Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-12920	22/08/29	Asubpeeschoseewagong Netum Anishinabek	Letter	Letter communication from Great Bear to Chief of ANA with a request from GBR to set up a discussion regarding the Great Bear Project in the Red Lake District. It introduces GBR as the new owner of the project and outlines its current exploration activities. The company plans to renew its mineral exploration permits in the fall and has been advised by the Ministry of Mines to notify ANA as a potentially interested community. GBR acknowledges the Ministry's role in consultation but expresses a desire to engage directly with ANA to understand its interests, potential concerns, and any effects on its people and lands. The company also seeks to establish a communication protocol for ongoing discussions. GBR states that, based on its understanding, its activities are outside ANA Territory but is open to updating this understanding through discussions. The letter invites ANA to coordinate a meeting—either in person or virtually—and provides a link for more information on the Great Bear Project.	Engagement not related to Project
C-12921	22/08/29	Asubpeeschoseewagong Netum Anishinabek	Email	Email communication from ANA Chief in response to letter communication dated August 29, 2022 noting that "We prefer our land to continue its healing journey which in turn our people will heal from the land . We do not wish to meet . There are many other areas in the Province yous can take your proposal . Miigwetch for respecting our stand to keep our territory clean."	
C-00897	22/11/11	Asubpeeschoseewagong Netum Anishinabek	Email	Great Bear issues congratulatory note to Chief and the ANA Council on their recent election and wishes them success in their term. The company, which recently acquired the Great Bear Project southeast of Red Lake, remains in the exploration phase and is renewing its mineral exploration permit and a permit to take water for drilling. As advised by the Ministry of Mines, ANA was notified of these applications, with a previous outreach to the previous Chief resulting in a respectful decline to meet, as the community focuses on healing. GBR continues to work closely with Wabauskang and Lac Seul First Nations under an Exploration Agreement, with both providing letters of support. The company remains open to any questions from Chief and Council and welcomes community interest in visiting the project site. GBR expresses sincere respect for ANA's	Engagement not related to Project
C-01933	22/11/11	Asubpeeschoseewagong Netum Anishinabek	Email	Great Bear inquiry to hold a short call with ANA leadership. Great Bear notes that they did hear from the Ministry of Mines that they had issued ANA an email this week, with information included about our Early Exploration permit application. Great Bear notes that we recognize that you and your Council and staff likely already have a number of your own projects underway, and settling in as new Chief and Council. Great Bear staff inquiry to check in with you, to help you with any questions you might have and to be sure you received the	Engagement not related to Project
C-01497	22/12/16	Asubpeeschoseewagong Netum Anishinabek	Email	Great Bear notice to ANA that it has submitted the Great Bear Resources Advanced Exploration Project Definition document and Notice of Project Status to the Ministry of Mines.	Engagement not related to Project
C-01934	22/12/16	Asubpeeschoseewagong Netum Anishinabek	Email	Great Bear notice to ANA that it has submitted the Great Bear Resources Advanced Exploration Project Definition document and Notice of Project Status to the Ministry of Mines for early review. All documentation issued to ANA for review. Request from Great Bear to meet with ANA in the new year to review this information and to understand key areas of interest to ANA. Great Bear request to confirm if there is anyone else on your Council or advisory team who should also be receiving this information, Great Bear notes they are happy to know and reach out to connect.	Engagement not related to Project
C-00973	23/02/08	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Email	Great Bear acknowledges ANAs request for a timeline extension on Exploration Permit PR-22-000284 and reaffirms the importance of the excluded claims. While supporting meaningful consultation, Great Bear does not oppose the extension, provided it remains reasonable and does not unduly impact its interests. If granted, Great Bear requests prior written notice and regular updates from the Ministry on any	Engagement not related to Project
C-00977	23/02/14	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Email	Email confirming timeline extension for ANA requested additional time to review the PR-22-000284 permit, specifically the 44 claims that were removed for further consultation. In response to the request, MINES sent a letter today (February 14th) requesting substantive comments regarding potential adverse impacts from the proposed exploration activities for this permit with comment period close on February 28, 2023. MINES will be in a position to make a decision on amending the permit to include the additional 44 mining claims, taking into account any specific comments received by that date.	Engagement not related to Project

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-01337	23/06/22	Asubpeeschoseewagong Netum Anishinabek	Phone Call	Introduction meeting and discussion with ANA, detailing their history and involvement in community, the practices they have on the land. ANA presented a video on advancing Indigenous rights through Indigenous Protected and Conserved Areas, highlighting their ongoing land protection efforts and strong support from Chief and Council. The community has a long history of living off the land and has faced significant environmental and health impacts, including mercury contamination in the English and Wabigoon Rivers, clear-cut logging, and mining permits issued without consent. ANA declared a moratorium on industrial activity in 2007 and enacted a land declaration in 2018, banning mineral staking and exploration. ANA is committed to Free, Prior, and Informed Consent (FPIC) and has concerns about recent mining activity in their territory. ANA noted that they seek more meaningful engagement with GBR, including answers to their questions about laws and rights, and clarity on whether consent will be sought before moving forward with the project. GBR has committed to seeking consent but has not yet satisfied ANA's concerns. ANA is open to further dialogue and requests transparent, respectful communication, especially considering the language	Engagement not related to Project
C-01922	23/06/27	Asubpeeschoseewagong Netum Anishinabek	Email	Meeting planning between GBR and ANA Land Protection Team, along with follow up regarding questions about consultation, and ensuring that the Initial Project Description be shared prior to submission to the Impact Assessment Agency to initiate. GBR provides thanks for the opportunity to meet with the ANA Protection Team. As discussed, responses to the questions regarding the Early Exploration Permit application from October 2022 will be provided through the Ministry of Mines to ensure clear communication, with a response letter sent today. Our outreach last week was related to an upcoming advanced exploration permit application for the same project. GBR would appreciate the chance to further discuss the Great Bear Project and are setting up a SharePoint site for document sharing and feedback on the Advanced Exploration Project. Additionally, GBR will share the Initial Project Description of the main project before submitting it to the Impact Assessment Agency of Canada to initiate the impact assessment phase	Engagement not related to Project
C-01400	23/07/07	Asubpeeschoseewagong Netum Anishinabek Great Bear Gold Project Projet Aurifère Great Bear Impact Assessment Agency of Canada (IAAC)	Virtual	IAAC wanted to thank GBR for the opportunity to meet with the team regarding the Great Bear Gold Project, and for providing an overview of the Project. During the meeting, IAAC referenced a Project, specifically in relation to Asubpeeschoseewagong Netum Anishinabek (also known as ANA). IAAC pointed to section 9.3 of the Environmental Assessment Report, which describes the historical context, the Agency's engagement, and the views shared by the community with the Agency. The Agency encouraged GBR to think about how to collaborate with the Indigenous communities and include similar information in GBR documents.	
C-01290	23/07/24	Asubpeeschoseewagong Netum Anishinabek	Email	GBR providing an update to Asubpeeschoseewagong Netum Anishinabek and access to the Sharepoint.	
C-01347	23/08/15	Asubpeeschoseewagong Netum Anishinabek	Email	Introduction of External Relations Manager from GBR to ANA and sharing the AEX Environmental Compliance Approval Industrial Sewage Works Technical Support Document via SharePoint site. This document includes essential components such as supporting maps, technical data concerning discharge limits, the assimilative capacity of the Chukuni River ecosystem, a preliminary monitoring program, and the proposed treatment methodology. This document has been provided to Lac Seul First Nation, Wabauskang First Nation, and to the Ministry of Environment, Conservation and Parks, with the aim of seeking valuable input and insights. The opportunity to meet at their convenience was also presented.	Engagement not related to Project
C-01499	23/09/01	Asubpeeschoseewagong Netum Anishinabek Impact Assessment Agency of Canada (IAAC)	Email	The Great Bear team sincerely appreciate Asubpeeschoseewagong Netum Anishinabek's contributions during the June 22, 2023, meeting. We look forward to continued meaningful engagement and reiterate our offer of capacity funding. Great Bear notes they wish to explore synergies between the community's interests and the Great Bear Project's objectives. Invitation to reach out, and welcome the opportunity to meet in the community to discuss our commitments and next steps in person.	GNFN_09012023_01.pdf
C-01502	23/09/07	Asubpeeschoseewagong Netum Anishinabek	Email	GBR provides details of the attached Great Bear Advanced Exploration Program Reclamation Strategy. Document was prepared to summarize the reclamation strategy for the AEX program. The purpose of this memorandum is to seek input from Indigenous communities regarding the proposed closure strategy for the AEX Program. This document has been provided to Lac Seul First Nation, and Wabauskang First Nation, with the aim of seeking valuable input and insights. The opportunity to arrange a meeting with GBR has also been offered.	Engagement not related to Project
C-01529	23/09/07	Asubpeeschoseewagong Netum Anishinabek	Email	Communication from ANA expressing that at this moment there is limited capacity to review the AEX Closing Strategy memo at ANA, and that due to the reduced capacity emails, reviews, and other communications might take longer than usual. This is in reply to the receipt of the AEX Closure	Engagement not related to Project
C-01594	23/09/14	Asubpeeschoseewagong Netum Anishinabek Great Bear Gold Project Projet Aurifère Great Bear Ontario Ministry of Energy & Mines (MOEM)	Email	Communication directed to the IAAC from ANA, mentioning notable concerns relating to capacity, Indigenous rights, and lack of actions taken by the federal government. Notable concerns were also related to protocol raised by community.	GNFN_09142023_01.pdf

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-01553	23/09/19	Asubpeeschoseewagong Netum Anishinabek Lac Seul First Nations Metis Nation of Ontario Ontario Ministry of Natural Resources (MNR) Wabaseemoong First Nation Wabauskang First Nation	Letter	MNRF providing GBR with letters and map sent to stakeholders and Indigenous communities regarding hunting closures needed for safety considerations of staff in designated area. The restriction is not intended to abrogate or restrict any rightsholder who is wishing to harvest.	GNFN_09192023_03.pdf GNFN_09192023_04.pdf
C-01638	23/09/26	Asubpeeschoseewagong Netum Anishinabek	Letter	Follow up to previous communication and in response to Asubpeeschoseewagong Netum Anishinabek's recent communication to the Impact Assessment Agency of Canada, the Great Bear team would like to reiterate its commitment to meeting with the Community and the Land Protection Team. Our goal remains to foster open and productive discussions regarding our Project, and we welcome discussion on capacity and participation considerations. Reiteration that the GBR team is open to arranging in-person, or virtual meetings at your convenience. The Great Bear team look forward to engaging in meaningful conversations with the Community. We are eager to identify potential synergies between the community's interests and the objectives of the Great Bear Project. Through this collaborative approach, our aim is to create a positive and mutually beneficial impact, contributing to community well-being.	GNFN_09262023_01.pdf
C-01670	23/09/28	Asubpeeschoseewagong Netum Anishinabek	Email	GBR provides details of the attached Great Bear Industrial Sewage Works Application Draft, and Great Bear ISW Aquatic Resources Monitoring Plan Draft supporting the Advanced Exploration (AEX) Program. Noted that both documents have been uploaded to the SharePoint site (links below). The Industrial Sewage Works and Aquatics application documents contain details related to: - Environmental setting - AEX Program project description - AEX Program water management plan - Assimilation Study, including CORMIX modelling - Proposed discharge limits to the Chukuni River (the proposed receiving environment) - Draft surface water monitoring programs - Draft aquatic monitoring programs The GBR team invites comment and input from the Land Protection Team. GBR reiterates that as part of the development of the Great Bear Project and the AEX Program is committed to robust mitigation and protection measures designed not only to meet regulatory standards but also to ensure the ongoing safeguarding of water resources. GBR requests the opportunity to arrange an in-person, brief call or virtual meetings at your convenience, in addition to dialogue on capacity and resources to support review.	Engagement not related to Project
C-01692	23/09/28	Asubpeeschoseewagong Netum Anishinabek	Email	In follow up to our earlier communications, GBR are happy to share with ANA the details of the attached Great Bear Environmental Compliance Approval for Air and Noise Draft, Emission Summary and Dispersion Modelling Report, Fugitive Dust Best Management Practices Plan supporting the Advanced Exploration (AEX) Program. All the documents have been uploaded to the SharePoint site. The GBR team welcomes comment and input from the Lands Protection Team. Consistent with GBR's prior communication GBR also provides the opportunity to arrange an in-person, call or virtual meeting at ANA's convenience, in addition to dialogue on capacity and resources to support review. The summary and cover letter are attached.	Engagement not related to Project
C-01728	23/10/06	Asubpeeschoseewagong Netum Anishinabek	Email	GBR provides details of the attached Great Bear Advanced Exploration Program, Permit to Take Water Application for Dewatering for draft input and review. The GBR team looks forward to your comments and ongoing input from the Lands Protection Team. As refelcted in the communication GBR offers to arrange an in-person, phone call or virtual meetings at your convenience. The GBR team welcomes the opportunity to discuss dialogue on resources to support ongoing input and review needs for advanced exploration documentation, and federal approvals for the Great Bear Project.	Engagement not related to Project
C-01869	23/10/06	Asubpeeschoseewagong Netum Anishinabek	Email	Details of the Great Bear Advanced Exploration Program, Permit to Take Water Application for Dewatering for draft input and review.	Engagement not related to Project
C-01983	23/10/06	Asubpeeschoseewagong Netum Anishinabek	Email	ANA requesting access to the WSP SharePoint to access the AEX PTTW for Dewatering report.	Engagement not related to Project
C-01898	23/10/19	Asubpeeschoseewagong Netum Anishinabek	Letter	Reception of letter from ANA FN Land Protection Team regarding their comments on the previous communications and IAAC concerns that have not been addressed. The letter expresses concern over IAAC's handling of the Great Bear Gold Project, citing lack of meaningful engagement, exclusion from the pre-planning phase, and failure to respect their unique circumstances, including grieving periods and capacity challenges. They argue the impact assessment process is premature, as GBR has not demonstrated a viable project, and unresolved strategic issues between ANA and the Crown remain. The letter calls for IAAC to terminate the current process and restart it only after addressing these fundamental concerns, ensuring ANA is meaningfully involved from the outset.	GNFN_10192023_01.pdf

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-01902	23/10/20	Asubpeeschoseewagong Netum Anishinabek	Email	Great Bear sharing the Advanced Exploration Program Preliminary Mine Rock Management and Monitoring Plan Memorandum for the Great Bear Project, detailing metal leaching and acid rock drainage considerations. The memorandum outlines current geochemical test data, management plans for mine rock and overburden, and mitigation strategies to minimize potential environmental impacts. A monitoring plan is also included, with updates planned as more data becomes available. GBR welcomes feedback from the Lands Protection Team and is open to meetings to discuss input, capacity support, and review needs. The document has also been shared with Lac Seul and Wabauskang First Nations for their input. Great Bear notes that this document will continue to be updated with additional program planning and geochemical information when available, along with a request for meeting.	Engagement not related to Project
C-01905	23/10/20	Asubpeeschoseewagong Netum Anishinabek	Email	Distribution of the AEX Hydrogeology Monitoring Plans and other information related to the Advanced Exploration Program (AEX) for the Great Bear Project in support of the previous Environmental Compliance Approval for Industrial Sewage Works. This plan includes details related to monitoring approaches, mitigation, contingency measures, and data reporting.	Engagement not related to Project
C-02001	23/10/31	Asubpeeschoseewagong Netum Anishinabek Impact Assessment Agency of Canada (IAAC)	Email	Communication from the IAAC to indicate that the ANA Lands Protection Team had emailed them to schedule a joint meeting and discuss the preparation of a process agreement and address capacity supports.	
C-01975	23/11/03	Asubpeeschoseewagong Netum Anishinabek	Email	Providing ANA with a Draft Closure Plan via SharePoint. The plan builds on the previously issued Closure Strategy Memorandum. The key objective of the draft Closure Plan with respect to the AEX Program are to: Provide for the rehabilitation of affected landscapes, and return of affected ecosystems to a self-sustaining and function state that considers the desires of local Indigenous groups; Seek to the extent practice promote vegetation communities that will support habitat for local terrestrial species, and aquatic habit that will support health fish populations; Prevent, reduce or mitigate the adverse environmental effects associated with construction and operations of the AEX Program, during the closure and post-closure phases; and Reduce the need for long-term monitoring and maintenance of the AEX Program area. GBR also adds that they are looking forward to receiving comments from ANA, and that they welcome the opportunity to discuss capacity resources to support ongoing input and review needs as well.	Engagement not related to Project
C-02046	23/11/07	Asubpeeschoseewagong Netum Anishinabek Impact Assessment Agency of Canada (IAAC)	Email	Communications with ANA and the IAAC regarding their availabilities for a meeting. The proposed meeting agenda from ANA addresses the issues with the IA process to date, the premature initiation of process, the pre-planning timeline and appropriate discussion along with demands to suspend process and restart if possible. Follow-up and by Great Bear team was proposed to ANA Lands Protection Team to discuss a pause to the Phase 1 process to allow for time to prepare a Process Agreement and address capacity supports.	GNFN_11072023_01.pdf
C-01967	23/11/10	Asubpeeschoseewagong Netum Anishinabek	Email	Sharing the draft Detailed Project Description for the Great Bear Project via SharePoint with ANA. Indicated by GBR that the comments anticipated are appreciated and that a follow-up meeting to discuss can be scheduled, and that Great Bear looks forward to the upcoming joint meeting with the IAAC. Great Bear notes commitment to ongoing dialogue and welcome the opportunity to confirm a mutually agreeable approach to ensure that the Lands Protection Team and leadership can participate in an informed and capacity supported manner.	
C-02076	23/11/10	Asubpeeschoseewagong Netum Anishinabek Impact Agency of Canada (IAAC)	In Person	Meeting between representation of ANA, GBR, and the Impact Assessment Agency of Canada. IAAC provided presentation materials ahead of meeting to support, note ANA provided notice that review of GBR provided materials will not be completed at this time. Principal dialogue occurred between representatives GBR and ANA. Request from ANA to apply a pause to all activities until former protocol agreement can be put in place to ensure information sharing. Noted commitment to affirm follow up meeting timing to address actions, including consideration to pause. GBR staff reaffirmed Company commitment to provide capacity to support informed dialogue, but will not pause the permit reviews. GBR has shared all the information starting in 2022. Key concerns articulated by ANA included a focus on community dialogue and integration of that knowledge over the course of the Project, lack of consultation to date, requirement for an appropriate protocol, and illustrating concerns that the Project presents an ongoing risk to the communities Aboriginal and Treaty Rights. ANA explained that it wants to resolve long-standing issues with Ontario and Canada first before it supports any development. ANA will not support the Project no matter what GBR does to resolve ANA concerns about the Project.	GNFN_11102023_01.pdf

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-01959	23/11/17	Asubpeeschoseewagong Netum Anishinabek	Email	Thank you message from GBR to ANA for meeting with the team on November 10th, GBR expressed their importance in understanding their interests as well as explaining ours, and emphasizing the value that they place on these relations. Commitment to community is also emphasized as they wish to continue engaging and keeping the community informed and receiving their input. A follow-up meeting was discussed to further proceed on positive footing and to establish a Process Protocol to define and facilitate Great Bear decisions and to also review project timelines and permitting and the request from ANA to pause all activities. A follow-up meeting with dates and methods were provided to ANA.	GNFN_11172023_01.pdf
C-02032	23/11/20	Asubpeeschoseewagong Netum Anishinabek	Email	Contact from GBR to ANA regarding archeological findings. Further condolences and understanding is extended to the community, along with ensuring that timely information sharing from GBR will still occur and not to worry about delays from the Lands Protection Team. The Great Bear team completed a Stage 2 Archaeological Assessment this year as part of the ongoing development of the Project. Our team has received preliminary information that several sites were identified as requiring a Stage 3 Archeological Assessment. A Stage 3 archaeological assessment is planned for 2024 to determine the extent, depth, and complexity of these sites. Collaboration with Indigenous partners is sought to develop investigation strategies and mitigation measures. The final Stage 2 report will be shared upon completion, and discussions are encouraged for Stage 3 planning and mitigation approaches. Assessment work is intended to accomplish two primary objectives: to determine the extent and complexity of the archaeological resource identified at Stage 2 and to work with Indigenous Communities in developing strategies for investigating the sites and for determining appropriate mitigation measures. The Great Bear team welcomes the participation of the Lands Protection Team in its completion, and hope this can be discussed and planned to move forward.	
C-02023	23/11/27	Asubpeeschoseewagong Netum Anishinabek	Email	Following up and thanking the ANA for meeting with the GBR team on November 10, 2023. Great Bear communicated that they understand the interests and acknowledged current community conditions and direction of ANA. This consideration was emphasized along with the further engagement and consultation note and continuation across the Project. A follow-up meeting was discussed to establish a process protocol and define and facilitate further Great Bear discussions with the Lands Protection Team.	
C-02109	23/12/05	Asubpeeschoseewagong Netum Anishinabek	Email	GBR sending ANA a draft engagement protocol in anticipation for the upcoming meeting between ANA and GBR.	GNFN_12052023_01.pdf
C-02094	23/12/15	Asubpeeschoseewagong Netum Anishinabek	In Person	Meeting between representation of ANA and GBR. Key Considerations and discussion centered on GBR applying a pause to project related activities, consent of ANA to the project, and considerations to ANA law. Noted dialogue on capacity funding and formation of a fulsome engagement agreement. Note that no dialogue related to project components outside of considerations to timeline of project.	Confidential engagement
C-02099	23/12/15	Asubpeeschoseewagong Netum Anishinabek	Letter	Follow-up from November 10th meeting with ANA. GBR expresses the importance of establishing good relations and understanding interests, along with the suggestion of a follow-up to proceed, and develop a process protocol. A follow-up meeting was established for December 15th over Zoom, with the Agenda including: Pause to IA process proposed by ANA, ANA law, Right to Consent, Engagement Protocol, and Capacity Funding. ANA also provided two documents to assist with the discussion which include the List of Issues for Negotiation between ANA and Mines, and the ANA assumptions for Great Bear Project Capacity Supports.	Confidential engagement
C-02258	24/01/02	Asubpeeschoseewagong Netum Anishinabek	Email	Funding agreement and timeline distributed to ANA in response to the December 15th, 2023 meeting. GBR extended their thanks to ANA and stated that they look forward to meeting with the Lands Protection Team and are excited to	Confidential engagement
C-02390	24/01/02	Asubpeeschoseewagong Netum Anishinabek	Letter	Distribution of the Funding Agreement and Timeline to ANA in follow-up to the December 15th, 2023, meeting. Great Bear provides detailed timelines and anticipated submission dates to ANA for consideration. Great Bear reiterates their eagerness to continue dialogue and meet with the Lands Protection Team into 2024. Capacity funding formally offered for consideration by ANA Lands Protection Team.	Confidential engagement
C-02358	24/01/31	Asubpeeschoseewagong Netum Anishinabek	Email	GBR providing an update on the proposed Work Permit(s) for the work on two rights-of-way (ROWs) over Crown land and leased land in support of the Advanced Exploration Program for the effluent discharge pipeline and associated infrastructure along with the connection of the natural gas pipeline with existing Enbridge metering station. Files included a Summary of Project Description for determination of a class EA, the Work Permit Application for Easement and Culvert Crossings; the Land Use Permit to cover the land tenure until land is brought to lease, and Request for Review from Department of Fisheries and Oceans. GBR also notes that a power line is mentioned in the WP however due to the decision not to heat trace the effluent line this distribution line is no longer needed now. Shapefiles related to the right of way, and	Engagement not related to Project
C-02467	24/01/31	Asubpeeschoseewagong Netum Anishinabek	Email	GBR providing an update on the proposed Work Permit for two ROWs over Crown Land and leased land in support of AEX, which further supports effluent discharge pipelines and associated infrastructure, and a natural gas pipeline in connection to the Enbridge metering station. GBR informed ANA regarding the submission to the MNRF submission along with which files are currently under review. A follow-up meeting with GBR was offered, along with anticipation of any immediate questions.	Engagement not related to Project

C-02404	24/02/02	Asubpeeschoseewagong Netum Anishinabek	Email	Notification to ANA of the lease applications being sent to the Provincial Mining Recorder to start the Lease Mining Claims as of Februaty 2nd, 2024. Four separate lease packages and location maps were attached for review.	ANA_020224_01.pdf ANA_020224_02.pdf ANA_020224_03.pdf ANA_020224_04.pdf
C-02415	24/02/02	Asubpeeschoseewagong Netum Anishinabek	Email	Distribution of materials to ANA to better understand the approach Great Bear is currently taking to regional work relating to Species at Risk. The Lands Protection Team expressed interest in our environmental approach and its connection to the land and species. Our terrestrial ecology work has identified Wolverine as a notable species. To build on this research, we will be submitting an application and proposed scope of work to the MNRF for Wolverine run poles. GBR proposes constructing and operating two to three baited run poles as part of monitoring requirements under the provincial Endangered Species Act (ESA) for early mineral exploration. Run poles, a non-invasive method, help identify individual Wolverines by their unique chest markings. This approach aligns with successful monitoring efforts in Red Lake by the Wildlife Conservation Society. Great Bear looks forward to discussing our baseline program and terrestrial findings in our next meeting.	Engagement not related to Project
C-02409	24/02/08	Asubpeeschoseewagong Netum Anishinabek	Email	Distributing the Notice of Commencement for the Great Bear Temporary Power Project to ANA prior to the public distribution of the notice for radio, event boards, Facebook, and the Chronicle Journal.	GNFN_02082024_01.pdf
C-02424	24/02/09	Asubpeeschoseewagong Netum Anishinabek	Email	ANA request to have SharePoint Site Access. GBR replied that they had provided access.	
C-02470	24/02/16	Asubpeeschoseewagong Netum Anishinabek	Email	Further distribution of the Work Permit/ROW for the AEX program to ANA legal team.	Engagement not related to Project
C-04271	24/02/28	Asubpeeschoseewagong Netum Anishinabek	Email	Confirmation from ANA that they were able to download the AEX documents sent.	Engagement not related to Project
C-04272	24/02/28	Asubpeeschoseewagong Netum Anishinabek	Email	ANA confirming they have reviewed the funding agreement proposal, and sending over the assumptions and budget reflecting capacity needs for engagement in the Great Bear Project.	Confidential engagement
C-06433	24/02/28	Asubpeeschoseewagong Netum Anishinabek	Email	ANA stating that they have reviewed the funding agreement proposal, and issue back an attached assumptions and budget reflecting the capacity needs in order to engage with the GBR Project moving forward.	Confidential engagement
C-04279	24/03/07	Asubpeeschoseewagong Netum Anishinabek Impact Assessment Agency of Canada (IAAC) Ontario Ministry of Northern Economic Development and Growth (MNEDG)	Letter	ANA issued communication and memorandum report on their preliminary concerns about the Great Bear Project. Letter issued to GBR, Ministry of Mines and IAAC. In the letter, ANA explains their deep concern about the project and the impact it will have on the community. ANA formally rejects the Great Bear Project, asserting its inherent jurisdiction and governance over its lands. ANA opposes all permitting and approvals, citing environmental risks to water, wildlife, and traditional land use. It emphasizes a long-standing commitment to resisting industrial resource extraction and insists that no consultation or mitigation can justify the project. ANA demands that federal and provincial authorities respect Anishinaabe law and governance, reaffirming its sovereignty and right to self-determination.	GNFN_030724_01.pdf
C-06390	24/03/07	Asubpeeschoseewagong Netum Anishinabek Environment and Climate Change Canada Great Bear Gold Project Projet Aurifère Great Bear Ontario Ministry Indigenous Affairs & First Nations Economic Reconciliation (IAFNER) Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Natural Resources (MNR)	Email	Correspondence attached from the Chief and Council of ANA concerning the Great Bear Gold Project. The letter explains ANA's views on the Crown's outstanding obligations to ANA, and the ANA concerns surrounding the process of Ontario's current approach, and the path to reconciliation. The letter also highlights ANA preliminary specific concerns regarding the downstream, and on-site, landscape, spiritual, and other impacts.	GNFN_030724_02.pdf
C-06434	24/03/07	Asubpeeschoseewagong Netum Anishinabek	Letter	GBR distributing a response letter to ANA in response to the budget request. GBR offered to provide ANA with interim funding to facilitate review for the AEX Permit Application. GBR invited ANA to a meeting at a time convenient to the Lands Protection Team after March 11th. Budget request is in relation to that issued by ANA to GBR on February 28th, 2024.	Engagement not related to Project
C-06435	24/03/07	Asubpeeschoseewagong Netum Anishinabek	Email	ANA response to GBR's letter regarding funding. ANA confirmed availability for a meeting on March 21st.	Confidential engagement
C-06436	24/03/07	Asubpeeschoseewagong Netum Anishinabek	Email	GBR agrees to proposed meeting time by ANA. GBR also reiterates that they look forward to speaking with the Lands Protection Team. They also asked ANA to confirm if their team will provide a link to a virtual meeting, or if they would prefer GBR sent one.	
C-06438	24/03/08	Asubpeeschoseewagong Netum Anishinabek	Email	ANA providing the details for the Zoom meeting on March 21st from 3-4 PM CDT.	
C-06439	24/03/08	Asubpeeschoseewagong Netum Anishinabek	Email	GBR thanking ANA for providing the call-in details in anticipation for the March 21st meeting. GBR reiterates their thanks for the meeting and inquires if ANA would appreciate a presentation on the status of the Project or any other recent	
C-06440	24/03/08	Asubpeeschoseewagong Netum Anishinabek	Email	ANA thanks GBR for their previous capacity office to support review of Advanced Exploration materials, and notes that at this time no discussion on materials will occur. ANA states that do to lack of capacity funding to engage with GBR the only purpose of the meeting is to discuss capacity funding and budget request. ANA also reiterates that the proposed capacity funding is insufficient at this time.	Engagement not related to Project

C-06441	24/03/12	Asubpeeschoseewagong Netum Anishinabek	Email	WSP providing the emails which gave ANA members the access to the Sharepoint site.	
C-07763	24/03/21	Asubpeeschoseewagong Netum Anishinabek	Virtual	ANA and GBR held a virtual meeting on March 21, 2024. In this meeting, GBR reiterated the stance that the capacity funding committed is intended to be interim in nature, to support immediate participation while the Lands Protection Team and GBR discuss the larger budget request and define the communication protocol forward for the Great Bear Project.	Confidential engagement
C-07569	24/03/22	Asubpeeschoseewagong Netum Anishinabek Great Bear Gold Project Projet Aurifère Great Bear	Email	The Impact Assessment Agency of Canada (Agency) is of the opinion that a federal impact assessment is warranted for the Great Bear Gold Project, as proposed by GBR (the Proponent). This opinion is based on the Agency's review of the Detailed Project Description and the responses to the Summary of Issues, along with the consideration of other factors, including comments received to date from Indigenous communities, federal authorities, provincial ministries, and the	GNFN_032224_01.pdf
C-06487	24/03/26	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Letter	ANA reiterated concerns regarding the permitting process for the Great Bear Gold Project to the Ministry of Mines and copied Great Bear, emphasizing the significant barriers that prevent meaningful engagement. Despite repeated communications about these challenges, ANA expressed concern that MINES will proceed without addressing them. The proposed advanced exploration activities are extensive and akin to opening a small to medium-sized mine, with significant potential impacts on water quality, fish, wildlife, and ANA's rights and interests. Of particular concern is the risk of mercury methylation, given the existing contamination in the river system. A preliminary review of the permit application revealed substantial gaps in information, particularly regarding the release of substances into the environment and their effects on downstream communities. ANA asserts that free, prior, and informed consent (FPIC) is required and requests additional time and capacity support to conduct a thorough assessment. The community cautions that its inability to respond in detail at this stage should not be misinterpreted as a lack of concern. The consultation process has been flawed from the outset, with MINES erroneously assessing the duty to consult as "low," failing to seek input from ANA on its rights and land use, and improperly delegating consultation to GBR. The assessment overlooked key factors, including ANA's historical and ongoing use of the project area for hunting and other activities, its position as the first downstream community, and the severe cumulative effects the community has already endured. Despite recent developments, MINES has not committed to addressing cumulative impacts, land use control	Confidential engagement

C-06488	24/03/29	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Letter	ANA issues communication to GBR and Ministry of Mines. Communication details ANA's evaluation of the expected water quality both during and after Advanced Exploration from the Minesite Drainage Assessment Group. The letter states that the project cannot be started with sufficient certainty of environmental protection and avoidance of all off site contamination due to missing, preliminary and contradictory ML-ARD information inconsistent with regulations. The email distributing the letter also stated that they continue to urge Mines/GBR to not make a decision until complete information has been provided and ANA's review is completed.	Engagement not related to Project

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-07667	24/04/04	Asubpeeschoseewagong Netum Anishinabek Great Bear Gold Project Projet Aurifère Great Bear Ontario Ministry Indigenous Affairs & First Nations Economic Reconciliation (IAFNER) Ontario Ministry of Energy & Mines (MOEM)	Letter	ANA letter to IAAC in response to the March 22, 2024 correspondence to Chief Turtle advising the IAAC opinion that a federal assessment is warranted for the Great Bear Gold Project. ANA reaffirms its expectation that the consultation process for the Great Bear Gold Mine Project adhere to the standard of free, prior, and informed consent (FPIC), as outlined in the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) and Canada's UNDRIP Act. ANA insists that the Impact Assessment Agency of Canada (IAAC) align the federal impact assessment process with the principles of FPIC, particularly in relation to projects impacting Indigenous lands and resources. Canada's endorsement of UNDRIP requires this standard of consultation, and ANA expects that the Agency respect its right to either provide or withhold consent throughout the process. The letter emphasizes several expectations for the impact assessment: the process must be co-created with ANA, tailored to their unique circumstances, and require ANA's consent. The Impact Assessment should be paused until the concerns expressed by ANA are addressed, and consent is obtained. Additionally, the assessment should include a determination of whether ANA's FPIC has been secured, and its scope must encompass all activities that could affect the Nation's rights and interests. The letter further stresses that no project-related impacts under federal authority should proceed without obtaining ANA FPIC. ANA requests a written response outlining how Article 32 of UNDRIP will be implemented in the	GNFN_040424_01.pdf
C-07668	24/04/04	Asubpeeschoseewagong Netum Anishinabek Impact Assessment Agency of Canada (IAAC) Ontario Ministry of Energy & Mines (MOEM)	Letter	GBR's response to ANA communication letters sent on March 6th, 2024 and March 27th, 2024. Great Bear distributed multi part response letter, citing the March 27th letter, a memo on the AEX program regarding the water and water quality, and project footprint, and the consultation record between GBR and ANA. GBR notes in communication that it acknowledges ANA's concerns outlined in the 6 March 2024 letter and seeks to establish positive relations with local Indigenous communities, including ANA, through transparent engagement. Great Bear is committed to explaining the Project, listening to community interests, and working to reconcile various perspectives. Many of the concerns raised by ANA are already included in the scope of the planned federal impact assessment, where they will be addressed. For concerns related to GBR's Advanced Exploration (AEX) Permit, GBR has provided specific responses. GBR will continue to engage with ANA throughout the project's review stages to gather input, inform planning, and address reasonable concerns.	Engagement not related to Project
C-07670	24/04/05	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Email	Distribution of the finalized Closure Plan to ANA, along with re-sending ANA the letter distributed on March 27, 2024 and GBR's response. This document attached outlines GBR's response to the comments in the MSDAG Letter on behalf of Asubpeeschoseewagong Netum Anishinabek (ANA), particularly regarding the geochemical information in the Advanced Exploration Program Draft Closure Plan (AEX Program Draft CP). GBR has addressed these concerns in the table provided. Since submitting the AEX Program Draft CP, GBR has continued environmental baseline investigations, geochemistry programs, and engineering designs, incorporating new findings into the plan. While updates are being made to reflect the latest results, the overall project design and reclamation strategy remain unchanged. GBR is committed to meeting or exceeding regulatory requirements and will share the Final AEX Program Closure Plan with ANA once completed.	Engagement not related to Project
C-07806	24/04/16	Asubpeeschoseewagong Netum Anishinabek	Email	GBR confirming with ANA that this message was received, and GBR will discuss internally and get back to on a proposal for the budget meeting.	
C-07795	24/04/25	Asubpeeschoseewagong Netum Anishinabek Crown-Indigenous Relations and Northern Affairs Canada Environment and Climate Change Canada Impact Assessment Agency of Canada (IAAC) Indigenous Services Canada Ontario Ministry Indigenous Affairs & First Nations Economic Reconciliation (IAFNER) Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Labour, Immigration, Training and Skills Development (MLITSD) Ontario Ministry of Natural Resources (MNR)	Letter	Letter from ANA Lands Protection Team, concerning the Great Bear Gold Project directed to IAAC, and Mines and GBR in copy. The correspondence includes two documents prepared by Dr. Kevin Morin concerning metal leaching and acid rock drainage, water quality and hydrogeology. ANA raises their concerns regarding the Great Bear Gold Project, citing expert analysis from Dr. Kevin Morin of MDAG. MDAG findings highlight multiple environmental risks related to metal leaching, acid rock drainage, water quality, and hydrogeology, many of which he argues are either unrecognized or inadequately addressed by Great Bear. These concerns apply to both the advanced exploration phase and the proposed full-scale mining operation. ANA asserts that the project is advancing too quickly without sufficient environmental assessments, posing risks to the environment, public health, and the inherent, Treaty, and Indigenous rights of the community. They are calling for an immediate freeze on the regulatory process until comprehensive environmental data is available and meaningful Indigenous involvement is ensured. Additionally, ANA demands that the project, including what they consider extensive bulk sampling equivalent to full-scale mining, undergo a rigorous environmental assessment. Until these conditions are met, they maintain that moving forward with the project would be premature and irresponsible.	GNFN_042524_01.pdf

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-08252	24/05/28	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Letter	GBR distributing the attached response to the Riverbank Mercury Methylation Study in relation to the Great Bear Project to ANA Lands Protection team for consideration. The study was included in the Prelim Comments -Supporting Materials-Great Bear AEX Closure Plan and Other Authorizations 4856-449v.1 which ANA sent to GBR on May 23, 2024. The response reiterates that these conditions in the study are not present in the Chukuni River, which is the proposed receiving environment for the effluent from the Great Bear Project, and that the conditions in the study which caused methylmercury to be present will not be sufficient to activate sulphate reducing bacteria, which then release methylmercury.	Engagement not related to Project
C-10000	24/05/29	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Energy & Mines (MOEM)	Email	Request from ANA to MINES regarding the June 10th deadline for comments for the AEX Closure Plan. ANA will need more time in order for expert responses to have a chance to prepare their reports. ANA reiterates their concern regarding the possibility of additional contributions of additional methylation to the river system. ANA urged MINES to provide a pause on the review of the Closure Plan until the end of June in order to accommodate ANA for the receipt of their expert's advice. ANA notes that if there is any potential for the Great Bear Gold project to contribute additional methylation to the river system, impacting on fish that travel throughout that system, is of significant concern to ANA and has the potential to have not just adverse but severe impacts on the community.	Engagement not related to Project
C-10001	24/06/05	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Email	MINES communication to ANA Lands Protection team that it is preparing a response to a May 23, 2024 letter from ANA. MINES had initially requested comments by June 10, 2024, regarding potential adverse impacts on ANA's treaty or Aboriginal rights due to the Great Bear Advanced Exploration Project's Closure Plan. In response to ANA's May 29, 2024 request for an extension, MINES has agreed to extend the deadline to June 30, 2024. This extension allows ANA's expert, Dr. Branfireun, additional time to review Great Bear Resources' May 28, 2024 response on the River Mercury Methylation Study. MINES hopes to decide by July 2, 2024, whether to invite the proponent to submit the Closure Plan.	Engagement not related to Project
C-08542	24/06/07	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Environment and Climate Change Canada Great Bear Gold Project Projet Aurifère Great Bear	Email	The Lead Negotiator for the ANA Lands Protection Team provided GBR with ANAs initial comments on the Indigenous Engagement and Participant Plan for the Great Bear Gold Project Impact Assessment. These comments were submitted via the Agency's online Registry earlier today. Initial comments on the Tailored Impact Statement Guidelines have been submitted separately by ANA's co-counsel. ANA states they have not had enough time or capacity support funding to complete its review of the IEPP. ANA argues that 30 days is not enought to review and provide comments on the IEPP and other documents like the draft Tailored Impact Statement Guidelines. The Agency takes nearly a month to respond to short letters from ANA, even though it has extensive capacity and experience with this process. ANA repeats their request that the Impact Assessment process be paused until the concerns and barriers expressed in our previous letters have been resolved and ANA's consent for the Impact Assessment process is obtained.	Confidential engagement
C-08445	24/06/12	Asubpeeschoseewagong Netum Anishinabek	Email	ANA prepared a response to the GBR offer. GBR to review the response and reply. One key point to address is the scope of the budget proposal. ANA wants it understood that this is a preliminary budget, and that further funding will be required through the permitting process.	Confidential engagement
C-08540	24/06/14	Asubpeeschoseewagong Netum Anishinabek Lac Seul First Nations Ontario Ministry of Natural Resources (MNR) Wabauskang First Nation	Email	MNRF providing GBR with a letter providing an update on the delegation of consultation. In the letter MNRF states that they are in the process of sending letters to WFN and LSFN to give them an update on the project status and status on the delegation. MNRF will continue to keep GBR updated as they receive comments from the communities. MNRF states that unless there are outstanding questions and concerns raised regarding the FRL/PTR and Work Permit, MNRF may be in a position to deem consultation with the communities listed above complete. MNRF continues to respond to ANA regarding the authorizations and Consultation.	Engagement not related to Project
C-08443	24/06/16	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	Comments from CELA, co-counsel for ANA, on behalf of ANA on the PTTW. ANA states that the proposed PTTW should not be issued to GBR as they view, the PTTW is premature, unreasonable in light of the applicable law/policy framework and could result in significant environmental harm.	Engagement not related to Project
C-08448	24/06/17	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Environment and Climate Change Canada Great Bear Gold Project Projet Aurifère Great Bear Impact Assessment Agency of Canada (IAAC)	Email	GBR copied on a letter to IAAC and Environment and Climate Change Canada, in which ANA states their preliminary position with respect to an aspect of the scope of the Great Bear Gold Project Impact Assessment. ANA believes that the Advanced Exploration ("AEX") activities proposed by GBR, specifically bulk sampling and associated activities, constitute a designated project under the Impact Assessment Act. ANA requests that the Minister chooses to suspend consideration of the designation requests, until the rules of the Impact Assessment process are clear and the Minister is able to consider designation requests that are needed to protect the environment and the rights, health, and wellbeing of	Engagement not related to Project

TI was ANA's understanding that there are no major issues and that GBR would take the budget back to the GBR team and respond to ANA with a version of the Capacity Budget that GBR are ready to support, and a proposed short agreement to go with it. ANA is open to the payment arrangement that GBR proposed, whereby Great Bear would make direct payment on most expenses after receiving from ANA a brief invoice from the	Confidential engagement
C-09977	24/06/17	Asubpeeschoseewagong Netum Anishinabek	Email	GBR writing to ANA that the GBR internal team will be meeting soon to review the latest ANA budget, and that a response will come soon along with the invoicing requirements. GBR reiterated that they believe they are close to an agreeable arrangement for capacity funding.	Confidential engagement
C-08961	24/06/24	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	Request from ANA to designate the Great Bear Resources Mine Project to a Part II.3 Comprehensive Environmental Assessment under the Ontario Environmental Assessment Act. The formal request cites previous reports sent to IAAC regarding mercury and metal leaching, along with reiteration of cumulative impacts which need to be examined due to other land uses in the land surrounding ANA for the reasoning behind the request.	GNFN_062424_01.pdf GNFN_062424_02.pdf
C-09978	24/06/26	Asubpeeschoseewagong Netum Anishinabek	Email	ANA response to Capacity funding conversation if there was a version of the proposed offer in a table to share and if this is a short draft agreement. ANA reiterated that there are a number of deadlines for both AEX and the IA coming up and that capacity support is one of the foundations of being able to be informed on the GBR project.	Engagement not related to Project
C-09581	24/06/30	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Letter	Letter sent from ANA to Mines with GBR copied on June 30, 2024. In the letter, ANA states that they will continue to rely on information from their experts, and reiterated previous letters and issues. ANA also stated that they felt there have been inadequate responses to these previous letters and issues stated from both Mines and GBR. ANA also responded to previous comments from GBR regarding the mercury methylation study and stated that GBR's response was inadequate. The review of the Closure Plan from ANA with the recommended response being "rejection" of the Project was also attached. Letter communication from ANA Lands Protection team articulates the formal objections of ANA to the proposed Closure Plan for the Advanced Exploration (AEX) phase of the Great Bear Gold Project. ANA contends that the Closure Plan is fundamentally flawed and poses a significant threat to their inherent, Aboriginal, Treaty, and Indigenous rights, as well as to the environmental integrity of their territory. A central grievance is the perceived inadequacy of Great Bear and the Ministry of Mines' responses to ANA apprehensions. ANA further argues that the Ministry of Mines has demonstrated a lack of due diligence in its assessment of the Closure Plan, prioritizing expediency over substantive engagement with the First Nation and its expert evidence. ANA criticizes the insufficiency of the Provincial Water Quality Objectives (PWQO) as a regulatory standard, highlighting its failure to account for the unique vulnerabilities of the ANA community and the bioaccumulation of mercury in the aquatic	Engagement not related to Project
C-09987	24/07/03	Asubpeeschoseewagong Netum Anishinabek	Email	Distribution of the capacity budget proposal to ANA. C-09156	24/07/07	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association	Letter	ANA submission to MECP Client Services and Permissions Branch regarding the GBR ECA ISW submission and previously submitted letters to IAAC and Mines. In the letter regarding GBR ECA ISW, ANA requests that the MECP reject the GBR application for ECA ISW due to the previously sent letters concerning riverbank mercury methylation from May 14, 2024, the response to the WSP memo dated June 27, 2024, a letter from researchers dated July 5, 2024, which critiqued the lack of sulphate monitoring in the ECA application which researchers state could continue the impact on methylmercury, a 2003 guideline on mercury published in the Canadian Water Quality Guidelines for the Protection of Aquatic Life, The Ministry of Environment for the Province of British Columbia's Ambient Water Quality Guidelines for Sulphate Technical Appendix from 2013, the April 25th, 2024 ANA letter to IAAC, Mines, and GBR, and ANA's review of the ECA application. The new July 7, 2024 letter stated reasons behind the decision citing believed inadequacies behind the scientific and technical documents supporting the application, Ontario red tape reduction which repealed provincial mining effluent limits, the lack of consistency in the ECA proposal and how it was developed with the MECP's Statement of Environmental Values, along with citing the past conduct of Kinross and/or its wholly owned subsidiaries in other jurisdictions which they state will afford ANA with reasonable grounds to believe that applicants will not engage in activities in accordance with the EPA, the Ontario Water Resources Act, or regulations made under either of these acts. A legal proceeding between Kinross and the Okanogan Highlands Alliance and State of Washington	Engagement not related to Project
C-09583	24/07/09	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Environment and Climate Change Canada	Letter	GBR July 9, 2024, Letter response to IAAC regarding the June 17 letter sent from ANA to IAAC in regards to the request for the review panel. The letter establishes the Minister's decision criteria, how mining activity in Red Lake is common and the effects are well understood, the support of local Indigenous communities if their interests are met, and that the location, nature and scale of the Project will not create a potential for adverse impacts which would warrant the Review Panel.	GNFN_070924_01.pdf
C-09989	24/07/16	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	GBR response to MoM and MECP Ministers regarding ANA's request to designate the Great Bear Project for a Provincial Environmental Assessment under the Environmental Assessment Act. GBR outlines the ongoing consultation with ANA, and highlights the ongoing review from WFN and LSFN and MoM. The concerns regarding water quality are also taken into account, with further commitments to water quality previously made in the ISW application previously sent, along with the testing results showing a below detection level of mercury in cell test results. GBR also notes that the Project will be subject to a comprehensive federal review, and will follow leading industry practice.	
C-09990	24/07/25	Asubpeeschoseewagong Netum Anishinabek Crown-Indigenous Relations and Northern Affairs Canada Environment and Climate Change Canada Indigenous Services Canada Ontario Ministry Indigenous Affairs & First Nations Economic Reconciliation (IAFNER) Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Natural Resources (MNR)	Letter	GBR response to ANA's comments on the Great Bear Closure plans from the June 30th, 2024, letter sent to Mines. GBR responded to the responses from Dr. Branfireun regarding the Mercury Methylation study, along with a further attachment of a memorandum which further details responses pertaining to water quality previously highlighted. Additionally, GBR responded to the comments from Dr. Morin surrounding closure, and PAG rock.	Engagement not related to Project
C-12926	24/07/31	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	GBR providing a response to the letter from ANA’s counsel dated June 16, 2024, regarding Great Bear’s Permit to Take Water application.	Engagement not related to Project

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

C-09991	24/08/01	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	GBR's response to the ANA comments made on the Industrial Sewage Works Proposal for the AEX Project. GBR responded to the comments previously made and had reiterated that they have provided comprehensive and timely information in support of its AEX permit applications and committed to following leading industry practices and applicable regulatory requirements. GBR also highlights the irrelevance of the comments to the project regarding the recent changes to Ontario's metal mining effluent regulations, and the GBR discharge permit in Washington state, and stated that the MECP should disregard comments on this point.	Engagement not related to Project
C-09994	24/08/01	Asubpeeschoseewagong Netum Anishinabek	Email	ANA distributing the amended draft funding agreement documents, with ANA's edits indicated by track changes in order to reflect previous conversations. ANA states that they would be eager to meet further in order to go over the proposed amendments.	Confidential engagement
C-09995	24/08/01	Asubpeeschoseewagong Netum Anishinabek	Email	ANA re-sending the proposed Workplan and Budget for Capacity funding with updated track changes.	Confidential engagement
C-09996	24/08/01	Asubpeeschoseewagong Netum Anishinabek	Email	GBR acknowledging the receipt of the updated ANA capacity funding agreement. GBR stated they will review internally prior to responding the ANA.	Confidential engagement
C-09998	24/08/02	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Energy & Mines (MOEM)	Email	GBR distributing the SharePoint link to the Final updated Advanced Exploration Closure Plan dated August 1, 2024 to ANA, along with a concordance table to identify minor additions.	Engagement not related to Project
C-09999	24/08/02	Asubpeeschoseewagong Netum Anishinabek	Email	ANA response to GBR's updated AEX Closure Plan. ANA states that the initial review suggests significant changes and additional information which will require time to review. ANA reiterates their concern based on previous Closure Plan submissions, and states that they will be in communication with MINES to advise them that they will need approximately 90 days' time to consult and respond to the Closure Plan and Great Bear's reply to submission. ANA states that it would be unreasonable, dangerous and contrary to the Crown's duty to engage to approve this amended Closure Plan before ANA has had a meaningful opportunity to respond.	Engagement not related to Project
C-09671	24/08/06	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Energy & Mines (MOEM)	Email	Distribution of the Record of Consultation for the Great Bear AEX Project to ANA. MoEM is also copied on the email.	Engagement not related to Project
C-09992	24/08/06	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	Letter from ANA to the MECP requesting a pause to be taken for an unspecified period of time prior to any further decisions on the ECA ISW application in order to have the time for ANA to continue to have the time in order to respond to GBR's previous response to comments.	Engagement not related to Project
C-12930	24/08/07	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	ANA has reviewed GBR's response to their comments on the proposed Permit to Take Water (PTTW) and disagrees with GBR's claim of adequately addressing their concerns. They argue that GBR's summary charts do not address substantive issues, and the revised proposal for a smaller water taking is seen as a "bait and switch." ANA requests a re-opening of the public comment period and emphasizes that the original PTTW application was incomplete. They have also asked for the project to be designated under the Environmental Assessment Act, making it inappropriate to issue the PTTW until this request is resolved. ANA urges the Ministry to refrain from approving any water takings proposed by GBR.	
C-12937	24/08/07	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	MECP confirming receipt of email response from ANA in response to GBR's letter in regard to comments on the PTTW.	
C-12938	24/08/12	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	ANA thanks the Ministry's for the acknowledgement of receipt and advises that the ANA August 7th email to the Ministry constitutes ANA's preliminary response to GBR's July 31st correspondence, and that ANA will be submitting detailed expert and other submissions on the deficiencies within the PTTW application and on the new "scoped" water taking proposal.	
C-09997	24/08/15	Asubpeeschoseewagong Netum Anishinabek	Email	ANA requesting GBR's response to the latest iteration of the capacity support documents regarding changes made. ANA believes that the changes made were only minor and that they were consistent with the discussions previously had. ANA stated that there are a large number of permitting and IA processes underway, and ANA has yet to receive meaningful capacity support, and that funding remains a major capacity barrier to ANA.	Confidential engagement
C-10982	24/08/28	Asubpeeschoseewagong Netum Anishinabek	Email	GBR response to ANA regarding the previously discussed budget and funding agreement. GBR notes assumptions regarding the funding timeline and responses to previously discussed items. GBR also notes they are willing to connect again to discuss outstanding points.	Confidential engagement
C-10983	24/08/28	Asubpeeschoseewagong Netum Anishinabek	Email	ANA response to GBR regarding the draft budget proposal. ANA states that while they feel closer to finalizing, there are some items which may require a discussion in order to ensure GBR and ANA are on the same page. ANA provides a date and time to meet and discuss.	
C-10984	24/08/28	Asubpeeschoseewagong Netum Anishinabek	Email	Confirmation from GBR that the date and time proposed to meet regarding the ANA draft budget proposal works for the team, as well as a further inquiry regarding the possibility of meeting sooner.	

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

C-11322	24/09/03	Asubpeeschoseewagong Netum Anishinabek Environment and Climate Change Canada Headwaters LLP Impact Assessment Agency of Canada (IAAC) Lac Seul First Nations Wabauskang First Nation Woodward and company	Letter	Letter from GBR to ECCC and IAAC regarding the ANA request for a review panel. GBR further reiterates that for reasons previously set out in the Great Bear letter dated 9 July 2024, GBR maintains that a Review Panel will not be required for this Project. GBR also notes that they understand that LSFN and WFN have filed or will file a submission which states why they believe that this review panel would be unnecessary. GBR also notes that LSFN and WFN have designed an Anishinaabe-led Assessment (ALIA) process which complements an Agency-led review of the Great Bear Project, rather than a panel review. GBR also states that they have agreed to assist LSFN and WFN on this ALIA, and will	ANA_090324_01.pdf
C-10556	24/09/06	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Crown-Indigenous Relations and Northern Affairs Canada Environment and Climate Change Canada Great Bear Gold Project Projet Aurifère Great Bear Indigenous Services Canada Ontario Ministry Indigenous Affairs & First Nations Economic Reconciliation (IAFNER) Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Natural Resources (MNR)	Letter	Distribution of letter from ANA regarding the Great Bear Project's application for Approval of Closure Plan. The letter restated previous items brought to MINES in discussions surrounding the Closure Plan which had been addressed by GBR, such as PAG and NPAG, and methylmercury. The letter further discusses ANA's concerns with the adaptive management plan, and the consultation process, specifically surrounding the provincial government. ANA brought up a lack of capacity support, and other applications associated with the GBR such as the ECA PTTW. ANA stated that approving this would be dangerous to ANA, and would cause more pollution, as well as attaching two reports dated September 5, 2024 which respond to the ECA ISW, and the AEX Closure Plan and ECA PTTW.	Engagement not related to Project
C-10540	24/09/10	Asubpeeschoseewagong Netum Anishinabek	Email	Distribution of the Preliminary Economic Assessment press release for the Great Bear Project to ANA. GBR also noted that an updated mineral resource estimate was released which provided an increase to the inferred resource estimate. GBR noted that if there were any questions to contact the team, or join the conference call on September 10, 2024 at 9:00 am	GNFN_091024_01.pdf
C-10985	24/09/12	Asubpeeschoseewagong Netum Anishinabek	Email	ANA ~~noting they are excited~~ to discuss the capacity agreement as scheduled for the upcoming afternoon. ANA have attached proposed revisions and comments on areas for discussion.	
C-10297	24/09/17	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Environment and Climate Change Canada Lac Seul First Nations Wabauskang First Nation Woodward and company	Email	Response from ANA's legal team regarding the July 9, 2024 and September 3, 2024 letters sent by GBR. ANA states that they have reviewed the correspondence from GBR and LSFN and WFN and state that they believe there is no compelling factual, legal, technical, or scientific reasons against referring the project to the Review Panel. ANA states that the GBR letter added nothing new to previous claims, and that the joint letter from WFN and LSFN regarding their Indigenous Led assessment do not have enough details, and that the proposed regulations are not in existence and are not available for the federal government to enter into an assessment agreement at this time. ANA further stated that this would not satisfy the duty to consult ANA, and that they have different interests as ANA is the only community downstream from the project. ANA also states that GBR should not be against the review panel if they have the credibility in their report that they state. ANA requests that no weight should be given to the submitted letters, and the review panel request is still relevant,	
C-10307	24/09/20	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	GBR reiterating that concerns about water quality, specifically sulfate levels, raised by ANA are outside the scope of the PTTW application, which deals with water taking. Water quality issues are addressed under a discharge permit. MECP and the Ministry of Mines have reviewed these issues extensively and found no problems related to sulfate levels. Great Bear will comply with the mobile ECA for water discharge. The consultation record is comprehensive, and there is no need to expand the PTTW review to include out-of-scope issues.	
C-10986	24/09/27	Asubpeeschoseewagong Netum Anishinabek	Email	GBR issuing the blackline of the funding agreement and budget regarding language regarding rights mentioned, proposed language around the circumstances to trigger a re-evaluation of funding amounts, and drafting around the use of government funding.	Confidential engagement
C-10987	24/10/01	Asubpeeschoseewagong Netum Anishinabek	Email	Budget discussion from ANA to GBR regarding funding from additional government sources. ANA proposes to re-word part of the budget and delete the item in order to align with ANA's recommendation.	Confidential engagement
C-10993	24/10/01	Asubpeeschoseewagong Netum Anishinabek	Email	GBR confirming they are alright with the changes proposed to the draft budget agreement by ANA. GBR also distributed an updated version of the draft budget which aligns with these changes, and notes that they will need to set-up ANA in the system in order to process payments, and they may need to speak with ANA's finance department.	Confidential engagement
C-10994	24/10/01	Asubpeeschoseewagong Netum Anishinabek	Email	ANA notes there should be a change to the Workplan and Budget document as well, and shared a version with edits in track change for GBR review.	Confidential engagement
C-10995	24/10/01	Asubpeeschoseewagong Netum Anishinabek	Email	GBR noting to ANA that the edit was appended to the agreement, and they will update the standalone Workplan and Budget as well to reflect the requested changes.	Confidential engagement
C-10996	24/10/03	Asubpeeschoseewagong Netum Anishinabek	Email	ANA following up with GBR regarding the agreement and asking when GBR anticipates sending over a signed	
C-10997	24/10/03	Asubpeeschoseewagong Netum Anishinabek	Email	GBR providing ANA with their signature on the ANA draft budget proposal.	
C-10998	24/10/04	Asubpeeschoseewagong Netum Anishinabek	Email	Distribution of the fully executed agreement for the ANA draft budget agreement. ANA also requests that the paperwork GBR previously referenced regarding financial paperwork to submit before receipt of invoices.	Confidential engagement

C-12833	24/11/27	Asubpeeschoseewagong Netum Anishinabek	Email	ANA writing to GBR, noting that they are continuing their work in reviewing permits and IA documents. ANA requests if GBR can provide a comprehensive GIS package which shows all past, present, and proposed activities related to the Great Bear Project, including roads, trails, lines, drill holes, stripped areas, pits, and related infrastructure.	
C-12834	24/12/10	Asubpeeschoseewagong Netum Anishinabek	Email	ANA following up with GBR regarding their November 27, 2024 request if GBR can provide a comprehensive GIS package which shows all past, present, and proposed activities related to the Great Bear Project, including roads, trails, lines, drill holes, stripped areas, pits, and related infrastructure.	
C-11780	24/12/12	Asubpeeschoseewagong Netum Anishinabek	Email	GBR distributing a letter to ANA's land protection team which outlines an offer for assistance to progressing the items outlined in an attached workplan, in accordance with the Funding Agreement. GBR also notes that they would like to meet to discuss plans for the Preliminary Land Use and Occupancy Study.	Confidential engagement

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-12835	24/12/19	Asubpeeschoseewagong Netum Anishinabek	Email	GBR responding to ANA's request for a GIS package including past, present, and proposed Great Bear activities, by distributing the GBR Shapefile Package and providing a link. GBR also notes that they have further broken down the request and provided packages based on Future Considerations, including plans to date (AEX, DPD, and Early Exploration Test Pit Permit), Post KGC illustrating what has been conducted to date, and Pre KGC, which details the impacts inherited. GBR also noted that they attached their proposed methylmercury study plan and noted that the preparation of this study plan was included in the Project's Tailored Impact Statement Guidelines, noting it's open for review and comment by applicable Indigenous communities including ANA, with the cutoff date for comments being January 30, 2025. GBR also noted the water study was not settled in the funding agreement, noting they are open to funding an expert/consultant in order to assist with the review of the proposed study. GBR asked for ANA to let GBR know if there are any questions regarding the material sent.	Engagement not related to Project
C-14523	24/12/20	Asubpeeschoseewagong Netum Anishinabek	Email	ANA thanking GBR for the distribution of the GIS packages, but notes that they do appear to be limited to the AEX. ANA requested shapefiles which would show all the included works in the IA process. ANA also notes that they will require assistance from their expert team in order to review the methylmercury study plan, and that given their availability the January 30th deadline proposed is not feasible.	Engagement not related to Project
C-14524	24/12/23	Asubpeeschoseewagong Netum Anishinabek	Email	GBR responding to ANA"s request for further shapefiles which describe the main project. GBR notes that the file package sent to ANA on December 19, 2024, contained a map with future considerations for the main project portion.	
C-12836	24/12/30	Asubpeeschoseewagong Netum Anishinabek GeoPraxis	Email	ANA requesting access to the materials GBR shared regarding GIS for their GIS and mapping consultant. ANA notes that the external consultant does not have access to the WSP site which the materials were uploaded to, and requests access.	
C-12837	24/12/31	Asubpeeschoseewagong Netum Anishinabek GeoPraxis WSP	Email	GBR asking WSP if ANA's consultant can have access to the GBR GIS files sent. ANA was copied on the communication.	
C-12284	25/01/02	Asubpeeschoseewagong Netum Anishinabek	Email	ANA requesting access to a SharePoint that includes comprehensive GIS package that shows all past, present and proposed activities related to GBR. GBR provided access to all documents related to past, present and proposed activities including the proposed Methylmercury Study Plan. Following some access issues, ANA can now download documents and begin review.	Engagement not related to Project
C-12838	25/01/02	Asubpeeschoseewagong Netum Anishinabek GeoPraxis WSP	Email	WSP confirming to ANA and GBR that the ANA GIS consultant should have access to the distributed files on the SharePoint.	Engagement not related to Project
C-12839	25/01/02	Asubpeeschoseewagong Netum Anishinabek GeoPraxis	Email	ANA's GIS consultant confirming that access had been granted to WSP's SharePoint and noting that the GIS files had been downloaded without problem. GBR also sharing the shapefile data for PR-24-000245.	Engagement not related to Project
C-12282	25/01/03	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	ANA's legal counsel distributing the OLT Appeal Form 1A to GBR following their submission to the OLT regarding the Leave to Appeal PTTW 3438-D7RQRJT.	Engagement not related to Project
C-12830	25/01/03	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Land Tribunal Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	CELA acting on behalf of ANA as counsel in relation to the ANA EBR Application for Leave to Appeal PTTW. CELA notes that pursuant to Sections 38 to 48 of the Environmental Bill of Rights, they have submitted a Cover Letter dated January 3, 2025, ANA's Application for Leave to Appeal PTTW 3438-D7RQJT, as well as the Applicant's Book of Documents to the Ontario Land Tribunal. GBR was copied on this communication.	Engagement not related to Project

C-12814	25/01/08	Asubpeeschoseewagong Netum Anishinabek	Email	Email response from ANA regarding the December 12, 2024, letter GBR sent to ANA's land protection team regarding an offer of assistance for progressing items detailed in the workplan. ANA responded to the offer with progressing the Land Use and Occupancy study, noting the Lands Team has the work in-hand and do not require assistance apart from assurance that submitted invoices will be paid promptly, and not subject to mis-readings of the funding agreement. ANA also notes that the funding agreement was only completed a short while ago, and the work has only just begun and will take some time to complete. ANA also suggests that GBR should take care to not proceed with the IA work that should be informed by the study, and reiterates that ANA demands that the work to be paused in order to allow ANA to catch up.	Confidential engagement

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-12828	25/01/13	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Crown-Indigenous Relations and Northern Affairs Canada Environment and Climate Change Canada Great Bear Gold Project Projet Aurifère Great Bear Indigenous Services Canada Ontario Ministry Indigenous Affairs & First Nations Economic Reconciliation (IAFNER) Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Natural Resources (MNR)	Letter	The letter from ANA to Minister of the Environment, Conservation, and Parks raises significant concerns regarding the approval of a scoped Permit to Take Water (PTTW) for the Great Bear Advanced Exploration Project. ANA emphasizes the need to address substantial environmental risks and procedural deficiencies in the permitting and consultation processes. The community highlights concerns about potential impacts on water systems, particularly Dixie Creek and the English River, which are integral to their ecosystem and way of life. ANA notes its experts assert that the water extraction proposed under the permit could harm fish and aquatic life, particularly during drought conditions. ANA states that the removal of soil and overburden is also flagged as a source of contamination, with runoff and groundwater flow potentially introducing pollutants such as methylmercury, sulfate, and dissolved metals into the watershed. ANA restates that the baseline studies and proposed mitigation measures are insufficiently robust, with gaps in critical data and deficiencies in the design and capacity of the proposed water treatment systems. The letter also raises procedural concerns, asserting that the consultation process has been inadequate and fails to meet the Crown's obligations to engage meaningfully with the First Nations. ANA indicates that key decisions and agreements were made without their knowledge or consent, and that Ontario's consultation framework disregards their governance and legal processes. Limited resources for reviewing technical documents, along with delays and incomplete information, have compounded their concerns about the transparency and	Engagement not related to Project
C-12840	25/01/13	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	ANA sharing materials pursuant to sections 38 to 48 of the Environmental Bill of Rights, in support of the application for leave to appeal of the PTTW. ANA attached a cover letter from CELA dated January 3, 2025, ANA's application for Leave to Appeal PTTW 3438-D7RQJT, and the applicant's Book of Documents. ANA also attached the OLT Appeal Form 1A regarding the ANA application for leave to appeal PTTW 3438-	Engagement not related to Project
C-12893	25/01/14	Asubpeeschoseewagong Netum Anishinabek	Email	Email response from GBR to ANA regarding the December 12, 2024, letter GBR sent to ANA's land protection team regarding an offer of assistance for progressing items detailed in the workplan. GBR noted that they provided the capacity funding so ANA would have reasonable resources to participate in the Impact Assessment in a reasonable and timely way. The funding agreement was executed on October 3rd, 2024 and GBR believes there has been sufficient time to advance the studies beyond the preliminary stages. GBR mentioned that they will not pause our work on the Impact Assessment because but must adhere to the IA timelines and would like insight on the progress of the Lands Protection Team's study work and requests an estimated completion date. It emphasizes the importance of adhering to the Impact Assessment timelines and integrating findings as they become available. The allocated funding for the land use study is confirmed. GBR also requests input on the Methylmercury Monitoring Plan was by January 30, 2025. Additionally, the GBR expresses openness to funding costs for ANA's review of the plan and asks for an estimate to amend the funding	Confidential engagement
C-12957	25/01/23	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Letter	ANA response to GBR letters dated November 13, December 20, and December 30, 2024, on early exploration permits. ANA has expressed concerns to MINES and the proponent regarding proposed mining activities in their Interim Core Area of Interest, particularly the Great Bear Gold Project. They have communicated potential impacts on their waters, lands, and wildlife, as well as their Aboriginal and Treaty rights, since March 2024. Despite this, they were not consulted about exploration permits until now. The project area is upstream of their community and affects local wildlife, including walleye, moose, and caribou. The proposed mechanized land clearing poses health risks to the environment and the community.	Engagement not related to Project
C-12962	25/01/23	Asubpeeschoseewagong Netum Anishinabek Lac Seul First Nations Ontario Ministry of Energy & Mines (MOEM) Wabauskang First Nation	Letter	Mines distributing the PR-24-000262 Early Exploration Permit.	Engagement not related to Project
C-12970	25/01/23	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Email	The Ministry of Mines is addressing concerns about community capacity and consultation processes related to an early exploration permit application. While capacity support is not deemed necessary for permitting to date, Ontario is open to funding a Mineral Development Advisor for the community. The permit allows specific exploration activities, with strict regulations to protect the environment, including a 30-meter buffer from water bodies. Concerns about impacts on local wildlife, such as walleye and moose, are acknowledged, but the Ministry believes risks are minimal. The proponent must adhere to environmental regulations, including proper handling of hazardous materials and waste. The Ministry is willing to engage further with the community regarding any additional concerns or impacts on Aboriginal and treaty rights. The Ministry has made the decision to issue an early exploration permits in response to the Applications, with the additional term and condition	Engagement not related to Project
C-14525	25/01/27	Asubpeeschoseewagong Netum Anishinabek	Email	ANA responding to GBR noting that the GIS package did not include data for an Early Exploration proposal for application PR-24-000245, noting that ANA would like to know why the permit was excluded and if there are other omissions in the data package. ANA further notes they require this GIS data as well as additional data in order to assess potential impacts.	Engagement not related to Project

C-14508	25/01/31	Asubpeeschoseewagong Netum Anishinabek Great Bear Gold Project Projet Aurifère Great Bear Impact Assessment Agency of Canada (IAAC)	Letter	ANA's legal team distributing ANA's preliminary comments on the proposed Mercury and Methylmercury study plan, as well as preliminary reports from Dr Branfireun and Dr. Morin. ANA reiterates that they will be requiring more time in order to complete a fulsome and meaningful review of the document with further expert review and request a 90-day extension to provide comments. Three response letters were attached, with the first being a response letter from ANA noting that concerns have been raised regarding the quality and quantity of baseline data and monitoring completed. ANA addresses several concerns noting their request for extension to provide comments, noting they have provided preliminary comments. ANA states the reliance from GBR on achieving water quality which complies with PWQO and Canadian Council of Ministers of the Environment (CCME) water quality guidelines is inappropriate when it comes to mercury and methylmercury. ANA further states that they believe the background data is insufficient in order to detect if the Project will have a measurable impact on fish mercury levels. ANA also notes they believe the metal leaching and acid rock drainage prediction methods are improper, and that the assimilative capacity of the receiving waters as a mitigation strategy for excess sulphate loading is not supported by data available. Lastly, in the response letter ANA states that the proposed model GBR plans to use cannot technically deliver on outcomes related to sulphate changes, mercury and methylmercury concentrations in downstream activities, and mercury concentration in fish. The January 27, 2025, letter from Dr. Branfireun contained a study regarding sulfate-reducing bacteria in constructed wetlands, the Ambient Water	ANA_013125_01.pdf ANA_013125_02.pdf ANA_013125_03.pdf
C-14535	25/01/31	Asubpeeschoseewagong Netum Anishinabek	Email	GBR distributing the TK Secondary Sources Memos for ANA to review and ensure that the sources used can be utilized to understand community context for ANA. GBR notes that in order to support the traditional land and resource use baseline conditions in the Impact Statement for the Great Bear Project, asking for the TK sources and information to be validated by the Nation as required by the TISG for the Project received from IAAC. GBR also further notes that they are requesting written permission from the Nations for the use of all secondary sources of traditional knowledge, as detailed in the attachment in order to be incorporated into the Impact Statement. GBR requests ANA responds by February 14th, and notes for ANA to reach out of there are any further	Confidential engagement
C-15133	25/01/31	Asubpeeschoseewagong Netum Anishinabek	Email	Secondary source letter sent to ANA and MNO. The memo details the secondary sources that are anticipated to be utilized to understand community context.	Confidential engagement
C-12884	25/02/05	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	GBR distributing a letter response to additional technical comments made by ANA on Great Bear's ECA ISW application. GBR notes this letter will respond to written feedback received from Dr. Brian Branfireun on behalf of ANA regarding water quality, hydrological, and geochemical aspects. GBR noted the maximum discharge rate to the Chukuni River. The comments received discuss the adaquecy of the baseline water quality dataset, and bring up concerns about mercury in the water, as well as methylmercury and noting preceived inadaquecies within the program, as well as questions surrounding sulphate. GBR responded and reiterated that the water quality results do not operate randomly or lack utility as implied in the October 7, 2024, letter noting the water samples were using industry approvd methods at accredited laboratories, noting that the sulphate effluent is not at risk for exceeding the limits as ore milling will take place off site, which is the main cause for high sulphate effluent in mining operations. GBR also responded regarding the concern of further mercury and the formation of methylmercury downstream, noting that mixing of sulphate at a higher quantity than the Chukuni currently has is not anticipated to be from the Project. The MECP was also copied	Engagement not related to Project
C-14552	25/02/06	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	GBR distributing additional technical comments on the Great Bear Resources ECA ISW Application. The response letter provides detailed responses to the October 10, 2024, letter received from Dr. Branfireun, where GBR reiterates that the water quality results are conducted using industry-approved methods at accredited laboratories, and sulphate and mercury monitoring have been undertaken, with GBR having sufficient data for their baseline water quality. GBR also restates that they have provided approximate conservative models to show concentrations of sulphate in the Chukuni River, with modelling being adequate. GBR also states that their models show that the concentration of sulphate will not deviate far from existing conditions, and notes that they acknowledge the issue of methylation downstream but continues to note that this is not anticipated.	Engagement not related to Project
C-14514	25/02/08	Asubpeeschoseewagong Netum AnishinabekGreat Bear Gold Project Projet Aurifère Great Bear Impact Assessment Agency of Canada (IAAC)	Email	GBR responding to ANA's preliminary comments and request for a 90-day review extension on the Great Bear Mercury and Methylmercury Study Plan. GBR notes that the review period is open until February 28, 2025, noting that GBR believes the additional time is substantial and that the comments received from ANA appear substantial and comprehensive, noting that other communities consulted on the plan have completed their review and submitted final comments within the requested deadline. GBR reiterates that they understand the importance of this issue for ANA, and will accept the impacts on project scheduling in order to accommodate this request, and that they are willing to provide reasonable capacity support funding in order to support this review.	

