelling are listed below in Table 11.

a. **Lower Age** represents age of stand at beginning of modelling term (10 year).
b. **inf** represents no upper age limit for harvesting. Natural succession dictates when stand no longer available for harvest.
c. **na** for lower or upper age represent ineligible treatment (does not exist). Applied to current or future forest unit/silvicultural intensity combinations.

Table 11 Clearcut Harvest Operability Ranges

Revised Operability Limits

AIISU	Present		Extensive		Basic 1		Intensive 1		
Forest Unit	Lower	Upper	Lower	Upper	Lower	Upper	Lower	Upper	
BFM	60	inf	65	inf	na	inf	na	inf	lowered to improve clean-up.
CMX	55	inf	65	inf	60	inf	na	inf	lowered to improve clean-up.

POD	55	inf	55	inf	na	inf	na	inf	increase piece size.
PRW	65	inf	65	inf	65	inf	65	inf	improve sawlog piece size.
SBL	90	inf	90	inf	90	inf	na	inf	reduced to allow spatial operability.
SPD	70	inf	70	inf	60	inf	60	inf	better piece size overall.
SPM	60	inf	70	inf	60	inf	60	inf	

Notes:
Rationale for Lower Harvest Operability Ages:

- Ages generally correspond to 80 cubic metres per hectares harvest volumes.

Harvest operability ages revised and accepted by Strategic Task Team July 12, 2010. Base Model Review.

6.2.3.2 Clearcut Growing Stock Volumes Left Unharvested

Clearcut Growing Stock Volumes Left Unharvested

The unharvest volume percentage in the strategic modelling is used to account for several types of reductions to available harvest volumes:

Component (1) - Unharvested volumes associated with scattered live wildlife trees retained according to the Stand and Site Guide.

Calculations for volumes associated with retention of scattered wildlife trees included consideration for the average size of trees at average harvest age by forest unit by silvicultural intensity , and number of live trees required to make up the average 25 tree per hectare required by the Stand and Site Guide. See discussion (1a) for details and rationale (below). The yield curve by forest unit at the average age of harvest to determine the volume per hectare associated with the number of live trees expected to be retained. The unharvested volume percentages by tree species within each forest unit were calculated to achieve the calculated "retained" volume based on the estimated number of live trees required by tree species (Calculation 1b).

Component (2) - Retention of area-based volume associated with inoperable area or unmapped residual areas allocated as part of the harvest area, but not able to be harvested.

Unharvested area within the harvest blocks is assigned based on expected operability by forest unit. The same average forest unit proportion (of residual) is assigned to each species in the yield curve equally since yield curves include proportional volume based on species composition. Unharvested volume percentages by forest unit were based on estimated unmapped residual retention according to the Stand and Site Guide requirement for an average of 0.5 ha of residual within each 50 ha polygon of harvest area (equals 1% of harvest area).

Note: Associated estimated riparian area is already netted out in the SFMM initial land base and is not considered in unharvested volume percentages.

The above two components are combined to determine the total unharvested volume percents for each tree species within each yield curve for each forest unit.

(1a) Considerations for the Retention of Wildlife Trees

Stand & Site Guide Direction

Stand and Site Guide requires an avg. of 25 stems/ha (>10cm.) of which >=10 large (= 25cm. Dbh) living or large stubs/ha (>=3 m.ht.) with a minimum of 5 large living trees/ha. Stubbing 80%+ (>=20 stems/ha.) is recommended for Sb and Pj trees.

Large Living Trees Direction

The operational intention is that 10 large living (full crowns) trees/ha will be left after harvest. Large poplar are the desired species to leave behind to meet the 10 large living stems/ha. behind as they provide the best opportunities for cavity nesters and stick nesters; however when not available jack pine, white spruce, black spruce and black ash will be chosen. Stubbing is not currently practiced extensively on the Whiskey Jack Forest so it is not reflected in the volumes.

Small Trees Direction

Of the 15 remaining required small stems, it is likely that 5 will be alive and 10 will be dead. White birch typically does not meet the diameter size requirement of 25 cm. dbh to be considered a 'large' living tree and will be typically left on site to meet the requirement to leave a minimum of 15 stems/ha of smaller diameter stems. If no white birch volume was found, then other species such as cedar, spruce and larch will be left to meet the requirements.

• The trees per metre is based on reference to Plonski's Yield Tables and local MNR experience and volume sampling don

Calculated Merchantable Tree Length Volume

(2) Calculation for Area-based Volume Associated with Allocated Inoperable Areas

Inoperable percentages below do not include mistyped or merchantable areas that will be harvested in the future.
- These percentages by forest unit are carried forward into the "Volumes Left Unharvested" along with Component 1.
- Average of 1% per forest unit estimated for all forest units as exact measurements were not possible since insular residual and inoperable not mapped.
- Only Component 2 is also considered in the calculation of the need for additional "Areas Reserved From Harvesting" as this component is areas based and can be mapped. Volumes associated with scattered wildlife trees are not mappable and do not contribute to area-based forest retention.

<== Carry forward percent by forest unit to areas reserved from harvesting worksheet.

Same percentage used for each tree species in yield curve as inoperable percentage applies to the forest unit area as a whole.

(blank signifies "0")

SSG 0.5 ha in every 50 ha = retention of 0.01 (1%) of area, but periphery of harvest blocks will not need additional 0.5 ha patches retained.
SFMM tracks net downs in volume to the nearest full percentage, therefore no additional net down required for insular residual patches.

6.2.3.3 Clearcut Post-Renewal Forest Succession and Costs

Strategic silviculture renewal options represent the broad renewal treatments appropriate for the forest. Renewal strategies reflect the most appropriate treatment or blend of treatments for the average forest unit condition. Various renewal intensity options (e.g. extensive, basic and intensive silvicultural treatments) were incorporated into the Strategic Forest Management Model for each forest unit, and included assumptions about how the forest will develop after these general treatments are applied, their associated costs, success rates and future forest conditions. Clearcut post-renewal forest succession identifies the level of treatment of the forest, regardless of what intensity it was at harvest.

Standard proportions were used for all investigations to direct SFMM to transfer area from one forest unit to another, based on the silvicultural intensity of the applied treatment. The information on post-renewal forest succession is a vital link between the acceptable silvicultural treatments for each ground rule included in Table FMP-4, and the strategic silvicultural assumptions included in the SFMM model. While the silvicultural ground rules included in Table FMP-4 should remain reasonably constant over time, the post-renewal forest succession is refined regularly (from term to term) as more detailed post-treatment survey data is available. Adjustments were made from the 2004 to 2012 FMP for post-renewal forest succession forest unit transitions, proportions and costs.

The strategic silvicultural options were developed based on the renewal strategy for the Whiskey Jack Forest. The post harvest renewal rules and cost were based on forest unit criteria, yield curve development strategy, planning inventory and the silvicultural ground rules. With input from MNR foresters and MNR Science and Information Advisors, the best knowledge and experience was used to develop the strategic post-renewal rules. Renewal data from the 2004 FMP was reviewed and compared to actual renewal treatments and regeneration survey results. Renewal inputs were revised to reflect the revised forest unit definitions. For each forest unit renewal level, an analysis of the planning inventory was completed. The most appropriate treatments were identified by proportion and associate cost for those treatments were calculated. Based on the proportion of treatments by renewal intensity, the appropriate future forest condition was determined. The main assumptions of assigning proportions of treatment were based on 100% of forest unit area being treated. It is acknowledged that the most appropriate treatment for the area will be applied in the field and not all term allocations are representative of the entire managed forest unit area. Associated with the success of those rules, renewal limits were identified. These limits reflect the proposed renewal strategy.

Projected costs per hectare were included for each silvicultural treatment level by forest unit. The costs associated with extensive treatments include general forest management planning and renewal assessment costs. Strategic silvicultural options and associated costs used in the SFMM modelling are documented in Table 12.

6.2.3.4 Stumpage Values and Timber Harvesting Costs

Stumpage values are the contributions to the Forest Renewal Trust Fund (FRTF) on a per cubic metre of harvested timber basis (by tree species). Stumpage rates do not represent real timber prices, or mill-gate values of wood harvested. The renewal rates modelled were sufficient for future forest projections. FRTF rates are set annually, and no other scoping of renewal rates was required. Changes through inflation factors between planning terms are not accounted for in any SFMM runs. The renewal fund contribution rate per cubic metre of wood harvested is documented in Table 13. Harvesting costs were not included in the SFMM modelling.

Table 13 Stumpage Values and Timber Harvesting Costs

Tree Species	Product	Stumpage Values	Harvesting Costs
Pw	All	$11.00	$ -
Pr	All	$11.00	$ -
Pj	All	$5.50	$ -

Mh	All		$ -
UH	All		$ -
LH	All	$0.75	$ -

(Species with no stumpage value are generally not harvested.)

6.2.3.5 Areas Reserved from Harvesting

Areas reserved from harvesting are represented as percentages of harvest area which is not harvested but transferred to reserved forest classes. SFMM tracks reserved forest classes throughout the remainder of the planning horizon, as they accumulate area and increase in age. Proportions of forest harvest area transferred to reserve forest classes can be found in Section 6.1.1.8.

Estimated riparian reserve, nest reserves and tourism reserves were included in the initial SFMM land base and were therefore not added to this “areas reserved” screen in SFMM. This inclusion of estimated reserve area for modelling purposes reflects the “best information available” to the Planning Team and shows improvement in modelling assumptions since the 2004 FMP.

Analysis was conducted to check that the area being left unharvested during operations was strategically sufficient to account for estimated residual area required by the Stand and Site Guide. This analysis considered the area-based inoperable area already accounted for in the Unharvested Volume Percentages (Section 6.2.3.2), and the estimated reserve area included in the initial land base for riparian, nest and tourism reserves. This analysis is documented below. The analysis indicated that more than enough residual area is projected to be left unharvested to meet Stand and Site Guide targets through the application of normal operations and regular implementation of area of concern prescriptions.

SILVICULTURAL OPTIONS

Whiskey Jack Forest 2012 FMP

Areas Reserved from Harvesting

Accumulating Reserves

- Accumulating riparian reserves (lake and streams) were estimated for each forest unit using slope based DEM data and classified in the initial SFMM land base. No additional riparian reserves required. Estmated tourism and nest reserves were added to initial land base as reserve. No additional nest reserves required. All reserves classified as "EstRes" in SFMM.

- Accumulating reserves may apply to first rotation (i.e. up to first 30-80 years), but are not further deducted during second harvest.

- The estimated reserves from the initial land base, the area-based unharvested volume percentages, and the target percentages for landscape pattern (Stand and Site Guide) were compared to determine if additional residual (RESID) reserve percentages were required in the SFMM modeling.

Calculation for Additional Accumulating Reserve Residual Required

Planned residual already accounted for through riparian reserves, other AOCs (tourism, nests), and area based unharvested volume reductions:

No Additional residual accumulating area is required to be included in the modelling as per June 2010 estimates.

Stand and Site Guide Direction:

Pg. 19

25 ha residual in 500 ha circle (mapped, greater than 0.1 ha in size).

5 ha of the above 25 ha must be in patches of greater than or equal to 5 ha.

- equals 5% and includes adjacent stands that are at least 10 m tall or older than 20 years.
- expect this residual will be met through AOCs, inoperable areas and adjacent unallocated stands.

0.5 ha residual in 50 ha circle (mapped, greater than 0.1 ha in size).

- equals 1% but includes adjacent stands that are at least 10 m tall or older than 20 years.
- may be met through estimated inoperable areas, nest reserves, etc.
- determine if additional net-down in SFMM modelling required (use unharvested volumes if not mapping in advance, use areas reserved if will map in advance at FMP stage).

Decision to map whole harvest areas and then determine inoperable areas and residual as appropriate. Therefore mapped harvest areas will include any estimated inoperable areas and planned harvest area is not amended into the plan if additional residual or inoperable areas are retained within the harvest blocks than estimated. Likewise, if guide residual requirements are met and less inoperable area is encountered than strategically estimated, the company will harvest the harvest blocks more fully.

Pg. 21

>= 25 wildlife trees per ha on average (>= 10 cm dbh), NOTE: only portion are live, see Volumes Left Unharvested worksheet.

>= 10 large wildlife trees or stubs on average per ha (>= 25 cm dbh) of which a minimum of 5 must be living.

- wildlife trees must be well dispersed with a minimum of 15 trees per ha (other 10 trees per ha may be clumped).
- residual trees accounted for in the unharvested volume percentages in the SFMM modelling

6.2.3.6 Conversion of Harvested Areas to Non-Forest Land

SFMM inputs contain rates of harvest area converting to non-forested land. These rates represent the portion of harvested area that is not regenerated back to forest, but instead transfers to non-forest land types. This input is used to reduce the potential available harvest area by forest unit to account for the construction of addition permanent primary and branch roads and landings. SFMM classifies the resulting accumulating roads and landings as "non'-forest" area and reduces the available land base accordingly. This input does not consider operational roads that will be constructed and decommissioned promptly after forest management activities are complete.

The Whiskey Jack Forest is generally well accessed at Plan Start, with minimal construction of primary access roads required. It is estimated that approximately 1% of the Available Harvest Area will convert to roads and landings over the next two 10-year terms (2012-2032) in the non-caribou management zone. Thereafter, road construction will be equal to future road decommissioning, except in caribou subunits that are still being accessed and harvested for the first time (caribou zone road construction extended out to 110 years when last blocks are being cut for the first time).

The projected loss of harvested area to non-forest, through road development, is set at 1% for 20-110 years (Table 14) based on the caribou zone and non-caribou zone. This conversion of harvested productive land to permanent non-productive roads is projected to be 1,300 hectares over the next 110 years.

6.2.3.7 Strategic (Biological) Forest Renewal Limits by Proportion

Forest renewal limits by proportion are set in the Base Model to represent biological limitations of local conditions on the Whiskey Jack Forest. These proportions reflect local knowledge of suitable sites for silvicultural treatment packages included in Table FMP-4, and common, effective silvicultural practices. For example, if funding and planting stock were not limited, it is expected that only 80% of the jack pine dominant (PJD) could be planted or seeded and result in a Basic1 jack pine plantation due to site conditions (limited those stands with low competition, site class 2 or better and not wet ecosites).

The biological limits documented below were duplicated for all terms of the strategic modelling. Biological limits are ecologically site related and are consistent with the definitions used in the development of yield curves to represent current and future forest conditions. Biological limits

are not related to funding or desired future forest condition. These inputs were included in the SFMM base model, all subsequent investigations and development of the LTMD (Table 15).

Table 15 Biological Forest Renewal Limits by Proportion

Applies to AllSU combined and is duplicated for all 15 10-year terms within the SFMM model.
Grey shading indicates invalid treatment intensities.

NOTE	Forest Unit	Treatment Intensity	Treatment Description	Min/Max Limit	Rationale
1	BFM	BASIC	Mech SIP, Plant or seed	50% Max	Ecological consideration to apply treatment only to sites where there is growth potential. This would include wet sites or where access for mechanical site preparation is limited.
2	CMX	BASIC	Mech SIP, Plant or seed	60% Max	Treatments are limited to where hardwood competition will not prevent successful application of this treatment. Limits also include unproductive sites or wet sites.
3	CMX	INTEN	Mech SIP, Plant and spacing	15% Max	Apply treatment only to sites where there is best growth potential. Limits to potential area for treatment includes wet sites, restricted access for mechanical site preparation and low productive site class 3.
4	HMX	BASIC	Mech SIP, Plant or seed	10% Max	Treatments are limited to where hardwood competition will not prevent successful application of this treatment of conversion to conifer dominated stands. Limits also include unproductive sites or wet sites.
5	PJD	BASIC	Mech SIP, Plant or seed	80% Max	The treatment should be limited to sites where hardwood competition would not prevent successful application of this treatment. Limits to treatment also include unproductive sites, wet sites or unsuitable ecosites.
6	PJD	INTEN	Mech SIP, Plant or seed and spacing	10% Max	10% of sites are suitable for the application of this treament based on site class, management considerations, suitable ecosites (based on silvicultural effectivenesss results for the forest).
7	PJM	BASIC	Mech SIP, Plant or Seed	70% Max	The treatment should be limited to sites where hardwood competition would not prevent successful application of this treatment. Limits to treatment also include unproductive sites of wet sites.
8	PJM	INTEN	Mech SIP, Plant or seed and spacing	10% Max	10% of sites are suitable for the application of this treament based on site class, management considerations, suitable ecosites (based on silvicultural effectivenesss results for the forest).
9	SPD	BASIC	Mech SIP, Plant or Seed	no limit	The treatment should be limited to sites where hardwood competition would not prevent successful application of this treatment. Limits to treatment also include unproductive sites of wet sites.
10	SPD	INTEN	Mech SIP, Plant and spacing	10% Max	10% of sites suitable for the application of this treament based on site class, management considerations and ecosites.
11	SPM	BASIC	Mech SIP, Plant or Seed	no limit	the treatment should be limited sites where hardwood competition would not prevent successful application of this treatment. Limits to treatment include unproductive sites of wet sites.
12	SPM	INTEN	Mech SIP, Plant or seed and spacing	10% Max	10% of sites are suitable for the application of this treament based on site class, management considerations, suitable ecosites (based on silvicultural effectivenesss results for the forest).
13	SBL	BASIC	Mech SIP, Plant and spacing	20% Max	Percentage of area in lowland condition that will convert to non-forest without a minimum amount of silviculture. For successful regeneration to productive forest, Sb must be planted promptly on site.
14	PRW	INTEN	Mech SIP, Plant and spacing	15% Max	The treatment should be limited sites where hardwood competition would not prevent successful application of this treatment. Limits to treatment also include unproductive sites of wet sites.

6.2.3.8 Mid-rotation Tending and Non-forest Rehabilitation Options

Juvenile spacing is conducted as a component of stand establishment and was factored into the refinement of the post-renewal forest succession treatment costs and forest unit transitions associated with intensive treatment options for CMX, PRW, SPD, SPM, PJD and PJM forest units (Section 6.2.3.3). No commercial thinning options are included in the strategic modelling as none are operationally implemented on the management unit.

6.2.4 Correlation to the Simulated Range of Natural Variation (SRNV)

In accordance with management objectives, it is desirable that the FMP project forest management activities that will create a future forest landscape with a composition and structure that is similar to those created by natural processes. During development of the Base Model, it was important to correlate the SFMM natural forest dynamics (without fire suppression) to the Simulated Ranges of Natural Variation (SRNV) incorporated into the Ontario Landscape Tool (OLT), so that both models projected similar future natural forest conditions. If this correlation was not completed, there could be a situation where planning teams could not achieve desirable target results, no matter what was projected for harvest and renewal in the Long-term Management Direction. This correlation ensures that OLT SRNVs are achievable, or in fact may identify where certain OLT projections are not reasonable for the FMP considering the planning inventory used. In this latter situation, differences would be identified and desirable levels for management objective indicators would need to be developed from sources other than the OLT model.

The first step in this correlation was the development of a SFMM run to simulate the natural forces of change in the forest, which are disturbance (principally fire disturbance with no fire suppression) and old age succession (stands convert to different species composition through time, or stands break up to form younger stands from understory trees). The Natural Scenario (Natural12) is this simulation using the Strategic Forest Management Model (SFMM) of how the forest might develop in the absence of human intervention.

The result of the correlation of SFMM natural forest projections (no fire suppression or harvesting) was that natural (old age) succession and fire disturbance (cycles and transitions) were reviewed and refined in SFMM as necessary to align with the OLT SRNV projections using BFOLDs inputs. This was an iterative process and resulted in the two models generally being comparable for the forest composition classes being reviewed: landscape classes, caribou habitat, old forest area, forest unit area.

The following components were initially identified as not being comparable between SFMM and OLT otherwise the team achieved a good correlation between the two models:

(a) The Mature and Late Successional Lowland Landscape Class (**MLl**) was not well correlated between the OLT model as compared to the SFMM model. Plan Start values for MLl for SFMM are 2,889 hectares (based on forest inventory sort) whereas the OLT simulation suggests a Plan Start level of 15,219 hectares and a lower simulated range of natural variation (SRNV) of 12,845 hectares. Since MLl area is related to only lowland ecosites and also to only the mature and older age classes, it is considered impossible to project forest management activities in SFMM to increase the MLl area significantly enough to ever reach the lower SRNV area.

(b) Old forest Spruce Lowland (**SLo**) was also not well correlated between the OLT model and SFMM. This area is lowland ecosite and old age related as is the Mature/Late Lowland landscape class discussed above (all SLo old forest area would also be classified as MLl landscape class area). Based on the inventory, SFMM projected only 97 hectares of SLo at 2012, whereas the OLT model was based on 1,631 ha at 2012 and calculated a lower SRNV of 3,319 ha for SLo. While it is possible to increase the area of SLo through time (some conversion from OCL), it was not

possible to convert enough area to SBL and let it age to create enough old spruce lowland forest in the future up to the projected OLT minimum levels.

(c) NOTE: in Sept. 2010 when Run 27a was developed, the land base contained an adjustment correcting the classification of 15,800 ha of SPD to the SBL forest unit. This adjustment corresponded to the correct application of the forest unit script and related to standard forest unit definitions. This the results of this correction served to make the correlation between SFMM and OLT land bases better for the (a) MLl landscape class and the (b) SLo old forest area. The natural scenario was not revised at this late time as the correlation of the SFMM model to the OLT model was already completed.

Details of the comparison of SFMM natural scenario to the OLT model follow.

SRNV:	All ages Target to not decrease
Upper Quartile	497,902 conifer %.
Median	481,681 (don't want more hardwood)
Lower Quartile	457,260
Year0 OLT	389,842
Year0 SFMM	419,205
	497,902
	457,260

Observations:

PRW Forest unit area decreases through time.
May want to adjust PRW nat succ so it is stable.
Maintaining conifer in the caribou zone looks OK. This conifer component will increase with forest renewal options.

6.2.5 Base Model and LTMD Management Options

The management objectives inputs are used to define current policies, practices, targets, and strategies that apply to specific forest management situations in investigations or development of the long-term management direction. Inputs related to management decisions are discussed in the following sub-sections. Various inputs were used to define specific scoping investigations and also were added through development of the Proposed LTMD to aid in projections of forest sustainability or objective achievement.

6.2.5.1 Silvicultural Budgets, Distribution and Discount Rates

The base model did not include any constraints to renewal budgets. It allowed all necessary silvicultural expenditures to be projected ("infinite" budget). The LTMD does limit the renewal expenditures to the level generated by revenues to the Forest Renewal Trust Fund based on projected harvest volumes per term, all subunits combined.

6.2.5.2 Stability of Forest Unit Areas

The SFMM model does not constrain the variation in area in each forest unit from term to term, unless specific constraints are added to limit increases or decreases in area. Percentages are a measure of allowable change in the total productive forest through time as compared to the initial land base in 2012. Constraints on one input parameter can inadvertently affect the results concerning another parameter therefore the use of constraints should be minimized. No forest unit area stability constraints were added to the Base Model, nor were any used in the Long-term Management Direction and the area by forest unit was limited through the use of other constraints (Section 6.2.5.3 and Section 6.2.5.5).

6.2.5.3 Age Class Area Limits by Forest Unit Group and Age Class Group

This input was not used in the Base Model. During investigations and development of the LTMD, the Strategic Task Team reviewed projected results for the forest units by age grouping (immature versus mature+). The task team decided to constrain the model to improve projected results for the mature+ age grouping by forest unit. The area in the immature age group by forest unit was not considered a priority to force in the SFMM model as sufficient younger forest would be projected to be retained through time in order to meet the mature+ area targets included in the model.

Certain forest units required constraints in the LTMD for area of mature+ added: HMX, OTH, PJD, PJM, and SBL as documented in Table 16.

Table 16 Age Class Area Limits by Forest Unit and Age Group

None used in Base Model.

The LTMD includes targets for minimum hectares of mature/late successional forest by forest unit.

This input was used to improve the projected area by foest unit by development stage, however it was noted that the achievement of other OLT landscape indicators would be considered more important in the hierarchy of balancing objective achievement.

			Regulation of forest unit area by age grouping						Upland Pine and Spruce	

6.2.5.4 Age Class Proportion Limits by Forest Unit (Old Forest Area)

Not used in the Base Model or LTMD as old forest was regulated using Growing Stock targets (Section 6.2.5.5, item 4).

6.2.5.5 Growing Stock Targets

Four types of growing stock limits were used in the strategic modelling.

1. A minimum total **Growing Stock Limit** in the available forest (all subunits combined) was added to control a potential over harvest at the end of the planning horizon (35.0 million of net merchantable cubic metres in Term 16 only). Otherwise, without additional constraints, SFMM will project maximum harvest areas in order to maximize the value of harvest volumes. The addition on the one constraint serves to regulate the activities projected at the end of the planning horizon into more reasonable ranges. This constraint was included in the Base Model and all subsequent investigations, including the Long-term Management Direction.

2. Growing Stock Limits by Species Groups were included as a surrogate for **Landscape Class Area** targets (related to Section 4.1.4.3).

Landscape classes were included in the SFMM strategic modeling inputs, not as area, but as volume placeholders. This approach was supported by regional advisors which ensured regional consistency in landscape class modelling inputs.

Each landscape class was represented as a unique "tree species" that was not available to be harvested. This allowed tracking of hectares per landscape class through time, and also allowed for the addition of minimum or maximum targets for each landscape class. This

approach did not affect projected harvest volumes at all as these volumes were assumed to be 100% unharvested. These classification inputs were included in the Base Model and all subsequent investigations, including the LTMD.

The seven landscape classes are:

1 Pre-sapling
2 Immature Conifer
3 Immature Hardwood
4 Mature/Late Successional Balsam Fir
5 Mature/Late Successional Lowland Spruce
6 Mature/Late Successional Hardwood
7 Mature/Late Successional Conifer

During development of the LTMD, the Strategic Task Team decided include minimum targets for the landscape class areas to ensure the projected forest condition would meet minimum desirable levels for the landscape class area indicator (Table 17). The Planning Team was satisfied that they had met the direction from the draft Landscape Guide which was supported by the best available science incorporated into the Ontario Landscape Tool (OLT).

Table 17 Growing Stock Targets by Species Group – Landscape Class Area

The following minimum areas for mature/late successional landscape classes were included in the LTMD:
(applies to AllSU, target for mature/late successional classes as per Landscape Guide indicator direction.)

3. Growing Stock Limits by Species Groups were included as a surrogate for **Caribou Habitat Area** targets.

Caribou habitat classes were included in the SFMM strategic modeling inputs, not as area, but as volume placeholders, in a similar fashion as landscape classes.

Caribou habitat minimum targets were not included in the Base Model. Minimum caribou habitat area targets were included in various investigations and the Long-term Management Direction (Table 18).

Caribou habitat as included in the Ontario Landscape Tool (OLT) were included in the SFMM strategic modeling inputs, not as area, but as volume placeholders. These placeholders were applied to only the caribou subunits (CarXX SUBMUs only; not LOW, PAK, or PAT).

Each caribou habitat class was represented as a unique "tree species" that was not available to be harvested (100% unharvested volume). This allowed tracking of hectares per habitat type class through time, and also allowed for the addition of minimum or maximum targets for each caribou habitat type. This approach did not affect projected harvest volumes.

Table 18 Growing Stock Targets by Species Group – Caribou Habitat

The three caribou habitat types from OLT are:

1 Cr - Caribou refuge
2 Cwu - Caribou winter used
3 Cwp - Caribou winter preferred

The following minimum areas for caribou habitat were included in the LTMD:
(applies to caribou subunits only (CarSU)).

T16	150,000	38,000	40,000

4. Growing Stock Limits by Species Groups were included as a surrogate for **Old Forest Area** targets.

Old forest groupings were included in the SFMM strategic modeling inputs, not as area, but as volume placeholders, in a similar fashion as landscape classes.

Old forest area definitions were based on criteria from the *Old Growth Forest Definitions for Ontario*. Old forest area definitions based on primary working group species growing on the primary ecosite (from forest unit analysis). The definitions for old forest were consistent with the old forest area calculated in the Ontario Landscape Tool (OLT) model which was used to set desirable levels for this indicator.

The groupings of Old Forest related to OLT (with the corresponding PLANFUs noted) are:

1 BFo - Old Forest BF (BFM) (>80 years)
2 CLo - Old Forest Conifer Lowland (OCL) (>100 years)
3 CMo - Old Forest Conifer Mixedwood (CMX) (>100 years)
4 HWo - Old Forest Hardwood (POD, HWD) (>100 years)
5 OHo - Old Forest Other Hardwood (OTH) (>90 years)
6 PJo - Old Forest Jack Pine (PJD, PJM) (>100 years)
7 SLo - Old Forest Black Spruce Lowland (SBL) (>160 years)
8 SPo - Old Forest Upland Spruce (SPD, SPM) (>110 years for SPM and >120 years for SPD)

Note: PRW is not included in the OLT old forest calculations, and was not unintentionally missed. A desirable level was later added for old forest PRW (>140 years old) based on maintaining the Plan Start amount of area, as no OLT SRNV was available.