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-12934	25/02/11	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	MECP communication to ANA and CELA noting that the Ministry has received updated materials for Great Bear Resources Ltd.'s Environmental Compliance Approval application (Ref. No. 9390-D49KGX). MECP informs ANA that GBR previously shared the application in May 2024. MECP issued the Mine Water Holding Pond memorandum and updated Design Brief for reference. The Ministry reiterates they remain committed to ongoing consultation with ANA and will consider all comments received. Ongoing invitation for questions or feedback provided to ANA and CELA. GBR was not copied, but MECP forwarded GBR the email.	
C-14526	25/02/14	Asubpeeschoseewagong Netum Anishinabek	Email	ANA following up with GBR regarding GIS data requested for Early Exploration Permit PR-24-000245. ANA notes that MINES stated GBR will be providing this information, but ANA still has yet to receive it.	Engagement not related to Project
C-13104	25/02/18	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Email	GBR provided GIS Data to ANA on the Sharepoint site.	
C-13106	25/02/18	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Letter	ANA sharing their preliminary comments in response to Great Bear's early exploration permit application. It was noted that significant information remains outstanding, and the GIS data requested from the proponent was only received this morning. On February 4, 2025, MINES informed GBR that the proponent indicated that it would provide them with the information that they requested on January 27, 2025, including GIS data for this application which the proponent had previously omitted from its data package. However, despite their attempts to access this information from the proponent, they only received the GIS data this morning. GBR require additional time to review, map, and assess this new data and its impacts on ANA's rights, and to provide more fulsome comments following this review. GBR trust that ANA will provide them with additional time to complete this review and to provide additional comments on this application.	Engagement not related to Project
C-14527	25/02/18	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Email	GBR distributing the requested shapefile data for Early Exploration PR-24-000245 to ANA, with MOEM copied.	Engagement not related to Project
C-14540	25/02/19	Asubpeeschoseewagong Netum Anishinabek	Email	GBR following-up on the previously sent TK Secondary Sources Memo sent to ANA regarding the requested review process. GBR further notes that they are requesting written permission from all Nations regarding the use of all secondary sources of traditional knowledge, as detailed in the previously attached memo in order to be incorporated into the Impact	Confidential engagement
C-20778	25/02/19	Asubpeeschoseewagong Netum Anishinabek	Email	ANA requesting a 90-day extension to respond to the TK Secondary Sources.	Confidential engagement
C-13123	25/02/21	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	CELA sending GBR comments and 12 attachments for the ANA Comments on GBR new PTTW application - ERO Number 025-0078. ANA attached a letter from ANA on concerns of the Great Bear scoped Permit to Take Water, a letter from Dr Morin with MDAG comments on submission of the respondent Great Bear Resources, a letter outlining ANA comments on PTTW, letter from Dr Morin on responses to ANA concerns for AEX, a letter from Dr Branfireun on reponse to PTTW leave of Appeal, a letter from Dr Branfireun on response to GBR ECA, a letter from Dr. Branfireun on GB ECA ISW, a reply letter from Dr. Branfireun on the WSP memo, a technical report from Dr. Branfireun on the Riverbank Mercury Methylation, a letter from Dr Morin on the review of the ECA Application documents for AEX, a letter on ANA's concerns on the closure plan and ECA, and a letter from Dr Freed on the source review of the GB scoped PTTW leave to appeal.	Engagement not related to Project
C-13115	25/02/24	Asubpeeschoseewagong Netum Anishinabek	Email	GBR reaching out to ANA asking for the attached memo on secondary sources be validated by their Nation. Please note that this is a requirement noted in the TISG that Great Bear has received from IAAC. They are requesting written permission from the Nations for use of all secondary sources of traditional knowledge, as detailed in the attached, to be incorporated into the Impact Statement. ANA informing they will need more time to review the memo. They have asked for a 90 day extension. GBR wrote back indicating the ANA letter on March 6, 2024 include some references on the relevant topics, so those are already incorporated. Given ANA's review and submissions to date on the Project on these topics, your request for 90 days is not reasonable in relation to a review of the SLR memo. Also, the secondary source information will be further informed by the Traditional Land and Resource Use report that we anticipate receiving from ANA in April 2025 to inform the Impact Statement.	Engagement not related to Project
C-14541	25/02/24	Asubpeeschoseewagong Netum Anishinabek	Email	ANA responding to GBR regarding the TK Secondary Sources Memo distributed, noting that they request an extension of 90 days in order to respond to the request for ANA review. ANA also further notes that the use of the sources, if permission is given by ANA, will not replace the need for an ethnohistorical report and fulsome land use and occupancy study.	Confidential engagement

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-14544	25/02/24	Asubpeeschoseewagong Netum Anishinabek	Email	GBR responding to ANA's request for a 90-day extension to review the TK Secondary Sources Memo. GBR notes that the memo consists of five public documents, with one being an ANA letter and is two pages long. GBR further notes that the document details public information available relating to ANA, and that if there are any additional resources which ANA would like to share that they would be grateful to receive. GBR specifically notes that they are looking for information on items such as trapping, fishing, plant gathering, cultural/heritage areas and Indigenous governance systems which would be helpful. GBR notes that they do not require permission to utilize public documents in the report but will respect any confidential information which ANA may wish to share. GBR also notes that the ANA letter received March 6, 2024, includes reference to important topics and noted that those were incorporated. GBR notes that given previous ANA submissions to date on these topics, the request for a 90-day review period is not reasonable in relation to the memo. GBR also further responds to the note from ANA regarding the ethnohistorical report, and notes that the secondary source information will be further informed by the Traditional Land and Resource Use Report anticipated from ANA in April of 2025 to further inform the Impact Statement.	Confidential engagement
C-12903	25/02/27	Asubpeeschoseewagong Netum Anishinabek Great Bear Gold Project Projet Aurifère Great Bear Impact Assessment Agency of Canada (IAAC)	Letter	ANA providing Preliminary Comments on Great Bear Resources Mercury Study Plan. ANA distributed 3 letters responding to the study plan. The first letter responds to the Study Plan noting the TISG requirement to submit the mercury study plan with sufficient time to review with a detailed and robust analysis in order for ANA to assess any effects on Aboriginal and Treaty rights. ANA requested an extension to provide comments in line with IAAC's statement that the study plan should have sufficient time for review by experts and interested parties, noting that preliminary comments were provided. The two additional letters were penned by Dr. Morin and Dr. Branfireun, with Dr. Morin noting concerns regarding geochemical characterization regarding federal standards, lack of groundwater modelling and the possible effects from groundwater drawn, and the water quality modelling methods used, noting that there is uncertainty regarding their quality. Dr. Branfireun notes opinions regarding on- and off-site water quality guidelines are inaccurate when dealing with mercury/methylmercury in regard to mercury concentration in wildlife, and that further data collection should take place in order to better understand information. Dr. Branfireun also notes that the water quality model used for fish and biota concentration will be inadequate in assessing the concentration in addition to the frequency of sampling which occurs quarterly. Both note that they believe the Study Plan is misleading for the prediction of mercury/sulphate accumulation and expect further accuracy in determining metal or mineral leaching	ANA_022725_01.pdf
C-13153	25/02/27	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Email	ANA's legal team reaching out on behalf of ANA in response to the data GBR has shared with ANA on the SharePoint filesharing site. ANA's legal team notes that the files provided do not include the proposed road and trail locations to the drill collars and asks for this to be provided as well.	
C-14515	25/02/27	Asubpeeschoseewagong Netum Anishinabek Great Bear Gold Project Projet Aurifère Great Bear Impact Assessment Agency of Canada (IAAC)	Email	ANA's response to GBR's extension for the Great Bear Mercury and Methylmercury Study Plan. ANA noted that the extension to February 28, 2025, is inadequate and requests more time, noting submission can be expected for March 28, 2025. ANA reiterates their decades long experience with mercury contamination and noted that their experts are well positioned to provide important and helpful comments on the proposed study plan, but that ANA is still experiencing a mercury crisis and the cumulative impacts which creates barriers to meaningful engagement. ANA further reiterates that that their needs are different than those of other communities and that ANA needs more time to review and assess this proposal and provide comments.	
C-14529	25/02/27	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM)	Email	ANA responding to GBR regarding the shapefiles distributed for Early Exploration PR-24-000245. ANA notes that the shapefiles do not include a proposed road and trail location to the drill collars as indicated within the application and request a shapefile which reflects their anticipated location.	Engagement not related to Project
C-21148	25/03/03	Asubpeeschoseewagong Netum Anishinabek	Email	Great Bear Resources request to complete on-reserve socio-economic interviews to collect data with service providers.	
C-13611	25/03/10	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Land Tribunal Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	Ontario Land Tribunal issuing a decision regarding ANA's application for the subject to leave appeal regarding the MECP decision to issue a Permit to Take Water (PTTW) ECA for GBR to take water for the Great Bear Gold Project's AEX program. The OLT spoke to the application ANA submitted, and the support given in favor of the application including letters from Dr. Branfireun and Dr. Morin regarding mercury and ML-ARD in relation to the MECP's precautionary principal approach. OLT notes that the MECP did not take the precautionary principal in granting the PTTW as there is scientific uncertainty noted in the ANA materials, and specifically the sensitivity within the Dixie Creek to methylation, and methylmercury production cited by Dr. Branfireun. OLT concludes based on the evidence ANA has provided, the Tribunal finds that there is good reason to believe no reasonable person could have made the decision to approve the permit, noting the additional environmental condition in the area, and further sensitivity to methylmercury. OLT noted that there is onus on the Applicant to satisfy the Tribunal and show that this permit would pass the significant harm test. The Tribunal ruled in favor of ANA regarding the leave to appeal	Engagement not related to Project

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-13171	25/03/12	Asubpeeschoseewagong Netum Anishinabek	Email	GBR reaching out to ANA Lands Protection team informing that SLR will be collecting community-specific information from on-reserve service providers to determine what, if any impact the great bear project could have on regional residents. Outlined the two different approaches for how to collect this data and asked the team if they would prefer to collect the data internally. They need to respond by March 10th indicating what their preferred approach is. Cavalluzzo contacted GBR indicating they are still considering the proposal. Also indicated, SLR should not reach out to on-reserve service providers until you hear from us.	
C-21145	25/03/17	Asubpeeschoseewagong Netum Anishinabek	Email	Great Bear Resources confirmed that they will not reach out to on-reserve social-service providers and the Impact Statement will proceed without socio-economic data unless ANA chooses to provide it.	
C-13753	25/03/27	Asubpeeschoseewagong Netum Anishinabek	Email	GBR sharing with ANA legal team a link to the Lakes and Rivers Improvement Act (LRIA) application prepared in support of the proposed treated effluent discharge structure within the Chukuni River, associated with the Great Bear Advanced Exploration Program.	Engagement not related to Project
C-14717	25/04/03	Asubpeeschoseewagong Netum Anishinabek Lac Seul First Nations Ontario Ministry of Energy & Mines (MOEM) Wabauskang First Nation	Email	MINES emailed GBR to provide the early exploration permit on behalf of the Director of Exploration NW.	
C-14756	25/04/10	Asubpeeschoseewagong Netum Anishinabek	Email	GBR provided ANA the link for information related to potential fish offsetting compensation. GBR requested feedback.	ANA_041025_01.pdf
C-15005	25/04/10	Asubpeeschoseewagong Netum Anishinabek Deputy Minister's Office Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Natural Resources (MNR)	Letter	This letter from the Asubpeeschoseewagong Netum Anishinabek (ANA) to Great Bear Resources Ltd. informs the company that they hold claims, leases, or other mining tenures within the ANA Interim Core Area of Interest for Mining. The ANA expresses concern that Great Bear Resources Ltd. has staked or acquired claims within this Core Area and on their Territory without informing the First Nation of their plans. The letter emphasizes the longstanding connection of the ANA's community to the claimed area, their practice of the Anishinaabe way of life, and the importance of the area for exercising their Treaty rights. The ANA also highlights the cumulative effects of past industrial impacts on their community and territory, including mercury pollution, damming, industrial logging, and mining activity, which have caused significant harm. The letter asserts ANA's Treaty rights, the potential impact of mining claims on their Treaty Land Entitlement claim, and ongoing litigation related to Crown failures to protect their rights. It also raises concerns about unmet legal duties and the need for the Crown and industry to respect ANA's laws and rights. The ANA calls on Great Bear Resources Ltd. to halt all staking and mineral exploration activities in the Core Area, commit to obtaining free, prior, and informed consent for any activities, and engage with the community to address their concerns.	Engagement not related to Project
C-15138	25/04/10	Asubpeeschoseewagong Netum Anishinabek	Email	GBR provided a link to share informaiton related to potential fish offsetting compensation plans for the Project. GBR noted that they would appreciate the opportunity to meet and discuss further.	
C-21150	25/04/11	Asubpeeschoseewagong Netum Anishinabek	Letter	ANA provided comments on the MeHg Study Plan.	
C-21151	25/04/14	Asubpeeschoseewagong Netum Anishinabek	Letter	ANA opposing the MECP granting a 5 year PTTW.

ANA objects to the Crown's delegation of consultation responsibilities to Great Bear, emphasizing that consultation with a treaty partner must remain a direct Crown duty under the nation-to-nation relationship established through Treaty 3. ANA asserts that the LRIA application is premature, as Great Bear does not yet have the required environmental permits — including a Permit to Take Water and an Environmental Compliance Approval — necessary for discharging effluent. ANA raises serious concerns that the proposed discharge would exacerbate mercury and methylmercury contamination in the English-Wabigoon River System, harming the health, cultural practices, and Treaty 3-protected rights of ANA community members. Furthermore, ANA strongly criticizes Ontario's scoping of consultation at the low end of the duty to consult spectrum, arguing that a cumulative impacts approach is necessary to properly assess industrial activities in their territory. ANA further explains that a cumulative impacts analysis demonstrates that its free, prior, and informed consent is required for LRIA approval. ANA provides evidence of its long-standing connection to the Red Lake area, citing historical reports, fur trade records, church records, and ethnological work documenting traditional activities such as hunting, fishing, trapping, gathering, gardening, spiritual practices, and trading	Engagement not related to Project
C-15036	25/04/23	Asubpeeschoseewagong Netum Anishinabek	Email	ANA response letter to Great Bear Resources Request for "Lakes and Rivers Improvement Act" Location Approval. The letter highlighted consultation requirements and the need for ANA's consent.	Engagement not related to Project

C-15139	25/04/25	Asubpeeschoseewagong Netum Anishinabek	Email	Email to GBR to note that ANA requires additional information before they can consider the proposal and requested the baseline information referenced in the presentation. Cavalluzzo also noted that ANA will need 120 days to review the information before they can consider meeting and providing feedback.	
C-15400	25/04/25	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	ANA's legal team distributing a response letter to GBR regarding the proposal for Environmental Compliance Approval for Industrial Sewage Treatment Works and suggesting to the MECP that they should reject the submission from GBR. ANA cites a lack of consistency with the MEND 2009 sampling approach and geochemistry testing methods, the Project potential to contribute to methylmercury formation in area water bodies due to the release of sulphate. The ANA legal team cites these reasons for the MECP to not approve the application, noting that this would be reckless and dangerous to ANA, and has the ability to add further harm to	Engagement not related to Project
C-14911	25/04/28	Asubpeeschoseewagong Netum Anishinabek	Email	ANA formally advised GBR that all engagement regarding the proposed Great Bear Gold Project must occur through the ANA Land Protection Team, which holds the mandate from Chief and Council to represent the community. ANA expresses concern that GBR representatives have been approaching individual ANA members and trapline holders directly. The letter emphasizes that Aboriginal and Treaty rights are collective rights held by the community, and therefore consultation must respect the collective authority of Chief and Council. ANA expects GBR to cease direct engagement with individuals and work exclusively through the authorized Land	ANA_042825_01.pdf
C-15140	25/04/29	Asubpeeschoseewagong Netum Anishinabek	Email	GBR provided a link to the completed baseline reports for the Project. GBR noted that some reports are interim and advised that they will provide notice when the reports are finalized.	
C-14927	25/04/30	Asubpeeschoseewagong Netum Anishinabek	Email	GBR emailed ANA to advise that the Archeological reports were included in the baseline reports that were previously	
C-14928	25/04/30	Asubpeeschoseewagong Netum Anishinabek	Email	ANA emailed GBR to request the documents related to the archeological assessments.	
C-15085	25/04/30	Asubpeeschoseewagong Netum Anishinabek	Email	ANA communicates that it was not included in the Stage 2 Archaeological Assessment conducted by Great Bear or in the planning or discussions related to the Stage 3 Assessment for culturally significant sites. The community has not received any related documentation. ANA is requesting full disclosure of all archaeological assessment materials associated with the Great Bear Project, including background studies, field notes, planning documents, site details, inspection reports, maps, and related records.	
C-15086	25/04/30	Asubpeeschoseewagong Netum Anishinabek SLR Consulting	Email	Great Bear provides notice to ANA that archaeological reports are included in baseline link issued on April 29th	
C-15148	25/04/30	Asubpeeschoseewagong Netum Anishinabek	Email	GBR email to note that archaeological reports are included in the baseline reports that were previously provided.	
C-15087	25/05/02	Asubpeeschoseewagong Netum Anishinabek	Email	ANA expressed concern over delays in receiving baseline and archaeological reports, noting that the community has been requesting this information for some time. They emphasized that GBR committed to timely sharing of such materials and providing opportunities for input prior to work being undertaken—commitments they feel have not been met. ANA stated that GBR proceeded with archaeological investigations and reporting without their involvement, despite potential cultural and historical significance. They have requested that all archaeological work be halted until they have reviewed and responded to the information and that any activities potentially affecting archaeological sites also cease. ANA further requested immediate notice of any outstanding documents and that the significance of any shared materials be clearly communicated.	
C-15149	25/05/02	Asubpeeschoseewagong Netum Anishinabek	Email	Email to GBR to note their frustrations with the timing of receiving the archaeological reports. Noted that it is ANA expectation that the reports are provided immediately. They also noted their frustration with not being included in the assessment or reporting.	
C-15088	25/05/06	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Fisheries and Oceans Canada (DFO) Indigenous Affairs and First Nations Economic Reconciliation Indigenous Services Canada Ministry of Energy and Electricification Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Natural Resources (MNR)	Email	ANA raised concerns about the integrity of the Impact Assessment process for the Great Bear Project, citing a lack of trust in IAAC and the exclusion of their selected experts from the External Technical Review (ETR). They objected to experts proposed without their input and submitted alternative candidates for consideration. ANA also emphasized their loss of faith in Ontario's permitting system, particularly following the scoped Permit to Take Water (PTTW) approval—later revoked after their successful appeal—which they believe demonstrates the province's inability to protect the environment or Indigenous rights. ANA reiterated that the Advanced Exploration (AEX) phase must be included in the federal assessment due to its potential impacts on their lands and waters. Additionally, they objected to being excluded from discussions on the Environmental Compliance Approval (ECA) and demanded full transparency and participation in future decisions affecting their territory. ANA requested a pause in the assessment process until they have reviewed key technical information, including baseline data and the ML-ARD report. They reaffirmed that no project activities should proceed without their free, prior, and informed consent.	

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

C-14738	25/05/13	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Natural Resources (MNR)	Email	ANA emailed GBR to provide a letter and map regarding the GBR Project. The letter outlined the following: Area Subject to ANA Interests, Area Subject to Cumulative Effects, Area Subject to Treaty Land Entitlement Claim, Area Subject to Litigation, Area Subject to Unmet Legal Duties, ANA law and rights, and request to meet and identify any third party interests.	ANA_051325_01.pdf ANA_051325_02.pdf
C-15089	25/05/22	Asubpeeschoseewagong Netum Anishinabek Cavalluzzo Environment & Climate Change Canada (ECCC) Fisheries and Oceans Canada (DFO)Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Natural Resources (MNR)	Email	ANA reiterated that Great Bear has not responded to their January 31, 2025 concerns regarding the proposed Mercury Study Plan. They emphasized the need for additional time to consult with experts and submitted a third expert report from Source Environmental Associates, which identified further deficiencies. Key concerns include non-alignment with the Tailored Impact Statement Guidelines, lack of mapping and cumulative effects analysis, exclusion of historically contaminated downstream areas, and weaknesses in baseline methodology. ANA called for more comprehensive and frequent sampling, improved site selection, and justification for omissions, including unnamed waterbodies. They continue to seek meaningful revisions before the study proceeds.	ANA_052225_01.pdf
C-15169	25/05/22	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Great Bear Gold Project Projet Aurifère Great Bear Impact Assessment Agency of Canada (IAAC)	Email	ANA highlighted the need for more time and support to meaningfully participate in the Impact Assessment process for the Great Bear Gold Project. They noted that short response timelines have limited their ability to fully engage, conduct internal reviews, consult with experts, and carry out necessary studies, including those related to land use, social conditions, and baseline environmental data. ANA emphasized the importance of ensuring community-led processes that reflect their lived experience, including the impacts of historical mercury contamination. They requested additional time—specifically, 180 days—to prepare a submission on social impacts and to review secondary sources of traditional knowledge. ANA also recommended that revisions to the Mercury Study Plan be completed in consultation with their experts and reviewed by the upcoming IAAC Expert Technical Review group. They asked GBR to consider a pause in the process to allow for more collaborative engagement and requested written confirmation that the project team will support ANA's ability to participate meaningfully at all stages.	ANA_052225_02.pdf
C-15617	25/05/29	Asubpeeschoseewagong Netum Anishinabek Environment and Climate Change Canada Impact Assessment Agency of Canada (IAAC) Ministry of Energy and Electricification Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP) Ontario Ministry of Natural Resources (MNR)	Email	ANA provided an update on its Preliminary Land Use and Occupancy Study. While full studies typically take three to ten years, the team is working to produce a preliminary report within six to eight months due to the accelerated Impact Assessment timelines. ANA emphasized that this information is critical for informed decision-making and requested that the assessment process allow sufficient time to incorporate land use data. They also urged that no project activities proceed that could affect ANA's land use until this information is properly considered. Communication also included an overview of the approach by a consultant anthropologist supporting ANA. The communication notes that she is assisting with the preparation of a Preliminary Land Use and Occupancy Study focused on ANA's Interim Core Area of Interest for Mining, particularly areas potentially affected by the proposed Great Bear Mine. The consultant, a tenured professor at Ohio State University with expertise in Anishinaabe land use and environmental relationships, noted that full land use studies typically require 3–10 years. Given the compressed timelines of the Impact Assessment process, ANA is working as efficiently as possible to produce a preliminary report, which is expected to take an additional 6–8 months. Initial findings confirm both historic and ongoing traditional land use in the vicinity of the proposed mine, including hunting, fishing, trapping, gathering, and travel. The study has also documented strong community concerns regarding potential water contamination from mining and industrial activities. It is closed with a note that further updates will be provided as work progresses.	ANA_052925_01.pdf ANA_052925_02.pdf
C-15154	25/06/03	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	The Canadian Environmental Law Association, on behalf of ANA, submitted a formal response opposing the Environmental Compliance Approval (ECA) application by Great Bear Resources (GBR) for the proposed Great Bear Advanced Exploration Project. ANA maintains that GBR has failed to meaningfully address the substantive concerns previously raised. The company's February 2025 response merely highlighted past commentary without offering any new or responsive information. Independent expert reviews—particularly from Dr. Kevin Morin and Dr. Brian Branfireun—identified fundamental technical deficiencies in GBR's approach. Dr. Morin concluded that GBR's methods for assessing metal leaching and acid rock drainage (ML-ARD) do not align with the 2009 federal MEND guidelines, and that GBR has failed to produce the comprehensive geochemical assessments required for such projects. Dr. Branfireun found that GBR's treatment of sulphate and mercury data was flawed, with inaccurate data handling and unreliable analytical techniques that undermine the integrity of mercury risk assessments. The communication notes that ANA has also raised concerns that effluent discharge limits, accepted by the Ministry of the Environment, Conservation and Parks (MECP) in 2023 without notice to the community, are inadequate and do not protect against risks from pollutants such as methylmercury and sulphate. These limits do not account for the unique environmental conditions and cumulative industrial impacts already affecting the ANA watershed. The proposed treatment system is viewed as vague and incapable of removing the pollutants that threaten water quality and fish safety. ANA emphasized that GBR's application fails to	Engagement not related to Project

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-15457	25/06/12	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	GBR submitted issues a formal response to technical concerns raised by the Canadian Environmental Law Association (CELA) and ANA regarding GBR's application for an Environmental Compliance Approval (ECA) for industrial sewage treatment works at the Great Bear Advanced Exploration Project (ERO No. 019-8718). GBR confirms that its methodologies for acid rock drainage (ARD) and metal leaching (ML) are consistent with MEND 2009 and Ontario Regulation 240/00, and have been implemented by qualified experts with independent third-party review. GBR rejects allegations of non-compliance or inadequate data and affirms that mitigation measures exceed regulatory requirements, including conservative design elements to eliminate off-site risk. GBR maintains that its baseline data, analytical methods, and interpretation meet applicable scientific and regulatory standards, and that concerns raised represent differences of professional opinion rather than deficiencies in the technical record. GBR cautions against misrepresentation of its submissions and reiterates its commitment to compliance and environmental protection.	Engagement not related to Project
C-15456	25/06/17	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Natural Resources (MNR)	Email	On June 17, 2025, the Ontario Ministry of Natural Resources (MNR) issued a written response to ANA (Asubpeeschoseewagong Netum Anishinabek) regarding concerns about the MNR's authorization for the Great Bear Resources Project. The letter confirms that procedural consultation responsibilities for the Lakes and Rivers Improvement Act location approval have been delegated to the proponent, who has the technical expertise to address community questions. The MNR affirms that ultimate consultation responsibility remains with the Crown, which will maintain oversight and participate in meetings as required. The Ministry acknowledges ANA's broader concerns about multiple approvals and has directed its district office to provide additional written follow-up. The community was encouraged to continue liaising directly with the Red Lake–Sioux Lookout District Manager to address ongoing matters.	
C-15597	25/06/18	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	GBR emailed to provide their responses to the comments received from ANA dated February 21, 2025 (preliminary submission) and April 11, 2025 (proposed permit to take water). GBR's response highlights significant differences between the 2025 application and previous drafts, particularly regarding water quantity and quality assessments. GBR argues that the 2025 application focuses on water management and hydrologic function, while water quality issues are addressed under separate environmental compliance regulations. The response also critiques the reliance on preliminary reports and emphasizes the importance of final, certified documents for regulatory approval. Concerns about groundwater modeling, potential contamination from exploration drill holes, and the adequacy of water quality monitoring are raised, with GBR asserting that their studies comply with regulatory standards. GBR further emphasizes that water quality is managed under a separate Environmental Compliance Approval and that they have incorporated feedback from community consultation. Overall, Great Bear Resources states that they will continue to align with regulatory standards while ensuring environmental protection.	Engagement not related to Project
C-16144	25/07/02	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	Great Bear Resources Ltd. (GBR) has provided detailed responses to comments submitted by ANA and associated experts concerning its Permit to Take Water (PTTW) application (ERO No. 025-0579) for the Advanced Exploration Project submitted on July 2nd, 2025 by CELA. The company maintains that the scope of water taking under the PTTW is distinct from discharge activities, which are regulated under the Environmental Compliance Approval (ECA). All water discharge will be governed by the ECA, with strict conditions requiring water quality parameters, including sulphate concentrations, to meet natural background levels within the Chukuni River. GBR emphasizes that this approach reflects a precautionary and adaptive management framework intended to prevent environmental harm and that potential concerns about methylmercury generation have been addressed through these proactive measures. GBR rejects assertions that the data supporting the PTTW are incomplete or inadequate, stating that the baseline studies—initiated in 2022—are comprehensive, have undergone third-party laboratory analysis, and were reviewed by the Ministry of the Environment, Conservation and Parks (MECP). The company notes that adjustments to the mixing zone and flow statistics were made in response to regulatory input. GBR also clarified the sequencing and evolution of its PTTW submissions, indicating that the current application consolidates prior water-taking volumes and activities into a single streamlined proposal, with no overlap between project phases. Concerns regarding untreated water or reliance on mobile treatment systems were addressed by confirming that the	Engagement not related to Project

Appendix C Record of Consultation: Asubpeeschoseewagong Netum Anishinabek (Jan 1, 2022 to Jan 16, 2026)

Ref. no.	Date	Organizations	Communication Type	Summary	Attachment ID
C-16204	25/07/07	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	CELA submission on behalf of ANA, dated July 7, 2025, consolidates expert evidence indicating that the proposed ECA for the Great Bear Advanced Exploration Project (ERO No. 019-8718) must be rejected in the opinion of ANA and CELA. Drawing on technical assessments from Dr. Kevin Morin (MDAG), Dr. Brian Branfireun (Western University), and Source Environmental Associates Inc., the submission outlines and asserts multiple critical deficiencies in GBR'S application and supporting documentation, particularly in relation to predicted contamination, sulphate discharge, and the failure to adhere to best practices as outlined in the federal ML-ARD Prediction Manual. Dr. Kevin Morin's MDAG report highlights significant and unresolved deficiencies regarding the prediction and mitigation of metal leaching and acid rock drainage (ML-ARD). Despite ongoing exploration activity since 2021, GBR has failed to submit a comprehensive ML-ARD assessment as required under federal guidance. Dr. Morin asserts that the limited, outdated, and laboratory-constrained data submitted to date are insufficient for full-scale predictive modelling, and consequently, render the current detailed engineering design invalid. Notably, the proportion of potentially acid-generating (PAG) rock is now estimated at 70%, double the initial estimate, yet no redesign of the AEX plan has been proposed. Further, the water treatment plant (WTP) proposed by GBR is found to be inadequate; the design omits effective sulphate removal and relies on dilution in the Chukuni River, a strategy that is non-protective and contrary to standard environmental safeguards. The MDAG report also identifies that basal liners	Engagement not related to Project
C-16251	25/07/07	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Environment, Conservation and Parks (MECP)	Letter	On July 7, 2025, ANA submitted comments on Great Bear Resources Ltd.'s (GBR) proposed Environmental Compliance Approval (ECA) for sewage works associated with the Advanced Exploration Project (AEX Project). The submission reiterated a series of previously raised technical concerns relating primarily to metal leaching and acid rock drainage (ML-ARD), water treatment design and performance, sulphate discharge levels, and baseline environmental data sufficiency. GBR responded by referencing and affirming the adequacy of its earlier submissions, notably those dated February 5, May 28, June 12, and July 3, 2025. In response to concerns about increased volumes of potentially acid-generating rock and ML-ARD predictions, GBR clarified that interpretations based on humidity cell testing were inaccurate and that mine rock proportions were calculated using a block model. Regarding treatment design, GBR maintained that the effluent treatment plant (ETP) design is appropriate for the scale and duration of the exploration program and that sulphate levels will meet background concentrations at the end of the approved mixing zone, as supported by its May 29 supplemental mixing study. GBR also clarified that generated sludge would be safely stored on lined rock pads in geo-tube bags. On broader concerns regarding methylmercury formation and sulphate loading raised by Dr. Brian Branfireun, GBR disagreed with the application of local riverbank study results to the entire downstream watershed. It further stated that sulphate discharge limits under the proposed ECA are protective and developed in accordance with Ontario's	Engagement not related to Project
C-16435	25/07/15	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	GBR emailed MECP to provide their responses to ANA comments sent July 7th. Comments addressed concerns related to water quality, ETP design and surface water monitoring plan.	Engagement not related to Project
C-21154	25/07/24	Asubpeeschoseewagong Netum Anishinabek	Letter	ANA submitted comments regarding the AEX PTTW submission from Great Bear Resources.	
C-21156	25/07/28	Asubpeeschoseewagong Netum Anishinabek	Letter	Great Bear Resources provided responses to ANA's July 24th, 2025 comments on the PTTW application.	
C-16600	25/07/30	Asubpeeschoseewagong Netum Anishinabek	Email	GBR emailed to request the raw data from the Riverbank Study including method blanks, matrix spikes, and all raw data for the parameters tested.	
C-17202	25/09/05	Asubpeeschoseewagong Netum Anishinabek	Letter	MECP forwarded two letters from ANA regarding the PTTW and ECA applications dated August 19th, and August 20th, to GBR for response.	
C-17212	25/09/08	Asubpeeschoseewagong Netum Anishinabek	Email	GBR emailed ANA links to provide comments on the Land Use Permit for monitoring well installation and forestry clearing permit application. GBR sent a follow up email to note an error with the links and provided updated links.	Engagement not related to Project
C-17187	25/09/09	Asubpeeschoseewagong Netum Anishinabek	Email	GBR emailed ANA to provide a link with information regarding Early Exploration Test Pits and Geophysics for the Project.	Engagement not related to Project
C-17248	25/09/10	Asubpeeschoseewagong Netum Anishinabek	Email	GBR emailed ANA to provide a link for the following information; Methylmercury Predictive Modelling, Introduction to Water Management, Fish and Fish Habitat, and Migratory Birds.	
C-17303	25/09/16	Asubpeeschoseewagong Netum Anishinabek	Email	GBR followed up on a previous email to ANA providing information on Methylmercury Predictive Modelling, Introduction to Water Management, Fish and Fish Habitat, and Migratory Birds, also extending an invitation to meet and discuss any of the topics.	
C-17386	25/09/22	Asubpeeschoseewagong Netum Anishinabek	Email	GBR distributing the First Phase of the Great Bear Gold Project Impact Statement Submission submitted to IAAC to ANA which was submitted on September 18th, 2025. GBR notes that as previously discussed the IS will be provided in multiple phases, and further highlighted their commitment to providing information to ANA as it becomes available. GBR notes for ANA to reach out if they have any questions or would like to meet to discuss.

C-21158	25/09/25	Asubpeeschoseewagong Netum Anishinabek	Letter	MECP shares two emails including letters from Source Environmental with Great Bear Resources, September 9th letter on ECA application, September 13th letter on PTTW	
C-17845	25/09/30	Asubpeeschoseewagong Netum Anishinabek	Email	GBR reaching out to ANA in order to request a status update on the progress of ANA's land use and occupancy study to date, noting they are available to meet with ANA in order to discuss any information that ANA would like to share regarding the Land Use and Occupancy Study.	Confidential engagement
C-18280	25/10/01	Impact Assessment Agency of Canada (IAAC) Asubpeeschoseewagong Netum Anishinabek	Email	GBR distributing the comments provided from ANA and GBR's responses to IAAC in response to their earlier request to receive comments received and GBR's response regarding the 2024 Mercury Study Plan. GBR provided the initial comment and responses received on the plan, as well as further letter responses from Doctors on behalf an ANA issued January 27, 2025, and January 31, 2025. A January 31, 2025 letter from ANA was also provided in addition to a memo summarizing comments which was provided on May 2, 2025.	ANA_100125_01.pdf ANA_100125_02.pdf ANA_100125_03.pdf ANA_100125_04.pdf ANA_100125_05.pdf ANA_100125_06.pdf
C-18340	25/10/03	Asubpeeschoseewagong Netum Anishinabek	Email	GBR distributing the Fish Habitat Offsetting and Compensation Plan (FHCOP) as well as the draft Mine Waste Alternatives report for ANA's review and comment. GBR notes that they welcome a meeting with ANA to further discuss the documents	
C-18343	25/10/03	Asubpeeschoseewagong Netum Anishinabek	Email	GBR distributing the Methylmercury Modelling Approach report for ANA's review and comment. GBR notes that they welcome a meeting with ANA to further discuss the documents	ANA_100325_01.pdf
C-18380	25/10/07	Asubpeeschoseewagong Netum Anishinabek Ontario Ministry of Natural Resources (MNR)	Email	GBR emailed ANA to address concerns in ANA's letter regarding GBR's application for a Land Use Permit under the Public Lands Act. GBR noted that the request for a permit to install monitoring wells and drive points along Dixie Creek was at the request of the MECP to monitor ground and surface water around the AEX site. The permit for these wells will enhance environmental monitoring, and will not result in taking or treating water or infrastructure development. GBR noted they have entered into a capacity funding agreement with ANA for engagement, and will follow all permit conditions and environmental protection measures.	Engagement not related to Project
C-18373	25/10/08	Asubpeeschoseewagong Netum Anishinabek	Email	GBR provided access to the Great Bear Gold Project Impact Statement Technical Supporting Documents, which include assessments on ambient light, GHG, net zero plans, best practices, vibration, economic modeling, climate risk, noise, and viewshed. These documents are shared for early review and input before the official Phase 2 filing. Additional documents will be provided as they become available, and feedback is welcomed.	
C-18371	25/10/10	Asubpeeschoseewagong Netum Anishinabek Cavalluzzo Ontario Ministry of Energy & Mines (MOEM)	Email	ANA responds to a September 11, 2025 notice regarding Great Bear Resources' proposed early exploration activities. ANA formally objects to the activities—geophysical surveys, mechanized drilling, stripping, and line cutting—due to their contribution to cumulative industrial impacts already affecting the community, including mercury pollution and other environmental harms. The response calls for recognition of ANA's rights and the need for genuine, respectful engagement aligned with reconciliation. GBR addresses concerns regarding the Great Bear Test Pits and Geophysics Project, clarifying that the proposed activities are low-impact and short-duration, with minimal environmental effects. GBR has provided funding support for project review and engagement, sharing detailed information and remaining available for further discussions.	Engagement not related to Project
C-18427	25/10/14	Asubpeeschoseewagong Netum Anishinabek Cavalluzzo Ontario Ministry of Natural Resources (MNR)	Email	GBR email response to the letter sent by ANA on September 23, 2025, which was addressed to the MNR and GBR. GBR responded to comments and clarified points regarding the AEX clearing application for the substation and distribution line. GBR responded to comments from ANA which stated that it is premature to approve additional tree clearing as the Project lacks permitting stating that the work in the AEX clearing application is part of an approved AEX program which has received an approved Closure Plan, and Endangered Species Act Permit. GBR further responded to a comment from ANA which noted concern that these activities will add to cumulative impacts which ANA has been subjected to, and this cannot be considered in isolation from other historical, current, and proposed Projects. GBR responded to this comment and noted that the request is limited to land-based clearing activities already authorized under the closure plan, noting that there is no water taking, water movement, or water treatment associated with this activity and disagree that this will contribute to cumulative downstream activities. GBR further responded to ANA comments which noted that issuing this approval would allow for infrastructure for the Project to be built for a Project which may not be approved. GBR responded to this comment and stated that the Closure Plan requires progressive reclamation and noting that any areas cleared will be stabilized and restored. GBR further responded to the comment made by ANA which notes that there is no rationale provided for the early issuance of this approval which would justify the potential adverse and cumulative impacts. GBR responded and noted that the rationale is that the clearing is necessary to prepare infrastructure for the AEX Program and	Engagement not related to Project
C-18531	25/10/24	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	GBR emailed MECP to provide GBR's responses to ANA letters and comments. GBR also noted it does not intend to continue responding to ANA comment letters, as ANA experts do not accept the data or agree with the responses and communications are becoming repetitive. GBR requested MECP make a decision on the permits based on the provided information.	ANA_102425_01.pdf ANA_102425_02.pdf ANA_102425_03.pdf ANA_102425_04.pdf

C-20359	26/01/16	Asubpeeschoseewagong Netum Anishinabek Canadian Environmental Law Association Great Bear Gold Project Projet Aurifère Great Bear Ontario Ministry of Energy & Mines (MOEM) Ontario Ministry of Environment, Conservation and Parks (MECP)	Email	GBR responded to concerns raised by ANA regarding fish consumption risks related to mercury contamination. GBR acknowledges the need for a comprehensive risk assessment that reflects historical fish consumption rates and the unique health risks faced by ANA due to past mercury exposure. The response emphasizes the importance of including ANA in the technical review process and highlights the community's treaty rights to fish. GBR plans to use updated methodologies for health risk assessments, focusing on traditional consumption rates and the need for remediation of mercury levels in fish. The ANA response also critiques the reliance on outdated studies and stresses that any increase in mercury levels from the project would be unacceptable. Overall, GBR commits to ensuring that the project does not exacerbate existing mercury contamination and supports the community's right to restore their traditional fishing practices. Dear Impact Assessment Agency of Canada,

RE: Failure to notify ANA and to provide capacity support for IAAC review of Great Bear Project

I am writing as Chief of Asubpeeschoseewagong Anishinabek (Grassy Narrows) to express my concern about the Impact Assessment Agency of Canada's (IAAC) process with respect to Kinross Gold Corporation's proposed Great Bear Project.

The Grassy Narrows village is the first community downstream of the Great Bear Project Site. As well, our people have historically used, and continue to use, the Great Bear Project area, and the areas downstream, downwind, and down migration from there. We have already experience intense cumulative impacts from hydro dams, mercury contamination and poisoning, clearcut logging, and mining related activity. We are deeply concerned about the proposal to build this mine. We have alerted both the proponent and the Ontario Ministry of MINES to these concerns and expect that they would have made you aware of this.

Grassy Narrows' communication protocol with respect to Lands and Environment related matters, including resource extraction proposals, is that all communications should be sent to our Land Protection Team (copied here), while important communications should also be copied to the Chief, who holds the Lands portfolio. This protocol has been communicated to Ontario, including the Ministry of MINES, Canada, Great Bear Resources, and Kinross many times. The Land Protection Team will deal with this matter under the direction of Grassy Narrows Chief and Council. Any notices or correspondence that have not been sent to our Land Protection Team were not sent properly and you should assume that they have not been received. Unlike the Ministry or a large corporation, we do not have staff who can manage our correspondence and monitor it for messages that have not been sent to the right people. Our communication protocol must be followed.

As far as I and the Lands Protection Team are aware, Grassy Narrows has not been notified about the IAAC assessment of the Great Bear Project. As a result, I am very concerned about the fairness and sincerity of this process. While MINES and Kinross staff mentioned that an IAAC submission was

expected, no one informed us that it had been submitted nor posted for comments. One of our advisors stumbled upon the IAAC request for comments yesterday purely by chance while performing a Google search. (https://iaac-aeic.gc.ca/050/evaluations/proj/85832?culture=en-CA)

This raises a number of concerns, and requires a number of corrective actions.

1. IAAC has not communicated with Grassy Narrows about your assessment.

   ACTION REQUIRED: Provide written reasons why we were not communicated with, apologize, and include the Grassy Narrows Land Protection Team in all communications about this project.

2. Grassy Narrows was not engaged by your agency at the Pre-Planning stage of your assessment. Your literature indicates that the agency's role in the Pre-Planning stage is:

   • Informs Indigenous groups about the impact assessment process to support them in understanding how they can participate in the process

   • Learns the views and contexts of the Indigenous groups, including potential effects and how they wish to be engaged.

   This was not done.

   ACTION REQUIRED: Freeze the assessment process, return to the start of the Pre-Planning stage, reach agreement with Grassy Narrows on reasonable capacity support for the Pre-Planning stage, and then fulfill your role with respect to Grassy Narrows at the pre-planning stage. This should include reviewing the process and reaching agreement with Grassy Narrows on any customization of the process that is required to make it fair in our unique circumstances.

3. Yesterday we found out by chance that on August 17th you posted a request for comments from Indigenous groups on the summary of the Initial Project Description. The deadline is September 18, only one month from when you posted this complex technical document and only five days from when we discovered the call for comments. This is not a fair process.

   ACTION REQUIRED: Once the Pre-Planning stage is completed correctly, reach agreement with Grassy Narrows providing reasonable capacity support for the Planning stage, then re-post the revised Initial Project Description with a reasonable review period for Grassy Narrows' circumstances, and any other agreed modifications to the process (to be agreed upon during pre-planning stage).

4. Yesterday, we found out by chance that on August 20th you posted an invitation for capacity support requests from Indigenous groups for the review and preparation of comments on the Initial Project Description. The deadline for applications is September 21. This deadline is after the deadline for submission of comments. Grassy Narrows is an impoverished First Nation with even fewer financial resources than the average First Nation in Canada due to the ongoing impacts of our mercury crisis. To date, Grassy Narrows has received no capacity support from

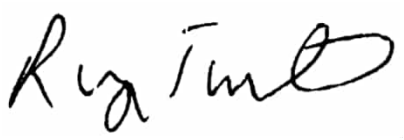
Ontario, nor from any other source for work on the Great Bear Project. We cannot carry out the work require to engage fairly in this complex and technical process until after agreed upon capacity support has been provided.

ACTION REQUIRED: Provide reasonable capacity support (in mutually agreed amounts) in advance of the start of any work on this assessment, including engagement, review of materials, community meetings, governance, and preparation of comments/submissions.

We are deeply concerned about the way that this project has been pursued by Great Bear Resources, Kinross, and the Ministry of MINES. We are also deeply concerned about the way in which this assessment is being carried out. It appears that the conclusion is already foregone, and that everyone has decided, without us, that a gold mine will be built. This gold mine would add to the many risks, impacts, and fears that we have endured for many generations.

We hope that you will correct your transgressions and that your agency will carry out an assessment that is fair to us, takes our concerns seriously, respects our rights, and does not have a foregone conclusion.

Awsa,



Chief Rudy Turtle

Crosshatched/Restricted Zone

Attention Hunters
No Hunting or Discharge of Firearms Area 2023.
Crosshatched Areas in Red Lake District Closed From Oct 7th to Dec 15th.
Please Observe and Obey All Signs.

Ontario Government Notice: Attention hunters. Portion of Tuzyk's Road in Ear Falls and Red Lake areas will be closed to "NO HUNTING OR DISCHARGE OF FIREARMS" from OCT 7th, 2023 to DEC 15th, 2023 inclusive.

Firearms must be encased when traveling through cross-hatched area when signs are present.

The areas will be clearly signed and hunters are requested to obey these signs.
Maps showing the exact closed areas will be available for viewing in the MNRF office Red Lake and at gas stations or major issuers of hunting licenses in the Ear Falls and Red Lake areas.
All closures are made under the authority of subsection 10(2) of the Fish and Wildlife Conservation Act, R.S.O. 1997, Chapter 41, for the purposes of safety of Kinross employees.

SUBJECT: Notice of No Hunting or Discharge of Firearms Area

The Ministry of Natural Resources and Forestry (MNRF) Red Lake Sioux Lookout District would like to advise you of a No Hunting or Discharge of Firearm Restriction on a portion of Tuzyk's Road in the Ear Falls and Red Lake Area. The Restriction will take place from October 7, 2023, to December 15, 2023. Please see enclosed map.

The areas will be clearly signed, and hunters are requested to obey these signs. Maps showing the exact closed areas will be available for viewing in the MNRF Red Lake office and at gas stations or major hunting licenses issuers in the Ear Falls and Red Lake area.

The public is permitted to travel through the area. However, **firearms must be encased when traveling through cross-hatched area (see map) when signs are present.**

All closures are made under the authority of subsection 10(2) of the Fish and Wildlife Conservation Act, R.S.O.1997, Chapter 41, for the purpose of safety of Kinross employees.

For further information regarding the request for temporary closure and ongoing operations please contact Ian Russell, Site Manager, Great Bear Resources Ltd. by phone at (807) 728-3882 or by email at ian.russell@kinross.com. Should you have any comments or concerns regarding this temporary closure please contact Tyson Kan, Integrated Resource Management Technical Specialist by phone at (807) 728- 1941 or by email at Tyson.Kan@ontario.ca with the MNRF by October 5, 2023.

Sincerely,

Myles Perchuk

Chief and Council
General Delivery c/o Asubpeeschoseewagong Netum Anishinabek Band Office
Grassy Narrows, ON
P0X 1B0
Attention: Lands Protection Team

Dear Chief Turtle and the Lands Protection Team,

In response to Asubpeeschoseewagong Netum Anishinabek's communication to the Impact Assessment Agency of Canada, we at Kinross would like to offer our apologies for the misstep in communication. Previous communications from Kinross have been directed and shared with the Mercury Justice Team.

Further to the letter previously sent out, our goal remains to foster open and productive discussions regarding our Project. To this end, we would like to restate our offer to discuss capacity funding to be provided by Kinross to Asubpeeschoseewagong Netum Anishinabek and the Lands Protection Team, to facilitate and support technical review of environmental and regulatory documents related to the Great Bear Advanced Exploration Permitting and Main Mine Project Impact Assessment. The Kinross team welcomes and can facilitate an in-person meeting as per the direction of the Lands Protection Team and leadership of Asubpeeschoseewagong Netum Anishinabek. Kinross as part of the development of the Great Bear Project is committed to robust mitigation and protection measures designed not only to meet regulatory standards but also to ensure the ongoing safeguarding of water resources. This commitment underscores our firm dedication to this vital principle.

The Kinross team would welcome the opportunity to discuss capacity funding, a pathway forward with the Lands Protection Team and to explore opportunities for review and dialogue. The previous steps and the establishment of a SharePoint documentation portal provide the relevant information for the Lands Protection Team. We will ensure that all those identified are provided access. Kinross looks forward to continuing to explore this option with the team, as this platform not only facilitates the progression and evaluation of advanced exploration activities but also federal regulatory needs ahead. Kinross sees this as a continuing dynamic resource to facilitate and inform dialogue.

Kinross and the Great Bear team look forward to engaging in meaningful conversations with the Community. We are eager to identify potential synergies between the community's interests and the objectives of the Great Bear Project. Through this collaborative approach, we aim to create a positive and mutually beneficial impact, contributing to community well-being.

We extend our gratitude for your continued engagement and support.

Regards,

Mac Potter

Email: GreatBear@iaac-aeic.gc.ca

Dear Impact Assessment Agency of Canada,

RE: Great Bear Gold Project

I am writing to you on behalf of Grassy Narrows as the Lead Negotiator for Land Protection. I am very concerned by your recent response to my letter and to the previous letter from Chief Turtle.

We have clearly told you that we need time, capacity, and a respectful mutually agreed process to meaningfully engage. We have explained to you some of the extreme challenges that our First Nation faces and we have explained the fear, anxiety, and harm that industrial proposals cause to our people who are already overburdened.

Instead of respecting us, you are forging ahead with a very fast, one-size-fits all process that was determined unilaterally by you before talking to us. This process does not consider our unique circumstances and we are unable to engage in a meaningful way. For example, we have recently buried multiple community members who passed away too young. Your timelines leave no space for our burial process and our grieving.

It appears the IAAC prioritizes advancing this project quickly without care for its impacts on us. This is despite the fact that we have informed you that we are the first community downstream of the project and that we already have suffered harms that go far past the point of any reasonable impact to our health, way of life, society, environment, and rights. The result is that we are being left behind in the Impact Assessment of a project that places us at tremendous and irreversible harm.

In spite of the many important concerns that we have raised, our exclusion from IAAC's pre-planning phase (and many other aspects of this project), the absence of sufficient capacity funding in place for meaningful engagement, and our calls for corrective action, the IAAC is moving ahead without us. When we write to the companies and to the Crown we often have to wait years for responses. If Kinross wants an extension on any step in the process you will grant it. When we say that we need more time you grant us one additional week and then forge ahead without us. And yet we are the party in this process that lacks capacity due to the impacts of colonization and industry.

While you say that you will take our input seriously if we submit it later, this is hard to believe. First, you attempted to contacted us in a way that does not respect our protocols and only at the very last minute at the same time as you gave notice to the general public online. Second, when we became aware of your assessment by chance, we clearly communicated our concerns and solutions, but you have largely ignored the substance of the concerns that we have raised to date. Third the process is already moving forward quickly without us, completing foundational steps (such as deciding who will be engaged and identifying the issues) which will determine the nature of the rest of the process. This has been done without our input.

It is unclear how it will be possible to take our input into account retroactively after so many important decisions have been made. At the current pace you may soon decide that an Impact Assessment is not needed before we are even able to review the hundreds of pages of technical documents which we have received, nor talk to our Elders, landusers, women, and youth, receive expert, legal, policy, and other advice, carry out our governance process, and make relevant submissions to you. How would our input be meaningfully considered then?

How can we trust that you will take our concerns seriously and carry out a fair process when you have ignored the concerns that we have raised so far? How can we trust that you will take our concerns seriously when you forge ahead without us and offer only vague assurances that our concerns will somehow be taken into account later after foundational decisions have already been made without us.

We call on IAAC to terminate this process and to restart the process, if warranted, at a later date.

The main reasons for this include:

1. **The launch of the IA process is premature.**

The launch of the IA is premature because Kinross has not established that a credible and viable project exists. For example, the economic and technical feasibility studies are not yet complete. Before initiating the Impact Assessment, the proponent should be required to present an analysis based on an economically and technically credible mine plan; and supported by an independent, rigorous economic and ecological analysis of the alternatives.

The premature launch of the IA creates hardship for ANA by creating undue burden on ANA's strained capacity which is required to address the intense crisis in Grassy Narrows, and by creating stress and fear for ANA people who are already suffering from hardship including a child and youth suicide crisis.

The IAAC must ensure that only credible and viable projects are allowed to initiate the IA process. Otherwise, ANA (and others) could be burdened unnecessarily by this process at the whim of any over eager proponent seeking to get a head start on their regulatory timelines.

2. **Strategic issues unresolved.**

The Crown has unresolved obligations to Grassy Narrows. including obligations related to Treaty 3 and obligations arising from the commitment to increase Grassy Narrows' control over local lands and resources as part of addressing the damage that mercury has done to the environment on which Grassy Narrows depends.

These obligations are not yet fulfilled and require reaching a new, mutually agreeable arrangement with respect to land ownership, jurisdiction, decision making, landuse designations, protected areas, cumulative effects, source water protection, remediation, monitoring, and other related matters.

The Ministry of MINES has indicated that they will finally come to the table with ANA, and CIRNAC has indicated that they would join a table if Ontario is present. However, ANA continues to await a response from the Minister of MINES on which of ANA's issues Ontario is willing to have on the table. The table has yet to be established, but we have hope that it will resolve the unresolved issues.

Proceeding with a unilateral regulatory process for a specific gold mining proposal conflicts with the commitment to resolve in good faith the matters identified in the 1978 MOU between Grassy Narrows, Ontario and Canada, and the duty of the Crown to act honourably and the Crown's fiduciary obligations towards Grassy Narrows. It further prejudices and makes more intractable the successful resolution of these important issues between Grassy Narrows and the Crown.

3. **The foundational steps of the IA process were fatally flawed**

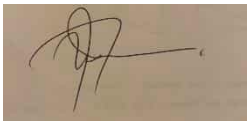
ANA was excluded from the pre-planning phase. As a result, ANA's preferred way of engaging on this project has not been identified nor implemented by IAAC. Instead, a one-size-fits all process has been used that has made meaningful engagement by ANA impossible and has left ANA behind.

Key decisions, such as the process, and the identification of the issues, have been carried out without ANA. A very preliminary read of the issues indicates that issues important to ANA are omitted and a number of ANA specific issues raised by Indigenous Services Canada are also omitted. Issues specific to ANA's unique circumstances, history, cumulative impacts, and location downstream of the project are not sufficiently reflected.

The Great Bear IA should be terminated. Once the project has reached the appropriate stage, and the strategic issues have been resolved between ANA and the Crown, the pre-planning process should be re-started with ANA's involvement from the outset (with sufficient capacity support provided in advance). The pre-planning process has no time limit associated with it and should be carried out in a respectful way until there is a satisfactory outcome in the context of ANA's unique circumstances.

I urge you not to continue with this fatally flawed process. It is not too late to start again and to do it properly.

Awsa,



_____

Great Bear Project

Proposed Underground and Open Pit Gold Mine

Asubpeeschoseewagong Netum Anishinabek
November 10, 2023

KINROSS

We are honored to be working
in the traditional territory of the collective members of the Anishinaabe Nation in Treaty #3

We and all our contractors recognize and respect
the inherent and treaty rights of the Indigenous Nations on whose traditional territory we operate.

We are committed to meaningful dialogue
and working with Indigenous peoples, learning from Indigenous Knowledge and applying those learnings to our work across the organization.