Old forest minimum targets were not included in the Base Model. Minimum old forest area targets were included in various investigations and the Long-term Management Direction (Table 19).

Table 19 Growing Stock Targets by Species Group – Old Forest Area

The following minimum areas for Old Forest were included in the LTMD:
(applies to AllSU).

6.2.5.6 Timber Volume Species Group Definitions & Harvest Flow Policies

Timber volume species groups included in the strategic modelling reflect the volume species groups used by the Forest Resource Assessment Policy required for this 2012 FMP.

This SFMM input is used to define harvest volume by groupings of timber species. For the Whiskey Jack Forest FMP, Spruce-Pine-Fir (SPF), Red Pine – White Pine (PWR), Poplar (PO) and White Birch (BW) were defined and reported. Also additional volume groups for the total of all species (TOTAL) and for the total of poplar and birch (PO+BW) were defined to aid analysis and inclusion of management objective targets. Major harvest volume group definition inputs for SFMM are documented in Table 20.

Ontario Forest Accord Advisory Board (OFAAB) data does not include significant volumes for the OC (other conifer, cedar, larch) or TOL (tolerant hardwood) species volume groups. Therefore these volume groups are not considered major on the forest, and will not be included in SFMM investigations.

Table 20 Major Harvested Timber Species Groups

Major Species Group Definitions:
Inclusion in a species group denoted by "1", exclusion denoted by "0".

	Tree Species:													
FU	Pw	Pr	Pj	Sb	Sw	Bf	Ce	La	He	Po	Bw	Mh	UH	LH
SPF	0	0	1	1	1	1	0	0	0	0	0	0	0	0
PO	0	0	0	0	0	0	0	0	0	1	0	0	0	0
BW	0	0	0	0	0	0	0	0	0	0	1	0	0	0
PWR	1	1	0	0	0	0	0	0	0	0	0	0	0	0
TOTAL	1	1	1	1	1	1	1	1	1	1	1	1	1	1
PO+BW	0	0	0	0	0	0	0	0	0	1	1	0	0	0

In the SFMM model, additional definitions were included for harvest volume groups to be proxies for each of the Landscape Classes, Old Forest Areas and Caribou Habitat Types. These proxy species groups allowed the inclusion of targets for area by landscape class, old forest and caribou habitat to be entered into the strategic modelling. However the modelling team did not use these species group targets in the modelling, but rather used growing stock targets that accomplished the same result (Section 6.2.5.5).

For the Base Model and LTMD, no harvest flow control limits were used. The LTMD included targets by major species group therefore additional volume flow constraints were not needed.

Various harvest volume targets were included in investigations and the LTMD in order to either define the investigation (investigate achievement of specific volumes per term), or to aid in the overall harvest volume achievement of certain runs. No harvest volume targets were included in the Base Model. Harvest volume targets included in the LTMD are documented in Table 21. No volume targets by individual species were included in the Base Model or the LTMD.

Table 21 Harvest Volume Targets By Species Group

None in the Base Model. Volume levels added to LTMD to regulate harvest volumes.

Annual Volume in 1,000s:	Tree Species Group:				
	SPF	PO	BW	TOTAL	
Term	Lower	Lower	Lower	Lower	
T1	340	190			Term 1 volume to meet short-term harvest volume indicator.
T2	340	130			Mid- and Long-term targets set to regulate SPF and PO volume through time (predictable and sustainable).
T3	340	90			
T4	340	90			
T5	340	90			No upper limits used (infinite)
T6	340	90			
T7	340	90			
T8	340	100			
T9	340	100			
T10	340	100			
T11	340	100			
T12	340	100			
T13	340	100			
T14	340	100			
T15	340	100			

Volume targets = Binding for the LTMD

6.2.5.7 Sub-Unit Harvest and Renewal Operability Timing

This input is used to prevent scheduling of harvest and silviculture in an entire subunit during a planning term. Subunits were included in the modelling to allow scheduling of the caribou habitat subunits (Car01 to Car11 series). No timing limits on LOW, Pak and PAT (Table 22).

Table 22 Operability Windows for Harvest and Renewal Activities by Subunit

BASE MODEL INPUTS: Same for LTMD.
"1" denotes subunit not operable during term.

Harvest term start		Subunit: Car01	Car02	Car03	Car04	Car05	Car06	Car07	Car08	Car09	Car10	Car11
T1	2012	1	1	1	1	1					1	1
T2	2022	1	1	1	1	1	1	1	1	1	1	1
T3	2032	1	1	1	1	1	1	1	1	1	1	1
T4	2042	1	1	1	1	1	1	1	1	1	1	1
T5	2052	1	1	1	1	1	1	1	1	1	1	1
T6	2062	1	1	1	1		1	1	1	1	1	1
T7	2072	1	1		1	1	1	1	1	1		1
T8	2082	1	1	1	1	1	1	1	1		1	1
T9	2092	1	1	1	1	1	1		1	1	1	1
T10	2102	1		1		1	1	1	1	1	1	1
T11	2112		1	1	1	1	1	1	1	1	1	
T12	2122	1	1	1	1	1	1	1	1	1	1	1
T13	2132	1	1	1	1	1		1		1	1	1
T14	2142	1	1	1	1	1	1	1	1	1	1	1
T15	2152	1	1	1	1	1	1	1	1	1	1	1

terms when forest management activites may be scheduled.

6.2.5.8 Stability of Harvest Areas (Area Regulation)

This input is used to constrain the amount of change in harvest area between 10-year terms by forest unit. This input is typically used to reflect the biological limitations to operational harvest areas (i.e. must moderate lowland spruce area since you want some winter harvest every year). This constraint may be used to moderate projected harvest area for small forest units or other sensitive sites (shallow soiled forest units). Finally, constraints may be considered for other forest units that have projected harvest area significantly fluctuating between terms. Ensuring some harvest area is projected in each term ensures that operational block planning will not leave patches of unallocated mature timber simply because there is no available harvest areas for certain forest units for a full 10-year period. Constraints must be kept general enough to not dictate the specific Available Harvest Area (AHA) by forest unit.

No Harvest Area regulation constraints were included in the Base Model, investigations or the Long-term Management Direction.

6.2.5.9 Harvest Area Limits by Forest Unit

No harvest area limits were included in the Base Model. During development of the LTMD, the projected harvest area by forest unit was reviewed and an additional minimum harvest area target (Term 1 10 ha/year) was added for PRW to ensure there was some harvest area in this plan period. Also a maximum harvest area was added for SBL for Terms 1-3 (80 ha/year) to ensure there was not too much lowland harvest area in any term due to the operational limitations of implementing winter harvest.

6.2.5.10 Forest Renewal Limits by Proportion (Biological Limits and Management Decisions)

The Base Model renewal proportions limits are documented in Table 23 and were based on biological site limitations to forest renewal and management decisions. These limits are ecologically or site related and are based on successful achievement of the defined renewal strategy for each silviculture treatment level. No additional changes to the biological limits were required for the LTMD. Projected renewal activities (proportion by intensity for each forest unit) and were assessed as being reasonable and operationally achievable.

Table 23 Forest Renewal Limits by Proportion

No minimum proportion limits used in the modelling.

Forest Unit	Maximum proportion renewed:				
	Prsnt	EXTEN	BASC1	INTN1	Basc2
BFM	0		0.5		0
CMX	0		0.6	0.15	0
HMX	0		0.1		0
OCL	0				0
OTH	0				0
PJD	0		0.8	0.1	0
PJM	0		0.7	0.1	0
POD	0				0
PRW	0			0.15	0
SBL	0		0.2		0
SPD	0			0.1	0
SPM	0			0.1	0

During the development of the Proposed LTMD, questions were raised concerning the maximum limits placed on intensive renewal treatments for PJD, PJM, SPD and SPM forest units. The Strategic Task Team considered the 10% maximum treatment level to be consistent with those sites where silvicultural success was expected to achieve the forest conditions defined by the intensive silvicultural intensity condition for these forest units.

The definition of intensive used for this plan must be recognized as being narrower than is traditionally classified as “intensive”. The suite of basic treatments in this plan are considered a “blended approach” of seeding, planting and tending – all resulting in a “basic” forest condition that is either not well-stocked, or over stocked, or not density regulated. The intensive, well-stocked, density regulated forest condition defined for this 2012 FMP was used as the basis for the intensive growth and yield curves that are expected to result 100% of the time when intensive treatments are applied to PJD, PJM, SPD, and SPM areas on the Whiskey Jack Forest. The definitions of the jack pine and spruce intensive forest conditions were consistently applied to development of the yield curves, the silvicultural ground rules, the post-renewal forest succession assumptions (i.e. treatment components, success rates, resulting forest units and intensities and associated treatment costs) and the forest renewal treatment limits by proportion.

After further discussion, it was agreed that recent intensive treatments on the Whiskey Jack Forest have not typically resulted in well-stocked, density regulated (intensive) forests. This finding was also noted during the last Independent Forest Audit which resulted in a

recommendation to use silvicultural survey information during development of the silvicultural program for this FMP.

The Strategic Task Team reviewed the available Silvicultural Effectiveness Monitoring (SEM) survey results to guide them in determining the appropriate level of intensive treatment to be used in the modeling. As there were only 2-3 years of treated area assessed, the reasons for low success could not be accurately quantified. The task team could not determine with any degree of confidence the reason for this low silvicultural success rate of intensive treatments.

The task team has concluded that more silvicultural success information must be collected and evaluated in order to accurately asses the success or failure of this forest renewal treatment. Additional information and local knowledge should allow for a better understanding of the biological and management decision limits for intensive treatments for the next plan. The task team believes that a cautious approach to applying intensive, density regulated silviculture is warranted and that the maximum intensive treatment limits of 10% for PJD, PJM, SPD and SPM forest units would be applied for the 2012 plan.

Additional Rationale for Decision - The Strategic Task Team and regional advisors tested the sensitivity of the decision to limit intensive silviculture to ten percent through the completion of an additional investigative SFMM run - 27e_INTEN. In this investigation, the modelling inputs were kept the same as the Proposed LTMD Run 27d_OLTMS except that the maximum limits for intensive treatment for PJD, PJM, SPD and SPM forest units were relaxed (increased) from 10% to 75% of the treated area. The results of Run 27e_INTEN (documented in Appendix 2) showed that:

- Similar results as Run 27d_OLTMS. Same average total harvest volume T1-4;. Increasing intensive silviculture results in no significant change in total harvest volume for the next 150 years. Intensive treatment will likely result in a density regulated condition, with potentially a higher proportion of large sawlogs .
- Increased intensive treatments results in approximately 300 ha more intensive treatment per year in T1, and 800 ha/year more T2-4 with increased treatment proportion limits.
- SFMM does not project an increase in PJM and SPM intensive treatments even if treatment limits are increased - change occurs in SPD and PJD.
- Run 27e_INTEN does project some differences as a result of conducting more intensive treatments as compared to LTMD 27d_OLTMS; pure jack pine and pure black spruce stands are increased while mixed conifer stands are decreased over time.
- Average renewal cost increase of $84,000/year T1-4 with increased intensive treatment, however, the LTMD Run 27d_OLTMS has unspent funding in T1-2 therefore the increased intensive renewal will not exceed estimated stumpage.

DECISION: The precautionary principle was applied in the Base Model as the task team was not certain of the success of the intensive silviculture. It was agreed that the 10% maximum intensive treatment limit for PJD, PJM, SPD, and SPM forest unit areas would remain in the LTMD for the 2012 FMP. More information must be analyzed to refine the forest renewal limits by proportion for the next 2022 FMP. It is expected that a better understanding of past operations and the resulting forests may support an increase in the proportion of intensive treatment for future plans.

6.2.5.11 Mid-rotation Tending Limits and Partial Harvest Options

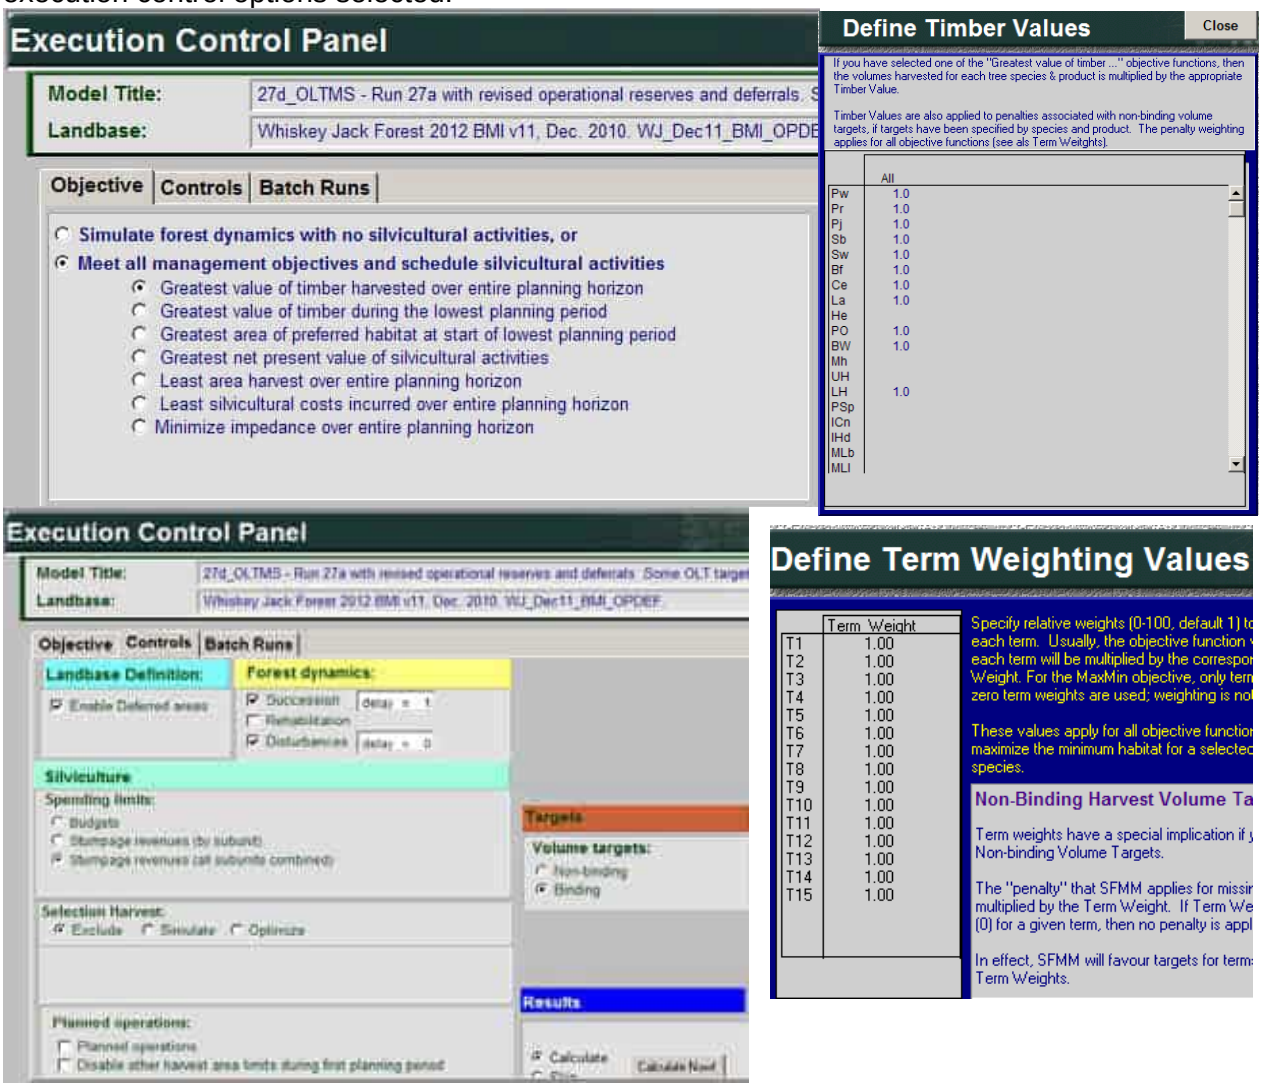
Input not used.

6.2.5.12 Timber Values

Strategic task team members determined relative timber values which were set to reflect estimated relative value of each tree species' volume. Timber values were constant for all investigations at 1.0 for all timber species expected to be harvested. These timber values were used consistently in the Base Model, investigations and development of the LTMD.

6.2.5.13 Execution Control Options

The following screen grabs from the SFMM Long-term Management Direction confirm the execution control options selected:



6.3 Documentation of the Base Model Inventory and Base Model Checkpoint

Progress Checkpoint #3 approval of the Base Model Inventory and the Base Model was received on October 8, 2010.

Subject: Whiskey Jack Base Model Checkpoint

We have now received the latest version of the base model inventory for the Whiskey Jack Forest. With that, **I can confirm that the Region supports the information and products associated with the base model and base model inventory (FMPM Part A Sect. 1.2.4) for the Whiskey Jack 2012 FMP**.

Rob Bowen R.P.F.

Ministry of Natural Resources

7.0 Documentation of SFMM Model Results

The results of all strategic planning investigations were assessed for projections and implications on forest conditions (forest composition and age structure components), caribou habitat, wood supply and other non-timber resources (e.g. old forest conditions) for the short-term (10 years), medium-term (20-80 years) and long-term (90-100 years).

The investigations and development of the LTMD were documented with key investigations included in the analysis package. Investigations are part of the iterative process used in the development of the management strategy, therefore not all of the investigations were considered noteworthy.

A three-page results summary forms the documentation for the key investigations and includes:

(a) changes and/or additions that are made to base model inputs and assumptions;
(b) results by forest condition, wildlife habitat, old forest and harvest area and volumes; and
(c) conclusions.

Results for the Long-term Management Direction are summarized in Appendix 3. Any other key investigation results are summarized and included in Appendix 2. The ASCII text input and results files for the Long-term Management Strategy are included in electronic files provided to MNR. The executable SFMM files for investigations, LTMD development runs, and the proposed LTMD do not form part of the electronic FMP, but are supplied to MNR for review and verification purposes.

PART 4: MANAGEMENT OBJECTIVES

8.0 Introduction

This section of the Analysis Package documents the information, assumptions, and decisions made during the determination of management objectives during development of the Long-term Management Direction (LTMD).

Required information is included or referenced in the following sub-sections:

(a) Results of the planning team's review of management objectives from the current forest management plan including rationale for decisions to confirm, update or revise existing management objectives;
(b) How background information, specifically recommendations from the Year Seven management unit annual report and forest management guides, was considered in the development of management objectives;
(c) Summary of scoping investigations and significant conclusions or results including:
    (i) changes and/or additions that are made to base model inputs and assumptions;
    (ii) results and conclusions that provide rationale for specific management objectives, indicators and desired levels and;
    (iii) a digital copy of a selected model run(s) that best represents each investigation;
(d) Documentation of Management Objectives Checkpoint.

8.1 Review of Objectives from the 2004 FMP

This review is included in Section 3.4.1 of the FMP text.

The Planning Team and Local Citizens Committees (Kenora and Red Lake) reviewed and discussed objectives from the 2004-2024 forest management plan to confirm which objectives were still desired forest and benefits applicable to the 2012 FMP. The following desired forest and benefits from the 2004 FMP were confirmed as being important to include in this forest management plan.

Each 2004 FMP management objective is noted below with reference to the decision to include or not include the objective in this 2012 FMP. Several 2004 FMP objectives are not carried forward as management objectives in this FMP, but will continue to be considered through operational planning or plan implementation strategies.

1. Forest Structure Objective:
The objective is to maintain or move toward a natural age class structure that is within the estimated bounds of natural variation for the Whiskey Jack Forest through management planning and silviculture.

Targets: - Maintain old forest area;
- Forest age class distribution.

Consideration in 2012 FMP:

- Area of old forest assessment required by FMPM and draft Landscape Guide. Old forest indicator carried forward and included in Objective 2 Forest Composition by area of old forest and area of mature and late successional landscape classes.

2. Forest Composition Objective:

The objective is to maintain or move toward a range of forest units and age classes within the bounds of natural variation as developed for the Whiskey Jack Forest.

Targets: - Area of each forest unit by age class;
- Maintain or increase the amount of PRWMX forest unit.

Consideration in 2012 FMP:

- Forest type (forest unit) and age grouping indicators carried forward and included as indicators in Objective 2. Forest Composition as required by the FMPM.
- Red pine and white pine forest (PRW) area indicator carried forward as required by FMPM(2009) and draft Landscape Guide.

3. Natural Disturbance Pattern Emulation Objective:

The objective is to emulate natural disturbance patterns, characteristic of the Whiskey Jack Forest.

Targets: - Maintain or move toward a pattern of natural forest disturbance;
- Disturbance size class and frequency distribution;
- Percentage of planned clearcuts >260 ha;
- Amount of peninsular and insular residual forest retained; and
- Retention of wildlife trees.

Consideration in 2012 FMP:

- Natural disturbance pattern (originally required by the *Natural Disturbance Pattern Emulation Guideline)* was initially replaced by mandatory biodiversity indicators as required by the Draft Landscape Guide (see Section 3.4.2: Indicators Resulting from New MNR Direction). Incorporated into Objective 1: Landscape Pattern. During LTMD development, the Planning Team was informed that the Landscape Guide would not be approved in time for full implementation for 2012 FMPs, therefore the landscape disturbance frequency by size class indicator from the NDPE guide and 2004 FMP was added back into the suite of indicators for the 2012 FMP.
- The stand level residual component from the NDPE guide is now required as per the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales.* Residual and wildlife tree requirements are related to operational practices and are included in the forest management plan as Conditions on Regular Operations (Section 4.2.2.2) and are not included as objectives or indicators.

4. Sustained Wood Supply Objective:

The objective is to provide a predictable and continuous supply of wood to the forest products industry from the Whiskey Jack Forest.

Targets: - Maintain specific minimum annual harvest volume by species group (spruce-pine-fir, poplar and white birch)

Consideration in 2012 FMP:

- Long-term annual harvest volume carried forward as a mandatory FMPM (2009) indicator in Objective 4: Wood Supply.
- Variance of projected harvest volumes between 10-year terms will be assessed during development of the Long-term Management Direction for acceptability to the Planning Team of projected harvest volumes in the short-term and long-term in relation to the balanced achievement of all management objectives.

5. Working with Aboriginal Peoples Objective:

The objective is to work with local Aboriginal peoples, whose communities are situated in or adjacent to the Whiskey Jack Forest, to identify and implement forest operations (harvest, access, renewal, maintenance and protection) that will maintain or enhance social and economic benefits to Aboriginal peoples.

Targets: - Provide opportunity to harvest 10,000m^3, on an annual basis, to members of the Grassy Narrows First Nation.

Consideration in 2012 FMP:

- Harvest area allocations and assignment of licensees will occur during development of the forest management plan. All licensee commitments will be incorporated into the planned operations and reported in Table FMP-14 Planned Harvest Volume and Wood Utilization.

6. Forest Resources for Personal and Commercial Use Objective:

The objective is to make available incidental volumes of timber for other uses such as fuelwood, building logs, furniture and other materials. (These incidental volumes will come from areas allocated within this FMP).

Targets: - Provide opportunities for the public to obtain fuelwood; and
- Provide opportunities for the public to obtain incidental quantities of timber for a variety of uses including building logs.

Consideration in 2012 FMP:

- Delete as a management objective. Harvest area allocations, including the identification of public fuelwood collection areas, will occur during operational planning for the forest management plan. Provision of fuelwood areas is carried forward and included in harvest area and volume included in Objective 4: Wood Supply. Fuelwood areas are specifically discussed in the FMP text Section 4.2.2.3 Silvicultural Treatments of Special Public Interest.
- Harvest of specific incidental quantities of timber will be considered either during planned harvest allocation development by the SFL (if known) or by MNR after plan implementation through regular incidental harvest volume permits.

7. Tourism, Commercial and Non-Commercial Forest Users Objective:

The objective is to select and prescribe forest operations (harvest, renewal, maintenance, protection and access) that consider the requirements of other forest users, allowing continued use of the forest while minimizing conflict between forest operations and other forest users.

Targets: - Maintain a system of active forest access roads available for public travel;
- Contact licensed tourism operators for RSA negotiations; and
- Minimize conflict between forest industry and all other users.

Consideration in 2012 FMP:

- Delete as a separate forest users management objective.
- It is required that all resource-based tourism operators must be contacted early in the planning process and offered the opportunity to negotiate Resource Stewardship Agreements.
- The planning process requires that known stakeholders and identified values be considered during operational planning for harvest, renewal and tending activities and for road access planning. Conflict between the forest industry and other users will be minimized through implementation of this requirement.
- Mandatory consideration for stakeholders and known values are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern, text Section 4.2.2.2 Conditions on Regular Operations, text Section 4.5.3 to 4.5.4 Area of Concern Crossings – Roads, and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).
- Maintenance of road access is a component of the mandatory road density indicator required by the FMPM(2009)(Objective 8: Road Density). See new mandatory indicators Section 3.4.2, FMPM (2009).

8. Other Land Uses Objective:

The objective is to conduct forest management activities in a manner that considers private land, parks and other land designations or values.

Targets: - Protect known values through implementation of the area of concern prescriptions approved in the forest management plan.

Consideration in 2012 FMP:

- Delete as a separate Other Land Uses management objective.
- The planning process requires that known stakeholders and identified values, including land ownership and management status, be considered during operational planning for harvest, renewal and tending activities and for road access planning.
- Consideration for stakeholders and known values are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern, and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).

9. Cultural Heritage Values Objective:

The objective is to protect identified, registered, or high potential archaeological and cultural heritage sites from conditions that could potentially damage or cause an increase in rates of deterioration.

Targets: - No negative impacts on identified archaeological or cultural heritage values resulting from forest management activities;
- Minimal fibre loss and archaeological mitigation costs through value protection

Consideration in 2012 FMP:

- Delete as a separate Cultural Heritage Values objective.
- The planning process requires that cultural heritage values, including archaeological potential areas, be considered during operational planning for harvest, renewal and tending activities and for road access planning.
- Mandatory consideration for known values, including cultural heritage values, are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).

10. Wildlife Habitat Objectives

10(a) Selected Wildlife Species Objective:

The objective is to provide suitable/preferred habitat within the bounds of natural variability for the selected wildlife species within the Whiskey Jack Forest.

Targets: - Maintain habitat for selected species within a specified range; and
- Avoid any significant reductions in habitat available for selected species.

Consideration in 2012 FMP:

- Modelled wildlife non-spatial preferred habitat is not required for species other than the Species At Risk (carried forward in Objective 3). Habitat for selected species are accounted for in the multiple forest biodiversity, forest composition and structure indicators that are indicators of various habitats (Objectives 1-3).

10(b) Caribou Objective:

The objective is to maintain or improve contribution of the Whiskey Jack Forest to continued range occupancy and healthy populations of woodland caribou in Northwestern Ontario.

Target: - NWEST portion of the forest to contribute to the habitat range for woodland caribou.

Consideration in 2012 FMP:

- Consideration for woodland caribou habitat (a Species At Risk) is carried forward in the 2012 plan in Objective 3: Wildlife Habitat. This consideration is required by the Endangered Species Act 2007 and is in accordance with the Caribou Recovery Plan 2009.
- Management zones were identified, one of which is the area of the forest to be management primarily for woodland caribou habitat. These management zones are discussed in plan text Section 2.1.2.3.
- The draft *Forest Management Guide for Boreal Landscapes (Landscape Guide)* suggested two new indicators that relate to caribou habitat in the caribou zone.
  - Amount of woodland caribou habitat (refuge, winter)(Objective 3); and
  - Texture (arrangement) of woodland caribou habitat (refuge, winter)(Obj. 3).
- The FMPM(2009) requires an indicator for habitat for forest-dependent Species At Risk. Therefore the Landscape Guide indicator for amount of woodland caribou habitat (first bullet above) also satisfies the FMPM requirement.

10(c) Marten Objective:

The objective is to maintain or move toward having 10-20% of capable marten habitat area in suitable conditions arranged in core areas of 3,000 to 5,000 hectares.

Target: - Maintain specific portion of suitable forest land base in marten core habitat areas.

Consideration in 2012 FMP:

- Marten core areas were required by the *Forest Management Guidelines for the Provision of Marten Habitat* for the 2004 FMP. This habitat management guide is still in effect as the Landscape Guide has not been approved in time for full application for 2012 FMPs. The Draft Landscape Guide also suggests direction and indicators for forest diversity, including landscape forest composition, pattern and texture. The Stand and Site Guide requires the provision of large landscape patches. Therefore, marten core areas are carried forward in the 2012 FMP in Objective 3: Wildlife Habitat, as well as consideration in the new landscape indicators in Objective 1: Landscape Pattern.

10(d) Moose Objective:

The objective is to retain a year round supply of suitable habitat (including foraging and winter habitat) for moose on the Whiskey Jack Forest.

Target: - Amount of preferred habitat for moose foraging and moose winter habitat.

Consideration in 2012 FMP:

- Consideration for moose habitat is carried forward in the 2012 plan.
- Management zones were identified, one of which is the area of the forest to be management primarily for moose habitat. These management zones are discussed in plan text Section 2.1.2.3.
- Habitat for selected species, including moose, are accounted for in the multiple forest biodiversity, forest composition and structure indicators that are indicators of various habitats.
- The draft Landscape Guide includes suggested biodiversity indicators for mature and late successional forest and for young forest distribution (see Section 3.4.2: Indicators Resulting from New MNR Direction). These indicators are incorporated into Objective 2: Forest Composition and in Objective 1: Landscape Pattern and will measure some components of moose habitat.
- The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* provides direction for the consideration of Moose Emphasis Areas. If MEAs are warranted for the management unit, discussion is included in text Section 2.1.2.3 Management Zones, with detailed analysis of the MEAs included in plan supplementary documentation. Operational planning of harvest areas must consider proportion of area in specific forest composition classes with MEAs if MEAs are identified for a FMP.

10(e) Stick Nest Objective:

The objective is to provide for the protection of nest sites and associated habitat of bald eagle, osprey, great blue heron and other locally significant forest dwelling raptors.

Target: - Minimize negative impacts on stick nests (i.e. bald eagle, great blue heron, osprey, and forest dwelling raptors).

Consideration in 2012 FMP:

- Delete as a separate stick nest management objective.
- The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* provides mandatory direction for prescriptions for the protection of nests for many bird species, including stick nests.

- Mandatory consideration and appropriate prescriptions for the protection of stick nests are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern, text Section 4.2 Prescriptions for Operations, text Section 4.2.2.2 Conditions on Regular Operations, text Section 4.5.3 to 4.5.4 Area of Concern Crossings – Roads, and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values, including stick nests, is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).

11. Soil Objective:

The objective is to minimize any possible adverse effects of forest practices on soil quality.

Targets: - No forest operations in areas where forest practices threaten the long-term site productivity;
- No Forest Operations Compliance Information System (FOCIS) reports with non-compliances related to site damage; and
- Limit area of roads and landings to 1% of area proposed for forest operations.

Consideration in 2012 FMP:

- Delete as a separate forest users management objective.
- The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* provides direction for management practices that prevent, minimize or mitigate site damage, and practices to mitigate erosion, hydrological impacts, loss of productive land, and nutrient retention on shallow soil sites.
- Consideration for sensitive sites is documented in text Section 4.2.2.1 Silvicultural Ground Rules, Section 4.2.2.2 Conditions on Regular Operations, and Section 4.7.2 Monitoring and Assessment for Exceptions.
- The success in implementation of management practices that prevent, minimize or mitigate site damage is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).
- Maintenance of sustainable amounts of Crown managed forest available for timber production is carried forward as it is a mandatory indicator required by the FMPM (2009) in Objective 5: Managed, Crown Forest. This indicator is directly affected by the quantity of productive land converted to roads and landings.

12. Fisheries and Water Quality Function Objective:

The objective is to maintain riparian habitat, water quality and to prevent the harmful alteration, disruption or destruction of fisheries habitat where forest management activities occur.

Targets: - Minimize impact to riparian areas from harvest through the application of no-cut reserves; and
- To implement forest practices that do not create the harmful alteration, disruption or destruction of fisheries habitat without Department of Fisheries and Oceans consent.

Consideration in 2012 FMP:

- Delete as a separate fisheries and water quality management objective.
- The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* provides mandatory direction for the protection of fisheries and water quality values.

- The planning process requires that identified values be considered during operational planning for harvest, renewal and tending activities and for road access planning.
- Mandatory consideration and appropriate prescriptions for the protection of known values are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern, text Section 4.2 Prescriptions for Operations, text Section 4.2.2.2 Conditions on Regular Operations, text Section 4.5.3 to 4.5.4 Area of Concern Crossings – Roads, and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values, including aquatic values, is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).

13. Silviculture Objective:

The objective is to apply the most appropriate level of silviculture that will ensure the long-term forest sustainability while consistent with all other objectives of this plan.

Target: - Assess and silviculturally treat depleted areas to achieve the level of forest cover and wood supply required to sustain the forest resources of the Whiskey Jack Forest.
- Lowest achievable silviculture costs per cubic metre.
- Maximize yield and product quality.

Consideration in 2012 FMP:

- Maintenance of sustainable amounts of Crown managed forest available for timber production is carried forward as it is a mandatory indicator required by the FMPM (2009) in Objective 5: Managed, Crown Forest.
- Consideration for silvicultural treatment costs is included in the development of silvicultural option assumptions in the strategic modelling during development of the Long-term Management Direction. Projected LTMD silvicultural treatments are determined after consideration for the achievement of management objectives, treatment costs and estimated available funding from the Forest Renewal Trust Fund.
- The FMPM(2009) requires three new indicators of regeneration success (achieve free-growing status), silvicultural success (free-growing to projected forest unit) and strategic silvicultural planning (area treated by planned silvicultural treatment intensity) (see Section 3.4.2: Indicators Resulting from New MNR Direction). These three indicators are incorporated into Objective 9: Forest Renewal.
- Successful regeneration (three indicators above) will contribute to the maximization of timber yields through time (Objective 4: Wood Supply).

8.2 Consideration of Background Information and MNR Guides

Background information considered during development of management objectives and indicators included forest management guides (including new MNR forest management guides and direction) and general findings from the 2009 Independent Forest Audit. There has not been any Year Seven Annual Report required to be prepared for the Whiskey Jack Forest.

Forest Management Guides

Since the approval of the 2004 FMP, several major MNR guidance documents have been revised or prepared that are being implemented on the Whiskey Jack Forest for the first time for this 2012 forest management plan. These documents contain new (and some previously measured) indicators of forest sustainability to be included in forest management plan development. Where new indicators are prescribed by new MNR direction, the indicators may be assessed in association with existing, confirmed management objectives from the 2004 FMP (if appropriate), or be included with new objectives for the 2012 FMP. The documents containing new MNR direction include:

1. Forest Management Planning Manual for Ontario's Crown Forests (Dec. 2009)

The Forest Management Planning Manual prescribes the requirements for Ontario's forest management planning system including a detailed description of the planning process and the products. The forest management planning cycle, established by the manual, consists of planning, implementation, monitoring and reporting. Since preparation of the 2004 FMP, the FMP manual was revised twice: once in 2004 for implementation by 2007-2011 FMP planning teams, and again in late 2009 for implementation by 2011+ FMP planning teams.

The FMPM(2009) requires certain new indicators of forest sustainability be included in each forest management plan. Indicators that were previously included in the 2004 FMP and are being carried forward into this plan (Section 3.4.1) are not duplicated in the following bullets:

New Indicators:

- Indicator for Aboriginal community involvement in plan development (Obj. 6);

  The Aboriginal communities and MNR recognized that information in previous FMPs on Aboriginal values and background community information have not been as complete or accurate as they could have been with information reviewed or supplied by the communities themselves. Additional indicators have been added to the 2012 FMP (Objective 6) to ensure better communication with Aboriginal communities and input throughout the forest management planning process. These indicators reflect opportunities for involvement provided to, and involvement of Aboriginal Communities in the plan development process. The indicators include:

  (a) Number of Aboriginal communities in or adjacent to the Whiskey Jack Forest with representation on the planning team;

(b) Number of Aboriginal communities (that are in or adjacent to the Whiskey Jack Forest) that contribute information to the planning process.

- Indicator for Local Citizens Committee self-evaluation of its effectiveness in plan development (Objective 7);

  This is a new objective for this plan included for the associated mandatory indicator from the *Forest Management Planning Manual (2009)* required for this FMP. This indicator will relate to both the Kenora LCC and the Red Lake LCCs. While involvement of the LCCs has been encouraged and well received during preparation of past plans, the quality and effectiveness of the LCCs involvement will now form one of the indicators by which forest sustainability is measured.

  (a) Local citizens committee's self-evaluation of its effectiveness in plan development.

  Specific desired forest conditions and goods and services discussed with the Local Citizens Committees are included in Sections 3.4.1 to 3.4.3. The management objectives and indicators are detailed in Section 3.5 with rationale for desirable levels.

- Indicator for habitat for species at risk (Objective 3):

  The importance of considering the forest dependent species at risk is discussed in text Section 2.1.3.1. In recognition of this importance, the FMPM (2009) requires the inclusion of an objective indicator related specifically to the non-spatial habitat estimated for Species at Risk (Objective 3).

  (a) Area of habitat for forest-associated species at risk.

  The only Species at Risk on the Whiskey Jack Forest that have habitat that can be effectively modelled non-spatially through time in the strategic modelling is the woodland caribou. Reporting will occur at the time of Long-term Management Direction and in Year Seven and Year Ten Annual Reports.

New Indicators:

- Actual harvest area by forest unit (% of planned)(Objective 4);
- Actual harvest volume by species group (% of planned)(Objective 4);
- Kilometres of SFL roads per square kilometre of Crown forest (Objective 8);
- Regeneration Success: Percent of harvested forest assessed as free-growing by forest unit (Objective 9);
- Silvicultural Intensity: Planned and actual percent of harvest area treated by silvicultural intensity (Objective 9);
- Silvicultural Success: Planned and actual percent of area successfully regenerated to the projected forest unit by forest unit (Objective 9);
- Percent of forest operation inspections in non-compliance by activity and remedy type (Objective 10);
- Compliance with management practices that prevent, minimize or mitigate site damage (% of inspections in non-compliance, by remedy type)(Objective 11); and
- Compliance with management practices that protect water quality and fish habitat (% of inspections in non-compliance, by remedy type)(Objective 11).

2. Ontario's Woodland Caribou Conservation Plan (Oct. 2009)

The Caribou Conservation Plan provides broad policy direction regarding woodland caribou conservation and recovery. This plan states that in areas licensed for forest management within the continuous extent of caribou occurrence, Ontario will ensure that forest management practices fully consider both current and future Woodland Caribou habitat needs, reflecting natural forest conditions and dynamics. The plan requires that all management plans include:

(a) Provision for caribou habitat during forest management planning by requiring the development of a "dynamic caribou habitat schedule" for each forest management plan.
(b) A caribou-based objective for silviculture to be included in all forest management plans within the geographic distribution of caribou.
(c) Use of the Silvicultural Effectiveness Monitoring to assess the effectiveness of forest renewal for caribou, provide recommendations for improvements, and monitor how successfully logged areas are tracking toward a suitable future habitat condition.
(d) Determination of densities (thresholds) of roads to support caribou persistence.

The Planning Team has considered these requirements and included a dynamic caribou habitat schedule (formerly referred to the "caribou mosaic" in the previous FMPs) in the management zones and strategic planning for the management plan. The following objective indicators are included in the plan and address points (b) to (d) above.

New Indicators:

- Indicator for % of upland conifer dominated forest units in caribou zone. (Objective 3);
- Indicator for % of conifer species composition in caribou zone. (Objective 3);
- Indicator for density of SFL road per square kilometre of Crown forest, specifically in the caribou zone of the forest (Objective 8).

3. (DRAFT) Forest Management Guide for Boreal Landscapes

This draft guide may be considered by 2012 Planning Teams as suggested direction for maintaining or enhancing natural landscape structure, composition and patterns that provide for the long-term health of forest ecosystems in an efficient and effective manner. When approved, the Landscape Guide will replace existing landscape, stand and site scale direction previously found in several other documents. In the meantime, the science package developed by MNR to support the Landscape Guide is considered the best available science and information for many of the landscape related indicators. The Planning Team also relied on the Ontario Landscape Tool (OLT) that was developed by MNR to support the Landscape Guide (when approved) for the determination of desirable levels for many management indicators. The OLT projections were considered more appropriate for the forest than just relying on broad descriptions included in the historic forest condition.

The Landscape Guide suggests several new indicators of forest biodiversity be included in each forest management plan. The Planning Team reviewed these suggested indicators and decided to include them in the 2012 FMP:

New Indicators:

- Landscape class area for mature and older age classes (Objective 2);
- Old forest by appropriate grouping (plan forest unit or landscape guide forest unit)(Objective 2);
- Red pine and white pine forest unit areas (grouped)(Objective 2);
- Upland spruce and jack pine dominated forest areas (grouped)(Objective 2);
- Texture (arrangement) of the mature and old forest (all forest units combined)(Objective 1);
- Young forest patch size (Objective 1);
- Amount of woodland caribou habitat (refuge, winter)(Objective 3); and
- Texture (arrangement) of woodland caribou habitat (refuge, winter)(Objective 3).

4. Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (March 2010)

The Stand and Site Guide provides direction on various aspects of conserving biodiversity, including aquatic and wetland habitats and shoreline forests, special habitat features (e.g. bird nests, dens, bat hibernacula), and habitat for species at risk. It also addresses topics like road and water crossing construction and maintenance, category 14 aggregate pits, and soil and water conservation (e.g. rutting, erosion, nutrient loss), and salvage and biofibre harvest operations. The Stand and Site Guide replaces existing stand and site scale direction previously found in numerous forest management guides.

While most direction in the Stand and Site Guide is “operational direction” at the stand and site level, the guide contains some landscape level direction that may be applicable in the Long-term Management Direction of a forest management plan. Each planning team will determine if any direction from this guide warrants an indicator in the strategic planning of the FMP. No indicators have been included in the Whiskey Jack Forest FMP that relate to Stand and Site Guide direction.

5. Landscape Direction from Existing MNR Guides

Landscape direction from the following guides was included in the 2012 FMP. (Note: These guides would have been replaced by the Landscape Guide, but it was not approved for full implementation in this FMP.)

Forest Management Guide for Natural Disturbance Pattern Emulation (2001)

- Landscape pattern (Objective 1), disturbance frequency and planned clearcuts.
- Note: the approved Stand and Site Guide replaces stand level direction from the NDPE guide.

Forest Management Guidelines for the Provision of Marten Habitat (1996)

- Marten core habitat (Objective 3).
- During development of the LTMD, it was thought that the marten guide was going to be replaced by the Landscape Guide for use in the FMP. The Planning Team decided to include one additional indicator to approximate the landscape pattern of concentrated (>60%) mature and old conifer (Objective 1) in addition to the other indicators suggested by the draft Landscape Guide. There was concern that the combination of indicators for mature/old landscape pattern (spatial),

mature/late conifer landscape class (non-spatial), and upland pine and spruce (non-spatial) may not cover all the area currently assessed according to the marten habitat guide. This concentrated conifer indicator area is similar to marten core habitat but allows a greater range in sizes and distribution of this older conifer area. This indicator is measured through use of the OLT Model. This concentrated conifer landscape pattern indicator was retained in the Whiskey Jack plan after the provincial decision was made to continue use of the marten habitat guide.

Independent Forest Audit (IFA)

Independent Forest Audits (IFA) are required to occur on the Whiskey Jack Forest at least every five years. The last IFA was conducted in 2009 resulting in recommendations, some of which were relevant during preparation of this forest management plan. While the audit report is not public at this time, a general summary of issues and how they were considered during development of this plan follows:

i) Update the forest resources inventory with free-to-grow information and barren and scattered survey information.

Considerations in FMP: The planning composite inventory was updated by MNR with all recent free-to-grow information and barren and scattered survey results. This update was approved in Progress Checkpoint #1 of the planning process.

ii) Use silvicultural survey information to develop the silvicultural program.

Considerations in FMP: The planning composite inventory was updated by MNR with recent free-to-grow and silvicultural effectiveness monitoring information. Silvicultural effectiveness monitoring results were also used in the development of post-renewal forest succession assumptions for the strategic modelling component of LTMD development (what forest units are expected to result from various regeneration treatments). A discussion of silvicultural treatments that are successful on the Whiskey Jack Forest is included in FMP Section 4.2.2.1 Silvicultural Ground Rules and documented in Table FMP-4.

iii) Silvicultural strategies are reflected in the operational renewal program.

Considerations in FMP: For each forest unit, the Silvicultural Ground Rules (Table FMP-4) identify broad silvicultural strategies and specific acceptable operational treatments in accordance with approved provincial silvicultural guides. The strategic renewal assumptions are included in the strategic SFMM modelling during development of the Long-term Management Direction. The linkage between strategic and operational silviculture and the application of the LTMD projected renewal program is discussed in FMP Section 4.4 Renewal and Tending Operations and Table FMP-17. Projections from the LTMD are considered during operational planning of the renewal program. Confirmation that the implementation of the operational silvicultural program will support the LTMD is included in FMP Section 4.9 Comparison of Proposed Operations to the LTMD, the SFMM modelling Final Test of Sustainability (plan supplementary documentation), and Section 5.0 Determination of Sustainability.

iv) The natural condition be considered in development of indicator desirable levels.

Considerations in FMP:

The support tool for the draft Landscape Guide, the Ontario Landscape Tool (OLT), provides Simulated Ranges Natural of Variation (SRNV) for the indicators included in the

model. These SRNV s are based on the best available science and reflect the estimated natural forest condition. These SRNV s will be incorporated into desirable levels for many FMP indicators, and assessed during development of the Long-term Management Direction.

v) Moose habitat shelter patches.

Considerations in FMP:

Moose management strategies are discussed in text Section 2.1.2.3 Management Zones. The Stand and Site Guide directs the consideration of forest cover for moose habitat. Planned and mapped residual forest patches are identified on the geospatial information layer (MU490_12PRP00.E00) submitted in the FMP. During harvest operations, some patches of mapped residual may be moved as long as the patches are designated as being acceptable to move (e.g. not required in a certain specific location for habitat) and the same amount of residual forest area is retained as was approved in the FMP.

vi) Operations on fine-textured soils.

Considerations in FMP:

This is an operational consideration related to implementation of planned operations. Conditions on Regular Operations (Section 4.2.2.2) are included in the FMP to direct operations on sensitive sites, and conditions to minimize erosion, rutting and compaction.

vii) Quality of site preparation results.

Considerations in FMP:

This is an operational consideration related to implementation of the silvicultural program, including site preparation, as forecast in Table FMP-17. Site preparation quality standards are included in work contracts issued for site preparation to ensure payment for a good quality result, suitable for subsequent planting or seeding treatments. Monitoring and assessment of regeneration (Section 4.7.3) to confirm that Silvicultural Ground Rule (Table FMP-4, Section 4.2.2.1) regeneration standards are met that will contribute to the achievement of management objectives (Section 3.6).

viii) Less common species planted on appropriate sites.

Considerations in FMP:

This is an operational consideration related to implementation of the silvicultural program. Silvicultural Ground Rules (Table FMP-4 and Section 4.2.2.1) identifies acceptable species and regeneration standards for each ground rule on specific ecosites. Forest Operations Prescriptions are prepare annually and confirm specifically what SGR and what acceptable treatments will be carried out on what area during that operating year. Planned silvicultural treatments must conform to approved SGRs.

ix) Slash management in harvest areas.

Considerations in FMP:

Slash pile management and limited loss of productive land to landings and slash piles is included in Conditions on Regular Operations (Section 4.2.2.2).

x) Survey silviculturally treated areas and identify any areas requiring retreatment or tending.

Considerations in FMP:

The monitoring procedures for the assessment of regeneration success are documented in Section 4.7.3 of the forest management plan. Survey methodology will include the timing of assessments and survey for the identification of areas requiring additional treatments. The Silvicultural Ground Rules (Table FMP-4) include reference to regeneration standards used to determine regeneration success.

xi) Adequate tree seed for implementation of the regeneration program.

Considerations in FMP:

Renewal support including tree seed and planting stock required for the five-year term of the plan is discussed in Section 4.4.2.2 Cone Collections and Planting Stock Procurement. Implementation of the identified renewal support activities will ensure adequate tree seed and planting stock to carry out the forecast renewal program (Table FMP-17).

xii) Road decommissioning strategy.

Considerations in FMP:

Table FMP-18 Road Construction and Use Management identifies all roads to be decommissioned during the plan period. Road use management strategies (Section 4.5.8 and Supplementary Documentation 14) outline use management strategies, including decommissioning and rehabilitation options, when the roads are no longer required for forest management purposes. Road decommissioning is included as a silvicultural strategy to

xiii) Water crossing monitoring strategy.

Considerations in FMP:

Water crossing monitoring and assessment is discussed in the FMP in Section 4.74 Roads and Water Crossings. Conditions on water crossings in areas of concern are detailed in Table FMP-19 and supplementary Documentation 13. Conditions on Roads, Landings, and Aggregate Pits outside of areas of concern are discussed in text Section 4.5.7.

xiv) Forestry aggregate pit rehabilitation.

Considerations in FMP:

Forestry Aggregate Pits are discussed in FMP Section 4.5.6 and include operational standards accordance with the FMPM (2009) Appendix VII. Conditions on operations associated with aggregate pits in areas of concern are detailed in Table FMP-19 Road Crossings, Landings and Aggregate Pits in Areas of Concern. Conditions on Roads, Lands, and Aggregate Pits (Section 4.5.7) discuss conditions on operations outside of areas of concern.

8.3 Summary of Scoping Investigations

Desirable levels that were not provided directly by guides or other sources of direction were refined through scoping analysis. Scoping analysis is an iterative process that involves a series of investigations to provide insight to what the forest is capable of producing in order to develop realistic and feasible desirable levels for objective indicators. Scoping investigations consider implications on wood supply, forest conditions, habitat, and other non-timber resources for the short- term, medium-term, and long-term.

For all scoping investigations, unless specifically noted otherwise, the following management decisions were consistently included in each investigation as per the Base Model:

- management decisions for caribou management (SUBMUs and operational timing);
- large landscape patch deferrals (includes marten core habitat management);
- estimated reserve areas as per the Stand and Site Guide (riparian, nests) and estimates of known tourism reserves;
- crude control of projected TOTAL harvest volumes of +/- 20% variance allowed between 10-year terms; and
- execution of SFMM for the greatest volume of timber harvested over the entire planning period.

Specific SFMM model inputs varied for each investigation and projected results are documented in a standardized 3-Page Summary for all documented investigations in Appendix 2. Digital copies of selected model runs (labels with SFMM Case code noted in bold below) that best represent the following investigations to support strategic analysis are included in the SFMM executable DAT file provided to MNR for review. They do not form part of the public portion of the electronic FMP.

The following summary of scoping investigations and significant conclusions or results were considered in the development and rationalization of desirable levels for management indicators.

(a) An investigation into the ability of the forest to meet forest diversity and forest cover desirable levels (based on current forest condition and forest dynamics);

Investigations on impact of forcing the achievement of the SNRV (stay within "box" ASAP) for various Landscape Guide/OLT indicators.

SFMM Case:	Description:
01-OLT-70	Achieve SRNV for OLT combined - (below) parameters together:
02-OLT-50	Achieve SRNV for mature/late OLT landscape classes
	Achieve SRNV for OLT old forest classes
	Achieve SRNV for OLT upland conifer
	Achieve SRNV for OLT Caribou Habitat (Cr, Cwu, Cwp)
03-FUgroup	Achieve SRNV for forest units by immature/mature+ stages

Based on results, it was investigated when the Simulated Range of Natural Variation (SRNV) achievement for OLT investigations could occur (e.g. in 70 years, or in 50 years).

From runs **01-OLT-70** and **02-OLT-50** it was observed that OLT minimum SRNV levels for mature/late landscape classes, old forest classes, upland conifer and caribou habitat

could be generally met from 50 years (Term 6) onwards with two exceptions. It was initially noted that one component in each of two indicators showed limitations in achieving OLT desirable levels (note this was corrected point (iii) below):

i) The Mature and Late Successional Lowland Landscape Class (MLl) was not well correlated between the OLT model as compared to the SFMM model. Plan Start values for MLl for SFMM are 2,889 hectares (based on forest inventory sort) whereas the OLT simulation suggests a Plan Start level of 15,219 hectares and a lower simulated range of natural variation (SRNV) of 12,845 hectares. Since MLl area is related to only lowland ecosites and also to only the mature and older age classes, it is considered impossible to project forest management activities in SFMM to increase the MLl area significantly enough to ever reach the lower SRNV area.

ii) Old forest Spruce Lowland (SLo) was also not well correlated between the OLT model and SFMM. This area is lowland ecosite and old age related as is the Mature/Late Lowland landscape class discussed above (all SLo old forest area would also be classified as MLl landscape class area). Based on the inventory, SFMM projected only 97 hectares of SLo at 2012, whereas the OLT model was based on 1,631 ha at 2012 and calculated a lower SRNV of 3,319 ha for SLo. While it is possible to increase the area of SLo through time (some conversion from OCL), it was not possible to convert enough area to SBL and let it age to create enough old spruce lowland forest in the future up to the projected OLT minimum levels.

iii) Prior to the Base Model Inventory and Base Model Progress Checkpoint #3 being approved, there was an error identified and corrected related to the classification of the SBL forest unit productive area in the Base Model Inventory. Approximately 16,000 ha. had been classified as SPD forest unit area whereas it should have been classified as SBL forest unit area. This correction was made prior to selection of the LTMD (runs 27 and 27a). The correction served to decrease the SPD forest unit area, decrease the MLc landscape class area and decrease the SPo old forest area. These decreases were not significant as these classes all had large areas in them and the change was proportionately small. The corresponding increases in classes associated with lowland spruce (MLl landscape class and SLo old forest area) were equivalent in hectares, but more significant in magnitude because these classes contained smaller areas. The positive result of this correction was that it confirmed better correlation between SFMM and the OLT Plan Start values for MLl and SLo and allowed the minimum OLT SRNV area levels to be appropriately used as desirable levels for these indicators.

CONCLUSION: There was no reason to not meet OLT suggested minimum levels within 50-60 years (e.g. not meeting levels until 70-100 years in the future) for all OLT landscape classes, old forest, upland conifer area and non-spatial caribou habitat except MLl as noted above. Desirable levels for mature/late landscape class area (Indicator 2a), old forest class area (Indicator 2d), upland conifer (Indicator 2e) and caribou habitat (Indicator 3a) were agreed to be the minimum OLT SRNV levels.

CONCLUSION: From run **03-FUgroup**, it was concluded that constraints to force the general achievement of projected forest unit area by age grouping (young versus mature/late) to OLT minimum SRNV levels could not be utilized in the absence of OLT desirable level constraints. In isolation, forest unit age groupings had reasonable projections but the achievement of landscape class areas and old forest areas were negatively impacted.

CONCLUSION: Constraints for the mature age groupings by forest unit from Term 8 (70 years) were considered acceptable for forest unit / age grouping desirable levels for Indicator 2b. Control of forest unit area for the young age grouping was not considered as significant to manage as was the need to ensure sufficient area in the mature and older age grouping. The LTMD Task Team and Planning Team also agreed that the achievement of desirable levels for landscape class area was a higher priority as compared to total forest unit area through time, or forest unit by age grouping (young versus mature/late).

CONCLUSION: The total area of the PRW forest unit was consistently below the range projected by OLT (SFMM 2012 - 3,312 ha versus OLT 2012 - 0 ha with a minimum SRNV of 46,338 ha). It was recognized that OLT does not adequately simulate the forest dynamics for red pine and white pine regeneration and natural succession. Therefore a desirable level of maintaining a minimum of the Plan Start PRW value (no decrease) was adopted rather than a level prescribed by the OLT model.

CONCLUSION: The LTMD Task Team and Planning Team agreed that spatial indicators for landscape pattern/texture and caribou habitat would have desirable levels as projected by the OLT model. This represented the best science and information on natural landscape pattern. This related to Indicators 1a, 1b, 1c, 3b and 3c.

The management objectives, indicators, desirable levels and the timing of assessment for each indicator are documented in Table FMP-9.

(b) An investigation and assessment of the ability of the forest to continue to supply forest benefit levels associated with the current forest management plan;

Several items related to wood supply, forest condition and age, and wildlife habitat were reviewed to complete this assessment.

Wood Supply - First, a SFMM investigation was completed that incorporated wood supply by species group from the 2004 FMP, with the objective of sustaining 2004 wood supply levels for as many terms as possible. This investigation was built upon the 02-OLT-50 run to ensure the projections would be favourable for landscape class area, old forest, upland conifer and caribou habitat (just to investigate a balance of forest and benefits, not just wood supply).

SFMM Case:	Description:
04-2004Wood	Achieve approved plan T1 volume for as long as possible

Inputs:

Unlimited budget, will determine if minimum demand volumes by species group are achievable, and for how many terms, and at what future cost to wood. Binding volume targets added for as long as they can be met. Volume flow constraints infinite for allowable decreases and increases between terms.