Agenda

1. Great Bear Project
   A. Our Commitments
2. Federal Approval Process
   A. Status
   B. General Arrangement
   C. Timeline
3. Advanced Exploration
   A. Introduction to Advanced Exploration
   B. Community Led Technical Review and Participation
   C. AEX Features and Permits
   D. Water Management Approach
4. Pathway Forward

KINROSS

Our Vision for Great Bear

Strong Partnerships
With local Indigenous communities, rightsholders, and communities in which we operate

Long Life OP & UG Mine

Low Emissions Mine
Via electrification and clean Ontario grid power

Local Employment
700 – 1,000 potential direct jobs created

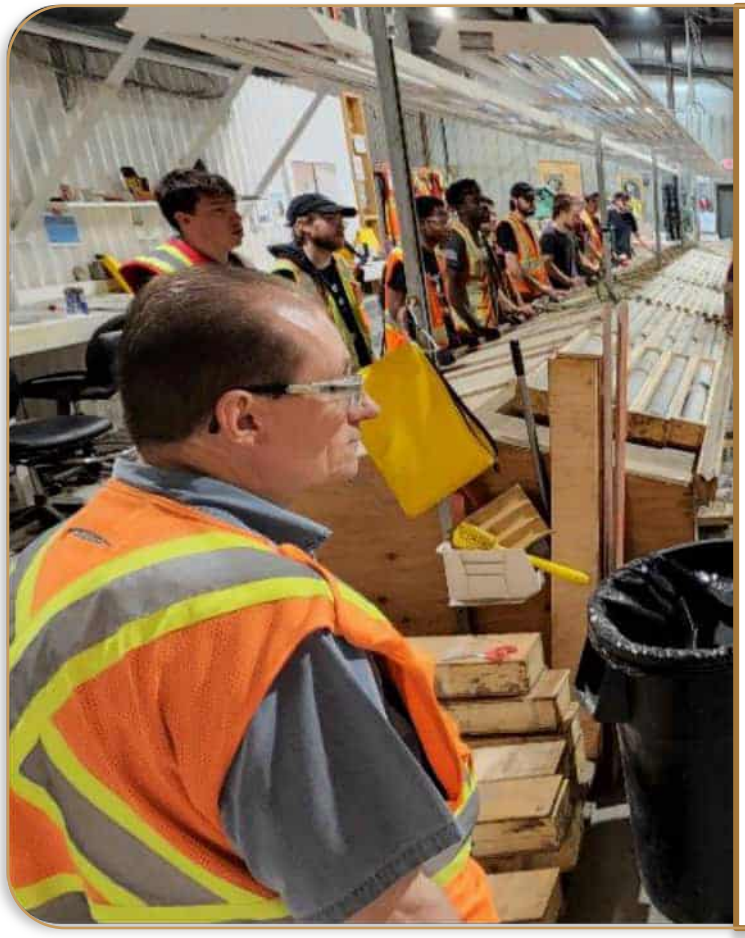
Best in Class Mine
Driven by workforce skill, design, efficiency and automation

Creating a Lasting Legacy in Red Lake, Ontario

KINROSS

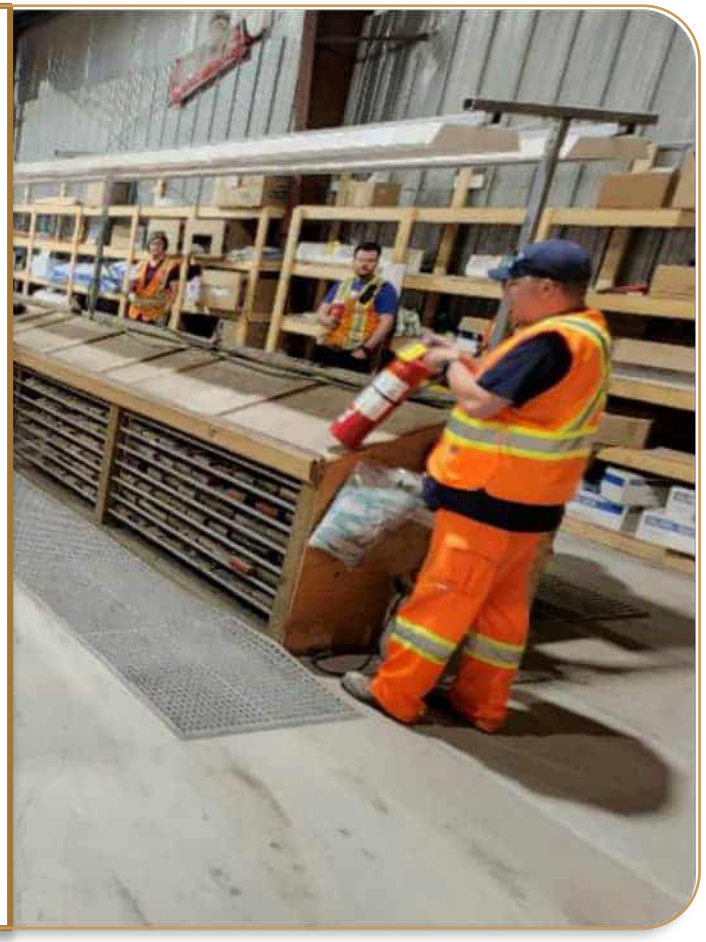
Committed to Operating Responsibly

Focus on prioritizing health and safety above all else



We value the health and safety of our workforce above all other priorities

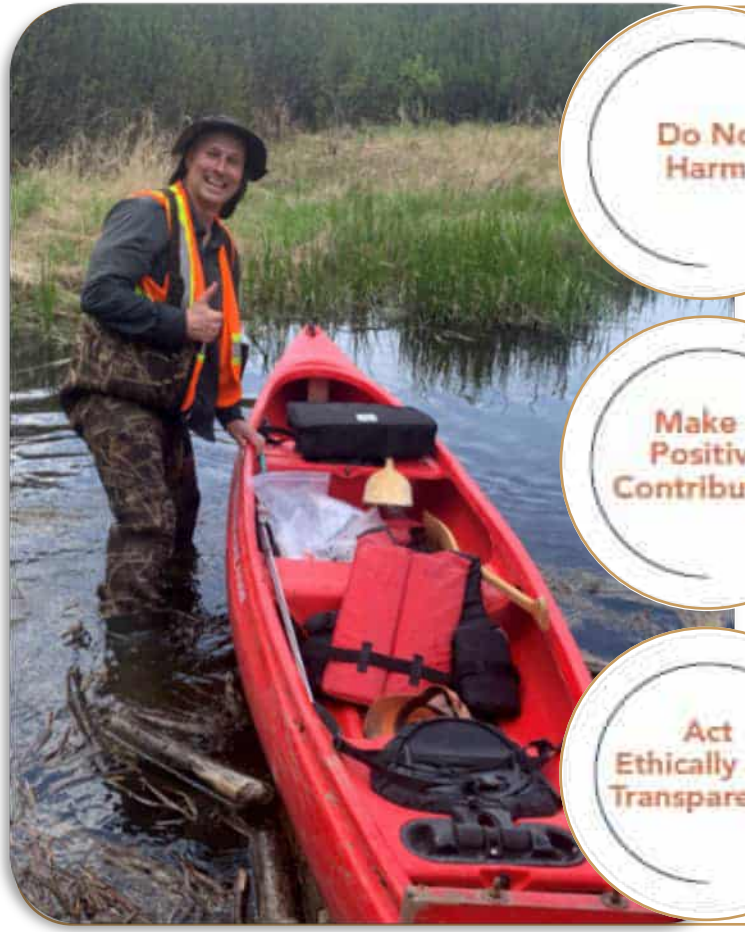
We implement risk controls, training, and leadership to ensure a culture of safe work at all sites at all times



KINROSS

Committed to Operating Responsibly

Our approach to sustainability



Do No Harm

We work to protect our workforce, environment and host communities from negative impacts

Make a Positive Contribution

We aim to provide meaningful livelihoods for employees, opportunities for suppliers and improvements in our host communities

Act Ethically and Transparently

We operate with respect for human rights and we engage with our stakeholders

Continuous Improvement

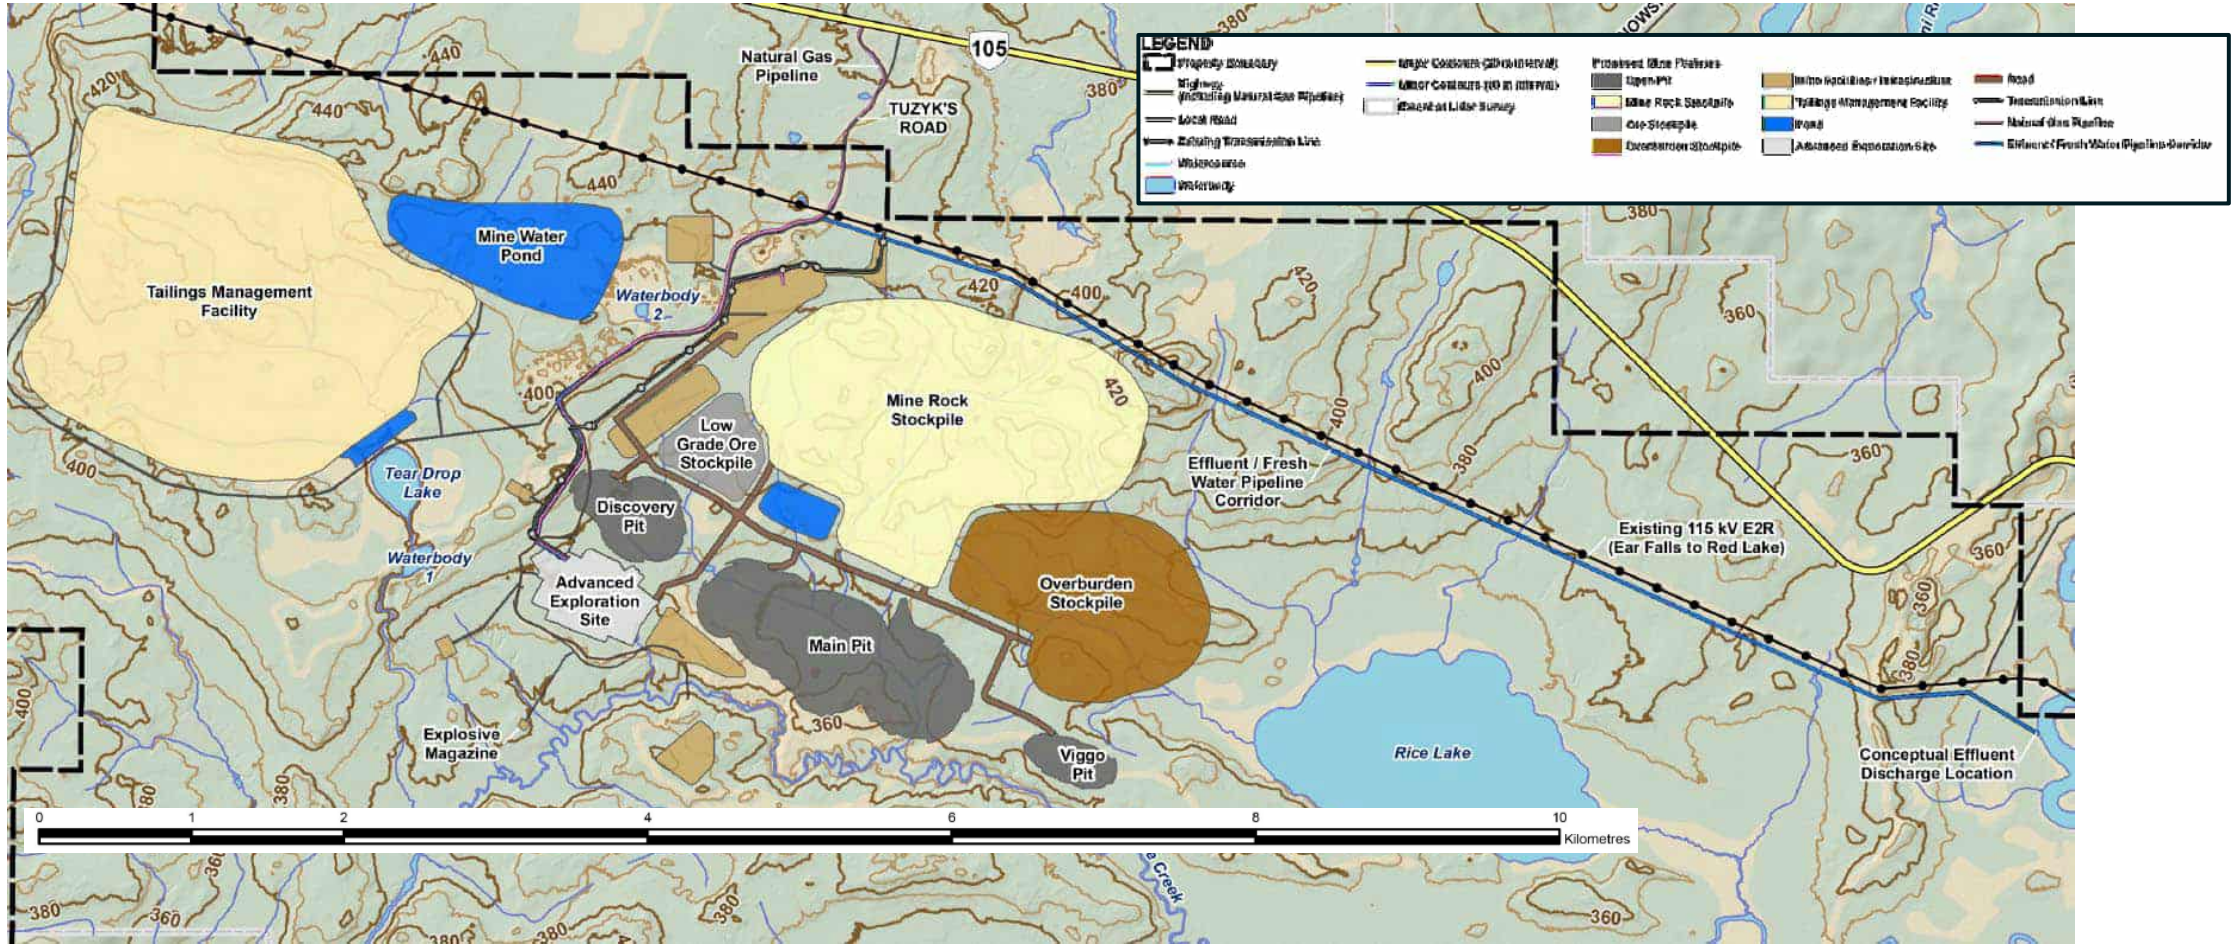
We strive to improve our approach to corporate responsibility practices

BUILDING A LEGACY IN RED LAKE, ONTARIO
Main Project
Impact Assessment
KINROSS

IAAC Process (as of October 13th, 2023) – Planning Phase

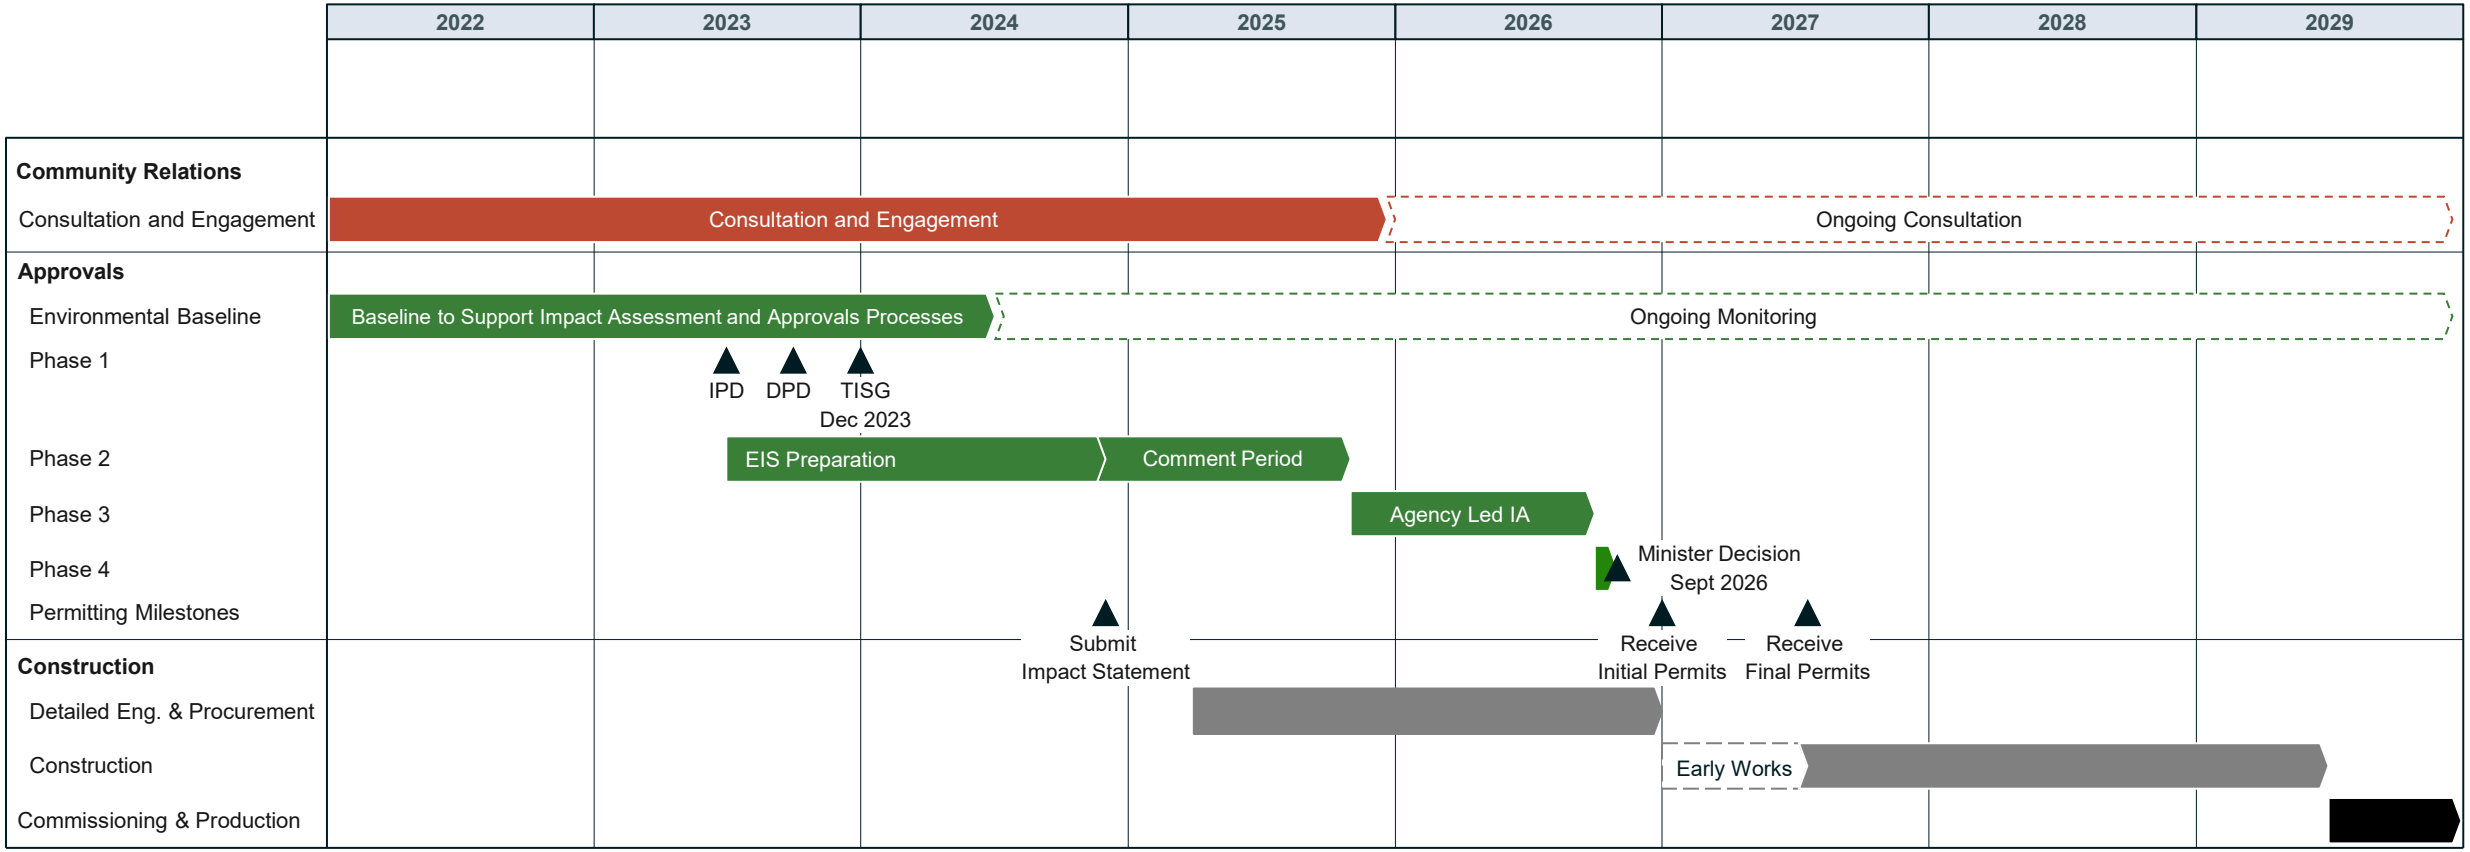
- Objective of Phase 1:
  - Identify issues of importance to communities including opportunities for collaboration and cooperation. Identify pathways to set the stage for meaningful engagement and consultation throughout the process
  - Formally determine whether an impact assessment is required and receive tailored Impact Statement Guidelines
  - Plan the Impact Assessment and prepare plans that establish the process for participants
- Status:
  - The Agency posted the Initial Project Description (IPD) for public and Indigenous review (August 17, 2023)
  - The Agency has compiled a Summary of Issues detailing concerns they have heard during their engagement (provided to Kinross on September 29, 2023)
  - Kinross preparing its responses to issues raised during IAAC engagement within its Detailed Project Description (DPD)
- Next Steps:
  - After accepting DPD, Agency determines whether an Impact Assessment is required
  - Agency develops several planning documents, and the assessment moves to Phase 2 (preparation of the Impact Statement)

Main Project – General Arrangement



KINROSS

Timeline within IAAC Process



BUILDING A LEGACY IN RED LAKE, ONTARIO

Advanced Exploration

KINROSS

Overview and Approach

- The purpose of Advanced Exploration is to obtain additional information on:
  - Mineralized zones through underground drilling
  - Extract a bulk sample of up to 60,000 tonnes by underground mining methods
- Bulk sample will be transported up an underground ramp to surface by truck for crushing, sorting, sampling and stored in stockpiles. Samples will be transported by truck to test facility off site
- Testing provides a better understanding of grade and metallurgical recoveries to support a viable commercial production scenario

KINROSS

Community Led Technical Review and Participation

- The team at Wabauskang First Nation and Lac Seul First Nation has been an active participant in baseline activities, inspections, and technical reviews on draft applications for the advanced exploration permitting
- Technical reviews have been led by Dillion/SOAR, and Sapo'nuk Sustainability, with input and guidance from staff and leadership
- Wabauskang, Lac Seul and Kinross have formed an environmental committee to help review work, and ensure community input going forward
- As part of our partnership, notice is provided of upcoming business opportunities, employment, and has provided training to Wabauskang and Lac Seul staff working on the Project

Sapo'nuk Sustainability

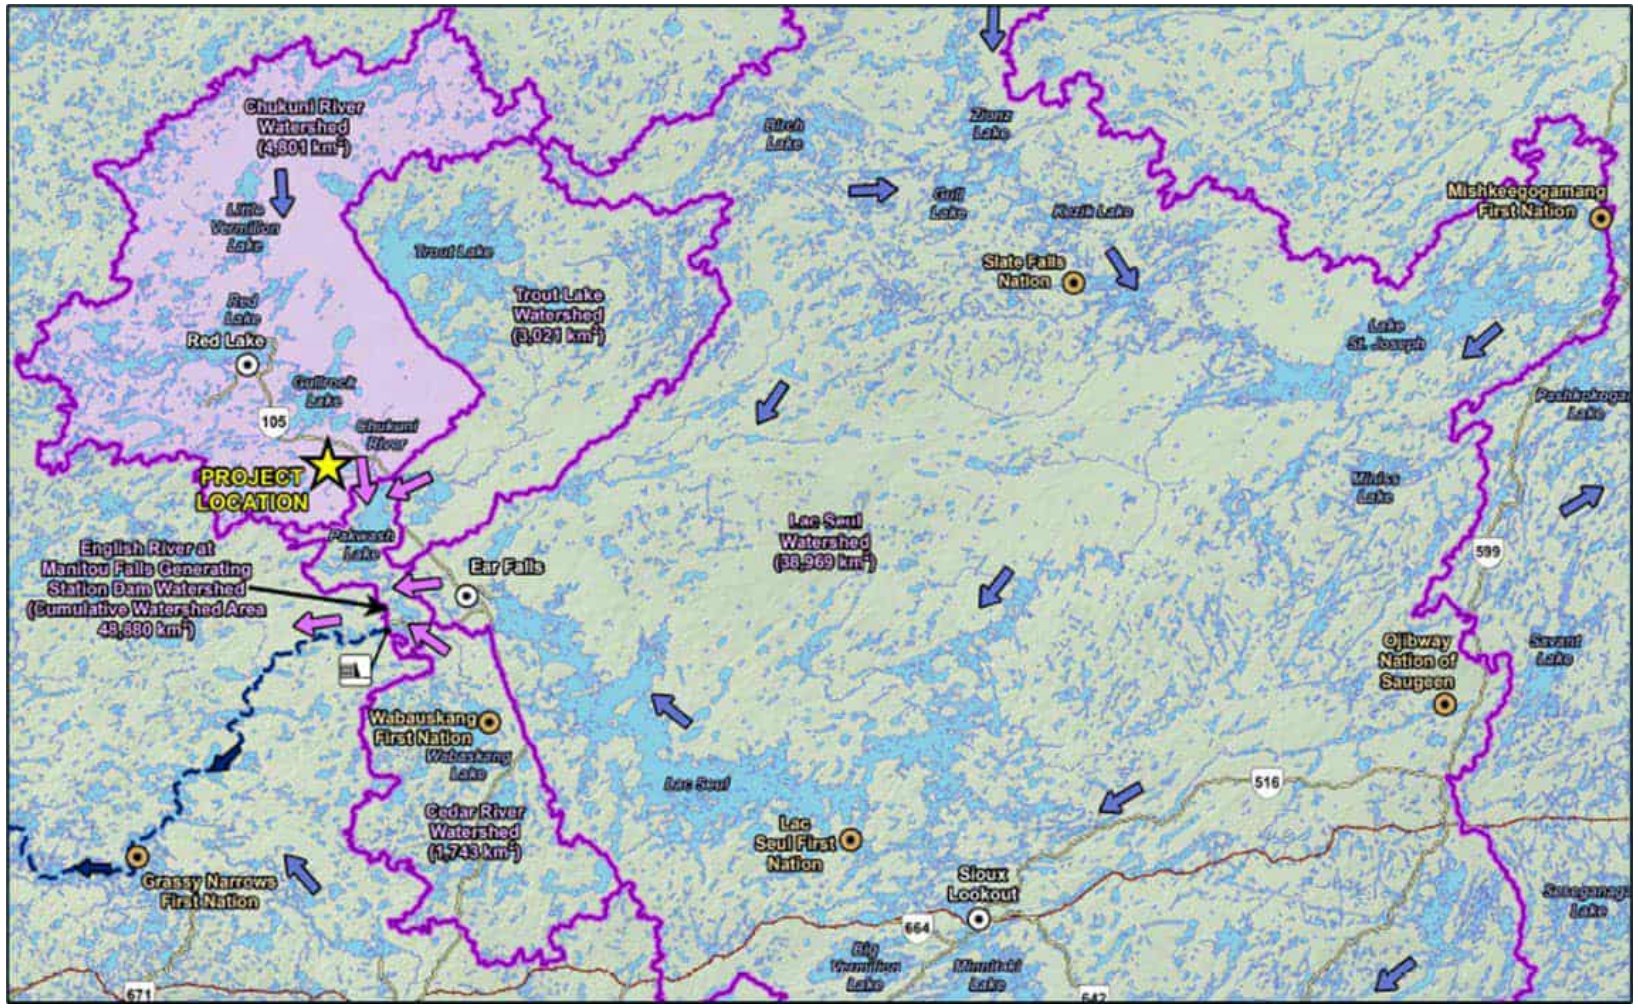
DILLON CONSULTING

SOAR Professional Services

KINROSS

Watershed Focus

- The Great Bear Project is located in the Chukuni River watershed
- Water from the Chukuni River flows into Pakwash Lake and English River
- Our local watersheds have driven the approach to surface water sampling, hydrology assessments, and our aquatics programs



KINROSS

Features and Overview

Area	Design	Justification
Twin Declines	• Twin portals and ramps	• Safety is first priority at Kinross. Show this by Safety in Design • Creating secondary egress from Day 1
Underground Development	• ~9,000 m of development to access the deposit. Incl. ventilation, utilities, dewatering, etc.	• 3 deposits targeted (LP, Hinge and Limb) • Need to get down to >600m vertical depth to drill deeper sections of the deposit more efficiently
Power	• Natural gas power generation for start up of activities. Transition to grid power during AEX program if possible • Diesel generation is for backup and the construction stage	• Power connection timelines uncertain. Transition when possible
Camp	• 100 person camp on property	• Temporary influx of personnel into region • Limits fatigue as camp nearby and provides personnel oversight
Rock – Mine Rock Management	• Separate PAG and NAG storage • Return PAG underground at closure • Sampling programing during AEX	• Best mine rock management practices • Potential re-use of NAG for aggregate or construction
Water Treatment	• Robust water treatment design	• Striving for high-standard of water treatment and management. Priority for Kinross
Water Management	• Collection of all runoff with appropriate treatment and storage	• Water management is critical to project and Kinross
Effluent Discharge	• Chukuni river via pipeline (potentially to Dixie Creek at start)	• Water will be treated prior to discharge and all regulatory requirements will be met (water quality and flows)

Advanced Exploration Permits

Agency	Permit	Comments
Ministry of Mines	Closure Plan (Final Filing)	▪ A written plan on how the site will be rehabilitated ▪ Financial assurance required prior to construction start
Ministry of Environment and Parks	Class EA Temporary Power (construction)	▪ Required for temporary diesel power between 1 and up to 5 MW during the construction phase of the AEX project. ▪ Assess the operation of diesel generator and identify mitigation measures
	Environmental Compliance Approval (ECA) Air (Operations)	▪ Required for air emissions related to all activities for AEX including noise for AEX Operations
	Permit to Take Water (PTTW) Underground and Surface	▪ Required for all water taking and or transfers. Includes underground dewatering and construction front activities that require the movement of water. ▪ Required to initiate AEX footprint construction activities
	ECA Industrial Water Management	▪ Required to manage and discharge treated water back to the environment. All water that flows through or on the site will need to be collected and treated prior to discharging to the environment. ▪ Required to initiate AEX footprint construction activities
Ministry of Natural Resources and Forestry	Crown Resource Class EA Screening	▪ Required to assess the potential impacts of timber clearing activities.
	Forestry Resource License	▪ Required to remove any timber from crown land, obtained after the Class EA Screening is complete
	Land Use Permits	▪ Required for any activity on Crown land that has not been brought to lease. A large section of the WTP effluent pipeline is anticipated to be on crown land. ▪ A portion of the Natural Gas pipeline may also require a land use permit for AEX

KINROSS

FOR DISCUSSION PURPOSES ONLY- PRIVILEGED & CONFIDENTIAL

Permit to Take Water

- A key component of AEX activities is control, management, and protection of water resources. To ensure proper management Kinross will need to both actively manage surface water (including creek systems) but also dewater the underground workings
- Kinross has taken a conservative approach in pumping to ensure safety for staff underground in the case of an unexpected event like a power outage

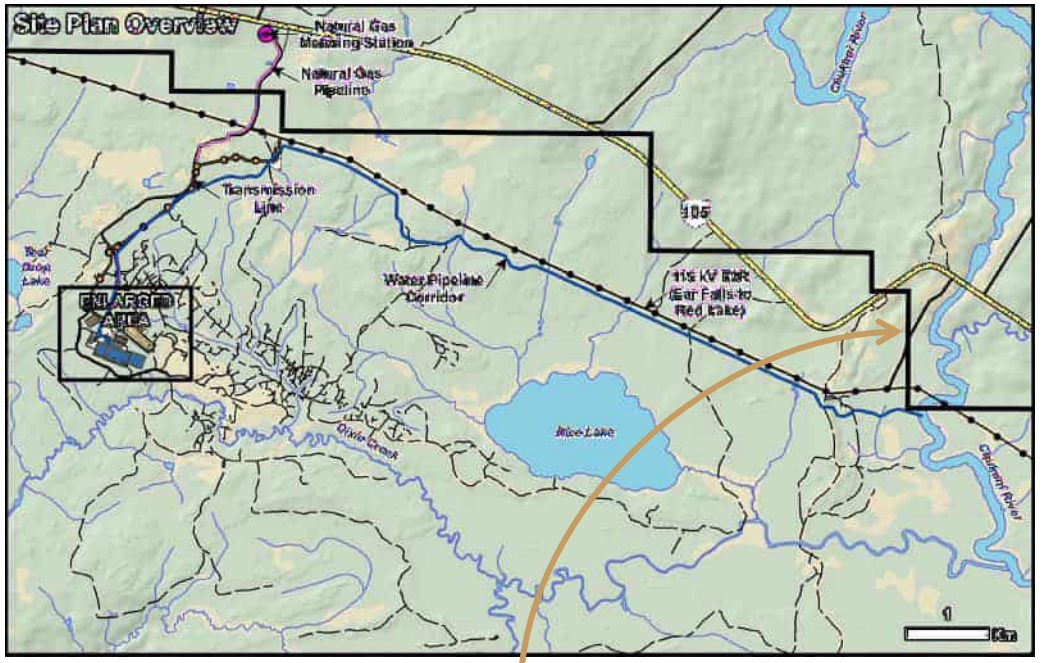
Table 4-1: Requested Water Takings

No.	Source Name / Description	Source Type	Taking Specific Purpose	Taking Major Category	Maximum Taken (m^3/min)	Maximum Number of Hours Taken per Day	Maximum Taken per day in m^3	Maximum Number of Days Taken per Year	Location (Easting / Northing)
1	Underground Portal	Groundwater	Dewatering	Industrial	1.39	24	2,000	365	455377 / 5634568
2	Underground Dewatering, Uncertainty Event (Contingency) [1]	Groundwater	Dewatering	Industrial	3.13	24	4,500	30	455377 / 5634568
3	4 Pond Excavations [2]	Surface water	Dewatering	Industrial	0.12	24	170	365	455340 / 5634390
4	4 Pond Excavations	Groundwater	Dewatering	Industrial	0.54	24	783	365	455340 / 5634390
5	Dixie Creek	Surface Water	Other-Industrial	Industrial	0.17	24	250	365	455994 / 5633961
						Total Requested Water Taking	**7703**		

Notes:
[1] In support contingency planning with respect to underground dewatering, Kinross is also requesting pumping at higher rates to remove water after an interruption in pumping, as required (for example, due to a power failure or some other unexpected events)
[2] Combined estimate for dug-out Mine Water Pond 1, Mine Water Pond 2, Settling Pond and Polishing Pond.

KINROSS

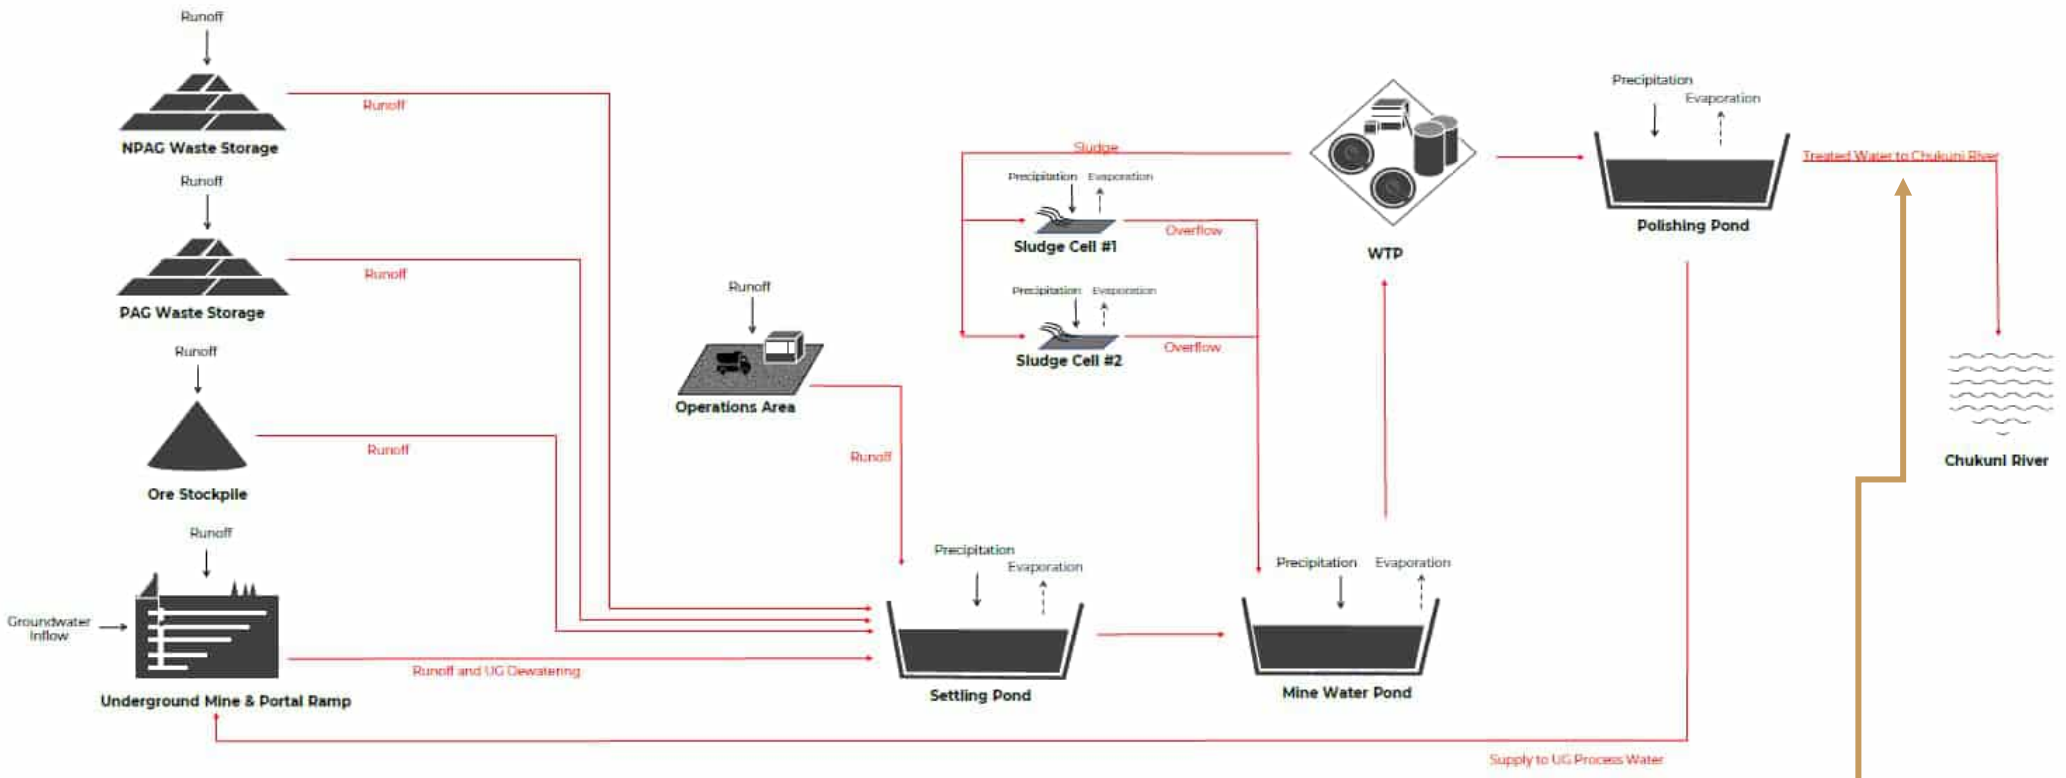
Environmental Compliance Approval (ECA)
Water Management and Permit to Take Water



Water management design, structure, control, and mitigation is **key** to our approach to AEX and future operations. **We are committed** to an approach that is **protective of human, plant, and animal life** in the Chukuni River watershed

KINROSS

Water Balance



All collected water discharged to the Chukuni River will be managed to protect the environment and achieve regulatory requirements. All water set to be released will be subject to water treatment

KINROSS

Water Treatment

- Contact water discharged to the Chukuni River will be managed to achieve regulatory requirements.
- This includes a multi-stage treatment process that includes:
  - Ammonia Treatment – Moving Bed Biofilm Reactor (MBBR)
  - pH adjustment, clarification
  - Additional ultrafiltration
- Kinross is committed to applying adaptive management practices in the development of the approach to water management on site. This includes sharing trending data, duplicate sampling, and ongoing transparent dialogue with Indigenous communities

Table 5-6: Proposed Discharge Limits

Parameter	Calculated Limits [1]	Proposed Discharge Limits [1]	
		Maximum Monthly Average Concentration	Maximum (Daily) Concentration
pH	-	pH of discharge maintained between 6.5 and 8.5, inclusive, at all times	
Total Suspended Solids	-	15	30
Arsenic	0.009	0.009	0.018
Copper	0.103	0.1	0.2
Lead	0.303	0.08	0.16
Nickel	0.73	0.25	0.5
Zinc	0.34	0.34	0.68
Un-ionized Ammonia	0.32	0.32	0.64
Phosphorus	0.22	0.22	0.24

Notes:
All units are mg/L, save pH (unitless)
[1] The Chukuni River is a large receiver, with high assimilative capacity for most parameters. Where the back-calculated monthly average limits were greater than MDMER criteria, the calculated limits were subsequently reduced to MDMER specified effluent criteria, as applicable

Our discharge approach is to meet the lower of the monthly average limits on a daily frequency, ensuring ongoing protection of the aquatic environment, and downstream users.

KINROSS

Water Treatment – Ammonia, Clarification, and Filtration

- The system proposed has been used successfully in local and regional operations across northwestern Ontario
- Ammonia Treatment – Moving Bed Biofilm Reactor (MBBR)
  - Uses small plastic carriers that allow microorganisms to grow and break down the ammonia.
  - Allows natural breakdown and consumption of ammonia
- Actiflo System – Supporting pH adjustment, clarification, and filtration
  - Increase solids contact to initiate precipitation. Solids fall to bottom of the tank and are removed.
  - Clean water is forced upwards and is clarified.
  - Ultra filtration (not shown in image) will be applied to further remove contaminants creating world class treatment system

MBBR Reactors in Northern Quebec Gold Mine

Path Forward
KINROSS

Input and Path Forward with Asubpeeschoseewagong Netum Anishinabek

- Kinross remains open to discussing capacity funding to be provided by Kinross to Asubpeeschoseewagong Netum Anishinabek and the Lands Protection Team, to facilitate and support technical review of environmental and regulatory documents related to the Great Bear Advanced Exploration Permitting and Main Mine Project Impact Assessment
- Kinross also remains open to discuss ongoing procurement and business opportunities with those businesses partnered with Asubpeeschoseewagong Netum Anishinabek
- Kinross is open to working with Asubpeeschoseewagong Netum Anishinabek and the Lands Protection Team to determine a path to establish independent community water monitoring

Hydrometric Monitoring Site

Table 2-2: Hydrometric Monitoring Rationale

ID	Station Name	Rationale for Selection
Off-site Stations		
HF-01	Dixie Creek at Tote Road	Measure flows and levels on Dixie Creek downstream of all project development.
HF-02	Rice Lake Outflow above Dixie Creek	Characterize seasonal behaviour of Rice Lake, contributions to Dixie Creek from Rice Lake Trib.
HF-03	Dixie Creek DS of LP Trib	Measure flows through Dixie Creek, estimate contributions from second order tributaries along Dixie Creek.
HF-04	LP Fault Trib US of Dixie Creek	Characterize flows through Tributary 3 and the defined drilling area.
HF-06	Tear Drop Lake Outflow	Characterize seasonal behaviour of Tear Drop Lake, contributions to Dixie Creek from Tear Drop Lake Trib.
HF-07	Dixie Lake Outflow	Measure flows and levels on Dixie Creek, upstream of any project development.
HF-08	Genessee Lake Trib towards Dixie Lake	Characterize flows out of Genessee Lake, contributions to Dixie Lake from Genessee Lake Trib.
HF-10	Stone Lake Outflow	Measure flows and levels from Stone Lake to Gullrock Lake, watershed potentially impacted by project development.
HL-01	Genessee Lake	Characterize seasonal behaviour of Genessee Lake.
HL-02	Gullrock lake	Characterize seasonal behaviour of Gullrock Lake.
HL-03	Chukuni River	Estimate potential tailwater conditions on Dixie Creek caused by Chukuni River levels.
On-site Stations		
-	Settling Pond	Pumping to Mine Water Pond(s); Primary AEX water management surge pond, used to provide TSS and residual ammonia management, and to moderate the effluent feed rate to the Effluent Treatment Plant
-	Mine Water Storage Ponds	Pumping to Effluent Treatment Plant; Holding pond, represents influent to Effluent Treatment Plan
-	Effluent Treatment Plant	Pumping to Polishing Pond; Removal of metals and potentially other contaminants from AEX effluent prior to discharge to the Chukuni River
-	Polishing Pond	Final Compliance Point, discharge to Chukuni River via pipeline and diffuser

Grassy Narrows – Kinross – IAAC Joint Meeting

1. **Executive Summary**

Client Name	Kinross Gold Corporation	**Project No:**	**TBD**
Project Name	Great Bear Project		
Meeting Type:	In-Person [ ]	Virtual [X]	Hybrid [X]
Location:	Virtual		
Time:	12:00 PM CT – 1:30 PM CT		
Date:	November 10, 2023		
Executive Summary:	Meeting between representation of Grassy Narrows First Nation, Kinross Gold, and the Impact Assessment Agency of Canada. IAAC provided presentation materials ahead of meeting to support, note GNFN provided notice that review of Kinross provided materials will not be completed at this time. Principal dialogue occurred between representatives of Kinross and GNFN. Request from GNFN to apply a pause to all activities until former protocol agreement can be put in place to ensure information sharing. Noted commitment to affirm follow up meeting timing to address actions, including consideration to pause. Kinross staff reaffirmed Company commitment to provide capacity to support informed dialogue. Key concerns articulated included a focus on community dialogue and integration of that knowledge over the course of the Project, lack of consultation to date, requirement for an appropriate protocol, and illustrating concerns that the Project presents an ongoing risk to the communities Aboriginal and Treaty Rights.		
Key Actions:	a. Kinross and GNFN Lands Protection Team to confirm follow up meeting timing. b. Kinross as part of follow up meeting to affirm decision on protocol agreement, and consideration to a pause as requested by Lands Protection Team.		

2. **Attendance**
    a. Kinross
        i. Ian Russell
        ii. Mac Potter
        iii. Nathan Longnecker
        iv. Luke Crosby
        v. Aaron MacDonell
        vi. Ashley Moncrief
    b. Grassy Narrows First Nation
        i. Jospeh Fobister
        ii. Mike Fobister
        iii. Jackie Esmonde
            1. Legal Counsel
        iv. David Sone
            1. Advisor
        v. David Mossip-Balkwill
            1. Advisor
    c. IAAC
        i. Ian Lindsay

ii. Owais Khurdis
iii. Natalie Boyd

3. Agenda and Attachments

1) Introductions
2) Grassy Narrows concerns with the relationship to date
3) Pausing the process
4) Need for a Process Agreement
5) Capacity Supports

Kinross-Grassy Narrows Project Upda

Note that presentation was provided by IAAC to GNFN, GNFN provided direction to the Agency that they were not amendable to a Project update as part of the meeting.

4. Minutes

a. Opening Prayer and Remarks
   i. The meeting was opened with a prayer and comments from community member and Lands Protection Lead from GNFN. They spoke to their connection to the land, and ongoing concern with the process. They noted that it was only recently that they became aware of the Project, and it must be considered.
   ii. GNFN noted that the historical conditions, residential schools, movement of the community, and historical legacy of the mill have challenged the community.
   iii. GNFN noted that they need to be involved in the work in the territory, especially with those Projects interconnected via the watershed. Our community needs to understand how the activity will impact us, and that requires a clear process forward. They noted GNFN success in challenging industrial activity and logging. If there is no action they have had success using protest, the legal system and the media in ensuring our peoples protection.
   iv. GNFN spoke to ongoing communication with GNFN, and that all received to date is ungenuine in nature. She raised that GNFN reached out to GBR historical to no response, and Kinross has expressed a similar pattern. GNFN noted that it is clear that Kinross has engaged with the other Nations in the area and have ignore GNFN, and that from our meeting in June 2023 these concerns have been ignored.
   v. GNFN noted the continued lack of capacity to support activities and review of work. The Lands Protection Team strongly disagrees that concerns have been met, and this reflects the shortcomings of Kinross.

b. Discussion
   i. GNFN asked why has GBR/Kinross not engaged with GNFN since 2018?
      1. GBR noted that communication and dialogue has occurred and they are seeking a pathway forward not a reflection of the work in the past, and prior to Kinross acquiring the Project
      2. GBR noted that prior to March 2022 activities of Great Bear were governed under the previous ownership.

ii. GNFN noted that our primary concerns are those contaminants of concern, including mercury and the impact to the people. They are trying to ensure they protect those people.
    1. GNFN noted it is imperative that they understand and agree on a process. They want to understand value, address concerns, ceremony, and ensure that if applicable design measures to meet the community's health crisis. GNFN added that decision and direction have been made without dialogue with the community, they spoke to the agreements in place with other communities and the lack of action is a sign of insincerity by Kinross. They cannot go back but to ensure steps forward they need to determine a protocol and process.

iii. GNFN stated that as part of this process, our request is to Kinross to pause all activities until this can be determined.
    1. GNFN spoke to lack of defined capacity funding, and that this action is by way of the historical approach of the Company. If Kinross is sincere and would like to advance things a pause is required to ensure they meet that. Grassy has agreements of similar nature with the Crown to meet items such as this.
    2. GNFN noted that they need to reset the relationship, and this covers all things. If no action on Kinross these deadlines will pass and the Community will take action to protect its rights. GNFN affirmed prior statement by that the community will take action via protest or other form to protect its interest.

iv. GNFN restated if Kinross is open to pause?
    1. GBR noted that they are in the planning process for the Project, and that decisions are not final with either the Provincial or Federal Crown at this point. They welcome the opportunity to continue this dialogue and develop an appropriate process forward. GBR confirmed that a decision on accepting a pause cannot be made at this time. However, they reaffirmed that they are serious about funding capacity. Kinross is focused to ensure proper capacity is in place, they are not breaking ground tomorrow, information and dialogue is the key.

v. GNFN responded that the approach and is an excuse and commitment to shareholders is not our concern. Our community seeks to be involved, and our community members have little to no understanding of the Project.
    1. This direction was reinforced by other GNFN participants, noted lack of resources limits any ability to participate.
    2. GNFN noted that if agreement is required it would take approximately 3 weeks at a minimum to review and ensure it aligns. Leadership then will have to discuss, community, and then instruction to execute has to be levied.
        a. GNFN reiterated previous message on health crisis, and concerns in the community. That is the priority for our leaders.
        b. GNFN acknowledged that Kinross has provided a significant amount of information about the Project but they have no capacity to review in an informed manner.
            i. GBR noted that they can commit to that process and timelines and they understand and acknowledge the hardships. A protocol is important as is structure dialogue supporting it.

vi. GNFN responded that will Kinross discuss a pause, before speaking key terms required within a Process Agreement. GNFN noted that these is no template and they will have to discuss terms. They need to ensure this process is engaged as soon as possible as these things take time.

1. GBR noted that they are committed to process and going forward. GBR inquired to group on meeting date to discuss terms. No response issued by group.
2. GBR reiterated question on timing, noting historical offers by Kinross have not been received or considered by GNFN to date.
    a. **ACTION**
        i. GNFN response that GNFN does not have the capacity to respond but affirmed that they will provide meeting times in follow up, and Kinross will coordinate with GNFN on timing.

vii. GNFN asked Kinross for timing on a response on a pause for the Project.
1. GBR noted that ultimatums are not functional and noted decision to defer with IAAC. He noted the importance of discussion and accommodating interest.
    a. GNFN noted that lecturing GNFN is not supportive of dialogue ahead.
    b. GNFN noted that the current pathway is an ultimatum to the Community.
2. **ACTION**
    a. Noted dialogue acknowledging that the expectations will be a response on consideration for pause, in addition to initial draft of protocol agreement for consideration.

viii. GNFN inquired on current dialogue with MINES?
1. GBR noted that MINES have delegated the process to us.
    a. GNFN inquired when this decision was made?
        i. GBR confirmed April 6, 2023.
            1. **ACTION**
                a. Kinross to reach out to MINES to reissue communication to Lands Protection Group

ix. Dialogue between Kinross staff and GNFN advisory members on interaction and connection of AEX work, and IAAC process. Noted that the process is separate.
1. IAAC affirmed that integration of the Provincial Crown in the IAAC process is critical and that they provide comment on the IS. Noted that several operational permits are required following the completion of a Federal IS.

x. GNFN raised that GNFN is seeking a table with MINES to discuss current issues and impacts on the land.

5. Action Items

a. Kinross and GNFN Lands Protection Team to confirm follow up meeting timing.
b. Kinross as part of follow up meeting to affirm decision on protocol agreement, and consideration to a pause as requested by Lands Protection Team.
c. Kinross to reach out to MINES to reissue communication related to Delegation to Consult with GNFN provided previously on April 6, 2023.

Attention: Lands Protection Team

Lands Protection Team,

Thank you for meeting with the Great Bear / Kinross team on November 10th, 2023. These meetings are important to us since we want to understand your interests and explain ours.

We value good relations with all local communities. As the project proponent, Great Bear takes guidance from the Ministry of Mines on the communities that it should consult to determine the interests of those communities and how our project may affect them.

Great Bear has engaged with ANA based on the Ministry's guidance (see the attached list of communications) and will continue to engage with your community to keep you informed and to receive your input. You have explained that you want deeper engagement on the project, and we want to respond to that interest.

We suggest a follow up meeting to discuss how to proceed on a positive footing. We would like to establish a Process Protocol with Asubpeeschoseewagong Netum Anishinabek to define and facilitate our discussions on the Great Bear Project and Asubpeeschoseewagong Netum Anishinabek's interests. We can also review the overall project timeline, related permitting and your request for a pause on all activities. In brief, we want our relationship to be constructive and are ready to work through the issues with you.

We followed up with the Ministry regarding the Delegation to Consult as it relates to the proposed Great Bear Advanced Exploration Program. The Ministry has confirmed that they will reissue this communication to the Asubpeeschoseewagong Netum Anishinabek Lands Protection Team.

Our team is available at any time between November 20th through November 24th, November 27th to December 1st or a date of your convenience to meet again and continue the dialogue. We can arrange for the meeting to occur in-person, by telephone or virtually.

We look forward to your response.

Regards,

Mac Potter

Grassy Narrows – Record of Engagement

Date	Organizations	Communication Type	Summary	File name
20/2/25	**Grassy Narrows**	**Letter**	Letter communication from Grassy Narrows First Nation to Great Bear Resources speaking to IPCA consideration, respect to the Land Declaration, identification of any interests that potentially could have off-site impacts, and commit to resolve those conflicts.	
20/10/01	**Grassy Narrows**	**Letter**	Letter communication from Grassy Narrows First Nation with series of questions posed to Great Bear Resources to respond to, relating to ongoing exploration efforts at the Great Bear Project.	
22/8/8	**Grassy Narrows Ministry of Mines**	**Email**	Communications from MINES that consultation list for Early Exploration includes Grassy Narrows First Nation.	
22/8/17	**Grassy Narrows Ministry of Mines**	**Email**	Communication with MINES on clarification on Grassy Narrows First Nation inclusion in the consultation list for Early Exploration.	
22/8/29	**Grassy Narrows**	**Letter**	Introductory letter issued to Grassy Narrows First Nation by Kinross.	
22/8/29	**Grassy Narrows**	**Email**	Email response issued by Grassy Narrows stating that they do not wish to meet stating that Grassy Narrows prefer our land to continue its healing journey which in turn our people will heal from the land. Grassy Narrows communicates that they do not wish to meet. Request that Kinross take your proposal to other areas of the Province. Grassy Narrows provides its thanks for respecting our position and stand to keep our territory clean.	
22/9/17	**Grassy Narrows**	**Email**	Kinross provides communication to Grassy Narrows First Nation with all relevant documentation related to Early Exploration aspects including permit forms, maps, and GIS data.	
22/9/15	**Grassy Narrows**	**Letter**	Letter communication from Grassy Narrows First Nation speaking to IPCA consideration, respect to the Land Declaration, identification of any interests that potentially could have off-site impacts, and commitment to resolve those conflicts.	
22/11/11	**Grassy Narrows**	**Phone Call**	Kinross placed phone call with newly elected Chief from Grassy Narrows First Nation. Kinross and Chief speak to introductory details about the Company and Project, communication of permits in process, prior communication records, and confirmation of contact details.	
22/11/11	**Grassy Narrows**	**Email**	Email communication sent to newly elected Grassy Narrows Chief with introduction, project location map relative to Indigenous Nations and Forestry Management Areas, further detailed provided on permits in progress and invitation to reach out or visit project at any time.	
23/05/15	**Grassy Narrows Ministry of**	**Email**	Questions received from Asubpeeschoseewagong Netum Anishinabek (Grassy Narrows First Nation – "ANA") - on April 21st MINES staff prepared draft responses to ANA's questions and shared that material	<External> RE: Follow up.eml

Date	Organizations	Communication Type	Summary	File name
	Mines		with Kinross so that the company could add in the project specific information. If Kinross would like to discuss the draft responses, including any further support required from MINES we would be happy to do so.	
23/06/22	**Grassy Narrows**	**Teleconference**	Introduction meeting and discussion with Grassy Narrows FN, detailing their history and involvement in community, the practices have on the land. The communication detailed concern about previous mining activity and the previous suffering which has happened in the community due to mining activity. The meeting stated commitment to early engagement and continuation of one-on- one meetings and concerns regarding prior lack of communication. A request to follow-up with another meeting to learn more about Kinross and the project and approach was also given from Grassy Narrows FN at this meeting. Date	Organizations	Communication Type	Summary	File name
23/09/07	**Grassy Narrows**	**Email - Outgoing**	Kinross provides details of the attached Great Bear Advanced Exploration Program Reclamation Strategy Memorandum. Document was prepared to summarize the reclamation strategy for the AEX program. The purpose of this memorandum is to seek input from Indigenous communities regarding the proposed closure strategy for the AEX Program. This document has been provided to Lac Seul First Nation, and Wabauskang First Nation, with the aim of seeking valuable input and insights. The opportunity to arrange a meeting with Kinross has also been offered, with reiterated position that Kinross is amendable to discussing capacity needs for Grassy Narrows First Nation.	GBR_AEX_Closure_Strategy_Memo_5Sep2023.pdf
23/09/07	**Grassy Narrows**	**Email - incoming**	Communication from GNFN expressing that at this moment there is limited capacity to review the AEX Closing Strategy memo at Grassy Narrows, and that due to the reduced capacity emails, reviews, and other communications might take longer than usual. This is in reply to the receipt of the AEX Closure Strategy Memorandum.	
23/09/14	**Grassy Narrows** **Ministry of Mines**	Letter	Communication directed to the IAAC, mentioning notable concerns relating to capacity, Indigenous rights, and lack of actions taken by the federal government. Notable concerns were also related to protocol raised by community.	2023 09 14 ANA Letter to Impact Assessment Agency of Canada 4875-2190-3231 2.pdf
23/09/19	**Grassy Narrows** **Lac Seul** **Wabauskang** **Metis Nation of Ontario** **Ministry of Natural Resources and Forestry**	**Letter**	MNRF providing Kinross with letters and map sent to stakeholders and Indigenous communities regarding hunting closures needed for safety considerations of staff in designated area. The restriction is not intended to abrogate or restrict any rightsholder who is wishing to harvest.	2023-09-13-FWCA-GreatBear-HuntingRestriction- Wabauskang.pdf, 2023-09-13-FWCA-GreatBear-HuntingRestriction-Lac Seul.pdf, RestrictedHuntFinal.pdf, Kinross hunting closure notice_signed.pdf
23/09/20	**Grassy Narrows** **Ministry of Mines**	**Email - incoming**	Attached correspondence to IAAC from Grassy Narrows concerning the Great Bear Gold Project and issues that the Grassy Narrows First Nation have raised. Issues include a lack of inclusion of protocol for communications with the GNFN, a lack of compliance in understanding the GNFN views and context, and concern in the level of engagement as expressed by Indigenous Services Canada.	2023 09 20 ANA Letter to IAAC Gold Bear Project 4881-7177- 8177 3.pdf

Date	Organizations	Communication Type	Summary	File name
23/09/26	**Grassy Narrows**	**Letter**	Follow up to previous communication and in response to Asubpeeschoseewagong Netum Anishinabek's recent communication to the Impact Assessment Agency of Canada, the Kinross and Great Bear team would like to reiterate its commitment to meeting with the Community and the Land Protection Team. Our goal remains to foster open and productive discussions regarding our Project, and we welcome discussion on capacity and participation considerations. Reiteration that the Kinross team is open to arranging in-person, or virtual meetings at your convenience. Kinross and the Great Bear team look forward to engaging in meaningful conversations with the Community. Kinross expresses an eagerness to identify potential synergies between the community's interests and the objectives of the Great Bear Project. Through this collaborative approach, our aim is to create a positive and mutually beneficial impact, contributing to community well-being.	Kinross-ANA Letter - Capacity, Meeting Request Great Bear Project (9).pdf
23/09/08	**Grassy Narrows**	**Email – Outgoing**	Kinross provides details of the attached Great Bear Industrial Sewage Works Application Draft, and Great Bear ISW Aquatic Resources Monitoring Plan Draft supporting the Advanced Exploration (AEX) Program. Noted that both documents have been uploaded to the SharePoint site (links below). The Industrial Sewage Works and Aqautics application documents contain details related to: • Environmental se□ng • AEX Program project descrip□on • AEX Program water management plan • Assimila□on Study, including CORMIX modelling • Proposed discharge limits to the Chukuni River (the proposed • receiving environment) • Dra□ surface water monitoring programs • Dra□ aqua□c monitoring programs The Kinross team invites comment and input from the Land Protection Team. Kinross reiterates that as part of the development of the Great Bear Project and the AEX Program is committed to robust mitigation and protection measures designed not only to meet regulatory standards but also to ensure the ongoing safeguarding of water resources. Kinross requests the opportunity to arrange an in-person, brief call or virtual meetings at your convenience, in addition to dialogue on capacity and resources to support review. 23/10/06	**Grassy Narrows**	**Email - incoming**	Grassy Narrows First Nation is unable to access AEX PTTW Dewatering documentation.	
23/10/06	**Grassy Narrows**	**Email - Outgoing**	Kinross provides details of the attached Great Bear Advanced Exploration Program, Permit to Take Water Application for Dewatering for draft input and review. The Kinross team looks forward to your comments and ongoing input from the Lands Protection Team. As refelcted in the communication Kinross offers to arrange an in-person, phone call or virtual meetings at your convenience. The Kinross team welcomes the opportunity to discuss dialogue on resources to support ongoing input and review needs for advanced exploration documentation, and federal approvals for the Great Bear Project.	GBP_AEX_PTTW_for_Dewatering_3Oct2023_Final Draft.pdf
23/10/19	**Grassy Narrows**	**Letter**	Reception of letter from Grassy Narrows FN Land Protection Team regarding their comments on the ANA Letter and IAAC concerns to be addressed. The letter calls for the Great Bear IA to be terminated as concerns were not addressed by technical feasibility studies as they had not yet been finished, obligations from the Crown to Grassy Narrows have not been resolved in a timely manner, and the IAAC have not been courteous to impacts on Grassy Narrows, nor have they resolved concerns on other projects.	2023 10 19 ANA Ketter to IAAC re Great Bear Gold Project 4862-2003-7255 4.pdf

29 Nov 2023

PROJECT ENGAGEMENT PROTOCOL

THIS PROTOCOL ("**Protocol**") is effective as of 1 December 2023 ("**Effective Date**"),

B E T W E E N :

Asubpeeschoseewagong Netum Anishinabek (Grassy Narrows First Nation)

("**ANA**")

– and –

Great Bear Resources Ltd.

("**Great Bear**")

A. ANA holds and exercises Treaty and Aboriginal rights in its traditional Anishinaabe territory within the Treaty 3 region in northwestern Ontario ("**Traditional Territory**").

B. In 2018, ANA enacted its Land Declaration to define its approach to land use decisions within its Traditional Territory based on ANA Anishinaabe tradition and law.

C. Great Bear is engaged in exploration activities to support the development of its Great Bear Gold Project ("**Project**") located near Red Lake, Ontario, which is within the boundaries of Treaty 3.

D. ANA's community is downstream of the Project and ANA has an interest in understanding the potential impacts of the Project on its community and Traditional Territory.

E. Great Bear wishes to conduct its activities related to Project ("**Activities**") in accordance with good practice that respects ANA Aboriginal Rights.

F. The Parties are entering into this Protocol to establish respectful communications to understand each other's interests and how those interests may be reconciled and aligned.

NOW THEREFORE, the Parties agree as follows:

1. DEFINITIONS

1.1 In this Protocol:

"Aboriginal Rights" means aboriginal and treaty rights that are recognized and affirmed under section 35(1) of the *Constitution Act, 1982*.

"Activities" means any Great Bear activities related to the Project that may affect ANA Aboriginal Rights or other interests.

"**Communications Representative**" means the person designated under section 3.1 to be the primary representative for communications for a Party.

"**Disclosing Party**" means a Party that has disclosed Confidential Information to another Party.

"**Land Protection Team**" means the representatives that ANA appoints to its Land Protection Team.

"**Liaison Committee**" means the Communication Representatives from each Party that are assigned the responsibilities under section 3.

"Protocol" means this communication and engagement protocol.

"Quarter" means a period of three calendar months ending on March 31, June 30, September 30, or December 31.

"**Receiving Party**" means a Party that receives Confidential Information from another Party.

"**Representatives**" means, regarding any Party, its Affiliates and each of their respective directors, officers, Councillors, employees, investors, potential investors, financial, legal and accounting and advisors who have a need to know the Confidential Information

"**Regulatory Application**" means an application by Great Bear for a Regulatory Approval.

"**Regulatory Approval**" means a government approval necessary to construct and operate the Project.

"Senior Representatives" means the ANA Chief or a senior member of ANA Council and a senior executive of Great Bear.

"**Work Plan**" means the work plan and budget agreed to by the Parties in accordance with section 4.1.

2. Objectives OF THIS PROTOCOL

2.1 The objectives of this Protocol are to:

(a) establish and maintain a positive relationship based on sincere communication, understanding, trust and respect,

(b) define the appropriate framework for communication between the Parties on Regulatory Applications,

(c) share information about Great Bear's Activities, Project timeline, related Regulatory Approvals, and related ANA interests,

(d) consult with ANA on Great Bear Activities and Regulatory Approvals that may affect ANA Aboriginal Rights and other interests and any changes to those Activities,

(e) identify any potential impacts of Great Bear Activities on ANA Aboriginal Rights and interests,

(f) collaborate on risk management and mitigation measures to resolve concerns,

(g) work together to understand and reconcile each other's interests,

(h) identify opportunities for alignment of interests and mutual benefit, and

(i) facilitate the negotiation and implementation of future agreements.

3. Communication – Liaison Committee

3.1 Within 15 days of the Effective Date, each Party will appoint a Communication Representative to be its primary representative for the purpose of this Protocol and any related communications.

3.2 Each Party's Communication Representative will have the authority to speak for the Party on communications relating to the Project, and the other Party may rely on that authority.

3.3 Together, the Parties' representatives will form the Liaison Committee for this Protocol and will manage the communications under this Protocol, including establishing the following administrative details: a) the procedures for meetings; b) the format of meetings (in-person or virtual); and c) recording the items discussed and follow up actions.

3.4 The Liaison Committee will communicate not less than once a Quarter or as often as reasonably necessary to:

(a) update each other on significant developments related to:

(i) Great Bear Activities,

(ii) the status of Regulatory Approvals related to Great Bear Activities,

(iii) issues or requirements regarding the Activities, conduct or procedures of the other Party, and

(iv) ANA Aboriginal Rights and other interests related to Great Bear Activities and Regulatory Approvals,

(b) comply with their respective commitments set out in this Protocol and those related to Great Bear Activities,

(c) attempt in good faith to resolve any concerns related to Great Bear Activities or other matters affecting the Parties' relationship, and

(d) identify opportunities for alignment of interests and mutual benefit.

3.5 The Senior Representatives of the Parties will communicate at least once every six months, or more often if needed, to review the relationship and effectiveness of the Protocol, the relationship of the Parties and identify opportunities for improvement.

4. Engagement on Regulatory Approvals

4.1 Within 30 days of the Effective Date, the Liaison Committee will meet to review Great Bear planned Activities and Regulatory Approvals for the next 12 months.

(a) Great Bear will give ANA's Communication Representative and Land Protection Team a list and description of the Regulatory Approvals ("**Permit List**") and expected application dates for the upcoming year. Great Bear will update the Permit List at the end of each Quarter.

(b) ANA's Communication Representative will review the Permit List to identify and notify Great Bear of the Regulatory Permits that may:

(i) affect ANA Aboriginal Rights and other interests and will require further review by the Land Protection Team, and

(ii) require less review because of their minor nature.

(c) The Liaison Committee will establish a work plan ("**Work Plan**") and budget ("**Budget**") for the review of Regulatory Approvals that require attention and will review and adjust the work plan and budget each quarter, as needed.

4.2 For any Great Bear proposed Regulatory Application that may affect ANA Aboriginal Rights and other interests, Great Bear will:

(a) notify ANA's Communication Representative and Land Protection Team of the proposed Regulatory Application in advance of filing it with the regulatory agency,

(b) give ANA's Communication Representative and Land Protection Team a copy of the Regulatory Application and its supporting information once the draft application is ready for review,

(c) answer ANA's Communication Representative and Land Protection Team questions and provide further reasonable information requested by ANA about the Regulatory Application in a timely and transparent manner,

(d) receive input from ANA related to the potential effects of the Regulatory Application on ANA Aboriginal Rights and other interests, and

(e) review with ANA's Communication Representative and Land Protection Team reasonable measures to avoid or mitigate any adverse effects that are identified by ANA.

5. FUNDING

5.1 If ANA engages with Great Bear in accordance with this Protocol, Great Bear will contribute to the reasonable costs incurred by the ANA related to the Protocol activities, based on Work Plan and Budget established under section 4.1(c).

5.2 ANA will send Great Bear itemized monthly invoices of all reasonable expenses incurred in accordance with the Budget, along with relevant receipts. Great Bear may seek clarification on supporting documentation, but otherwise Great Bear will pay all undisputed amounts in such invoices within 30 days of receipt of an invoice.

5.3 The Budget represents the Parties' reasonable expectations of the capacity requirements of the ANA to carry out the activities of this Protocol. The Parties will adjust the Budget as reasonable and necessary to align with the activity under the Protocol, by agreement in advance of ANA incurring additional expenses.

6. TERM AND TERMINATION

6.1 This Protocol commences on the Effective Date and will remain in force until the earlier of:

(a) Great Bear's decision to cease the Activities permanently;

(b) this Protocol is replaced by a subsequent agreement; or

(c) following 30 days written notice from either Party the other.

6.2 ANA will submit their final invoices relating to negotiation expenses incurred within 20 days of the date of termination.

7. CONFIDENTIALITY

7.1 A Receiving Party will keep confidential and not disclose any Confidential Information to a third party, other than their Representatives, without first obtaining the written consent of the Disclosing Party.

7.2 The Receiving Party will:

(a) direct its Representatives who receive Confidential Information to comply with the obligations in section 6 this Protocol; and

(b) notify a Disclosing Party in writing of any breach of the obligations in section 6 of this Protocol, promptly after learning of a breach.

7.3 A Receiving Party and its Representatives will not use any Confidential Information for:

(a) its own benefit or the benefit of any other Person; or

(b) any purpose that is inconsistent with the objectives of this Protocol.

7.4 All proprietary rights in and to the Confidential Information remain the property of the Disclosing Party.

7.5 If a Receiving Party or its representative must by law disclose any Confidential Information, that Party will promptly notify the Disclosing Party so that compliance with the terms of this Protocol may be waived. The Party required to disclose Confidential Information will disclose only such Confidential Information as its legal counsel advises is legally required to be disclosed and will exercise all reasonable efforts to obtain reliable assurance that confidential treatment will be accorded the disclosed Confidential Information.

7.6 At any time upon the request of a disclosing Party, the receiving Party will return or destroy all copies of Confidential Information received from the disclosing Party, except to the extent the receiving Party may be required by law to retain information.

8. DISPUTE RESOLUTION

8.1 If a dispute arises in connection with this Protocol, the Parties will refer the matter to the Senior Representatives of the Parties by providing written notice to the other Party of a meeting request.

8.2 Following receipt of such request, the Senior Representatives will meet within 10 business days to try to resolve the dispute, in good faith, to respect each Party's interests.

8.3 If the Senior Representatives are unable to resolve to the dispute after 20 days, then the Parties may by agreement seek to resolve the dispute through mediation with the assistance of a mediator that both parties agree on.

8.4 Nothing in this Section limits the right of either Party to pursue any available legal remedies.

9. GENERAL

9.1 Any notices required pursuant to this Protocol must be in writing and delivered personally, by prepaid courier, or email to the applicable Party at the address set out below:

To:	Grassy Narrows First Nation
With a copy to:	Land Protection Team
Address:	P.O. Box 180, Grassy Narrows, ON, P0X 1B0
Attention:	Chief and Council
Email:	[EMAIL]

To:	Great Bear Resources Ltd
Address:	25 York Street, 17th floor, Toronto, ON M5J
Attention:	General Counsel and Corporate Secretary
Email:	Legal.Notices@Kinross.com

9.2 Nothing in this Protocol will abrogate or derogate from

(a) any Aboriginal Rights ANA may have or assert, or

(b) the Crown's legal duties to ANA, including the duty to consult and accommodate.

9.3 This Protocol will be construed in accordance with the applicable laws of Ontario and Canada.

9.4 Any amendments to this Protocol must be in writing and executed by the Parties.

IN WITNESS WHEREOF the Parties have executed this Protocol as of the Effective Date.

Dear Mining Recorder,

Great Bear Resources Ltd. – Notice of Intent to Lease Mining Claims (Stage #4 ML3)

Great Bear Resources Ltd. (GBR), a subsidiary of Kinross Gold Corporation, is continuing to explore and develop the Great Bear Project. In order to facilitate future development, please accept this application to lease selected mining claims, pursuant to Section 81 of the Mining Act. Background information related to this application is provided below.

- A single lease with perimeter survey is requested for the claims listed in Schedule A.
- The Lease request is for both the surface rights and mining rights covering the claims listed in Schedule A and in accordance with the Location Map 1 also attached.
- The minimum five (5) units of assessment work have been completed for the claims.
- The undersigned is an officer and Vice President of Great Bear Resources Ltd.
- GBR holds a 100% interest in the claims.
- GBR has engaged Mr. Peter deHaan at TBT Engineering, Ontario Land Surveyor.
  Tel: 807.632.7594 pdehaan@tbte.ca
- The claims for the requested Lease abuts Crown owned surface rights and claims that are held by GBR, there are no mining rights or surface rights that are held by a third party within or abutting the requested Lease. The requested Lease is not in a municipality.

We can confirm that there are no privately held lands within and contiguous to the requested lease area (including patent, leasehold and licenced interests). Due to this, we will not be providing block maps or PINs for the requested lease area. As no surface rights parcels exist within the requested lease area, no surface rights compensation agreement(s) will be required. It is our understanding that a 120-metre surface rights reservation will be imposed along the shore of Dixie Creek and Rice Lake (see Location Map 2).

Thank you for your consideration of this matter. Please contact Bruno Almeida at 647-206-5946 if there are any clarifications required or if GBR can do anything to be of assistance.

Sincerely,

Luke Jalsevac

Vice President and Project Director
Great Bear Resources Ltd.

Dear Mining Recorder,

Great Bear Resources Ltd. – Notice of Intent to Lease Mining Claims (Stage #4 ML2)

Great Bear Resources Ltd. (GBR), a subsidiary of Kinross Gold Corporation, is continuing to explore and develop the Great Bear Project. In order to facilitate future development, please accept this application to lease selected mining claims, pursuant to Section 81 of the Mining Act. Background information related to this application is provided below.

- A single lease with perimeter survey is requested for the claims listed in Schedule A.
- The Lease request is for both the surface rights and mining rights covering the claims listed in Schedule A and in accordance with the Location Map 1 also attached.
- The minimum five (5) units of assessment work have been completed for the claims.
- The undersigned is an officer and Vice President of Great Bear Resources Ltd.
- GBR holds a 100% interest in the claims.
- GBR has engaged Mr. Peter deHaan at TBT Engineering, Ontario Land Surveyor.
  Tel: 807.632.7594 pdehaan@tbte.ca
- The claims for the requested Lease abuts Crown owned surface rights and claims that are held by GBR, there are no mining rights or surface rights that are held by a third party within or abutting the requested Lease. The requested Lease is not in a municipality.

We can confirm that there are no privately held lands within and contiguous to the requested lease area (including patent, leasehold and licenced interests). Due to this, we will not be providing block maps or PINs for the requested lease area. It is our understanding that a surface rights reservation will be imposed over the Highway, the Aggregate Permits 500311 and 20063, as well as a 50-metre-wide reservation over the Hydro Line and a 120-metre surface rights along the shore of Chukuni River and Rice Lake (see Location Map 2).

Thank you for your consideration of this matter. Please contact Bruno Almeida at 647-206-5946 if there are any clarifications required or if GBR can do anything to be of assistance.

Sincerely,

Luke Jalsevac

Vice President and Project Director

Dear Mining Recorder,

Great Bear Resources Ltd. – Notice of Intent to Lease Mining Claims (Stage #4 ML1)

Great Bear Resources Ltd. (GBR), a subsidiary of Kinross Gold Corporation, is continuing to explore and develop the Great Bear Project. In order to facilitate future development, please accept this application to lease selected mining claims, pursuant to Section 81 of the Mining Act. Background information related to this application is provided below.