Group:	Demand	thousands of m3 per year.	
PWR	1.6	from T1 2004 FMP.	**BUILT ON OLT_50 investigation, vol targets added.**
SPF	400.0	from T1 2004 FMP.	
PO	265.0	from T1 2004 FMP.	
BW	25.0	from T1 2004 FMP.	
Total	691.6		

CONCLUSION: The Spruce-Pine-Fir and the Red Pine-White Pine wood supplies were projected to be met for 40 years (Terms 1-4). Hardwood volumes (Poplar, Birch) were limited after Term 2 or 3 respectively. Wood supply can be comparable to the 2004 FMP for this plan period, but without added constraints to force the projected increase in hardwood volumes in Terms 3-7, future hardwood will be less than projected in the 2004 FMP. This is not unexpected as the yield curves were revised for this plan and it was noted that hardwood volumes in the curves were lower than previous plans, but appeared to be reasonable for Whiskey Jack Forest conditions and available data.
NOTE: Additional comparison of wood supply projections between plans is included in PART 5, Section B (c) Historic Wood Utilization.

Productive Area by Forest Unit – This comparison is a reflection of the forest condition that contributes to other desired forest and benefits such as wildlife habitat, forest diversity and harvest area. Habitat for selected wildlife species are no longer measured in the strategic modelling, rather the combination of landscape class area, old forest groupings and landscape pattern/texture indicators are considered as better measure of forest condition. However landscape class area and many of the old forest and landscape pattern indicators from this 2012 FMP were not included in the 2004 FMP. Hence, a comparison of productive area by forest unit is provided. Forest units from the 2004 FMP are aligned to roughly correspond to the 2012 FMP PLANFUs, though it must be noted that this is a rough comparison only. Barren and Scattered (B&S) and LOWNAT area is included in the table as it contributes to the productive forest land base.

The table below shows some minor variance in productive area by forest unit between plans, but differences are minor (mainly due to refined forest unit definitions) and should not compromise the Whiskey Jack Forest's ability to continue to provide forest benefits associated with the productive forest.

2004 FMP			2012 FMP	
PLANFU	**Ha**		**PLANFU**	**Ha**
CEDAR	5,202		OCL	2,217
COSHA	77,726		BFM	27,150
MIXED	58,550		CMX	88,492
			HMX	107,239
OTHWD	1,813		OTH	1,995
PJDOM	235,392		PJD	182,832
			PJM	61,845
PODOM	133,214		POD	73,977
PRWMX	4,216		PRW	3,312
SBLOW	12,542		SBL	17,611
SPDOM	197,610		SPD	112,785
			SPM	45,937
TOTAL	726,265		TOTAL	725,394

Old Forest Area – Next, the quantity of old forest was compared for Plan Start 2004 and 2012. The comparison utilizes the PLANFUs and old forest definitions used in each of the plans, with 2004 PLANFUs organized and grouped to roughly align with the 2012 FMP old forest groupings. It is evident that through aging of the forest over the past eight years, significantly more area has now aged enough to be classified as old forest. Therefore, this increase in area of old forest may be detrimental to future wood supply and provide a greater fire hazard in some portions of the forest, it does provide more of the inherent benefits associated with older forest structure (e.g. wildlife habitat for those species preferring old forest, forest diversity).

Old Forest Area at Plan Start

2004 FMP			2012 FMP	
PLANFU	Ha		PLANFU	Ha
CEDAR >140 years	329		OLD - BFo >80 years	3,707
COSHA > 110 years	1,554		OLD - CLo >100 years	1,851
MIXED >100 years	1,875		OLD - CMo >100 years	8,811
PODOM >100 years	5,812		OLD - HWo >100 years	17,199
OTHWD >100 years	146		OLD - OHo >90 years	1,252
PJDOM >110 years	4,598		OLD - PJo >100 years	23,309
SBLOW >160 years	-		OLD - SLo >160 years	2,007
SPDOM >120 years	4,879		OLD - SPo >110-120 years	10,207
PRWMX >130 years	456		OLD - PRW >140 years	457
TOTAL	19,649		TOTAL	68,801

Caribou Habitat – A similar dynamic caribou habitat schedule was spatially applied for both the 2004 and 2012 forest management plan land bases. Therefore it is expected that the projected benefits to caribou are comparable for both plans.

Marten Habitat – a similar spatial distribution of marten core areas was incorporated into both the 2004 and 2012 FMPs. Plan Start achievement of % suitable of total capable % was 3.7% for the 2004 FMP (13 cores) and 4.9% for the 2012 FMP (17 cores or Large Landscape Patches). These results support the forest's ability to continue to supply spatial marten core area.

CONCLUSION: Based on the comparison of projected wood supply, productive forest area, old forest area, caribou habitat and marten habitat, it is expected that the 2012 Whiskey Jack Forest will continue to be able to supply forest benefit levels associated with the 2004 forest management plan.

8.4 Documentation of the Management Objectives Checkpoint

Progress Checkpoint #4 approval of the Management Objectives was received on January 13, 2011.

From: Hole, Scott (MNR)
To: Duda, Steve (MNR) ; Mohamed, Hassan (MNR) ; Pochailo, Kurt (MNR) ; Susan Jarvis
Cc: Salter, David (MNR) ; Ride, Kevin (MNR)
Sent: Thursday, January 13, 2011 3:09 PM
Subject: Whiskey Jack Forest Management Objectives Checkpoint

All:

I have received confirmation from the Regional advisors that the materials submitted for the Management Objectives Checkpoint satisfy the requirements of the Forest Management Planning Manual.

Provided the rest of the advisors and planning team members agree, the checkpoint can be considered passed.

Scott Hole, R.P.F.
Resource Analyst
Northwest Region Planning Unit

PART 5: PROPOSED LONG-TERM MANAGEMENT DIRECTION

9.0 Introduction

This section of the Analysis Package documents the development of the proposed Long-term Management Direction (LTMD). Information required by the FMPM in this section of the Analysis Package includes:

(a) How management objectives were represented in the analysis;
(b) How the achievement of objectives was interpreted from the model results;
(c) A summary of changes to the base model and rationale for those changes;
(d) A summary of modelling results including:
    (i) key results and conclusions that provide rationale for adjustment to targets, if applicable; and
    (ii) the conclusions of the analysis, with a digital copy of the model run for the proposed long-term management direction.
(e) Documentation of Support for the Proposed Long-Term Management Direction, Determination of Sustainability and Primary Road Corridors Checkpoint

This information and a summary of development of the LTMD are documented in the following sections.

9.1 Management Objective Representation and Interpretation of Results in the Analysis

How management objectives and indicators were represented in the analysis and how the achievement of objectives was interpreted from the model results (points (a) and (b) above) are documented in the following table (Table 24).

1 **Table 24 How Management Objectives were Represented and Interpreted from the Analysis**

OBJECTIVE	INDICATOR	HOW REPRESENTED IN ANALYSIS	HOW INTERPRETED FROM RESULTS
1 Landscape Pattern	1a % mature and old forest	spatial measurement in OLT model at 500 ha and 5,000 ha scales.	Results are compared at the 500 ha and 5,000 ha scales to assess if results achieve minimum desirable levels (from OLT projection) or are showing movement from Plan Start % towards desirable level.
	1b young forest patch size by size class	spatial measurement in OLT model.	Results compared to projected proportions by size class from OLT for this indicator to assess if results achieve minimum desirable levels or are showing movement from Plan Start % towards desirable level.
	1c % mature and old conifer forest	spatial measurement in OLT model at 500 ha and 5,000 ha scales.	Results are compared at the 500 ha and 5,000 ha scales to assess if results achieve minimum desirable levels (from OLT projection) or are showing movement from Plan Start % towards desirable level.
2 Forest Composition	2a Crown productive forest by landscape class	SFMM model includes extra "species" in yield curves to track area by landscape class through time.	Projected area of the mature and late successional landscape classes is compared to minimum desirable levels to determine achievement.
	2b Crown productive forest by forest unit and age grouping	SFMM projected area by forest unit and 10-year age class.	Forest unit area is summed by age grouping based on split between young/immature and mature/late ages (varies by forest unit). Projected area is compared to minimum desirable levels by age grouping to determine achievement.
	2c amount and distribution of old forest	SFMM model includes extra "species" in yield curves to track area by old forest grouping through time.	Projected area by old forest class is compared to minimum desirable levels to determine achievement.
	2d amount of red pine and white pine forest	SFMM projected area by forest unit.	Projected area of PRW forest unit (all ages) is compared to minimum desirable level to determine achievement.
	2e amount of upland pine and spruce	SFMM projected area by forest unit.	Projected area of PJD, PJM, SPD and SPM is summed and compared to the minimum desirable level to determine achievement.
3 Wildlife Habitat	3a Area of habitat for forest-dependent Species At Risk.	SFMM model includes extra "species" in yield curves to track area by caribou habitat type (3 types: refuge, winter used and winter preferred).	Projected areas for the 3 caribou habitats are compared to minimum desirable levels to determine achievement.
	3b % caribou refuge habitat in caribou zone	spatial measurement in OLT model at 6,000 ha and 30,000 ha scales.	Results are compared at the 6,000 ha and 30,000 ha scales to assess if results achieve minimum desirable levels (from OLT projection) or are showing movement from Plan Start % towards desirable level.
	3c % caribou winter habitat in caribou zone	spatial measurement in OLT model at 6,000 ha and 30,000 ha scales.	Results are compared at the 6,000 ha and 30,000 ha scales to assess if results achieve minimum desirable levels (from OLT projection) or are showing movement from Plan Start % towards desirable level.
	3d marten core habitat	OMA model used to classify and summarize suitable marten in identified core areas with subsequent measurement in GIS system.	Core areas are identified and then the percentage is calculated for suitable habitat in cores divided by total capable habitat. This proportion is comapred to the desirable range percentages to assess achievement. Marten core areas are included as deferrals in the SFMM modelling during development of the LTMD but SFMM is not used to assess this indicator.
	3e % conifer dominated forest units in the caribou zone	Not measured in strategic modelling. GIS query of the updated forest inventory	In the caribou zone, total productive forest area of targeted conifer forest units (only PJD, PJM, SBL, SPD and SPM forest units) divided by the total productive area, expressed as a percentage. Information is reported by forest unit, but indicator is for combined total percentage of the targeted forest units in the caribou zone (not individually).
	3f % jack pine and spruce species composition by forest unit in the caribou zone	Not measured in strategic modelling. GIS query of the updated forest inventory	Forest composition to be derived using the Base Model Inventory with the species composition string parsed out. Indicator calculated for only PJD, PJM, SBL, SPD and SPM forest units within the caribou zone: the combined species composition percentage for jack pine, black spruce and white spruce (only) is calculated, based on the area weighted average tree species composition by forest unit.
4 Wood Supply	4a Long-term projected available harvest area	SFMM projected AHA by forest unit.	Projected total available harvest area is compared to the minimum desirable level to determine achievement.
	4b Long-term projected available harvest volume	SFMM projected AHV by species group.	Projected available harvest volume by species group is compared to the minimum desirable level to determine achievement.
	4c Short-term projected available harvest volume	SFMM projected total AHV for Term 1.	Projected Term 1 total available harvest volume is compared to the minimum desirable level to determine achievement.
	4d % actual harvest area by forest unit	Not measured in strategic modelling. Measurement based on analysis of GIS updated harvest area.	Not assessed through strategic analysis.
	4e % actual harvest volume by species group	Not measured in strategic modelling. Measurement based on analysis of actual harvest volumes.	Not assessed through strategic analysis.
5 Managed Crown Fores	5a managed Crown forest available for timber production	SFMM projected total available area.	Projected total long-term (Term 11) available forest area is compared to minimum desirable level to determine achievement.
6 Aboriginal Involvemer	6a Representation on the Planning Team	Not included in strategic modelling.	Not assessed through strategic analysis.
	6b Aboriginal communities that contribute information to the planning process	Not included in strategic modelling.	Not assessed through strategic analysis.
7 LCC Involvement	7a LCC self-evaluation on its effectiveness in plan development	Not included in strategic modelling.	Not assessed through strategic analysis.
8 Road Access	8a km SFL road per km2 of prodctive forest	Not included in strategic modelling.	Not assessed through strategic analysis.
9 Forest Renewal	9a Regeneration Success: Percent of Harvested Forest Area Assessed as Free-Growing by Forest Unit	Not included in strategic modelling.	Not assessed through strategic analysis.
	9b Silviculture Intensity: Planned and Actual Percent of Harvested Area Treated by Silvicultural Intensity	Not included in strategic modelling.	Not assessed through strategic analysis.
	9c Silvicultural Success: Planned and Actual Percent of Harvested Forest Area Assessed as Free-Growing and Successfully Regenerated to the Projected Forest Unit	Not included in strategic modelling.	Not assessed through strategic analysis.
10 Forest Values	10a % of forest operation inspections in non-compliance, by activity and remedy type (i.e. severity).	Not included in strategic modelling.	Not assessed through strategic analysis.
11 Soil and Water Resou	11a % of forest operations inspections in non-conpliance with management practices that prevent, minimize or mitigate site damage (by remedy type)	Not included in strategic modelling.	Not assessed through strategic analysis.
	11b % of forest operations inspections in non-compliance with prescriptions developed for the protection of water quality and fish habitat (by remedy type)	Not included in strategic modelling.	Not assessed through strategic analysis.

2

9.2 Summary of Development of the Long-term Management Direction

The base model was used as the starting point for the development of the proposed long-term management direction. The Strategic Forest Management Model (SFMM) was used as a decision support system during strategic analysis. Strategic analysis is an iterative process used to determine the types and levels of access, harvest, renewal, and tending activities required to balance the achievement of management objectives associated with the management of forest cover, and to develop achievable targets in the proposed long-term management direction.

Targets were established for each indicator. The establishment of targets for each indicator considered:

(a) The current forest condition;
(b) A balance of social, economic and environmental considerations;
(c) The associated indicator and the desirable level;
(d) The potential achievement for the short term (10 years), medium term and long-term; and
(e) Projections from past forest management plans and historical levels of objective achievement.

In addition, for harvest level indicators, the targets also considered:

(a) Ontario Forest Accord Advisory Board benchmark harvest levels, as identified in the Regional Wood Supply Strategies;
(b) Maximum even-flow harvest volume by major species group; and
(c) Historic wood utilization.

Upon completion of the investigation of the types and levels of activities and setting of desirable levels (FMP Section 3.5.1 and 3.5.2) and conducting broad and specific scoping investigations, the Planning Team began developing a Long-term Management Direction (LTMD). All investigations conducted for the development of the LTMD considered implications on wood supply, forest conditions, habitat, and other non-timber resources for the short-term (10 years), medium-term (20-70 years) and long-term (80-100 years). These values were also considered throughout the 160-year planning horizon. These investigations were part of the iterative process used in the development of the Long-term Management Direction. All strategic modelling was conducted and reviewed co-operatively between SFL staff and MNR district staff, with valued input and advice from the plan advisors.

Specific SFMM model inputs varied for each investigation and projected results are documented in a standardized 3-Page Summary for all documented investigations in Appendix 3. Digital copies of selected model runs (labels with SFMM Case code noted in bold below) that best represent the following investigations to support strategic analysis are included in the SFMM executable DAT file provided to MNR for review. They do not form part of the public portion of the electronic FMP.

The following summary of investigations and significant conclusions were considered in the development of the Long-term Management Direction and indicator target levels.

(a) Ontario Forest Accord Advisory Board (OFAAB) benchmark harvest levels, as identified in the Regional Wood Supply Strategies.

SFMM Case:		Description:
05-BENCH		Achieve OFAAB benchmark volumes by species group
Group:	**Bench**	thousands of m3 per year
PWR	0.6	
SPF	354.0	**BUILT ON OLT_50 investigation, vol targets added. Non-binding to allow solve.**
PO	149.0	
BW	4.0	
Total	507.6	

CONCLUSION: OLT landscape indicator targets achievement was good due to the constraints added to all LTMD development scenarios. PWR (red pine – white pine), SPF (spruce-pine-fir) and BW (white birch) OFAAB benchmark volume targets were able to be met in all terms. The PO (poplar) species group benchmark level was projected to be met in all terms except Terms 4-6.

(b) Maximum even-flow harvest volume by major species group.

SFMM Case:	Description:
06-Flat-PWR	Even PWR volume all terms
07-Flat-SPF	Even SPF volume all terms
08-Flat-PO	Even PO volume all terms
09-Flat-BW	Even BW volume all terms

BUILT ON OLT_50, no vol targets added, only vol flow control.
Volume flow constraints of 0% decrease and 0% increase for each species group as individual scoping runs, no volume
Will determine lowest point that can be achieved for timber by each species group in any given term.

The even flow (flat line) harvest volume investigations gave ballpark estimates of how much volume by species group could be sustained through time if there was the same volume projected in every term. Additional information was derived from the even-flow runs to see what volumes were projected if volumes could increase, but not decrease, between terms. This information was recorded as the non-declining volumes by species group but are not saved investigations. The non-declining information gave an indication of what terms limited the projected harvest volumes for each species group.

Results	**Even Flow Volumes (m3/year)**
06-Flat-PWR	1,290 m3
07-Flat-SPF	392,370 m3
08-Flat-PO	110,507 m3
09-Flat-BW	17,467 m3
09-Flat-TOTAL	551,399 m3

Non-declining volumes: **(Information point only, not saved cases.)**

1,290 increases to 1,431 in T9 and then 2,178 in T13 and 2,200 in T15.

389,174 then increases to 474,804 T7 to end.

110,051 limited to T6, then incr to 117,878 in T7. Incr to 134,591 in T15.

Same as even flow, so limited by last term

546,319 m3 to T6, then incr to 616,460 m3 in T7-T14, then incr to 705,091 m3 for T15.

CONCLUSION: Increased volumes can be realized by allowing increases in volumes between terms or by adjusting the OLT achievement targets or timeframe for achievement. Poplar volumes were confirmed to be a challenge that needed to be addressed in the LTMD, particularly for the short-term. Spruce-Pine-Fir projected volumes were generally at an acceptable level.

Development of the LTMD Management Strategy

After approval of the Base Model, work progressed to develop a Long-term Management Direction.

10_MS – This run was built on run 02_OLT_50 (with OLT class minimum SRNV levels built into the SFMM model for mature/late landscape class area, old forest area, upland pine and spruce area and non-spatial caribou habitat). Minimum volume targets were added for Term 1 (table below) and also for SPF all terms to balance wood flow more evenly. The budget was balance by all subunits combined. Also an additional deferral was added (WC2 called LLP_00) for area near Grassy Narrows in preparation for additional investigations, but this area did not have any operational timing deferrals included in this scenario (deferral turned OFF).

Group:		thousands of m3 per year.	
PWR	1.5	T1 only	
SPF	390.0	all terms	
PO	200.0	T1 only	(Lower than 2004 FMP (265), but higher than even flow (110)).
BW	20.0	T1 only	
Total	600.0	all terms	

11_MS – This run was a refinement of run 10_MS with additional constraints from Term 6 onwards to ensure achievement the minimum SRNV area of mature and late successional area by forest unit. Also included a volume flow control of a maximum of 10% decrease in total volume between terms.

12_medOLT – This run included increased OLT targets at the median level, rather than the lower SRNV level (solved for all classes except left at min. SRNV for PSp, MLI, CLo, and SPo). These targets were included from Term 11 onwards as it took longer (than T6 used in previous scenarios) for enough change to the current forest condition to achieve the higher median values.

16_MS – This run was built on run 11_MS with OLT targets raised above minimum SRNV levels but not as high as median levels (14_OLT50+). This improved overall OLT area projections. Additional constraints were added to ensure the minimum OLT SRNV levels of the mature/late successional age grouping by forest unit were achieved from Term 6 onwards.

17_MS – This run included refined non-binding harvest volume targets to reduce Term 1 volume as noted below, and to control the variation in poplar harvest volume T1 through to T15. Overall volume projections were acceptable but there was significant variation for individual species groups between terms.

Group:		thousands of m3 per year.	
PWR	1.5	T1-T2 only	
SPF	350.0	T1-T2 only	
PO	200.0	T1-T2 only	then T3-T15 at 100.00
BW	20.0	T1-T2 only	
Total	500.0	all terms	

20_MS – Harvest volume targets were added for TOTAL volume (all terms) and PO (Terms 1-6) to better balance harvest volumes. These constraints served to increased and stabilize future total harvest volumes, and project acceptable short-term volumes.

Group:		thousands of m3 per year.
PWR		
SPF		
PO	200.0	T1 only, then T2 150, T3-6 90.
BW		
Total	520.0	all terms to raise harvest in lowest terms

22_OLTPO – This scenario included some minor refinements to subunits and LLP deferrals to closely align with the projected deferrals for marten core areas. Other LLPs were revised to be deferred for 30 years rather than the original 60 year estimate (LLP_27-32, and LLP_28 was turned OFF). An additional operational deferral was included (LLP_40, deferral of 7,616 ha) to reflect area that was not expected to be operated for the next 40 years.

27_OLTMS – This scenario included a constraint for non-declining PRW area compared to the Plan Start level (as per an objective indicator). In order for this to solve, a refinement in the minimum target for old forest CMo was needed to allow the conversion of a small amount of area from the CMX to PRW forest units. The resulting minimum target of 21,000 ha CMo was still above the minimum SRNV as was considered acceptable to the Planning Team.

CONCLUSION: This scenario was reviewed at length by the Strategic Task Team and Planning Team and considered a viable LTMD option. It provided a good balance of objective achievement and included forest management activities of harvest and renewal that were reasonable for the forest and had the potential to be successfully implemented.

As previously noted, after scenario 27 was investigated, there was an error identified and corrected related to the **classification of the SBL forest unit productive area** in the Base Model Inventory. Approximately 16,000 hectares had been classified as SPD forest unit area whereas it should have been classified as SBL forest unit area. This correction was made prior to selection of the LTMD (between runs 27 and 27a). The correction served to decrease the SPD forest unit area, decrease the MLc landscape class area and decrease the SPo old forest area. These decreases were not significant as these classes all had large areas in them and the change was proportionately small. The corresponding increases in classes associated with lowland spruce (MLl landscape class and SLo old forest area) were equivalent in hectares, but more significant in magnitude because these classes contained smaller areas. The positive result of this correction was that it confirmed better correlation between SFMM and the OLT Plan Start values for MLl and SLo.

27a_OLTMS – The initial land base and deferred areas from Run 27 were updated with the reclassification of SPD to SBL area described above. The projected harvest area by forest unit was reviewed and an additional minimum harvest area target (Term 1 10 ha/year) was added for PRW to ensure there was some harvest area in this plan period, and a maximum harvest area was added for SBL for Terms 1-3 (80 ha/year) to ensure there was not too much lowland harvest area in any term due to the operational limitations of winter harvest. The OLT targets were again reviewed for achievement. Targets were added for mature/late SBL, mature/late Lowland and old forest SLo as these classes did not already have targets because they had not been well correlated to the OLT ranges before the forest unit classification correction, and now could be controlled to ensure favourable projections. Results were again reviewed in detail by the Strategic Task Team and Planning Team and accepted for further spatial planning.

Scenario 27a_OLTMS was considered as a potential Proposed Long-term Management Direction. Eligible harvest areas on the forest were reviewed to investigate if the projected available harvest area in Run 27a was feasible for implementation. Several areas were classified as being available for harvest that the Operations Task Team did not think were realistic to allocate due to bypassed areas that were not feasible to harvest or would be better suited for harvest when adjacent areas were old enough to be included in operationally feasible operating blocks. The task team decided that the LTMD run should be refined to remove the area of estimated bypass from the available forest in SFMM (reserve category PASS added 33,417 ha), and to defer other areas from being projected for harvest for the next 40 years (7,823 ha). At this time, regional input was also received to consider the balancing of Spruce-Pine-Fir harvest volumes through time rather than having the level of variation that was included in Run 27a. Another run was built onto Run 27a to balance the SPF wood supply with the revised land base (PASS and deferrals).

27d_OLTMS – After preliminary harvest allocations and regional MNR review, further adjustments to operational reserves and deferrals and the balancing of Spruce-Pine-Fir harvest volume was completed in Dec. 2010. Adjustments to poplar and total wood supply targets were included as well as for SPF, as were very minor refinements in OLT forest condition modelling targets. There was no change in the minimum desirable levels for forest condition related indicators – all desirable levels were still being met. The task team simply agreed that a predictable wood supply was necessary and that a higher achievement of OLT desirable levels within the SRNV was not as critical. All targets in Run 27a were maintained with minor reductions in the modelled targets for Mature/Late hardwood landscape class (Term 6 onwards) and Old PJ from Term 8 onwards. The projected AHA by forest unit was feasible to allocate. Results of this revised run and preferred harvest allocations based on this run were reviewed by the task team, Planning Team, regional advisors and LCCs.

Scenario 27d_OLTMS was selected as the Proposed Long-term Management Direction.

(c) Historic wood utilization

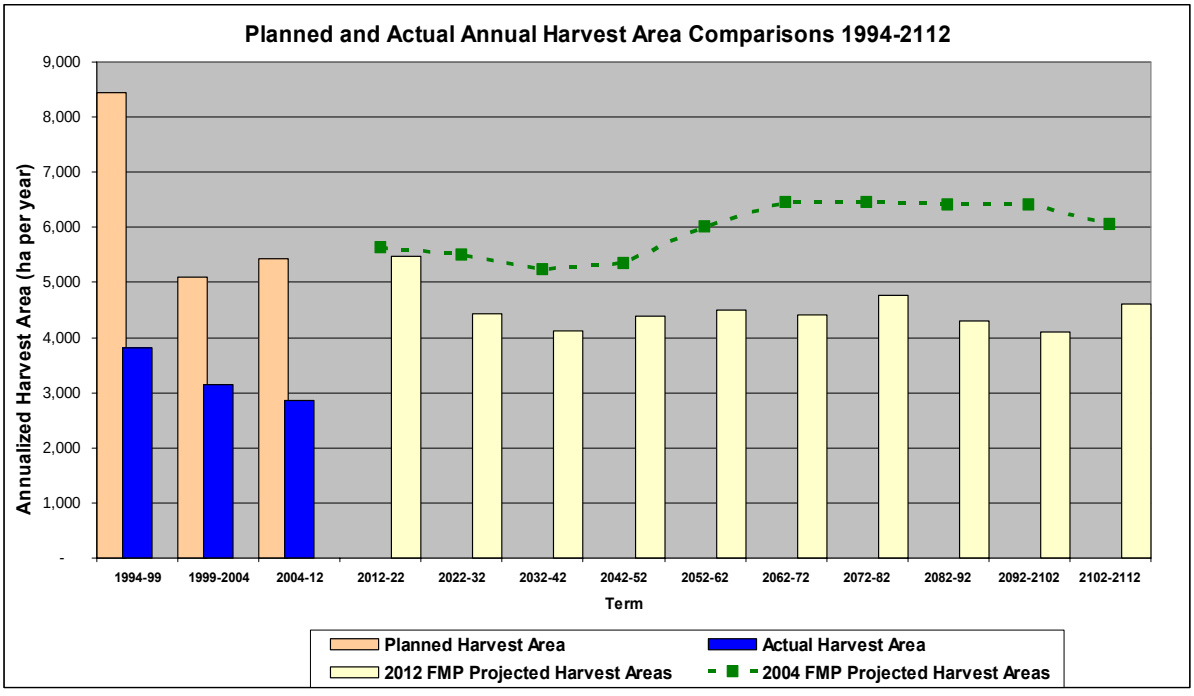
Short-term Harvest Areas 2012-2022

The Long-term Management Direction (27d_OLTMS) projects a harvest of 5,483 hectares per year from 2012-2022. The projected annual harvest area in the LTMD was compared to the historical planned and actual total harvest areas for 1994 through to 2112 (Figure 6). The total available harvest area planned for 2012-2022 (5,483 ha per year) is comparable to the total harvest area projected in the 2004 FMP (5,423 ha per year), and similar to planned harvest areas approved in the previous 1999 forest management plan (5,099 ha per year). This level of harvest for the 2012-2022 plan period was determined in response to identified management considerations for short-term harvest volumes (Indicator 4c) while balancing long-term objective achievement and forest sustainability.

Long-term Harvest Areas 2022-2112

The total annual harvest area (AHA) is projected to average approximately 4,500 hectares per year for the next 100 years, lower than projections in the 2004 FMP (average of 5,950 ha per year over 100 years). The lower long-term projected harvest area in this plan is a result of (a) a major revision to the objective indicators and desirable levels based on the OLT model simulated ranges of natural variation and (b) the balancing of socio-economic benefits from the Whiskey Jack Forest within the context of overall forest sustainability.