- A single lease with perimeter survey is requested for the claims listed in Schedule A.
- The Lease request is for both the surface rights and mining rights covering the claims listed in Schedule A and in accordance with the Location Map 1 also attached.
- The minimum five (5) units of assessment work have been completed for the claims.
- The undersigned is an officer and Vice President of Great Bear Resources Ltd.
- GBR holds a 100% interest in the claims.
- GBR has engaged Mr. Peter deHaan at TBT Engineering, Ontario Land Surveyor.
  Tel: 807.632.7594 pdehaan@tbte.ca
- The claims for the requested Lease abuts Crown owned surface rights and claims that are held by GBR, there are no mining rights or surface rights that are held by a third party within or abutting the requested Lease. The requested Lease is not in a municipality.

We can confirm that there are no privately held lands within and contiguous to the requested lease area (including patent, leasehold and licenced interests). Due to this, we will not be providing block maps or PINs for the requested lease area. It is our understanding that a 50-metre-wide surface rights reservation will be imposed over the Hydro Line (see Location Map 2).

Thank you for your consideration of this matter. Please contact Bruno Almeida at 647-206-5946 if there are any clarifications required or if GBR can do anything to be of assistance.

Sincerely,

Luke Jalsevac

Vice President and Project Director
Great Bear Resources Ltd.

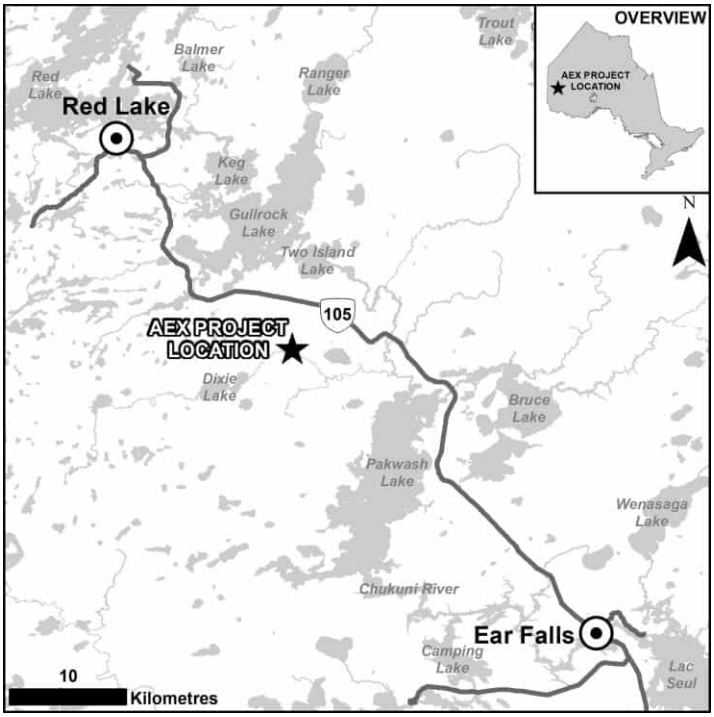
Notice of Commencement of a Screening

Great Bear Temporary Power Project

The Study

This Notice of Commencement is provided to inform the public, Indigenous communities and interested parties that Great Bear Resources Ltd., a wholly owned subsidiary of **Kinross Gold Corporation (Kinross)** is beginning an environmental study to determine the potential environmental effects of the installation of between 1 megawatts and 5 megawatts of diesel-fired generation (the **Temporary Power Project**) at the Great Bear property.



Background

The Great Bear advanced exploration program is located approximately 25 kilometres southeast of Red Lake in northwestern Ontario. The advanced exploration program requires a reliable power supply to support onsite activities early in the program. The **Temporary Power Project** will provide temporary power to be replaced with a more favourable power supply option once it can be established.

The Process

The study will be carried out in accordance with the Ministry of the Environment, Conservation and Parks Environmental Screening Process for Category B Projects set out in Ontario Regulation 116/01 (the *Electricity Projects Regulations*).

On completion of the study, an Environmental Screening Report will be completed and made available for a 30-day public review period.

A Notice of Completion will advise interested parties of the locations where the report can be reviewed.

Comments

Members of the public, Indigenous communities and other interested persons are encouraged to actively participate in the planning process. Notice of all upcoming consultation events will be advertised in local papers and radio. Alternatively, all members of the public, Indigenous communities and other interested persons seeking to review supporting materials for the application can speak to Great Bear staff directly at 104 Howey Street, Red Lake, Ontario.

Please direct any inquiries, comments or requests regarding the **Temporary Power Project** to:

Aaron MacDonell, Director, Environmental Services
Great Bear Resources / Kinross Gold Corporation

Boozhoo MINES, IAAC, Kinross and Great Bear Resources:

RE: The Great Bear Gold Mine Project

On behalf of Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows First Nation"), we write to share with you Grassy Narrows' preliminary position with respect to your activities in relation to the Great Bear Gold Project.

The Project will have an adverse impact and requires an impact assessment

Grassy Narrows is deeply concerned by the Great Bear Gold Project being pursued by Kinross and Great Bear Resources with support from the Ministry of MINES as well as the process recently begun by the Impact Assessment Agency of Canada (IAAC).

Decades of industrial activity, authorized and encouraged by Ontario and contrary to Grassy Narrows' will, have led to well-documented and extensive harm to our Territory, our way of life, our rights, and our health. As a result, our people suffer intensely from impacts including premature death, disease, poverty, and suicide.

The Great Bear Gold Project falls within the area that Grassy Narrows people have historically and currently use for the exercise of our rights and way of life. It is also upstream from our community. Pollutants in the water and impacts on the surrounding land, fish and wildlife will have a direct impact upon us and could also exacerbate mercury contamination in our waterways.

ANA has repeatedly and clearly communicated with the Crown and the mining industry that our people are in crisis, the environment which supports us is severely impacted, our health is failing. The cumulative impacts continue to significantly interfere with our treaty, Aboriginal and inherent rights.

The Great Bear Gold Project will have an impact upon areas that Canada claims as within federal jurisdiction, such as species at risk, fisheries, waterways and Indigenous peoples. Grassy Narrows asserts that the IAAC must conduct an impact assessment in the circumstances.

The Crown's outstanding obligations to Grassy Narrows should be resolved in a nation-to-nation process.

For many years, ANA has written to Ontario to invite the Crown to a government-to- government table to address fundamental issues between us, including the Crown's unmet obligations to us about our rights, our land, our self-determination, and the impacts of industry and government policy on our land and people. These issues have been unresolved between our governments for many decades. Reaching agreement in good faith through a government-to-government table is the way to resolve these important issues and to put in place effective measures to protect us from further harm.

Ontario and Canada have yet to accept this invitation. Most recently, by letter dated November 27, 2023, Ontario explicitly refused to participate in a table to discuss "jurisdictional issues" raised and rejected nearly all of the issues proposed by ANA including most of those related to mining.

Instead, Ontario has explicitly recommended that mining companies explore on and around our Territory, has unilaterally granted roughly 6,000 mining claims on our Indigenous Protected and Conserved Area, and allowed companies to pursue increasingly advanced work towards mines that pose a serious threat to Grassy Narrows. This activity has occurred without our consent, without meaningful consultation and accommodation, and usually without even prior notice under the antiquated "free entry" mining regime.

Grassy Narrows' concerns about the process

Until recently, the Crown and the companies associated with the Great Bear Gold Project have shown little willingness to meet with us, nor respond substantively to many of our communications. Indeed, we have only recently learned that the Crown and companies provided notice to other Indigenous Nations of permit applications concerning the Great Bear Gold Project

as early as 2017 and have signed Advanced Exploration Agreements with Wabauskang and Lac Seul First Nations. In contrast, Ontario approved a number of permits without notice of any kind to Grassy Narrows.

Now that gold has been found, the Crown and Kinross are suddenly interested in giving the appearance of consulting with us, but only to the extent that it furthers the already advanced plans, made without Grassy Narrows' involvement, to develop an industrial gold mine in our headwaters.

Even if Ontario had complied with its own laws, Ontario's "free entry" mining exploration and mine development process is not the correct way to make key decisions between our two governments. This process is deeply unfair and biased in the favour of multi-billion-dollar mining companies. It ignores our laws, our vision for our land and people, and our processes for making decisions affecting our territories.

Our ongoing and urgent crisis leaves us unable to meaningfully engage about mining. To make matters worse, we receive no support from Ontario to inform ourselves, gain technical and legal advice, and to engage in a fair way about mining. The IAAC has offered a mere $5,000 in capacity funding to respond to a 100-page technical Initial Project Description and the funding was made available only after the submission deadline for comments has passed.

The path to reconciliation

We are on a healing journey to recover from the extreme damage that colonization, and attempted forced assimilation have done to our people, including through the imposition of Crown policy and regulatory schemes related to residential schools, dams, relocation, mercury contamination, child apprehension, industrial logging, and mining. We need to allow the land to heal because healthy land will help to heal our people. This is what reconciliation means to Grassy Narrows. Let us protect our land and water so that we can heal our people.

The boom in mining exploration in our area is causing great anxiety and fear among our people. It is setting back our healing. If the Crown decides to allow mining, and the risk of further pollution and other impacts, there will be more heartache, sickness and loss for our people. This mining activity will only lead to more grassroots resistance, litigation, and public controversy over conflict minerals. It will take the relationship between the Crown and Grassy Narrows further away from the path of healing and reconciliation.

Grassy Narrows says 'no' to the Great Bear mine and related activities.

We strongly urge the Crown and your companies to reconsider your unilateral and bullying approach to pushing mining activity on our First Nation. We urge you to seize this opportunity to set a course for a future that is free of conflict over mining in Ontario.

We call on the Crown and your companies to respect the healing path for Grassy Narrows and not to further impair the exercise of our constitutionally protected Aboriginal and treaty rights, our inherent Indigenous rights, our health, and wellbeing.

Grassy Narrows provides preliminary comment on the project under duress

We know that Ontario and Canada will move ahead with approvals for damaging mining activity if we do not speak up. For that reason, we are writing to you under duress to express our preliminary concerns about this project before it advances any further. These serious concerns with both how the project has been pursued and the impacts on our rights and interests, are set out in the attached document. These submissions are by necessity preliminary in the absence of capacity and support to conduct our own studies and obtain expert technical advice.

Please ensure that you copy our Land Protection Team on all communications on this and related matters.

VIII. A Choice, an Opportunity 52

I. The Context

Who is Grassy Narrows

Asubpeeschoseewagong Anishinabek (Grassy Narrows First Nation) is an Anishinaabe First Nation with traditional territory in what is called northwestern Ontario. Grassy Narrows people exercise inherent Indigenous rights, and Aboriginal and Treaty rights. We have cared for and lived on our lands for countless generations. Grassy Narrows people hunt, trap, fish and practice our Anishinaabe way of life to provide for ourselves, our families and community.

We exercise our inherent right to self-determination and law-making powers. Our inherent rights are given to us by the Creator. In addition to our inherent rights, Grassy Narrows people exercise Aboriginal rights and established Treaty 3 rights which are protected by section 35 of the *Constitution Act, 1982*.

In 1873, the Anishinaabe adhered to Treaty 3. The Treaty 3 Commissioner promised the Anishinaabe that the Treaty promises would protect our harvesting practices forever, which would allow our people to hunt, fish, trap, gather, and harvest throughout the Territory as they had before "as long as the sun shone and the waters flowed." This promise was more than a continuation of our pre-existing harvesting rights. The Anishinaabe did not agree to the erosion of our harvesting rights.[1]

Our territory is located in the Boreal Shield ecoregion in a mixed forest transition zone from the Great Lakes St Lawrence Forest to the Boreal Forest. The Whiskey Jack Forest is the English name of the forest that covers a large portion of the Territory; the English-Wabigoon River System is a central waterway in the Territory. The land and waterways of the Territory sustain Grassy Narrows peoples' way of life.

Grassy Narrows' Territory is the foundation of who Grassy Narrows people are as Anishinaabe people. We follow the teachings of the Elders to be responsible for the Territory and to *Manaachitootaa Aki* (protect the land).

Social and Cultural Impacts of Crown Law and Policy.

Despite these sacred promises, for many generations the Crown has imposed harmful law and policy on us, including through the *Indian Act*, the banning of our ceremonies, regulation of our hunting and trapping, residential schools, regulation of the wild rice, relocation, the 60s scoop, the underfunding of our schools, inadequate health care, and the ongoing removal of our children from the community.

These policies have caused grave harm to our people and impaired the exercise of our rights. They have undermined our strong society and way of life and have left us more

---

[1] *Keewatin v Minister of Natural Resources*, 2011 ONSC 4801 [*Keewatin* ONSC], rev'd 2013 ONCA 1158, aff'd 2014 SCC 48 ["*Keewatin* litigation"].

vulnerable to the impacts of industry.

The Cumulative Effects of the Mercury Crisis and Industrial Activities Impacts.

Starting in at least 1962, a chlor-alkali plant in Dryden, Ontario, began discharging mercury into the English-Wabigoon River system. Approximately 9,000 kilograms of mercury were discharged into the river system that flows through our Territory and is a lifeline for Grassy Narrows people. Our live-giving river became a source of invisible poison.

The impacts of the mercury contamination have been devastating to the people of Grassy Narrows and our Territory. The presence of mercury led to the methylmercury contamination of the fish and Grassy Narrows people. The local commercial fishery shut down; Grassy Narrows' economy collapsed; Grassy Narrows people descended into poverty; Grassy Narrows people suffered, as they continue to do, from debilitating health symptoms and premature death; and our Anishinaabe way of life was gravely threatened and changed when we could no longer safely eat fish and exercise our fishing practices as we had before.

In the 1970s and 1980s, Grassy Narrows called on Ontario to respond to the mercury crisis by taking concrete action, including by agreeing that Grassy Narrows would control our Territory. As the river was poisoned, we wanted to have more control over our Territory and the natural resources in it to be able to protect and benefit from the part of our Territory that was still healthy – the land. Instead, Ontario authorized extensive clearcut logging in the Territory from roughly 1980 to 2008, which likely released new, or additional, sources of mercury into the watershed, and increased methyl mercury contamination of fish.

Multiple expert reports and publications have detailed the impacts of mercury contamination on the health of Grassy Narrows people, including the following, which are enclosed:

- 2015 Expert Report of Dr. Donna Mergler
- Grassy Narrows Community Health Assessment Summary Reports, 2018
- Philibert et. al. (2020), "Mercury exposure and premature mortality in the Grassy Narrows First Nation community: a retrospective longitudinal study", *The Lancet: Planetary Health* Vol. 4(4), E141-E148
- Philibert et. al. (2022), "Past mercury exposure and current symptoms of nervous system dysfunction in adults of a First Nation community (Canada)" *Environmental Health* 21:34.
- Mergler. D. et. al. (2023), "The Contribution across Three Generations of Mercury Exposure to Attempted Suicide among Children and Youth in Grassy Narrows First Nation, Canada: An Intergenerational Analysis" *Environmental Health Perspectives* 131(7).

These reports highlight the grave impacts of mercury on the health and wellbeing of

Grassy Narrows. They establish that Grassy Narrows people cannot withstand further impacts from the release of new mercury into Grassy Narrows' land, lakes, rivers, fish, and people, nor an increase in the net methylation of existing mercury. Our rights have already been highly compromised by the mercury crisis. Our nation cannot withstand further infringements of rights. No further impairment of our rights, our health, and our wellbeing can be justified.

Our fish in the Wabigoon River remain the most mercury contaminated in the province. Our people of all ages continue to suffer from mercury related diseases and loss of wellbeing. Our employment remains far below what it was in the 1960s following the collapse of our subsistence, sport, and commercial fishery due to mercury.

The mercury crisis is but one in a long series of industrial attacks which have been imposed on us against our will. These include the damming of our rivers, industrial logging, and mining activity. Each of these industrial attacks has had grave impacts on its own. In addition, each of these industrial attacks has compounded the existing harm that remains from previous attacks, creating unbearable cumulative impacts, thereby prolonging, and exacerbating our inter-generational crisis.

These extreme and compounding industrial impacts have been authorized and encouraged by the Crown without any serious consideration of their cumulative effects on Grassy Narrows and the exercise of Grassy Narrows' rights. We have raised clear concerns since at least the 1970s that our environment, rights, way of life, and our health, were at or beyond, the breaking point due to the impacts of industry on the resources on which we have heavily relied for our wellbeing, livelihood and the viability of our community. In the 1980s, and again in 2007, we declared moratoria on further industry on our Territory so that we could heal our people and rebuild our independence and wellness.

And yet, to this day, with respect to our Territory and vicinity, Ontario has failed to increase our control and use, failed to conduct a collaborative Landuse Plan; failed to complete a source water protection plan; failed to carry out a comprehensive environmental assessment; and failed to undertake an assessment of cumulative effects. The repeated failures of the Crown to act honourably to resolve the crisis have resulted in serious, compounding adverse impacts over time, including:

(1) Severe cumulative impacts on our territory and Treaty harvesting, hunting and fishing rights, making these rights impossible to exercise in a meaningful way;

(2) Severe adverse health effects and death, including, as found in recent scientific research, high rates of conditions impacting learning in children, disease, suicide attempts, and the premature death of our people; and

(3) Extreme poverty, food insecurity, loss of Anishinaabe way of life, and other poor socio-economic indicators of wellbeing which are ranked significantly worse than average Indigenous communities in Ontario and Canada.

(4) Collective impacts to our society and community.

Ontario ignored our pleas and our moratoria and continued to allow industrial activity, including the granting of mining claims on our Territory against our will, and advancement of mines all around us, without considering how mining activities add to, compound, exacerbate, and prolong previous harms. The cumulative impacts of industry have been devastating. The impacts include, but are not limited to:

- Our river that gives us life remains poisoned.
- Our walleye are unsafe to eat.
- Our sturgeon are rare.
- Our moose are scarce.
- Our caribou are nearly extirpated.
- Our pine marten habitat is depleted.
- Our forests are fragmented.
- Our medicines are tainted.
- Our sacred landscape is desecrated and scarred and traplines have been clear cut.
- Our way of life is diminished.
- Our people suffer from poverty, food insecurity, disease, premature death, and suicide.
- Our inherent, aboriginal, and treaty rights are impaired
- Our health has been harmed.
- We have been discriminated against.

II. Ongoing Breaches of Crown Obligations: The 1978 Memorandum of Understanding, Honour of the Crown, and Fiduciary Duty

Ontario and Canada (collectively, the "Crown") are our treaty partners. As elaborated below, through the treaty relationship and Crown actions over time, including entering into legal agreements following the start of the mercury crisis, the Crown assumed obligations and duties owing to Grassy Narrows. The Crown must uphold the treaty promises, uphold terms of its agreements, and act honourably in its dealings with Grassy Narrows.

Authorizing and permitting mining activities in our territory without our consent violates Ontario's and Canada's outstanding obligations and duties to Grassy Narrows and violates the Crown's duty to act honourably in all its dealings with Grassy Narrows.

1978 MOU and Dishonourable Conduct.

In 1978, Ontario and Canada signed a Memorandum of Understanding with Grassy Narrows in which the Crown committed to resolve in good faith the impacts of mercury on the environment that Grassy Narrows people rely upon for the viability of our community, and the related health, social, economic, cultural, and environmental impacts on the people of Grassy Narrows ("1978 MOU"). It was agreed that the issues would be resolved through a combination of financial compensation and land, and

furthermore in a manner that would enhance Grassy Narrows' self-determination, self-sufficiency, and control over local affairs wherever possible.

Some agreements were reached that partially implemented some of the 1978 commitments. For example, agreements were reach with Canada in 1984 and with Canada, Ontario and the mercury polluters in 1985.

However, the Crown has outstanding obligations owing under the 1978 MOU. These outstanding obligations include (but are not limited to) increasing Grassy Narrows' access to, protection of, and control over lands and natural resources in our Territory.

Moreover, the Crown has engaged in a course of dishonourable conduct before, during the negotiations, and since, and has consequently failed to meaningfully support Grassy Narrows' recovery from the mercury crisis.

The Crown's unmet fiduciary duties

The Crown and Grassy Narrows have a *sui generis* fiduciary relationship, and our treaty rights attract fiduciary obligations. In the time since the Crown and Grassy Narrows entered into a treaty relationship, the Crown seized functional management and control of our lands and water. The Crown assumed a duty to Grassy Narrows when exercising that control over our Indigenous interests including our pre-existing legal interests in exercising our fishing, hunting and trapping rights and other traditional practices such as medicine gathering and wild rice picking.

Grassy Narrows has been at the mercy of the exercise of Ontario's imposed fiduciary decision-making over our land as Ontario unilaterally authorized industrial activity, and otherwise has made decisions that affect the land, water and other natural resources of our area which we rely on to exercise our rights, practice our way of life, and maintain our health.

Under imposed Crown management and discretionary control, the health of our land and our people have seriously declined, our way of life has been degraded, and the exercise of our treaty rights has been impaired.

The Crown's abandonment of negotiations required by the 1978 MOU

From the outset of our discussions under the 1978 MOU, Grassy Narrows was clear that to recover from the impacts of mercury and other harms, we need Crown recognition of Grassy Narrows' ownership, control, and protection of a large part of Territory, which will allow Grassy Narrows to make decisions with respect to our land that support our way of life and our livelihood. In the 1970s, 1980s, and 1990s Ontario committed to negotiate increased Grassy Narrows control over our lands, in addition to providing meaningful compensation for our people.

In the 1980s, and since, we called for a moratorium on industrial activity in our Territory until our negotiations with Ontario were concluded. However, rather than honour this moratorium, the treaty promises, and the 1978 MOU obligations, Ontario unilaterally

abandoned the negotiations in the mid 1990s and exercised its imposed control in a way that further unleashed industry on our area to our detriment.

Ontario has repeatedly acted unilaterally to encumber and degrade our Territory against our will, including by granting industrial logging licenses and nearly 6,000 mining claims; industrially logging our forests; and constructing industrial access roads and bridges (e.g. The Separation Lake Road and bridge) to facilitate further resource extraction and environmental degradation. Canada has stood by and watched, allowing our lands, waters, rights, and way of life to be trampled.

The Crown's dishonourable conduct and abandonment of its fiduciary obligations continue. Ontario's Ministry of Mines has granted thousands of mining claims against our will, including granting mining exploration permits without any prior notice to us.

Ontario has failed to accurately identify the ANA Area of Interest on mining activities.

The Ontario Ministry of Mines has never meaningfully addressed the question of the extent of Grassy Narrows' area of interest with respect to mining.

In the 1980s, the Ontario Ministry of Natural Resources created its own map to identify a Grassy Narrows Traditional Land Use Area (the "1980s TLUA Map") for the purposes of mediated negotiations between Grassy Narrows and Ontario with respect to a section of the Territory required by Grassy Narrows to restore its economic self-sufficiency. The map used straight lines, which are not reflective of the boundaries of the full Territory and does not include the northern portion of the Territory.

Between 2008 and 2017 Grassy Narrows and Ontario engaged in discussions on forestry pursuant to the Grassy Narrows Ontario Process Agreement (the "Process Agreement"). As part of that process, Grassy Narrows submitted a map of the "Grassy Narrows area of interest for forestry", which included areas that are outside the 1980s TLUA Map boundaries.

When Grassy Narrows passed our Land Declaration in 2018, we shared a map of an area we have identified as the "Indigenous Protected and Conservation Area" (IPCA). The IPCA boundaries mirror part of the area of interest for forestry. The IPCA boundaries have always been provisional, as Grassy Narrows continues to engage in a process of reviewing the knowledge of our historical and current land use. In addition, the western notion of linear boundaries on maps conflicts with our Indigenous knowledge systems, which are based on relationships and complex webs of protection, use, kinship, sharing, travel and trade that do not begin and end at a line.

Shockingly, Ontario relied on the 1980s TLUA Map as the consultation area for mining, despite having knowledge that the map was not accurate.

Grassy Narrows is currently pursuing litigation challenging nine mining exploration permits (not related to the Great Bear Gold Project) that Ontario approved without

notice to Grassy Narrows.[2]

Among other relief, Grassy Narrows seeks the following remedies in the litigation:

> a declaration that Ontario cannot consider mining activities in the subject area of the Territory, including issuing exploration permits, until the parties negotiate and reach agreement on **timely enforceable mechanisms to assess and manage the cumulative impacts of mining, logging, hydro-electricity projects, other industrial development, mercury contamination, and governmental policies or programs that may infringe Grassy Narrows' treaty rights, and to ensure that these constitutional rights are respected**;

These mechanisms are not yet in place and the judicial review remains unresolved.

As further described below, Grassy Narrows has only very recently learned that the Ministry of MINES approved a number of permits for the Great Bear Gold mine with no notice to Grassy Narrows.

It is only in very recent times, and after much conflict, that Ontario has begun to ask Grassy Narrows about what our area of interest for mining is. After many years of advocacy by Grassy Narrows, Ontario's Minister responsible for mines finally responded on November 1, 2022 with a new map that Ontario proposed as the area for consultation on mining related activities.

Ontario's proposed consultation area on mining appeared to deliberately carve out the Great Bear Project Area. The information provided by Ontario to explain how they arrived at the proposed boundaries was cursory and insufficient for understanding how the boundaries were arrived at. Grassy Narrows informed the Ministry that their proposed map is not complete and requested capacity support to do the work necessary to respond. However, no support has been provided to date.

On November 2, 2023, Grassy Narrows provided two versions of a map setting out our Interim "Area of Interest" for mining. The maps differed in scale only. The map was provided with the following cautions:

- The maps are an interim product created under duress arising from the escalation of imposed mining activity by the Crown and industry and for the sole purpose of identifying an interim area for negotiations on mining related activity.

- The maps are not a complete representation of Grassy Narrows' area of interest. Due to the unique circumstances and capacity constraints, Grassy Narrows has not completed comprehensive studies required to fully determine its area of interest including, but not limited to, land use and occupancy, ethnohistory, archaeology, biology, and hydrology. For example, rights and interests

[2] Grassy Narrows First Nation v. Director of Exploration, Ministry of Northern Development, Mines, Natural Resources and Forestry, Ontario Divisional Court File No. 881/21.

associated with air quality, migratory birds, travel routes, marten, lake sturgeon, wolves, eastern cougar, landscape intactness, climate resilience, biodiversity, genetic diversity, and many other factors are not reflected in these maps.

- In addition, linear boundaries are an imposed non-Indigenous concept that do not accord with the nature of Grassy Narrows' relationship with the land which includes extensive interconnectedness, reciprocity, travel, sharing, and trade.

- These maps do not limit any claims by Grassy Narrows people to assert their rights and interests throughout their territory and to protect themselves from harm to their health, rights, way of life, livelihood, society, and environment. Grassy Narrows people have Treaty rights, and practice them, throughout the Treaty 3 area. Grassy Narrows people also have inalienable inherent rights given by the Creator, some of which are affirmed in international law and instruments. The Grassy Narrows people are the true experts about their land, rights, and interests.

<u>The Great Bear project area falls within the core area of Grassy Narrows' Interim Area of Interest for Mining map.</u>

Despite Grassy Narrows' efforts to further these negotiations, there is no agreed upon area for consultation on mining activities.

Sharing of information about our Homeland is a sensitive topic that requires deep trust. After so many decades of having our trust, our vulnerability, and our lands abused by Ontario, many of our knowledge holders do not consent to sharing sensitive lands information with Ontario. Trust must be rebuilt to meaningfully engage on this topic.

Grassy Narrows Laws Have Not Been Respected.

Neither the Crown nor the companies have formally acknowledged and respected Grassy Narrows' moratorium and Land Declaration. The Crown has not joined us to harmonize Crown law with Grassy Narrows law and to find a path forward towards reconciliation that provides space for Grassy Narrows' inherent Indigenous rights and constitutionally protected Aboriginal and treaty rights to be meaningfully realized and protected.

We have written many times to request that the Crown come to a senior negotiation table with Grassy Narrows to address the wrongs committed against our people, the effects of which continue to this day, and to prevent further damage. We call on Ontario to return to the mediation process first established in 1978 in response to the mercury disaster to finally reach an honourable agreement regarding the control and protection of our Territory and fair compensation for Grassy Narrows people.

Instead of coming to the table to honourably resolve outstanding issues and obligations, Ontario has unilaterally granted mining claims and permits and now is supporting the development of a gold mine in our headwaters.

III. The Crown Must Address Capacity Barriers

Grassy Narrows has repeatedly advised both the Crown and the Companies that it cannot meaningfully engage in negotiations while it faces significant and unique barriers.

1) Insufficient information: Upon learning of the Great Bear Gold project, Grassy Narrows immediately requested additional information about the project and the extent to which our Laws had been taken into account and its adverse impacts considered. This information is essential for us to understand and respond to any efforts at engagement. After a lengthy delay, the Ministry recently provided responses that can only be characterized as preliminary and partial.

2) Capacity funding: The process of evaluating proposed mining activities and engaging with MINES, the IAAC, and mining companies comes at an expense to ANA. We must hire staff, engage our community, carry out our governance process, and obtain professional support from experts, lawyers, and advisors to engage in a meaningful way.

Grassy Narrows is even more impoverished than our First Nation peers due to the ongoing impacts of mercury poisoning. We lack the funds required to engage in an informed and fair way.

During the summer of 2023, MINES staff indicated that, after many years of requests, MINES will fund some ANA capacity needs. We provided MINES with a document summarizing the kinds of capacity supports that we would need in order to meaningfully engage on mining, including compensation for staff and to hire experts. After many months of awaiting an update, on November 27, 2023 MINES clarified that its promises of capacity supports amount only to funding in an unspecified amount for a “Mineral Development Advisor”, a position that Grassy Narrows has never requested funding for.

No funding is currently in place. MINES must come to the table on our issues and commit to funding ANA’s reasonable costs of engaging in an informed and fair way.

While IAAC offered $5,000 in capacity funding to ANA, this funding was offered after the deadline for submissions on the List of Issues. The amount offered is insufficient to meaningfully review lengthy technical documents that engage many areas of expertise, to engage with our people, to carry out our governance process, and to prepare a response. This is the same on-size-fits-all funding offered to other First Nations, NGOs, and other ‘stakeholders’. It does not consider our unique circumstances nor our position as an Indigenous nation.

3) Pandemic Considerations: COVID-19 infection rates, as well as other respiratory illnesses in this region of Ontario are high again. Our people are especially vulnerable to disease because of our high pre-existing rates of co-morbidity, crowded and inadequate housing, inadequate nutrition due to food insecurity, and the immune impacts of mercury. The health of our people is our priority. We are informing you that, in addition to our other concerns, mining exploration proposals are unwelcome during outbreaks

and other public health emergencies.

4) Mercury Crisis and Industrial Impacts: Our territory has already experienced a great deal of harm from industrial activities including mercury, damming, industrial logging, and mining. The cumulative effects of these industrial impacts have already passed the point of an unreasonable, unjustifiable impact on the exercise of our Treaty rights, and on our health and wellbeing. As a result, our community suffers from unusually high rates of conditions including poverty, food insecurity, disease, neurological conditions, conditions affecting learning, premature death, and child and youth suicide. The social conditions created by mercury poisoning and the cumulative impacts of industry place us in an ongoing extreme crisis. As a result, we are unable to meaningfully engage on mining exploration in the absence of the necessary supports to resolve and recover from the ongoing mercury crisis.

5) Fundamental outstanding issues must be addressed before meaningful engagement can occur: As described above, many fundamental issues remain unresolved between Grassy Narrows and the Crown including unmet obligations, broken promises, conflicting laws, cumulative impacts, violated trust, justice owed, and outstanding reconciliation. These are upstream strategic issues to which individual mining projects are subsidiary. We cannot address one mining project meaningfully, when the fundamental questions are not addressed. These questions include:

- How will the Crown respect Grassy Narrows' inherent rights and rights recognized under international law and related instruments?
- How can the Treaty relationship between the Crown and Grassy Narrows be respected and restored?
- How can the written text of the Treaty be reconciled with the oral and written histories, and Ontario Superior Court findings, that the taking up clause and the cede and surrender clause were never discussed nor agreed to?
- Who has decision making authority over lands and resources in our area?
- How can Grassy Narrows law and Crown law be harmonized with respect to the land?
- What lands should be open to mining and what lands should be protected?
- How will the Crown's unmet obligations arising from the Treaty, the 1978 MOU, and other sources be fulfilled?
- How will Grassy Narrows' ownership, control, and use of our lands be increased as promised?
- How can the damage already done to our land and our water be restored?
- How can the harm to our sacred landscape, our spirituality, and our relations be repaired?
- How can we assess and prevent the cumulative impacts of industrial activity from further harming us?
- How can the collective damage to our society, our community, and our families be reversed?
- How can our health, our wellness and our way of life be returned to its former status?

- How can our self-determination, our independence, and our self-sufficiency be rebuilt?
- Is it possible to reconcile while the harm continues, while we bury our youth?

For many years we have been seeking to resolve important issues with the Crown that relate to mining. A summary list of some of these issues can be found at **APPENDIX A**.

The Crown apparently has little interest in these questions and little willingness to address them with us, to act honourably, nor even to come to the table with us about them. When we meet with senior officials from MINES and MNRF, they tell us that they have no mandate to discuss these issues, but they will bring them to the Minister.

After years of seeking a meeting with the Minister our then Chief and Council finally met with then MNDMNRF Minister Rickford in Toronto on November 18, 2021. At the long-awaited meeting Minister Rickford refused to discuss our mining concerns but promised to come to Grassy Narrows soon to discuss mining at an open forum in our community. Neither Minister Rickford nor his successors have honoured this promise.

In a largely analogous situation where Grassy Narrows and the Crown had a conflict over a different form or resource extraction, the 2004-2009 Whiskey Jack Independent Forest Audit found that:

> There are fundamental differences in the viewpoints between GNFN and MNR regarding forest management principles and practices. It is the audit team's opinion that these differences cannot be resolved without the Province setting aside many of the requirements to manage the Whiskey Jack Forest under the CFSA and the FMPM, and relinquishing significant authority to the First Nation to manage portions of the Whiskey Jack Forest according to the desires of the GNFN community. The audit team further believes that the forest management planning process did not anticipate, nor was it designed to resolve the type of dispute currently being experienced on the Whiskey Jack Forest.

Similarly, the *Mining Act* and its regulations and the IAAC regulations did not anticipate, nor were they designed to resolve the serious grievances, outstanding obligations, and the type of dispute currently being experienced over mining around Grassy Narrows. Resolving this dispute will require sincere, honourable, government-to-government engagement on the fundamental issues that have brought us to this point. Only once that occurs, can we meaningfully engage about specific permits and projects without repeating and exacerbating the legacy of past and ongoing harms.

IV. The Great Bear Gold Project: The Crown's failure to inform, meaningfully consult, and gain our consent for project activities.

The Great Bear Gold Project falls within Grassy Narrows' Interim Area of Interest for Mining

We have enclosed a copy of Grassy Narrows' map of our Interim Area of Interest for Mining, which is described above.

The limited preliminary research that we have been able to conduct confirms that the Great Bear Gold Project is within the area where Grassy Narrows people have historically, and continue to, practice our way of life and our Treaty rights.

There is strong ethno-historical evidence that Grassy Narrows has a longstanding connection to this area dating back to the time of the Treaty and before. This includes historical reports, fur trade records, ethnological work, and other records. Grassy Narrows First Nation historically hunted, fished, trapped, collected plants, gardened and conducted spiritual practices in and around the Red Lake fur trading routes, and traded products obtained in the area.

There are Grassy Narrows families with continuing family ties to this area and the surrounding areas. Grassy Narrows people, including the Chief, continue to practice our inherent and Treaty rights in this area, including the moose hunt. The moose hunt is extremely important to our way of life and sustenance. Due to the precipitous decline in moose elsewhere in our area, the area south of Red Lake is one of the only remaining productive moose hunting grounds that our people use.

The Great Bear Gold Project falls within moose, wolverine and caribou habitat that ranges within our IPCA. In addition, walleye within the project area migrate to the waterways on which Grassy Narrows exercises its treaty rights to fish and on which the community reliese for food. The project area is also within nearby quatermary watersheds that flow into the IPCA.

Grassy Narrows people fish extensively on the English River around Grassy Narrows. Grassy Narrows people also fish on the English River and its tributaries near the inflow of the Chukuni River. We are aware that the fish that we eat swim a distance of 30 km, or more, up and downstream in the course of their lifecycle and are exposed to, and bioaccumulate, toxins throughout their travels. In particular, our walleye travel long distances upstream in order to spawn.

Caribou are an important clan animal to Grassy Narrows and used to be seen throughout our Territory. The Great Bear Gold Project area is within the range of the Sydney Caribou herd, the last remaining herd in our Territory. This range is already degraded beyond the threshold at which it is able to sustain Caribou in the long term, unless its intactness is restored. All of the habitat within the range is considered critical.

As noted above and confirmed by the Supreme Court, the Treaty 3 Commissioner promised the Anishinaabe that the Treaty promises would protect our harvesting practices forever which would allow our people to hunt, fish, trap, gather, and harvest throughout the Territory as they had before “as long as the sun shone and the waters flowed”. The Anishinaabe did not agree to an increasing erosion of our harvesting rights that would significantly interfere with the exercise of our rights.[3]

---

[3] *Keewatin v Minister of Natural Resources*, 2011 ONSC 4801 [*Keewatin* ONSC], rev’d 2013 ONCA 1158, aff’d 2014 SCC 48 [“*Keewatin* litigation”].

Grassy Narrows has a communal connection, right, and interest in this area. It is possible that other First Nations do too, but that does not in any way diminish our own connection, rights and interests nor the Crown's obligations to us.

In addition, Grassy Narrows must be consulted on activities that may have off-site impacts on our territory, such as downstream, downwind, or migratory species impacts. Grassy Narrows continues to document the full extent of its Territory and the "ANA Preliminary Area of Interest With Respect to Mining" is without prejudice to the determination of the full geographical extent of Grassy Narrows' Territory.

The Crown requires Grassy Narrows' consent for the Great Bear Gold Project

The standard that correctly applies to this project is the right to say 'no', also known as the right to give or withhold "free prior and informed consent."

Under Grassy Narrows law, we are the first people of this land. The Creator gave us this land and only the Creator can take it away. We live in relationship with the land; we care for it and the land provides for us. We must take care of the land and not disrupt this balance. Nothing that threatens this balance may take place on the land without our permission. We say no to mining.

The United Nations has recognized this right in the *UN Declaration on the Rights of Indigenous Peoples* and in other international laws and instruments to which Canada is a signatory.

The *Declaration on the Rights of Indigenous Peoples* requires States to consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free, prior and informed consent before adopting and implementing legislative or administrative measures that may affect them (article 19). This includes:

- The adoption of legislation or administrative policies that affect indigenous peoples (article 19)
- The undertaking of projects that affect indigenous peoples' rights to land, territory and resources, including mining and other utilization or exploitation of resources (article 32).

The principle of free, prior and informed consent is linked to treaty norms, including the right to self-determination affirmed in common Article 1 of the International Human Rights Covenants. When affirming that the requirement flows from other rights, including the right to develop and maintain cultures, under article 27 of the International Covenant on Civil and Political Rights (ICCPR) and article 15 of the International Covenant on Economic Social and Cultural Rights (ICECSR), the treaty bodies have framed the requirement also in light of the right to self-determination.

Canada is bound by international law to these abide by these standards.

While Crown law has often failed to adequately implement international human rights standards, and often seeks to take a reductionist view of its international obligations to us, even under Crown law our consent is required for this project for reasons including, but not limited to:

a) The cumulative impacts of Crown policy and industry on our people already exceed any reasonable threshold of impact on our rights, our way of life, our people, and our environment. No further impacts can be made without consent.

b) The Companies' goal is to open a gold mine. A recent study demonstrated the extensive impacts of metal mining contamination on rivers and floodplains across the world, with an estimated 23 million people believed to be affected by potentially dangerous concentrations of toxic waste.[4] Gold mines have high risk of impact to our well established and strong rights, including our rights under Treaty #3. Our waters are already contaminated with mercury. Therefore, we are at the high end of the consultation spectrum where consent is required.

c) The "taking up" clause and the "cede and surrender" clause which the Crown relies on for its asserted legal authority were never explained, translated, discussed, nor agreed to, during the negotiation of Treaty #3. This is reflected consistently in the multiple, independent, written records of the Treaty negotiations. To the contrary, Treaty Commissioner Simon Dawson informed the legislature that "As an inducement to the Indians to sign the Treaty, the commissioners pointed out to them that, along with the land reserves and money payments, they would forever have the use of their fisheries. The point was strongly insisted upon and it had great weight with the Indians, who for some years previously had persistently refused to enter into any Treaty" (NA RG 10 vol 3800 file 48542, 28 May 1888). The Ontario Court of Justice found that the Indigenous signatories to Treaty 3 were not advised and did not understand that the Crown could authorize land uses inconsistent with Harvesting Rights and pass legislation to extinguish or limit Harvesting rights. They expected that Canada would protect their harvesting rights away from the Dawson Route or CPR right or way, not limit, extinguish or ignore them.[5] No court of appeal, including the Supreme Court of Canada has overturned this finding of fact.

Beyond the requirements under Grassy Narrows Law, International Law, and Crown Law to obtain consent in these circumstances, there is the simple practical requirement for consent in today's business, investment, and political environment.

The business case for obtaining consent is reflected in the mining industry's own trade association policies through the International Council on Mining & Metals (ICMM) position statement on Indigenous Peoples and Mining, which states that "[t]he outcome

---

[4] Phys.Org (September 21, 2023), "Global study reveals extensive impact of mining contamination on rivers and floodplains."

[5] Keewatin v. Minister of Natural Resources, 2011 ONSC 4801 (CanLII), at para 865, <https://canlii.ca/t/fmzc4#par865>, retrieved on 2023-09-23

is that Indigenous Peoples can give or withhold their consent to a project, through a process that strives to be consistent with their traditional decision-making processes while respecting internationally recognised human rights and is based on good faith negotiation."[6]

Even Barrick Gold, infamous for their violations of human rights internationally, stated in their $100M statement of claim against Red Lake Gold when addressing the need to for Grassy Narrows' consent that:

> Virtually all successful mining ventures in Canada require a strong and genuine working relationship with local communities, including First Nations. Without such a relationship, it can be extraordinarily difficult, if not impossible, to proceed with a mining venture beyond early stage exploration work and into development work (e.g., by constructing a working mine).
>
> Strong, genuine and reliable relationships with First Nations are built on mutual trust and respect. Any perceived or actual breach of that trust or respect can have devastating consequences for a mining venture or company, and these commercial and reputational consequences can extend well beyond any particular project or First Nation group.[7]

No large mine has opened in Canada for decades without Indigenous consent. It is simply too difficult and risky to carry out such an expensive and intensive project without all relevant First Nations on board.

As a First Nation living immediately downstream from this project, we will live with the consequences for many generations to come. It is our children who will drink the water, eat the fish, pick the wild rice, swim, and learn what it means to be *Asubpeeschoseewagong Anishinabek* on this river whose waters will carry the effluent from this gold mine if it is built. It is our people who will search in vain for moose and caribou to hunt on the landscape that has had its forests fragmented and degraded by access roads, clearcuts, seismic lines, pits, trenches, clearings, and mines. It is our people who will be impacted if the tailings dam fails. It is our people who will be poisoned if toxics leach into the water. It is our people whose fear and anxiety, already far to high and fatal due to the mercury crisis, will be heightened by the threat this mining project poses to our wellbeing.

We know, and everyone in Canada who has cared to learn our story knows, that decisions made and activities carried out upstream can have a devastating impact on us. The chlor-alkali plant in Dryden that discharged mercury into the Wabigoon River was 150 km upstream of our village. But the flow of the river does not obey any human boundaries. The distance did not stop the mercury from being carried downstream,

---

[6] International Council on Mining & Metals (May 16, 2013), "Indigenous Peoples and Mining: Position Statement".
[7] Barrick Statement of Claim against Red Lake Gold, 2022/23, p. 20, 21.

bioaccumulating in the fish that we eat, destroying our livelihood, poisoning our people, and dramatically disrupting our way of life. More than 50 years after the discharge of mercury was ordered halted, our mercury crisis rages on. There is no end in sight to the contamination of our river and to the intergenerational impacts of mercury.

The correct standard for this project, which threatens to impact Grassy Narrows' future for many generations, is consent. Grassy Narrows has not given its consent. Grassy Narrows says 'no'.

Far from seeking consent, Ontario has approved numerous permits for the Great Bear Gold Project with no notice to Grassy Narrows

With respect to the Great Bear Gold Project, there has been a failure to inform, to consult meaningfully with ANA and to gain our consent, even though the ANA village site is the first community downstream from the project site. In spite of the infamous pre-existing impacts on the English River and Grassy Narrows from hydro damming, mercury pollution, and clearcut logging, and Grassy Narrows' well knowns concerns about mining exploration. The fact that Grassy Narrows is downstream of this project, potentially impacted, and likely concerned should be evident to any diligent person with access to Google.

Exploration permits for this project date back to January 2017, including permits for extensive exploration work, drilling, stripping of the land, and taking of water. The following permits were authorized without notice to Grassy Narrows and, for the most part, prior to any communications from either the Crown or the companies with our First Nation:

- January 6, 2017: PR-16-10995 – permit for mineral exploration
- April 11, 2019: PR-18-000295 – permit for mineral exploration
- November 22, 2019: PR-19-000264 – permit for mineral exploration
- November 27, 2019: PR-19-000227 – permit for mineral exploration
- July 16, 2020: PR20-000178 – permit for mineral exploration
- October 13, 2020: PR20-000276 – permit for mineral exploration
- July 13, 2021: PR-21-000190 – permit for mineral exploration
- October 4, 2021: PR-21-000258 – permit for mineral exploration
- August 15, 2022: 5115-CJ9QRR – permit to take water
- September 15, 2022: Permit 5115-CJ9QRR to take water

The failure to take the minimal step of giving notice to Grassy Narrows about any of the above permits is all the more shocking because while this extensive work was being done on the Great Bear Gold Project, Grassy Narrows was writing to Ontario and to the companies seeking to share information and initiate negotiations about protection for Grassy Narrows' lands, waters, and people. Grassy Narrows has written to Ontario repeatedly about land protection concerns for decades, and most recently in a long series of official letters dating back to 2018 requesting a government-to-government table to resolve Lands issues including mining.

The history of communications between Grassy Narrows, Great Bear Resources, Kinross and Ontario's Ministry of Mines demonstrates that none of these parties have demonstrated a genuine intention to meaningfully engage with Grassy Narrows. This summary is current to December 15, 2023:

- **February 25, 2020:** Having learned about Great Bear Resource's presence in the area, but unaware of the permit applications and authorizations, Grassy Narrows Chief and Council wrote to Great Bear Resources to notify the Company about ANA's mining concerns and to ask if Great Bear Resources had any proposed work that would put Grassy Narrows at risk and conflict with our laws. There was no response. Indeed, Great Bear Resources has never responded to Grassy Narrows' communications.

- **October 1, 2020:** Upon learning of Kinross's presence in the area, Grassy Narrows Chief and Council wrote to Kinross Gold Corp. with a request to meet and a list of questions about their work.

- **October 6, 2020:** Chief and Council wrote to Great Bear Resources.

- **October 7, 2020:** Chief and Council wrote to follow up with Kinross.

- **November 2, 2020:** Kinross responded to acknowledge our letter but did not provide any substantive response to our questions, make any mention of the Great Bear Project, nor accept our request to meet. We did not hear from Kinross again for almost two years.

- **December, 2021:** Kinross reached an agreement with Great Bear Resources.

- **August 29, 2022:** Kinross sent a letter of introduction to our Chief.

- **September 15, 2022:** Less than three weeks later, Kinross submitted an exploration permit to Ontario claiming to have consulted with Aboriginal communities.

- **October 4, 2022:** Grassy Narrows wrote again to Great Bear Resources.

- **October 6, 2022:** Grassy Narrows received its first notice of an application for an exploration permit related to this project from Ontario (PR-22-000284). Ontario gave Grassy Narrows only one month to provide comment on the application.

- **November 18, 2022:** With no capacity, and in the midst of the COVID-19 pandemic, Grassy Narrows wrote back to advise Ontario that we intended to respond but could not do so substantively within the time provided.

- **November 24, 2022:** MINES notified Grassy Narrows that Kinross's application (PR-22-000284) had been approved with the exception of 44 claims that were

being held pending further comment from Grassy Narrows but offering no capacity supports.

- **December 28, 2022:** MINES notified Grassy Narrows of seven mining lease applications and advised that MINES would proceed if it did not receive comments by February 26, 2023.

- **January 19, 2023:** MINES notified Grassy Narrows that it was considering granting the mining permit for the 44 claims that had been held, pending comments from Grassy Narrows by February 3, 2023. Again, no capacity supports were offered.

- **February 6, 2023:** Grassy Narrows wrote to MINES to reiterate the barriers to participation that had been communicated over many years; in the absence of addressing those barriers Grassy Narrows cannot engage or comment substantively to the permit applications.

- **February 14, 2023:** MINES gives Grassy Narrows until February 28, 2023 to respond with comments.

- **February 27, 2023:** Grassy Narrows official writes to MINES indicating that Grassy Narrows does want to comment but that further time is required to review the information, and that the company has yet to respond to the questions that ANA has sent them.

- **March 3, 2023:** Grassy Narrows sent a follow up letter to MINES regarding the seven proposed mining leases and Grassy Narrows' requests for a government-to-government negotiation table.

- **March 10, 2023:** MINES wrote to Grassy Narrows to ask for a copy of the questions posed to the companies in 2020.

- **March 20, 2023:** Grassy Narrows wrote to Great Bear and Kinross to request a meeting about the Great Bear Gold Project in early April and for an answer to the questions posed to the company in 2020.

- **March 21, 2023:** MINES followed up on its request for a copy of the questions posed to the companies in 2020.

- **March 31, 2023:** Grassy Narrows followed up with Great Bear Resources and Kinross to request a meeting in early April and to obtain answers to the questions posed in 2020.

- **April 12, 2023:** Grassy Narrows repeated its request for a meeting with MINES and answer to questions concerning Great Bear Resources and Kinross.

- **April 24, 2023:** Kinross finally responds to the request to meet.

- **June 22, 2023:** Kinross attended an introductory meeting with Grassy Narrows. The meeting was not a consultation on the project. Kinross representatives stated that MINES would be providing answers to the questions posed in 2020. Grassy Narrows raised serious concerns about the project, including capacity constraints and concerns about impacts.

- **June 27, 2023:** Kinross wrote to confirm that MINES would be providing answers to the questions posed in 2020. MINES did in fact provide a partial and incomplete response to the questions posed in 2020. MINES gives Grassy Narrows two weeks to provide comment on the 44 outstanding claims.

- **July 12, 2023:** MINES gives Grassy Narrows a further extension to July 27, 2023.

- **July 24, 2023:** Kinross wrote to invite Grassy Narrows to a meeting to learn about the project and to advise that it was setting up a Sharepoint site to share information about the project. The Sharepoint link was not provided. Kinross further advised that the federal impact assessment process had been initiated.

- **July 28, 2023:** MINES wrote to advise Grassy Narrows that Ontario will not provide capacity support for consultation and asked for comments on the 44 claims by August 10, 2023.

- **August 11, 2023:** MINES approves the mining exploration permit for the 44 claims.

- **August 12, 2023:** Kinross provided a copy of Great Bear industrial Sewage Works documentation. Grassy Narrows does not have capacity to analyze or respond to this technical document.

- **September 7, 2023:** Kinross provided a copy of the Great Bear Advanced Exploration Reclamation Strategy for comment. Grassy Narrows does not have capacity to analyze or respond to this technical document.

- **September 13, 2023:** Chief Turtle writes to the IAAC to advise that Grassy Narrows has learned that Kinross and Great Bear have initiated the interim assessment process. Grassy Narrows was not provided notice in accordance with its protocols and demanded that the process recommence in accordance with procedural requirements.

- **September 14, 2023:** Grassy Narrows sent a follow up inquiry to the IAAC.

- **September 15, 2023:** IAAC provided a two-week extension to respond to Kinross's Initial Project Description.

- **September 20, 2023:** Grassy Narrows responded to IAAC by reiterating that the IAAC had not complied with procedural requirements for the pre-planning stage and repeating its demand to recommence the process.

- **September 26, 2023:** Kinross wrote to Grassy Narrows to request a meeting to discuss capacity funding.

- **September 28, 2023:** Kinross wrote to Grassy Narrows to provide two technical documents for comment (AEX Industrial Sewage Application and Aquatics Monitoring Plan; AEX ECA Air and Noise, Emissions Modelling and Dust Management). Kinross offered to meet and provide capacity support.

- **October 4, 2023:** Kinross wrote to Grassy Narrows about a draft permit to take water application.

- **October 6, 2023:** Grassy Narrows Lands Protection Team was given access to the Great Bear Sharepoint site, with extensive technical documents that were not shared previously. IAAC also provided its Summary of Issues for comment and offered to meet.

- **October 20, 2023:** Kinross provided its groundwater monitoring plan for the project and its preliminary mine rock management and monitoring plan.

- **November 3, 2023:** Kinross provided its draft closure plan for comment.

- **November 10, 2023:** Kinross provided its Detailed Project Description for comment. Grassy Narrows met with Kinross and IAAC. Grassy Narrows asked Kinross to pause the impact assessment process until an engagement protocol could be put in place along with capacity supports.

- **November 14, 2023:** Ontario wrote to Grassy Narrows with belated notice that in or around April 2023 it had delegated the “procedural” aspects of consultation on certain matters relating to the Great Bear Gold Project to Great Bear Resources. Ontario’s letter to this effect dated April 6, 2023 was sent to the Chief and not pursuant to Grassy Narrows consultation protocols. Ontario takes the position that the duty to consult is at the “low end” of the spectrum.”

- **November 20, 2023:** Kinross wrote to Grassy Narrows concerning participation in a Stage 3 Archaeological Assessment.

- **December 15, 2023:** Kinross meets with Grassy Narrows and refuses to pause its activities for any length of time to accommodate Grassy Narrows’ unique circumstances.

As the foregoing chronology demonstrates, the companies and Crown left Grassy Narrows in the dark for years about the Great Bear Gold Project. Since September 2023, Grassy Narrows has been flooded with technical documents, belated offers of capacity support, none of which has flowed, and impossible deadlines for engagement.

Kinross spent billions to buy the project and has clearly already decided to build a gold mine regardless of Grassy Narrows' wishes. Failing to engage with Grassy Narrows on this project for more than four and half years was not an error of omission, but rather a deliberate decision not to engage, and to withhold, information about this project from Grassy Narrows. The fact that other First Nations, who are located far upstream of the project, but who have a reputation for welcoming mining activity, were engaged far earlier (as early as 2017), raises the question of whether a decision was made not to engage Grassy Narrows because of Grassy Narrows' well-known concerns about mining exploration.

It took Ontario and the companies nearly three and half years to provide initial responses to questions posed by Grassy Narrows to Great Bear Resources in February of 2020. And yet, within 60 days of providing those initial responses, without providing any capacity support to review them, and without addressing Grassy Narrows' many other barriers and fundamental issues, the Ministry approved further work on the project in spite of Grassy Narrows' request for capacity support and time.

Even Indigenous Services Canada flagged concern about Kinross's level of engagement to date with Grassy Narrows in its comment to the IAAC:

> The perception of contamination to the land, water, traditional food sources and Indigenous Peoples by industrial development may be a serious concern for the identified Indigenous Nations, especially for Grassy Narrows ... During the late 1990s and early 1970s, the English-Wabigoon River system was contaminated with inorganic mercury from a pulp mill located upstream in Dryden, Ontario. This discharge of inorganic mercury contaminated their water and traditional food sources (i.e. fish) and lead to cases of mercury poisoning and intergenerational challenges. The proponent, Kinross Gold Corporation, started engaging with Grassy Narrows First Nation in 2022, whereas their engagements with Wabuskang First Nation and Lac Seul First Nation began in 2017. Due to Grassy Narrows First Nation's negative and detrimental experience with industrial development, it is recommended that more engagement take place. The Indigenous Nations need to gain a greater understanding of the contaminants that may be released into the environment. They should be provided an opportunity to express concerns or uncertainties about potential exposure to chemicals used in the gold mining process, such as cyanide and heavy metals.[8]

Given this history, including the Crown's outstanding obligations to Grassy Narrows, it is highly inappropriate for Ontario to delegate any aspect of consultation to Great Bear

[8] Indigenous Services Canada, Federal Authority Advice Record – Great Bear Gold Project, p. 5.

Resources. Grassy Narrows does not agree that the Crown can delegate its duty to consult with a treaty nation to a third party. Nor does Grassy Narrows agree, given Grassy Narrows' strong rights, existing cumulative impacts, and the companies' intention to open large gold mines upstream from the community, that the duty is at the low end of the spectrum.

The IAAC has failed to consult as required with Grassy Narrows

According to the attached IAAC document summarizing the impact assessment process, the process begins with Phase 0 (Pre-Planning), a phase that requires engagement by both the Proponent and the Agency with Indigenous groups. None of the required pre-planning steps with respect to Grassy Narrows have been complied with.

The Proponent was required to engage Grassy Narrows to present the project, learn Grassy Narrows' views, including potential effects and how we wish to be engaged and to incorporate this information into the Initial Project Description. Grassy Narrows has expressed, both in writing and in meetings on June 22, 2023, and November 10, 2023 with representatives from Kinross, our significant concerns about potential impacts upon our community, which are not reflected in the Initial Project Description. Grassy Narrows also provided Kinross with our communications protocol, which includes communication with the Lands Protection Team. That protocol was not included in the Initial Project Description.

The Agency was aware, based on the Initial Project Description, that Grassy Narrows may be affected by the project. In the pre-planning phase, the Agency was required to inform Grassy Narrows about the impact assessment process to support us in understanding how we can participate. The Agency was obligated to learn Grassy Narrows' views and context, including potential effects and how we wish to be engaged. The Agency did not comply with these requirements of the pre-planning stage.

Crown and Company efforts to engage Grassy Narrows since 2022 have been performative and do not meet the standards required for engagement

The decisions to open our land to mineral staking and exploration, to carry out extensive exploration, and to build a gold mine, have already been made, and billions of dollars spent towards that end, all behind Grassy Narrows' back. In this context, it is hard to believe that requests for belated input at this late stage are sincere. Clearly, the companies and Ontario have already decided to build a gold mine if investors will support it and we are an afterthought.

Kinross is now flooding us with technical documents created by highly paid experts, while knowing that we have no capacity support to engage experts to review the technical documents, nor to engage our community about them. When we sought a pause in the process to gain capacity support, retain experts, complete a process agreement, and engage in our governance process, we are refused. In this context it is hard to believe that anything Grassy Narrows says will be taken seriously and will have

the potential to meaningfully influence the major decisions that have been made.

We live downstream, our established rights and our health are at stake, and we are concerned. Under Crown law the Crown clearly had a duty to meaningfully consult and meaningfully accommodate us at every stage of this project, including during the strategic level upstream decisions (such as land use planning, land use designation, tenure, etc.) as well as the more minor decisions which flow from them (such as specific exploration permits, water takings, leases, etc.). As a First Nation whose Treaty rights and health have already been severely impacted by the cumulative impacts of industry and government decisions our consent is required. Under our inherent rights, Anishaabe law, and International law our consent is also required.

Ontario has failed for many years in their duty to consult on this project and we call for an immediate freeze on all project activities until sufficient capacity support has been provided to allow Grassy Narrows to complete an ethno-historical report, land use and occupancy study, archaeological assessment of the area and study into cumulative impacts, and until we have been meaningfully engaged and our free, prior and informed consent obtained.

V. Adverse Impacts: ANA Preliminary Specific Concerns

As Asubpeeschoseewagong Anishinabek we have a holistic, interconnected, and spiritual relationship to our sacred landscape. We are the land and the land is us. What happens to the land happens to us and to our children for many generations.

This is an area where our ancestors have practiced, and we currently practice our Anishinaabe way of life; a way of life that relies on a healthy environment and is central to our identity, health, wellness, and livelihood. This area is part of the whole that forms the sacred landscape which gives us life and which we are in relationship within every aspect of our lives, hearts, spirits, and dreams.

While some areas may appear to an outside observer to be on the periphery of our Territory, this is a grave misperception. All our territory is core to our way of life and connection to the land. For example, we have always traveled to hunt. A moose that is harvested a few days' travel from our village site will still feed a family for many weeks and be shared with Elders, relatives, and friends. The dramatic decline in the moose population near our village means that the area around Red Lake is even more critical to our moose hunt. These areas are deeply embedded in our memories, our lives, and our hearts. We are strongly tied to this land.

We know that MINES, IAAC and the companies do not respect this relationship and seek to reduce it to a series of finite, bounded sites of 'values'. Our concerns are disregarded unless they are expressed in extremely specific and reductionist terms that ties adverse impacts to particular pieces of the land that are viewed in isolation from the whole. MINES and IAAC want us to engage in an exercise of, for example, identifying a specific hole that is a specific distance from a specific cabin and thus should be moved a bit to the west. Or, this type of machinery produces noise that will make hunting

difficult in this specific blind during this month, so please do not use it in October. Or, this wastewater discharge site is next to that fishing hole, so please put it a bit further downstream.

This approach fails to see the forest for the trees. What use is a remote cabin retreat without the serenity of the surrounding area from which we draw our physical and spiritual sustenance? How can we use it for healing and to teach our children their way of life while over the ridge heavy machinery encroaches ever closer and non-native users buzz around us in ATVs and motorboats? What use is a hunting site if the ancestral moose trails have been destroyed, there is no winter refuge, and unmanaged access routes have allowed non-native hunters to deplete the population precipitously? What use is a fishing spot if the fish has absorbed a dangerous burden of toxins from its food sources everywhere it swims throughout its life, including those carried from upstream? How can we carry out our ceremonies when the spirits who live in the rocks have been disturbed by drilling and blasting. What point is there in commenting on a small drill program in isolation, when everyone knows that your plan is to open a huge open pit and underground gold mine?

In spite of this fundamental difference in world view, the barriers, unresolved fundamental issues, and concerns noted above, we know that MINES, the Companies and IAAC will try to proceed with this project unless we raise specific concerns. In the absence of the necessary supports, Grassy Narrows cannot substantively respond to the technical information provided to date about the Great Bear Gold Project. We provide these preliminary concerns under protest and based upon the limited research we can undertake, which should not be taken as a complete overview of our concerns.

Industrial disturbances will release even more mercury into our ecosystem and further impair our Treaty rights.

The Great Bear Gold Project will require industrial mining exploration, access roads, clearing of trees, modification to water levels and other activity within the English River watershed. The waters from those areas flow into the English River in short order via the Chukuni River. They flow into the areas where we fish, boat, camp, and practice our way of life, and directly past our community.

The scientific literature establishes that industrial activity in the boreal forest releases mercury into local lakes and rivers.

Building machine tracks, trails, and roads is a common part of mining exploration and mine development work. However, simply driving heavy machinery through the boreal forest can contribute to the release of mercury. In one documented instance, a temporary machine track was inadvertently placed across a small, long-term reference catchment. This disturbance increased outputs of MeHg by a factor of over five for more than a decade.[9]

[9] J. Munthe and H. Hultberg (2004), “Mercury and Methylmercury in Runoff from a Forested Catchment -

Clearing the forest has also been found to release mercury into local water bodies where it bioaccumulates in fish to dangerous levels. The foremost study on this subject was completed in Quebec by Dr. Carignan. The study found that 100% of lakes with clearcut watersheds had walleye and pike with mercury levels that exceeded the World Health Organization advisory limit for human consumption. Meanwhile, only 18% of unlogged lakes, and only one burned lake exceeded the limit.[10]

In the only field study on the topic done by Ontario of which we are aware, there was roughly a doubling of mercury exported from a watershed near Thunder Bay via a stream after logging activity. This release of mercury occurred even though all the required regulatory measures, including those with respect to riparian buffers, were followed.

Despite these findings, Ontario does no downstream monitoring of actual industrial operations to monitor or assess mercury impacts.[11]

Both the Carignan and Ontario studies concluded that that the increase in mercury export is largely due to changes in local watershed level hydrology from the loss of tree cover. Mining exploration and mining activity also involve the clearing of trees from the land and risk similar impacts to local hydrology (e.g., Lower evapotranspiration rates, changes to snow and rain interception, etc.) and therefore leads to similar increases in mercury export to local logging.

Mining exploration and mining activities often have the effect of artificially changing water levels. This can happen through water takings, water discharges, dewatering of areas, and other industrial processes. Studies have found that the artificial lowering and raising of water levels in boreal water bodies often causes the release of mercury. Monitoring studies of the De Beers Victor Diamond Mine have found increased levels of mercury in fish in water bodies downstream.

For a more detailed discussion of the science on mercury and boreal forest clearing please refer to our enclosed evidentiary record filed with the Divisional Court in our 2015 Judicial Review Application, and the associated expert reports by Dr. Carignan, Dr. Podur, Dr. Mergler, and Dr. Willow.

Mining exploration and mining activities also risk altering water quality in ways that increase the methylation of existing mercury in downstream watersheds. This can be through the addition of sulfate, change in acidity, water colour, temperature, and other parameters. In Grassy Narrows, where mercury levels are already elevated by emissions from Dryden, any increase in net methylation is intolerable.

Concentrations, Fluxes, and Their Response to Manipulations", Vol. 4 at 607-618.

[10] Globe and Mail (March 12, 2001), "Mercury levels tied to logging practices."

[11] Toronto Star (September 14, 2016), "Ontario environment officials concerned that clear-cut logging releases mercury."

The Crown still has no remediation plan for the mercury that remains in the English-Wabigoon River system from discharges in the 1960s and 1970s. Mercury released into the watershed or methylated as a result of mining activity, especially dissolved mercury, will eventually find its way into the English River and further raise the mercury levels in fish and poison our people, exacerbating and prolonging our mercury crisis.

This is not acceptable. We cannot tolerate any additional mercury.

New releases of mercury or increased methylation will unjustifiably impair Grassy Narrows' treaty rights, health and wellbeing, and are discriminatory. This is an intolerable outcome for our treaty partner to impose on us against our will in the absence of consent.

Adverse impacts on Grassy Narrows' Treaty Land Entitlement Claim.

Grassy Narrows has an active Treaty Land Entitlement Claim (TLE) that has been accepted by the Crown and is under negotiation for resolution. Part of the resolution of the claim will include an addition to Grassy Narrows' reserve lands, and compensation for lost use. Grassy Narrows is currently engaged in a process to select its additional reserve lands. All the area around Grassy Narrows is currently potential reserve lands additions under consideration.

The Crown has asserted that lands which have encumbrances, such as mining claims and leases, will be more challenging to designate as additional reserve lands. This means that your mining claims and leases adversely impact our ability to select reserve land additions and are an impediment to the successful resolution of our TLE.

Further, lands which have been impacted by mining exploration such as cutting lines, pitting, trenching, stripping, and drilling, decline in ecological health, experience a degradation of their intactness, and therefore become less suitable as additional reserve lands.

Lands which are downstream of industrial projects also have their value, and suitability as additional reserve lands degraded. Lands along the shores of the English River and its tributaries have been core to our people for countless generations and are prime candidates for our reserve lands additions. If you were selecting lands for your home, your cottage, or your reserve, would you want a huge industrial gold mine to be opened up stream of them? No one would.

Over the last few decades vast parts of our Territory have been encumbered and degraded through industrial actions imposed on Grassy Narrows and upstream of Grassy Narrows. This has severely restricted the available suitable additional reserve lands.

Grassy Narrows has been clear that there should be no new encumbrances on our area, and no new degradation to our area (including from upstream), as this would unfairly further reduce the available suitable additional reserve lands (in addition to other impacts outlined elsewhere). This would impair the ability to correct the injustice

that was done to us by having been denied a fairly sized reserve for over a century.

On-site Impacts

According to the Ontario Auditor General "Mining activities can have a significant impact on the surrounding environment. They can affect groundwater and surface water, aquatic life, soil, vegetation, wildlife and air quality. The changes mining makes to the environment can have serious implications for public safety and health."[12]

While we are unable to meaningfully review the thousands of pages of technical documents that have been sent to us, it appears that the on-site impacts of the project will be extreme.

Large parts of the site will be deforested for decades at least. Three open pit mines will be created along with three underground mines, large tailings holding areas will be created, and a large ore processing facility will be built.

The project area will effectively be completely removed for the foreseeable future from the land base that is accessible to us to live our way of life and to practice our rights.

It also appears that water bodies including lakes and creeks on the site will be at extremely risk because they will be located immediately adjacent to and downstream / downgradient of heavy industrial operations including mining, ore processing, and tailings storage. We are concerned that the on-site water bodies will be damaged and we know that once they are damaged it can be hundreds, if not thousands of years before they are safe again.

Downstream / wind / migration impacts

We know far too well that industry can have impacts far beyond the industrial site itself. The chlor-alkali plant in Dryden that discharged mercury into the Wabigoon River was 150 km upstream of our village. The distance did not stop the mercury from being carried downstream, bioaccumulating in the fish that we eat, destroying our livelihood, poisoning our people, and dramatically disrupting our way of life. More than 50 years after the discharge of mercury was ordered halted, our mercury crisis rages on.

We fear that the impacts from the Great Bear Gold Project site will extend far beyond the mine site itself, further disrupting the balance of the environment that the Creator has established for us and which gives us what we need for a good life.

Impacts from industrial sites can propagate off site in many far-reaching ways and we cannot list them all here. Pollutants can be carried hundreds of kilometers downstream. Water quality changes that may appear innocuous in themselves, and which are not regulated, can alter the cycling of pollutants, nutrients, and other aquatic processes in damaging ways. For example, dissolved organic carbon (DOC), sulphate, and other

---

[12] Auditor General of Ontario (2015), "2015 Annual Report: chapter 3.11: Mines and Minerals Program."

substances are a naturally occurring part of aquatic ecosystems and are not considered toxic. However, they known to play a strong role in mercury cycling affecting mercury speciation, solubility, mobility, and toxicity in the aquatic environment. Alteration of water chemistry can have serious consequences.