Figure 6 Planned and Actual Annual Harvest Area Comparisons 1994-2112



Short-term Harvest Volume 2012-2022

The 2012-2022 Long-term Management Direction annual harvest area is projected to yield approximately 574,000 cubic metres of timber each year from 2012-2022. This is comprised of 340,000 cubic metres of Spruce-Pine-Fir (SPF), 190,000 cubic metres of Poplar (PO), 33,000 cubic metres White Birch (BW) per year and 4,000 cubic metres per year of Red Pine and White Pine (PWR). Incidental species (cedar, larch and black ash) total approximately 7,000 cubic metres per year but are not considered major species groups.

The annual total harvest volume level in the LTMD for the 2012 Whiskey Jack FMP (574,600 cubic metres) is 20% lower than the harvest volumes projected in the selected management alternative for the 2004-2024 FMP (718,300 cubic metres per year). The decrease in harvest area and associated harvest volume is a result of desired forest and benefits while balancing other socio-economic indicators and forest sustainability. The Planning Team carefully considered the impact of the 2012-2022 projected harvest area on long-term harvest area/volume and future desired forest and benefits. The Planning Team supports this balance of long-term objective achievement.

Associated with the available harvest volumes are additional potential volumes of defect volume (branches, twigs, leaves, bark) and undersize volumes (top wood). These defect and undersized volumes were estimated through use of a MNR NW Region spreadsheet calculation based on the available harvest volume in the Long-term Management Direction. As reported in Table FMP-8, there are an estimated 104,400 m3 per year of defect volume and 20,700 m3 per year of undersized volume potentially available through harvest of the full available harvest area during this 10-year plan period. The total of available harvest volume, defect and undersized volume is estimated to be 6,997,400 m3 for this plan period 2012-2022 (699,700 m3 per year).

Long-term Harvest Volume 2022-2112

The LTMD projects that the total harvest volume will be sustained at 501,000 m3 per year in the 2022-2032 period, later decreasing to approximately 477,000 m3 per year from 2032 through to 2112. Strategic total harvest volumes projections are lower in this FMP as compared to the 2004 forest management plan. Spruce-Pine-Fir volume is projected to be comparable for 2012-2052 period as was projected in the 2004 FMP but then volumes are projected to be lower than the 2004 FMP for the following 60 years to 2112. Poplar volumes are projected to be significantly lower than 2004 projected levels. This variance is attributed to the refinement of the growth and yield curves and revision of modelling assumptions for the 2012 FMP and also due to the maximization of harvest area and total volumes, rather than forcing constant levels for any particular volume species groups. White Birch harvest volume is projected to be very variable in this 2012 FMP but is on average comparable to 2004 FMP volume projections for the next 50 years.

OFAAB Benchmark Levels

The projected volume in the LTMD was compared to the historical and benchmark levels identified in the Ontario Forest Accord Advisory Board (OFAAB) report. The following graphs show the historical and benchmark harvest levels which have occurred on the Whiskey Jack Forest from 1994 to the present. The planned and actual harvest volumes are also illustrated by 10-year FMP term from 1994 to 2012 (includes three additional years for 2009-2012 Contingency Plan period), and planned volumes from 2012 to 2112. Volume comparisons are included for all volumes (TOTAL, Figure 7), Spruce-Pine-Fir (Figure 8), Poplar, (Figure 9), White Birch (Figure 10) and White Pine and Red Pine, (Figure 11).

LTMD projections for Spruce-Pine-Fir harvest volumes are above the OFAAB level in this plan period, but then are projected to be comparable or marginally lower than the benchmark level through the long-term. Poplar harvest volumes are projected to be greater than the OFAAB benchmark level for this plan period, then are projected to be lower than the benchmark through the long-term. The fluctuation in poplar volume is a result of revised modelling assumptions and yield curves and the maximization of short-term harvest volume (not by species group) noted above. White Birch projections are consistently above the OFAAB benchmark. Red Pine – White Pine is also projected to exceed the OFAAB benchmark level for this 10-year plan period, then to be comparable to the benchmark over the following 80 years (except 2032-2042 when no PWR is projected to be harvested). Total harvest volume (not a provincial species group, but informative) is projected to be sustainable at a level slightly below the OFAAB total volume benchmark level.

9.3 Long-term Management Direction Documentation

The management objectives, indicators, desirable levels, target levels and the timing of assessment for each indicator are documented in Table FMP-9. Projected results for the Long-term Management Direction are documented or discussed in:

FMP Tables:

FMP-5	Projected Forest Condition for the Crown Productive Forest
FMP-6	Projected Habitat for Species at Risk and Selected Wildlife Species
FMP-7	Projected Available Harvest Area by Forest Unit (10-Year)
FMP-8	Projected Available Harvest Volume by Species Group (10-Year)
FMP-9	Assessment of Objective Achievement

FMP Text Sections:

3.6	Long-term Management Direction
5.0	DETERMINATION OF SUSTAINABILITY
5.1	Collective Achievement of Management Objectives
5.2	Preliminary Spatial Assessment
5.3	Social and Economic Assessment
5.4	Prescriptions for the Protection of Values
5.5	Conclusion on the Sustainability of the FMP

9.4 Documentation of Proposed LTMD Checkpoint

This progress checkpoint confirmed support by the MNR district and regional staff for the information and products associated with the long-term management direction, the preliminary determination of sustainability and the primary road corridors developed in the FMPM Part A, Section 1.2 to 1.2.7.

Progress Checkpoint #5 approval of the Proposed Long-term Management Direction was received on March 9, 2011.

From: Hole, Scott (MNR)
To: Duda, Steve (MNR) ; Susan Jarvis ; Mohamed, Hassan (MNR) ; Pochailo, Kurt (MNR)
Cc: Salter, David (MNR) ; Ride, Kevin (MNR) ; Schaefer, Chris (MNR)

Subject: Whiskey Jack LTMD Checkpoint

All

The Region has completed its review of the materials and information supplied for the Proposed Long Term Management Direction, Determination of Sustainability and Preliminary Spatial Assessment checkpoint for the Whiskey Jack Forest. We are satisfied that the requirements of this checkpoint have been met. Provided the rest of the team and relevant advisors are in agreement, the district can consider this checkpoint passed.

Introduction

This report documents the production of yield curves for the Kenora and Whiskey Jack forests.

Forest Units

Two versions of the standard forest unit SQL were used. The first uses ecosite, the second does not use ecosite but uses stocking to identify shallow sites. If ecosite was available, the first version was used. Otherwise, the second version was used.

The SQL for the Kenora and Whiskey Jack forest units (Planfu) is given in Table 3. The original SQL was modified so the breakpoints corresponded to 0.05 fractions of basal area rather than 0.1 fractions as much of the data had a finer resolution than the species composition in the inventory.

Table 1. The standard forest unit SQL using ecosite is given.

Order	Name	Description	Query
1	PwDom	White pine dominated	([PW]>=40)

Forest Resources Inventory

The FRI was provided by the OMNR (Figure 1). Only the productive (formod="RP") and available (avail="A") forest polygons were used to summarize the present forest.

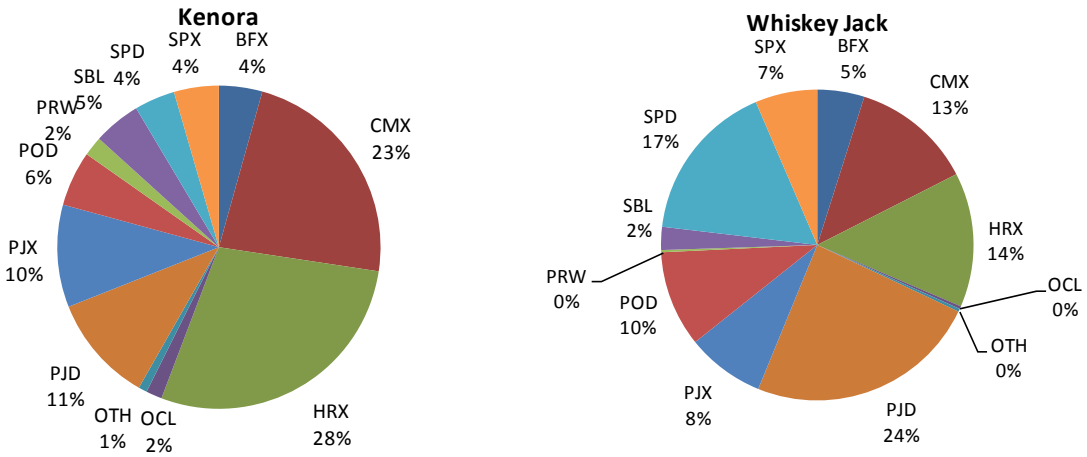

Figure 1. The areas of the Kenora and Whiskey Jack productive forests are summarized by forest unit.

Data

The main data sources were the historic cruise data recovered by the MNR-Northwest Region, the Forest Ecosystem Science Coop and MNR permanent growth plots (PGPs), and the MANDO dataset (Table 4).

1 **Table 4.** The datasets used in this project are given by origin.

Source	Company	Cruise Type	Year	Management Units	Concessions
Whiskeyjack Patricia	Boise Cascade	OPC	1987		
Lakc Seul	Buchanan	FRI	1999		
Wabigoon	Canadian Pacific Forest Products	OPC	1991		
Dryden	Crown	FRI	1998

3 **Table 5.** The data used in yield curve development are summarized by plan forest unit. The means are
4 followed in brackets by the range.

Planfu	N	Age (years)	Stocking	Basal area (m^2/ha)	Density (stems/ha)	Gross total volume (m^3/ha)	N GTV
BFX	732	52 (8 - 156)	0.77 (0.02 - 2.63)	23.5 (0.3 - 49.3)	1792 (35 - 6898)	73 (1 - 198)	732
CMX	903	71 (10 - 152)	0.81 (0.01 - 2.30)	22.5 (0.1 – 56.0)	1028 (33 - 9434)	126 (0 - 334)	903
HRX	877	67 (9 - 141)	0.8 (0.02 - 2.40)	19.1 (0.2 – 52.0)	1009 (17 - 10903)	129 (1 - 411)	877
OCL	70	96 (24 - 160)	0.78 (0.03 - 1.93)	25.5 (0.8 – 56.0)	1417 (35 - 4181)	66 (3 - 193)	70
OTH	30	80 (32 - 141)	0.66 (0.13 - 1.51)	17.6 (5.3 – 38.0)	938 (69 - 2637)	87 (44 - 153)	30
PJD	203 4	69 (8 - 157)	0.97 (0 - 2.85)	22.2 (0 - 56.7)	867 (17 - 15031)	100 (0 - 329)	203 4
PJX	725	72 (12 - 123)	1.17 (0.06 - 2.35)	28 (1.3 – 56.0)	1041 (52 - 6271)	118 (7 - 290)	725
POD	481	64 (11 -	0.79 (0.02 -	20.1 (0.2 –	895 (17 - 5100)	171 (2 -	481

Planfu	N	Age (years)	Stocking	Basal area (m^2/ha)	Density (stems/ha)	Gross total volume (m^3/ha)	NGTV
		141)	2.46)	52.0)		502)	
PRW	70	83 (9 - 150)	0.65 (0.01 - 1.37)	22.9 (0.3 - 50.5)	758 (17 - 3575)	153 (2 - 410)	70
SBL	68	104 (19 - 155)	0.36 (0.01 - 1.04)	11.4 (0.5 - 34.9)	896 (35 - 3350)	78 (3 - 297)	68
SPD	172 5	86 (11 - 160)	0.68 (0.01 - 2.63)	24.9 (0.3 – 60.0)	1053 (17 - 10702)	88 (1 - 313)	172 5
SPX	617	77 (20 - 159)	0.7 (0.07 - 1.70)	26.5 (2.1 - 56.7)	1053 (86 - 6255)	113 (12 - 256)	617

For the MANDO plots, plot age was estimated as follows. For some plots individual tree heights, Dbh's and ages were available. If so, the average age was calculated, weighted by tree basal area (giving more weight to the larger trees). The year of origin was calculated by subtracting the average age from the measurement year. If no tree ages were available, the plot summary table was checked. For some plots and age class was given, generally in 20 year age classes, e.g., 1-20, 21-40, 41-60, etc. If no tree ages were available and a plot age class was given, the plot was assigned the midpoint of the age class (e.g., age class 21-40 was assigned an age of 31). If tree ages were not available and age class was unavailable, no age was assigned.

Ht-dbh curves were fit by species and plot and measurement, if data were available.

$$ht = 1.3 + a_0 \cdot (1 - e^{b_0 \cdot dbh^{c_0}})$$

If sufficient data were not available, equations were fit by species and study.

$$ht = 1.3 + (a_0 + a_1 \cdot age) \cdot (1 - e^{b_0 \cdot dbh^{c_0}})$$

Very few poplar heights were available for the MANDO plots so a poplar ht-dbh curve was estimated from the FEC, Patricia 86, Coop PGPs and the MANDO data.

Data Censoring: There were a number of plots in the calibration data that were older (generally 130+ years) and had low stocking (< 30%). These were all associated with the Mando dataset. These were omitted for two reasons. The first is that these plots are likely going through succession with considerable mortality occurring in the dominant canopy layer. The second is that these plots are not considered productive forest. Removing these plots had a significant impact on the gross total and gross merchantable volume estimates (and consequently affected the net merchantable volume estimates).

Individual tree volumes were estimated using Zakrzewki's (1999) taper model.

For each plot, the Dbh and height (some heights were measured and some estimated) for each tree was used to predict the individual tree volume. For each tree, the gross total volume, gross merchantable volume and close utilization volume were estimated. These were then summed across all live trees to estimate the volume/ha.

Yield Predictions

Height development

Top height was predicted using published site index curves.

Table 6. The references for the site index curves are given by species.

Species	Reference
Jack pine	Carmean (2001) equation 3.
Black spruce, larch	Carmean (1996) figure 11
Trembling aspen	Carmean et al. (2002)
Cedar	Carmean et al (1989) figure 57
White Pine	Woods and Miller (1996)
Red pine	Woods and Miller (1996)
White birch	Carmean (1996) figure 14

Basal area and density

For natural origin stands, basal area (BA) was predicted as a function of stocking, site index, and age.

(1) $$\hat{BA} = stocking \cdot (\alpha_0 + \alpha_1 \cdot \hat{SI}) \cdot (1 - e^{-\beta_0 \cdot age^{\gamma_0}})$$

Stocking was predicted as a function of age from the FRI data (Figure 7). Only polygons with ages between 40 and 160 were used except for aspen leading which had to be between 20 and 160 years old. A normal distribution was assumed.

(2) $$stocking = \frac{b_2}{\sqrt{2\pi} \cdot b_1} \cdot e^{\frac{(age - b_0)^2}{2 \cdot b_1^2}}$$

After peaking, stocking generally declines sharply with age. Stocking for intensities other than *present*, the stocking are scaled by relative stocking. For instance, if the stocking for *present* is 0.85 and the average stocking for *extensive* is 0.70, the stocking curve for *extensive* is the stocking curve for *basic* scaled by 0.70/0.85. Density was estimated as a function of SI, stocking, BA, and age.

(3) $$\hat{stems} = \frac{x_0}{SI} \cdot stocking^{-x_1} \cdot \hat{BA} \cdot age^{-x_2}$$

The variance of the residuals increased with predicted stems so the observations were weighted by $\frac{1}{\hat{BA}}$ resulting in a more homogenous variance for the residuals. For some forest units, the density increases initially and then starts to decrease. The density is only those stems > 5cm Dbh (this is partly an artifact of sample plots which generally don't include stems less than some minimum Dbh). So part of the increase is due to trees growing larger than the lower threshold. There are few data points for young natural stands so the density estimates, in particular, are poor at young ages.

Species composition

The species composition over time was examined by looking at the inventory. In general, for the more pure planFUs, the species composition was relatively constant with age except for the BFM CMX, OCL, OTH and PRW planFUs. ConMx contains Pj, Sb, Po and Ce leading polygons and is difficult to model as a homogenous planFU. Therefore, it was split by leading species and each predicted separately. These leading species curves were combined into an area-weighted average curve for use in SFMM. There is some evidence of a decline in jack pine and

increase in black spruce with age for the PJD. This is partly an artifact of the SQL which allows lower Pj content at older ages.
The species composition trends with age observed in the FRI may be an artifact of selecting particular stands for harvesting in the past as well as other disturbances (fire, insects, windthrow). These events are not necessarily random and may not have the same occurrence pattern in the future. Nevertheless, the FRI species composition is likely the most reliable source of composition trends for the Kenora and Whiskey Jack forests.

Volume

The following equation form was used to predict total stem volume (m^3/ha). The coefficient is analogous to the cylindrical form factor $f = \frac{vol}{BA \cdot ht}$ (Husch et al. 1972).

(4) $\hat{vol} = z_0 \cdot \hat{BA} \cdot \hat{topht}$

The variance of the residuals increased with predicted volume so the observations were weighted by $\frac{1}{\hat{BA}}$ resulting in a more homogenous variance for the residuals.

Crown Standard (NMV crown) has the following utilization standards. These are the volumes that appear in the tab "SFMM input" and in column P of the present tab.

Table 7. NMV crown or scale utilization standards.

Species	Crown standard	
	Stump height (cm)	Top outside bark diameter (cm)
Pw, Pr,	30	13.1
Other conifer	30	9.1
Poplar, white birch	30	13.1
Other hardwood	30	17.1

Merchantable volume was predicted as a function of total volume and quadratic mean Dbh (Dbh_q).

(5) $\hat{mvol} = z_3 \cdot (1\text{-}e^{-z_1 * Dbh_q^{z_2}}) \cdot \hat{vol}$

The relationship between net merchantable volume and age was obtained by fitting the following equation to the cull factors from OMNR (1978), by species. This predicts the cull fraction increases as a sigmoidal function of age.

(6) $\hat{cull}_i = (1 - e^{-d_0 \cdot age})^{d_1}$

For each species, the relationship between the volume (GTV) to basal area ratio (VBAR), site index and age was estimated using the entire data set.
For each species, the net merchantable volume was estimated using the following equation.

(7) $\hat{nmvol}_i = \frac{sppba_i \cdot \hat{cull}_i \cdot \hat{vbar}_i}{\sum_i sppba_i \cdot \hat{cull}_i \cdot \hat{vbar}_i} \cdot \hat{mvol}$ where $sppba_i$ is the basal area for species i

Product volumes were estimated from the NMV.

Table 8. The product specifications for SPF. Note the products are mutually exclusive. First any SPF16 products are removed from the SFP volume. Then SPF8 is estimated from the residual volume.

Product Name	Species	Length	Small end diameter	Additional requirements
SPF16	Pw, Pr, Pj, Sw, Sb, Bf	5.0m	16cm	Dbh_q > 16cm
SPF8	Pw, Pr, Pj, Sw, Sb, Bf	2.5m	16cm	Dbh_q > 12cm
SPF2	Pw, Pr, Pj, Sw, Sb, Bf	2.5m	12cm	Dbh_q > 12cm
SFP3	Pw, Pr, Pj, Sw, Sb, Bf	None	None	

Age to breast height

The number of years to reach breast height in the draft curves is given below. The planning team should review these.

Table 9. The number of years to reach breast height is given by species and intensity. For the CMX, the age to breast height is also given by leading species.

PlanFU	Years to breast height
	Present
BFM	10
CMX	Ce-5, Pj-5, Sb-14, Po-5
HRX	5
OCL	
OTH	
PJD	5
PJX	5
POD	5
PRW	
SBL	8
SPD	8
SPX	8

Cull

Provincial cull figures are included in the yield tables.

Curve Tails

The yield of overmature stands is not well predicted due in part to a lack of PSPs in older age classes and the higher variation in development patterns for overmature stands relative to younger stands. Table 10 gives the area by age class by forest. The Kenora forest has very little area in stands greater than 140 years old. On the Whiskey Jack, the lowland forest units (OCL, SBL) and white and red pine units (PRW) have a higher proportion of area in older age classes but these forest units do represent a large parto f the land base..
Overmature stands have higher incidences of damaging agents and differential mortality rates by species. As a consequence, the stocking development is highly variable and there is a higher probability of shifting to different forest units (succession). Due to the high variation and

the lack of data, the estimation of yields for overmature stands should incorporate expert knowledge.

Table 10. The available forest area is given by forest unit and age class.

Forest	Planfu	% of landbase	Stocking	Site Class	% of area by age class							
					10	30	50	70	90	110	130	141+
Kenora	BFX	4%	0.56	14.7	13%	16%	31%	30%	9%	1%	0%	0%
	CMX	23%	0.67	16.4	22%	12%	19%	33%	11%	2%	1%	0%
	HRX	28%	0.66	21.2	16%	11%	26%	41%	6%	0%	0%	0%

The results of Uhlig et al. (2001) to identify the age of onset and the duration of old growth were used to estimate the yield curve tails. The yield at the onset of old growth was taken from the data. The yield at the end of old growth was estimated as 30% of unmodified yield. Note the old growth definitions are intended to identify when the original leading species starts to fall out of the stand. In general, the leading species is replaced by another more shade tolerant species. Only the drop in leading species is built into the yield curves, not ingrowth.
The age of onset of old growth and the duration of old growth are given in Table 11.

Table 11. The age of onset of old growth and the duration are given by species and are taken from Appendix A (p. 34) of Uhlig et al. (2001).

Species	PlanFU	Uhlig et al. (2001) Forest Unit	Age of onset of old growth	Duration
Pj	PJD	Pj (Pure)	100	55
	All others	Con Mix 1	100	50
Sb	SBL	Sb (Low)	160	190
	SPD	Sb (Deep)	120	55

Species	PlanFU	Uhlig et al. (2001) Forest Unit	Age of onset of old growth	Duration
	All others	Sb (Mix)	110	40
Sw	All	Sb (Mix)	120	60
Bf	All	Bf (Dominant)	80	55
Ce	All	OC	140	210
La	All	OC	100	NA (used 100)
Po	POD	Po (Pure)	100	45
	All others	Hardwood (Mix)	100	35
Bw	All	Harwood (Mix)	110	30

An example of the effects of modifying the tails of the yield curve is given in the following figure. The old growth modifier was the based on the cumulative normal distribution with a mean equal to (age of onset + 0.5*duration) and a standard deviation equal to (duration/4).

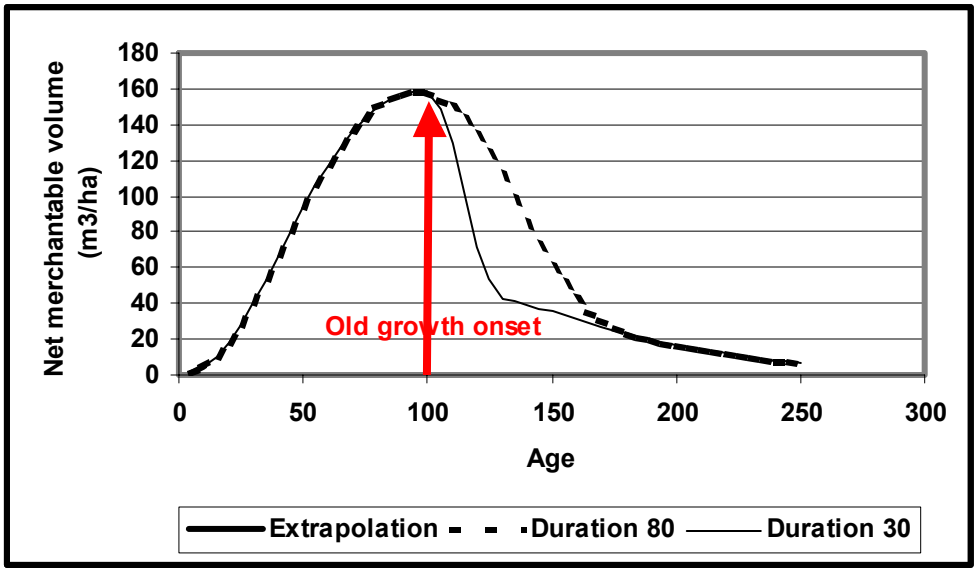

Figure 2. The extrapolated yield curve (solid, bold line) is compared to using the old growth definition with a duration of 80 years (dashed line), and duration of 30 years (thin line).

Netdowns not accounted for

The yield curves predict NMV by species. This does not account for retention trees or losses due to waste and breakage or losses due to unproductive areas within a stand. These reductions are accounted for in a term called “additional netdown”. This term is set to 5% of net merchantable volume for all intensities. The NDPEG netdowns are dealt with separately in SFMM as is are unproductive areas within a stand (including bypass).

Yield Table inputs

Present intensity

The inputs for the *Present* management intensity were derived from the FRI.

Stocking - The stocking values for the *Present* intensity are the area-weighted average for productive (formod="RP") and available (avail="A") forest polygons. In addition, the polygons had to have an age between 40 and 160, except for aspen leading which had to be between 20 and 160.
Site Index – Site Class averages for the *Present* intensity were derived in the same manner as stocking (see above) and then converted to site index.

Managed intensities

Yield curves for managed intensities have not yet been developed.

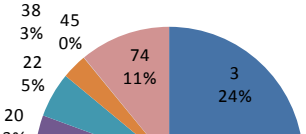
Notes

BFM – The stocking profile fit to the Whiskey Jack forest predicted a dramatic decline with stocking with age and showed none of the peak observed in the Kenora forest. The bulk of the area in the BFM for the WhiskeyJack is in young ages classes. Without much area in the older age classes, there was little to base a stocking profile on. Therefore, the shape of the Kenora stocking pofile was used for the Whiskey Jack.

ConMx – This forest unit was split into Jack pine leading, Spruce leading (including balsam fir) and aspen (including birch). This was because the different leading species showed different growth trajectories. Separate curves were estimated and then combined by intensity.

Whiskey CMX area by leading speces



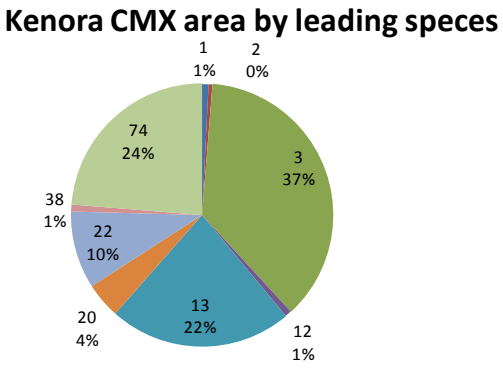


Figure 3. The area of the CMX forest unit by leading species and management unit.

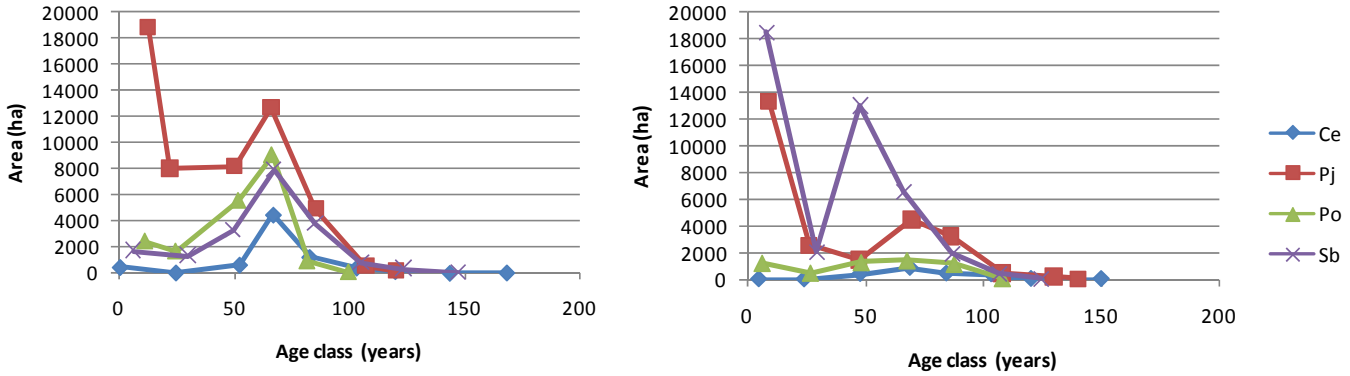

Figure 4. The area by age class for the Kenora (left) and WhiskeyJack (right) forests. The Whiskey Jack has much more area in spruce-leading forests and little area older than 30 except in spruce leading. The Kenora crown has more area in 40-80 year old stands.

HMX – The HMX is a combination of the BwDee, BwSha, HrDom and HrdMw standard forest units.

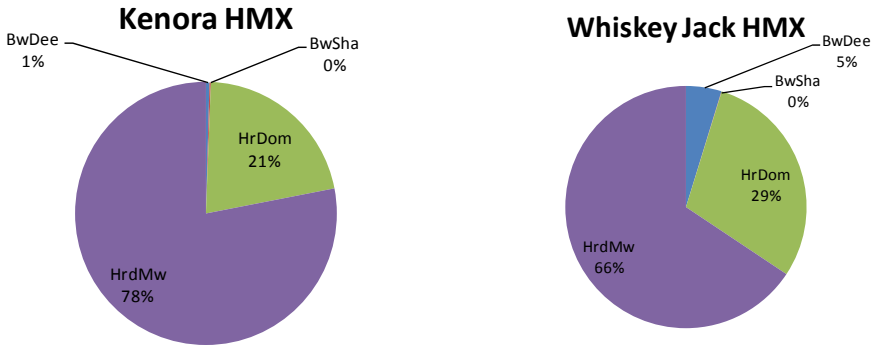

Figure 5. The HMX is largely composed of HrdMx with some HrDom in both the Kenora and Whiskey Jack. The birch forest units are minor components.