The wind can carry pollutants and other chemicals long distances before they are breathed by our people and deposited on the ground and in the water. For example, PCBs generated in the industrial centers can be deposited in the arctic and bioaccumulate to levels that are dangerous for subsistence consumers. Acid rain created by the Sudbury mines killed hundreds of lakes for scores of kilometers downstream and the area has yet to fully recover many decades later. We fear that the operation of the mine, including heavy machinery, blasting, and ore processing, will create airborne pollution and changes that can be carried long distances throughout our Territory and beyond, and will compound the existing impacts of other sources of airborne pollution including the Dryden and Kenora mills, other mines, and municipalities.

Off-site impacts can also happen through animals, fish, and birds and other forms of life that travel. If moose can no long find winter refuge on the project site, or if roads, trails and clearings created associated with the project increase access and success for non-native hunters and predators, then fewer moose will be available to hunt. That impact will not be restricted to the boundary of the project site but will extend as far as a moose would range from the project site, or conversely the area from which moose would range into the project site and face predation, hunting, and lack of suitable habitat.

Other animals like wolverine, wolf, bear and cougar travel even further distances. Impacts to their populations, their travel routes, and their hunting success in turn influence the populations of the moose, caribou, rabbits, and other animals that are important to us.

We know that walleye travel large distances throughout their lifespan, especially when they are spawning. Throughout their travels they breath the water, eat the local food sources, and are exposed to local toxins. Many of these toxins stay in the walleye for a very long time and accumulate throughout their lifespan, which can be decades long. As a result, walleye that are not at the project site, nor even within a downstream area impacted by the project site, may migrate into impacted areas and accumulate toxins which we are exposed to when we eat them. In turn, otters, eagles, pelicans and other beings eat the fish and then travel further distances, carrying the toxins with them.

Landscape impacts (e.g. intact forests)

Beyond the on-site and off-site impacts, the project will have landscape-level impacts. Looking at each site in isolation fails to see that the landscape as a whole and its many processes and functions that sustain life. The many parts of the landscape work together, each playing their part. If one is disturbed, then all are disturbed. If too many are disturbed, then the landscape's ability to sustain our good Anishinaabe way of life can be severely undermined.

For example, intact forest landscapes “are critical for stabilizing terrestrial carbon storage, harboring biodiversity, regulating hydrological regimes, and providing other ecosystem functions.”[13] Many species rely on intact forests. For example, the Government of Canada believes that once a landscape exceeds 35% disturbance it crosses a threshold beyond which the landscape becomes unable to reliably sustain a population of woodland caribou and extirpation becomes likely.

Indeed, this is what we experienced in the southern part our Territory where no single project alone caused the local extinction of caribou, but rather it was a death of a thousand cuts as more and more impacts over time made the landscape unable to sustain caribou. We know that the landscape in the range of the Sydney Caribou herd already exceeds this disturbance threshold and is need of recovery. The Gold Bear Gold project will add further disturbance, making the local extinction of caribou even more likely.

Caribou are a sentinel species whose fate is an indicator of the health of the landscape and a range of species and values that rely on intact forests.

Although they behave very differently, moose also rely on a healthy landscape. When there is too much industry, the dense mature conifer forests that moose require for winter shelter become too small, fragmented, and scattered to support moose. When too may roads are put in, outside hunters gain easier access, and when clearings are made those hunters have higher kill rates. When the forest becomes too disturbed, the deer move in, and with them comes sicknesses that hurt the moose.

Again, no one project alone can be blamed for the loss of our moose. But taken together the many industrial changes to our landscape have led to the near elimination of our once healthy moose population.

In spite of our many requests, Ontario refuses to work with us to plan at a landscape level to ensure that our health and way of life can be maintained and recovered. Instead, Ontario allows more and more disturbances to compound each other, further and further degrading the landscape that we rely on. The Great Bear Gold project will further undermine the forest landscape.

Spiritual Impacts

Spiritual impacts are a sensitive topic because it involves some of our deepest and most personal aspects of our selves. It is also sensitive and difficult to share because, not long ago, our spiritual practices were outlawed and we suffered persecution for them. To this day our spirituality is mis-represented, misunderstood, and disrespected by government and industry. For these reasons, this information is only the tip of the iceberg pointing to the presence of a deep and far larger concern.

Our people believe that may aspects of a human being are important to health,

---

[13] Intact Forests, “Intact Forest Landscapes”.

wellness, and the good way of life. A critical aspect is spirituality. The landscape and our way of life are connected and sacred. We have a spiritual relationship of reciprocity with the landscape that requires us to take care of the land so that the land can continue to provide for us. This is a sacred responsibility given to us by the Creator.

Our sacred relationship and responsibility is with the landscape as a whole, and with all of its parts. It is not restricted to a finite set of point values such as ceremony sites, burial sites, and medicine patches. Although those are important, they are focal points in a far broader and all-encompassing spiritual fabric. Our spirituality emanates from, and is infused by the entire landscape. It is practiced throughout the landscape and supported by the entire landscape.

Without the spiritual landscape intact, the spiritual sites are desecrated and cannot function. The medicines do not work if they grow in a clearcut, or if herbicides and pollution have drifted on the wind towards them. How can the ceremony summon a spirit who has fled from the noise of machinery and blasting? How can an offering be made to a spirit-being whose trails and territory have been destroyed? How can the prayer for the success of our hunters be answered when our industrially transformed landscape is nearly empty of moose? How can we fulfill our responsibilities to our clan animals Atik (woodland caribou) and Numeh (sturgeon) when they are extirpated or at risk in much of our Territory? How can we fulfill our duties and ceremonies to the water when it has been polluted, dammed, and an invisible remains within it? How can we identify our grave sites when our people have been laid to rest throughout this land for countless generations?

In addition to our broader sacred relationship with the landscape, there are spirit beings who inhabit the landscape and who have relationships with the Anishinaabe and important roles in the landscape. We have duties to carry out in our relationships with these beings and if we do not fulfill our duties there can be negative repercussions. Some of these important spirit beings live in the rocks. When the are disturbed, hammered, drilled, bulldozed, blasted, or extracted, these spirit beings are impacted, and the spiritual realm is disrupted.

Past government policies and industrial activities have already deeply disrupted our spirituality and the spiritual dimensions of our way of life and wellness. If the Great Bear gold mine, and associated work, goes ahead, then it will have a further intense spiritual impact.

Spiritual impacts lead to bad things for our people. When we cannot fulfill our sacred duties it causes feelings of sadness, anxiety, loss of identity, loss of meaning, depression, and helplessness. When the spiritual realm and relationships are disrupted, it can cause fear, accidents, discord, conflict, bad harvest, unsuccessful hunts, drought, floods, hunger, ill health, and other terrible things.

We understand that the government and industry have a different way of seeing things, and that you see the natural world as separate from you, inanimate, spiritless, and there for the taking. We know that you always tell us that you know best and that the industrial

activities you plan will only cause minor, contained, short term impacts and that we need not worry. And yet, we are suffering from all the terrible consequences that our ancestors warned us would come from your industry and your violation of our spiritual landscape including illness, poverty, hunger, depression, suicide, and conflict.

Our way of understanding the world deserves respect. It is not right for you to force your worldview and all its impacts on us while we suffer the consequences.

Long-term risks – Tailings

We are particularly and deeply concerned by the long-term nature of the changes that you are making to the landscape and the risks that you are creating.

On August 13, 1970, a few months after closing the fisheries due to mercury pollution, the Ontario Minister of the Environment, George Kerr, declared that the Wabigoon River would recover on its own, without a cleanup or intervention. He said it would happen naturally in 12 weeks.[14] More than five decades later, our walleye in the Wabigoon River remain the most mercury contaminated in all of Ontario and it is unsafe to eat even one meal. Recent studies indicate that it will take many hundreds, if not thousands, of years for river sediment to recover on its own. Many sites are not recovering at all, and some are getting worse.

Some of the long-term risks that you are proposing to create include the creation of huge piles of waste rock that contains acid, heavy metals, the creation of new lakes in former open pit mines and tunnelling deep underground. These activities create long-term risks of leaching, groundwater contamination, dam failure, cave ins and falls, among many other things. We know that the impacts of industry can last many generations and for thousands of years.

And yet, our Treaty is only 150 years old. In that time the Crown has shown little ability to plan for the long term in a way that is not disastrous for us. How can we believe that the risks that you are creating will be safely taken care of for longer than Canada has existed as country, for longer than the time that Europeans have been in contact with us? How can we know that Canada, Ontario, Kinross, or Great Bear Resources will even exist in the timeframe that these risks will exist, let alone fulfil your responsibilities to take care of these risks in a way that you never have before?

You say that you will contain, monitor, and prevent these risks from impacting us, our water, and our landscape. But Ontario's own Auditor General has repeatedly found a failure to effectively remediate and monitor mining risks (see the section on failure to regulate below). Senior officials in the provincial government have noted the urgent and dangerous gaps in Ontario's regulatory ability to ensure the safety of tailings dams. You cannot safely carry out these duties now. Who will maintain the tailings dams in 100

[14] The Guardian (October 16, 2018), "The Warrior Society rises: how a mercury spill in Canada inspired a movement."

years? Who will monitor in 200 years?

We, the people living downstream, do not accept these risks.

Impacts to relationship with the Crown

The Great Bear Gold project is a massive one, with great risks to Grassy Narrows and that can have a major impact on many aspects of Grassy Narrows' relationship with the Crown including our Treaty, the honour of the Crown, fiduciary duties, outstanding obligations, unmet duties, and reconciliation.

Yet, the Crown refuses to come to the table with us about the major issues from which all these problems flows. At the same time, Ontario is attempting to delegate nearly all aspects of our relationship with the Crown to a gold mining company that is not party to our Treaty and that is primarily accountable to creating profits for its shareholders. A gold mining company has no ability to address our important issues with the Crown. We do not accept a gold mining company stepping into the shoes of our Treaty partner.

Adding insult to injury, Ontario has informed the company that the duty to consult on this project is at the low end of the spectrum. This is incorrect. For many reasons, even under Crown law, we are at the high end of the spectrum where consent is required. The reasons include but are not limited to the significant potential adverse impacts of the proposed project on our rights and health, the strength of our rights, the cumulative impacts of past industry, the outstanding Crown obligations and unmet duties towards us, the honour of the Crown, and fiduciary duties.

The failures of the Crown have led to a situation where we have been notified of this project only after the land was designated as "general use" and open to mineral exploration, after cumulative impacts of industry had been allowed to severely impact our rights and our health, after mining claims to the land were registered, after five years of exploration work had taken place, after over a billion dollars had been spent to purchase the property, and after the company had decided to open up a huge gold mine here.

The Great Bear Gold project is a runaway train, and we have no meaningful opportunity to shape decisions that will forever impact our people and our land. These decisions include: determining what parts of the landscape should be protected and what should be exploited; the threshold for industrial impacts that can occur before our rights are infringed and our health is harmed; the process for making decisions among Treaty partners; the role of third parties seeking to profit in the Treaty relationship; how to repair harms created in the past but impacting the present; how to prevent future harms; how to reconcile the relationship between the Crown and Grassy Narrows.

The Crown acts as though Grassy Narrows has no say in these decisions. The Crown seems to think that we should accept that a massive gold mine is a foregone conclusion and we should only have a say in things like where the effluent pipe discharges, where the tailings piles are located, and where the processing plant should be sited. We disagree.

This project, the failure of the relationship with the Crown which has allowed the project to become so advanced without our involvement and consent, is having, and threatens to have further major impacts to our relationship with the Crown. Rather than taking a minimal and reductionist view of the minimum that the Crown can do in this situation, a robust understanding of the duties is required, as well as an appreciation for the unique circumstances and history of Grassy Narrows. Only involvement of senior representatives of the Crown can resolve this problem.

Federally Regulated Impacts

Federal involvement is required because of the numerous areas of claimed federal jurisdiction that will be affected by the Great Bear Gold project, including the completion of a Federal Impact Assessment.

Some, but not all, of these areas of claimed federal authority are listed here:

Species at Risk: The Federal Crown claims authority within the Constitutional division of powers over Species at Risk. Although we have not been able to carry out a thorough assessment due to the lack of capacity supports, the project site has a strong potential to impact the following species at risk:

- Woodland Caribou – the project site is within the range of the Sydney Caribou Herd. The range of the Sydney Caribou Herd is currently approximately 64% disturbed (likely higher due to recent fires in Woodland Caribou Provincial Park). This amount of disturbance exceeds the threshold above which the range becomes unlikely to be able to support a viable caribou population. The range is in need of recovery to lower the level of disturbance and therefore the entire range is considered critical habitat. The project will add disturbance, further degrading the ability of the range to sustain caribou and increasing the likelihood that Woodland Caribou, a threatened species, will be extirpated from this area. Caribou is an important clan animal for Grassy Narrows.

  It should be noted that while Ontario does have a *Species at Risk Act*, it has exempted mining and logging from the applicability of that Act. The provincial government cannot be counted on to ensure that the Great Bear Gold project proceeds in a manner that protects species at risk.

- Wolverine – Wolverine play an important and unique role in our ecosystem and in the balance of life. The company has indicated that wolverine have been observed on the project site using trail cameras. Direct observation of wolverines is a rare. Wolverine avoid humans and human impacted areas. The project is almost certain to permanently displace the wolverine that have been observed at the site and to destroy any wolverine dens, trails, habitat, and food sources that are on the site.

  The Committee on the Status of Endangered Wildlife in Canada (“COSEWIC”) reports that wolverines prefer ecologically intact areas and avoid disturbance.

According to COSEWIC "[a] study of the cumulative effects of developments on Arctic wildlife (Johnson et al. 2005) found that mines and other major developments had the largest negative effect on species occurrence, followed by exploration activities, and outfitter camps."[15]

Due to past degradation of southern habitats, wolverine left Grassy Narrows' area. However, our success in stopping logging has resulted in the beginning of a return of wolverine. Grassy Narrows is now near the southern edge of the currently occupied range of wolverine. If the project goes ahead, wolverine will leave our area and may not come back, further disrupting the balance of the landscape.

- Sturgeon – Sturgeon are an important clan animal in Grassy Narrows an important food source for the Anishinaabe of the Treaty 3 area. The damming of the English River has had a big impact on sturgeon. A small and delicate population remains in the river, which we are trying to protect and recover. Sturgeon live for many years, are sensitive to industrial disturbances, and can accumulate large amounts of toxins in their bodies.

There are many other species at risk that may be affected by the Great Bear Gold project, including bats, birds, turtles, Eastern Cougar, American Badger, and others. Each have a role to play in the web of life.

Fisheries: The Federal Government claims jurisdiction over inland fisheries, the prevention of harm to fish from pollution, and the protection of their habitat.

While the Federal Government has cooperative agreements with Ontario for licensing of fisheries the Federal Government maintains jurisdiction and responsibility for prevention of harm and protection of fish habitat.

Under Crown law, even the construction of a small water crossing can trigger the need to apply to the Department of Fisheries and Oceans for permits. In contrast, Ontario does not require a provincial impact assessment before a mine is opened.

We are a river people and fish have always played an extremely important role in our way of life, our sustenance, and our livelihood.

The companies propose to take water from our river system, use it in the industrial gold extraction process, and then return it to our river. The companies propose to create three open pit mines, three underground mines, store large amounts of waste rock and operate an industrial ore processing facility, all in close proximity to water bodies and streams that flow into our river system. Finally, the companies propose to create three new lakes in the empty open pits created by gold mine, and to allow water to flow out of those pits and into other local water bodies. All these activities, and others, put our fish

[15] Government of Canada, "Wolverine (Gulo gulo): COSEWIC assessment and status report 2014" (date modified: January 6, 2015).

at risk.

The Crown has failed to protect our fish for many decades from the impacts of mercury and this has had grave consequences for the rights, health and wellbeing of our people. Given the Crown's failure, and its ongoing impacts, all levels of the Crown should be diligent and alert in carrying out their duty to protect our fish from further harm.

Indigenous Peoples: The Federal Government claims jurisdiction over Indigenous Peoples and the lands reserved for them. This jurisdiction includes claimed authority over our health, culture, and wellbeing, responsibility for environmental contaminants and their impacts on Indigenous traditional foods and on the health of Indigenous Peoples.

The Great Bear Gold project has potential to impact Grassy Narrows' relationship with the Crown, the safety of our traditional foods, and our health, culture, and wellbeing. The project also has the potential to impact waters that flow into and through our reserve and which can impact our reserve.

Due to the Crown's longstanding and ongoing failures to meet its duties to Grassy Narrows, all levels of the Crown should be diligent and alert in carrying out their duty to protect us, our health, our traditional foods, and our further harm.

There are further areas of Federal claimed authority that likely apply here as well and that are at risk in this project, including but not limited to migratory birds, transboundary waters, transboundary air pollutants, international laws and instruments.

Due to the many important areas of claimed Federal authority that are at serious risk in this project, it is essential that a robust and comprehensive Federal Impact Assessment is carried out.

Grassy Narrows seeks to engage with the Federal Government and our consent is required to the form that the Impact Assessment will take.

Site-specific parameters and guidance levels needed

In its Initial Project Description, Kinross states that water, effluent, tailings leachate, and other substances will be tested and will be released back into the environment after they meet guideline levels. However, the Initial Project Description does not identify the guideline levels that will be used. Guideline levels are a very important and complex topic that must be explored in far more detail. Our discussion here is intended to illuminate that there is a serious problem.

Although there are many substances of concern here, we are most familiar with mercury and so we will use it as an example.

There are many guidelines that we have seen applied upstream of our community for allowable mercury levels. Some of these guidelines are wildly inappropriate, but all of them are insufficient.

According to the Government of Canada "(m)ercury is a toxic element and serves no beneficial physiological function in man; a maximum acceptable concentration of 0.001 mg/L (1 µ g/L) in drinking water has therefore been established."[16]

A concentration of 0.001 mg/L corresponds to **1000 ng/L** (nanograms per liter), which is the unit we will use here.

One might think that if the mercury level is good for drinking, then it would be fine to put in our river, but that is not the case. Provincial Water Quality Objectives ("PWQO") are numerical and narrative criteria that serve as chemical and physical indicators representing a satisfactory level for surface waters (i.e. lakes and rivers) and, where it discharges to the surface, the ground water of the Province.

The PWQO guideline level for mercury in surface water is **200 ng/L.**

The PWQO guideline has historically been applied to mercury contaminated groundwater seeping out of the banks of the Wabigoon River next to the Dryden mill to claim that it is safe. However, this too, is irresponsible.

The Canadian Council for Ministers of the Environment (CCME) provides guidelines for mercury levels in freshwater bodies that attempt to account for the risk to fish and wildlife through exposure to mercury.

The CCME guideline level for mercury in surface water is **26 ng/L.**

One might think that if this level of mercury in water is safe for the fish and wildlife, it must be safe to put water with that level of mercury into Grassy Narrows' river. However, the CCME guideline does not consider bioconcentration of mercury as it moves up through the food chain.

As the Government of Canada explains "[t[he presence of mercury in water has become a source of concern because of the finding that organic mercury is bioconcentrated by fish. Elevated mercury levels have been found in all freshwater fish taken from areas with suspected mercury contamination and frequently render the fish unacceptable for human consumption."[17]

The mercury levels that are found in predatory fish like the walleye, can commonly be a million times the level that is found in the water that they swim in.

Recent monitoring studies of the Wabigoon River upstream from the Dryden mill show that **baseline level of mercury in the Wabigoon River is around 1 ng/L.** Even at those baseline levels of mercury in water, large adult walleye in Wabigoon Lake often exceed 0.5 ppm mercury, the level above which the commercial sale of fish for human

---

[16] Health Canada (1986), "Healthy Living: Water and Mercury."
[17] Health Canada (1986), "Healthy Living: Water and Mercury."

consumption is banned.

If the level of mercury in the River is raised to **2 ng/L**, then mercury levels in adult walleye will approximately double, making them far more dangerous to eat. If other chemicals that stimulate net methylation in the environment are added as well, then the effect will be even more grave.

That means that river water with 2 ng/L of mercury will have serious impacts on the health of Grassy Narrows people's ability to safely practice their right to fish, even though this level is less than 10% of the level allowed by the CCME guideline, the most restrictive of the guidelines we are aware of.

A similarly broad range of guidelines exist and are applied for mercury levels in fish safe for human consumption.

The Ontario Ministry of the Environment "Guide to Sportfish Consumption" allows for some consumption of fish by the non-sensitive population (adult men and women who are not of child bearing age) if the fish have mercury levels below **1.8 ppm.**

On the other hand, the sale of fish for human consumption in Canada is banned if the fish have mercury levels over **0.5 ppm**. Grassy Narrows fishermen have been charged for selling their catch based on this rule.

In the 1980s, Canada established **0.2 ppm** as the guideline limit for safe consumption of fish by Grassy Narrows and other Indigenous subsistence eaters of fish.

The US Environmental Protection Agency ("EPA") lists **0.1 ppm** as their guideline level for Indigenous subsistence eaters of fish.

Renowned mercury expert Dr. Mergler has written in expert reports (some of which are enclosed), all of which have been provided to Ontario, that among these guidelines the US EPA level is most relevant to Grassy Narrows. However, she notes that all these guidelines are based on safe levels for a lifetime of exposure in a regular population. Mercury impacts are cumulative throughout the lifespan. None of these guidelines take into account the high, and far above guideline, levels of exposure that many Grassy Narrows people have already been exposed to. She writes that Grassy Narrows people have generally already been exposed to too much mercury and cannot safely be exposed to any additional mercury.

Clearly, off-the-shelf guidelines are not sufficient. It is necessary to develop and apply in close collaboration with Grassy Narrows locally specific guidelines that take into account the local background levels, ecology, food chain, cultural practices, and cumulative impacts from other industry, and history of exposure.

Other specific concerns

Given the constraints that we have noted, it is not possible to provide a comprehensive list of concerns here. However, some further concerns that we have identified to date,

which will require future elaboration, include:

- The contamination of the water within our Territory and water that flows into our Territory from effluents, discharges, by-products, leaching (including of metals), and changes in mercury cycling
- The creation of acid rock drainage and other forms of toxic drainage
- Changes to the flow, level, and quality of our water from water takings and discharges.
- The contamination of our air and air that flows into our Territory
- The loss of our caribou and moose, and of those who travel into and out of our Territory through impacts including habitat degradation and outside hunting pressure
- Disrupting the delicate balance of animals, predators, prey, and the web of life that supports us.
- The contamination and loss of our fish for food, commercial fishing, sport fishing, and way of life, including fish that migrate in and out of our Territory
- The loss and contamination of our birds and insects including migratory birds
- The loss of our valuable fur bearing animals including marten and otter
- The fragmentation and degradation of our forests and the loss of intact forest landscapes and old growth forest areas
- The changing of mercury exports and mercury cycling, including methylation
- The creation of additional anxiety, fear, depression, disempowerment, and despair among our people
- The further disruption of our society, our culture, and our way of life.
- The exacerbation of our suicide crisis
- The desecration of our sacred landscape
- The disturbing of spirits and beings that live in the rocks
- The tainting of our medicines
- The disruption of our people who are out on the land living their way of life
- The loss of peace and quiet for our people who are out on the land

- The loss of the ability to use the land as a healing place for our people
- The loss of our ability to teach our kids our way of life, identity, knowledge, and ways of wellness
- Impacts to our individual and collective health and wellbeing
- The loss of our ability to make a living in a way that is harmonious with our culture
- The violation of our Indigenous laws and jurisdiction
- The violation of our Treaty rights, our Treaty relationship
- The violation of the honour of the Crown and Fiduciary duties.

Other harmful impacts of industry on ANA people and Territory include, but are not limited to, the following:

- Impacts to game animal populations and their habitat including moose, and caribou which are central to our hunt and an important part of our way of life, our sustenance, our livelihood, and the exercise of our Treaty rights;
- Impacts to fur bearing animal populations and their habitat including pine marten which are central to our trapping and an important part of our way of life, our sustenance, our livelihood, and the exercise of our Treaty rights;
- Changes in forest composition including a shift from extensive coniferous dominated stands to fragmented deciduous dominated stands;
- Failure to regenerate forests or failure to regenerate to their previous composition;
- Loss of productive land base through tertiary roads, machine trails, landings, mines, tailings, buildings, erosion, etc.;
- Loss of species and genetic diversity;
- Loss of shrubs, including berries and medicines including through the use of herbicides;
- Tainting of our medicines and rendering areas unfit for sacred medicine harvesting and ceremony;
- degradation of forest soils, including compaction, rutting, scarification, and erosion;

- Disruption of nutrient cycles including the depletion of calcium in our watersheds, leading to calcium deficiency in aquatic biota;

- Increased competition with non-Indigenous hunters and fishers using forest access roads and associated depletion of animal and fish populations;

- Increased road traffic and danger of collision of people and wildlife with forest industry vehicles;

- Loss of traditional travel routes, sacred places, heritage, and archaeological sites;

- Negative impacts on water quality, fish habitat, fish populations, and fish contaminants;

- Risk of increased violence against ANA people, including gender-based violence, from an influx in workers coming into the Territory to log, and the potential establishment of man camps;

- Lack of recognition of cultural Anishinaabe way of being;

- Violation of our inherent, Treaty, and Aboriginal rights; and

- Violation of ANA Law and the will of our people.

Failure to Effectively Regulate and Remediate

According to the Government of Ontario, there "are over 5,700 abandoned mine sites in Ontario that have over 17,000 mine features, known as hazards… Deaths due to mine hazards in Ontario are rare, but deaths happen in North America every year."[18]

As of 2015, only four mines were listed as fully closed out. Only three are identified as undergoing remediation. On the other hand, there were 56 abandoned mines with 629 contaminated sites meeting provincial criteria for liability recognition. A further 306 abandoned mines had over 3,000 contaminated sites that do not meet the criteria for liability recognition.[19]

There are already many abandoned mine sites in our Interim Area of Interest for Mining, mostly in the Red Lake Area, many of which have been left in an unremediated state for decades. A number are classified as dangerous by the Ministry.

According to the Ontario Auditor 2015 report, the Ministry of Mines has not estimated

[18] Ontario, "Abandoned mines hazards" (last updated February 17, 2023).
[19] Auditor General of Ontario (2015), "2015 Annual Report: chapter 3.11: Mines and Minerals Program."

the total cost of rehabilitating the 4,400 abandoned mine sites in Ontario since 1993 and therefore does not know the current cost for doing so. It also does not have a long-term plan for rehabilitating these sites. These sites may pose risks to public health and safety and the environment.[20]

The Auditor General found that the "Ministry conducts minimal inspection and follow-ups on abandoned mines."[21] In the five years before the audit "the Ministry has inspected only about 6% (248) of abandoned mines to ensure that they do not pose a risk to public health and the environment."[22]

The Crown often assures us that despite the legacy of past bad practices, mining regulation is done safely now. To the contrary, the Auditor General found many glaring flaws in Ontario's regulatory regime for current mining, including that "Ontario is the only province in Canada that does not require a provincial environmental assessment to be performed for mining projects."[23] The Auditor General's report further explained that "in Ontario, the *Mining Act* only requires mining companies to submit closure plans prior to the development of the mine… In other provinces in Canada, larger mining projects automatically trigger a provincial environmental assessment."[24]

The Auditor General found that the closure plan process lacks sufficient funding, is subject to pro-industry bias, plans are not updated, and inspections are insufficient to ensure safety.

As of 2022, the government had not inspected nearly half of Ontario's operational mines since 2011.[25] The news media has also reported that Ontario senior officials are highly concerned that following several recent tailings dam failures "there is little to no legislative authority to prevent similar situations from occurring in Ontario."[26] According to the media the regulatory gap is outlined in a section of a briefing binder for Minister Pirie dedicated to "critical decisions. Senior bureaucrats, who told Minister Pirie that the gap in offline tailings dam rules was a "high-risk gap in the regulatory framework that requires urgent attention."

Far from improving the overall mining regulatory situation, the Government of Ontario has recently watered down its regulations with respect to requirements for closure planning and closure funding through the *Build More Mines Act*. The Act gives the Minister extremely broad discretion over nearly all aspects of mining including closure planning and funding. Under the new rules the position of Director of Mine Rehabilitation

[22] Auditor General of Ontario (2015), "2015 Annual Report: chapter 3.11: Mines and Minerals Program."
[23] Auditor General of Ontario (2015), "2015 Annual Report: chapter 3.11: Mines and Minerals Program."
[24] Auditor General of Ontario (2015), "2015 Annual Report: chapter 3.11: Mines and Minerals Program."
[25] The Narwhal (June 24, 2023), "Ontario minister was privately urged to fix 'high-risk gap' to avoid mining disaster."
[26] The Narwhal (June 24, 2023), "Ontario minister was privately urged to fix 'high-risk gap' to avoid mining disaster."

was removed, Ministry staff no longer review closure plans and instead industry staff may carry out the review, contrary to the Auditor's 2015 recommendations.

Given this context, Grassy Narrows does not trust that the appropriate regulations are in place to ensure mining sites will be kept safe for many generations to come. You have not earned our trust.

Lack of Protected Areas, Need for Regional Balance.

There is an imbalance in the region because nearly all forests south of Red Lake are open to industrial mining. For example, much of our Territory is in ecodistrict 4S-2 where only 4.1% of the ecodistrict is protected. Part of our Territory is in ecodistrict 4S-3 where only 3.3% of the ecodistrict is protected. The lack of protection for our landscape is the clear outcome of an unbalanced landuse designation process that did not involve us meaningfully and ignored our rights and interests.

In contrast, conservation biology generally dictates that at least half of an ecosystem must be protected to avoid loss of biodiversity and ecosystem functions. Ontario has committed to community-based land use planning in the Far North based on a joint planning process between the First Nations and the province.[27] It committed to protecting 50% of the landbase in partnership with First Nations following First Nations-led landuse planning.

Canada has committed to protecting 30% of the land in Canada by 2030 in partnership with First Nations. Respecting ANA's efforts to protect our environment will contribute to the maintenance and recovery of biodiversity and ecosystem functions and will support a balance in this region, where the vast majority of forests have been open to industrial logging and mining.

Nature Based Climate Change Solutions

Climate change and biodiversity loss are major threats to Grassy Narrows and to the world. Nature based solutions have been identified as an important part of preventing and mitigating both problems. The boreal forest is one of the world's largest storehouses of carbon. After logging or clearing of the land for mining, much of this carbon is released from the forest, plants and soils, contributing to climate change. On the other hand, protecting forests helps to keep the carbon safely stored and safeguards biodiversity. These are important ecosystem-based services that contribute to mitigating climate change and that have a significant value.

Fighting climate change and biodiversity loss are important priorities for Grassy Narrows and for Canada and respecting Grassy Narrows' land protection will contribute to progress on these priorities.

---

[27] *Far North Act, 2010*, SO 2010, c 18.

VI. Mining activity without Grassy Narrows' consent risks conflict

Barrick writes that "[a]ny perceived or actual breach of … trust or respect can have devastating consequences for a mining venture or company, and these commercial and reputational consequences can extend well beyond any particular project or First Nation group." In so writing, Barrick raises the spectre of conflict minerals, also commonly knowns as blood minerals.

Global concerns about unethical practices by mining companies, including Canadian gold mining companies, have led to increased scrutiny of the social, environmental, and ethical practices of mining companies. For the mining industry, the problem with conflict minerals is that no one wants them. Conflict minerals are hard to market, and they increase corporate risks and uncertainties associated with investment, timelines, regulatory approvals, litigation, social conflict, and brand damage.

As a consequence, Ontario and Canada have sought to market themselves as stable, safe, ethical, jurisdictions from which to source conflict-free, or ethical minerals. While there are cheaper jurisdictions in which to operate, the conflict-free reputation of Ontario and Canadian minerals is a significant competitive advantage relative to many of other global mining jurisdictions.

However, as Barrick noted, for the mining industry and a mining jurisdiction, trust is hard to gain and easy to lose. It only takes one high profile conflict to taint an entire company, a sector and an entire jurisdiction and to undermine decades of marketing.

Ontario learned this lesson in the analogous conflict with Grassy Narrows over unwanted logging. After decades of unliterally forcing clearcuts on Grassy Narrows against their will, the First Nation turned to protests, boycotts, media campaigns, public education, litigation, and grassroots blockades. Within six years, major sourcing contracts were being threatened and shortly afterwards Abitibi, the world's largest newsprint producer, withdrew from Grassy Narrows Territory.

The City of Kenora, in their 2009 report to the Ontario Good Roads Association / Rural Ontario Municipalities Association, wrote that "[t]he issue with Grassy Narrows on the Whiskey Jack Forest must be resolved... Without resolution of these issues, **the wood coming off the Whiskey Jack Forest cannot be sold**. **There is no current customer willing to accept wood products from a forest unit which is involved in a perceived controversy."** (emphasis added)

This dynamic is beginning now with respect to mining. A long and growing list of mining companies, including Barrick, Trillium, Bounty, and Kenorland have voluntarily committed not to explore without consent or have left the area. Their withdrawal reflects an enduring reality in the mining industry where compliance with international law, third party certification standards, customer, investor, and shareholder expectations, and social license preclude the use of conflict minerals.

The Crown would be wise to avoid instigating conflict with Grassy Narrows again by approving unwanted mining. Controversy with Grassy Narrows about one mine could

taint the reputation of Ontario as a conflict-free place to mine. It could give the entire regional industry a stain that heightens risk and uncertainty and discourages investment throughout the supply and production chain.

The entire region and industry benefit from an environment free of conflict. It is in the interest of Ontario and industry to resolve, not inflame, the conflict with Grassy Narrows.

VII. Gold does not justify the impact to Grassy Narrows

Gold does not serve an essential and irreplaceable function in society. The largest use of gold by far is for jewelry, followed by investment and central banks demand. Technology, a distance fourth, used only six percent of gold production in 2022 (309t out of 4,721t produced globally). Much of that technology is electronics with short life spans and abysmal recycling rates.

Because gold is not essential, but is valuable, the rationale for mining gold by Great Bear and Kinross is purely financial. Shareholders demand a return on their investment, but Ontario need not repeat the mistake of sacrificing Grassy Narrows' rights and wellbeing for the interests of corporate shareholders.

The flow of resource wealth has been used to justify the damming of our river, dumping of mercury, logging of our trees, and now proposed gold mining. The impacts we have suffered from this approach are extreme and ongoing. The mine is projected to operate for a mere 25 years, but we will be here for many generations. No longer can the Crown and third-party companies seek to sacrifice our health, way of life, livelihood, rights, and environment for short term shareholder gains. Enough is enough.

It is important to remember that it is tourism, recreation and services – not resource extraction – that now forms the backbone of Kenora's employment. This shift is not due to a lack of available wood or minerals, but rather reflects increasing mechanization and marginal profitability in the extractive sector in contrast to the growing demand and labour intensiveness of the non-extractive sector. Grassy Narrows' work to protect our landscape and our environment have helped to foster Kenora's greatest economic strength.

The Kenora and Red Lake area enjoy substantial benefits for tourism, wildlife, hunters, fishers, trappers, recreational users, and non-extractive industries. According to the municipal website "[t]he City of Kenora has transitioned from a pulp and paper mill town to a destination and lifestyle community."[28]

The tourism and services industries are Kenora's largest employers by far. The visitor and cottager sectors contribute $300 million annually to the Kenora economy. In contrast, it is estimated that the Weyerhaeuser mill contributes $60 million to the local economy, even when counting indirect economic benefits throughout the region.

---

[28] City of Kenora, "Key Industries" (accessed January 23, 2021)

Kenora's tourism labour force makes up 38% (3,314 jobs) of Kenora's total employment, while Tourism related occupations account for 51.5% (4,405 jobs) of Kenora's total employment.[29] The growth of this industry is key to Kenora's economic plans.

According to the current Whiskey Jack Forest Management Plan ("FMP"), "[t]here are numerous tourist operators in the Whiskey Jack Forest. The recreational activities provided by these outfitters include options for fishing, hunting, camping and other eco-tourism opportunities. The number of individuals, residents and non-residents, procuring services from these tourist establishments are numerous, and they contribute a significant amount of economic resources to local communities ... The Sunset Country Economic Study reports that in 2001, 443 operators provided employment to 3,785 persons of which 1,221 were located in the Whiskey Jack Forest".[30]

In contrast, the Evolution gold mine in Red Lake employs 740 people, only a sixth of the number employed in tourism related jobs in Kenora and is chronically at risk of shutting down if profitability cannot be increased for its Australian owner.[31]

As set out in the Lake of the Woods Tourism Sector Report, "[o]ngoing investments in tourist services and resources only compliment the pristine natural environment that has attracted visitors to Lake of the Woods for over a century."[32]

The current FMP notes that "public and municipal officials should be aware that provincial parks help to make their communities attractive for business as well as for tourists and retirees. The retirement community brings in pension income, which is often indexed to inflation and is "recession proof'.[33]

Respecting and supporting Grassy Narrows' efforts to protect the landscape would contribute to the region's tourism economy and maintain opportunities to grow that economy as well as to become a leader in the conservation economy through future protected areas and associated eco-tourism attractions. A conservation economy creates long-term sustainable employment potential for local and regional residents by maximizing existing skills and knowledge.

VIII. A Choice, an Opportunity

Our youth are crying out. They want to see the land protected so that we can use it to heal our people and our spirits. This is reconciliation for us. They deserve to see the light at the end of the tunnel. We do not want to have to fight, again and again, to protect out land.

However, the community of Grassy Narrows is strong. We know our history, our rights,

our language, our teachings, and our way of life. We have allies across the country and across the world. The days of forcing harm on us against our will are over.

Respecting Grassy Narrows' land protection is the best available way to minimize conflict and move towards a path of reconciliation and respect for our inherent, Aboriginal and Treaty rights in compliance with international Indigenous rights standards.

Grassy Narrows has borne the brunt of the impacts of industry in the region, while our voice has long been ignored by Crown and industry decision makers. Part of the outcome of this mistreatment has been conflict over logging and one of Canada's most infamous environmental poisoning sagas. As a consequence, the region, and the country, has a stain on its honour, its reputation and credibility.

Times have changed. It is no longer acceptable, nor viable for the Crown to approve extractive industrial activities without Indigenous parties' consent. Across Canada there is a commitment and an expectation for reconciliation. We have an opportunity now to learn from the mistakes of the past and to heed the voice of Grassy Narrows. In the process, we can move from conflict to cooperation, from destruction to restoration, from harm to hope. Grassy Narrows invites the Crown to join us in righting this historical wrong. Respecting Grassy Narrows' land protection would be an important show of good faith that would be a positive step on the path towards reconciliation.

The Crown is at a crossroads.

On the one hand, the companies are proposing to open a large and toxic gold mine upstream from us against our will. If implemented, the mine risks irreparable harm to Grassy Narrows' rights and interests including, but not limited to, harms caused by cumulative effects, neglected obligations, Treaty infringement, harm to our health, release of mercury, and loss of way of life and livelihood. This harm would be immoral, unjustified, unreasonable, dishonourable, and a breach of Ontario's fiduciary duties to Grassy Narrows.

On the other hand, respecting Grassy Narrows land protection would have a beneficial impact on the exercise of Treaty rights and on the environment, cause no harm to anyone's health, and be beneficial for the growing non-extractive economy. There is an opportunity for calm that will allow ANA and the Crown to focus on long-term resolution of our issues and that will help ANA return to the health, self-determination, and prosperity that we once enjoyed.

We are inviting you to walk with us on the path of protection, healing and reconciliation. Will you work with us, or against us?

APPENDIX A

INTERIM Issues for Negotiation/Engagement/Consultation with MINES

August 18, 2023

1. Recognition and respect for ANA inherent, aboriginal and Treaty rights
2. Recognition and respect for the ANA Land Declaration
3. Recognition and respect for the ANA IPCA
4. Harmonization of Crown Law and ANA Law with respect to mining related activities
5. Repairing the Crown – ANA relationship with respect to mining related activities
6. Outstanding Ontario obligations to ANA including those arising out of the 1978 MOU and subsequent commitments such as increased ANA control and ownership over its land base
7. Land-use redesignation of the ANA IPCA
8. Interim measures including the withdrawal of the ANA IPCA from staking
9. Suspension of all mining exploration activities on the ANA IPCA and vicinity
10. Resolution of existing third-party mining interests on the ANA IPCA created by the Crown
11. Issuing a Notice of Caution for mining related activities on lands where ANA rights and interests could be impacted
12. MINES Minister's unfulfilled commitment of November 2021 to visit Grassy Narrows to discuss mining issues in an open forum.
13. Cumulative impacts of past mining related activities on ANA
14. Cumulative impacts of mining activities and other industrial and crown policy impacts on ANA including mercury
15. Resolution of issues arising from past mining related activities which have occurred without ANA consent (restoration, compensation, apology, etc.)
16. Ending Free Entry mining exploration and resolving the issues it has created
17. ANA concerns re off-site impacts and risks of existing mining activity (e.g. at Red Lake and Goliath mines, Red Lake and Separation Rapids exploration) on ANA
18. ANA concerns and MINES failure to take into account risk of off-site impacts of proposed mining exploration and other mining related activity on ANA (including downstream, migratory, downwind, landscape level, and other impacts)
19. Addressing ANA concerns re: Changes to the Mining Act
20. Addressing ANA concerns re: Regulation and enforcement of tailings management
21. Impacts of mining related activity on mercury mobilization and cycling
22. Impacts of mining related activity on Intact Forest Landscapes and associated values and ecosystem functions
23. Impacts of mining related activity on source water protection and source water planning and management
24. Impacts of mining related activity on moose, caribou, marten, fish, and other wildlife
25. Impacts of mining related activity on ANA sacred landscape, spirituality, ceremonies, medicines

26. Impacts of mining related activity on ANA land based healing
27. Impacts of mining related activity on ANA travel routes, camp sites, occupancy sites, burials, etc.
28. Impacts of mining related activity on ANA archaeological and historical values
29. Impacts of mining related activity on ANA safety, and risk of racial and gender based violence including man camps.
30. Unanswered correspondence from ANA to MINES and Ontario
31. Barriers to meaningful ANA engagement including the ongoing Mercury Crisis, housing crisis, water crisis suicide crisis
32. Reimbursement of past ANA expenses for unfunded engagement with the Crown and mining companies.
33. Capacity support required by ANA to begin meaningful engagement
34. ANA Consultation Area with respect to mining
35. Proposed and existing mining exploration and other mining related permits

Boozhoo MINES, IAAC, Kinross and Great Bear Resources:

RE: The Great Bear Gold Mine Project

On behalf of Asubpeeschoseewagong Anishinabek ("ANA" or "Grassy Narrows First Nation"), we write to share with you Grassy Narrows' preliminary position with respect to your activities in relation to the Great Bear Gold Project.

The Project will have an adverse impact and requires an impact assessment

Grassy Narrows is deeply concerned by the Great Bear Gold Project being pursued by Kinross and Great Bear Resources with support from the Ministry of MINES as well as the process recently begun by the Impact Assessment Agency of Canada (IAAC).

Decades of industrial activity, authorized and encouraged by Ontario and contrary to Grassy Narrows' will, have led to well-documented and extensive harm to our Territory, our way of life, our rights, and our health. As a result, our people suffer intensely from impacts including premature death, disease, poverty, and suicide.

The Great Bear Gold Project falls within the area that Grassy Narrows people have historically and currently use for the exercise of our rights and way of life. It is also upstream from our community. Pollutants in the water and impacts on the surrounding land, fish and wildlife will have a direct impact upon us and could also exacerbate mercury contamination in our waterways.

ANA has repeatedly and clearly communicated with the Crown and the mining industry that our people are in crisis, the environment which supports us is severely impacted, our health is failing. The cumulative impacts continue to significantly interfere with our treaty, Aboriginal and inherent rights.

The Great Bear Gold Project will have an impact upon areas that Canada claims as within federal jurisdiction, such as species at risk, fisheries, waterways and Indigenous peoples. Grassy Narrows asserts that the IAAC must conduct an impact assessment in the circumstances.

The Crown's outstanding obligations to Grassy Narrows should be resolved in a nation-to-nation process.

For many years, ANA has written to Ontario to invite the Crown to a government-to- government table to address fundamental issues between us, including the Crown's unmet obligations to us about our rights, our land, our self-determination, and the impacts of industry and government policy on our land and people. These issues have been unresolved between our governments for many decades. Reaching agreement in good faith through a government-to-government table is the way to resolve these important issues and to put in place effective measures to protect us from further harm.

Ontario and Canada have yet to accept this invitation. Most recently, by letter dated November 27, 2023, Ontario explicitly refused to participate in a table to discuss "jurisdictional issues" raised and rejected nearly all of the issues proposed by ANA including most of those related to mining.

Instead, Ontario has explicitly recommended that mining companies explore on and around our Territory, has unilaterally granted roughly 6,000 mining claims on our Indigenous Protected and Conserved Area, and allowed companies to pursue increasingly advanced work towards mines that pose a serious threat to Grassy Narrows. This activity has occurred without our consent, without meaningful consultation and accommodation, and usually without even prior notice under the antiquated "free entry" mining regime.

Grassy Narrows' concerns about the process

Until recently, the Crown and the companies associated with the Great Bear Gold Project have shown little willingness to meet with us, nor respond substantively to many of our communications. Indeed, we have only recently learned that the Crown and companies provided notice to other Indigenous Nations of permit applications concerning the Great Bear Gold Project

as early as 2017 and have signed Advanced Exploration Agreements with Wabauskang and Lac Seul First Nations. In contrast, Ontario approved a number of permits without notice of any kind to Grassy Narrows.

Now that gold has been found, the Crown and Kinross are suddenly interested in giving the appearance of consulting with us, but only to the extent that it furthers the already advanced plans, made without Grassy Narrows' involvement, to develop an industrial gold mine in our headwaters.

Even if Ontario had complied with its own laws, Ontario's "free entry" mining exploration and mine development process is not the correct way to make key decisions between our two governments. This process is deeply unfair and biased in the favour of multi-billion-dollar mining companies. It ignores our laws, our vision for our land and people, and our processes for making decisions affecting our territories.

Our ongoing and urgent crisis leaves us unable to meaningfully engage about mining. To make matters worse, we receive no support from Ontario to inform ourselves, gain technical and legal advice, and to engage in a fair way about mining. The IAAC has offered a mere $5,000 in capacity funding to respond to a 100-page technical Initial Project Description and the funding was made available only after the submission deadline for comments has passed.

The path to reconciliation

We are on a healing journey to recover from the extreme damage that colonization, and attempted forced assimilation have done to our people, including through the imposition of Crown policy and regulatory schemes related to residential schools, dams, relocation, mercury contamination, child apprehension, industrial logging, and mining. We need to allow the land to heal because healthy land will help to heal our people. This is what reconciliation means to Grassy Narrows. Let us protect our land and water so that we can heal our people.

The boom in mining exploration in our area is causing great anxiety and fear among our people. It is setting back our healing. If the Crown decides to allow mining, and the risk of further pollution and other impacts, there will be more heartache, sickness and loss for our people. This mining activity will only lead to more grassroots resistance, litigation, and public controversy over conflict minerals. It will take the relationship between the Crown and Grassy Narrows further away from the path of healing and reconciliation.

Grassy Narrows says 'no' to the Great Bear mine and related activities.

We strongly urge the Crown and your companies to reconsider your unilateral and bullying approach to pushing mining activity on our First Nation. We urge you to seize this opportunity to set a course for a future that is free of conflict over mining in Ontario.

We call on the Crown and your companies to respect the healing path for Grassy Narrows and not to further impair the exercise of our constitutionally protected Aboriginal and treaty rights, our inherent Indigenous rights, our health, and wellbeing.

Grassy Narrows provides preliminary comment on the project under duress

We know that Ontario and Canada will move ahead with approvals for damaging mining activity if we do not speak up. For that reason, we are writing to you under duress to express our preliminary concerns about this project before it advances any further. These serious concerns with both how the project has been pursued and the impacts on our rights and interests, are set out in the attached document. These submissions are by necessity preliminary in the absence of capacity and support to conduct our own studies and obtain expert technical advice.

Please ensure that you copy our Land Protection Team on all communications on this and related matters.

ANA PRELIMINARY CONCERNS ABOUT THE GREAT BEAR GOLD PROJECT

Table of Contents

I. The Context 8

Who is Grassy Narrows 8

Social and Cultural Impacts of Crown Law and Policy. 8

The Cumulative Effects of the Mercury Crisis and Industrial Activities Impacts. 9

II. Ongoing Breaches of Crown Obligations: The 1978 Memorandum of Understanding, Honour of the Crown, and Fiduciary Duty 11

1978 MOU and Dishonourable Conduct. 11

The Crown's unmet fiduciary duties 12

The Crown's abandonment of negotiations required by the 1978 MOU 12

Ontario has failed to accurately identify the ANA Area of Interest on mining activities. 13

Grassy Narrows Laws Have Not Been Respected. 15

III. The Crown Must Address Capacity Barriers 16

IV. The Great Bear Gold Project: The Crown's failure to inform, meaningfully consult, and gain our consent for project activities. 18

The Great Bear Gold Project falls within Grassy Narrows' Interim Area of Interest for Mining 18

The Crown requires Grassy Narrows' consent for the Great Bear Gold Project 20

Far from seeking consent, Ontario has approved numerous permits for the Great Bear Gold Project with no notice to Grassy Narrows 23

Crown and Company efforts to engage Grassy Narrows since 2022 have been performative and do not meet the standards required for engagement 29

V. Adverse Impacts: ANA Preliminary Specific Concerns 30

Industrial disturbances will release even more mercury into our ecosystem and further impair our Treaty rights. 31

Adverse impacts on Grassy Narrows' Treaty Land Entitlement Claim. 33

On-site Impacts 34

Downstream / wind / migration impacts 34

Landscape impacts (e.g. intact forests) 35

Spiritual Impacts 36

Long-term risks – Tailings 38

Impacts to relationship with the Crown 39

Federally Regulated Impacts 40

Site-specific parameters and guidance levels needed 42
Other specific concerns 44
Failure to Effectively Regulate and Remediate 47
Lack of Protected Areas, Need for Regional Balance. 49
Nature Based Climate Change Solutions 49
VI. Mining activity without Grassy Narrows' consent risks conflict 50
VII. Gold does not justify the impact to Grassy Narrows 51
VIII. A Choice, an Opportunity 52

I. The Context

Who is Grassy Narrows

Asubpeeschoseewagong Anishinabek (Grassy Narrows First Nation) is an Anishinaabe First Nation with traditional territory in what is called northwestern Ontario. Grassy Narrows people exercise inherent Indigenous rights, and Aboriginal and Treaty rights. We have cared for and lived on our lands for countless generations. Grassy Narrows people hunt, trap, fish and practice our Anishinaabe way of life to provide for ourselves, our families and community.

We exercise our inherent right to self-determination and law-making powers. Our inherent rights are given to us by the Creator. In addition to our inherent rights, Grassy Narrows people exercise Aboriginal rights and established Treaty 3 rights which are protected by section 35 of the *Constitution Act, 1982*.

In 1873, the Anishinaabe adhered to Treaty 3. The Treaty 3 Commissioner promised the Anishinaabe that the Treaty promises would protect our harvesting practices forever, which would allow our people to hunt, fish, trap, gather, and harvest throughout the Territory as they had before "as long as the sun shone and the waters flowed." This promise was more than a continuation of our pre-existing harvesting rights. The Anishinaabe did not agree to the erosion of our harvesting rights.[1]

Our territory is located in the Boreal Shield ecoregion in a mixed forest transition zone from the Great Lakes St Lawrence Forest to the Boreal Forest. The Whiskey Jack Forest is the English name of the forest that covers a large portion of the Territory; the English-Wabigoon River System is a central waterway in the Territory. The land and waterways of the Territory sustain Grassy Narrows peoples' way of life.

Grassy Narrows' Territory is the foundation of who Grassy Narrows people are as Anishinaabe people. We follow the teachings of the Elders to be responsible for the Territory and to *Manaachitootaa Aki* (protect the land).

Social and Cultural Impacts of Crown Law and Policy.

Despite these sacred promises, for many generations the Crown has imposed harmful law and policy on us, including through the *Indian Act*, the banning of our ceremonies, regulation of our hunting and trapping, residential schools, regulation of the wild rice, relocation, the 60s scoop, the underfunding of our schools, inadequate health care, and the ongoing removal of our children from the community.

These policies have caused grave harm to our people and impaired the exercise of our rights. They have undermined our strong society and way of life and have left us more

---

[1] *Keewatin v Minister of Natural Resources*, 2011 ONSC 4801 [*Keewatin* ONSC], rev'd 2013 ONCA 1158, aff'd 2014 SCC 48 ["*Keewatin* litigation"].

vulnerable to the impacts of industry.

The Cumulative Effects of the Mercury Crisis and Industrial Activities Impacts.

Starting in at least 1962, a chlor-alkali plant in Dryden, Ontario, began discharging mercury into the English-Wabigoon River system. Approximately 9,000 kilograms of mercury were discharged into the river system that flows through our Territory and is a lifeline for Grassy Narrows people. Our live-giving river became a source of invisible poison.

The impacts of the mercury contamination have been devastating to the people of Grassy Narrows and our Territory. The presence of mercury led to the methylmercury contamination of the fish and Grassy Narrows people. The local commercial fishery shut down; Grassy Narrows' economy collapsed; Grassy Narrows people descended into poverty; Grassy Narrows people suffered, as they continue to do, from debilitating health symptoms and premature death; and our Anishinaabe way of life was gravely threatened and changed when we could no longer safely eat fish and exercise our fishing practices as we had before.

In the 1970s and 1980s, Grassy Narrows called on Ontario to respond to the mercury crisis by taking concrete action, including by agreeing that Grassy Narrows would control our Territory. As the river was poisoned, we wanted to have more control over our Territory and the natural resources in it to be able to protect and benefit from the part of our Territory that was still healthy – the land. Instead, Ontario authorized extensive clearcut logging in the Territory from roughly 1980 to 2008, which likely released new, or additional, sources of mercury into the watershed, and increased methyl mercury contamination of fish.

Multiple expert reports and publications have detailed the impacts of mercury contamination on the health of Grassy Narrows people, including the following, which are enclosed:

- 2015 Expert Report of Dr. Donna Mergler
- Grassy Narrows Community Health Assessment Summary Reports, 2018
- Philibert et. al. (2020), "Mercury exposure and premature mortality in the Grassy Narrows First Nation community: a retrospective longitudinal study", *The Lancet: Planetary Health* Vol. 4(4), E141-E148
- Philibert et. al. (2022), "Past mercury exposure and current symptoms of nervous system dysfunction in adults of a First Nation community (Canada)" *Environmental Health* 21:34.
- Mergler. D. et. al. (2023), "The Contribution across Three Generations of Mercury Exposure to Attempted Suicide among Children and Youth in Grassy Narrows First Nation, Canada: An Intergenerational Analysis" *Environmental Health Perspectives* 131(7).

These reports highlight the grave impacts of mercury on the health and wellbeing of

Grassy Narrows. They establish that Grassy Narrows people cannot withstand further impacts from the release of new mercury into Grassy Narrows' land, lakes, rivers, fish, and people, nor an increase in the net methylation of existing mercury. Our rights have already been highly compromised by the mercury crisis. Our nation cannot withstand further infringements of rights. No further impairment of our rights, our health, and our wellbeing can be justified.

Our fish in the Wabigoon River remain the most mercury contaminated in the province. Our people of all ages continue to suffer from mercury related diseases and loss of wellbeing. Our employment remains far below what it was in the 1960s following the collapse of our subsistence, sport, and commercial fishery due to mercury.

The mercury crisis is but one in a long series of industrial attacks which have been imposed on us against our will. These include the damming of our rivers, industrial logging, and mining activity. Each of these industrial attacks has had grave impacts on its own. In addition, each of these industrial attacks has compounded the existing harm that remains from previous attacks, creating unbearable cumulative impacts, thereby prolonging, and exacerbating our inter-generational crisis.

These extreme and compounding industrial impacts have been authorized and encouraged by the Crown without any serious consideration of their cumulative effects on Grassy Narrows and the exercise of Grassy Narrows' rights. We have raised clear concerns since at least the 1970s that our environment, rights, way of life, and our health, were at or beyond, the breaking point due to the impacts of industry on the resources on which we have heavily relied for our wellbeing, livelihood and the viability of our community. In the 1980s, and again in 2007, we declared moratoria on further industry on our Territory so that we could heal our people and rebuild our independence and wellness.

And yet, to this day, with respect to our Territory and vicinity, Ontario has failed to increase our control and use, failed to conduct a collaborative Landuse Plan; failed to complete a source water protection plan; failed to carry out a comprehensive environmental assessment; and failed to undertake an assessment of cumulative effects. The repeated failures of the Crown to act honourably to resolve the crisis have resulted in serious, compounding adverse impacts over time, including:

(1) Severe cumulative impacts on our territory and Treaty harvesting, hunting and fishing rights, making these rights impossible to exercise in a meaningful way;

(2) Severe adverse health effects and death, including, as found in recent scientific research, high rates of conditions impacting learning in children, disease, suicide attempts, and the premature death of our people; and

(3) Extreme poverty, food insecurity, loss of Anishinaabe way of life, and other poor socio-economic indicators of wellbeing which are ranked significantly worse than average Indigenous communities in Ontario and Canada.

(4) Collective impacts to our society and community.

Ontario ignored our pleas and our moratoria and continued to allow industrial activity, including the granting of mining claims on our Territory against our will, and advancement of mines all around us, without considering how mining activities add to, compound, exacerbate, and prolong previous harms. The cumulative impacts of industry have been devastating. The impacts include, but are not limited to:

- Our river that gives us life remains poisoned.
- Our walleye are unsafe to eat.
- Our sturgeon are rare.
- Our moose are scarce.
- Our caribou are nearly extirpated.
- Our pine marten habitat is depleted.
- Our forests are fragmented.
- Our medicines are tainted.
- Our sacred landscape is desecrated and scarred and traplines have been clear cut.
- Our way of life is diminished.
- Our people suffer from poverty, food insecurity, disease, premature death, and suicide.
- Our inherent, aboriginal, and treaty rights are impaired
- Our health has been harmed.
- We have been discriminated against.

II. Ongoing Breaches of Crown Obligations: The 1978 Memorandum of Understanding, Honour of the Crown, and Fiduciary Duty

Ontario and Canada (collectively, the "Crown") are our treaty partners. As elaborated below, through the treaty relationship and Crown actions over time, including entering into legal agreements following the start of the mercury crisis, the Crown assumed obligations and duties owing to Grassy Narrows. The Crown must uphold the treaty promises, uphold terms of its agreements, and act honourably in its dealings with Grassy Narrows.

Authorizing and permitting mining activities in our territory without our consent violates Ontario's and Canada's outstanding obligations and duties to Grassy Narrows and violates the Crown's duty to act honourably in all its dealings with Grassy Narrows.

1978 MOU and Dishonourable Conduct.

In 1978, Ontario and Canada signed a Memorandum of Understanding with Grassy Narrows in which the Crown committed to resolve in good faith the impacts of mercury on the environment that Grassy Narrows people rely upon for the viability of our community, and the related health, social, economic, cultural, and environmental impacts on the people of Grassy Narrows ("1978 MOU"). It was agreed that the issues would be resolved through a combination of financial compensation and land, and

furthermore in a manner that would enhance Grassy Narrows' self-determination, self-sufficiency, and control over local affairs wherever possible.

Some agreements were reached that partially implemented some of the 1978 commitments. For example, agreements were reach with Canada in 1984 and with Canada, Ontario and the mercury polluters in 1985.

However, the Crown has outstanding obligations owing under the 1978 MOU. These outstanding obligations include (but are not limited to) increasing Grassy Narrows' access to, protection of, and control over lands and natural resources in our Territory.

Moreover, the Crown has engaged in a course of dishonourable conduct before, during the negotiations, and since, and has consequently failed to meaningfully support Grassy Narrows' recovery from the mercury crisis.

The Crown's unmet fiduciary duties

The Crown and Grassy Narrows have a *sui generis* fiduciary relationship, and our treaty rights attract fiduciary obligations. In the time since the Crown and Grassy Narrows entered into a treaty relationship, the Crown seized functional management and control of our lands and water. The Crown assumed a duty to Grassy Narrows when exercising that control over our Indigenous interests including our pre-existing legal interests in exercising our fishing, hunting and trapping rights and other traditional practices such as medicine gathering and wild rice picking.

Grassy Narrows has been at the mercy of the exercise of Ontario's imposed fiduciary decision-making over our land as Ontario unilaterally authorized industrial activity, and otherwise has made decisions that affect the land, water and other natural resources of our area which we rely on to exercise our rights, practice our way of life, and maintain our health.

Under imposed Crown management and discretionary control, the health of our land and our people have seriously declined, our way of life has been degraded, and the exercise of our treaty rights has been impaired.

The Crown's abandonment of negotiations required by the 1978 MOU

From the outset of our discussions under the 1978 MOU, Grassy Narrows was clear that to recover from the impacts of mercury and other harms, we need Crown recognition of Grassy Narrows' ownership, control, and protection of a large part of Territory, which will allow Grassy Narrows to make decisions with respect to our land that support our way of life and our livelihood. In the 1970s, 1980s, and 1990s Ontario committed to negotiate increased Grassy Narrows control over our lands, in addition to providing meaningful compensation for our people.

In the 1980s, and since, we called for a moratorium on industrial activity in our Territory until our negotiations with Ontario were concluded. However, rather than honour this moratorium, the treaty promises, and the 1978 MOU obligations, Ontario unilaterally

abandoned the negotiations in the mid 1990s and exercised its imposed control in a way that further unleashed industry on our area to our detriment.

Ontario has repeatedly acted unilaterally to encumber and degrade our Territory against our will, including by granting industrial logging licenses and nearly 6,000 mining claims; industrially logging our forests; and constructing industrial access roads and bridges (e.g. The Separation Lake Road and bridge) to facilitate further resource extraction and environmental degradation. Canada has stood by and watched, allowing our lands, waters, rights, and way of life to be trampled.

The Crown's dishonourable conduct and abandonment of its fiduciary obligations continue. Ontario's Ministry of Mines has granted thousands of mining claims against our will, including granting mining exploration permits without any prior notice to us.

Ontario has failed to accurately identify the ANA Area of Interest on mining activities.

The Ontario Ministry of Mines has never meaningfully addressed the question of the extent of Grassy Narrows' area of interest with respect to mining.

In the 1980s, the Ontario Ministry of Natural Resources created its own map to identify a Grassy Narrows Traditional Land Use Area (the "1980s TLUA Map") for the purposes of mediated negotiations between Grassy Narrows and Ontario with respect to a section of the Territory required by Grassy Narrows to restore its economic self-sufficiency. The map used straight lines, which are not reflective of the boundaries of the full Territory and does not include the northern portion of the Territory.

Between 2008 and 2017 Grassy Narrows and Ontario engaged in discussions on forestry pursuant to the Grassy Narrows Ontario Process Agreement (the "Process Agreement"). As part of that process, Grassy Narrows submitted a map of the "Grassy Narrows area of interest for forestry", which included areas that are outside the 1980s TLUA Map boundaries.

When Grassy Narrows passed our Land Declaration in 2018, we shared a map of an area we have identified as the "Indigenous Protected and Conservation Area" (IPCA). The IPCA boundaries mirror part of the area of interest for forestry. The IPCA boundaries have always been provisional, as Grassy Narrows continues to engage in a process of reviewing the knowledge of our historical and current land use. In addition, the western notion of linear boundaries on maps conflicts with our Indigenous knowledge systems, which are based on relationships and complex webs of protection, use, kinship, sharing, travel and trade that do not begin and end at a line.

Shockingly, Ontario relied on the 1980s TLUA Map as the consultation area for mining, despite having knowledge that the map was not accurate.

Grassy Narrows is currently pursuing litigation challenging nine mining exploration permits (not related to the Great Bear Gold Project) that Ontario approved without

notice to Grassy Narrows.[2]

Among other relief, Grassy Narrows seeks the following remedies in the litigation:

> a declaration that Ontario cannot consider mining activities in the subject area of the Territory, including issuing exploration permits, until the parties negotiate and reach agreement on **timely enforceable mechanisms to assess and manage the cumulative impacts of mining, logging, hydro-electricity projects, other industrial development, mercury contamination, and governmental policies or programs that may infringe Grassy Narrows' treaty rights, and to ensure that these constitutional rights are respected**;

These mechanisms are not yet in place and the judicial review remains unresolved.

As further described below, Grassy Narrows has only very recently learned that the Ministry of MINES approved a number of permits for the Great Bear Gold mine with no notice to Grassy Narrows.

It is only in very recent times, and after much conflict, that Ontario has begun to ask Grassy Narrows about what our area of interest for mining is. After many years of advocacy by Grassy Narrows, Ontario's Minister responsible for mines finally responded on November 1, 2022 with a new map that Ontario proposed as the area for consultation on mining related activities.

Ontario's proposed consultation area on mining appeared to deliberately carve out the Great Bear Project Area. The information provided by Ontario to explain how they arrived at the proposed boundaries was cursory and insufficient for understanding how the boundaries were arrived at. Grassy Narrows informed the Ministry that their proposed map is not complete and requested capacity support to do the work necessary to respond. However, no support has been provided to date.

On November 2, 2023, Grassy Narrows provided two versions of a map setting out our Interim "Area of Interest" for mining. The maps differed in scale only. The map was provided with the following cautions:

- The maps are an interim product created under duress arising from the escalation of imposed mining activity by the Crown and industry and for the sole purpose of identifying an interim area for negotiations on mining related activity.

- The maps are not a complete representation of Grassy Narrows' area of interest. Due to the unique circumstances and capacity constraints, Grassy Narrows has not completed comprehensive studies required to fully determine its area of interest including, but not limited to, land use and occupancy, ethnohistory, archaeology, biology, and hydrology. For example, rights and interests

[2] Grassy Narrows First Nation v. Director of Exploration, Ministry of Northern Development, Mines, Natural Resources and Forestry, Ontario Divisional Court File No. 881/21.

associated with air quality, migratory birds, travel routes, marten, lake sturgeon, wolves, eastern cougar, landscape intactness, climate resilience, biodiversity, genetic diversity, and many other factors are not reflected in these maps.

- In addition, linear boundaries are an imposed non-Indigenous concept that do not accord with the nature of Grassy Narrows' relationship with the land which includes extensive interconnectedness, reciprocity, travel, sharing, and trade.

- These maps do not limit any claims by Grassy Narrows people to assert their rights and interests throughout their territory and to protect themselves from harm to their health, rights, way of life, livelihood, society, and environment. Grassy Narrows people have Treaty rights, and practice them, throughout the Treaty 3 area. Grassy Narrows people also have inalienable inherent rights given by the Creator, some of which are affirmed in international law and instruments. The Grassy Narrows people are the true experts about their land, rights, and interests.

<u>The Great Bear project area falls within the core area of Grassy Narrows' Interim Area of Interest for Mining map.</u>

Despite Grassy Narrows' efforts to further these negotiations, there is no agreed upon area for consultation on mining activities.

Sharing of information about our Homeland is a sensitive topic that requires deep trust. After so many decades of having our trust, our vulnerability, and our lands abused by Ontario, many of our knowledge holders do not consent to sharing sensitive lands information with Ontario. Trust must be rebuilt to meaningfully engage on this topic.

Grassy Narrows Laws Have Not Been Respected.

Neither the Crown nor the companies have formally acknowledged and respected Grassy Narrows' moratorium and Land Declaration. The Crown has not joined us to harmonize Crown law with Grassy Narrows law and to find a path forward towards reconciliation that provides space for Grassy Narrows' inherent Indigenous rights and constitutionally protected Aboriginal and treaty rights to be meaningfully realized and protected.

We have written many times to request that the Crown come to a senior negotiation table with Grassy Narrows to address the wrongs committed against our people, the effects of which continue to this day, and to prevent further damage. We call on Ontario to return to the mediation process first established in 1978 in response to the mercury disaster to finally reach an honourable agreement regarding the control and protection of our Territory and fair compensation for Grassy Narrows people.

Instead of coming to the table to honourably resolve outstanding issues and obligations, Ontario has unilaterally granted mining claims and permits and now is supporting the development of a gold mine in our headwaters.

III. The Crown Must Address Capacity Barriers

Grassy Narrows has repeatedly advised both the Crown and the Companies that it cannot meaningfully engage in negotiations while it faces significant and unique barriers.

1) Insufficient information: Upon learning of the Great Bear Gold project, Grassy Narrows immediately requested additional information about the project and the extent to which our Laws had been taken into account and its adverse impacts considered. This information is essential for us to understand and respond to any efforts at engagement. After a lengthy delay, the Ministry recently provided responses that can only be characterized as preliminary and partial.

2) Capacity funding: The process of evaluating proposed mining activities and engaging with MINES, the IAAC, and mining companies comes at an expense to ANA. We must hire staff, engage our community, carry out our governance process, and obtain professional support from experts, lawyers, and advisors to engage in a meaningful way.

Grassy Narrows is even more impoverished than our First Nation peers due to the ongoing impacts of mercury poisoning. We lack the funds required to engage in an informed and fair way.

During the summer of 2023, MINES staff indicated that, after many years of requests, MINES will fund some ANA capacity needs. We provided MINES with a document summarizing the kinds of capacity supports that we would need in order to meaningfully engage on mining, including compensation for staff and to hire experts. After many months of awaiting an update, on November 27, 2023 MINES clarified that its promises of capacity supports amount only to funding in an unspecified amount for a “Mineral Development Advisor”, a position that Grassy Narrows has never requested funding for.

No funding is currently in place. MINES must come to the table on our issues and commit to funding ANA’s reasonable costs of engaging in an informed and fair way.

While IAAC offered $5,000 in capacity funding to ANA, this funding was offered after the deadline for submissions on the List of Issues. The amount offered is insufficient to meaningfully review lengthy technical documents that engage many areas of expertise, to engage with our people, to carry out our governance process, and to prepare a response. This is the same on-size-fits-all funding offered to other First Nations, NGOs, and other ‘stakeholders’. It does not consider our unique circumstances nor our position as an Indigenous nation.

3) Pandemic Considerations: COVID-19 infection rates, as well as other respiratory illnesses in this region of Ontario are high again. Our people are especially vulnerable to disease because of our high pre-existing rates of co-morbidity, crowded and inadequate housing, inadequate nutrition due to food insecurity, and the immune impacts of mercury. The health of our people is our priority. We are informing you that, in addition to our other concerns, mining exploration proposals are unwelcome during outbreaks

and other public health emergencies.

4) Mercury Crisis and Industrial Impacts: Our territory has already experienced a great deal of harm from industrial activities including mercury, damming, industrial logging, and mining. The cumulative effects of these industrial impacts have already passed the point of an unreasonable, unjustifiable impact on the exercise of our Treaty rights, and on our health and wellbeing. As a result, our community suffers from unusually high rates of conditions including poverty, food insecurity, disease, neurological conditions, conditions affecting learning, premature death, and child and youth suicide. The social conditions created by mercury poisoning and the cumulative impacts of industry place us in an ongoing extreme crisis. As a result, we are unable to meaningfully engage on mining exploration in the absence of the necessary supports to resolve and recover from the ongoing mercury crisis.

5) Fundamental outstanding issues must be addressed before meaningful engagement can occur: As described above, many fundamental issues remain unresolved between Grassy Narrows and the Crown including unmet obligations, broken promises, conflicting laws, cumulative impacts, violated trust, justice owed, and outstanding reconciliation. These are upstream strategic issues to which individual mining projects are subsidiary. We cannot address one mining project meaningfully, when the fundamental questions are not addressed. These questions include:

- How will the Crown respect Grassy Narrows' inherent rights and rights recognized under international law and related instruments?
- How can the Treaty relationship between the Crown and Grassy Narrows be respected and restored?
- How can the written text of the Treaty be reconciled with the oral and written histories, and Ontario Superior Court findings, that the taking up clause and the cede and surrender clause were never discussed nor agreed to?
- Who has decision making authority over lands and resources in our area?
- How can Grassy Narrows law and Crown law be harmonized with respect to the land?
- What lands should be open to mining and what lands should be protected?
- How will the Crown's unmet obligations arising from the Treaty, the 1978 MOU, and other sources be fulfilled?
- How will Grassy Narrows' ownership, control, and use of our lands be increased as promised?
- How can the damage already done to our land and our water be restored?
- How can the harm to our sacred landscape, our spirituality, and our relations be repaired?
- How can we assess and prevent the cumulative impacts of industrial activity from further harming us?
- How can the collective damage to our society, our community, and our families be reversed?
- How can our health, our wellness and our way of life be returned to its former status?

- How can our self-determination, our independence, and our self-sufficiency be rebuilt?
- Is it possible to reconcile while the harm continues, while we bury our youth?

For many years we have been seeking to resolve important issues with the Crown that relate to mining. A summary list of some of these issues can be found at **APPENDIX A**.

The Crown apparently has little interest in these questions and little willingness to address them with us, to act honourably, nor even to come to the table with us about them. When we meet with senior officials from MINES and MNRF, they tell us that they have no mandate to discuss these issues, but they will bring them to the Minister.

After years of seeking a meeting with the Minister our then Chief and Council finally met with then MNDMNRF Minister Rickford in Toronto on November 18, 2021. At the long-awaited meeting Minister Rickford refused to discuss our mining concerns but promised to come to Grassy Narrows soon to discuss mining at an open forum in our community. Neither Minister Rickford nor his successors have honoured this promise.

In a largely analogous situation where Grassy Narrows and the Crown had a conflict over a different form or resource extraction, the 2004-2009 Whiskey Jack Independent Forest Audit found that:

> There are fundamental differences in the viewpoints between GNFN and MNR regarding forest management principles and practices. It is the audit team's opinion that these differences cannot be resolved without the Province setting aside many of the requirements to manage the Whiskey Jack Forest under the CFSA and the FMPM, and relinquishing significant authority to the First Nation to manage portions of the Whiskey Jack Forest according to the desires of the GNFN community. The audit team further believes that the forest management planning process did not anticipate, nor was it designed to resolve the type of dispute currently being experienced on the Whiskey Jack Forest.

Similarly, the *Mining Act* and its regulations and the IAAC regulations did not anticipate, nor were they designed to resolve the serious grievances, outstanding obligations, and the type of dispute currently being experienced over mining around Grassy Narrows. Resolving this dispute will require sincere, honourable, government-to-government engagement on the fundamental issues that have brought us to this point. Only once that occurs, can we meaningfully engage about specific permits and projects without repeating and exacerbating the legacy of past and ongoing harms.

IV. The Great Bear Gold Project: The Crown's failure to inform, meaningfully consult, and gain our consent for project activities.

The Great Bear Gold Project falls within Grassy Narrows' Interim Area of Interest for Mining

We have enclosed a copy of Grassy Narrows' map of our Interim Area of Interest for Mining, which is described above.

The limited preliminary research that we have been able to conduct confirms that the Great Bear Gold Project is within the area where Grassy Narrows people have historically, and continue to, practice our way of life and our Treaty rights.

There is strong ethno-historical evidence that Grassy Narrows has a longstanding connection to this area dating back to the time of the Treaty and before. This includes historical reports, fur trade records, ethnological work, and other records. Grassy Narrows First Nation historically hunted, fished, trapped, collected plants, gardened and conducted spiritual practices in and around the Red Lake fur trading routes, and traded products obtained in the area.

There are Grassy Narrows families with continuing family ties to this area and the surrounding areas. Grassy Narrows people, including the Chief, continue to practice our inherent and Treaty rights in this area, including the moose hunt. The moose hunt is extremely important to our way of life and sustenance. Due to the precipitous decline in moose elsewhere in our area, the area south of Red Lake is one of the only remaining productive moose hunting grounds that our people use.

The Great Bear Gold Project falls within moose, wolverine and caribou habitat that ranges within our IPCA. In addition, walleye within the project area migrate to the waterways on which Grassy Narrows exercises its treaty rights to fish and on which the community reliese for food. The project area is also within nearby quatermary watersheds that flow into the IPCA.

Grassy Narrows people fish extensively on the English River around Grassy Narrows. Grassy Narrows people also fish on the English River and its tributaries near the inflow of the Chukuni River. We are aware that the fish that we eat swim a distance of 30 km, or more, up and downstream in the course of their lifecycle and are exposed to, and bioaccumulate, toxins throughout their travels. In particular, our walleye travel long distances upstream in order to spawn.

Caribou are an important clan animal to Grassy Narrows and used to be seen throughout our Territory. The Great Bear Gold Project area is within the range of the Sydney Caribou herd, the last remaining herd in our Territory. This range is already degraded beyond the threshold at which it is able to sustain Caribou in the long term, unless its intactness is restored. All of the habitat within the range is considered critical.

As noted above and confirmed by the Supreme Court, the Treaty 3 Commissioner promised the Anishinaabe that the Treaty promises would protect our harvesting practices forever which would allow our people to hunt, fish, trap, gather, and harvest throughout the Territory as they had before “as long as the sun shone and the waters flowed”. The Anishinaabe did not agree to an increasing erosion of our harvesting rights that would significantly interfere with the exercise of our rights.[3]

---

[3] *Keewatin v Minister of Natural Resources*, 2011 ONSC 4801 [*Keewatin* ONSC], rev’d 2013 ONCA 1158, aff’d 2014 SCC 48 [“*Keewatin* litigation”].

Grassy Narrows has a communal connection, right, and interest in this area. It is possible that other First Nations do too, but that does not in any way diminish our own connection, rights and interests nor the Crown's obligations to us.

In addition, Grassy Narrows must be consulted on activities that may have off-site impacts on our territory, such as downstream, downwind, or migratory species impacts. Grassy Narrows continues to document the full extent of its Territory and the "ANA Preliminary Area of Interest With Respect to Mining" is without prejudice to the determination of the full geographical extent of Grassy Narrows' Territory.

The Crown requires Grassy Narrows' consent for the Great Bear Gold Project

The standard that correctly applies to this project is the right to say 'no', also known as the right to give or withhold "free prior and informed consent."

Under Grassy Narrows law, we are the first people of this land. The Creator gave us this land and only the Creator can take it away. We live in relationship with the land; we care for it and the land provides for us. We must take care of the land and not disrupt this balance. Nothing that threatens this balance may take place on the land without our permission. We say no to mining.

The United Nations has recognized this right in the *UN Declaration on the Rights of Indigenous Peoples* and in other international laws and instruments to which Canada is a signatory.

The *Declaration on the Rights of Indigenous Peoples* requires States to consult and cooperate in good faith with the indigenous peoples concerned through their own representative institutions in order to obtain their free, prior and informed consent before adopting and implementing legislative or administrative measures that may affect them (article 19). This includes:

- The adoption of legislation or administrative policies that affect indigenous peoples (article 19)
- The undertaking of projects that affect indigenous peoples' rights to land, territory and resources, including mining and other utilization or exploitation of resources (article 32).

The principle of free, prior and informed consent is linked to treaty norms, including the right to self-determination affirmed in common Article 1 of the International Human Rights Covenants. When affirming that the requirement flows from other rights, including the right to develop and maintain cultures, under article 27 of the International Covenant on Civil and Political Rights (ICCPR) and article 15 of the International Covenant on Economic Social and Cultural Rights (ICECSR), the treaty bodies have framed the requirement also in light of the right to self-determination.

Canada is bound by international law to these abide by these standards.

While Crown law has often failed to adequately implement international human rights standards, and often seeks to take a reductionist view of its international obligations to us, even under Crown law our consent is required for this project for reasons including, but not limited to:

a) The cumulative impacts of Crown policy and industry on our people already exceed any reasonable threshold of impact on our rights, our way of life, our people, and our environment. No further impacts can be made without consent.

b) The Companies' goal is to open a gold mine. A recent study demonstrated the extensive impacts of metal mining contamination on rivers and floodplains across the world, with an estimated 23 million people believed to be affected by potentially dangerous concentrations of toxic waste.[4] Gold mines have high risk of impact to our well established and strong rights, including our rights under Treaty #3. Our waters are already contaminated with mercury. Therefore, we are at the high end of the consultation spectrum where consent is required.

c) The "taking up" clause and the "cede and surrender" clause which the Crown relies on for its asserted legal authority were never explained, translated, discussed, nor agreed to, during the negotiation of Treaty #3. This is reflected consistently in the multiple, independent, written records of the Treaty negotiations. To the contrary, Treaty Commissioner Simon Dawson informed the legislature that "As an inducement to the Indians to sign the Treaty, the commissioners pointed out to them that, along with the land reserves and money payments, they would forever have the use of their fisheries. The point was strongly insisted upon and it had great weight with the Indians, who for some years previously had persistently refused to enter into any Treaty" (NA RG 10 vol 3800 file 48542, 28 May 1888). The Ontario Court of Justice found that the Indigenous signatories to Treaty 3 were not advised and did not understand that the Crown could authorize land uses inconsistent with Harvesting Rights and pass legislation to extinguish or limit Harvesting rights. They expected that Canada would protect their harvesting rights away from the Dawson Route or CPR right or way, not limit, extinguish or ignore them.[5] No court of appeal, including the Supreme Court of Canada has overturned this finding of fact.

Beyond the requirements under Grassy Narrows Law, International Law, and Crown Law to obtain consent in these circumstances, there is the simple practical requirement for consent in today's business, investment, and political environment.

The business case for obtaining consent is reflected in the mining industry's own trade association policies through the International Council on Mining & Metals (ICMM) position statement on Indigenous Peoples and Mining, which states that "[t]he outcome

---

[4] Phys.Org (September 21, 2023), "Global study reveals extensive impact of mining contamination on rivers and floodplains."

[5] Keewatin v. Minister of Natural Resources, 2011 ONSC 4801 (CanLII), at para 865, <https://canlii.ca/t/fmzc4#par865>, retrieved on 2023-09-23

is that Indigenous Peoples can give or withhold their consent to a project, through a process that strives to be consistent with their traditional decision-making processes while respecting internationally recognised human rights and is based on good faith negotiation."[6]

Even Barrick Gold, infamous for their violations of human rights internationally, stated in their $100M statement of claim against Red Lake Gold when addressing the need to for Grassy Narrows' consent that:

> Virtually all successful mining ventures in Canada require a strong and genuine working relationship with local communities, including First Nations. Without such a relationship, it can be extraordinarily difficult, if not impossible, to proceed with a mining venture beyond early stage exploration work and into development work (e.g., by constructing a working mine).
>
> Strong, genuine and reliable relationships with First Nations are built on mutual trust and respect. Any perceived or actual breach of that trust or respect can have devastating consequences for a mining venture or company, and these commercial and reputational consequences can extend well beyond any particular project or First Nation group.[7]

No large mine has opened in Canada for decades without Indigenous consent. It is simply too difficult and risky to carry out such an expensive and intensive project without all relevant First Nations on board.

As a First Nation living immediately downstream from this project, we will live with the consequences for many generations to come. It is our children who will drink the water, eat the fish, pick the wild rice, swim, and learn what it means to be *Asubpeeschoseewagong Anishinabek* on this river whose waters will carry the effluent from this gold mine if it is built. It is our people who will search in vain for moose and caribou to hunt on the landscape that has had its forests fragmented and degraded by access roads, clearcuts, seismic lines, pits, trenches, clearings, and mines. It is our people who will be impacted if the tailings dam fails. It is our people who will be poisoned if toxics leach into the water. It is our people whose fear and anxiety, already far to high and fatal due to the mercury crisis, will be heightened by the threat this mining project poses to our wellbeing.

We know, and everyone in Canada who has cared to learn our story knows, that decisions made and activities carried out upstream can have a devastating impact on us. The chlor-alkali plant in Dryden that discharged mercury into the Wabigoon River was 150 km upstream of our village. But the flow of the river does not obey any human boundaries. The distance did not stop the mercury from being carried downstream,

---

[6] International Council on Mining & Metals (May 16, 2013), "Indigenous Peoples and Mining: Position Statement".
[7] Barrick Statement of Claim against Red Lake Gold, 2022/23, p. 20, 21.

bioaccumulating in the fish that we eat, destroying our livelihood, poisoning our people, and dramatically disrupting our way of life. More than 50 years after the discharge of mercury was ordered halted, our mercury crisis rages on. There is no end in sight to the contamination of our river and to the intergenerational impacts of mercury.

The correct standard for this project, which threatens to impact Grassy Narrows' future for many generations, is consent. Grassy Narrows has not given its consent. Grassy Narrows says 'no'.

Far from seeking consent, Ontario has approved numerous permits for the Great Bear Gold Project with no notice to Grassy Narrows

With respect to the Great Bear Gold Project, there has been a failure to inform, to consult meaningfully with ANA and to gain our consent, even though the ANA village site is the first community downstream from the project site. In spite of the infamous pre-existing impacts on the English River and Grassy Narrows from hydro damming, mercury pollution, and clearcut logging, and Grassy Narrows' well knowns concerns about mining exploration. The fact that Grassy Narrows is downstream of this project, potentially impacted, and likely concerned should be evident to any diligent person with access to Google.

Exploration permits for this project date back to January 2017, including permits for extensive exploration work, drilling, stripping of the land, and taking of water. The following permits were authorized without notice to Grassy Narrows and, for the most part, prior to any communications from either the Crown or the companies with our First Nation:

- January 6, 2017: PR-16-10995 – permit for mineral exploration
- April 11, 2019: PR-18-000295 – permit for mineral exploration
- November 22, 2019: PR-19-000264 – permit for mineral exploration
- November 27, 2019: PR-19-000227 – permit for mineral exploration
- July 16, 2020: PR20-000178 – permit for mineral exploration
- October 13, 2020: PR20-000276 – permit for mineral exploration
- July 13, 2021: PR-21-000190 – permit for mineral exploration
- October 4, 2021: PR-21-000258 – permit for mineral exploration
- August 15, 2022: 5115-CJ9QRR – permit to take water
- September 15, 2022: Permit 5115-CJ9QRR to take water

The failure to take the minimal step of giving notice to Grassy Narrows about any of the above permits is all the more shocking because while this extensive work was being done on the Great Bear Gold Project, Grassy Narrows was writing to Ontario and to the companies seeking to share information and initiate negotiations about protection for Grassy Narrows' lands, waters, and people. Grassy Narrows has written to Ontario repeatedly about land protection concerns for decades, and most recently in a long series of official letters dating back to 2018 requesting a government-to-government table to resolve Lands issues including mining.

The history of communications between Grassy Narrows, Great Bear Resources, Kinross and Ontario's Ministry of Mines demonstrates that none of these parties have demonstrated a genuine intention to meaningfully engage with Grassy Narrows. This summary is current to December 15, 2023:

- **February 25, 2020:** Having learned about Great Bear Resource's presence in the area, but unaware of the permit applications and authorizations, Grassy Narrows Chief and Council wrote to Great Bear Resources to notify the Company about ANA's mining concerns and to ask if Great Bear Resources had any proposed work that would put Grassy Narrows at risk and conflict with our laws. There was no response. Indeed, Great Bear Resources has never responded to Grassy Narrows' communications.

- **October 1, 2020:** Upon learning of Kinross's presence in the area, Grassy Narrows Chief and Council wrote to Kinross Gold Corp. with a request to meet and a list of questions about their work.

- **October 6, 2020:** Chief and Council wrote to Great Bear Resources.

- **October 7, 2020:** Chief and Council wrote to follow up with Kinross.

- **November 2, 2020:** Kinross responded to acknowledge our letter but did not provide any substantive response to our questions, make any mention of the Great Bear Project, nor accept our request to meet. We did not hear from Kinross again for almost two years.

- **December, 2021:** Kinross reached an agreement with Great Bear Resources.

- **August 29, 2022:** Kinross sent a letter of introduction to our Chief.

- **September 15, 2022:** Less than three weeks later, Kinross submitted an exploration permit to Ontario claiming to have consulted with Aboriginal communities.

- **October 4, 2022:** Grassy Narrows wrote again to Great Bear Resources.

- **October 6, 2022:** Grassy Narrows received its first notice of an application for an exploration permit related to this project from Ontario (PR-22-000284). Ontario gave Grassy Narrows only one month to provide comment on the application.

- **November 18, 2022:** With no capacity, and in the midst of the COVID-19 pandemic, Grassy Narrows wrote back to advise Ontario that we intended to respond but could not do so substantively within the time provided.

- **November 24, 2022:** MINES notified Grassy Narrows that Kinross's application (PR-22-000284) had been approved with the exception of 44 claims that were

being held pending further comment from Grassy Narrows but offering no capacity supports.

- **December 28, 2022:** MINES notified Grassy Narrows of seven mining lease applications and advised that MINES would proceed if it did not receive comments by February 26, 2023.

- **January 19, 2023:** MINES notified Grassy Narrows that it was considering granting the mining permit for the 44 claims that had been held, pending comments from Grassy Narrows by February 3, 2023. Again, no capacity supports were offered.

- **February 6, 2023:** Grassy Narrows wrote to MINES to reiterate the barriers to participation that had been communicated over many years; in the absence of addressing those barriers Grassy Narrows cannot engage or comment substantively to the permit applications.

- **February 14, 2023:** MINES gives Grassy Narrows until February 28, 2023 to respond with comments.

- **February 27, 2023:** Grassy Narrows official writes to MINES indicating that Grassy Narrows does want to comment but that further time is required to review the information, and that the company has yet to respond to the questions that ANA has sent them.

- **March 3, 2023:** Grassy Narrows sent a follow up letter to MINES regarding the seven proposed mining leases and Grassy Narrows' requests for a government-to-government negotiation table.

- **March 10, 2023:** MINES wrote to Grassy Narrows to ask for a copy of the questions posed to the companies in 2020.

- **March 20, 2023:** Grassy Narrows wrote to Great Bear and Kinross to request a meeting about the Great Bear Gold Project in early April and for an answer to the questions posed to the company in 2020.

- **March 21, 2023:** MINES followed up on its request for a copy of the questions posed to the companies in 2020.

- **March 31, 2023:** Grassy Narrows followed up with Great Bear Resources and Kinross to request a meeting in early April and to obtain answers to the questions posed in 2020.

- **April 12, 2023:** Grassy Narrows repeated its request for a meeting with MINES and answer to questions concerning Great Bear Resources and Kinross.

- **April 24, 2023:** Kinross finally responds to the request to meet.

- **June 22, 2023:** Kinross attended an introductory meeting with Grassy Narrows. The meeting was not a consultation on the project. Kinross representatives stated that MINES would be providing answers to the questions posed in 2020. Grassy Narrows raised serious concerns about the project, including capacity constraints and concerns about impacts.

- **June 27, 2023:** Kinross wrote to confirm that MINES would be providing answers to the questions posed in 2020. MINES did in fact provide a partial and incomplete response to the questions posed in 2020. MINES gives Grassy Narrows two weeks to provide comment on the 44 outstanding claims.

- **July 12, 2023:** MINES gives Grassy Narrows a further extension to July 27, 2023.

- **July 24, 2023:** Kinross wrote to invite Grassy Narrows to a meeting to learn about the project and to advise that it was setting up a Sharepoint site to share information about the project. The Sharepoint link was not provided. Kinross further advised that the federal impact assessment process had been initiated.

- **July 28, 2023:** MINES wrote to advise Grassy Narrows that Ontario will not provide capacity support for consultation and asked for comments on the 44 claims by August 10, 2023.

- **August 11, 2023:** MINES approves the mining exploration permit for the 44 claims.

- **August 12, 2023:** Kinross provided a copy of Great Bear industrial Sewage Works documentation. Grassy Narrows does not have capacity to analyze or respond to this technical document.

- **September 7, 2023:** Kinross provided a copy of the Great Bear Advanced Exploration Reclamation Strategy for comment. Grassy Narrows does not have capacity to analyze or respond to this technical document.

- **September 13, 2023:** Chief Turtle writes to the IAAC to advise that Grassy Narrows has learned that Kinross and Great Bear have initiated the interim assessment process. Grassy Narrows was not provided notice in accordance with its protocols and demanded that the process recommence in accordance with procedural requirements.

- **September 14, 2023:** Grassy Narrows sent a follow up inquiry to the IAAC.

- **September 15, 2023:** IAAC provided a two-week extension to respond to Kinross's Initial Project Description.

- **September 20, 2023:** Grassy Narrows responded to IAAC by reiterating that the IAAC had not complied with procedural requirements for the pre-planning stage and repeating its demand to recommence the process.

- **September 26, 2023:** Kinross wrote to Grassy Narrows to request a meeting to discuss capacity funding.

- **September 28, 2023:** Kinross wrote to Grassy Narrows to provide two technical documents for comment (AEX Industrial Sewage Application and Aquatics Monitoring Plan; AEX ECA Air and Noise, Emissions Modelling and Dust Management). Kinross offered to meet and provide capacity support.

- **October 4, 2023:** Kinross wrote to Grassy Narrows about a draft permit to take water application.

- **October 6, 2023:** Grassy Narrows Lands Protection Team was given access to the Great Bear Sharepoint site, with extensive technical documents that were not shared previously. IAAC also provided its Summary of Issues for comment and offered to meet.

- **October 20, 2023:** Kinross provided its groundwater monitoring plan for the project and its preliminary mine rock management and monitoring plan.

- **November 3, 2023:** Kinross provided its draft closure plan for comment.

- **November 10, 2023:** Kinross provided its Detailed Project Description for comment. Grassy Narrows met with Kinross and IAAC. Grassy Narrows asked Kinross to pause the impact assessment process until an engagement protocol could be put in place along with capacity supports.

- **November 14, 2023:** Ontario wrote to Grassy Narrows with belated notice that in or around April 2023 it had delegated the “procedural” aspects of consultation on certain matters relating to the Great Bear Gold Project to Great Bear Resources. Ontario’s letter to this effect dated April 6, 2023 was sent to the Chief and not pursuant to Grassy Narrows consultation protocols. Ontario takes the position that the duty to consult is at the “low end” of the spectrum.”

- **November 20, 2023:** Kinross wrote to Grassy Narrows concerning participation in a Stage 3 Archaeological Assessment.

- **December 15, 2023:** Kinross meets with Grassy Narrows and refuses to pause its activities for any length of time to accommodate Grassy Narrows’ unique circumstances.

As the foregoing chronology demonstrates, the companies and Crown left Grassy Narrows in the dark for years about the Great Bear Gold Project. Since September 2023, Grassy Narrows has been flooded with technical documents, belated offers of capacity support, none of which has flowed, and impossible deadlines for engagement.

Kinross spent billions to buy the project and has clearly already decided to build a gold mine regardless of Grassy Narrows' wishes. Failing to engage with Grassy Narrows on this project for more than four and half years was not an error of omission, but rather a deliberate decision not to engage, and to withhold, information about this project from Grassy Narrows. The fact that other First Nations, who are located far upstream of the project, but who have a reputation for welcoming mining activity, were engaged far earlier (as early as 2017), raises the question of whether a decision was made not to engage Grassy Narrows because of Grassy Narrows' well-known concerns about mining exploration.

It took Ontario and the companies nearly three and half years to provide initial responses to questions posed by Grassy Narrows to Great Bear Resources in February of 2020. And yet, within 60 days of providing those initial responses, without providing any capacity support to review them, and without addressing Grassy Narrows' many other barriers and fundamental issues, the Ministry approved further work on the project in spite of Grassy Narrows' request for capacity support and time.

Even Indigenous Services Canada flagged concern about Kinross's level of engagement to date with Grassy Narrows in its comment to the IAAC:

> The perception of contamination to the land, water, traditional food sources and Indigenous Peoples by industrial development may be a serious concern for the identified Indigenous Nations, especially for Grassy Narrows ... During the late 1990s and early 1970s, the English-Wabigoon River system was contaminated with inorganic mercury from a pulp mill located upstream in Dryden, Ontario. This discharge of inorganic mercury contaminated their water and traditional food sources (i.e. fish) and lead to cases of mercury poisoning and intergenerational challenges. The proponent, Kinross Gold Corporation, started engaging with Grassy Narrows First Nation in 2022, whereas their engagements with Wabuskang First Nation and Lac Seul First Nation began in 2017. Due to Grassy Narrows First Nation's negative and detrimental experience with industrial development, it is recommended that more engagement take place. The Indigenous Nations need to gain a greater understanding of the contaminants that may be released into the environment. They should be provided an opportunity to express concerns or uncertainties about potential exposure to chemicals used in the gold mining process, such as cyanide and heavy metals.[8]

Given this history, including the Crown's outstanding obligations to Grassy Narrows, it is highly inappropriate for Ontario to delegate any aspect of consultation to Great Bear

[8] Indigenous Services Canada, Federal Authority Advice Record – Great Bear Gold Project, p. 5.

Resources. Grassy Narrows does not agree that the Crown can delegate its duty to consult with a treaty nation to a third party. Nor does Grassy Narrows agree, given Grassy Narrows' strong rights, existing cumulative impacts, and the companies' intention to open large gold mines upstream from the community, that the duty is at the low end of the spectrum.

The IAAC has failed to consult as required with Grassy Narrows

According to the attached IAAC document summarizing the impact assessment process, the process begins with Phase 0 (Pre-Planning), a phase that requires engagement by both the Proponent and the Agency with Indigenous groups. None of the required pre-planning steps with respect to Grassy Narrows have been complied with.

The Proponent was required to engage Grassy Narrows to present the project, learn Grassy Narrows' views, including potential effects and how we wish to be engaged and to incorporate this information into the Initial Project Description. Grassy Narrows has expressed, both in writing and in meetings on June 22, 2023, and November 10, 2023 with representatives from Kinross, our significant concerns about potential impacts upon our community, which are not reflected in the Initial Project Description. Grassy Narrows also provided Kinross with our communications protocol, which includes communication with the Lands Protection Team. That protocol was not included in the Initial Project Description.

The Agency was aware, based on the Initial Project Description, that Grassy Narrows may be affected by the project. In the pre-planning phase, the Agency was required to inform Grassy Narrows about the impact assessment process to support us in understanding how we can participate. The Agency was obligated to learn Grassy Narrows' views and context, including potential effects and how we wish to be engaged. The Agency did not comply with these requirements of the pre-planning stage.

Crown and Company efforts to engage Grassy Narrows since 2022 have been performative and do not meet the standards required for engagement

The decisions to open our land to mineral staking and exploration, to carry out extensive exploration, and to build a gold mine, have already been made, and billions of dollars spent towards that end, all behind Grassy Narrows' back. In this context, it is hard to believe that requests for belated input at this late stage are sincere. Clearly, the companies and Ontario have already decided to build a gold mine if investors will support it and we are an afterthought.

Kinross is now flooding us with technical documents created by highly paid experts, while knowing that we have no capacity support to engage experts to review the technical documents, nor to engage our community about them. When we sought a pause in the process to gain capacity support, retain experts, complete a process agreement, and engage in our governance process, we are refused. In this context it is hard to believe that anything Grassy Narrows says will be taken seriously and will have

the potential to meaningfully influence the major decisions that have been made.

We live downstream, our established rights and our health are at stake, and we are concerned. Under Crown law the Crown clearly had a duty to meaningfully consult and meaningfully accommodate us at every stage of this project, including during the strategic level upstream decisions (such as land use planning, land use designation, tenure, etc.) as well as the more minor decisions which flow from them (such as specific exploration permits, water takings, leases, etc.). As a First Nation whose Treaty rights and health have already been severely impacted by the cumulative impacts of industry and government decisions our consent is required. Under our inherent rights, Anishaabe law, and International law our consent is also required.

Ontario has failed for many years in their duty to consult on this project and we call for an immediate freeze on all project activities until sufficient capacity support has been provided to allow Grassy Narrows to complete an ethno-historical report, land use and occupancy study, archaeological assessment of the area and study into cumulative impacts, and until we have been meaningfully engaged and our free, prior and informed consent obtained.

V. Adverse Impacts: ANA Preliminary Specific Concerns

As Asubpeeschoseewagong Anishinabek we have a holistic, interconnected, and spiritual relationship to our sacred landscape. We are the land and the land is us. What happens to the land happens to us and to our children for many generations.

This is an area where our ancestors have practiced, and we currently practice our Anishinaabe way of life; a way of life that relies on a healthy environment and is central to our identity, health, wellness, and livelihood. This area is part of the whole that forms the sacred landscape which gives us life and which we are in relationship within every aspect of our lives, hearts, spirits, and dreams.

While some areas may appear to an outside observer to be on the periphery of our Territory, this is a grave misperception. All our territory is core to our way of life and connection to the land. For example, we have always traveled to hunt. A moose that is harvested a few days' travel from our village site will still feed a family for many weeks and be shared with Elders, relatives, and friends. The dramatic decline in the moose population near our village means that the area around Red Lake is even more critical to our moose hunt. These areas are deeply embedded in our memories, our lives, and our hearts. We are strongly tied to this land.

We know that MINES, IAAC and the companies do not respect this relationship and seek to reduce it to a series of finite, bounded sites of 'values'. Our concerns are disregarded unless they are expressed in extremely specific and reductionist terms that ties adverse impacts to particular pieces of the land that are viewed in isolation from the whole. MINES and IAAC want us to engage in an exercise of, for example, identifying a specific hole that is a specific distance from a specific cabin and thus should be moved a bit to the west. Or, this type of machinery produces noise that will make hunting

difficult in this specific blind during this month, so please do not use it in October. Or, this wastewater discharge site is next to that fishing hole, so please put it a bit further downstream.

This approach fails to see the forest for the trees. What use is a remote cabin retreat without the serenity of the surrounding area from which we draw our physical and spiritual sustenance? How can we use it for healing and to teach our children their way of life while over the ridge heavy machinery encroaches ever closer and non-native users buzz around us in ATVs and motorboats? What use is a hunting site if the ancestral moose trails have been destroyed, there is no winter refuge, and unmanaged access routes have allowed non-native hunters to deplete the population precipitously? What use is a fishing spot if the fish has absorbed a dangerous burden of toxins from its food sources everywhere it swims throughout its life, including those carried from upstream? How can we carry out our ceremonies when the spirits who live in the rocks have been disturbed by drilling and blasting. What point is there in commenting on a small drill program in isolation, when everyone knows that your plan is to open a huge open pit and underground gold mine?

In spite of this fundamental difference in world view, the barriers, unresolved fundamental issues, and concerns noted above, we know that MINES, the Companies and IAAC will try to proceed with this project unless we raise specific concerns. In the absence of the necessary supports, Grassy Narrows cannot substantively respond to the technical information provided to date about the Great Bear Gold Project. We provide these preliminary concerns under protest and based upon the limited research we can undertake, which should not be taken as a complete overview of our concerns.

Industrial disturbances will release even more mercury into our ecosystem and further impair our Treaty rights.

The Great Bear Gold Project will require industrial mining exploration, access roads, clearing of trees, modification to water levels and other activity within the English River watershed. The waters from those areas flow into the English River in short order via the Chukuni River. They flow into the areas where we fish, boat, camp, and practice our way of life, and directly past our community.

The scientific literature establishes that industrial activity in the boreal forest releases mercury into local lakes and rivers.

Building machine tracks, trails, and roads is a common part of mining exploration and mine development work. However, simply driving heavy machinery through the boreal forest can contribute to the release of mercury. In one documented instance, a temporary machine track was inadvertently placed across a small, long-term reference catchment. This disturbance increased outputs of MeHg by a factor of over five for more than a decade.[9]

[9] J. Munthe and H. Hultberg (2004), “Mercury and Methylmercury in Runoff from a Forested Catchment -

Clearing the forest has also been found to release mercury into local water bodies where it bioaccumulates in fish to dangerous levels. The foremost study on this subject was completed in Quebec by Dr. Carignan. The study found that 100% of lakes with clearcut watersheds had walleye and pike with mercury levels that exceeded the World Health Organization advisory limit for human consumption. Meanwhile, only 18% of unlogged lakes, and only one burned lake exceeded the limit.[10]

In the only field study on the topic done by Ontario of which we are aware, there was roughly a doubling of mercury exported from a watershed near Thunder Bay via a stream after logging activity. This release of mercury occurred even though all the required regulatory measures, including those with respect to riparian buffers, were followed.

Despite these findings, Ontario does no downstream monitoring of actual industrial operations to monitor or assess mercury impacts.[11]

Both the Carignan and Ontario studies concluded that that the increase in mercury export is largely due to changes in local watershed level hydrology from the loss of tree cover. Mining exploration and mining activity also involve the clearing of trees from the land and risk similar impacts to local hydrology (e.g., Lower evapotranspiration rates, changes to snow and rain interception, etc.) and therefore leads to similar increases in mercury export to local logging.

Mining exploration and mining activities often have the effect of artificially changing water levels. This can happen through water takings, water discharges, dewatering of areas, and other industrial processes. Studies have found that the artificial lowering and raising of water levels in boreal water bodies often causes the release of mercury. Monitoring studies of the De Beers Victor Diamond Mine have found increased levels of mercury in fish in water bodies downstream.

For a more detailed discussion of the science on mercury and boreal forest clearing please refer to our enclosed evidentiary record filed with the Divisional Court in our 2015 Judicial Review Application, and the associated expert reports by Dr. Carignan, Dr. Podur, Dr. Mergler, and Dr. Willow.

Mining exploration and mining activities also risk altering water quality in ways that increase the methylation of existing mercury in downstream watersheds. This can be through the addition of sulfate, change in acidity, water colour, temperature, and other parameters. In Grassy Narrows, where mercury levels are already elevated by emissions from Dryden, any increase in net methylation is intolerable.

Concentrations, Fluxes, and Their Response to Manipulations", Vol. 4 at 607-618.

[10] Globe and Mail (March 12, 2001), "Mercury levels tied to logging practices."

[11] Toronto Star (September 14, 2016), "Ontario environment officials concerned that clear-cut logging releases mercury."

The Crown still has no remediation plan for the mercury that remains in the English-Wabigoon River system from discharges in the 1960s and 1970s. Mercury released into the watershed or methylated as a result of mining activity, especially dissolved mercury, will eventually find its way into the English River and further raise the mercury levels in fish and poison our people, exacerbating and prolonging our mercury crisis.

This is not acceptable. We cannot tolerate any additional mercury.

New releases of mercury or increased methylation will unjustifiably impair Grassy Narrows' treaty rights, health and wellbeing, and are discriminatory. This is an intolerable outcome for our treaty partner to impose on us against our will in the absence of consent.

Adverse impacts on Grassy Narrows' Treaty Land Entitlement Claim.

Grassy Narrows has an active Treaty Land Entitlement Claim (TLE) that has been accepted by the Crown and is under negotiation for resolution. Part of the resolution of the claim will include an addition to Grassy Narrows' reserve lands, and compensation for lost use. Grassy Narrows is currently engaged in a process to select its additional reserve lands. All the area around Grassy Narrows is currently potential reserve lands additions under consideration.

The Crown has asserted that lands which have encumbrances, such as mining claims and leases, will be more challenging to designate as additional reserve lands. This means that your mining claims and leases adversely impact our ability to select reserve land additions and are an impediment to the successful resolution of our TLE.

Further, lands which have been impacted by mining exploration such as cutting lines, pitting, trenching, stripping, and drilling, decline in ecological health, experience a degradation of their intactness, and therefore become less suitable as additional reserve lands.

Lands which are downstream of industrial projects also have their value, and suitability as additional reserve lands degraded. Lands along the shores of the English River and its tributaries have been core to our people for countless generations and are prime candidates for our reserve lands additions. If you were selecting lands for your home, your cottage, or your reserve, would you want a huge industrial gold mine to be opened up stream of them? No one would.

Over the last few decades vast parts of our Territory have been encumbered and degraded through industrial actions imposed on Grassy Narrows and upstream of Grassy Narrows. This has severely restricted the available suitable additional reserve lands.

Grassy Narrows has been clear that there should be no new encumbrances on our area, and no new degradation to our area (including from upstream), as this would unfairly further reduce the available suitable additional reserve lands (in addition to other impacts outlined elsewhere). This would impair the ability to correct the injustice

that was done to us by having been denied a fairly sized reserve for over a century.

On-site Impacts

According to the Ontario Auditor General "Mining activities can have a significant impact on the surrounding environment. They can affect groundwater and surface water, aquatic life, soil, vegetation, wildlife and air quality. The changes mining makes to the environment can have serious implications for public safety and health."[12]

While we are unable to meaningfully review the thousands of pages of technical documents that have been sent to us, it appears that the on-site impacts of the project will be extreme.

Large parts of the site will be deforested for decades at least. Three open pit mines will be created along with three underground mines, large tailings holding areas will be created, and a large ore processing facility will be built.

The project area will effectively be completely removed for the foreseeable future from the land base that is accessible to us to live our way of life and to practice our rights.

It also appears that water bodies including lakes and creeks on the site will be at extremely risk because they will be located immediately adjacent to and downstream / downgradient of heavy industrial operations including mining, ore processing, and tailings storage. We are concerned that the on-site water bodies will be damaged and we know that once they are damaged it can be hundreds, if not thousands of years before they are safe again.

Downstream / wind / migration impacts

We know far too well that industry can have impacts far beyond the industrial site itself. The chlor-alkali plant in Dryden that discharged mercury into the Wabigoon River was 150 km upstream of our village. The distance did not stop the mercury from being carried downstream, bioaccumulating in the fish that we eat, destroying our livelihood, poisoning our people, and dramatically disrupting our way of life. More than 50 years after the discharge of mercury was ordered halted, our mercury crisis rages on.

We fear that the impacts from the Great Bear Gold Project site will extend far beyond the mine site itself, further disrupting the balance of the environment that the Creator has established for us and which gives us what we need for a good life.

Impacts from industrial sites can propagate off site in many far-reaching ways and we cannot list them all here. Pollutants can be carried hundreds of kilometers downstream. Water quality changes that may appear innocuous in themselves, and which are not regulated, can alter the cycling of pollutants, nutrients, and other aquatic processes in damaging ways. For example, dissolved organic carbon (DOC), sulphate, and other

---

[12] Auditor General of Ontario (2015), "2015 Annual Report: chapter 3.11: Mines and Minerals Program."

substances are a naturally occurring part of aquatic ecosystems and are not considered toxic. However, they known to play a strong role in mercury cycling affecting mercury speciation, solubility, mobility, and toxicity in the aquatic environment. Alteration of water chemistry can have serious consequences.

The wind can carry pollutants and other chemicals long distances before they are breathed by our people and deposited on the ground and in the water. For example, PCBs generated in the industrial centers can be deposited in the arctic and bioaccumulate to levels that are dangerous for subsistence consumers. Acid rain created by the Sudbury mines killed hundreds of lakes for scores of kilometers downstream and the area has yet to fully recover many decades later. We fear that the operation of the mine, including heavy machinery, blasting, and ore processing, will create airborne pollution and changes that can be carried long distances throughout our Territory and beyond, and will compound the existing impacts of other sources of airborne pollution including the Dryden and Kenora mills, other mines, and municipalities.

Off-site impacts can also happen through animals, fish, and birds and other forms of life that travel. If moose can no long find winter refuge on the project site, or if roads, trails and clearings created associated with the project increase access and success for non-native hunters and predators, then fewer moose will be available to hunt. That impact will not be restricted to the boundary of the project site but will extend as far as a moose would range from the project site, or conversely the area from which moose would range into the project site and face predation, hunting, and lack of suitable habitat.

Other animals like wolverine, wolf, bear and cougar travel even further distances. Impacts to their populations, their travel routes, and their hunting success in turn influence the populations of the moose, caribou, rabbits, and other animals that are important to us.

We know that walleye travel large distances throughout their lifespan, especially when they are spawning. Throughout their travels they breath the water, eat the local food sources, and are exposed to local toxins. Many of these toxins stay in the walleye for a very long time and accumulate throughout their lifespan, which can be decades long. As a result, walleye that are not at the project site, nor even within a downstream area impacted by the project site, may migrate into impacted areas and accumulate toxins which we are exposed to when we eat them. In turn, otters, eagles, pelicans and other beings eat the fish and then travel further distances, carrying the toxins with them.

Landscape impacts (e.g. intact forests)

Beyond the on-site and off-site impacts, the project will have landscape-level impacts. Looking at each site in isolation fails to see that the landscape as a whole and its many processes and functions that sustain life. The many parts of the landscape work together, each playing their part. If one is disturbed, then all are disturbed. If too many are disturbed, then the landscape's ability to sustain our good Anishinaabe way of life can be severely undermined.

For example, intact forest landscapes “are critical for stabilizing terrestrial carbon storage, harboring biodiversity, regulating hydrological regimes, and providing other ecosystem functions.”[13] Many species rely on intact forests. For example, the Government of Canada believes that once a landscape exceeds 35% disturbance it crosses a threshold beyond which the landscape becomes unable to reliably sustain a population of woodland caribou and extirpation becomes likely.

Indeed, this is what we experienced in the southern part our Territory where no single project alone caused the local extinction of caribou, but rather it was a death of a thousand cuts as more and more impacts over time made the landscape unable to sustain caribou. We know that the landscape in the range of the Sydney Caribou herd already exceeds this disturbance threshold and is need of recovery. The Gold Bear Gold project will add further disturbance, making the local extinction of caribou even more likely.

Caribou are a sentinel species whose fate is an indicator of the health of the landscape and a range of species and values that rely on intact forests.

Although they behave very differently, moose also rely on a healthy landscape. When there is too much industry, the dense mature conifer forests that moose require for winter shelter become too small, fragmented, and scattered to support moose. When too may roads are put in, outside hunters gain easier access, and when clearings are made those hunters have higher kill rates. When the forest becomes too disturbed, the deer move in, and with them comes sicknesses that hurt the moose.

Again, no one project alone can be blamed for the loss of our moose. But taken together the many industrial changes to our landscape have led to the near elimination of our once healthy moose population.

In spite of our many requests, Ontario refuses to work with us to plan at a landscape level to ensure that our health and way of life can be maintained and recovered. Instead, Ontario allows more and more disturbances to compound each other, further and further degrading the landscape that we rely on. The Great Bear Gold project will further undermine the forest landscape.

Spiritual Impacts

Spiritual impacts are a sensitive topic because it involves some of our deepest and most personal aspects of our selves. It is also sensitive and difficult to share because, not long ago, our spiritual practices were outlawed and we suffered persecution for them. To this day our spirituality is mis-represented, misunderstood, and disrespected by government and industry. For these reasons, this information is only the tip of the iceberg pointing to the presence of a deep and far larger concern.

Our people believe that may aspects of a human being are important to health,

---

[13] Intact Forests, “Intact Forest Landscapes”.

wellness, and the good way of life. A critical aspect is spirituality. The landscape and our way of life are connected and sacred. We have a spiritual relationship of reciprocity with the landscape that requires us to take care of the land so that the land can continue to provide for us. This is a sacred responsibility given to us by the Creator.

Our sacred relationship and responsibility is with the landscape as a whole, and with all of its parts. It is not restricted to a finite set of point values such as ceremony sites, burial sites, and medicine patches. Although those are important, they are focal points in a far broader and all-encompassing spiritual fabric. Our spirituality emanates from, and is infused by the entire landscape. It is practiced throughout the landscape and supported by the entire landscape.

Without the spiritual landscape intact, the spiritual sites are desecrated and cannot function. The medicines do not work if they grow in a clearcut, or if herbicides and pollution have drifted on the wind towards them. How can the ceremony summon a spirit who has fled from the noise of machinery and blasting? How can an offering be made to a spirit-being whose trails and territory have been destroyed? How can the prayer for the success of our hunters be answered when our industrially transformed landscape is nearly empty of moose? How can we fulfill our responsibilities to our clan animals Atik (woodland caribou) and Numeh (sturgeon) when they are extirpated or at risk in much of our Territory? How can we fulfill our duties and ceremonies to the water when it has been polluted, dammed, and an invisible remains within it? How can we identify our grave sites when our people have been laid to rest throughout this land for countless generations?

In addition to our broader sacred relationship with the landscape, there are spirit beings who inhabit the landscape and who have relationships with the Anishinaabe and important roles in the landscape. We have duties to carry out in our relationships with these beings and if we do not fulfill our duties there can be negative repercussions. Some of these important spirit beings live in the rocks. When the are disturbed, hammered, drilled, bulldozed, blasted, or extracted, these spirit beings are impacted, and the spiritual realm is disrupted.

Past government policies and industrial activities have already deeply disrupted our spirituality and the spiritual dimensions of our way of life and wellness. If the Great Bear gold mine, and associated work, goes ahead, then it will have a further intense spiritual impact.

Spiritual impacts lead to bad things for our people. When we cannot fulfill our sacred duties it causes feelings of sadness, anxiety, loss of identity, loss of meaning, depression, and helplessness. When the spiritual realm and relationships are disrupted, it can cause fear, accidents, discord, conflict, bad harvest, unsuccessful hunts, drought, floods, hunger, ill health, and other terrible things.

We understand that the government and industry have a different way of seeing things, and that you see the natural world as separate from you, inanimate, spiritless, and there for the taking. We know that you always tell us that you know best and that the industrial

activities you plan will only cause minor, contained, short term impacts and that we need not worry. And yet, we are suffering from all the terrible consequences that our ancestors warned us would come from your industry and your violation of our spiritual landscape including illness, poverty, hunger, depression, suicide, and conflict.

Our way of understanding the world deserves respect. It is not right for you to force your worldview and all its impacts on us while we suffer the consequences.

Long-term risks – Tailings

We are particularly and deeply concerned by the long-term nature of the changes that you are making to the landscape and the risks that you are creating.

On August 13, 1970, a few months after closing the fisheries due to mercury pollution, the Ontario Minister of the Environment, George Kerr, declared that the Wabigoon River would recover on its own, without a cleanup or intervention. He said it would happen naturally in 12 weeks.[14] More than five decades later, our walleye in the Wabigoon River remain the most mercury contaminated in all of Ontario and it is unsafe to eat even one meal. Recent studies indicate that it will take many hundreds, if not thousands, of years for river sediment to recover on its own. Many sites are not recovering at all, and some are getting worse.

Some of the long-term risks that you are proposing to create include the creation of huge piles of waste rock that contains acid, heavy metals, the creation of new lakes in former open pit mines and tunnelling deep underground. These activities create long-term risks of leaching, groundwater contamination, dam failure, cave ins and falls, among many other things. We know that the impacts of industry can last many generations and for thousands of years.

And yet, our Treaty is only 150 years old. In that time the Crown has shown little ability to plan for the long term in a way that is not disastrous for us. How can we believe that the risks that you are creating will be safely taken care of for longer than Canada has existed as country, for longer than the time that Europeans have been in contact with us? How can we know that Canada, Ontario, Kinross, or Great Bear Resources will even exist in the timeframe that these risks will exist, let alone fulfil your responsibilities to take care of these risks in a way that you never have before?

You say that you will contain, monitor, and prevent these risks from impacting us, our water, and our landscape. But Ontario's own Auditor General has repeatedly found a failure to effectively remediate and monitor mining risks (see the section on failure to regulate below). Senior officials in the provincial government have noted the urgent and dangerous gaps in Ontario's regulatory ability to ensure the safety of tailings dams. You cannot safely carry out these duties now. Who will maintain the tailings dams in 100

[14] The Guardian (October 16, 2018), "The Warrior Society rises: how a mercury spill in Canada inspired a movement."

years? Who will monitor in 200 years?

We, the people living downstream, do not accept these risks.

Impacts to relationship with the Crown

The Great Bear Gold project is a massive one, with great risks to Grassy Narrows and that can have a major impact on many aspects of Grassy Narrows' relationship with the Crown including our Treaty, the honour of the Crown, fiduciary duties, outstanding obligations, unmet duties, and reconciliation.

Yet, the Crown refuses to come to the table with us about the major issues from which all these problems flows. At the same time, Ontario is attempting to delegate nearly all aspects of our relationship with the Crown to a gold mining company that is not party to our Treaty and that is primarily accountable to creating profits for its shareholders. A gold mining company has no ability to address our important issues with the Crown. We do not accept a gold mining company stepping into the shoes of our Treaty partner.

Adding insult to injury, Ontario has informed the company that the duty to consult on this project is at the low end of the spectrum. This is incorrect. For many reasons, even under Crown law, we are at the high end of the spectrum where consent is required. The reasons include but are not limited to the significant potential adverse impacts of the proposed project on our rights and health, the strength of our rights, the cumulative impacts of past industry, the outstanding Crown obligations and unmet duties towards us, the honour of the Crown, and fiduciary duties.

The failures of the Crown have led to a situation where we have been notified of this project only after the land was designated as "general use" and open to mineral exploration, after cumulative impacts of industry had been allowed to severely impact our rights and our health, after mining claims to the land were registered, after five years of exploration work had taken place, after over a billion dollars had been spent to purchase the property, and after the company had decided to open up a huge gold mine here.

The Great Bear Gold project is a runaway train, and we have no meaningful opportunity to shape decisions that will forever impact our people and our land. These decisions include: determining what parts of the landscape should be protected and what should be exploited; the threshold for industrial impacts that can occur before our rights are infringed and our health is harmed; the process for making decisions among Treaty partners; the role of third parties seeking to profit in the Treaty relationship; how to repair harms created in the past but impacting the present; how to prevent future harms; how to reconcile the relationship between the Crown and Grassy Narrows.

The Crown acts as though Grassy Narrows has no say in these decisions. The Crown seems to think that we should accept that a massive gold mine is a foregone conclusion and we should only have a say in things like where the effluent pipe discharges, where the tailings piles are located, and where the processing plant should be sited. We disagree.

This project, the failure of the relationship with the Crown which has allowed the project to become so advanced without our involvement and consent, is having, and threatens to have further major impacts to our relationship with the Crown. Rather than taking a minimal and reductionist view of the minimum that the Crown can do in this situation, a robust understanding of the duties is required, as well as an appreciation for the unique circumstances and history of Grassy Narrows. Only involvement of senior representatives of the Crown can resolve this problem.

Federally Regulated Impacts

Federal involvement is required because of the numerous areas of claimed federal jurisdiction that will be affected by the Great Bear Gold project, including the completion of a Federal Impact Assessment.

Some, but not all, of these areas of claimed federal authority are listed here:

Species at Risk: The Federal Crown claims authority within the Constitutional division of powers over Species at Risk. Although we have not been able to carry out a thorough assessment due to the lack of capacity supports, the project site has a strong potential to impact the following species at risk:

- Woodland Caribou – the project site is within the range of the Sydney Caribou Herd. The range of the Sydney Caribou Herd is currently approximately 64% disturbed (likely higher due to recent fires in Woodland Caribou Provincial Park). This amount of disturbance exceeds the threshold above which the range becomes unlikely to be able to support a viable caribou population. The range is in need of recovery to lower the level of disturbance and therefore the entire range is considered critical habitat. The project will add disturbance, further degrading the ability of the range to sustain caribou and increasing the likelihood that Woodland Caribou, a threatened species, will be extirpated from this area. Caribou is an important clan animal for Grassy Narrows.

  It should be noted that while Ontario does have a *Species at Risk Act*, it has exempted mining and logging from the applicability of that Act. The provincial government cannot be counted on to ensure that the Great Bear Gold project proceeds in a manner that protects species at risk.

- Wolverine – Wolverine play an important and unique role in our ecosystem and in the balance of life. The company has indicated that wolverine have been observed on the project site using trail cameras. Direct observation of wolverines is a rare. Wolverine avoid humans and human impacted areas. The project is almost certain to permanently displace the wolverine that have been observed at the site and to destroy any wolverine dens, trails, habitat, and food sources that are on the site.

  The Committee on the Status of Endangered Wildlife in Canada (“COSEWIC”) reports that wolverines prefer ecologically intact areas and avoid disturbance.

According to COSEWIC "[a] study of the cumulative effects of developments on Arctic wildlife (Johnson et al. 2005) found that mines and other major developments had the largest negative effect on species occurrence, followed by exploration activities, and outfitter camps."[15]

Due to past degradation of southern habitats, wolverine left Grassy Narrows' area. However, our success in stopping logging has resulted in the beginning of a return of wolverine. Grassy Narrows is now near the southern edge of the currently occupied range of wolverine. If the project goes ahead, wolverine will leave our area and may not come back, further disrupting the balance of the landscape.

- Sturgeon – Sturgeon are an important clan animal in Grassy Narrows an important food source for the Anishinaabe of the Treaty 3 area. The damming of the English River has had a big impact on sturgeon. A small and delicate population remains in the river, which we are trying to protect and recover. Sturgeon live for many years, are sensitive to industrial disturbances, and can accumulate large amounts of toxins in their bodies.

There are many other species at risk that may be affected by the Great Bear Gold project, including bats, birds, turtles, Eastern Cougar, American Badger, and others. Each have a role to play in the web of life.

Fisheries: The Federal Government claims jurisdiction over inland fisheries, the prevention of harm to fish from pollution, and the protection of their habitat.

While the Federal Government has cooperative agreements with Ontario for licensing of fisheries the Federal Government maintains jurisdiction and responsibility for prevention of harm and protection of fish habitat.

Under Crown law, even the construction of a small water crossing can trigger the need to apply to the Department of Fisheries and Oceans for permits. In contrast, Ontario does not require a provincial impact assessment before a mine is opened.

We are a river people and fish have always played an extremely important role in our way of life, our sustenance, and our livelihood.

The companies propose to take water from our river system, use it in the industrial gold extraction process, and then return it to our river. The companies propose to create three open pit mines, three underground mines, store large amounts of waste rock and operate an industrial ore processing facility, all in close proximity to water bodies and streams that flow into our river system. Finally, the companies propose to create three new lakes in the empty open pits created by gold mine, and to allow water to flow out of those pits and into other local water bodies. All these activities, and others, put our fish

[15] Government of Canada, "Wolverine (Gulo gulo): COSEWIC assessment and status report 2014" (date modified: January 6, 2015).

at risk.

The Crown has failed to protect our fish for many decades from the impacts of mercury and this has had grave consequences for the rights, health and wellbeing of our people. Given the Crown's failure, and its ongoing impacts, all levels of the Crown should be diligent and alert in carrying out their duty to protect our fish from further harm.

Indigenous Peoples: The Federal Government claims jurisdiction over Indigenous Peoples and the lands reserved for them. This jurisdiction includes claimed authority over our health, culture, and wellbeing, responsibility for environmental contaminants and their impacts on Indigenous traditional foods and on the health of Indigenous Peoples.

The Great Bear Gold project has potential to impact Grassy Narrows' relationship with the Crown, the safety of our traditional foods, and our health, culture, and wellbeing. The project also has the potential to impact waters that flow into and through our reserve and which can impact our reserve.

Due to the Crown's longstanding and ongoing failures to meet its duties to Grassy Narrows, all levels of the Crown should be diligent and alert in carrying out their duty to protect us, our health, our traditional foods, and our further harm.

There are further areas of Federal claimed authority that likely apply here as well and that are at risk in this project, including but not limited to migratory birds, transboundary waters, transboundary air pollutants, international laws and instruments.

Due to the many important areas of claimed Federal authority that are at serious risk in this project, it is essential that a robust and comprehensive Federal Impact Assessment is carried out.

Grassy Narrows seeks to engage with the Federal Government and our consent is required to the form that the Impact Assessment will take.

Site-specific parameters and guidance levels needed

In its Initial Project Description, Kinross states that water, effluent, tailings leachate, and other substances will be tested and will be released back into the environment after they meet guideline levels. However, the Initial Project Description does not identify the guideline levels that will be used. Guideline levels are a very important and complex topic that must be explored in far more detail. Our discussion here is intended to illuminate that there is a serious problem.

Although there are many substances of concern here, we are most familiar with mercury and so we will use it as an example.

There are many guidelines that we have seen applied upstream of our community for allowable mercury levels. Some of these guidelines are wildly inappropriate, but all of them are insufficient.

According to the Government of Canada "(m)ercury is a toxic element and serves no beneficial physiological function in man; a maximum acceptable concentration of 0.001 mg/L (1 µ g/L) in drinking water has therefore been established."[16]

A concentration of 0.001 mg/L corresponds to **1000 ng/L** (nanograms per liter), which is the unit we will use here.

One might think that if the mercury level is good for drinking, then it would be fine to put in our river, but that is not the case. Provincial Water Quality Objectives ("PWQO") are numerical and narrative criteria that serve as chemical and physical indicators representing a satisfactory level for surface waters (i.e. lakes and rivers) and, where it discharges to the surface, the ground water of the Province.

The PWQO guideline level for mercury in surface water is **200 ng/L.**

The PWQO guideline has historically been applied to mercury contaminated groundwater seeping out of the banks of the Wabigoon River next to the Dryden mill to claim that it is safe. However, this too, is irresponsible.

The Canadian Council for Ministers of the Environment (CCME) provides guidelines for mercury levels in freshwater bodies that attempt to account for the risk to fish and wildlife through exposure to mercury.

The CCME guideline level for mercury in surface water is **26 ng/L.**

One might think that if this level of mercury in water is safe for the fish and wildlife, it must be safe to put water with that level of mercury into Grassy Narrows' river. However, the CCME guideline does not consider bioconcentration of mercury as it moves up through the food chain.

As the Government of Canada explains "[t[he presence of mercury in water has become a source of concern because of the finding that organic mercury is bioconcentrated by fish. Elevated mercury levels have been found in all freshwater fish taken from areas with suspected mercury contamination and frequently render the fish unacceptable for human consumption."[17]

The mercury levels that are found in predatory fish like the walleye, can commonly be a million times the level that is found in the water that they swim in.

Recent monitoring studies of the Wabigoon River upstream from the Dryden mill show that **baseline level of mercury in the Wabigoon River is around 1 ng/L.** Even at those baseline levels of mercury in water, large adult walleye in Wabigoon Lake often exceed 0.5 ppm mercury, the level above which the commercial sale of fish for human

---

[16] Health Canada (1986), "Healthy Living: Water and Mercury."
[17] Health Canada (1986), "Healthy Living: Water and Mercury."

consumption is banned.

If the level of mercury in the River is raised to **2 ng/L**, then mercury levels in adult walleye will approximately double, making them far more dangerous to eat. If other chemicals that stimulate net methylation in the environment are added as well, then the effect will be even more grave.

That means that river water with 2 ng/L of mercury will have serious impacts on the health of Grassy Narrows people's ability to safely practice their right to fish, even though this level is less than 10% of the level allowed by the CCME guideline, the most restrictive of the guidelines we are aware of.

A similarly broad range of guidelines exist and are applied for mercury levels in fish safe for human consumption.

The Ontario Ministry of the Environment "Guide to Sportfish Consumption" allows for some consumption of fish by the non-sensitive population (adult men and women who are not of child bearing age) if the fish have mercury levels below **1.8 ppm.**

On the other hand, the sale of fish for human consumption in Canada is banned if the fish have mercury levels over **0.5 ppm**. Grassy Narrows fishermen have been charged for selling their catch based on this rule.

In the 1980s, Canada established **0.2 ppm** as the guideline limit for safe consumption of fish by Grassy Narrows and other Indigenous subsistence eaters of fish.

The US Environmental Protection Agency ("EPA") lists **0.1 ppm** as their guideline level for Indigenous subsistence eaters of fish.

Renowned mercury expert Dr. Mergler has written in expert reports (some of which are enclosed), all of which have been provided to Ontario, that among these guidelines the US EPA level is most relevant to Grassy Narrows. However, she notes that all these guidelines are based on safe levels for a lifetime of exposure in a regular population. Mercury impacts are cumulative throughout the lifespan. None of these guidelines take into account the high, and far above guideline, levels of exposure that many Grassy Narrows people have already been exposed to. She writes that Grassy Narrows people have generally already been exposed to too much mercury and cannot safely be exposed to any additional mercury.

Clearly, off-the-shelf guidelines are not sufficient. It is necessary to develop and apply in close collaboration with Grassy Narrows locally specific guidelines that take into account the local background levels, ecology, food chain, cultural practices, and cumulative impacts from other industry, and history of exposure.

Other specific concerns

Given the constraints that we have noted, it is not possible to provide a comprehensive list of concerns here. However, some further concerns that we have identified to date,

which will require future elaboration, include:

- The contamination of the water within our Territory and water that flows into our Territory from effluents, discharges, by-products, leaching (including of metals), and changes in mercury cycling
- The creation of acid rock drainage and other forms of toxic drainage
- Changes to the flow, level, and quality of our water from water takings and discharges.
- The contamination of our air and air that flows into our Territory
- The loss of our caribou and moose, and of those who travel into and out of our Territory through impacts including habitat degradation and outside hunting pressure
- Disrupting the delicate balance of animals, predators, prey, and the web of life that supports us.
- The contamination and loss of our fish for food, commercial fishing, sport fishing, and way of life, including fish that migrate in and out of our Territory
- The loss and contamination of our birds and insects including migratory birds
- The loss of our valuable fur bearing animals including marten and otter
- The fragmentation and degradation of our forests and the loss of intact forest landscapes and old growth forest areas
- The changing of mercury exports and mercury cycling, including methylation
- The creation of additional anxiety, fear, depression, disempowerment, and despair among our people
- The further disruption of our society, our culture, and our way of life.
- The exacerbation of our suicide crisis
- The desecration of our sacred landscape
- The disturbing of spirits and beings that live in the rocks
- The tainting of our medicines
- The disruption of our people who are out on the land living their way of life
- The loss of peace and quiet for our people who are out on the land

- The loss of the ability to use the land as a healing place for our people
- The loss of our ability to teach our kids our way of life, identity, knowledge, and ways of wellness
- Impacts to our individual and collective health and wellbeing
- The loss of our ability to make a living in a way that is harmonious with our culture
- The violation of our Indigenous laws and jurisdiction
- The violation of our Treaty rights, our Treaty relationship
- The violation of the honour of the Crown and Fiduciary duties.

Other harmful impacts of industry on ANA people and Territory include, but are not limited to, the following:

- Impacts to game animal populations and their habitat including moose, and caribou which are central to our hunt and an important part of our way of life, our sustenance, our livelihood, and the exercise of our Treaty rights;
- Impacts to fur bearing animal populations and their habitat including pine marten which are central to our trapping and an important part of our way of life, our sustenance, our livelihood, and the exercise of our Treaty rights;
- Changes in forest composition including a shift from extensive coniferous dominated stands to fragmented deciduous dominated stands;
- Failure to regenerate forests or failure to regenerate to their previous composition;
- Loss of productive land base through tertiary roads, machine trails, landings, mines, tailings, buildings, erosion, etc.;
- Loss of species and genetic diversity;
- Loss of shrubs, including berries and medicines including through the use of herbicides;
- Tainting of our medicines and rendering areas unfit for sacred medicine harvesting and ceremony;
- degradation of forest soils, including compaction, rutting, scarification, and erosion;

- Disruption of nutrient cycles including the depletion of calcium in our watersheds, leading to calcium deficiency in aquatic biota;

- Increased competition with non-Indigenous hunters and fishers using forest access roads and associated depletion of animal and fish populations;

- Increased road traffic and danger of collision of people and wildlife with forest industry vehicles;

- Loss of traditional travel routes, sacred places, heritage, and archaeological sites;

- Negative impacts on water quality, fish habitat, fish populations, and fish contaminants;

- Risk of increased violence against ANA people, including gender-based violence, from an influx in workers coming into the Territory to log, and the potential establishment of man camps;

- Lack of recognition of cultural Anishinaabe way of being;

- Violation of our inherent, Treaty, and Aboriginal rights; and

- Violation of ANA Law and the will of our people.

Failure to Effectively Regulate and Remediate

According to the Government of Ontario, there "are over 5,700 abandoned mine sites in Ontario that have over 17,000 mine features, known as hazards… Deaths due to mine hazards in Ontario are rare, but deaths happen in North America every year."[18]

As of 2015, only four mines were listed as fully closed out. Only three are identified as undergoing remediation. On the other hand, there were 56 abandoned mines with 629 contaminated sites meeting provincial criteria for liability recognition. A further 306 abandoned mines had over 3,000 contaminated sites that do not meet the criteria for liability recognition.[19]

There are already many abandoned mine sites in our Interim Area of Interest for Mining, mostly in the Red Lake Area, many of which have been left in an unremediated state for decades. A number are classified as dangerous by the Ministry.

According to the Ontario Auditor 2015 report, the Ministry of Mines has not estimated

[18] Ontario, "Abandoned mines hazards" (last updated February 17, 2023).
[19] Auditor General of Ontario (2015), "2015 Annual Report: chapter 3.11: Mines and Minerals Program."

the total cost of rehabilitating the 4,400 abandoned mine sites in Ontario since 1993 and therefore does not know the current cost for doing so. It also does not have a long-term plan for rehabilitating these sites. These sites may pose risks to public health and safety and the environment.[20]

The Auditor General found that the "Ministry conducts minimal inspection and follow-ups on abandoned mines."[21] In the five years before the audit "the Ministry has inspected only about 6% (248) of abandoned mines to ensure that they do not pose a risk to public health and the environment."[22]

The Crown often assures us that despite the legacy of past bad practices, mining regulation is done safely now. To the contrary, the Auditor General found many glaring flaws in Ontario's regulatory regime for current mining, including that "Ontario is the only province in Canada that does not require a provincial environmental assessment to be performed for mining projects."[23] The Auditor General's report further explained that "in Ontario, the *Mining Act* only requires mining companies to submit closure plans prior to the development of the mine… In other provinces in Canada, larger mining projects automatically trigger a provincial environmental assessment."[24]

The Auditor General found that the closure plan process lacks sufficient funding, is subject to pro-industry bias, plans are not updated, and inspections are insufficient to ensure safety.

As of 2022, the government had not inspected nearly half of Ontario's operational mines since 2011.[25] The news media has also reported that Ontario senior officials are highly concerned that following several recent tailings dam failures "there is little to no legislative authority to prevent similar situations from occurring in Ontario."[26] According to the media the regulatory gap is outlined in a section of a briefing binder for Minister Pirie dedicated to "critical decisions. Senior bureaucrats, who told Minister Pirie that the gap in offline tailings dam rules was a "high-risk gap in the regulatory framework that requires urgent attention."

Far from improving the overall mining regulatory situation, the Government of Ontario has recently watered down its regulations with respect to requirements for closure planning and closure funding through the *Build More Mines Act*. The Act gives the Minister extremely broad discretion over nearly all aspects of mining including closure planning and funding. Under the new rules the position of Director of Mine Rehabilitation

was removed, Ministry staff no longer review closure plans and instead industry staff may carry out the review, contrary to the Auditor's 2015 recommendations.

Given this context, Grassy Narrows does not trust that the appropriate regulations are in place to ensure mining sites will be kept safe for many generations to come. You have not earned our trust.

Lack of Protected Areas, Need for Regional Balance.

There is an imbalance in the region because nearly all forests south of Red Lake are open to industrial mining. For example, much of our Territory is in ecodistrict 4S-2 where only 4.1% of the ecodistrict is protected. Part of our Territory is in ecodistrict 4S-3 where only 3.3% of the ecodistrict is protected. The lack of protection for our landscape is the clear outcome of an unbalanced landuse designation process that did not involve us meaningfully and ignored our rights and interests.

In contrast, conservation biology generally dictates that at least half of an ecosystem must be protected to avoid loss of biodiversity and ecosystem functions. Ontario has committed to community-based land use planning in the Far North based on a joint planning process between the First Nations and the province.[27] It committed to protecting 50% of the landbase in partnership with First Nations following First Nations-led landuse planning.