Appendix A – stocking trends

The stocking over age trends for the Kenora forest are given in Figure 6 and for the Whiskey Jack in Figure 7.

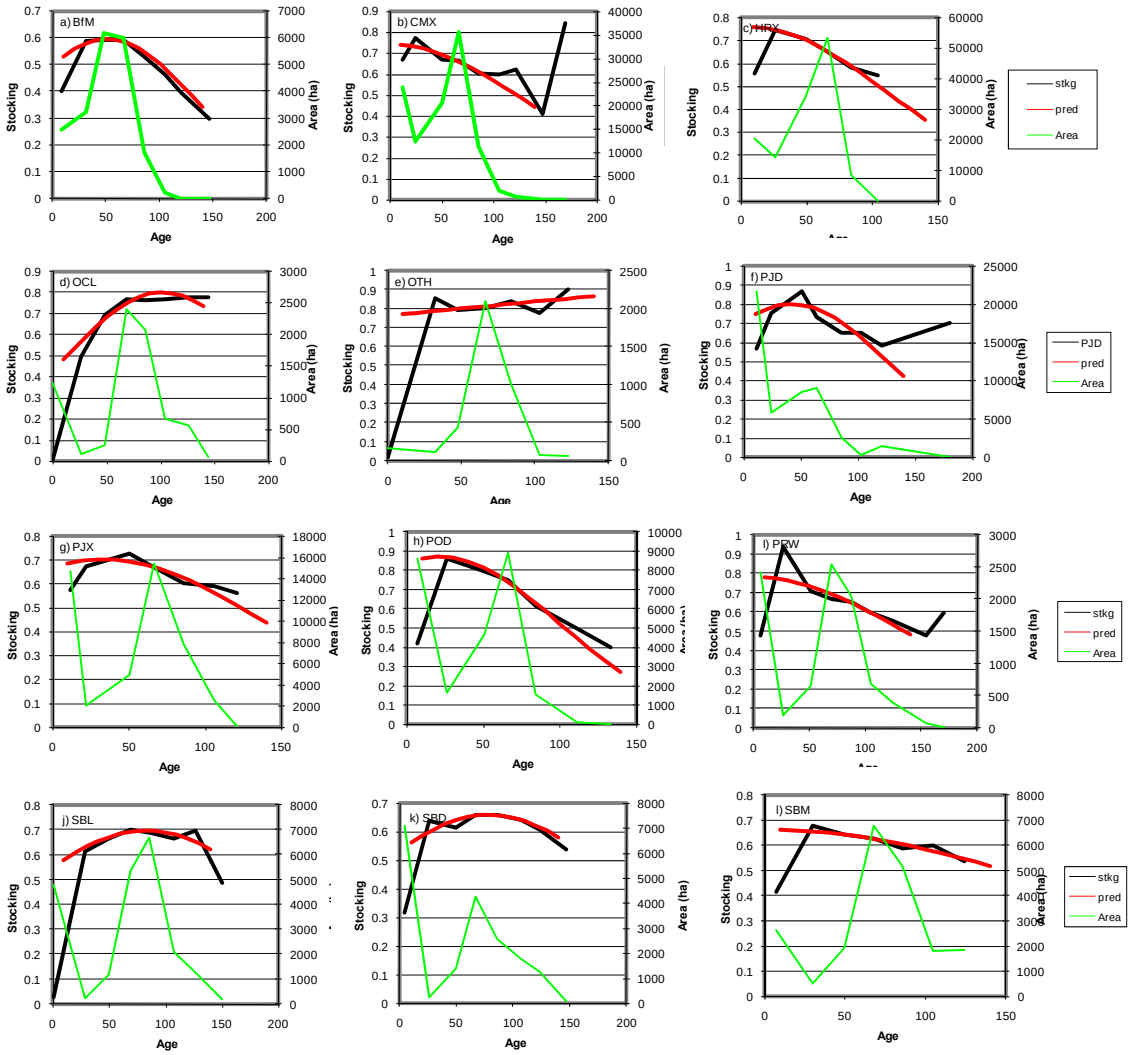

Figure 6. The actual stocking (—), predicted stocking (—) and area (—) are given by age and planFU for the Kenora Forest

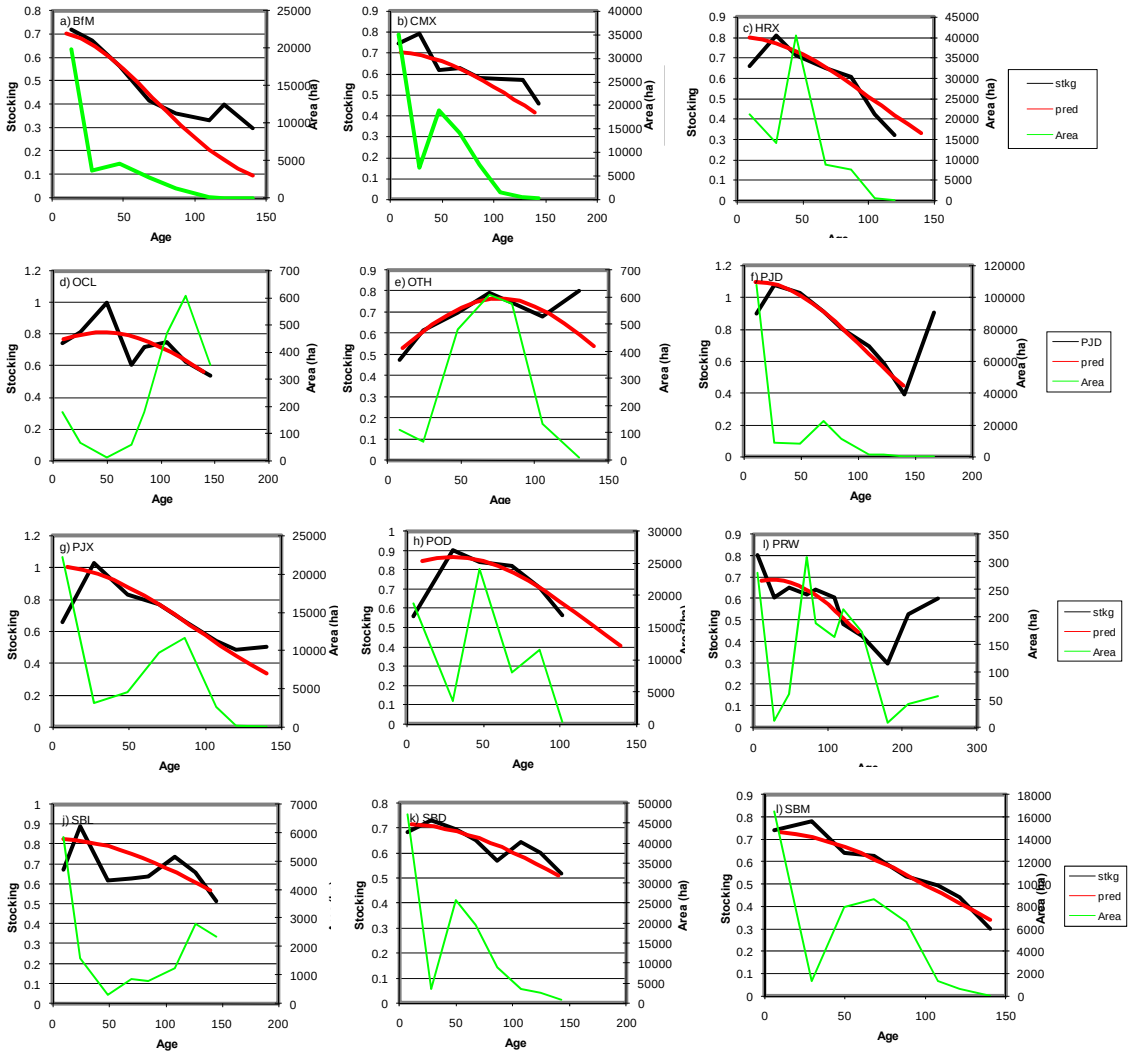

Figure 7. The actual stocking (—), predicted stocking (—) and area (—) are given by age and planFU for the Whiskey Jack Forest.

Appendix B – species composition trends

The species composition trends are given in Figure 8 for the Kenora forest and in Figure 9 for the Whiskey Jack forest.

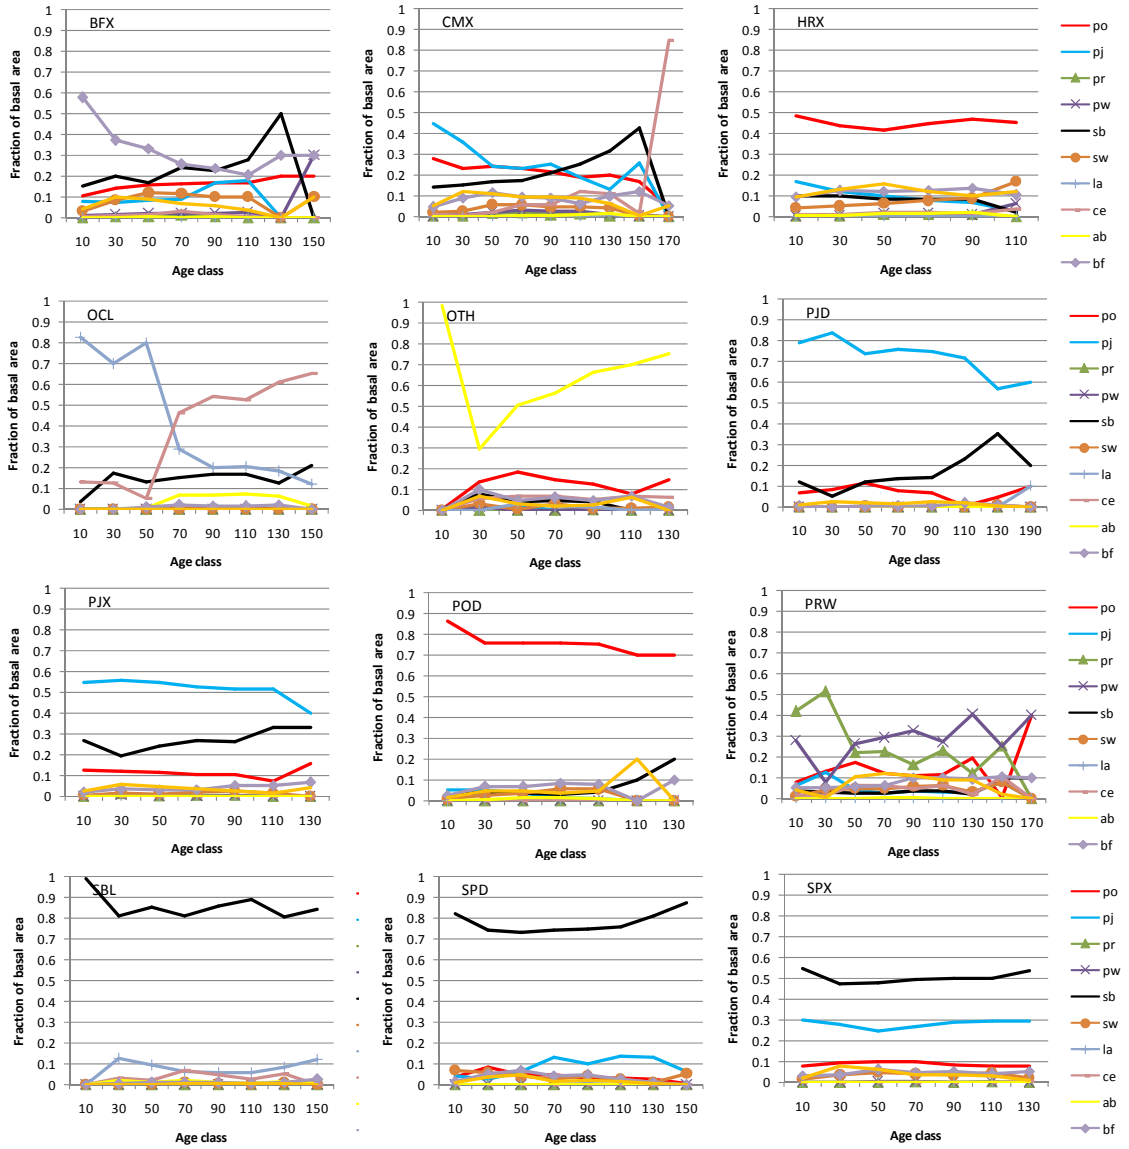

Figure 8. The relationship between species composition and age is given by planFU for the Kenora forest.

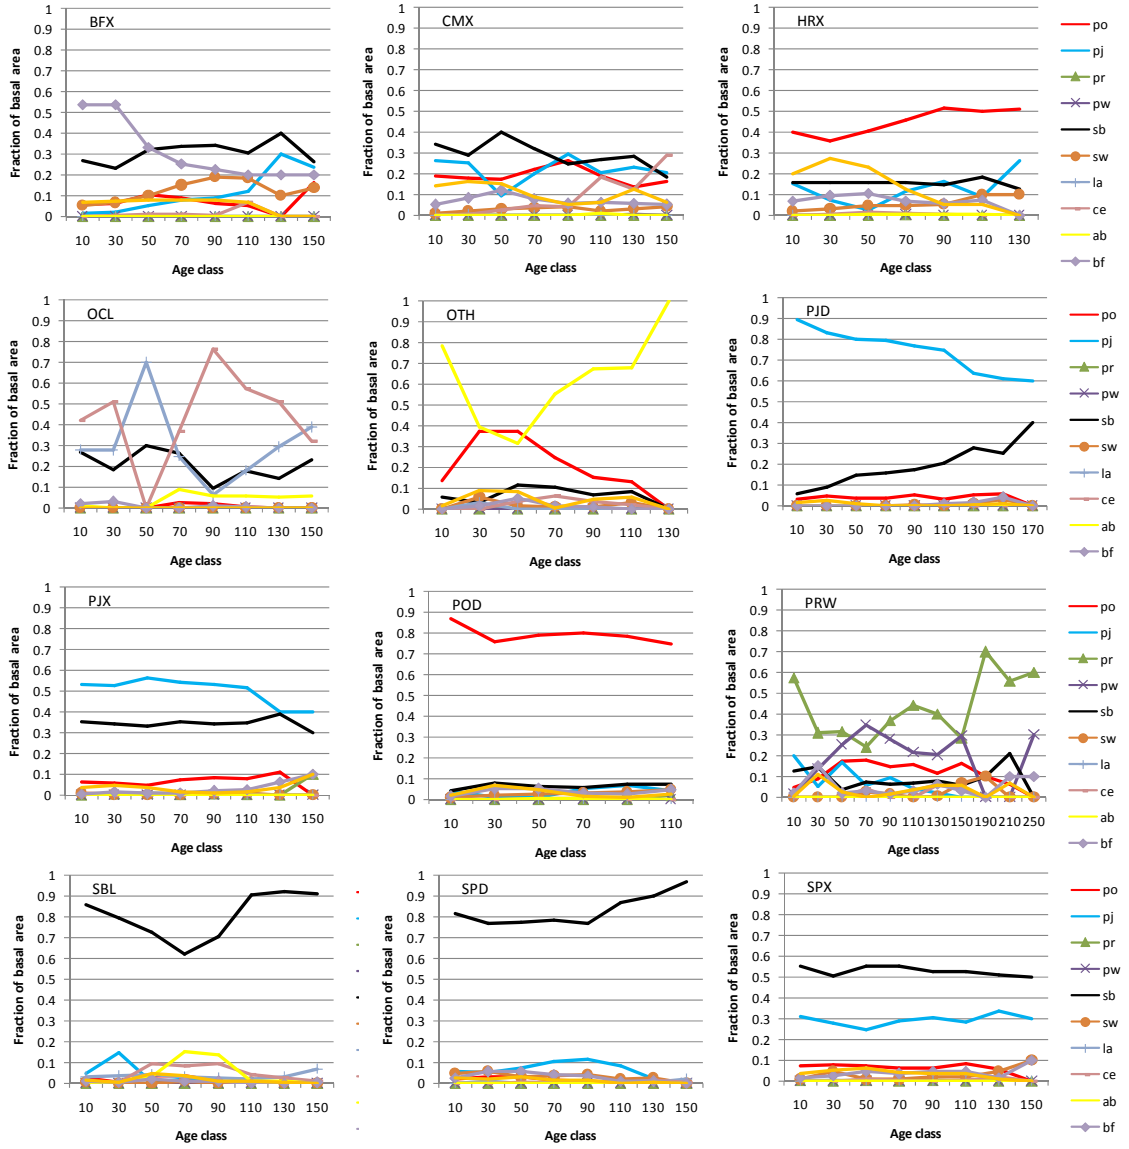

Figure 9. The relationship between species composition and age is given by planFU for the Whiskey Jack forest.

Appendix 2

Summary of Investigation and LTMD Development Results

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATIONS - OVERVIEW**

Desirable levels that are not provided directly by guides or other sources of direction are refined through scoping analysis. Scoping analysis is an iterative process that involves a series of investigations to provide insight to what the forest is capable of producing in order to develop realistic and feasible desirable levels for objective indicators. Scoping investigations will consider implications on wood supply, forest conditions, habitat, and other non-timber resources for the short-term, medium-term, and long-term.

For all investigations, unless specifically noted otherwise, the following management decisions were consistently included in each investigation as per the Base Model:

- management decisions for caribou management (SUBMUs and operational timing)
- large landscape patch deferrals (includes marten habitat management),
- estimated reserve areas as per the Stand and Site Guide (riparian, nests) and estimates of known tourism reserves.
- crude control of projected TOTAL harvest volumes of +/- 20% variance allowed between 10-year terms.
- greatest volume of timber harvested over the entire planning period

Developing Management Objectives

The following investigations will be considered in the development of desirable levels (FMPM A-37):

(a) An investigation into the ability of the forest to meet forest diversity and forest cover desirable levels (based on current forest condition and forest dynamics);

Investigations on impact of forcing the achievement of the SNRV (stay within "box" ASAP) for various Landscape Guide/OLT indicators.

SFMM Case:	Description:	
01-OLT-70	Achieve SNRV for OLT combined - (below) parameters together:	Based on results, can vary when SNRV achievement occurs (i.e. 70 years, 50 years or earlier/later) for OLT runs and the LTMD.
02-OLT-50	Achieve SNRV for mature/late OLT landscape classes	
	Achieve SNRV for OLT old forest classes	
	Achieve SNRV for OLT upland conifer	
	Achieve SNRV for OLT Caribou Habitat (Cr, Cwu, Cwp)	
03-FUgroup	Achieve SNRV for forest units by immature/mature+ stages	Based on results, can vary when SNRV achievement

(b) An investigation and assessment of the ability of the forest to continue to supply forest benefit levels associated with the current forest management plan;

Development of the Proposed Long-term Management Direction

The establishment of targets for each indicator will consider (FMPM A-38):

(a) the current forest condition;
(b) a balance of social, economic and environmental considerations;
(c) the associated indicator and the desirable level;
(d) the potential achievement for the short term (10 years), medium term and long term; and
(e) projections from past forest management plans and historical levels of objective achievement.

In addition, for harvest level indicators, the targets will also consider:

(a) historic wood utilization;

Current wood demand by species group:

SFMM Case:	Description:
04-DEMAND	Achieve approved plan T1 volume for as long as possible

Inputs:

Unlimited budget, will determine if minimum demand volumes by species group are achievable, and for how many terms, and at what future cost to wood.
Binding volume targets added for as long as they can be met. Volume flow constraints infinite for allowable decreases and increases between terms.

Group:	Demand	thousands of m3 per year.
PWR	1.6	from T1 2004 FMP. **BUILT ON OLT_50 investigation, vol targets added.**
SPF	400.0	from T1 2004 FMP.
PO	265.0	from T1 2004 FMP.
BW	25.0	from T1 2004 FMP.
Total	691.6	

(b) Ontario Forest Accord Advisory Board benchmark harvest levels, as identified in the Regional Wood Supply Strategies; and

Benchmark volume by species group (OFAAB):

SFMM Case:	Description:
05-BENCH	Achieve OFAAB benchmark volumes by species group

Group:	Bench	thousands of m3 per year
PWR	0.6	
SPF	354.0	**BUILT ON OLT_50 investigation, vol targets added. Non-binding to allow solve.**
PO	149.0	
BW	4.0	
Total	507.6	

(c) maximum even-flow harvest volume by major species group.

Volume flow constraints of 0% decrease and 0% increase for each species group as individual scoping runs, no volume targets.
Will determine lowest point that can be achieved for timber by each species group in any given term.

SFMM Case:	Description:	
06-Flat-PWR	Even PWR volume all terms	**BUILT ON OLT_50, no vol targets added, only vol flow control.**
07-Flat-SPF	Even SPF volume all terms	
08-Flat-PO	Even PO volume all terms	
09-Flat-BW	Even BW volume all terms	

Next Steps:

10-MS + others	**Integration of all objectives into a LTMD**

Review investigations to determine combinations of target achievement to project the best balance of objective achievement and forest sustainability.
Conflicts in achievmeent of all objectives may dictate the minor refinement of previous decisions or target levels.
Review silvicultural projections and add any management limitations required.
Review any additional desired levels or investigations that are suggested by the planning team, advisors, LCC, etc.
Only key scenarios or conclusions are documented for development of the Proposed LTMD.
Proposed LTMD is reviewed by planning team, LCC, plan advisors (Progress Checklpoint #5) and ultimately the public.

When acceptable, the 10-year harvest from the Proposed LTMD is allocated to confirm that projections are reasonable and able to be implemented.
Spatial analysis is conducted on the proposed allocations. Assessment of objective achievement, determination of sustainability and primary road corridor planning.

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: NATURE11 **Input File:** NATURE11.inp **Date:** July 19, 2010.

Purpose: NATURAL SCENARIO. Use to compare SFMM natural forest dynamics to OLT projections (calibration).

Specific Inputs: Pre-suppression fire cycles by forest unit. Operational and LLP deferrals ON.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS

Implications on Forest Condition -

Good correlation to OLT after iterative review and revisions.
Mature/Late lowland lowland, CMo and SLo compared to OLT.
PWR and SBL forest unit areas consistently lower than OLT projections through time.
Caribou refuge and winter preferred habitat lower than OLT through time.

NOTES:

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: NATURE12 **Input File:** NATURE12.inp **Date:** July 26, 2010.

Purpose: NATURAL SCENARIO. Use to compare SFMM natural forest dynamics to OLT projections (calibration).

Specific Inputs: Pre-suppression fire cycles(5) by forest unit. Adjusted for OLT calibration. Operational and LLP deferrals ON.
SUBMU revision for WC1 incorporated (most not caribou zone)

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS

Implications on Forest Condition - Good correlation to OLT after iterative review and revisions.
Mature/Late lowland lowland, CMo and SLo compared to OLT.
PWR and SBL forest unit areas consistently lower than OLT projections through time.
Caribou refuge and winter preferred habitat lower than OLT through time.

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 01_Base **Input File:** 01_Base.inp **Date:** July 27, 2010.

Purpose: BASE MODEL inputs only. Use as building block for harvest investigations. Not a viable LTMD option without target achievement incorporated.

Specific Inputs: BASE model inputs. Suppression fire cycle of 299 years. Operational and LLP deferrals ON, budget infinite.
Harvest TOTAL Volume flow control of +/- 20% between terms to very roughly control volumes through time.
Updated with final forest dynamics refinements.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS

Implications on Forest Condition - No targets for OLT achievement. Will need controls for mature Landscape Classes and Old Forest.
Harvest declines significantly through next 60 years until marten deferrals off and caribou SUBMUs are operable.
Harvest area and volumes will need regulation for predictability.
PRW and SBL forest unit areas are lower than OLT projections - same underachievement as NATURE. HMX also low.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 01_OLT_70 **Input File:** 01_OLT_70.inp **Date:** July 27, 2010.

Purpose: Investigation to see if OLT minimum SNRV targets are achievable in 70 years and maintained thereafter.

Specific Inputs: BASE MODEL inputs plus minimum SNRV for OLT landscape classes, old forest, caribou habitat and upland conifer from T8 onwards as per OLT min below. MLb, SLo no targets added.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS

Implications on Forest Condition -

Min SNRVs (or better) achieved T8 onwards, except for MLI, SLo as noted above. No forest unit targets included.
PRW and SBL underachieved - calibration issue - not resolved with targets. HMX low but may be able to be improved.
Good caribou habitat projections with targets.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 02_OLT_50 **Input File:** 02_OLT_50.inp **Date:** July 27, 2010.

Purpose: Investigation to see if OLT minimum SNRV targets are achievable in 50 years and maintained thereafter.

Specific Inputs: BASE MODEL inputs plus minimum SNRV for OLT landscape classes, old forest, caribou habitat and upland conifer from T6 onwards as per OLT min below.
MLI, SLo no targets added.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS

Implications on Forest Condition - Min SNRVs achieved T6 onwards, except for MLb, SLo as noted above.
Min SNRV can be generally achieved in 50 years, or earlier.
PRW and SBL underachieved - calibration issue - no targets added to fix. HMX low but may be able to be improved.
Good caribou habitat projections with targets.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 03_FUgroup **Input File:** 03_FUgroup.inp **Date:** July 27, 2010.

Purpose: Investigation to see if forest unit grouping minimum SNRV targets are achievable in 50 years and maintained thereafter.

Specific Inputs: BASE MODEL inputs plus minimum SNRV for OLT forest unit area projections for all and mature+ ages from T6 onwards as per OLT min below (except PRW, SBL).

No min SNRV targets possible for OCL, OTH and SBL mature+ groups.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS

Implications on Forest Condition -

AllAC min OLT achieved immature for all forest units except PRW, SBL (as noted above).
AllAC min OLT achieved mature+ for all forest units except OCL, OTH and SBL (as noted above).
Matching forest unit groupings does not accommodate OLT Landscape Classes (that receive higher priority in achievement).
Worse achievement for caribou habitat when targets are only by forest unit age grouping.

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 04_DEMAND **Input File:** 04_DEMAND.inp **Date:** July 27, 2010.

Purpose: Investigation to how long Term 1 2004 FMP harvest volume is achievable with OLT minimum SNRV targets from T6 onwards.

Specific Inputs: 02_OLT_50 inputs plus lower volume targets by species group from 2004 FMP, and deleted volume flow controls. Non-binding.

Group:		thousands of m3 per year.
PWR	1.6	from T1 2004 FMP.
SPF	400.0	from T1 2004 FMP.
PO	265.0	from T1 2004 FMP.
BW	25.0	from T1 2004 FMP.
Total	691.6	

TOTAL vol flow +/- 20% between terms.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS

Implications on Forest Condition - OLT forest condition projections good due to constraints included in model (except MLI, Slo, PRW, SBL).
Forest unit total area generally good, but underachievement of PJD and PJM mature+ area.
Caribou habitat good.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 05_BENCH **Input File:** 05_BENCH.inp **Date:** July 27, 2010.

Purpose: Investigation to see if OFAAB Benchmark harvest volume is achievable with OLT minimum SNRV targets.

Specific Inputs: 02_OLT_50 inputs plus lower volume targets by species group from OFAAB Benchmark, non-binding.

Group:	Bench
PWR	0.6
SPF	354.0
PO	149.0
BW	4.0
Total	507.6

thousands of m3 per year.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS

Implications on Forest Condition - OLT forest condition projections good due to constraints included in model (except MLI, SPo as per NATURE).
Total forest unit area underachievement of PRW and SBL. Underachievment of PJD and PJM mature+ area (no constraints included).
HMX low in later terms but is controllable with added constraint if needed.
Caribou habitat projections good.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name:	**06-Flat-PWR**	**Input File:**	06-Flat-PWR.inp	**Date:** July 27, 2010.
	07-Flat-SPF		07-Flat-SPF.inp	
	08-Flat-PO		08-Flat-PO.inp	
	09-Flat-BW		09-Flat-BW.inp	

All runs based on OLT_50 so achievement of landscape class area, caribou habitat and old forest area is similar (or higher than 05_OLT_50).