Canada has committed to protecting 30% of the land in Canada by 2030 in partnership with First Nations. Respecting ANA's efforts to protect our environment will contribute to the maintenance and recovery of biodiversity and ecosystem functions and will support a balance in this region, where the vast majority of forests have been open to industrial logging and mining.

Nature Based Climate Change Solutions

Climate change and biodiversity loss are major threats to Grassy Narrows and to the world. Nature based solutions have been identified as an important part of preventing and mitigating both problems. The boreal forest is one of the world's largest storehouses of carbon. After logging or clearing of the land for mining, much of this carbon is released from the forest, plants and soils, contributing to climate change. On the other hand, protecting forests helps to keep the carbon safely stored and safeguards biodiversity. These are important ecosystem-based services that contribute to mitigating climate change and that have a significant value.

Fighting climate change and biodiversity loss are important priorities for Grassy Narrows and for Canada and respecting Grassy Narrows' land protection will contribute to progress on these priorities.

---

[27] *Far North Act, 2010*, SO 2010, c 18.

VI. Mining activity without Grassy Narrows' consent risks conflict

Barrick writes that "[a]ny perceived or actual breach of … trust or respect can have devastating consequences for a mining venture or company, and these commercial and reputational consequences can extend well beyond any particular project or First Nation group." In so writing, Barrick raises the spectre of conflict minerals, also commonly knowns as blood minerals.

Global concerns about unethical practices by mining companies, including Canadian gold mining companies, have led to increased scrutiny of the social, environmental, and ethical practices of mining companies. For the mining industry, the problem with conflict minerals is that no one wants them. Conflict minerals are hard to market, and they increase corporate risks and uncertainties associated with investment, timelines, regulatory approvals, litigation, social conflict, and brand damage.

As a consequence, Ontario and Canada have sought to market themselves as stable, safe, ethical, jurisdictions from which to source conflict-free, or ethical minerals. While there are cheaper jurisdictions in which to operate, the conflict-free reputation of Ontario and Canadian minerals is a significant competitive advantage relative to many of other global mining jurisdictions.

However, as Barrick noted, for the mining industry and a mining jurisdiction, trust is hard to gain and easy to lose. It only takes one high profile conflict to taint an entire company, a sector and an entire jurisdiction and to undermine decades of marketing.

Ontario learned this lesson in the analogous conflict with Grassy Narrows over unwanted logging. After decades of unliterally forcing clearcuts on Grassy Narrows against their will, the First Nation turned to protests, boycotts, media campaigns, public education, litigation, and grassroots blockades. Within six years, major sourcing contracts were being threatened and shortly afterwards Abitibi, the world's largest newsprint producer, withdrew from Grassy Narrows Territory.

The City of Kenora, in their 2009 report to the Ontario Good Roads Association / Rural Ontario Municipalities Association, wrote that "[t]he issue with Grassy Narrows on the Whiskey Jack Forest must be resolved... Without resolution of these issues, **the wood coming off the Whiskey Jack Forest cannot be sold**. **There is no current customer willing to accept wood products from a forest unit which is involved in a perceived controversy."** (emphasis added)

This dynamic is beginning now with respect to mining. A long and growing list of mining companies, including Barrick, Trillium, Bounty, and Kenorland have voluntarily committed not to explore without consent or have left the area. Their withdrawal reflects an enduring reality in the mining industry where compliance with international law, third party certification standards, customer, investor, and shareholder expectations, and social license preclude the use of conflict minerals.

The Crown would be wise to avoid instigating conflict with Grassy Narrows again by approving unwanted mining. Controversy with Grassy Narrows about one mine could

taint the reputation of Ontario as a conflict-free place to mine. It could give the entire regional industry a stain that heightens risk and uncertainty and discourages investment throughout the supply and production chain.

The entire region and industry benefit from an environment free of conflict. It is in the interest of Ontario and industry to resolve, not inflame, the conflict with Grassy Narrows.

VII. Gold does not justify the impact to Grassy Narrows

Gold does not serve an essential and irreplaceable function in society. The largest use of gold by far is for jewelry, followed by investment and central banks demand. Technology, a distance fourth, used only six percent of gold production in 2022 (309t out of 4,721t produced globally). Much of that technology is electronics with short life spans and abysmal recycling rates.

Because gold is not essential, but is valuable, the rationale for mining gold by Great Bear and Kinross is purely financial. Shareholders demand a return on their investment, but Ontario need not repeat the mistake of sacrificing Grassy Narrows' rights and wellbeing for the interests of corporate shareholders.

The flow of resource wealth has been used to justify the damming of our river, dumping of mercury, logging of our trees, and now proposed gold mining. The impacts we have suffered from this approach are extreme and ongoing. The mine is projected to operate for a mere 25 years, but we will be here for many generations. No longer can the Crown and third-party companies seek to sacrifice our health, way of life, livelihood, rights, and environment for short term shareholder gains. Enough is enough.

It is important to remember that it is tourism, recreation and services – not resource extraction – that now forms the backbone of Kenora's employment. This shift is not due to a lack of available wood or minerals, but rather reflects increasing mechanization and marginal profitability in the extractive sector in contrast to the growing demand and labour intensiveness of the non-extractive sector. Grassy Narrows' work to protect our landscape and our environment have helped to foster Kenora's greatest economic strength.

The Kenora and Red Lake area enjoy substantial benefits for tourism, wildlife, hunters, fishers, trappers, recreational users, and non-extractive industries. According to the municipal website "[t]he City of Kenora has transitioned from a pulp and paper mill town to a destination and lifestyle community."[28]

The tourism and services industries are Kenora's largest employers by far. The visitor and cottager sectors contribute $300 million annually to the Kenora economy. In contrast, it is estimated that the Weyerhaeuser mill contributes $60 million to the local economy, even when counting indirect economic benefits throughout the region.

---

[28] City of Kenora, "Key Industries" (accessed January 23, 2021)

Kenora's tourism labour force makes up 38% (3,314 jobs) of Kenora's total employment, while Tourism related occupations account for 51.5% (4,405 jobs) of Kenora's total employment.[29] The growth of this industry is key to Kenora's economic plans.

According to the current Whiskey Jack Forest Management Plan ("FMP"), "[t]here are numerous tourist operators in the Whiskey Jack Forest. The recreational activities provided by these outfitters include options for fishing, hunting, camping and other eco-tourism opportunities. The number of individuals, residents and non-residents, procuring services from these tourist establishments are numerous, and they contribute a significant amount of economic resources to local communities ... The Sunset Country Economic Study reports that in 2001, 443 operators provided employment to 3,785 persons of which 1,221 were located in the Whiskey Jack Forest".[30]

In contrast, the Evolution gold mine in Red Lake employs 740 people, only a sixth of the number employed in tourism related jobs in Kenora and is chronically at risk of shutting down if profitability cannot be increased for its Australian owner.[31]

As set out in the Lake of the Woods Tourism Sector Report, "[o]ngoing investments in tourist services and resources only compliment the pristine natural environment that has attracted visitors to Lake of the Woods for over a century."[32]

The current FMP notes that "public and municipal officials should be aware that provincial parks help to make their communities attractive for business as well as for tourists and retirees. The retirement community brings in pension income, which is often indexed to inflation and is "recession proof'.[33]

Respecting and supporting Grassy Narrows' efforts to protect the landscape would contribute to the region's tourism economy and maintain opportunities to grow that economy as well as to become a leader in the conservation economy through future protected areas and associated eco-tourism attractions. A conservation economy creates long-term sustainable employment potential for local and regional residents by maximizing existing skills and knowledge.

VIII. A Choice, an Opportunity

Our youth are crying out. They want to see the land protected so that we can use it to heal our people and our spirits. This is reconciliation for us. They deserve to see the light at the end of the tunnel. We do not want to have to fight, again and again, to protect out land.

However, the community of Grassy Narrows is strong. We know our history, our rights,

---

[33] Whiskey Jack Forest FMP 2012-2022, p 98.

our language, our teachings, and our way of life. We have allies across the country and across the world. The days of forcing harm on us against our will are over.

Respecting Grassy Narrows' land protection is the best available way to minimize conflict and move towards a path of reconciliation and respect for our inherent, Aboriginal and Treaty rights in compliance with international Indigenous rights standards.

Grassy Narrows has borne the brunt of the impacts of industry in the region, while our voice has long been ignored by Crown and industry decision makers. Part of the outcome of this mistreatment has been conflict over logging and one of Canada's most infamous environmental poisoning sagas. As a consequence, the region, and the country, has a stain on its honour, its reputation and credibility.

Times have changed. It is no longer acceptable, nor viable for the Crown to approve extractive industrial activities without Indigenous parties' consent. Across Canada there is a commitment and an expectation for reconciliation. We have an opportunity now to learn from the mistakes of the past and to heed the voice of Grassy Narrows. In the process, we can move from conflict to cooperation, from destruction to restoration, from harm to hope. Grassy Narrows invites the Crown to join us in righting this historical wrong. Respecting Grassy Narrows' land protection would be an important show of good faith that would be a positive step on the path towards reconciliation.

The Crown is at a crossroads.

On the one hand, the companies are proposing to open a large and toxic gold mine upstream from us against our will. If implemented, the mine risks irreparable harm to Grassy Narrows' rights and interests including, but not limited to, harms caused by cumulative effects, neglected obligations, Treaty infringement, harm to our health, release of mercury, and loss of way of life and livelihood. This harm would be immoral, unjustified, unreasonable, dishonourable, and a breach of Ontario's fiduciary duties to Grassy Narrows.

On the other hand, respecting Grassy Narrows land protection would have a beneficial impact on the exercise of Treaty rights and on the environment, cause no harm to anyone's health, and be beneficial for the growing non-extractive economy. There is an opportunity for calm that will allow ANA and the Crown to focus on long-term resolution of our issues and that will help ANA return to the health, self-determination, and prosperity that we once enjoyed.

We are inviting you to walk with us on the path of protection, healing and reconciliation. Will you work with us, or against us?

APPENDIX A

INTERIM Issues for Negotiation/Engagement/Consultation with MINES

August 18, 2023

1. Recognition and respect for ANA inherent, aboriginal and Treaty rights
2. Recognition and respect for the ANA Land Declaration
3. Recognition and respect for the ANA IPCA
4. Harmonization of Crown Law and ANA Law with respect to mining related activities
5. Repairing the Crown – ANA relationship with respect to mining related activities
6. Outstanding Ontario obligations to ANA including those arising out of the 1978 MOU and subsequent commitments such as increased ANA control and ownership over its land base
7. Land-use redesignation of the ANA IPCA
8. Interim measures including the withdrawal of the ANA IPCA from staking
9. Suspension of all mining exploration activities on the ANA IPCA and vicinity
10. Resolution of existing third-party mining interests on the ANA IPCA created by the Crown
11. Issuing a Notice of Caution for mining related activities on lands where ANA rights and interests could be impacted
12. MINES Minister's unfulfilled commitment of November 2021 to visit Grassy Narrows to discuss mining issues in an open forum.
13. Cumulative impacts of past mining related activities on ANA
14. Cumulative impacts of mining activities and other industrial and crown policy impacts on ANA including mercury
15. Resolution of issues arising from past mining related activities which have occurred without ANA consent (restoration, compensation, apology, etc.)
16. Ending Free Entry mining exploration and resolving the issues it has created
17. ANA concerns re off-site impacts and risks of existing mining activity (e.g. at Red Lake and Goliath mines, Red Lake and Separation Rapids exploration) on ANA
18. ANA concerns and MINES failure to take into account risk of off-site impacts of proposed mining exploration and other mining related activity on ANA (including downstream, migratory, downwind, landscape level, and other impacts)
19. Addressing ANA concerns re: Changes to the Mining Act
20. Addressing ANA concerns re: Regulation and enforcement of tailings management
21. Impacts of mining related activity on mercury mobilization and cycling
22. Impacts of mining related activity on Intact Forest Landscapes and associated values and ecosystem functions
23. Impacts of mining related activity on source water protection and source water planning and management
24. Impacts of mining related activity on moose, caribou, marten, fish, and other wildlife
25. Impacts of mining related activity on ANA sacred landscape, spirituality, ceremonies, medicines

26. Impacts of mining related activity on ANA land based healing
27. Impacts of mining related activity on ANA travel routes, camp sites, occupancy sites, burials, etc.
28. Impacts of mining related activity on ANA archaeological and historical values
29. Impacts of mining related activity on ANA safety, and risk of racial and gender based violence including man camps.
30. Unanswered correspondence from ANA to MINES and Ontario
31. Barriers to meaningful ANA engagement including the ongoing Mercury Crisis, housing crisis, water crisis suicide crisis
32. Reimbursement of past ANA expenses for unfunded engagement with the Crown and mining companies.
33. Capacity support required by ANA to begin meaningful engagement
34. ANA Consultation Area with respect to mining
35. Proposed and existing mining exploration and other mining related permits

Impact Assessment Agency of Canada | Agence d'évaluation d'impact du Canada

Chief Rudy Turtle
Grassy Narrows First Nation
General Delivery c/o Grassy Narrows Band Office
Grassy Narrows ON P0X 1B0

Subject: Notice of Opinion that a Federal Impact Assessment is Warranted for the Proposed Great Bear Gold Project and Next Steps

Dear Chief Rudy Turtle:

Thank you for your participation in the Planning Phase of the federal impact assessment process for the Great Bear Gold Project (the Project) as proposed by Kinross Gold Corporation (the Proponent). The Agency acknowledges receipt of your correspondence dated March 7, 2024, and will review and consider the information in the development of the forthcoming materials.

The purpose of this letter is to:

- inform you of the Impact Assessment Agency of Canada's (the Agency) opinion that a federal impact assessment is warranted for the Project;
- provide advance notice that a comment period on the planning documents, including the draft Tailored Impact Statement Guidelines and the draft Indigenous Engagement and Partnership Plan will be announced in the coming weeks;
- invite your community to comment on whether the Project should be referred to an independent review panel or continue as an Agency-led impact assessment;
- remind your community of the **$5,000.00** participant grant fund to support your review of the draft documents; and
- invite your community to meet with the Agency prior to and during the upcoming comment period.

…/2

As noted in our correspondence dated December 28, 2023, the Supreme Court of Canada (SCC) issued its decision on the constitutionality of the *Impact Assessment Act* (the IAA) on October 13, 2023. Following this decision, the Government of Canada released the Statement on the Interim Administration of the *Impact Assessment Act* Pending Legislative Amendments[1] on October 26, 2023.

The SCC's decision does not change the duty of the Government of Canada to consult with Indigenous Peoples on the impacts of major projects. Further, the Agency remains committed to the United Nations Declaration on the Rights of Indigenous Peoples, including the need for meaningful engagement with Indigenous Peoples.

Agency's Opinion on Impact Assessment
The Agency reviewed the Proponent's Detailed Project Description received on February 23, 2024, which includes the responses to the Agency's Summary of Issues. Based on the Agency's review of the Detailed Project Description and the responses to the Summary of Issues, along with the consideration of other factors, including comments received to date from Indigenous communities, federal authorities, provincial ministries, and the public, the Agency is of the opinion that a federal impact assessment is warranted for the Project.

The Summary of Issues, Detailed Project Description including the Proponent responses to the Summary of Issues, and the Agency's Notice of Opinion is available at: *https://iaac-aeic.gc.ca/050/evaluations/proj/85832*

Advanced Notice of a Comment Period on Impact Assessment Planning Documents
The Agency is currently developing guidelines and a series of plans to define the scope, content, and conduct of the impact assessment.

The Agency anticipates holding a **comment period** on the following documents:

- draft Tailored Impact Statement Guidelines
- draft Indigenous Engagement and Partnership Plan
- draft Public Participation Plan
- draft Permitting Plan
- draft Cooperation Plan

For a description of each of these required Planning Phase documents, please see the Agency's Practitioner's Guide to Federal Impact Assessments.[2]

[2] *https://www.canada.ca/en/impact-assessment-agency/services/policy-guidance/practitioners-guide-impact-assessment-act.html*

In the coming weeks, I will notify you of a comment period on the above-noted documents and specifically seek input from your community on the draft Tailored Impact Statement Guidelines and the draft Indigenous Engagement and Partnership Plan.

As the Consultation Lead for the Project, I welcome the opportunity to work collaboratively with your community in developing the Indigenous Engagement and Partnership Plan. In addition, I also invite you to identify features of a consultation process that would best suit your community.

Views about Referring to a Review Panel
Please note, the Minister of Environment and Climate Change Canada may refer the impact assessment of the Project to an independent review panel no later than 45 days after the end of the Planning Phase. If you have views on this aspect, you are welcome to provide them by the end of the forthcoming comment period at *GreatBear@iaac-aeic.gc.ca*.

Participant Grant Funding
As a reminder, to support Grassy Narrows First Nation's continued participation in the Planning Phase of the impact assessment process, including the review and comment on the draft documents listed above, a subsequent grant of **$5,000.00** will be available during the comment period. Thank you for confirming your interest in grant funding. An overview of eligible activities and expenses is enclosed (**Enclosure 1**). Following the Planning Phase, you will be able to apply for contribution funding to facilitate your community's participation throughout the subsequent phases of the federal impact assessment process. Additional grants may also be made available to support your participation during the assessment process.

Invitation to Meet with the Agency
If you are interested, the Agency wishes to schedule two meetings with your community:

- A virtual meeting in early-April 2024, in advance of the upcoming comment period, to introduce the concepts and purposes of the Tailored Impact Statement Guidelines and Indigenous Engagement and Partnership Plan, and to answer any questions you may have to prepare for the upcoming comment period. The Agency will follow up promptly to schedule this meeting.
- A virtual or in-person meeting during the forthcoming comment period, for a detailed discussion about the Tailored Impact Statement Guidelines and Indigenous Engagement and Partnership Plan, in relation to potential impacts on your community. The Agency encourages you to begin considering your community's availability and will contact you in the coming weeks to schedule this meeting.

…/4

Integration of Crown Consultation into the Impact Assessment Process
To support an appropriately scaled, resourced and flexible Crown consultation process, the Agency, on behalf of the Government of Canada, will form a Crown Consultation Team involving all relevant federal authorities who may have expertise to provide to inform the federal impact assessment.

In my role coordinating the Government of Canada's consultation process, I will:

- serve as point of contact within the Government of Canada for Indigenous communities in the federal impact assessment process;
- ensure project-related comments and concerns from Indigenous communities, federal authorities and the public are shared with the Proponent; and
- maintain an ongoing two-way dialogue and collaborative working relationship with Grassy Narrows First Nation focused on finding solutions to issues of concern.

More information on participation opportunities can be found in the Practitioner's Guide to Federal Impact Assessments on the Agency's website at: *https://www.canada.ca/en/impact-assessment-agency/services/policy-guidance/practitioners-guide-impact-assessment-act.html.*

IMPORTANT NOTE
Information submitted to the Agency to inform this project assessment may be posted online to the Canadian Impact Assessment Registry[3] (Reference #85832) subject to certain exceptions related to privacy, security or confidentiality. The Agency's Submission Policy[4] describes what submitted information can be shared publicly, and what should remain private. For more information on how we protect your privacy, please refer to the Privacy Notice[5]. If you wish to provide comments or documents containing sensitive information that you believe should not be disclosed to the public, please contact the Agency before submitting them.

Should you wish to provide confidential Indigenous Knowledge, note that such Knowledge can be protected as described in our guidance about confidential Indigenous Knowledge[6], but that it must not be submitted via the Registry, and you need to discuss confidentiality arrangements with the Agency prior to submitting any Indigenous Knowledge.

The Contribution across Three Generations of Mercury Exposure to Attempted Suicide among Children and Youth in Grassy Narrows First Nation, Canada: An Intergenerational Analysis

Donna Mergler,[1] Aline Philibert,[1] Myriam Fillion,[2,1] and Judy Da Silva[3]

[1]Centre de recherche interdisciplinaire sur le bien-être, la santé, la société et l'environnement, Université du Québec à Montréal, Montréal, Québec, Canada
[2]Département Science et Technologie, Université TÉLUQ, Montréal, Québec, Canada
[3]Grassy Narrows First Nation, Grassy Narrows, Ontario, Canada

Background: For 60 y, the people of Asubpeeschoseewagong Anishinabek (Grassy Narrows First Nation) have endured the effects of massive mercury (Hg) contamination of their river system, central to their traditions, culture, livelihood, and diet. In the years following the Hg discharge into the English–Wabigoon River system by a chloralkali plant in the early 1970s, there was a dramatic increase in youth suicides. Several authors attributed this increase solely to social disruption caused by the disaster.

Objective: This research examined the possible contribution of Hg exposure across three generations on attempted suicides among today's children (5–11 y old) and youth (12–17 y old), using a matrilineal intergenerational paradigm.

Methods: Information from the 2016–2017 Grassy Narrows Community Health Assessment (GN-CHA) survey was merged with Hg biomonitoring data from government surveillance programs (1970–1997). Data from 162 children/youth (5–17 years of age), whose mothers ($n = 80$) had provided information on themselves, their parents, and children, were retained for analyses. Direct and indirect indicators of Hg exposure included *a*) grandfather had worked as a fishing guide, and *b*) mother's measured and estimated umbilical cord blood and childhood hair Hg and her fish consumption during pregnancy with this child. Structural equation modeling (SEM) was used to examine significant links from grandparents (G0) to mothers' exposure and mental health (G1) and children/youth (G2) risk for attempted suicide.

Results: Mothers' (G1) median age was 33 y, 86.3% of grandmothers (G0) had lived in Grassy Narrows territory during their pregnancy, and 52.5% of grandfathers (G0) had worked as fishing guides. Sixty percent of children (G2) were <12 years of age. Mothers reported that among teenagers (G2: 12–17 years of age), 41.2% of girls and 10.7% of boys had ever attempted suicide. The SEM suggested two pathways that significantly linked grandparents (G0) to children's (G2) attempted suicides: *a*) through mothers' (G1) prenatal and childhood Hg exposure and psychological distress, and *b*) through maternal fish consumption during pregnancy (G1/G2), which is an important contributor to children's emotional state and behavior.

Discussion: Despite minimal individual information on G0 and G1 past life experiences, the findings support the hypothesis that Hg exposure over three generations contributes to the mental health of today's children and youth. The prevalence of Grassy Narrows youth ever having attempted suicide is three times that of other First Nations in Canada. https://doi.org/10.1289/EHP11301

Introduction

Since the first public evidence, 52 y ago, of the extent of the mercury (Hg) discharge into the English–Wabigoon River system by a chloralkali plant in Dryden, Ontario (Canada), much has been written about the Asubpeeschoseewagong Anishinabek (Grassy Narrows First Nation) and how the contamination of their waterways disrupted their culture, traditions, and economy.[1–8] For generations, fish provided people of Grassy Narrows with "meaning, social cohesion, and pride."[9] In the early 1960s, a large majority were gainfully employed in fish-based industries.[1–9] Approximately 80% of the households in Grassy Narrows had a least one family member who worked as a fishing guide and many were involved in commercial fishing; employment was 85%–90%.[1–3] During the tourist fishing season, all Grassy Narrows fishing guides reported eating fish every day as part of the customary shore meal for anglers, and almost all (92%) brought fish home to their family.[1]

In 1970, very high Hg levels were reported in fish in the English–Wabigoon River system; inorganic Hg released by the chloralkali plant was being converted into methylmercury (MeHg), a highly toxic compound that bioaccumulates and biomagnifies in the aquatic food chain.[5,10] Hg concentrations in fish reached up to 24 μg/g, almost 50 times the upper limit considered safe for human consumption.[10] Communities received contradictory messages about whether or not they should continue to eat fish. Some lodge owners downplayed the importance of Hg contamination and continued the practice of shore meals, thereby placing fishing guides into the situation of choosing between their health and their livelihood.[1] In 1975, the main fishing lodge had shut down and the commercial fisheries were closed.[1] Over time, fish Hg concentrations declined, stabilizing by around 1985,[10,11] but they have remained to this day higher than in other Ontario lakes and rivers.[12]

In the early 1970s, Canadian government biomonitoring programs for total Hg in hair, blood, and umbilical cord blood were initiated in the First Nation communities affected by the discharge into the English–Wabigoon River system.[13,14] In 1976, annual average individual peak blood total Hg was 23.8 μg/L, with concentrations ranging from 1.5 to 322.9 μg/L.[13] Fishing guides and their families were identified as the groups the most at risk; the highest blood total Hg concentration (660 μg/L) among Indigenous communities in Canada was reported for a Grassy Narrows fishing guide.[15] The biomonitoring programs continued into the 1990s, when average Hg biomarker concentrations declined below the Canadian Hg guidelines, mirroring the decline in fish Hg concentrations.[13,16]

The years following 1970 saw the loss of livelihood and were fraught with social upheaval.[1–5] There was an 8-fold increase of violent deaths from pre- to post-1970 and the prevalence of alcoholism was high.[1–4] Several authors have attributed the social crisis to the loss of traditional lifestyle and the destruction of the very foundation of their society.[1,2,4–6] In Grassy Narrows First Nation, the trauma of cultural dispossession and loss of livelihood was compounded by Hg poisoning from fish consumption. However, the possible direct contribution of high Hg exposure to the

psychopathology was not considered, despite reports of psychiatric disorders among patients with organic Hg poisoning. As early as 1971, Eyl[17] noted that the symptoms of organic Hg poisoning included a lack of interest in home and work, emotional instability with fits of anger, depression, or rage. In 1968, Tatetsu (cited in Ekino et al. 2007[18]) described the psychiatric profile of many patients with Minamata disease, who had been exposed to MeHg from the consumption of fish and shellfish, contaminated by the wastewater discharge from a chemical plant into the Minamata Bay: "They were egocentric, selfish, and paid little attention to the advice of others. Loss of inhibition was another feature of the disease's personality characteristics. They were often impolite, too friendly to others, easily burst into anger, restless, euphoric, and childish. Some of them spent money as much as they were given and threw away change."

Prior to 1970, no suicide had ever been recorded in Grassy Narrows.[2] Between 1974 and 1978, three of the four persons who took their life were teenagers, and in 1977–1978, 26 young persons between 11 and 19 years of age attempted suicide.[4] Between 1970 and 1977, the incidence of suicide was 3.6 times higher compared with another First Nation community, selected for its pre-1970 socioeconomic similarities to Grassy Narrows.[1] Neurological examinations, carried out in Grassy Narrows in the 1970s, focused primarily on motor and sensory functions, with results that appeared to be "elusive," although there were several signs and symptoms similar to those reported for patients with Minamata disease.[15] In 2010, Harada et al. examined 73 persons from Grassy Narrows using the protocol for the diagnosis of Minamata disease in Japan: 42 (57.4%) were diagnosed with Minamata disease or suspected Minamata disease, 15 (20.5%) exhibited emotional disturbances, and 10 (13.6%) showed intellectual deficits.[19] A recent study in Grassy Narrows reported a positive association between umbilical cord blood total Hg concentration and clustered symptoms of affect/mood disorders in adults.[20]

For the people of Grassy Narrows, the problems associated with Hg exposure may be compounded by the intergenerational consequences of the trauma caused by the Indian Residential School system.[21–24] Children were taken from their communities and sent to government-financed boarding schools, administered by Christian churches. Many children from Grassy Narrows were sent to these schools.[25,26] In 1953, the principal of the Presbyterian school in Kenora, Ontario, wrote: "We must face realistically the fact that the only hope for the Canadian Indian is eventual assimilation into the white race."[26] Mental health issues, particularly emotional well-being, are the most frequently identified intergenerational impacts of residential schools on Indigenous health and well-being in Canada.[27]

Little is known about the consequences of environmental exposures across generations. Depression in parents has been consistently found to be associated with children's behavioral problems and lower cognitive/intellectual/academic performance.[28] During pregnancy, maternal consumption of Hg-laden fish exposes the developing fetus; MeHg is actively transported across the placental barrier and umbilical cord blood MeHg is approximately twice that of maternal blood.[29] Studies of Inuit children in Canada report increased risk for borderline intellectual disability[30] and adolescent anxiety[31] in relation to umbilical cord blood total Hg.

By 2016, >90% of the adult population of Grassy Narrows were born since the beginning of the disaster in 1962[32]; most were exposed to Hg *in utero* and their parents experienced the immediate impact of the disaster. Today's children and youth live with this legacy. The present study seeks to explore intergenerational effects of Hg contamination in Grassy Narrows on children's emotions, behavior and attempted suicide, using a maternal-lineage transmission paradigm.

Materials and Methods

Study Design

Between December 2016 and March 2017, Grassy Narrows First Nation carried out a community health assessment, the Grassy Narrows Community Health Assessment (GN-CHA) survey. Participants provided information on themselves, their parents, and their children (0–17 years of age). Information from the GN-CHA on grandparents (G0), mothers (G1), and their children (G2) was merged with a database constructed from archived biomarkers of Hg exposure from a government monitoring program carried out between 1970 and 1997.[16]

GN-CHA Survey

The GN-CHA survey used a systematic house-to-house sampling strategy on-reserve, and convenience sampling off-reserve. Two coordinators from Grassy Narrows devised and supervised the field work, assisted by nine local surveyors. The questionnaire was web-based and participants could fill it out on their own, or with, when needed, the assistance of the surveyor.

The GN-CHA adult (≥18 years of age) survey included 266 questions covering the following areas: demographics, education, generational attendance of residential school, work activities and income, diet, general health status (including diabetes care), mental health and well-being, disabilities, injuries, health care access, physical activity, smoking, drinking and drug use, and participation in community activities. Most questions were taken from the First Nation Regional Health Survey 2008/2010,[33] providing a basis for comparison with other First Nation communities in Canada. Further questions addressed local fish consumption at different periods, as well as specific illnesses and symptoms that have been associated with Hg exposure. The large majority of adult participants filled it out on their own. Those who did not fill it out on their own were older persons for whom English was not their first language. Translation in Anishinabek was available.

Similar to the adult survey, the GN-CHA survey for children and youth included the same questions as the First Nation Regional Health Survey 2008/2010,[33] as well as questions on local fish consumption during mother's pregnancy and the child's current fish consumption (174 questions). Parents or caregivers provided the information on children. In some instances, the youth was present when the questionnaire was being filled out; some youth ≥15 years of age filled out the child questionnaire on their own.

On-reserve, 83.6% of the 213 houses were surveyed (302 persons); 89 persons (22.8%) living off-reserve, from 66 households were likewise surveyed. Data were collected for 391 adult Grassy Narrows Registered Band members and 353 children (0–17 years of age). The age and sex distributions of participants were similar to their distribution in the 2016 Statistics Canada Aboriginal Household Survey.[32] GN-CHA results were presented to and discussed with community members during several small group and community meetings. The final reports were approved by the Chief and Council and made public on 24 May 2018 for adults and on 5 December 2018 for children.

For the present study, we retained information provided for children between 5 and 17 years of age ($n = 162$) and their mothers ($n = 80$). All mothers had filled out the adult and child/youth questionnaires on their own; 17 youth (26.2%), between 13 and 17 years of age, were present when their mother filled out the child/youth questionnaire. The GN-CHA questions retained in the present statistical analyses are classified by generation as described below.

- **Children (G2):** Mothers provided information about each of their children for the following variables: age, sex, physical and mental health status (on a five-point Likert scale), current fish consumption, and diagnosed nervous system

disorders [yes/no for at least one of the following: cognitive or mental disabilities, attention-deficit and attention-deficit/hyperactivity disorder (ADD/ADHD), learning disabilities, speech/language difficulties, visual problems that cannot be corrected by glasses, hearing impairment, cerebral palsy, Bell's palsy and movement disorders]. Fetal alcohol spectrum disorder (FASD) was included in the questionnaire, but it was excluded from the list of at least one diagnosed nervous system disorder. Further questions asked whether in the past 6 months the child had more emotional or behavioral problems compared with other children of the same age and sex (yes/no) and whether the child had ever attempted suicide (yes/no). Children's school performance was grouped into three categories: very good/excellent, good, and fair/unsatisfactory.

Several questions addressed the mother's pregnancy with this child. The questions were worded: "If you are the birth mother, did you have …?" Gestational diabetes, hypertension, prematurity and difficulties during childbirth were grouped into yes/no. Questions likewise asked, "If you are the birth mother, did you drink a lot or take drugs during pregnancy?" (yes/no). The child's prenatal Hg exposure was based on mother's reported local fish consumption during her pregnancy with this child, grouped into three categories (less than once a month, once a month, at least once a week).

- **Mothers (G1):** The following variables were retained: age, education (years of education and having received a high school diploma), school success (five-point Likert scale from poor to excellent), having attended a residential school (yes/no), currently working (yes/no), reasons for not working, social support (yes/no), struggle to pay for food over the past 12 months (at least once a month vs. less), current smoking (yes/no), current heavy drinking as defined by the 2008/2010 Regional Health Survey[33] as five drinks in one drinking occasion at least once a month in the past 12 months (yes/no), and obesity categorized using body mass index $\geq 30\,kg/m^2$ (yes/no). Diagnosed nervous system disorders included at least one of the following conditions diagnosed by a health professional: ADHD, Alzheimer's disease, blindness or visual problems that cannot be corrected by glasses, Bell's palsy, cerebral palsy, cognitive/mental disorder, epilepsy, Kennedy's disease, learning disability, muscular dystrophy, Parkinsonism, psychological/nervous disorders, and senile dementia.

  Psychological distress was assessed using the Kessler Psychological Distress Scale (K10)[34] for symptoms of anxiety or depression experienced in the previous month and scored on a scale of 0–40 (0–5: low distress, 6–19: moderate distress, and ≥20: high psychological distress).[34] Several GN-CHA questions were about suicidal ideation and attempted suicide; here we retained the answers to the following questions: "In the past 12 months, has a close friend or family member died by suicide?" (yes/no), "Have you ever thought about committing suicide?" (yes/no), and "Have you ever attempted suicide?" (yes/no). "When did the suicide attempt occur?" [during the past year, as an adult, as an adolescent (aged 12–17 y old), as a child (<12 y old)].
- **Grandparents (G0):** From the information mothers (G1) filled out about their parents (G0), the following questions were retained for the present analyses: "Was your father a fishing guide when you were a child"? (yes/no) and "Did (your mother, father, grandmother, grandfather, other family members) attend a residential school?" (yes/no). Mothers provided further information about where their mother (G0) lived when she was pregnant with them and their place of birth.

For all questions, the GN-CHA survey provided the choices of "I do not know" and "Refused." Although few persons refused to answer, a substantial number of answers were "I do not know," which we considered as missing data.

Biomarkers of Hg Exposure

At the request of the Grassy Narrows Chief and Council, the First Nation and Inuit Health Branch of Indigenous Services, Canada, provided the authors with individual retrospective Hg biomarker data, collected by governmental biomonitoring programs for blood and hair (1970–1997) and umbilical cord blood (1970–1992).[13,16] Blood Hg concentrations were transformed into hair equivalent measures using a hair-to-blood Hg ratio of 1:250.[35] A 28-y Hg biomarker database was created using the highest measurement of equivalent hair Hg concentration for each year sampled (657 persons) and umbilical cord blood Hg concentration (201 persons).[20]

Year-based equivalent hair Hg data were available for 208 individuals of the 391 participants in the GN-CHA (53.2%); 137 had at least one Hg hair sample taken during childhood (between 5 and 15 years of age). Umbilical cord blood Hg concentrations were available for 99 persons, making up (48.5%) of the GN-CHA participants born at the local hospital within the time period.

G0/G1 prenatal exposure. For the 80 mothers retained for the present study, direct umbilical cord blood Hg measurements were used where available. For the missing umbilical cord blood data, we estimated Hg concentration from the complete umbilical cord blood Hg database ($n = 201$). For those born between 1970 and 1992, the umbilical cord blood Hg–predicted arithmetic mean for their year of birth was attributed as described in Philibert et al. (2022).[20] For those born between 1962 and 1970, the predicted arithmetic mean cord blood Hg in 1970 was used (65.1 μg/L). For women whose mother had spent her pregnancy and delivered elsewhere, umbilical cord blood Hg was set at 1.0 μg/L, which corresponded to the lowest 2.5th percentile of measured cord blood values. The correlation between measured and estimated values for umbilical cord blood Hg concentrations was rho = 0.22; $p = 0.023$.[20]

G1 childhood Hg exposure. Direct hair Hg concentration measurements, taken between 5 and 15 years of age, were available for 39 mothers. For the remaining mothers, childhood estimated Hg was derived from the overall arithmetic mean hair Hg in the year in which they turned 10 y old and then adjusted on the basis of reported child fish consumption and having attended a residential school, as previously described.[20] The correlation between measured and estimated childhood hair Hg concentrations was rho = 0.73; $p < 0.001$.[20]

No Hg measurements were available for the G0 or G2 generations. For the former, the G1 answer to the question: "Was your father a fishing guide when you were a child?" was used as an indicator of higher Hg exposure, and for children (G2), mother's fish consumption during this pregnancy (G1/G2) and child's current fish consumption, were used.

Statistical Analyses

Complex networks with causal pathways between variables are the essence of intergenerational analyses. Structural equation modeling (SEM) provides an appropriate framework for illustrating pathways and testing statistical associations. SEM allows for simultaneous consideration of multiple exposures and outcomes[36] while providing direct and indirect relations and flexibility in modeling covariances.[37–40] The SEM path diagrams

illustrate and quantify the contribution of variables and transmission of effects.

Using SEMs, we tested the pathways relevant to Hg exposure between G0, G1, and G2 with respect to the final outcomes of children and youth's emotional status and behavior and attempted suicide. The correlations between error terms of the different variables were verified and taken into account in the models. The pathways used a time order based on the premise of chronological occurrences (causes precede their effects). To control for confounding, we ensured that all backdoor paths on the SEM were closed (adjustment of covariates). Covariates along pathways were kept in the model at a $p \leq 0.10$ or if they substantively altered the model ($\geq 20\%$ change). Based on underlying assumptions, mediation (i.e., the chain of events) was tested by examining direct and indirect effects. The moderating effects of mothers' age or age at birth were tested.

Model goodness of fit was verified using the comparative fit index (CFI),[39,41] Tucker–Lewis index (TLI),[40] and global fit index (GFI),[38] as well as chi-square divided by the degrees of freedom ($\chi 2/\mathrm{df}$), root mean square error of approximation (RMSEA),[39,41] standardized root mean square residual (SRMR),[42] and Schwarz's Bayesian information criterion (BIC).[39,41,43] To improve goodness of fit, we tested the addition/deletion of variables, using modification indices (MIs).[39] The sequence of initial fit, modification, and refitting were repeated until we obtained the SEM with the best fit.

To support the SEM, in parallel, a series of directed acyclic graphs (DAGs) were performed to confirm the structure of relations between variables and to prevent misspecification or misinterpretation from possible biases. DAGs are useful for representing conditional independency among variables by evaluating data consistency and for controlling backdoor paths with minimal sufficient adjustment sets.[43,44] To support the nature and size of the relationship between two variables along the SEM pathways, a series of logistic regression models were used to examine the direct associations and provide an indication of the magnitude of effects.

Given the potential for errors associated with creating Hg exposure estimates from data based on surveillance programs with no precise sampling strategy,[13] as well as the inherent variance in blood to hair conversion[45,46] where possible, we examined the associations between measured Hg concentrations and reported fish consumption. We reran the SEM using reported G1 fish consumption during childhood in the place of estimated Hg exposure during childhood.

To ensure that the database of 80 mothers and their 162 children was sufficient to run SEM, two types of power analyses were performed: *a*) to detect model misspecification, and *b*) to detect target effects between associations.[39,41,43] Post hoc power analyses were run to detect model misspecification based on likelihood-ratio (LR) chi-square and RMSEA tests of close and not-close fit.[47–51] The power for detecting specific target effect for direct and indirect pathways was determined with simulated data in SEM for 100 and 500 simulations on the 162 children.[51] Because some children shared the same mother, we tested the nonindependent sample using clustering (mother), with the lavaan.survey R package.[52]

To reduce bias introduced by missing data, the full-information maximum likelihood (FIML) technique in the lavaan R package was used to handle missing data.[39,53] Even though several authors[54,55] consider that logit FIML can accommodate missing categorical data with unbiased errors and fit parameters, we verified the model with the weighted least squares (WLS) mean- and variance-adjusted chi-square test of model fit (WLSMV) estimator, which handles nonnormal and categorical variables, based on complete cases after multiple imputation.[39,56] When using FIML, we ran the maximum likelihood with robust standard errors (MLR), as well as the maximum likelihood estimation with Huber–White standard errors (Hubert–White sandwich), because it supports complete and incomplete data.[39]

Hg estimates for umbilical cord blood and childhood hair concentrations were calculated from exposure prediction models,[20] which included averaged year-based measured Hg exposure. Our assumption was that true Hg exposure varied randomly around the year-based average (Berkson type error). The Berkson type error would have the effect of lowering the power of analyses.[57] To control for this, we corrected with bootstrap confidence intervals (CIs) for relative risks.

Bootstrap standard errors and *p*-values analyses were carried out to increase SEM accuracy and its reliability (lavaan R package). The Bollen.stine technique, where data is first transformed such that the null hypothesis holds exactly in the resampling space, was verified to extract fit parameters from a fitted lavaan object.[58,59] We used the false discovery rate (FDR) measure for controlling type I error of multiple comparisons.[60]

We compared the performance of SEM by comparing the fit parameters, point estimates, and standard errors to the complex sampling design (cluster-based), which takes into account multiple children. In the case of small differences between non clustered-based and cluster-based analyses, we preferred to use the conventional analysis using FIML[53] rather than data imputation as required by the mother-clustered–based model (lavaan.survey R package).[39,61]

Variables with a skewed distribution were log (base 10) transformed. Threshold of statistical significance in all analyses was set at $p \leq 0.05$.

Database management and descriptive statistical analyses were performed using JMP Professional (version 16.0; Statistical Analysis Hardware; SAS Institute Inc.). All other analyses used the R statistical software (version 3.6.1; R Development Core Team). SEMs were computed with the lavaan R package.[39,62] Further analyses with DAGs used dagitty and ggdag R packages. Power analyses for model misspecification were computed using the semPower R package. An online tool[51] was used to assess power for detecting target effects. The clustering (mother) effect was tested with the lavaan.survey R package along with mice and mitools R packages for data imputation.

Results

The characteristics reported by mothers ($n = 80$) for themselves (G1) and their parents (G0) are presented in Table 1. The large majority of grandmothers (G0) resided in Grassy Narrows territory during their pregnancy ($n = 69$), and half of grandfathers (G0; $n = 42$) had been fishing guides. Many grandparents (G0) had attended residential schools; for all mothers (G1) ≥ 35 years of age ($n = 31$), at least one parent (G0) had been taken to a residential school.

Mothers' (G1; $n = 80$) median age was 33 y old, ranging from 23 to 55 [interquartile range (IQR): 29–37 y]. Most mothers (G1; $n = 77$) had some high school education, but only 21% ($n = 17$) had received a high school diploma (Table 1). At the time of the survey, approximately half of the mothers (G1; $n = 41$) were working; those who were not looking for work at the time of the survey were either an at-home parent, in poor health or disabled, or a student. The most prevalent nonneurologic chronic health conditions were allergies ($n = 25$; 33%), eczema ($n = 19$; 24%), arthritis ($n = 11$; 15%), and diabetes ($n = 11$; 15%). Diagnosed neurologic disorders were reported by 14 mothers (Table 1); all scored in the moderate/high K10 Psychological Distress Scale compared with 56% ($n = 34$) of those who reported no diagnosis.

A third of mothers ($n = 27$) reported that a family member or close friend had committed suicide, and half ($n = 40$) reported

Table 1. Descriptive characteristics for grandparents (G0) and mothers (G1) as reported by mothers (G1) in the Grassy Narrows Community Health Assessment (GN-CHA) survey; $n = 80$.

Characteristics	Yes [n (%)]	No [n (%)]	Missing [n (%)][a]
Generation grandparents (G0)			
Grandmother pregnant in GN territory	69 (86.25)	8 (10.00)	3 (3.75)
Grandfather a fishing guide	42 (52.50)	24 (30.00)	14 (17.50)
Grandmother attended a residential school	47 (58.75)	29 (36.25)	4 (5.00)
Grandfather attended a residential school	46 (57.50)	25 (31.25)	9 (11.25)
Generation mother (G1)			
Age <35 y	46 (57.50)	34 (42.50)	0
Education (high school diploma)	17 (21.25)	61 (76.25)	2 (2.50)
School success (very good/excellent)	28 (35.00)	49 (61.25)	3 (3.75)
Childhood fish consumption (≥several times a week)	38 (47.50)	36 (45.00)	6 (7.50)
Currently working	41 (51.25)	37 (46.25)	2 (2.50)
Unemployed but looking for work	19 (51.35)	16 (43.24)	2 (5.41)
Struggle to pay for food (at least once a month)	43 (53.75)	27 (33.75)	10 (12.50)
Health perception: thriving (very good/excellent)	17 (21.25)	63 (78.75)	0
At least one chronic health condition	56 (70.00)	23 (28.75)	1 (1.25)
At least one diagnosed nervous system disorder	14 (17.50)	65 (81.25)	1 (1.25)
Obesity ≥30 kg/m^2	44 (55.00)	34 (42.50)	2 (2.50)
Current heavy drinker	44 (55.00)	32 (40.00)	4 (5.00)
Family or close friend has died from suicide last 12 months	27 (33.75)	48 (60.00)	5 (6.25)
Suicidal ideation	40 (50.00)	34 (42.50)	6 (7.50)
Ever attempted suicide	31 (38.75)	43 (53.75)	6 (7.50)
K10 (moderate/high)	49 (61.25)	27 (33.75)	4 (5.00)

[a]For each question in the GN-CHA, persons could provide the reply "I don't know," "I can't recall," or "Refused", which were grouped as "Missing."

that they themselves had thought about suicide (Table 1). Among those who had ever thought about suicide, 31 (77.5%) had attempted suicide at least once in their lives; for over half of these ($n = 19$; 61.2%), the first suicide attempt occurred during childhood/adolescence. More mothers who had thought about suicide scored in the moderate-high range of the K10 Psychological Distress Scale compared with those who had not ($n = 31$; 81.6% vs. $n = 13$; 40.6% LR chi-square = 12.82; Fisher exact test: $p < 0.001$).

Some mothers (G1) did not know whether their father (G0) had been a fishing guide or not ($n = 14$; 17.5%). Comparison of the characteristics of mothers who reported that their father had been a fishing guide ($n = 42$) and those who reported that their father had not been a fishing guide ($n = 24$) are presented in Table S1. No difference was observed with respect to their parents (G0) having been placed a residential school; however, all mothers (G0) of the 42 women whose father had been a fishing guide, resided on Grassy Narrows territory during their pregnancy, compared with 75% for the mothers of the 24 women whose father had not been a fishing guide (Table S1).

For the mothers who knew whether their father had been a fishing guide (G1) ($n = 66$), no significant differences were observed with respect to the father (G0) having been a fishing guide or not for sociodemographic and health characteristics (Table S1), with the exception of diagnosed neurologic disorders: 23.8% ($n = 10$ of 42) of those who knew that their father had been a fishing guide and none of those who knew that he had not been a fishing guide (Table S1). Childhood fish consumption and suicidal ideation were higher among the women who reported that their father had been a fishing guide ($n = 24$; $n = 25$ of 42, respectively), but the difference was just above the significance threshold (Table S1). More women whose father had been a fishing guide scored in the high range of the K10 Psychological Distress Scale ($n = 11$; 26.8%) compared with only one for the others.

Table 2 contains the measured and estimated mean, median, and IQR values for mothers' umbilical cord blood and hair Hg. There was no difference in measured umbilical cord Hg between mothers who reported that their father had been a fishing guide compared with those who indicated that their father had not been a fishing guide [median = 8.5 μg/L; 75th percentile: 8.7 μg/L ($n = 17$) vs. median = 5.7 μg/L; 75th percentile: 17.5 μg/L ($n = 7$); Wilcoxon/Kruskal–Wallis tests (rank sums): $S = 108$; $p = 0.204$], but their measured childhood hair Hg was significantly higher [median = 0.77 μg/g; 75th percentile: 1.1 μg/g vs. median = 0.5 μg/g; 75th percentile: 0.7 μg/g; Wilcoxon/Kruskal–Wallis tests (rank sums): $S = 140$; $p = 0.045$], paralleling their reported fish consumption.

Table 3 contains information, reported by the mothers, for each pregnancy and the child's health and well-being (G2; $n = 162$). Mothers filled out the questionnaire for an average of two children, ranging from one to seven children. For almost 20% of children ($n = 31$), mothers reported eating fish at least once a week during their pregnancy (Table 3). Mothers' fish consumption during pregnancy reflected her own childhood fish consumption [Kendall's Tau-b: 0.46 (95% CI: 0.33, 0.57) Fisher's exact test: $p < 0.001$] and was higher among those whose father (G0) was a fishing guide [Kendall's Tau-b: 0.355 (95% CI: 0.210, 0.510) Fisher's exact test: $p < 0.001$]. Indeed, 21 mothers (28.4%), whose father (G0) had been a fishing guide reported eating fish at least once a week or more compared with only 2 (4.5%) among those whose father had not been a fishing guide (LR chi-square: 20.78; Fisher exact test: $p < 0.001$). No associations were observed for mothers' age, maternal age at pregnancy, or child's age with respect to G1/G2 fish consumption during pregnancy [Wilcoxon/Kruskal–Wallis tests (rank sums) one-way test chi-square = 3.39, $p = 0.188$; 2.15, $p = 0.342$; and 1.97, $p = 0.374$, respectively].

Table 2. Measured and estimated mothers' (G1) umbilical cord blood and childhood hair mercury (Hg).

	n	Mean	Median	IQR	Min–max
Measured umbilical cord blood Hg (μg/L)	29	7.65	5.70	2.35–8.80	1.5–35.7
Estimated umbilical cord blood Hg (μg/L)	51	15.15	5.25	3.59–16.86	1.0–65.2
Measured childhood hair Hg (μg/g)	39	1.50	0.50	0.50–0.90	0.50–11.4
Estimated childhood hair Hg (μg/g)	38	1.52	0.92	0.72–2.60	0.50–5.64

Note: IQR, interquartile range; max, maximum; min, minimum.

Table 3. Descriptive characteristics for pregnancy (G1/G2) and children/youth (G2), as reported by mothers (G1) in the Grassy Narrows Community Health Assessment (GN-CHA) survey: $n = 162$.

Characteristics	Yes [n (%)]	No [n (%)]	Missing [n (%)][a]
Pregnancy (G1/G2)			
Mother's age at birth of child (≥22 y)	93 (57.41)	69 (42.59)	0
Maternal fish consumption during pregnancy (≥once a week)	31 (19.14)	125 (77.16)	6 (3.70)
Problems during pregnancy/childbirth	33 (20.37)	125 (77.16)	4 (2.47)
Mother's drinking/drugs during pregnancy	24 (14.81)	134 (82.72)	4 (2.47)
Generation children/youth (G2)			
Age (≥12 y)	66 (40.74)	96 (59.26)	0
Sex (girls)	89 (54.94)	73 (45.06)	0
Grandfather was a fishing guide	74 (45.68)	49 (30.24)	39 (24.07)
Fish consumption past year (often)	25 (15.40)	121 (74.69)	16 (9.88)
Overall health (very good/excellent)	129 (79.63)	33 (20.37)	0
Mental health (very good/excellent)	98 (60.49)	62 (38.27)	2 (1.23)
Speech/language disorder	17 (10.49)	139 (85.80)	6 (3.70)
Anxiety or depression	16 (9.88)	134 (82.72)	12 (7.40)
Emotional or behavioral problems	42 (25.93)	102 (62.96)	18 (11.11)
Emotional or behavioral problems (12–17 y)	24 (36.36)	31 (49.97)	11 (16.67)
Ever attempted suicide (all children)	22 (13.58)	133 (82.10)	7 (4.32)
Ever attempted suicide (12–17 y)	17 (27.42)	45 (72.58)	4 (6.45)

[a]For each question in the GN-CHA, persons could provide the reply "I don't know," "I can't recall," or "Refused", which were grouped as "Missing."

Seventeen mothers (21.3%) reported drinking or taking drugs for 24 pregnancies (Table 3), representing 15.1% of pregnancies for which this information was available ($n = 158$). Mothers who reported drinking alcohol or taking drugs during pregnancy for their child (G0/G1) were significantly younger at childbirth compared with those who reported not drinking or taking drugs (median = 19 y; IQR: 18–21 y and median = 23 y; IQR: 20–27 y, respectively; Wilcoxon/Kruskal–Wallis chi-square: 11.83; Fisher exact test: $p = 0.001$). The proportion of pregnancies for which the mother reported drinking or taking drugs was higher for those whose father (G0) had been a fishing guide compared with those who reported that their father had not been a fishing guide ($n = 14$, 19.7% vs. $n = 2$, 4.2%). No association was observed between drinking or taking drugs during pregnancy and the mother's current drinking habits (LR chi-square: 0.06; Fisher exact test: $p = 0.801$). Few children ($n = 4$, 2.5%) had a diagnosis of FASD.

GN-CHA mothers' (G1) reports about their children (G2) are presented in Table 3. Children's median age was 10 y (IQR: 8–14). For almost one quarter ($n = 39$), their mothers did not know if their grandfather had worked as a fishing guide. Most children (74.7%; $n = 121$) had not eaten local fish often over the year prior to the survey (Table 3). The First Nations Regional Health Survey 2008/2010 defined a measure for conditions that "may have an impact on learning ability" as at least one of the following diagnosed conditions: cognitive or mental disabilities, ADD/ADHD, learning disabilities, speech/language difficulties[33]; 24 children (14.8%) fell into this category. No difference was observed between boys ($n = 14$) and girls ($n = 10$) (LR chi-square: 2.27; Fisher exact test: $p = 0.132$).

Mothers' perceived the mental health of almost 40% ($n = 62$) of their children as less than very good or excellent (Table 3), and for 25% of children, the mother reported that the child had more emotional or behavioral problems compared with other children of the same age and sex (Table 3). The prevalence of emotional or behavioral problems was twice as high in youth (≥12 years of age) compared with younger children (36.7%; $n = 24$ vs. 18.8%; $n = 18$; LR chi-square: 8.87; Fisher exact test: $p = 0.003$). Among younger children (<12 years of age), no difference was observed between boys and girls [$n = 9$ of 41 (22.95%) vs. $n = 9$ of 48 (18.75%), respectively; LR chi-square: 4.65; Fisher exact test: $p = 0.794$]. However, more adolescent girls (≥12 years of age) presented emotional or behavioral problems compared with boys [$n = 17$ of 30 (56.67%) vs. $n = 7$ of 25 (28.00%), respectively; LR chi-square: 4.65; Fisher exact test: $p = 0.031$].

Mothers reported that 13% ($n = 22$) of children/youth had attempted suicide, but the percentage rose to 27% ($n = 17$) when considering only those ≥12 years of age (Table 3). Among adolescents (≥12 years of age), suicide attempts were higher among girls ($n = 14$ of 34; 41.18%) compared with boys ($n = 3$ of 28; 10.71%; Fisher exact test LR chi-square: 7.70; $p = 0.006$). None of the children with a diagnosis of FASD had attempted suicide.

The SEM in Figure 1 presents the intergenerational pathways for children and youth attempted suicide, with the corresponding fit parameters in Table 4 and estimates of sequential mediations in Table 5. The pathways began with mothers' year of birth, which represented not only her age, but also accounted for the change in Hg exposure over time. Different pathways linked G0 through G1 with an increased risk for G2 attempted suicide.

One modeled pathway originated from mothers' umbilical cord blood Hg (G0/G1), a reflection of (G0) grandmothers' fish consumption, as well as maternal prenatal exposure, and grandfather having worked as a fishing guide (G0), both of which are seen to contribute to mothers' childhood Hg (G1) (Figure 1). Mothers' childhood Hg (G1) was then associated with her being diagnosed with at least one neurological disorder, which in turn, was associated with current psychological distress, to which suicidal ideation, over her lifetime, also contributed. The model further suggested an association between mothers' K10 psychological distress score (G1) and child's mental health status (G2), which was linked to the child's emotional state and behavioral problems, which, in turn, may contribute to an increased risk for attempted suicide, particularly among older girls.

A second modeled pathway lead from the father as a fishing guide (G0) (Figure 1) to daughters' fish consumption during pregnancy (G1) and consequently her children's prenatal Hg exposure (G1/G2). Maternal fish consumption during pregnancy (G1/G2) contributed to children's (G2) poor mental health and emotional and behavioral problems, the latter of which was directly associated to attempted suicide.

Another pathway showed associations between the grandfather having been a fishing guide (G0) and mothers' drinking or taking drugs during pregnancy (G1/G2) (Figure 1). The association between mothers' drinking and drugs during pregnancy and child's emotional and behavioral problems was not significant ($p = 0.14$).

For the SEM (Figure 1), power analyses on model misspecification showed that a sample size of 162 children was associated with a power of 71.8%, which was acceptable. Table 4 shows the SEM fit parameters for the final model and the sensitivity analyses

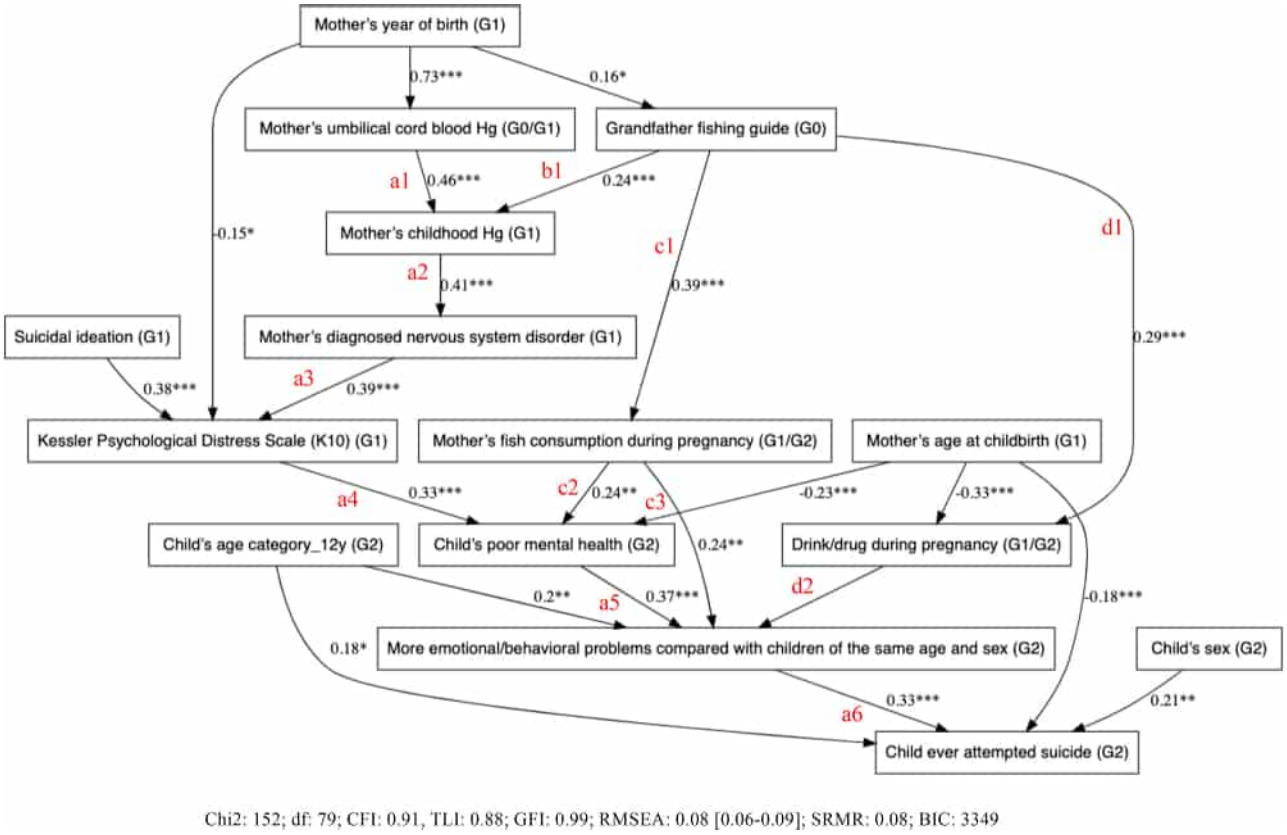

Figure 1. Structural equation model pathway diagram on the psychological impact of Hg exposure through a matrilineal lens across three generations. Intergenerational information, provided by mothers ($n = 80$) for the Grassy Narrows Community Health Assessment provided for 162 children. Mothers' umbilical cord Hg and childhood hair Hg concentrations were estimated from a 1970–1997 biomarker database. Note: BIC, Schwarz's Bayesian information criterion; CFI, comparative fit index; Chi2, chi-square; df, degrees of freedom; GFI, global fit index; Hg, mercury; RMSEA, root mean square error of approximation; SRMR, standardized root mean square residual; TLI, Tucker–Lewis index. *p*-Values: significance of pathway coefficient estimates: $^{*}p \le 0.05$; $^{**}p \le 0.01$; $^{***}p \le 0.001$.

using maternal childhood fish consumption and a mother-clustered–based model. The performance of the SEM models that *a*) replaced estimated maternal childhood Hg exposure by her reported fish consumption at ~10 years of age (G1), and *b*) used a mother-clustered–based model, with imputation, were similar.

Estimates of sequential mediation at different stages in the SEM pathways are presented in Table 5, with target effects power analyses simulation for each link. For all pathways toward children and youth (G2) attempted suicide, effects diminished over generations, but remained significant (Table 5). The strongest contributions passed through fish consumption during pregnancy. The pathway that passed through mothers' drinking or taking drugs during pregnancy (d1 × d2 × a6 in Figure 1) to children's attempted suicide was not significant (coefficient estimate = 0.01; $p = 0.17$).

Finally, children's risk of attempting suicide was significantly influenced by mothers' age at childbirth (Figure 1). The median age at childbirth for mothers of children who attempted suicide was 19.5 y (75th percentile: 22 y), whereas the median age at childbirth of mothers whose child had never attempted suicide was 23 y (75th percentile: 27 y) (Wilcoxon/Kruskal–Wallis chi-square: 12.2; $p = 0.001$).

Tables 1 and 3 include several characteristics that were tested in the SEM, but which were not retained in the final model. For G0, residential school attendance (grandmother and grandfather) did not enter the model ($p > 0.1$). A total of 59 mothers (78.7%) reported that at least one of their parents had attended a residential school; these mothers were significantly older than those whose parents had not been taken to a residential school [median = 36 y (IQR: 31–39 y) vs. median = 28.5 y (IQR: 25–30 y); Wilcoxon chi-square = 19.7; $p < 0.0001$]. For G1, the following variables were tested but did not enter the model ($p > 0.1$): education and school success, currently working, struggle to pay for food, heavy drinking, general health, obesity, at least one chronic health condition, and current fish consumption; for G1/G2: health issues during pregnancy, prematurity, and difficulties during childbirth; for G2: physical health, fish consumption over the past year, and school performance.

Table 4. SEM Fit parameters for the final model, the model with maternal childhood fish consumption and the mother-clustered–based model.

SEM model	Chi2	df	CFI	TLI	GFI	RMSEA (95% CI)	SRMR	BIC
Final model (Figure 1)	161	80	0.90	0.87	0.99	0.08 (0.06, 0.10)	0.09	3,352
Maternal childhood fish consumption	153	80	0.90	0.88	0.99	0.08 (0.06, 0.10)	0.09	3,793
Mother-clustered	201	80	0.86	0.82	0.99	0.10 (0.08, 0.11)	0.09	3,753

Note: BIC, Schwarz's Bayesian information criterion; CFI, comparative fit index; Chi2, chi-square; CI, confidence interval; df, degrees of freedom; GFI, global fit index; RMSEA, root mean square error of approximation; SEM, structural equation model; SRMR, standardized root mean square residual; TLI, Tucker–Lewis index.

Table 5. Estimates of sequential mediation in SEM pathways for Hg exposure across three generations to attempted suicide in children and youth.

	Pathways	Estimate	(95% CI)	p-Value	Power target simulations	
					$n = 100$	$n = 500$
Toward psychological distress (G1)						
Umbilical cord blood Hg (G0/G1)	a1 × a2 × a3	0.07	(0.02, 0.12)	0.017	1.00	1.00

Note: Pathways with "a" originated from mothers' umbilical cord blood Hg; Pathways with "b," "c," or "d" originated from grandfather a fishing guide. Hg, mercury; SEM, structural equation modeling. p-Values adjusted on bootstrap: significance of pathway coefficient estimates: $^{*}p \le 0.05$; $^{**}p \le 0.01$; $^{***}p \le 0.001$.

Table S2 presents a series of multiple regression models for the various components of the SEM pathways, without mediating variables. The results support the direct associations computed by the SEM.

Discussion

This study, which examined a matrilineal linkage over three generations, suggests an intergenerational impact of Hg exposure on Grassy Narrows First Nation children's emotions and behavior and attempted suicides. Mothers who participated in the GN-CHA provided information on their parents and children. Most of these women, born between 1962 and 1993, were exposed to Hg prenatally and as children, teenagers, and adults. During the years when Hg exposure was at its highest, their families suffered the dramatic consequences of the loss of their Indigenous culture and values, as well as their traditional food and livelihood.[1–6] In the absence of information on exposure of the grandparent generation (G0), we used the maternal father's occupation as a fishing guide as a proxy for grandfathers' high Hg exposure, based on biomonitoring data.[13,14] Maternal umbilical cord blood Hg (G0/G1) reflected grandmothers' Hg exposure through fish consumption during pregnancy.

The point of departure for the study was the prevalence of attempted suicide among today's children and youth. Mothers reported that 27.4% of adolescents ($n = 17$) had attempted suicide at least once: girls ($n = 14$; 41.2%) and boys ($n = 3$; 10.7%). These prevalences are considerably higher than those reported in the most recent First Nation and Regional Health Survey,[63] administered to 4,639 First Nation youth at the same period as the GN-CHA, in which 10.3% reported ever attempting suicide (15.6% of girls and 5.2% of boys).

In the SEM of the present study, several pathways linked grandparents (G0) Hg to an increased risk of attempted suicide for G2 children and youth. The pathway through mothers' (G1) childhood Hg exposure was mediated by her umbilical cord blood Hg concentration (G0/G1) and having a father a fishing guide (G0), both of which likely reflect grandparents fish consumption and Hg exposure. Mothers' (G1) childhood Hg exposure was directly associated with having at least one nervous system disorder, which, in turn, was associated with her current psychological distress. These findings are consistent with studies that have examined Hg exposure and psychological distress. Using the General Health Questionnaire (GHQ), a study in Japan reported a high prevalence of psychological distress among 86% of 133 women ≥40 years of age living in the Minamata area, where they were exposed to Hg as children.[64] In a recent study of an Indigenous community in the Brazilian Amazon, hair Hg among persons 12–72 years of age [mean age 27.4 y ($n = 109$)] was associated with depressive symptoms, as assessed with the Geriatric Depression Scale Short Form; persons with hair Hg ≥10 μg/g were 1.8 times more likely to manifest depressive symptoms.[65] In the GN-CHA, one mother in five reported a high level of psychological distress on the Kessler Psychological Distress Scale. This is consistent with Harada's observations in 2010 where 20% of 73 Grassy Narrows examinees manifested signs and symptoms of emotional disturbances.[19] In the present study, maternal psychological distress score was associated with child's poorer health. This association has been observed in many studies that have linked mothers' psychological distress to their children's mental health status.[66,67]

Based on the SEM, the strongest contribution of G0 on G2 was through grandfather's influence on mothers' fish consumption during pregnancy, suggesting that the tradition of fish consumption is passed on from father to daughter. Indeed, women who consumed fish as children, tended to consume fish as adults. Grassy Narrows elder J.D.S., co-investigator on the present study, notes that: "fish has always played a vital role in Anishinaabek natal traditions. The grandmothers used to say, 'Eat fish broth, and the breast milk will come out.'" In 2005, Chan et al.[68] reported a very high correlation between local fish consumption and hair Hg concentrations in Grassy Narrows; for women of

child-bearing age (18–40 y), the average fish intake varied by season and was highest during the summer months ($\sim$28 g/d) and lowest during the winter months ($\sim$2 g/d). In 2010, Neff et al.,[10] who analyzed Hg concentrations in fish in the English–Wabigoon River system, indicated that they had not declined significantly since the mid-1980s and may still present a potential health risk to humans.

In the SEM, maternal fish consumption during pregnancy (G1/G2), an indicator of prenatal MeHg exposure, was the major contributor to children's mental health and emotional state and behavior, suggesting that at recent fish Hg concentrations, MeHg was affecting fetal development. MeHg is actively transported across the placenta and its concentration in umbilical cord blood has been measured to be $\sim$1.7 times (95th percentile: 3.4) that of maternal blood.[29,69,70] Several studies have reported an association between prenatal Hg exposure and anxiety-related symptoms in children or adolescents.[18,31,71–73] These findings are supported by recent imaging studies of prefrontal brain areas of Inuit adolescents.[74] For the children and youth in the present study, there was a direct association between emotional state and behavioral problems and attempted suicide.

The SEM results suggested that despite the absence of specific information on G0 or about the trauma suffered by mothers (G1) during their own childhood or adolescence, a pathway linked grandfather having been a fishing guide to mothers' drinking or taking drugs during pregnancy. The vivid descriptions of life in Grassy Narrows in the years of the highest Hg exposures and the socioeconomic and cultural trauma suggest that the context in which these women were raised would be an important determinant of their adolescent and early adult behavior. Negative childhood experiences have been associated with early alcohol drinking.[75] In the present study, drinking alcohol or taking drugs was more prevalent during pregnancies at a younger age [$\leq$20 years of age; $n=14$ of 44 (31.82%)], compared with 10 of 114 (8.8%) for pregnancies at an older age. Although the GN-CHA did not specify the quantity of alcohol or drugs absorbed during pregnancy, the percentage of children whose mother drank or took drugs during her pregnancy (15.2%, $n=24$) was inferior to the prevalence for First Nations' pregnancies in Canada, estimated in a systematic review of six studies[76]: 36.5% for drinking and 22.1% for binge drinking during pregnancy.