Results	**Even Flow Volumes (m3 /year)**	**Non-declining volumes: (Info point only, not saved cases.)**
06-Flat-PWR	1,290 m3	1,290 increases to 1,431 in T9 and then 2,178 in T13 and 2,200 in T15.
07-Flat-SPF	392,370 m3	389,174 then increases to 474,804 T7 to end.
08-Flat-PO	110,507 m3	110,051 limited to T6, then incr to 117,878 in T7. Incr to 134,591 in T15.
09-Flat-BW	17,467 m3	Same as even flow, so limited by last term.
09-Flat-TOTAL	551,399 m3	546,319 m3 to T6, then incr to 616,460 m3 in T7-T14, then incr to 705,091 m3 for T15.

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 10_MS **Input File:** 10_MS.inp **Date:** July 27, 2010.

Purpose: Start of MS development with harvest volume targets and OLT minimum SNRV targets.

Specific Inputs: 02_OLT_50 inputs plus lower volume targets by species group as below. Non-binding. Balanced budget.

Group:		thousands of m3 per year.
PWR	1.5	T1 only
SPF	390.0	all terms
PO	200.0	T1 only
BW	20.0	T1 only
Total	600.0	all terms

Added non-constraining deferral for WC2 as LLP_00 for future investigations.

(Lower than 2004 FMP (265), but higher than even flow (110)).

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

FOREST CONDITION RESULTS

Implications on Forest Condition -

OLT forest condition projections good due to constraints included in model (except MLI, SLo as per NATURE).
Total forest unit area underachievement of PRW and SBL. Underachievment of PJD and PJM mature+ area (no age constraints included).
HMX total low in later terms but is controllable with added constraint if needed. POD increases significantly.
Caribou habitat projections good.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 10_MS **Input File:** 10_MS.inp **Date:** July 27, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF >390 all terms. PO met at 200 in Term 1, then avg 160 for T2-T3. Then lower T4-6.
Spike in total and SPF in T7 when LLP deferrals OFF, artificial gain but can control with incr targets or flow control.
AHA had big jump T1 to T2 CMX harvest. T5-6 lower AHA and vol limited by LLP deferrals and SUBMU timing.

Available Harvest Area by Term Data (hectares harvested annually)

NOTES:

Review targets - is 200 PO T1 adequate or is 265 from 2004 FMP actual hardwood demand?
Confirm SUBMUs operable for 10 years or open to 20 year window?

Mature+ forest unit area - investigate adding targets for mature+ OCL, PJD and PJM.

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 11_MS **Input File:** 11_MS.inp **Date:** July 27, 2010.

Purpose: Start of MS development with harvest volume targets and OLT minimum SNRV targets.

Specific Inputs: 10_MS inputs plus lower volume targets by species group as below. Non-binding. Balanced budget. Forest unit age group constraints to improve results.

Group:		thousands of m3 per year.	10% decr TOTAL between terms.
PWR	1.5	T1 only	
SPF	390.0	all terms	
PO	200.0	T1 only	(Lower than 2004 FMP (265), but higher than even flow (110)).
BW	20.0	T1 only	
Total	550.0	all terms	

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - OLT forest condition projections good due to constraints included in model (except MLI, SLo as per NATURE).
Total forest unit area underachievement of PRW and SBL. Improved forest unit by age group achievement (age constraints included).
POD increases significantly without constraint (as in 10_MS). Trade-off for lower POD area is significantly lower PO harvest vol.
Caribou habitat projections good.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 11_MS **Input File:** 11_MS.inp **Date:** July 27, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF >390 all terms. PO only 164 in Term 1, then decreases to T5.

TOTAL relatively even through time. Minor spike in SPF in T7 when LLP deferrals OFF, artificial gain. Big loss in HMX harvest by capping POD mature area.

AHA HMX and PJM no harvest in T2. T4-5 lower AHA and vol limited by LLP deferrals and SUBMU timing.

Available Harvest Area by Term Data (hectares harvested annually)

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 12_medOLT — **Input File:** 12_medOLT.inp — **Date:** July 29, 2010.

Purpose: Investigate borad impact of meeting OLT median values.

Specific Inputs: 10_MS revised with OLT median values for LC, old forest and car hab met T11 onwards (except PSp, MLI, Clo, Slo, and reduced car hab between low and med points)

Group:	
PWR	
SPF	
PO	
BW	
Total	

thousands of m3 per year. TOTAL vol +/- 20% between terms.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - Most OLT forest condition projections good through long-term but takes longer than MS runs to get higher areas.
Total forest unit area little worse than controlled MNS. Mature+ area not meeting ranges.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 14_OLT50+ **Input File:** 14_OLT50+.inp **Date:** July 29, 2010.

Purpose: OLT indicator investigation with min SNRV targets increased towards median.

Specific Inputs: OLT_50 raised above lower SNRV. No volume targets, flow TOTAL volume of -10% decr and 20% incr between terms. Infinite budget.

Group:	
PWR	
SPF	
PO	
BW	
Total	

thousands of m3 per year.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - OLT forest condition projections good due to increased constraints included in model (except MLI, SLo as per NATURE).
Total forest unit area underachievement of PRW and SBL. Underachievement of PJD and PJM mature+ area (no age constraints included).
HMX total low in later terms.
Upland conifer and Caribou habitat projections good.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 14_OLT50+ **Input File:** 14_OLT50+.inp **Date:** July 29, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF varies 228-519. PO T1 170, then 273 in T2. Need to regulate short-term flow better.
TOTAL varies 471 to 737 with very broad flow control. (overall average of 577 Mm3 per year)

Available Harvest Area by Term Data (hectares harvested annually)

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 15_MS **Input File:** 15_MS.inp **Date:** July 28, 2010.

Purpose: Start of MS development with harvest volume targets and OLT minimum SNRV targets.

Specific Inputs: 02_OLT_50 inputs plus lower volume targets by species group as below. Non-binding. Balanced budget. Mature+ FU constraints added for PJD and PJM.

Group:		thousands of m3 per year.	10% decr TOTAL between terms.
PWR	1.5	T1 only	
SPF	390.0	all terms	
PO	200.0	T1 only	
BW	20.0	T1 only	
Total	550.0	all terms	

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - OLT forest condition projections good due to constraints included in model (except MLI, SLo as per NATURE).
Total forest unit area underachievement of PRW and SBL. Underachievment of PJD and PJM mature+ area (no age constraints included).
HMX total low in later terms but is controllable with added constraint if needed. POD increases significantly.
Caribou habitat projections good.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 15_MS **Input File:** 15_MS.inp **Date:** July 28, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF >390 all terms. PO met at 200 in Term 1, then avg 160 for T2-T3. Then lower T4-6.
Spike in total and SPF in T7 when LLP deferrals OFF, artificial gain but can control with incr targets or flow control.
AHA had big jump T1 to T2 CMX harvest. T5-6 lower AHA and vol limited by LLP deferrals and SUBMU timing.

Available Harvest Area by Term Data (hectares harvested annually)

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 16_MS **Input File:** 16_MS.inp **Date:** July 28, 2010.

Purpose: MS development with harvest volume targets, OLT minimum SNRV targets, some forest unit/age improvements.

Specific Inputs: 15_MS with minor additions for mature+ forest unit area in long-term. Min for total HMX long-term.

Group:		thousands of m3 per year.	10% decr TOTAL between terms.
PWR	1.5	T1 only	
SPF	390.0	all terms	
PO	200.0	T1 only	
BW	20.0	T1 only	
Total	550.0	all terms	

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - OLT forest condition projections good due to constraints included in model (except MLI, SLo as per NATURE).
Total forest unit area underachievement of PRW and SBL. Mature+ forest unit area good due to constraints.
HMX total improved in later terms due to constraints. POD increases.
Caribou habitat projections good.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 16_MS **Input File:** 16_MS.inp **Date:** July 28, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF >390 all terms. PO met at 200 in Term 1, then avg 160 for T2-T3. Then lower T4-6.
Spike in total and SPF in T7 when LLP deferrals OFF, artificial gain but can control with incr targets or flow control.
AHA had big jump T1 to T2 CMX harvest. T5-6 lower AHA and vol limited by LLP deferrals and SUBMU timing.

Available Harvest Area by Term Data (hectares harvested annually)

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 17_MS **Input File:** 17_MS.inp **Date:** July 28, 2010.

Purpose: MS development with harvest volume targets, OLT min SNRV, some forest unit/age improvements, balanced wood supply.

Specific Inputs: 16_MS with added non-binding volume targets for more reliable and even projections as noted below with improved PO projections.

Group:		thousands of m3 per year.
PWR	1.5	T1-T2 only
SPF	350.0	T1-T2 only
PO	200.0	T1-T2 only then T3-T15 at 100.00
BW	20.0	T1-T2 only
Total	500.0	all terms

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - OLT forest condition projections good due to constraints included in model (except MLI, SLo as per NATURE).
Total forest unit area underachievement of PRW and SBL. Mature+ forest unit area good due to constraints.
HMX total improved in later terms due to constraints. POD increases.
Caribou habitat projections good.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 17_MS **Input File:** 17_MS.inp **Date:** July 28, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF >350 all terms. PO met at 200 in Term 1-2, then T3 is at 100. Below 100 for T4-6.
Spike in total and SPF in T7 when LLP deferrals OFF, artificial gain but can control with incr targets or flow control.
AHA had jump T1 to T2 CMX harvest. T4-5 lower AHA. T9 vol has more PO and less SPF if not constrained.

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 19_OLTFU — **Input File:** 19_OLTFU.inp — **Date:** July 29, 2010.

Purpose: OLT indicator investigation with min SNRV targets increased towards median and improvements on forest unit achievement.

Specific Inputs: OLT_50 raised above lower SNRV (some reductions within SNRV from Run 15 to allow solve). Some mat+ FUgroup constraints PJD, PJM, OTH, HMX. No volume targets, flow TOTAL volume of -10% and +15% between terms. Balanced budget.

Group:	
PWR	
SPF	
PO	
BW	
Total	

thousands of m3 per year.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - OLT forest condition projections good due to increased constraints included in model (except MLI, SLo as per NATURE).
Total forest unit area underachievement of PRW and SBL.
Upland conifer and Caribou habitat projections good.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 19_OLTFU **Input File:** 19_OLTFU.inp **Date:** July 29, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF varies 325-464. PO T1 172, then 222 in T2. Consider need to regulate short-term flow better.
TOTAL varies T1 659 to T5 432 with broad flow control. (overall average of 534 Mm3 per year)

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 20_OLTPO **Input File:** 20_OLTPO.inp **Date:** July 30, 2010.

Purpose: OLT indicator investigation with min SNRV targets increased towards median and improvements on forest unit achievement, PO T1-2 and TOTAL in lowest terms.

Specific Inputs: Start with 19_OLTFU (OLT_50 raised above lower SNRV, some reductions within SNRV from Run 15 to allow solve, Some mat+ FUgroup constraints PJD, PJM, OTH, HMX.) Add Binding volume targets for PO at T1 200, T2 150, T3-6 90 and TOTAL at 520 all terms. Balanced budget.

Group:		thousands of m3 per year.
PWR		
SPF		
PO	200.0	T1 only, then T2 150, T3-6 90.
BW		
Total	520.0	all terms to raise harvest in lowest terms

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - OLT forest condition projections good except MLI and SLo.
Total forest unit area underachievement of PRW and SBL.
Upland conifer and Caribou habitat projections good.

(2a) Productive Area by Landscape Class

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 22_OLTPO **Input File:** 22_OLTPO.inp **Date:** Aug. 5, 2010.

Purpose: Revise caribou subunits and deferrals to align with marten cores and add operational deferrals for 40 years. Other LLPs deferred only 30 years, not 60.

Specific Inputs: Run 20 with a revised land base (BMIv7), deferrals, and deferral timing. All other targets the same as Run 20.

Group:		thousands of m3 per year.
PWR		
SPF		
PO	200.0	T1 only, then T2 150, T3-6 90.
BW		
Total	520.0	all terms to raise harvest in lowest terms

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - OLT forest condition projections good except MLI and SLo.
Total forest unit area underachievement of PRW and SBL.
Upland conifer and Caribou habitat projections good.
Similar to Run 20 achievement.

Case Name: 22_OLTPO **Input File:** 22_OLTPO.inp **Date:** Aug. 5, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF varies 321 (T1) to 425 (T15). More available with revised deferrals. PO T1 200,T2 150, then 95 T3-6 as per targets.
TOTAL varies T1 563 decr to min 520. (overall slightly increased average of 527 Mm3 per year with revised deferrals).

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 23_OLTMS **Input File:** 23_OLTMS.inp **Date:** Aug. 5, 2010.

Purpose: Revise caribou subunits and deferrals to align with marten cores and add operational deferrals for 40 years. Other LLPs deferred only 30 years, not 60.

Specific Inputs: Run 22 with deferral for LLP_26 ON for 60. TOTAL T6-7 reduced to 500. All other targets the same as Run 22.

Group:		thousands of m3 per year.
PWR		
SPF		
PO	200.0	T1 only, then T2 150, T3-6 90.
BW		
Total	520.0	all terms to raise harvest in lowest terms, except T6-7 at 500.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition - OLT forest condition projections good except MLI and SLo.
Total forest unit area underachievement of PRW and SBL.
Upland conifer and Caribou habitat projections good.
Similar to Run 20 and 23 achievement.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 23_OLTMS **Input File:** 23_OLTMS.inp **Date:** Aug. 5, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF varies 288 (T1) to 421 (T11). PO T1 200,T2 150, then 90 T3-6 as per targets.
TOTAL varies T1 563 decr to min 500. (overall slightly increased average of 527 Mm3 per year with revised deferrals).
Better balance of CMX and HMX AHA T1-2. Looks to be operationally implementable.

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 27_OLTMS **Input File:** 27_OLTMS.inp **Date:** Aug. 18, 2010.

Purpose: Run 23 with non-declining PRW forest unit area.

Specific Inputs: Run 23 with non-declining PRW forest unit productive area. Reduced CMo old forest achievement target (21,000 ha), but still above lower SRNV.

Group:		thousands of m3 per year.
PWR		
SPF		
PO	200.0	T1 only, then T2 150, T3-6 90.
BW		
Total	520.0	all terms to raise harvest in lowest terms.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition -
OLT forest condition projections good except MLI and SLo.
Total forest unit area underachievement of PRW and SBL. PRW forest unit productive area maintained through time.
Upland conifer and Caribou habitat projections good.
Similar to Run 23 achievement.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 27_OLTMS **Input File:** 27_OLTMS.inp **Date:** Aug. 18, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF varies 306 (T1, improved) to 417 (T4). PO T1 200,T2 150, then 90 T3-6 as per targets.
TOTAL varies T1 549, decr to min 520 for rest of terms.
Looks to be operationally implementable. More PJD T1 than Run 23. Includes minor SBL AHA area. Improved balance of HMX T1-3.

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 27a_OLTMS **Input File:** 27a_OLTMS.inp **Date:** Sept. 25, 2010.

Purpose: Run 27 with initial land base adjustment for SBL PLANFU area and added min PRW AHA and max SBL harvest area.

Specific Inputs: Run 27 with adjusted SPD to SBL initial land base and deferrals, min T1 PRW AHA 10 ha, max SBL AHA T1-3 80 ha. Delayed Upland Conifer achievement from T6 to T7 (still 460,000 ha). Other contraints same as Run 27. Add min target to maintain mature/late SBL, M/L Lowland and SLo forest.

Group:		thousands of m3 per year.
PWR		
SPF		
PO	200.0	T1 only, then T2 150, T3-6 90.
BW		
Total	520.0	all terms to raise harvest in lowest terms.

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SNRV.

Implications on Forest Condition -
OLT forest condition projections good - improved (MLI and Slo) with increased SBL area.
Total forest unit area underachievement of PRW. PRW forest unit productive area maintained through time.
Upland conifer met T7 (Run 27 in T6) due to less SPD at plan start with SBL adjustment. Caribou habitat projections still good.
Similar to Run 27 achievement - improved lowland OLT achievement in this run.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 27a_OLTMS **Input File:** 27a_OLTMS.inp **Date:** Sept. 25, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - SPF varies 280 (T1) to 408 (T6). PO T1 200,T2 150, then 90 T3-6 as per targets.
TOTAL steady at 520 Mm3per year all terms (521 T1).
Looks to be operationally implementable. Includes minor SBL and PRW AHA area. Drop in harvest of HMX T2, but PO harvested from POD.

Available Harvest Area by Term Data (hectares harvested annually)

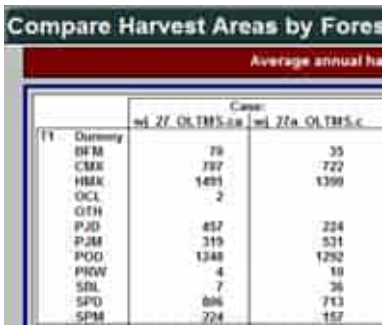
NOTES:

Revision of SBL area does not change projected forest condition or socio-economic results of Run 27 significantly.
Good to allocate and assess spatially.

Addition of lowland OLT SRNV targets causes shift in some projected available harvest areas by forest unit, compared to Run 27:



WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 27d_OLTMS **Input File:** 27d_OLTMS.inp **Date:** Dec. 16, 2010.

Purpose: Run 27a with initial land base adjustment for additional operational reserves and deferrals.

Specific Inputs: Run 27a with adjusted available, reserve and deferrals as per BMIv11 Dec. 11, 2010. Volume targets adjusted to include SPF and PO targets. OLT targets similar to Run 27a with minor reduction of MLI, BFo and PJo (still within SRNV box).

Group:	
PWR	
SPF	
PO	
BW	
Total	

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SRNV.

Implications on Forest Condition -

Good projections for forest composition and age due to targets included in the modelling.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 27d_OLTMS **Input File:** 27d_OLTMS.inp **Date:** Dec. 16, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - Projected SPF more even in this scenario (due to binding targets, regional request), though TOTAL varies more through time.
Poplar volume reduced slightly in T1-2 as compared to previous runs, but still within acceptable range.
Added reserves and deferrals resulted in harvest areas that are able to be operationally allocated.

Available Harvest Area by Term Data (hectares harvested annually)

NOTES:
Chosen by Planning Team as revised LTMD.

Investigate impact of 10% intensive treatment biological limit for PJD, PJM, SPD, SPM (see Run 27e_INTEN).
Run 27d_OLTMS has unspent funding in T1-2 therefore increased intensive renewal can be planned during plan implementation, IF APPROPRIATE SITES can be found.
Precautionary principle applied in 27d to not over estimate success by intensity where SEM data does not support the assumptions on WJF sites.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 27e_INTEN — **Input File:** 27e_INTEN.inp — **Date:** Jan. 4, 2011.

Purpose: Run 27d with increased biological limit for Pj, Sb intensive renewal.

Specific Inputs: Run 27d with maximum intensive renewal for PJD, PJM, SPD and SPM at 75%.
No other changes to inputs including no change to PRFS transitions or costs or resulting volume yields.

Group:	
PWR	
SPF	
PO	
BW	
Total	

75% suggested by region to show if a significant difference in biological limits would change the solution (comparative run).
It is expected that the successful regeneration of 75% of PJ or SP to intensive density regulated status would be significantly more expensive than is already included in the modelling and that the forest unit transitions and balance of Basic vs Intensive treatments would have to be adjusted (to not over estimate suitable sites or success).

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SRNV.

Implications on Forest Condition -

Similar OLT forest composition achievement as same targets were incorporated.
SPD overachieves at a slightly higher level than 27d with increased intensive renewal allowed.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 27e_INTEN **Input File:** 27e_INTEN.inp **Date:** Jan. 4, 2011.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - Similar results as Run 27d_OLTMS. Same average total harvest volume T1-4 with increased bio limits for intensive.
Marginally more SPF volume in T7-10 with increased intensive renewal treatments (assuming results are achievable).
Intensive treatment approx 300 ha more in T1, and 800 ha more T2-4 with increased biological limits. Avg cost increase of $84,000/yr T1-4.

NOTES:

Achievement of increased biological limits for same forest unit transitions, treatment costs and projected density-regulated growth and yield not supported by local SEM data.
Run 27d_OLTMS has unspent funding in T1-2 therefore increased intensive renewal can be planned during plan implementation, IF APPROPRIATE SITES are identified.
Precautionary principle was applied in the Base Model to not over estimate success by intensity where SEM data does not support higher assumptions on WJF sites.

Impact of not spending the extra $84,000/year T1-4 is a loss of total harvest volume of 5,000 m3/year for the next 150 years (Run 27d_OLTMS). If intensive treatment will actually result in a density regulated condition, then a slightly lower proportion of large sawlogs will also result if the additional intensive treatments are not conducted (as per 27e_INTEN).
SFMM does not project an increase in PJM and SPM intensive treatments even if biological limits are increased - change occurs in SPD and PJD.

The biological limit proportions of Basic and Intensive renewal treatments must consider that successful intensive results are limited to certain ecosites, species compositions, site classes and site related management conditions. SEM data for the forest also is considered to correlate intensive treatments to actual density regulated successes (as defined in the silvicultural intensity and as considered consistently in the post-renewal forest unit transitions and growth and yield assumptions).

BASIC intensity stands: All areas renewed with seeding or low density plantation/natural regeneration combination resulting in a non-density regulated stand. Tending will occur on some basically treated sites. (Also intensively treated stands that do not achieve well stocked, density-regulated intensive SI results are classified as basic stands.)

INTENSIVE stands: All stands identified as well stocked, density-regulated plantations. These areas include planted areas as well as spaced, seeded areas> Most Intensive stands will have received some tending for forest composition or competition control (and potentially multiple tending treatments).

WHISKEY JACK FOREST 2012 FMP — **SUMMARY of SFMM INVESTIGATION**

Case Name: 27d_OLTMS **Input File:** 27d_OLTMS.inp **Date:** Dec. 16, 2010.

Purpose: Run 27a with initial land base adjustment for additional operational reserves and deferrals.

Specific Inputs: Run 27a with adjusted available, reserve and deferrals as per BMIv11 Dec. 11, 2010. Volume targets adjusted to include SPF and PO targets. OLT targets similar to Run 27a with minor reduction of MLI, BFo and PJo (still within SRNV box).

Group:	
PWR	
SPF	
PO	
BW	
Total	

RESULTS: Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

FOREST CONDITION RESULTS Where projections do not relate to OLT projections, font is coloured red and results are not expected to correlate to OLT SRNV.

Implications on Forest Condition -

Good projections for forest composition and age due to targets included in the modelling.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

Case Name: 27d_OLTMS **Input File:** 27d_OLTMS.inp **Date:** Dec. 16, 2010.

HARVEST AREA and VOLUME RESULTS:

Implications on Wood Supply - Projected SPF more even in this scenario (due to binding targets, regional request), though TOTAL varies more through time.
Poplar volume reduced slightly in T1-2 as compared to previous runs, but still within acceptable range.
Added reserves and deferrals resulted in harvest areas that are able to be operationally allocated.

Available Harvest Area by Term Data (hectares harvested annually)

NOTES:
Chosen by Planning Team as revised LTMD.

Investigate impact of 10% intensive treatment biological limit for PJD, PJM, SPD, SPM (see Run 27e_INTEN).
Run 27d_OLTMS has unspent funding in T1-2 therefore increased intensive renewal can be planned during plan implementation, IF APPROPRIATE SITES can be found.
Precautionary principle applied in 27d to not over estimate success by intensity where SEM data does not support the assumptions on WJF sites.

WHISKEY JACK FOREST 2012 FMP **SUMMARY of SFMM INVESTIGATION**

2012 - 2022
Forest Management Plan
for the
Whiskey Jack Forest

Summary Text

Summary of the 2012 to 2022 Whiskey Jack Forest Management Plan

Location

The Whiskey Jack Forest Management Unit (MU) is located within the Kenora District and the Northwest Region of the Ministry of Natural Resources (MNR).

Public Contacts

The public contacts for the plan are:

Kurt Pochailo, R.P.F.	Plan Author	(807) 468-2597
Deb Weedon	MNR District Manager	(807) 468-2501
Wayne Bruce	Kenora LCC representative	
Dutchie Loman	Red Lake LCC Representative	

Management Responsibility

The Whiskey Jack Forest (Management Unit #490) has been a Crown Management Unit since Abitibi Company of Canada surrendered the Sustainable Forest Licence in August 2009. The Kenora District MNR administers its forest management planning activities and operations from the MNR District office located in Kenora, Ontario. More details about the administration of the forest can be found in section 1 of the plan. The management unit description is included in section 2 of the plan.

Local Citizen's Committee Participation

A member of the local citizen's committee (LCC) has participated in the preparation of the forest management plan as a planning team member and attended all information sessions. The proposed management strategy, long-term management direction and draft forest management plan were presented to the committee and input was requested on these products as well as the background information.

The LCC has prepared a brief statement of agreement or disagreement with the draft plan. This statement and the full LCC report can be found in the plan electronic submission.

Long-term Management Direction Summary

The Long-term Management Direction (LTMD) for the forest provides guidance for the levels of access, harvest, renewal and tending activities required to achieve the desired future forest and benefits. In the development of the LTMD, management objectives and indicators are identified and analytical methodologies, models and tools regarding forest regulation, social and economic assessment, wildlife habitat supply and landscape management are used. This is discussed in section 3 of the FMP which references supporting details found in the supplementary documentation to the plan.

The long-term management direction provides a means of assessing the sustainability of the management strategy through the measurement and monitoring of indicators that have been developed for each management objective. It is expected that a balanced achievement of the

quantitative and qualitative biological, social and economic objectives, will result in the desired long-term future forest condition and benefits.

Plan Objectives and Indicators

As required by the *Crown Forest Sustainability Act*, management objectives for the Whiskey Jack Forest must be compatible with the sustainability of the Crown forest, and indicators of objective achievement must be identified. In addition, the *Crown Forest Sustainability Act* requires that each FMP contain management objectives relating to:

(a) Crown forest diversity, including consideration for the conservation of natural landscape patterns, forest structure and composition, habitat for animal life and the abundance and distribution of forest ecosystems;

(b) Social and economic factors, including harvest levels and a recognition that healthy forest ecosystems are vital to the well-being of Ontario communities;

(c) The provision of forest cover for those values that are dependent on the Crown forest; and

(d) Silviculture for the harvest, renewal and maintenance of the Crown forest.

Table FMP-9 (located in Section 9.0) summarizes management objectives, indicators, desirable levels and associated targets and presents an assessment of achievement of desirable levels for each objective, for those which can be assessed at this time. The management objectives, indicators, desirable levels and targets were developed with input from the Kenora Local Citizens Committee (through the Desired Forest and Benefits meetings), the planning team, and MNR advisors. Sources of information considered in their development included, but were not limited to: the current FMP; background information; forest management guides and policies; Reports of Past Forest Operations; MNR forest management planning direction and training, and scoping investigations for the 2012 to 2022 FMP.

For each management objective, at least one indicator of objective achievement was developed, along with an associated desirable level(s) and target(s). Some objectives have multiple indicators to measure achievement. A desirable level is a specific number, a range or a trend for an indicator, to be achieved and maintained over time. As with desirable levels, targets are specific numbers, ranges, or trends, with a timeframe for achievement. The establishment of targets for each objective reflected a balancing of objective achievement and considered:

(a) Social, economic and environmental considerations;
(b) The associated indicator and its desirable level;
(c) The current forest condition; and,
(d) The short-term (10 years), medium-term (20 years) and long-term (80-100 years).

The rationale used in setting desirable levels and targets is summarized in section 3.5 of the plan. Modelling with the Strategic Forest Management Model (SFMM) assisted in quantitative scoping investigations and the development of the long-term management strategy (see section 3.6) that balances the achievement of management objectives over time. There are a total of 11 objectives and 30 indicators in this FMP.

The Long-term Management Direction

The Long-term Management Direction (LTMD) is represented by the types and levels of access, harvest, renewal and tending activities required to manage forest cover in a manner that balances the achievement of management objectives over time. The MNR approved Strategic Forest Management Model (SFMM) is used to develop the Long-term Management Direction.

The development of the Long-term Management Direction is an iterative process whereby results are examined and SFMM inputs adjusted as required to improve the model's ability to meet management objectives. This process commonly involves adjusting volume targets, harvest flow policies and targets for the forest diversity indicators – forest unit area, old forest area, mature forest and wildlife habitat. As each investigation is run, the resulting harvest volume, forest diversity indicators, silvicultural expenditures and the silvicultural treatment program are examined. The process continues until the planning team is satisfied that no further significant improvements can be made, that on balance objectives have been achieved, and that the solution is practical and can be implemented. The modelling process that led to the Long-term Management Direction is described in section 3.6 of the plan and the Analysis Package in Supplementary Documentation A.

The outputs of forest modelling for the Long-term Management Direction provide the source for the long-term (100-year) projections of quantifiable objectives and are documented within the plan in the following tables:

(a) Projected Forest Condition for the Crown Productive Forest (Table FMP-5);
(b) Projected Habitat for Selected Wildlife Species (Table FMP-6);
(c) Projected Available Harvest Area by Forest Unit (Table FMP-7); and
(d) Projected Available Harvest Volume by Species Group (Table FMP-8);

These tables can be found in section 9.0 of the FMP.

Planned Forest Operations for the 10-year Plan Period

Silvicultural Systems, Forest Units and Silvicultural Ground Rules

In order to describe the planned forest operations, it is necessary to first explain some forestry terminology:

The harvesting on the Whiskey Jack will be conducted using a silvicultural system wherein the mature trees are removed in one operation. This silvicultural system still involves the removal of the majority of the mature trees, however, the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010) require the retention of residual trees to be left after the harvest and often residual patches of uncut areas are to be left as well. This method of harvesting is an appropriate management system in the Boreal Forest for many mixedwood stands and stands to be managed for tree species that are intolerant of shade (e.g. poplar, white birch, jack pine).

Each stand is assigned to a forest unit based on species composition, stocking and history. All stands within a forest unit are managed under the same silvicultural system but may be managed with different treatments (e.g. planting, site preparation, tending) and may have different objectives in terms of different future forest conditions. The management strategy is indicated through the Silvicultural Ground Rule.

Each stand to be harvested is assigned a Silvicultural Ground Rule. Each Silvicultural Ground Rule (SGR) describes the components that make up an individual SGR, including a description of the current and future stand conditions, renewal treatment options and the regeneration standards that are to be met. Each SGR is intended to describe the harvest, renewal and tending activities that will be carried out on a given stand to allow the current Forest Unit, following harvest, to succeed to the Future Forest Unit, whether it is similar to the pre-harvest stand or a different Forest Unit.

Planned Harvest Operations

Results of the long-term strategic planning were used to plan operations for the ten-year period of this plan. The following table summarizes the harvest operations that are planned (i.e. in detail) for the first five-year term (2012-2017), and those which are proposed (i.e. less detail) for the second five-year term (2017-2022) of the FMP. The planned harvest area and percentage of the total 10-year planned harvest area for each of the three major silvicultural systems is listed below, however as reported, only the clearcut silvicultural system is being implemented on the Whiskey Jack Forest during this plan period (See section 4.3 of the FMP for more details):

Silvicultural System (i.e. Harvest System)	10-year Planned Harvest Area (ha)	% of 10-year Planned Harvest Area
Clearcut	51,941	100 %
Shelterwood	0	0 %
Selection	0	0 %
Total	**51,941**	**100%**

Harvest Area and Volume by Forest Unit and Species Group

The estimated available harvest areas for the 10-year plan period summarized by principal forest units and the harvest volumes (m3) associated with the harvest areas by the principal species groups are listed below:

Forest Unit	Planned Harvest Area (ha)
BFM	1,353
CMX	8,622
HMX	11,039
OCL	-
OTH	-
PJD	3,100
PJM	5,097
POD	11,349
PRW	204
SBL	297
SPD	6,791
SPM	4,118
Total	**51,941**

Species Group	Planned Harvest Volume (m3)
White Pine - Red Pine	20,106
Spruce-Pine-Fir	3,310,286
*** Other Conifer (Cedar, Larch)**	61,959
Poplar	1,833,791
White Birch	403,201
*** Tolerant Hardwood (Black Ash)**	20,346
Total	**5,549,689**

(Net merchantable volumes)

* Volumes for Other Conifer (Larch, Cedar) and Tolerant Hardwood (Black Ash) are reported but are not considered major species groups on the Whiskey Jack Forest.

Planned Road Access

The planned (10 year) road construction summarized for two road classes (primary and branch roads) that are needed to access all harvest and renewal operations over the 10-year period are listed below. Operational (i.e. tertiary) roads are not listed. (See section 4.5 of the FMP for more details).

Road Classification	Planned Road Construction (km)
Primary	37
Branch	19
Total	**56**

The Road Use Management Strategies for each Primary Road are located within FMP Supplementary Documentation G. The proposed Primary Road corridors associated with the 2012 FMP are illustrated on the FMP Summary Map and Composite Map (electronic version of FMP).

The management strategies for each road are consistent with those indicated in the Crown Land Use Policy Atlas.

Planned Forest Renewal and Tending Operations

The planned (10 year) renewal and maintenance activities that are required to meet the plan objectives are listed below by renewal activity type. These renewal activities will be carried out on the current planned harvest areas as well as areas harvested during past plan terms.

Artificial regeneration refers to tree planting and seeding. Supplemental treatment usually refers to an area that is regenerating naturally that needs some supplemental (usually tree planting) treatment to meet the regeneration standards. (See section 4.4. of the FMP for more details).

Renewal Activities	Planned Treatment Area (ha)
Natural Regeneration	25,631
Artificial Regeneration	27,839
Total Regeneration	53,470
Retreatment	0
Supplemental	0
Total Tending	8,065

Area of Concern Prescriptions

The forest provides for many forest values. Some values have the potential to be negatively impacted by forest management. The areas around these values are termed *Areas of Concern*.

An area of concern may be a social value such as an authorized hiking trail or an archaeological site or it may be an ecological or environmental value such as a stream or significant wildlife habitat feature (e.g. a great blue heronry, a hawk nest, deer wintering area, mineral licks or a provincially significant wetland).

The FMP includes Area of Concern prescriptions for many different values. These prescriptions may include a no-cut buffer zone, an area with access restrictions and/or a modified

management area wherein there may be restrictions on timing of harvest or silvicultural activity, method of harvest or types of trees that can be harvested. Some prescriptions are developed from the direction in a forest management guide and others are developed at the planning team level. A few examples of the many Area of Concern prescriptions follow to give the reader a sense of Area of Concern prescriptions:

> ***Example 1 (N01)**. A primary bald eagle nest receives a 200 m radius no cut reserve with no new access roads allowed. Outside this 200 m radius is a further 200 m wide zone in which harvesting may occur (subject to conditions on whether or not nest is occupied and relative potential impact of operations) and it must occur outside the critical breeding period to avoid disturbing the young birds.*
>
> ***Example 2 (M01)**. Mineral licks will receive a 120 m no cut reserve measured from the edge of woody vegetation averaging at least 2 m tall and with ≥25% canopy cover. This reserve is in excess of what is required for water quality and protection of fish habitat, but will provide additional protection and habitat cover for animals using the mineral lick.*
>
> ***Example 3 (TV01)**. Large tourism lakes will receive a 90 m no cut reserve. This prescription may be in excess to what is required to protect the water quality and fish habitat but it will provide a visual buffer from users of the lake.*

Operational prescriptions for areas of concern and silvicultural ground rules for regular operations have been prepared in accordance with the applicable forest management guides. There are no area of concern prescriptions and one silvicultural prescription that are exceptions to the guides. Full tree logging on NWO Ecosites 11 and 12, where total organic matter plus soil depth is less than 20 cm, is designated as a 'not recommended' practice in the *Silvicultural Guide to Managing for Black Spruce, Jack Pine, and Aspen on Boreal Forest Ecosites in Ontario* (MNR, 1997). The shallow soil sites on the Whiskey Jack Forest are, for the most part, productive and, it is felt, that using full tree logging in a careful manner will preserve the sites nutrient capacity. The forest industry is contributing to a comprehensive, region wide initiative to monitor the impacts of this treatment on these site conditions. Operational prescriptions for areas of concern have been prepared consistent with the Endangered Species Act to protect habitat related to species at risk known to exist on the forest (See section 4.2.1 of the FMP for more detail).

Issues

There are two issues affecting the 2012-2022 Whiskey Jack Forest Management Plan that have the potential to affect the implementation of the plan:

1. The August 2011 Court decision regarding the "Keewatin Lands" (north of the English River system) – Note that as per the stay ordered on consent of the parties, there will be no harvesting of trees for subsequent sale or other commercial purposes other than for firewood within the area of the Whiskey Jack Forest north of the English River, without the consent of Grassy Narrows First Nation.
2. More generally, Grassy Narrows has concerns with the Whiskey Jack Forest that are currently being addressed through the Process Agreement that was signed between ANA and MNR.

Ontario will continue to consult with Grassy Narrows First Nation, Naotkamegwanning First Nation (Whitefish Bay), Ochiichagwe'babigo'inning First Nation (Dalles), Wabaseemoong Independent First Nations (Whitedog), Wabauskang First Nation and Kenora Métis Council and respect any existing obligations in relation to their rights. The Planning Team and LCC will receive public and Aboriginal input via the consultation phases of the forest management plan.

Public Consultation

There is one remaining formal consultation opportunity for the Whiskey Jack Forest Management Plan. Public inspection of the MNR approved Forest Management Plan is tentatively scheduled from December 2013 to January 2014. There is an opportunity during the 30-day period for public inspection of the MNR approved forest management plan for any person to make a written request to the Director, Environmental Assessment and Approvals Branch, Ministry of the Environment for an individual environmental assessment of specific proposed forest management activities in the forest management plan (in accordance with the process described in Part A, Section 3.4.2).

Following the implementation of the Whiskey Jack Forest Management Plan, the Kenora District MNR will continue to work with local First Nation communities to ensure that new values are protected as they are identified.

A comment form is attached as Appendix 1.

Summary Map

Proposed harvest, renewal and tending operations, locations of existing and new primary and branch road construction corridors for the 10-year term are shown on the summary map labelled MU490_2012_FMP_P1_MAP_Sum. The map also contains an index/grid for identifying specific operational maps.

COMMENTS

The Ministry of Natural Resources is collecting comments and information regarding the forest management plan under the authority of the Crown Forest Sustainability Act to assist in making decisions and determining further public consultation needs. Your comments will be forwarded to the Plan Author and shared with the Kenora Local Citizens Committee (LCC) so that they may consider your concerns. Comments and opinions will be kept on file for use during the forest management plan period and may be included in study documentation which is made available for public review.

Under the Freedom of Information and Protection of Privacy Act (1987) personal information will remain confidential unless prior consent is obtained. However, this information may be used by the Ministry of Natural Resources to seek public input on other resource management surveys and projects. For further information regarding this Act, please contact Stephen Duda, MNR at (807) 468-2543.

There is one remaining formal consultation opportunity for the Whiskey Jack Forest Management Plan. Public inspection of the MNR approved Forest Management Plan is tentatively scheduled from December 2013 to January 2014. There is an opportunity during the 30-day period for public inspection of the MNR approved forest management plan for any person to make a written request to the Director, Environmental Assessment and Approvals Branch, Ministry of the Environment for an individual environmental assessment of specific proposed forest management activities in the forest management plan (in accordance with the process described in Part A, Section 3.4.2).

Comments may be forwarded to the Kenora District Office, Ministry of Natural Resources, 808 Robertson Street, Box 5080, Kenora, ON, P9N 3X9.

EARTHROOTS

This is Exhibit "C" referred to in the affidavit of AMBER ELLIS AND DAVID SONE sworn before me, this 21st day of AUGUST 20 15

Joseph Castrilli
A COMMISSIONER FOR TAKING AFFIDAVITS
JOSEPH CASTRILLI

January 22, 2014

Ian Parrott
Director of Environmental Assessment and Approvals Branch
Ontario Ministry of Environment
2 St Clair Ave W, Floor 12A
Toronto ON M4V1L5

Dear Mr. Parrott,

Re: Request for Individual Environmental Assessment of Whiskey Jack Forest Management Plan (EBR Registry No. 010-9240)

We are writing on behalf of Grassy Narrows First Nation (Grassy Narrows) and Earthroots to request an Individual Environmental Assessment of the Whiskey Jack Forest Management Plan 2012-2022 (the logging plan) that was approved on December 23, 2013 by the Ministry of Natural Resources.

Earthroots is a grassroots environmental organization dedicated to protecting Ontario's wilderness, wildlife and watersheds through research, education and action.

Asubpeeschoseewagong Netum Anishinabek (ANA) or Grassy Narrows First Nation is an indigenous Anishinabe community located within the Treaty 3 area.

The logging plan fails to adequately deal with the impacts of logging on mercury levels in boreal water and fish. As a result the logging plan fails to protect the environment and to ensure sustainability. In particular the logging plan will harm water quality, fish habitat, wildlife, and the health of people who eat the fish. The logging plan will also impact the inherent Aboriginal and Treaty rights to fish to an extent that precludes the meaningful exercise of those rights.

These shortcomings of the logging plan are in spite of the fact that peer reviewed scientific literature has demonstrated a clear link between clearcut logging and unsafe mercury levels in fish in boreal forest watersheds. While the research in support of this literature generally was not carried out in the Whiskey Jack Forest, the boreal forest conditions examined and logging activities considered in these studies are similar, if not identical, to the conditions and activities expected in Whiskey Jack if the logging plan proceeds as approved.

This failure of the logging plan is particularly grave because of the well-known existing mercury contamination problem in the English and Wabigoon River watersheds, and the well-documented prevalence of methylmercury poisoning arising from the consumption of contaminated fish (Minamata Disease) in Asubpeeschoseewagong (Grassy Narrows) and Wabaseemoong (White Dog).

The history of local mercury contamination, and its ongoing impacts, dictates that the highest level of caution and duty of care must be applied in any action that may deepen and prolong this problem by increasing the levels of mercury in the local food chain. Failure to do so would be a failure to protect the health of the environment and the sustainability of our forests, as well as a failure to uphold the honour of the Crown.

Grassy Narrows has a number of concerns with respect to the Ministry of Natural Resources' decision to approve the Forest Management Plan. These concerns include the failure to discharge the duty to consult, the failure to properly account for treaty rights and traditional use of the land, the failure to ensure that a proper forest inventory has been used to inform the Crown's decision making process, and a concern that the level of logging is unsustainable and unjustifiably infringes our aboriginal and treaty rights. The fact that we do not raise these issues below in relation to our bump-up request should not be taken as in any way suggesting that these concerns are unimportant or will not be raised in other fora.

Grassy Narrows and Earthroots submit that the logging plan warrants a review under an Individual Environmental Assessment because:

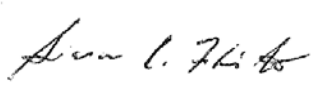
- the outstanding mercury issues (i.e., impacts upon human and ecosystem health) have not been addressed adequately, or at all, under the *Crown Forest Sustainability Act*, or in the forest management planning process, to date;
- similarly, they will not be adequately addressed in any other current or future regulatory or approvals process regarding the logging activities in Whiskey Jack Forest (e.g., in the *Lakes and Rivers Improvement Act* regarding water-crossings);
- these public interest issues raise matters of profound importance both to Grassy Narrows First Nation, and to other stakeholders and the public at large;
- to effectively and thoroughly address these issues it is necessary, as a preliminary step, for the proponent of the logging plan to prepare an Individual Environmental Assessment that fully examines (with public input) all matters listed in section 6.1(2) of the *Environmental Assessment Act*, especially in relation to:
    - the alleged purpose of, or rationale for, allowing clearcutting/logging activities to occur in Grassy Narrows Territory;
    - the alleged purpose of, or rationale for, allowing clearcutting/logging activities in close proximity to fish-bearing waterbodies within the Whiskey Jack Forest despite the risk of additional mercury contamination;
    - alternative sources of wood for the real wood supply needs of local mills;
    - alternatives to the proposed forestry activities and alternative methods of carrying out such activities;
    - the environment affected, and the environmental effects (direct, indirect, and cumulative) of the logging activities;
    - proven mitigation actions to prevent the risk of mercury contamination from logging activities; and
    - systematic evaluation of the advantages and disadvantages of the proposed activities and the alternatives.

The precise nature and scope of the foregoing factors can be developed (with public input) in the Terms of Reference which precede the preparation of the Individual Environmental Assessment. In summary, the potential mercury impacts are significant, adverse, long-lasting, and are

unresolved to date in the forest management planning process. These impacts are best addressed through a process that includes, but is not necessarily limited to, a robust Individual Environmental Assessment.

We go into more detail about the concerns of Grassy Narrows and Earthroots in the appended text. Where possible, we quote directly from peer-reviewed scientific journal articles to avoid misinterpretation of the available facts.

Sincerely,



Simon Fobister,
Grassy Narrows Chief

Amber Ellis,
Earthroots Executive Director

Enclosure: Bump-up Request for an Individual Environmental Assessment (IEA) submitted to the Ontario Ministry of the Environment regarding the Forest Management Plan for the Whiskey Jack Forest for the 10-year period April 1, 2012 to March 31, 2022 - Final Plan Inspection Approved by the Ministry of Natural Resources, December 23, 2013 - EBR Registry No. 010-9240

1. Clearcutting Impacts Water Quality Through Mercury Contamination

SUMMARY

Logging has been found to dramatically raise mercury (Hg or Hg_{tot}) levels in boreal lakes and rivers. It has also been found to raise the levels of methyl mercury (MeHg), the form of mercury that bio-accumulates in the food chain and acts as a neurotoxin in humans who eat fish.

EVIDENCE

"Boreal Canadian Shield forest watersheds serve as large reservoirs of Hg that shed their metal load when the soil and the land hydrology are disrupted by timber harvesting." (Desrosier et al., 2006)

"Clearcut logging increases the export of dissolved organic carbon [DOC] and Hg and can stimulate the bacterial production of methyl mercury (MeHg)." (Garcia and Carignan, 2005)

"Several subsequent studies have indicated that harvesting and other forest operations in boreal and nemoral climactic zones increase the loading of methyl mercury (MeHg) exported from catchments (12)" (Bishop et al., 2009)

"Harvesting of a 7 ha stand increased Hg_{tot} fluxes by a factor of four and MeHg by a factor of six." (Povari et al., 2003 as cited in Bishop et al., 2009)

"In Sweden, a temporary logging track inadvertently placed across a small brook in the long-term Gardsjon reference catchment increased outputs of MeHg by a factor of over five (18) for more than half a decade." (Munthe et al., 2004 as cited in Bishop et al., 2009)

"There is fairly compelling evidence that timber harvest (and wildfire) (sic) results in an increase in the movement of mercury from terrestrial to aquatic environments where it may be converted to MeHg (see above). Associated with this, there is a growing concern about the associated potential risk to wildlife and human health." (Stand and Site Guide Rationale)

CONCLUSION

Clearcutting on Grassy Narrows Territory will cause the discharge of mercury into the aquatic environment. Mercury is a contaminant which causes an adverse effect on water

quality.

2. Clearcutting Elevates Mercury Levels in Fish

SUMMARY

Logging has been found to increase the level of mercury in fish, often above the safe level for human consumption. This effect is most pronounced in fish at the top of the food chain like walleye and pike, the primary fish eaten by people in Grassy Narrows.

EVIDENCE

"Watershed manipulations can result in an increase of downstream MeHg concentrations (18) and fish Hg levels by an order of magnitude, without any additional input of Hg (19)." (Bishop et al., 2009)

"In the environment, particularly lakes, waterways and wetlands, mercury can be converted to a highly toxic, organic compound called methylmercury through biogeochemical interactions." (Environment Canada, website http://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=D721AC1F-1 accessed Jan. 14, 2014)

"[T]here is a clear indication that forest harvesting leads to increases in Hg_{tot} and MeHg loading, as well as increased bioaccumulation in downstream aquatic biota." (Bishop et al., 2009)

"Several subsequent studies have indicated that harvesting and other forest operations in boreal and nemoral climactic zones increase the loading of methyl mercury (MeHg) exported from catchments (12) and the amount of Hg found in downstream fish as well as other organisms (13)." (Povari et al., 2003, and Garcia and Carignan, 2000, as cited in Bishop et al., 2009)

"[T]his soil [Hg] pool and its mobilization due to forest management activities are definitely a threat to fish… the factors that promote methylation… are of particular concern." (Bishop et al., 2009)

"Hg concentrations exceeded the advisory limit for human consumption (0.5 ug/g wet wt) from the World Health Organization in all top predatory species (northern pike, walleye, and burbot) found in cut and two partially burnt lakes." (Garcia and Carignan, 2005)

"This limit was surpassed in only 18% of piscivorous species populations found in reference lakes and in no species from completely burned lakes." (Garcia and Carignan, 2005)

CONCLUSION

Clearcutting in Grassy Narrows Territory will result in the harmful alteration of fish habitat by causing levels of methyl mercury in the fish's environment and food chain to be elevated. This in turn leads to higher levels of methyl mercury in the fish.

3. Elevated Mercury Levels Impact Wildlife

SUMMARY

Elevated mercury levels impact wildlife, especially those species at the top of the food chain. Mercury impacted wildlife include species that are important to the exercise of Grassy Narrows' trapping rights including mink and river otter.

EVIDENCE

Mercury impacts have been identified in mink, river otter, loons, osprey, and bald eagles that eat contaminated fish. (Environmental Commissioner of Ontario. 2004)

"Mercury toxicity for fish, birds and mammals can lead to reduced reproductive success, impaired growth and development, behavioral abnormalities, and death." (Environmental Commissioner of Ontario, 2004)

"Although the long-term effects of mercury on whole ecosystems are unclear, the survival of some affected populations and overall biodiversity are at risk." (Environment Canada website, http://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=D721AC1F-1, accsessed Jan. 14, 2014)

"High levels of mercury are suspected to impair the loon's reproductive success as well as cause growth related problems. These problems inevitably lead to an increased death rate and a decreased birth rate, resulting in a reduction in the abundance of natural populations." (Environment Canada website, http://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=D721AC1F-1, accessed Jan 14, 2014)

"It is thought that elevated mercury levels in otters may cause early mortality due to toxicity and behavioral changes." (Environment Canada website, http://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=D721AC1F-1, accessed Jan. 14, 2014)

"In the past, mercury risk reduction strategies focused on restricting human consumption of heavily contaminated fish in order to protect human health. Such a strategy is clearly not adequate for the protection of wildlife. Species such as otter and mink cannot heed warning notices or fish consumption advisories. Since mercury is so widely distributed in the Canadian environment, their risk is real and immediate, especially when effects such as impaired growth and reproduction, neurological damage, kidney damage, and weight loss, which occur at relatively low concentrations, are considered." (Environment Canada website, http://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=D721AC1F-1, accessed Jan. 14, 2014)

"The U.S. Environmental Protection Agency's Great Lakes Initiative mercury water quality criterion for the protection of wildlife is 1.3 ng/L." (Environmental Commissioner of Ontario. 2009)

Levels of Hg_{tot} as high as 12 ng/L have been found in downstream water bodies after logging. (Bishop et al., 2009).

CONCLUSION

Increasing mercury levels in fish are likely to increase the impacts on local wildlife. These impacts may cause a decline in abundance, and may even put the local survival of some species at risk. The species likely to be impacted include animals that are important to the exercise by Grassy Narrows people of the right to trap.

4. Fish in Grassy Narrows Have Critical Levels of Mercury

SUMMARY

Food fish in Grassy Narrows Territory currently have mercury levels above, or near, the limit for safe human consumption.

EVIDENCE

Between 1962 and 1970, approximately 10 tonnes of mercury was dumped into English-Wabigoon river system by Dryden Chemicals, a subsidiary of Reed Paper. (Hutchison, 1977)

"Mercury is a toxic element and serves no beneficial physiological function in man." (Health Canada website, http://www.hc-sc.gc.ca/ewh-semt/pubs/water-eau/mercury-mercure/index-eng.php#a1, accessed Jan. 14, 2014)

In 2007 a Grassy Narrows fisherman pled guilty in a Kenora court to one count of unlawfully selling fish tainted by mercury contamination, contrary to the Ontario *Fish Inspection Act*. The fish were caught in Grassy Narrows Lake. Forensic tests on the fish, done at the Canadian Food Inspection Agency in Winnipeg, revealed mercury levels of 1.0 parts per million, twice the acceptable level of 0.5 parts per million. (Kenora Daily Miner and News, 2007)

A 2010 study by Grassy Narrows for the First Nations Environmental Contaminants Program found that 100% of fish flesh samples from the English-Wabigoon river area had mercury levels above the level at which Health Canada recommends against consumption by people who consume a lot of fish (0.2mg/kg). The study found 25% of samples were above the legal limit for commercially sold fish (0.5 mg/kg). (Sellers, 2010)

An earlier study found levels as high as 140% over the legal limit in a Grassy Narrows fish (Sellers, 2005). A wild foods study conducted by Hollow Water First Nation in nearby Manitoba found that concentrations of mercury in pickerel [a.k.a. walleye] flesh there was far lower, and ranged from 0.12 – 0.30 mg/kg. (Sellers and Scott, 2006)

The MOE *Guide to Eating Ontario Sport Fish* entry for Grassy Narrows Lake recommends that people in the 'General Population' not eat any walleye longer than 45 cm, and eat only 2 meals per month of walleye shorter than 45 cm. It recommends that women of childbearing age and children under age 15 eat no walleye and no northern pike. In safe lakes the guide recommends as many as 8 meals of walleye per month. (MOE online interactive Guide to Eating Ontario Sport Fish, accessed Jan. 14, 2014)

Many other lakes in Grassy Narrows territory are subject to similar warnings.

While mercury levels in fish in the area appear to have declined since the 1970's "there is evidence that this decline is either slowing or levelling off." Also, "current mercury levels are mostly higher than those in other regional water bodies." (Neff et al., 2012) Data in some lakes show an increase in mercury levels in walleye and pike since around 1995.

"Concentrations in the English-Wabigoon fish are elevated, and may still present a potential health risk to humans consuming fish from this system." (Neff et al., 2012)

CONCLUSION

Mercury levels in fish in many parts of Grassy Narrows territory are at critical levels and

despite some reductions have not returned to safe levels. Clearcutting and road building under the logging plan will further elevate these mercury levels. This will prolong and deepen the mercury problem.

5. Mercury Impacts Human Health in Grassy Narrows

SUMMARY

35 Years of study by renowned mercury expert Dr. Harada and his team have confirmed that people in Grassy Narrows are suffering from Minamata Disease as a result of methyl mercury ingested by eating local fish.

EVIDENCE

Doctor Harada's teams of researchers have studied mercury health impacts in Grassy Narrows for over 35 years starting in 1975.

"[I]t is an undoubtable fact that Minamata Disease occurred in [Grassy Narrows and White Dog], based on our long-term investigation result." (Harada et al., 2011)

Grassy Narrows people "were poisoned by eating fish contaminated with mercury." (Harada et al., 2011)

Findings by Harada et al., 2011

- 59% of the 160 people tested in GN and White Dog were affected by mercury.
- 34% were diagnosed with Minamata Disease (MD) using current Japanese diagnostic criteria (41% in GN --> 30 cases)
- 25% were diagnosed with suspected Minamata Disease (SMD)
- 44% of people aged 21-40 had MD or SMD. All these people were born after the mercury dumping was curtailed in 1971.

"[T]he possibility of congenital Minamata Disease occurrence is very high in these two communities. We examined 7 cases of cerebral palsy and 7 cases of mental deficiency…. Further epidemiological research on stillbirths and miscarriages needs to be done." (Harada et al., 2005)

All of Dr. Harada's patients who indicated mercury levels higher than the safety guideline of 50 ppm in 1975 were deceased by 2004. (Harada et al., 2005)

People in Grassy Narrows continue to eat fish as part of their sustenance, culture, and the exercise of their Aboriginal and Treaty rights.

"Methyl mercury is absorbed through the digestive tract and distributed throughout the body. It readily enters the brain, where it may remain for a long period of time. In a pregnant woman, it can also cross the placenta into the fetus, building up in the fetal brain and other tissues. Methyl mercury can also be passed to the infant through breast milk.

A child's developing nervous system is particularly sensitive to methyl mercury. Depending on the level of exposure, the effects can include a decrease in I.Q., delays in walking and talking, lack of coordination, blindness and seizures. In adults, extreme exposure can lead to health effects such as personality changes, tremors, changes in vision, deafness, loss of muscle coordination and sensation, memory loss, intellectual impairment, and even death." (Health Canada website, http://www.hc-sc.gc.ca/hl-vs/iyh-vsv/environ/merc-eng.php, accessed January 14, 2014)

"Today, the main effects of mercury exposure to humans are understood to be neurological, renal (kidney), cardiovascular and immunological impacts. Chronic exposure to mercury can cause damage to the brain, spinal cord, kidneys, liver and developing fetus. Exposure to mercury while in the womb can lead to neurodevelopmental problems in children. Mercury can impair the ability to feel, see, move and taste, and can cause numbness and tunnel vision. Long-term exposure can lead to progressively worse symptoms and ultimately personality changes, stupor, and in extreme cases, coma or death. Recent findings have described adverse cardiovascular and immune system effects at very low levels." (Environment Canada website, http://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=0EB35C98-1, accessed January 14, 2014)

"In addition, methylmercury has been classified as a possible human carcinogen by the U.S. Environmental Protection Agency. More recently, additional findings have described adverse cardiovascular and immune system effects at very low exposure levels." (Environment Canada website, http://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=0EB35C98-1#TE, accessed January 14, 2014)

CONCLUSION

Clearcutting in Grassy Narrows Territory will cause the release of mercury, a deleterious substance. This mercury forms part of a process of degradation of water quality so that it is rendered deleterious to use by people of fish that frequent that water.