The possible interaction between MeHg and ethanol has been examined in animal models.[77–80] In one study, ethanol lowered Hg accumulation in the prefrontal and motor cortex of mice that were administered chronic low doses of MeHg and ethanol equivalent to binge drinking; the authors suggest that ethanol intake could reduce central nervous system Hg levels associated with psychiatric and cognitive disorders in MeHg-intoxicated individuals.[80] Future studies in communities with high Hg exposure might consider addressing whether drinking might relieve or aggravate Hg-related symptoms.

In the present study, an inverse relation was observed between mothers' age at childbirth and children's attempted suicide. This is consistent with the findings of a systematic review and meta-analysis of attempted suicide in relation to *in utero* and perinatal factors, in which teenage pregnancy was identified as an important risk factor.[81] The review did not include environmental toxic exposures.

The GN-CHA focused primarily on current health, socioeconomic conditions, and well-being and as a result, no specific information was available on each mother's (G1) possible adverse experiences earlier in her life. The descriptions of psychological suffering in this community following the Hg discharge[1–9] resemble those of other environmental disasters, such as the *Deepwater Horizon* spill, where an increase in domestic partner fights, depression, memory loss, and inability to concentrate was reported for wives of clean-up workers 2 y after the spill.[82] Palinkas et al.[83] reported that the decline in subsistence activities was an important risk factor for post-traumatic stress disorder in Alaska Natives affected by the *Exxon Valdez* oil spill. Furthermore, children who lived closer to the *Hebei Spirit* oil spill in Korea, presented a higher prevalence of depressive symptoms compared with those who lived farther away.[84] The authors mention that adult suicides increased following the spill and suggested that parent psychopathology subsequent to a disaster influences children's psychological health.[84]

At the time of the GN-CHA, Statistics Canada reported that suicide risk among First Nation adults was three times higher than among the non-Indigenous population.[62] The GN-CHA use of the same questions as the First Nations Regional Health Survey 2008/2010,[33] administered to 11,043 First Nation adults from 216 communities in Canada, allowed us to compare Grassy Narrows with other First Nation communities. In the First Nations Regional Health Survey 2008/2010,[33] 11.8% of participants reported that a close friend or family member had committed suicide in the previous year. In the GN-CHA, 27 (36%) of the 75 mothers (G1) who answered this question responded in the affirmative. The prevalence of both suicidal ideation and attempted suicide during one's lifetime for mothers in the present study was also considerably higher compared with those of other First Nations in Canada who were 18–39 y old at the time of the survey[33]: Fifty percent ($n=40$) among the mothers of Grassy Narrows, compared with 22% in First Nation communities in Canada, and 40% ($n=32$) vs. 13.1%, respectively.[33]

Although prenatal Hg exposure was associated with emotional and behavioral problems and attempted suicide in today's children and youth (G2), this relation was not observed for their mothers (G1). Several reasons possibly explain this difference. For the mothers (G1), no individual information was available for other lifetime factors that could have contributed to suicidal ideation or attempted suicide, notably the breakdown of the mother's family in the years following the discharge; some families would have had more difficulty coping than others. Many historic descriptions of Grassy Narrows underline the high prevalence of successful suicides,[1,2,4,5] but no studies were performed on their possible relation to prenatal or childhood Hg exposure or whether their fathers (G0) had been fishing guides. A previous study in Grassy Narrows has linked higher lifetime Hg exposure with premature death ($n=154$ of 222).[16] It is possible that women with higher exposures may have died prior to the GN-CHA.

Although we cannot go back in time, we can certainly ask about the possible contribution of very high concentrations of prenatal and childhood Hg to the dramatic increase in youth suicide during the 10–12 y following the discharge of extremely high levels of Hg. Erikson,[4] who visited Grassy Narrows in 1979, reported that in the 11 months between 1977 and 1978, 26 young people between the ages of 11 and 19 years had attempted suicide.[4] In the same chapter, he provided a description of Hg poisoning that included "depression and apathy, memory loss and ... explosive shifts in mood", but then went on to explain how alcohol and "the way in which the Ojibway raise their children" accounted for the striking disorder in this community. In all the accounts of social disruption in the Grassy Narrows disaster, no one seriously considered whether Hg exposure may be a contributing factor, and no one considered whether drinking might relieve or aggravate Hg-related symptoms.

In the present study, we examined the possible contribution of family members having been placed in a residential school, but these variables were not retained in the SEM pathways. This may be due to the lack of variance given that almost 80% ($n=59$) of 75 mothers reported that at least one of their parents had attended

a residential school and they were significantly older than those whose parents had not been placed in a residential school.

There are important limitations to the present study owing to limited data availability. Generational SEM is inherently complex and, in the present study, this was compounded by the small size of the population, paucity of information on G0 and G1's early childhood experiences, and missing data. This is, indeed, a relatively small community; the census data for 2016 indicates that in Grassy Narrows, there were 160 women between the ages of 20 and 54 y and 175 children 5–19 years of age.[32] No specific information was available on individual grandfather's (G0) Hg exposure and behavior in the years following the discharge, and we relied on published reports and descriptions.[1–6,14] Information on mothers' childhood (G1) was limited to her childhood fish consumption, her father working as a fishing guide, and schooling and school performance. Missing Hg exposure data were handled using estimates, based on larger measurements.[16,20] Children's mental health was not assessed, but relied on mothers' perception. All of these factors contributed to limiting model performance. To ensure the performance of the SEM, we used a series of statistical techniques to address different types of error, and power analyses. We tested the reliability of the pathways, using a different childhood exposure variable (maternal fish consumption at 10 years of age) and mother-clustered–based modeling. The strengths of the associations were verified using logistic regression models without mediating variables. Although not perfect, the final SEM provided a plausible portrait of the contribution of Hg effects over three generations.

Although social disruption certainly played an important role in the psychological well-being of the people of Grassy Narrows First Nation following the disaster,[1–6] the findings of the present study suggest that Hg exposure over three generations likewise contributed to their mental health. However, to our knowledge, no study has carefully addressed the possible positive psychological impact on this community's fortitude and resilience over the past decades. In the mid-1970s, Grassy Narrows initiated demonstrations and then legal proceedings to obtain compensation for the harm that was done to their community.[1–3] In 1975, community members worked with M. Harada and his team from Japan to document their neurological health,[19] and since that time the community has maintained close relations with the Japanese physicians, who have carried out several series of examinations.[85] Over the past 50 y, successive Chiefs and Council and grassroots Grassy Narrows people have worked with scientists for Hg remediation[86,87] and protection of their territory.[9] Their actions are marked by memoirs to federal and provincial parliaments, demonstrations, a hunger strike, and the longest blockade in Canada to stop logging on their territory.[79] Willow, writing about the blockade, stated: "The story of the Grassy Narrows blockade cannot be understood apart from the community's multigenerational struggle to endure in the face of political, cultural, and environmental colonization."[88]

After several years of community lobbying of government ministries, Grassy Narrows First Nation obtained funding for their community health assessment, as well as access to their own historic Hg exposure data. This study was only possible through the leadership of Grassy Narrows First Nation and collaboration with an academic research team, based on the principles of ownership, control, access, and possession of First Nations' data [OCAP, a registered trademark of the First Nations Information Governance Centre (FNIGC)].[89] Several authors have aptly pointed out that Indigenous leadership throughout the research process is key to decolonizing health research.[90,91]

Understanding the intergenerational harm that was done to the people of Grassy Narrows should serve to support efforts to restore the health and well-being that this community enjoyed prior to the discharge of Hg into the river system of their traditional territory. From a public health perspective, a community-based interdisciplinary approach[92,93] would be useful to understand and act upon the social, economic, historical, cultural, physiological, and psychological consequences of this and other environmental disasters.

Acknowledgments

D.M. was invited by the Grassy Narrows First Nation as scientific advisor for the GN-CHA. She collaborated on study design, questionnaire content, data analyses, and preparing reports. She is principal investigator and main author of the present research. A.P. created the database, determined the statistical approaches and performed the analyses. She co-wrote the manuscript with D.M. M.F. participated in the analyses and dissemination of the GN-CHA. She participated in the writing and editing of the manuscript. J.D.S. is the initiator and organizer of the GN-CHA survey. She shared information on the history and context across generations and participated in data interpretation. All authors read and approved the final manuscript.

We thank all of the people of Grassy Narrows First Nation who organized and carried out the Grassy Narrows Community Health Assessment (GN-CHA): the community advisory committee, the fieldwork coordinators, and the surveyors. A special thank you to the people of Grassy Narrows who participated in the GN-CHA and agreed to share their biomarker data with us. We salute the resilience of the Grassy Narrows community who have fought for mercury justice over the past 50 years. The GN-CHA received financial support from Health Canada and the Ontario Ministry of Health and Long-Term Care, and technical support from these ministries and the Ontario Agency for Health Protection and Promotion, the Ontario Ministry of Indigenous Relations and Reconciliation, and the Northwestern Health Unit of Ontario. The present study was funded by the Canadian Institutes for Health Research (152882).

Ethics approval for the GN-CHA was obtained from the Manitoulin Anishinaabek Research Review Committee (MARRC), who issued an ethics certificate on 11 November 2016. The study was conducted according to the guidelines of the Declaration of Helsinki and approved by the institutional review board of the Université du Québec à Montréal (2016_e_1350; 6 September 2016) and Health Canada Research Ethics Board (REB 2017–0006; 3 August 2017).

Informed consent forms were signed by all participants. Consent included survey participation and the linking of the information from the GN-CHA to data obtained from previous surveillance programs or studies of Hg exposure.

The data sets generated and analyzed in the present study are the property of the Grassy Narrows First Nation. Permission for use of the data lies with the Grassy Narrows Chief and Council.

Part 2	
Overview	29
1. Mercury is highly toxic to human health. Impacts include fetal and child development, neurological disorders and cardiovascular changes.	30
2. Adults can be impacted at levels well below the old threshold level for risk of 50 µg/g in hair.	32

		PAGE
3.	Foetuses and children can be impacted at far lower levels than adults	34
4.	Mercury is bio-concentrated across the placenta.	35
5.	Population level impacts can be found at much lower levels of exposure than clear individual impacts	36
6.	Developmental impacts of mercury have life-long impacts.	37
7.	The health impacts of mercury exposure in adults can take a long time to manifest and can be long lasting and degenerative.	40
8.	Fish is the most important source of mercury in humans. Other sources of mercury in humans include fish eating wildlife (ducks, otters, etc.) and dental fillings	42
9.	In 1979 the Health and Welfare Canada recommended a limit of 0.2 ppm in fish as a fish consumption limit for Grassy Narrows and White Dog.	43
10.	The Canadian reference dose for preventing fetal neurotoxicity and developmental impacts is double that recommended by US EPA.	44
11.	Eating fish has a number of important health benefits.	44
12.	The Ontario Guide for Sport Fish Eaters	47
13.	People who have already experienced elevated mercury exposure	47
14.	Conclusions with respect to Grassy Narrows	48

Appendix A – Curriculum Vita

INTRODUCTION

I am a professor emerita at the *Université du Québec à Montréal* (UQAM), where I was a professor in the Department of Biological Sciences from 1970 to 2006. I hold a doctorate in physiology from McGill University. I am a former chair of the department (1982-1984), head of the doctoral program in environmental sciences (1993) and chair of the UQAM Institute for Environmental Sciences (2001-2003). I founded the Center for Interdisciplinary Research on Well-being, Health, Environment and Society (CINBIOSE) in 1985, and was director at different periods until 2000. From 1998 to 2013, I was director of the CINBIOSE World Health Organization-Pan American Health Organization Collaborating Center for the Prevention of Work and Environment-related illnesses. I was co-coordinator of the Latin American Community of Practice in Ecosystem Approaches to Human Health (2005-2013). Since 2008, I head the pan-Canadian research team on Gender, Environment and Health. I have been a member of the Quebec Council for Science and Technology (1984-1989) and the Science Advisory Board of the International Joint Commission of the Great Lakes (2001-2011). My teaching, research and writing have focused on the early neurotoxic effects in humans of environmental pollutants generally, including mercury. In 2006, I chaired an international scientific group that wrote a consensus document on mercury and human health. I have authored over 150 peer-reviewed scientific articles, including 50 scientific papers on the subject of mercury exposure and effects in freshwater fish-eating populations. I have given keynote addresses on mercury and human health at major international conferences and numerous presentations on the subject at national and international meetings, including the Office of Science and Technology Policy of the United States' White House (1988). I have written reports on mercury and health as it relates to the members of Grassy Narrows First Nation. My curriculum vita appears in Appendix A of this Expert Report.

I have been asked by Joseph F. Castrilli and Richard D. Lindgren of the Canadian Environmental Law Association on behalf of Grassy Narrows First Nation to prepare an expert report that responds to several questions. I am solely responsible for the preparation of this report.

QUESTIONS

1. For the documents referred to below, please indicate if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto.

A. The Grassy Narrows-Earthroots request, dated January 2014, of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May, July, September and November 2014 insofar as they relate to your area of expertise and the subject matter for your report.

B. Literature Review of the Mercury Disability Board, dated September 2010. This document (consisting of two reviews) is referred to in the September 2014 submission.

1.1 For the documents referred to below, please indicate your views on them to the extent they relate to the subject matter of your expert report and are within your area of expertise:

C. The article by Harada, et al. entitled "Mercury Poisoning in First Nations Groups in Ontario: 35 Years of Minamata Disease in Canada" (translated from the Japanese version published in the Journal of Minamata Studies in 2011).

D. The article by Takaoka, et al. entitled "Signs and Symptoms of methylmercury contamination in a First Nations community in Northwestern Ontario, Canada" published in the journal Science of the Total Environment in 2014.

2. Regarding the subject of mercury and human health:

a. Is mercury toxic to humans? If so, on the scale of toxic substances in the environment, where does mercury rank in terms of overall toxicity risk to humans?
b. If so, what are the clinical human health impacts of mercury?
c. Does exposure to mercury increase the risk of other health problems developing and, if so, identify those other health problems?

3. At what levels of exposure to mercury have adverse clinical health impacts on adults been documented in the scientific literature?

4. Does exposure to mercury affect the development of foetuses and children and, if so, what are the effects, and for what duration of time, if any, will those effects persist? At what exposure levels have these developmental effects been documented in the scientific literature?

5. Are there sub-clinical effects:

a. *In a community where mercury-related neurologic clinical disorders are present, could there be other persons with sub-clinical signs and symptoms?*
b. *What is the nature of these effects at each exposure level that have been documented in the scientific literature; and*
c. *Are developmental effects of mercury exposure affected by low socio-economic status based on such factors as education, income, etc.?*

6. *What are the sub-clinical population level effects, if any, of exposure to mercury? Compare these effects to individual clinical effects and to the mercury levels at which they are found? Comment on the nature and severity of the effect of these impacts at a community level?*

7. *Does mercury bio-concentrate across the placenta and, if so, what is the average concentration factor? What is the concentration factor at the 95th percentile?*

8. *Is there a delay in the manifestation of health effects following exposure to mercury? How do mercury impacts change with aging?*

9. *What evidence is there, if any, that mercury changes the rate or severity of degenerative neurological conditions such as Alzheimer, ALS, etc.?*

10. *What is the most important source of mercury in humans? How would you characterize the levels of mercury, if any, in piscivorous wildlife, such as ducks, loons, and otters? What effect, if any, do dental fillings have on human mercury body burden? How would you characterize the risk of methylmercury exposure from eating wild fish alone compared to the total mercury risk in an Aboriginal population that also eats ducks, otters, store fish, and has dental fillings?*

11. *What is the Health Canada – World Health Organization recommended fish mercury content limit (measured in parts per million – ppm) for subsistence eaters? What is the mercury limit measured in ppm for legal possession of lake fish meant for sale in Ontario?*

12. *In general, what is a reference dose? Compare the Canadian reference dose for preventing fetal neurotoxicity and developmental impacts with the reference dose adopted by the Environmental Protection Agency in the United States ("USEPA")? What caveats, if any, come with using the USEPA reference dose? Which of the two reference doses, in your professional opinion, is more appropriate and safe to use (1) for the general population, and (2) at Grassy Narrows, and why?*

13. *How does the USEPA reference dose, if at all, account for bio-concentration across the placenta? If it does not account for bio-concentration, how would it need to be modified in order to do so? How does the Canadian reference dose, if at all, account for bio-concentration across the placenta?*

14. *What are the health benefits, if any, of eating fish? What are the health benefits, if any, of the practice of fishing?*

15. *If there are health benefits to eating fish what, in your professional opinion and in the scientific literature of which you are aware, should be done with respect to practices that lead to the bio-accumulation of mercury in fish? How would this principle apply at Grassy Narrows?*

16. *How would you characterize the appropriateness of the health guidance contained in the Ontario Guide for Sport Fish Eaters for indigenous communities who eat fish? Which reference dose is used in developing the Guide?*

17. *Compare with the general population, the level of sensitivity of those who already have experienced elevated mercury exposure, or show symptoms of mercury poisoning, upon further exposure? Comment on the appropriateness of intake guidelines designed for the general population when applied to people exhibiting symptoms consistent with mercury poisoning?*

Grassy Narrows

18. *For document B listed above, and if not already addressed in response to question 1, please indicate the following:*

    a. *What role, if any, did you play in the preparation of document B?*
    b. *Are the findings and conclusions contained in document B still valid today? If not, indicate what material changes have occurred since the release of document B that would cause the need for significant revisions in its findings and conclusions?*
    c. *What would be the revised findings and conclusions, if any?*

19. *If not otherwise answered in response to question 1, above, please indicate if the statements are accurate that are contained in the first six pages of the September 2014 supplementary submission listed in item A that are attributed to your document B report?*

20. *Are you aware of a more thorough long-term study than that of Dr. Harada and his colleagues from Japan (including Takaoka and Fujino, et al.), on the issue of mercury exposure and effects at Grassy Narrows?*

21. *What risks, if any, do current mercury levels in pike and walleye present to the people of Grassy Narrows who eat fish caught from local waters?*

22. What risk is there, if any, to the health of people at Grassy Narrows who eat fish caught from local waters if mercury levels were to increase? How low an increase in fish mercury level would pose a health risk, if any?

ORGANIZATION OF EXPERT REPORT

The Expert Report is organized into two parts. Part 1 provides short summary answers to the questions listed above.

Part 2 updates the review of the scientific literature presented in the document entitled *Literature Review: The Impact of Mercury on Human Health* prepared by Dr. H.M. Chan and myself for the Mercury Disability Board in 2009, and in 2010 with a review of Dr. Harada's studies (Document B). Taken together, these provide the greater context and scientific background for the summary answers provided in Part 1.

PART 1

SUMMARY ANSWERS TO QUESTIONS

Question 1:

1. For the documents referred to below, please indicate if the views expressed in those documents that relate to the subject matter of this expert report, and/or that are attributed to you, are accurate in every material respect? If not, please indicate in your expert report the corrections, if any, that should be made with respect thereto.

> ***A. The Grassy Narrows-Earthroots request, dated January 2014, of the Ministry of the Environment for an individual environmental assessment (IEA) on the Whiskey Jack Forest Management Plan (2012-2022), and the supplementary submissions made to the Ministry dated May, July, September and November 2014 insofar as they relate to your area of expertise and the subject matter for your report.***

Answer to Question 1A: The information contained in these documents as concerns my expertise on mercury exposure and human health are accurate, with the following details

- **[IEA request, supplemental information, September, 2014 p. 3]** I verified this information with a colleague at the Minamata Institute, Dr. Mineshi Sakamoto, who informed me that the diagnostic criteria for Minamata disease have not changed. These

are the same diagnostic criteria that Dr. Harada used in Grassy Narrows. In Japan, a Law Concerning Special Measures to Provide Relief to Minamata Disease Victims, passed in 2009 was enacted in April, 2010[1]. On May 1, 2010, then Prime Minister Hatoyama attended and gave prayers at the Memorial Service for the Victims of Minamata Disease and was the first prime minister to do so. On the same day, the acceptance of applications for relief started, and eligible persons began to receive a lump sum payment in October 2010. By 2012, there were 48,327 applications for lump-sum payment and 16,824 applications for Minamata Disease Victims' Passbook. It is noteworthy that as early as 1977, the Japanese Ministry of the Environment initiated dredging because "even though the discharge of the methylmercury compound was stopped, the residual presence of mercury in the substratum of nearby waters could still cause the contamination of water and marine lives, making it necessary to remove the contaminated base sediment"[2].

- **[IEA request, supplemental information, September, 2014 p. 8]** The information written up in the Toronto Star (2003) was, in part, in error. I verified this information with Dr. Laurie Chan. While Dr. Chan did express his alarm at the high prevalence of persons still suffering from neurological symptoms after 30 years, he did not head a Health Canada financed study of neurological effects in Grassy Narrows. He did examine mercury in fish, fish consumption patterns and human exposure in Grassy Narrows[3].

- **[IEA request. Supplemental information, November, 2014]** While the psychological, social and economic impacts, cited in the Donnan 1986 report, are accurate, they do not do justice to the overall impact of mercury contamination and the ensuing reduced consumption of fish on the physical and mental health and well-being within the Grassy Narrow community.

- **[IEA request. Supplemental information, November, 2014; p. 13]** More precisely, the value for fish advisories at 0.049 µg/g is the EPA screening value for fish; it was derived specifically for subsistence fishers[4]. (see answer to Question 11)

- **[IEA request. Supplemental information, November, 2014; p. 13]** More precisely, as indicated in the text, the 0.2 µ/g wet weight was a recommendation made by the Medical Services Branch of Health and Welfare Canada for Grassy Narrows and White Dog in 1979.

[1] Japan Ministry of the Environment. Lessons from Minamata Disease and Mercury Management in Japan, (2013)
[2] Japan Ministry of the Environment Lessons from Minamata Disease and Mercury Management in Japan, (2013) p. 15
[3] Chan (2005)
[4] EPA Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories Volume 2 Risk Assessment and Fish Consumption Limits Third Edition, p. 1-6 (2000)

- **[IEA request. Supplemental information, November, 2014; p. 15]** I would rephrase the term 'the scientific literature recommends' in the following terms: There is scientific evidence to support that the EPA RfD, based on cord blood, may be too high since cord blood contains 60-70% more mercury than maternal blood, and approximately 100% higher for the upper 5% and recent studies have observed neurotoxic effects in children at these levels of prenatal exposure (see question 7 and Part 2; section 4).

B. Literature Review of the Mercury Disability Board, dated September 2010. This document (consisting of two reviews) is referred to in the September 2014 submission

Answer to Question 1B:

I was co-author of these reports and the information contained in these reports is still timely. Studies since that time further support and confirm the conclusions of these reports.

Question 1.1: For the documents referred to below, please indicate your views on them to the extent they relate to the subject matter of your expert report and are within your area of expertise:

C. The article by Harada, et al. entitled "Mercury Poisoning in First Nations Groups in Ontario: 35 Years of Minamata Disease in Canada" (translated from the Japanese version published in the Journal of Minamata Studies in 2011).

Answer to question 1.1 C.

In the article, Dr. Harada describes his experience over the past 35 years in the diagnosis of Minamata Disease in Grassy Narrows and White Dog. Dr. Harada was a clinical neurologist, with world-renowned expertise on Minamata Disease. He began examining patients with Minamata disease in 1961 and was the first to describe Fetal Minamata Disease from prenatal mercury exposure.

He relates in this article that since 1975 he has examined persons from Grassy Narrows and White Dog for signs and symptoms of Minamata Disease. Over the years, he has diagnosed many cases of Minamata Disease in these two communities. The studies up to 2004 are reviewed in our report to the Mercury Disability Board (see Document B).

In 2010, he lead a team, which included 5 neurologists/psychiatrists and internal medicine specialists in neurology. In Grassy Narrows, they examined 73 persons above the age of 20 years on the basis of the diagnostic criteria applied in Japan since 1975 for Minamata Disease. The

team identified 30 persons with Minamata Disease and a further 12 persons with "suspected Minamata Disease", among whom there were 5 cases reminiscent of Minamata developmental disorders from fetal exposure. Dr. Harada notes in this report that "fetal influence remains to be studied … there is no plan of investigation as of now."

The article reflects a great degree of thoughtfulness and care on the part of the physicians involved and, as Dr. Harada so aptly stated, ".. the undoubtable fact that Minamata Disease occurred in the corresponding districts in Canada, based on [their] long term investigation result."

D. The article by Takaoka, et al. entitled "Signs and Symptoms of methylmercury contamination in a First Nations community in Northwestern Ontario, Canada" published in the journal Science of the Total Environment in 2014.

Answer to question 1.1D.

In this article Takaoka and co-authors describe a comparison of signs and symptoms of 80 residents from Grassy Narrows above the age of 16 years with 88 mercury exposed Japanese residents and 164 Japanese non-exposed control residents. The group from Grassy Narrows was divided into 2 groups according to age: the older group from 45 years old to 76 years old and the younger (less than 45 years of age). The age of the two Japanese groups were similar to the older Grassy Narrows group. Their findings were:

- Although the Japanese exposed group reported more subjective symptoms, the more specific mercury related complaints were similar for the Japanese exposed and the Grassy Narrows older group.

- Neurological findings and quantitative sensory measurements were similar in the Grassy Narrows Older and Japanese Exposed groups than in the Japanese Control group.

- The results for the younger Grassy Narrows group fell between those of the Grassy Narrow Older and the Japanese Control groups.

- The authors mention the limitations of such a comparison due primarily to different living conditions and cultures, but emphasize the diagnostic validity of the examination.

- The authors conclude that the data collected from methylmercury-exposed indigenous residents of Grassy Narrows suggest that they were poisoned by methylmercury. The health abnormalities also appear to exist in a milder form in the younger generations from Grassy Narrows.

The findings of this study are consistent with the scientific literature on mercury poisoning. In

the absence of an epidemiologic study on neurotoxic effects of mercury exposure in Grassy Narrows, the study presents an innovative way of examining similarities and differences in signs and symptoms in communities who have been exposed to mercury. Ideally, it would have been useful to examine the signs and symptoms in Grassy Narrow residents with respect to past and present exposure and use a local reference group.

Question 2: Regarding the subject of mercury and human health:

a. Is mercury toxic to humans? If so, on the scale of toxic substances in the environment, where does mercury rank in terms of overall toxicity risk to humans?

Answer to Question 2a

Mercury is definitely toxic to humans. Every few years, the United States Agency for Toxic Substances establishes a Priority List of Hazardous Substances, which includes substances that have been determined to be of greatest public health concern to persons at or near National Priority List sites[12]. While this list considers aspects other than toxicity, it includes a measure of toxicity. The 2013, Registry[3] gives mercury the highest attributable toxicity points, at the same levels as arsenic and polychlorinated biphenyls (PCBs) and ranks mercury ranks third (after arsenic and lead) on the overall priority scoring list of 785 hazardous substances. It is noteworthy that mercury has held this ranking since 1991, when the first list was established.

b. If so, what are the clinical human health impacts of mercury?

The most severe clinical impacts of fetal and adult exposure to methylmercury are the neurodegenerative diseases: Fetal Minamata Disease and Minamata Disease, respectively.

Clinical effects in adults : Gait disturbance, loss of balance, speech disturbance constriction of visual fields, sensory disturbances (numbness, loss of feeling or tingling in extremities and around the mouth), hearing disturbances, muscle weakness, muscle cramps.

Clinical effects of in utero exposure: severe cerebral palsy-like symptoms, even when their mothers have mild or no manifestation of the poisoning: mental retardation, cerebellar ataxia (coordination and balance problems), primitive reflexes (present in infants, which normally disappear in adulthood), dysarthria (muscle speech disorders), and hyperkinesia (uncontrolled muscular movements).

[1] Agency for Toxic Substances Registry (http://www.atsdr.cdc.gov/spl/)
[2] It should be noted that this priority list is not a list of "most toxic" substances, but rather a prioritization of substances based on a combination of their frequency, toxicity, and potential for human exposure at NPL sites ((http://www.atsdr.cdc.gov/spl/))
[3] Agency for Toxic Substances Registry. Support Document to the 2013 list of hazardous substances that will be the subject of toxicological profiles.

c. Does exposure to mercury increase the risk of other health problems developing and, if so, identify those other health problems?

Mercury has been shown to increase the risk for learning disabilities in children and, in adults, the risk for cardiovascular disorders, such as myocardial infarction and hypertension. There is some evidence of an association between mercury exposure and metabolic syndrome, diabetes and autoimmune disorders, but more studies are required to confirm or not these associations (see Part 2, section 1)

Question 3: At what levels of exposure to mercury have adverse clinical health impacts on adults been documented in the scientific literature? What are the reported adverse clinical health effects in adults at these levels?

Answer to Question 3:

For clinical neurological effects in adults, there are case reports of moderate to severe neurological symptoms in patients with blood mercury concentrations from 12 – 38 µg/L[1,2].

It should be noted that, for adults, it is difficult to establish a level of exposure since mercury-related subtle neurological alterations may have existed since conception and the biomarkers of mercury exposure (hair and blood) only represent recent exposure. Thus, adults who have been prenatally exposed to mercury, with continued exposure through childhood and early adulthood, may suffer clinical effects that are not related to their current mercury exposure, but to their past exposure. Furthermore, the large majority of studies on adults include persons who eat marine fish, which have considerably higher concentrations of beneficial nutrients such as omega-3 fatty acids and selenium, compared to freshwater fish.

Question 4: Does exposure to mercury effect the development of foetuses and children and, if so, what are the effects, and for what duration of time, if any, will those effects persist? At what exposure levels have these developmental effects been documented in the scientific literature?

Answer to Question 4:

There is a very substantial scientific literature showing prenatal and early childhood exposure to mercury is associated with a decrease in children's intellectual capacities. This has been

[1] Silbernagel et al. (2011)
[2] Groth (2008)

confirmed in animal studies and in brain imaging and electrophysiological examinations (see Part 2; sections 5 and 6).

Follow-up studies of mercury-exposed children indicate that these deficits persist over time. For example, a study of Canadian Inuit children at 8 years of age, exposed prenatally to mercury, showed that 17.2% of the children whose cord blood mercury was above 7.5µg/L were below the clinical cut-off for learning disabilities compared to 4.3% for the others[1].

A 22-year follow-up study of children of mothers with high mercury exposure[2] shows that there are still deficits in major domains of brain function as well as general intelligence in relation to their cord blood mercury concentrations; the geometric mean of their current blood mercury concentrations was 2.53µg/L and hair mercury 0.68µg/g.

The lowest reference dose for the protection of foetus and children is the US EPA reference dose (5.8 µg/L blood mercury; 1 µg/g hair mercury), which includes a tenfold uncertainty factor[3]. However, since the mercury in the cord blood is higher than in mother's blood, it may be too high (see part 2, section 4).

Question 5: Are there sub-clinical effects:

a. *In a community where mercury-related neurologic clinical disorders are present, could there be other persons with sub-clinical signs and symptoms?*
b. *Nature of these effects at each exposure level that have been documented in the scientific literature; and*
c. *Developmental effects of mercury, if any, in children in families with low socio-economic status based on such factors as education, income, etc.?*

Answer to Question 5a:

Clinical manifestations of mercury poisoning constitute the tip of the iceberg with respect to the harmful health effects of mercury exposure. In a contaminated environment, for every person with clinical manifestations, there are many more with sub-clinical signs and symptoms and even more with symptoms of decreased well-being, which affect a person's physical, mental and social capacities.

Answer to Question 5b:

[1] Jacobson et al. (2005)
[2] Debes et al. (2015)
[3] Rice (2004)

In adults, the tip of the iceberg is composed of people with the most severe classical symptoms of mercury poisoning (described in answer to question 2b), a higher number of mercury-exposed persons present signs and symptoms that are less severe, but debilitating, such as poorer cognition, motor deficits, vision problems and cataracts. Cognitive deficits have been observed in freshwater fish-eating communities with hair mercury concentrations that ranged from 0.56 to 13.6 µg/g, with half of the participants having levels below 6 µg/g.

For cardiovascular effects, an analysis of existing studies by an expert committee indicate a twofold increased risk for myocardial infarction at equivalent hair concentrations less than 1.66µg/L[1] (see Part 2, section 1)

In children, the most severe classical symptoms of mercury exposure in their development years are described in question 2b. Many more children are exposed to lesser concentrations.

There is consensus on the fact that mercury exposure is associated with delayed learning, shortened attention span, memory deficits, delayed language acquisition, poorer motor control or coordination (see part 2, sections 5 and 6)

Even at very low concentrations of prenatal and early childhood exposures (maternal mean hair mercury 0. 0.53 (range 0–2.3) µg/g)[2], some of these effects are present in the developing child and the frequency and severity of these problems increases with the exposure dose.

In the study of Inuit children mentioned above, mothers' hair mercury at birth ranged from 1.4µg/g – 15 µg/g.

Electrophysiological and neuro-imaging techniques have confirmed altered brain activity in children with prenatal exposure to mercury.

Answer to Question 5c.

In addition to mercury exposure, children's development can be affected by other factors, such as poor nutrition and housing, pre-existing diseases and parents' unhealthy lifestyle, little access to health care, poor schooling, minimal parental stimulation (see Part 2, section 6).

Developmental mercury exposure can compound the effects of these conditions, resulting in, for example, a larger percentage of children with learning disabilities (see Part 2, Section 6, Figures 4,5 and 6)).

Question 6: What are the sub-clinical population level affects, if any, of exposure to mercury? Comment on the nature and severity of the effect of these impacts at a community level?

[1] Guallar et al. (2002)
[2] Oken et al. (2008)

What are the levels of mercury exposure documented in the scientific literature at which these effects can occur?

Answer to Question 6:

For adults, sub-clinical effects include poorer cognitive functions, poorer vision, poor motor function and earlier age-related cataracts. These affect people's capacity to earn their living and carry out daily activities (see part 2 sections 5, 6 and 7). Overall the community's capacity to develop is hindered. In some studies, cardiovascular and metabolic changes have been reported in relation to mercury exposure, but results are inconsistent and co-factors, such as nutritional status and lifestyle, may play a role (see Part 2, sections 1 and 2).

For children, even a small decrease in average cognitive function has striking repercussions for the community. For example, an average decrease of 5 IQ points, among exposed children means that in a community twice as many children have severe learning difficulties and half as many children are gifted (see Part 2, sections 5 and 6).

When other harmful factors (poor nutrition, lack of stimulation, poor education) are present, the effects of mercury may be greater (see Part 2, section 6). In a study of an Inuit community, an average loos of 4.8 IQ points resulted in over four times more children with learning disability[1]. (Part 2, section 6)

The loss of cognitive function has life-long effects for these children who do less well in school. Educational level is an important determinant of later-life earning capacity and health status.

Question 7: Does mercury bio-concentrate across the placenta and, if so, what is the average concentration factor? What is the concentration factor at the 95th percentile?

Answer to question 7:

Throughout pregnancy, the placenta concentrates methylmercury and blood mercury concentration in the umbilical cord, which nourishes the foetus, is higher than in the mother's blood.

At birth, the average cord mercury blood concentration is almost double that of the mother, while for one in twenty, that concentration is over three and a half times higher. (see part 2, section 4)

[1] Jacobson (2015)

Question 8: Is there a delay in the manifestation of health effects following exposure to mercury? How do mercury impacts change with aging?

Answer to Question 8:

Minamata Disease is a progressive disorder and some infants, who had a normal appearance at birth, slowly developed the disease over time.[1]

Studies of persons from the Minamata region show that even those that do not have the diagnosed disease show more signs of aging compared to persons from other regions (see Part 2, section 7 and Figure 6).

The aging brain is more sensitive to toxic assault and studies of aging fish-eaters exposed to mercury have shown mercury-related progressive visual disorders, even when exposure was reduced, and a higher prevalence of age-related cataracts. (see Part 2, section 7)

Question 9: What evidence is there, if any, that mercury changes the rate or severity of degenerative neurological conditions such as Alzheimer, ALS, etc.?

Answer to Question 9:

To my knowledge, there is no evidence of a higher prevalence of Alzheimer disease or amyotrophic lateral sclerosis (ALS). The features of fetal Minamata Disease are similar to cerebral palsy. However, because of the pervasive neurologic effects of mercury exposure, there may be misdiagnoses.

Question 10: What is the most important source of mercury in humans? How would you characterize the levels of mercury, if any, in piscivorous wildlife, such as ducks, loons, and otters? What effect, if any, do dental fillings have on human mercury body burden? How would you characterize the risk of methylmercury exposure from eating wild fish alone compared to the total mercury risk in an Aboriginal population that also eats ducks, otters, store fish, and has dental fillings?

Answer to Question 10:

The most important source of mercury exposure in humans is from the consumption of fish and fish-eating animals (see Part 2, section 8).

[1] Maruyama et al, (2012)

Mercury is accumulated and biomagnified through the food chain; the process is initiated through the action of bacteria that transform inorganic mercury, present in the water, to methylmercury.

Larger fish eat many small fish, incorporating all of their mercury. Fowl and mammals that eat fish will likewise accumulate mercury in the same way.

At the top of the food chain are humans. The risk depends on the total amount of mercury from each of the foods.

The risk for mercury exposure in Aboriginal populations that eat fish and fish-eating animals has been shown to be considerably higher than in other populations

A study of adult dietary practices among 7 Eeyou Istchee (Cree) communities in the James Bay area showed that blood mercury concentrations 3 – 20 times higher than those reported in the Canadian Health Measures Survey (CHMS) [1], which did not include Aboriginal communities living on reserves. (see Part 2, section 9).

In the study of the Cree community mentioned above, the geometric mean for blood mercury of persons with the highest traditional food intake was 5.3µg/L, for those who consumed the least traditional food, it was 3µg/L,[2] while for the general adult Canadian population, it is approximately 0.8 µg/L[3].

A further source of methylmercury exposure may come from wild rice that grows in sediments that have been contaminated with mercury.

Mercury in dental amalgams is inorganic mercury that can be measured in blood and urine, but not in hair. In the Canadian Health Measures Survey, blood mercury concentrations increased with the number of dental amalgams. The geometric mean for those with no mercury-based dental amalgams is 0.6 µg/L, while for those who have over 26 amalgams, it is 1.24µg/L[4].

Question 11: What is the Health Canada – World Health Organization recommended fish mercury content limit (measured in parts per million – ppm) for subsistence eaters? What is the mercury limit measured in ppm for legal possession of lake fish meant for sale in Ontario?

Answer to Question 11:

[1] Johnson-Down et al. (2015)
[2] Johnson-Down et al. (2012)
[3] Lye et al. (2013)
[4] Lye et al. (2013)

There are different types of recommended limits concerning fish consumption: (i) amount of mercury in the fish (expressed in mg/kg, µg/g or ppm); (ii) the amount of mercury considered safe to consume on a daily basis, considering persons' weight (µg/kg/day) over a lifetime; (iii) the average amount of fish that should be eaten (g/day or fish meals/month), based on a risk assessment of risks and benefits. Table 1 contains some of these recommendations from different agencies.

Table 1 Recommendations by different national and international agencies for limits for mercury on fish, mercury consumption and fish consumption

	Canada	Ontario	US-EPA	WHO/FAO
MERCURY IN FISH				
Commercial sale	0.5 ppm[a]			
Fishing for sale				
Recreational			0.4 ppm[c]	
Women of child-bearing age and children under 15		0.26 ppm[b] Do not eat: 0.52 ppm		
Others		0.61 ppm[b] Do not eat: 1.84 ppm		
Subsistence	0.2 ppm[h]		0.049 ppm[c]	
METHYLMERCURY IN THE PLATE				
Intake dose	0.2µg/kg body weight/day[d]		0.1µg/kg body weight/day[e]	0.23µg/kg body weight/day[f]
FISH CONSUMPTION				
General				
1-4 year old	10g/day[g]			
5-11 year old	14g/day[g]			
Adults	22g/day[g]			
Subsistence fishing				
1-4 year old	20g/day[g]			
5-11 year old	33g/day[g]			
Adults	40g/day[g]			

a. There are some exceptions to this for a few marine fish, with higher concentrations
b. These are the values used by the *Ontario Guide for Sport Fisher Eaters (2013-2014)* to

provide information on fish consumption for anglers (and their families) who consume moderate quantities of fish. The consumption advice is intended to protect individuals who follow the advice in the guide and consume no more than 8 meals per month of the fish they catch. Specific information is available for each lake.

c. Screening value from US Environmental Protection Agency *Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories Volume 2 Risk Assessment and Fish Consumption Limits Third Edition (2000)*
d. Canadian Total Daily Intake Value Health Canada
e. EPA website http://www.epa.gov/iris/subst/0073.htm;
f. A recent review of these guidelines by the European Food Safety Authority (2012) proposed that it be reduced to 0.19 µg/kg/body weight
g. Daily fish consumption recommended in the document *Human Health Risk Assessment of Mercury in Fish and Health Benefits of Fish Consumption.* Bureau of Chemical Safety Food Directorate Health Products and Food Branch, Health Canada (2007)
h. Health and Welfare Canada recommendation for Grassy Narrows and White Dog in 1979.

Question 12: In general, what is a reference dose? Compare the Canadian reference dose for preventing fetal neurotoxicity and developmental impacts with the reference dose adopted by the Environmental Protection Agency in the United States ("USEPA")? What caveats, if any, come with using the USEPA reference dose? Which of the two reference doses, in your professional opinion, is more appropriate and safe to use (1) for the general population, and (2) at Grassy Narrows, and why?

Answer to Question 12:

The US-EPA uses the term Reference Dose (RfD), defined as ''an estimate of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects during a lifetime.''[1] Some scientists have raised the issue that this RfD may be too high because it is based on cord blood and does not take into account methylmercury accumulation in the placenta[2].

Canada uses Toxicity Reference Values (TRVs) to derive Total Daily Intake, (TDI) defined as "the maximum amount of a chemical that can be ingested on a daily basis over a lifetime without increased risk of adverse health effects.

As indicated in the table above, for methylmercury, the US-EPA RfD is 0.1µg/kg body weight/day, while the Canadian TDI is 0.2µg/kg body weight/day.

My opinion is that the US-EPA reference offers better protection against the harmful effects of

[1] cited in Rice (2004)
[2] Stern (2005)

exposure to methylmercury to all populations. Mercury intake for most of the general Canadian population is well below this intake.

In 2003, Chan[1] calculated the intake of mercury in the Grassy Narrow community and estimated mercury intake from fish consumption using the actual values that were measured in fish species from the various lakes and the reported portion size per fish meal.

In Grassy Narrows, in 2003, the average mercury intake over the year was 0.2µg/kg body weight/day, with men having higher average intakes compared to women (0.3 µg/kg body weight/day vs. 0.1µg/kg body weight/day). The average intakes included people who don't eat fish; if the analysis had included only fish-eaters, the average mercury intake would have been higher.

By season, the highest mercury intake was by men in summer and spring (3.7 µg/kg body weight/day). Approximately 25% had estimated intakes above the Canadian TDI and 41% were above the US-EPA RfD.

The average mercury intake for Grassy Narrows women in 2003 was above the US-EPA RfD of 0.1 µg/kg body weight/day. It should be noted that this includes all women who were surveyed, including those that don't eat fish.

Cord blood data from Grassy Narrows between 1978 and 1992 shows that the concentration mercury was much higher, particularly in the earlier period (see Part 2, section 14a and Figure 8). Today, these persons are between the ages of 23 and 37 years old.

Given the information on estimated methylmercury intake from past and present exposures in Grassy Narrows, there are already effects on their health and well-being from mercury exposure and the EPA RfD would be more suitable for the Grassy Narrows population. However, this does not take into account the health, social and economic benefits of fishing and fish consumption.

Question 13: How does the USEPA reference dose, if at all, account for bio-concentration across the placenta? If it does not account for bio-concentration, how would it need to be modified in order to do so? How does the Canadian reference dose, if at all, account for bio-concentration across the placenta?

Answer to Question 13:

The US-EPA reference dose, which is based on cord blood, does not take into account bio-concentration across the placenta. It is based on a cord blood concentration of 58 µ/L and then

[1] Chan (2005)

uses a tenfold security factor to arrive at a cord blood concentration of 5.8µg/L from which mercury intake is derived as 0.1µg/kg body weight/day. Mahaffey, who was one of the committee members who set the EPA RfD, suggests that it should be based on a value of 3.5 µg/L to take into account bioconcentration[1]. The relation between maternal mercury intake and cord blood is not necessarily linear[2] and what one can say at this point is that it would be lower than 0.1µg/kg body weight/day.

The Canadian Total Daily Intake is based on maternal hair at birth[3] and did not take into account placental bioconcentration and thus did not account for the fact that hair mercury concentrations decrease over pregnancy (see Part 2; figure 2).

Question 14: What are the health benefits, if any, of eating fish? What are the health benefits, if any, of the practice of fishing?

Answer to Question 14:

Fish is a highly nutritious food, providing a wide variety of nutrients, including omega-3 fatty acids (see Part 2, section 11).

In utero and throughout lifespan, omega-3 fatty acids are likewise positive physical and mental health outcomes, including children's neurodevelopment, visual functions, blood pressure, cardiac function, vascular reactivity and lipids

Studies of children exposed to mercury through fish consumption show the negative effects of mercury exposure and the positive effects of omega-3 fatty acids on neurodevelopment. Studies of adults, as well, have shown the opposing effects of mercury and omega-3 fatty acids and visual function, as well as for the risk of myocardial infarction (Part 2, section 11, Figure 7)

The US-EPA advisory for subsistence fishing was developed in collaboration with representatives from Native American tribes. It indicates: "EPA recognizes, however, that Native American subsistence fishers are a unique subsistence fisher population that needs to be considered separately. For Native American subsistence fishers, eating fish is not simply a dietary choice that can be completely eliminated if chemical contamination reaches unacceptable levels; rather eating fish is an integral part of their lifestyle and culture. This traditional lifestyle is a living religion that includes values about environmental responsibility and community health as taught by elders and tribal religious leaders. Therefore, methods for balancing benefits and risks from eating contaminated fish must be evaluated differently than for the general fisher

[1] Mahaffey (2009)
[2] Stern (2003)
[3] Legrand et al (2010)

population"[1]."

Question 15: If there are health benefits to eating fish what, in your professional opinion and in the scientific literature of which you are aware, should be done with respect to practices that lead to the bio-accumulation of mercury in fish? How would this principle apply at Grassy Narrows?

Answer to Question 15:

In my professional opinion, based on the existing scientific literature, fish-eating practices should seek to maximize the nutritional benefits from fish consumption and minimize the toxic risk from mercury and other contaminants.

The Grassy Narrows community has been exposed to high concentrations mercury in fish for many years and individuals and the community are suffering the effects. **It would only add toxic insult to toxic injury to further expose this population to mercury**

While the community needs the nutrition from the fish, their intake of mercury needs to be minimal. To achieve this there needs to be a comprehensive plan:

- to reduce mercury at the source in the lake sediments;
- to never increase the mercury load in this environment;
- to eat more fish with little mercury;
- to initiate schooling and health programs to address the issue of mercury poisoning in this community.

Question 16: How would you characterize the appropriateness of the health guidance contained in the Ontario Guide for Sport Fish Eaters for indigenous communities who eat fish? Which reference dose is used in developing the Guide?

Answer to Question 16:

The Ontario Guide for Sport Fish Eaters is designed for "anglers (and their families) who consume moderate quantities of fish. The consumption advice is intended to protect individuals who follow the advice in the guide and consume no more than 8 meals per month of the fish they catch." The Guide notes that the advisory is based on the Canadian TDI. Their fish advisory recommends that "for women of child-bearing age and children under 15 years old, restrictions on consuming sport fish containing mercury begin at levels of 0.26 parts per million. Complete restriction (i.e., do not eat) is advised for levels above 0.52 parts per million. For the general population, consumption restrictions begin at levels above 0.61 parts per million. Complete

[1] US Environmental Protection Agency *Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories Volume 2 Risk Assessment and Fish Consumption Limits Third Edition (2000) p. 16*

restriction is advised for levels above 1.84 parts per million."[1]

The guide clearly indicates that it is not for heavy fish eaters. In Grassy Narrows, using the 2003 information on fish consumption from Chan, approximately 16% of persons eat more than 9 fish meals/month, and the average mercury content for several of the fish species in many of the lakes is above 0.52 ppm.

Question 17: Compare with the general population, the level of sensitivity of those who already have experienced elevated mercury exposure, or show symptoms of mercury poisoning, upon further exposure? Comment on the appropriateness of intake guidelines designed for the general population when applied to people exhibiting symptoms consistent with mercury poisoning?

Answer to Question 17:

There is ample evidence from animal and human studies that mercury modifies normal functioning of many systems, and in particular, the nervous system. While some of these changes result in symptoms and signs of damage, many remain undetectable because of the body's capacity to adapt. There is, however, a limit to this physiological adaptation and further exposure will build on the damage already present.

The guidelines for mercury intake refer to "over a lifetime". If exposures have been higher in the past than at present, the intake guidelines do not apply since over the lifespan, one's intake will be higher than those recommended by the guidelines.

Grassy Narrows

Question 18: For document B listed above, and if not already addressed in response to question 1, please indicate the following:

- ***a. What role, if any, did you play in the preparation of document B?***
- ***b. Are the findings and conclusions contained in document B still valid today? If not, indicate what material changes have occurred since the release of document B that would cause the need for significant revisions in its findings and conclusions?***
- ***c. What would be the revised findings and conclusions, if any?***

Answer to Question 18a:

I prepared document B in collaboration with Dr. Laurie Chan, Professor and holder of the Canada Research Chair in Toxicology and Environmental Health.

[1] Ontario Ministry of the Environment. 2013-2014 Guide to Eating Ontario Sport Fish, p. 16,

Answer to Question 18b:

The findings and conclusion of document B, which was submitted to the Mercury Disability Board in 2010, are still valid today. Since that time the science of mercury exposure and its effects on human health has continued to advance substantially and Part 2 of the present document updates the scientific evidence since that time. Studies published since 2010 on the effects of mercury on health and well-being, confirm the conclusions contained in Document B.

Answer to Question 18c:

The more recent studies indicate effects of mercury exposure are present at lower levels than previously thought and that they are long-lasting.

Question 19: If not otherwise answered in response to question 1, above, please indicate if the statements are accurate that are contained in the first six pages of the September 2014 supplementary submission listed in item A that are attributed to your document B report?

Answer to Question 19:

The statements are accurate and the scientific literature of the past 5 years provides strong confirmation. One further update: The law Concerning Special Measures to Provide Relief to Minamata Disease Victims, passed in 2009 was enacted in April, 2010 (see question 1 above).

Question 20: Are you aware of a more thorough long-term study than that of Dr. Harada and his colleagues from Japan (including Takaoka and Fujino, et al.), on the issue of mercury exposure and effects at Grassy Narrows?

Answer to Question 20:

Dr. Harada was a clinical neurologist, with world-renowned expertise on Minamata Disease, who began examining patients with Minamata Disease in 1961. He carried out a most thorough study of clinical manifestations of Minamata Disease in Grassy Narrows. No other group of scientists have carried extensive health studies with this community, although, as we indicated in the MDB report and Dr. Harada mentions in his 2011 report, there is a need for studies on the long-term effects of fetal exposure and the overall impact of mercury exposure on the physical and mental well-being of this community.

Question 21: What risks, if any, do current mercury levels in pike and walleye present to the people of Grassy Narrows who eat fish caught from local waters?

Answer to Question 21:

According to the 2005 report by Chan[1], the average mercury concentration in walleye in the lakes that are around Grassy Narrows (Ball Lake, Garden Lake and Indian Lake) are above almost all fish advisories guidelines for consumption. They are between twelve to twenty times higher than the US-EPA screening value for subsistence fish-eating. Northern Pike from these lakes are twelve to eighteen times higher than the screening value. Using the Ontario Fish advisories, all of the walleye and northern pike from these lakes are above the 'do not eat' concentration for women of child-bearing age and children (0.52 µg/g), while for the others, there would be restrictions for Ball and Indian Lake since the average mercury concentration in fish is above 0.62 µg/g).

Historical data from the English-Wabigoon River system from 1975 onwards show that there were much higher exposures in the past. While these high concentrations for walleye and northern pike declined rapidly from 1975 to 1985, the decline was much less and often stable until 2010[2].

When estimating the risk for mercury poisoning in Grassy Narrows, it is necessary to take into account past exposures (including prenatal exposure), as well as present exposures,. Even without actual data, it is clear that the risk for mercury poisoning is very high for walleye and northern pike fish-eaters.

It should also be mentioned that particularly for *in utero* exposures, immediately after ingestion of the fish, there would be a very large peak of mercury exposure at a critical moments in fetal development. Prenatal effects may differ depending upon the moment of this peak exposure during fetal development.

Question 22: What risk is there, if any, to the health of people at Grassy Narrows who eat fish caught from local waters if mercury levels were to increase?

Answer to Question 22:

There is no question that the mercury already present in the Grassy Narrow area poses important risks to health and well-being to the community and that any further addition of

[1] Chan (2005)
[2] Neff et al. (2012)

mercury would increase that risk. It would, indeed be adding insult to injury. In my opinion, based on the scientific literature and Dr. Harada's work, it would be shameless, and I would call it irresponsible, to add more mercury to this mercury-laden environment. The health and well being of this community has already been harmed not only through mercury poisoning of those who continue to eat fish, but also and by depriving important nutrients to those who reduced their fish consumption because of the mercury.

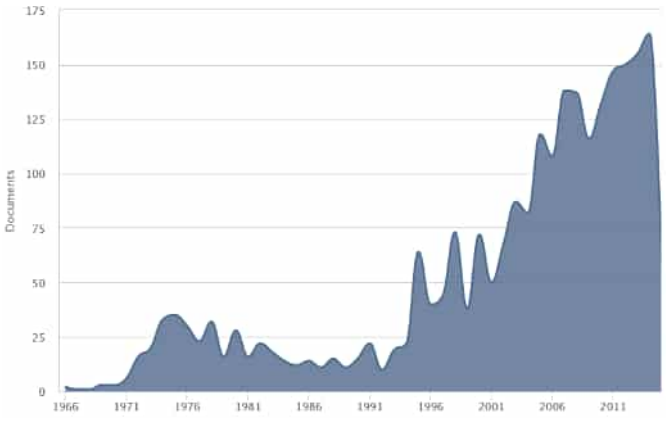
PART 2

OVERVIEW

> *"At first, methylmercury research was impaired by inappropriate attention to narrow case definitions and uncertain chemical speciation. It also ignored the link between ecotoxicity and human toxicity. As a result, serious delays affected the recognition of methylmercury as a cause of serious human poisonings in Minamata, Japan. Developmental neurotoxicity was first reported in 1952, but despite accumulating evidence, the vulnerability of the developing nervous system was not taken into account in risk assessment internationally until approximately 50 years later. Imprecision in exposure assessment and other forms of uncertainty tended to cause an underestimation of methylmercury toxicity and repeatedly led to calls for more research rather than prevention."*
>
> *Grandjean et al, 2010*

This review on general mercury and health facts sought to provide the most up-to-date information on mercury and human health, building on the information contained in the document entitled *Literature Review: The Impact of Mercury on Human Health* prepared by Dr. H.M. Chan and myself for the Mercury Disability Board in 2009, updated in 2010 with a review of Dr. Harada's studies. The two documents provide the scientific background for the answers to the questions above. Since 2010, over 800 articles have been published on methylmercury and fish, with half in the medical domain. Figure 1 shows the evolution of articles on methylmercury and fish since 1966. Approximately half of these are on health issues.

Figure 1 Evolution of scientific articles on methylmercury and fish since 1966



The literature review, here, is not exhaustive and serves to provide background for the questions that were posed. Relevant published scientific reviews and studies, since we wrote the report for the Mercury Disability Board in 2010 were identified, and where, possible, an

emphasis placed on those that examined methylmercury exposure and health effects in Canadian First Nation and Inuit communities.

The studies of the past years, reviewed here, support the following conclusions:

- There is no doubt that at the levels of exposure experienced in Grassy Narrows, the community has suffered and continues to suffer from mercury poisoning, individually and collectively.
- The scientific literature continues to provide evidence for Dr. Masazumi Harada and colleagues' clinical findings, reviewed by Chan and Mergler for the MDB[1] on the similarities between the neurologic signs and symptoms of persons from Grassy Narrows and White Dog and Minamata Disease in Japan. Using the diagnostic criteria for Minamata Disease, in Harada's 2010 he diagnosed Minamata Disease in 30 people from Grassy Narrows and 12 persons with 'suspected MInamata Disease.' (see question 1 C).
- The reduction of consumption of local fish and wildlife resulting from mercury pollution of the area deprived the people of Grassy Narrows of healthful nutrients, which have been shown to be beneficial for a large number of physiological functions and to be preventive for many and diseases.
- It is surprising that although the Japanese neurologists have identified many cases of Minamata Disease in Grassy Narrows and many persons have illnesses that have been associated with mercury intoxication, there has never been a scientifically sound epidemiologic study of the impact of pre and post natal mercury exposure on the health and well-being of this community.
- Any increase of exposure to this already 'sensitive' community to mercury contamination from sources, such as mining, logging and reservoirs, would further compound the harm to the health and well-being of the present and future generations.

1. Mercury is highly toxic to human health. Impacts include fetal and child development, neurological disorders and cardiovascular changes.

The effects of mercury from fish consumption on the nervous system has been extensively studied since the Minamata disaster and there is consensus on mercury neurotoxicity and its harmful neurologic effects during fetal and child development and in adults. Epidemiologic studies of exposed populations show increased risk for neurodevelopmental deficits, loss of cognitive and motor functions and visual deficits[2]. Changes in brain functioning in methylmercury-exposed persons have been confirmed in electrophysiological[3] and brain

[1] Chan and Mergler (2010)
[2] Grandjean et al. (2010)
[3] Ethier et al, (2012)

imaging[1] studies. Experimental studies with mercury-exposed animals provide extensive information on the mechanisms that underlie mercury toxicity[2].

More recently, the possible effects of mercury on other health endpoints have been examined. In 2011, the Environmental Protection Agency of the United States convened a workshop of experts on methylmercury exposure and cardiovascular endpoints[3]. The authors concluded that there was strong evidence for the relation between biomarkers of mercury exposure, measures in toenails or hair and myocardial infarction (MI). It is noteworthy that the range of the equivalent hair mercury exposure of the studies reviewed by this committee was from 0.34µg/g to 1.66µg/g[4]. Among the studies, upon which their conclusions were based, was an international study that showed a doubling of the risk for a first myocardial infarction for men in the highest quintile of hair mercury.

In addition, several studies have shown associations between biomarkers of methylmercury exposure and other cardiovascular disorders**,** including hypertension and changes in heart rate variability profiles[5]. In a study of Cree adults[6], the authors observed a positive association between altered heart rate variability parameters and blood mercury, after considering fish nutrients (omega-3 fatty acids and selenium) and other contaminants (lead and polychlorinated biphenyls) that are also present in the traditional diet of this population.

There is some evidence that mercury exposure increases the risk for Type II diabetes, but it is inconsistent. A recent 18-year follow-up study[7] of 3875 young United States' adults (20-32 years old), free of diabetes at the onset of the study, showed that those with the highest mercury exposure (equivalent of 1.2 – 1.5 µg/g hair mercury) had an elevated risk for diabetes compared to those with the lowest exposure, while another follow-up study of 2 cohorts did not show an association of incident cases of Type 2 diabetes and toenail mercury concentrations[8]. An analysis of data from the Korean National Health and Nutrition Examination Survey showed and increased risk for metabolic syndrome in men with respect to blood mercury, but not in women[9].

A recent study used the data from the United States' National Health and Nutrition Evaluation on 1352 women of reproductive age women (16 – 49 years) to examine biomarkers of the immune system. Low levels of blood and hair mercury, generally considered safe, were

[1] White et al. (2011)

[3] Roman et al. (2011)
[4] Guallar et al, (2002)
[5] Houston (2011)
[6] Valera et al (2011)
[7] He et al (2013)
[8] Mozaffarian et al. (2013)
[9] Chung et al, (2014)

associated with subclinical autoimmunity among reproductive-age females.[1]. The authors put forward that methylmercury exposure may be relevant to future autoimmune disease risk.

2. Adults can be impacted at levels well below the old threshold level for risk of 50 µg/g in hair.

With the increasing information from research on risks of methylmercury exposure and the evolution in our understanding of how subtle functional alterations in many individuals can translate into important risks for a community (see Part 2, section 5), regulatory agencies continue to revise recommended threshold levels for risk.

In Canada in the 1970's, the agency that later became the First Nation and Inuit Health Branch of Health Canada considered blood mercury levels below 20 µg/L (or 6 mg/kg in hair) as being "acceptable" and levels greater than 100 µg/L in blood (or 30 mg/kg in hair) as "at risk" based on the knowledge at that time and the unusually high mercury concentrations observed in Grassy Narrows and Whitedog[2]. Today, Health Canada provides different threshold levels for risk depending on age and sex. Legrand and co-authors[3] summarized existing Health Canada methylmercury blood guidance values for the general population and expanded them to include a harmonized provisional interim blood guidance value. The threshold action levels for pregnant women, women from birth to 49 years and men less than 18 years was reduced but those for women above 50 years and men over 18 years, they are the same as in the 1970s. The table below is adapted from the table in the article by Legrand et al. in 2010 entitled:

Table 2 Overview of Health Canada Existing and Harmonized Blood Methylmercury Guidance Values

	Blood mercury threshold action levels			
	1	2	3	4
• pregnant women • women from birth to 49 years • men less than 18 years	less than 8 µg/L	8 – 40 µg/L	above 40 µg/L	
• women above 50 years • men above 18	less than 20 µg/L	20 -100 µg/L		
• women and men all ages				above 100µg/L

[1] Somers et al. (2015)
[2] Legrand et al. (2010)
[3] Legrand et al. (2010)

Action levels:

1. No follow-up required
2. Repeat blood/hair test in 6 months; provide dietary advice
3. Repeat blood/hair test immediately; schedule an appointment with a public health professional to review exposure history to identify sources of mercury exposure; provide dietary advice;
4. Repeat blood/hair test immediately; schedule an appointment with a public health professional to review exposure history to identify sources of mercury exposure; provide dietary advice; refer study participant to a physician or medical toxicologist for assessment and follow-up in terms of checking basic neurological signs and symptoms and making a decision concerning appropriateness of any therapeutic intervention

Other regulatory agencies have one reference dose for all, based on the studies of prenatal exposure and effects. The US-EPA reference dose for oral exposure to methylmercury is 0.1µg/kg body weight/day, which corresponds to mercury concentration of 5.8 µg/L (1 µg/g hair mercury)[1]. The Joint Expert Committee on Food Additives and Contaminants (JECFA) of the Food and Agriculture Organization (FAO) and the World Health Organization (WHO) proposed 1.6µ/kg body weight/ week (0.23µg/kg body weight/day)[2]. However, a recent review of the JEFCA guidelines by the European Food Safety Authority (EFSA)[3], published in 2012 and based on European data for fish consumption, proposed that the tolerable weekly intake be reduced to 1.3 µg/kg/week (0.19µg/kg body weight/day).

It is difficult to propose a threshold value for adults since few studies have focused on adult men and non-pregnant women since the developing foetus and child are more vulnerable to toxics and mercury is actively transported from the mother to the foetus. Moreover, the results on the studies on adults are inconsistent, probably due to the fact that the adults under study have different life histories (including prenatal exposure), life styles and nutrition (including difference in consumption of marine and fresh-water fish). The Health Canada guidelines in the Table above consider blood mercury of 20µg/L, which is approximately 10µg/g hair mercury.

A study of Taiwanese 240 adults (36 – 70 years old), who had lived in the region of a chloralkali plant that had been in operation between 1942 and 1985, was undertaken in 2005[4]. Mean total blood mercury was 17.3 ± 10.9 µg/L, with 90% methylmercury. Comparison of those in the 75th percentile (greater or equal to 19.2µg/L; mean 27.1 ± 10.9) to the others (mean 11.6 ± 4.7 µg/L) showed higher abnormality rates for tests of remote memory, mental manipulation, orientation and verbal fluency, but not for tests covering recent memory, attention, abstract thinking, language and drawing. The authors indicate that they do not have information on historic exposures.

[1] http://www.epa.gov/iris/subst/0073.htm (referenced May 5, 2015)
[2] JECFA (2004)
[3] EFSA (2012)
[4] Chang et al. (2008)

3. Foetuses and children can be impacted at far lower levels than adults.

There is now a very large number of studies on prenatal exposure to mercury and adverse health effects, most notably on children's neurodevelopment. In their review of the literature, EFSA[1] identified 34 articles of children's neurodevelopment in relation to prenatal exposure since 2003; the results of these studies motivated their recommendation to reduce the threshold for intake from 1.6µ/kg body weight/week to 1.3 µ/kg body weight/week, which would correspond to a decrease in blood mercury from 12 µg/L to 9.6 µg/L. As noted above, Health Canada considers a guidance level for blood mercury of 8 µg/L (hair mercury 2µg/g considering a ratio of 250:1) for pregnant women and women of reproductive age.

The lowest reference dose for the protection of foetus and children is the US EPA reference dose, which was based on three cohort studies of fish-eating populations[2]. It was derived by taking the lower limit of the benchmark dose[3] for cord blood and dividing it by an uncertainty factor of ten to account for variability in elimination half-life and pharmacodynamics variability[4]. It does not take into account bioaccumulation of mercury across the placenta (see section 4 below). Recent studies, however, suggest that measurable neurobehavioral effects may be present at cord blood concentrations near the US EPA reference dose.[5,6,7]

It is noteworthy that the birth cohort studies of mother-child pairs in the Seychelles[8] Islands continue to show little or no effects of mercury exposure despite concentrations similar and even higher than those which have demonstrated mercury-related effects on performance on neuropsychological tests and on electrophysiological and imaging. However, the authors of the Seychelles' studies note that the benchmark dose estimates that serve as the basis for regulatory decision-making have been largely comparable across the Seychelles, Faroese and New Zealand studies. Several hypotheses have been proposed to explain the differences between this fish-eating population and others, such as nutrients in the ocean fish in this area and possible genetic heritage factors. Indeed, in longitudinal analysis of young children's development, positive effects of omega-3 fatty acids were observed as well as small negative effects of prenatal mercury[9] and a study of school achievement showed a slight negative association with postnatal mercury in boys[10].

[10] Davidson et al. (2010)

4. Mercury is bio-concentrated across the placenta.

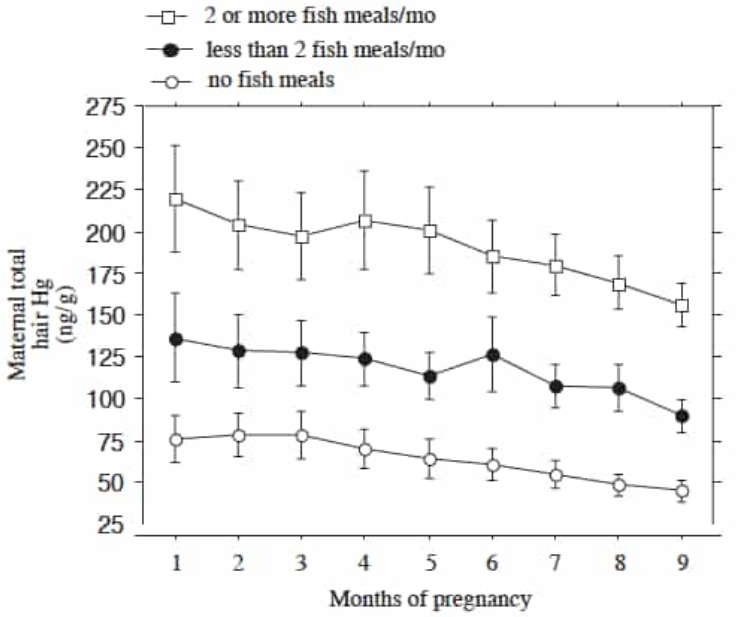
Throughout pregnancy, the placenta concentrates methylmercury and blood mercury concentration in the umbilical cord, which nourishes the foetus, is higher than in the mother's blood. A recent meta-analysis of cord to maternal blood ratios for methylmercury from 10 studies, using different modeling techniques, shows a mean cord to maternal blood ratio of 1.89 with the uppermost 95th percentile of 3.63.[1]. Thus, at birth, the average cord mercury blood concentration will be almost double that of the mother, while for one in twenty that concentration can be over three and a half times more.

Because methylmercury is concentrated across the placenta, biomarkers of maternal methylmercury decrease throughout pregnancy as the placenta takes up the methylmercury. Figure 2 shows the decline in hair mercury concentrations during pregnancy for women with different frequencies of fish consumption[2].

For biomonitoring purposes, blood mercury concentrations are measured in women of childbearing age and not in cord blood. In the study illustrated in the figure below mean maternal blood methylmercury in the first trimester was 0.48 µg/L and at birth 0.26 µg/L. Mean cord blood concentrations (0.45 µg/L) were similar to mothers' blood methylmercury concentrations in early pregnancy.

[1] Ou et al. (2014)
[2] Morrissette et al (2004)

Figure 2. Decline in Hair Mercury Concentrations During Pregnancy for Women with Different Frequencies of Fish Consumption



from Morrissette et al. (2004)

5. Population level impacts can be found at much lower levels of exposure than clear individual impacts (e.g. lower IQ). These can have major impacts at a community level.

The threshold concentrations of all of the above-mentioned agencies were based on neurobehavioral outcomes and not on illnesses. These statistically significant but individually subtle effects can greatly impact a community.

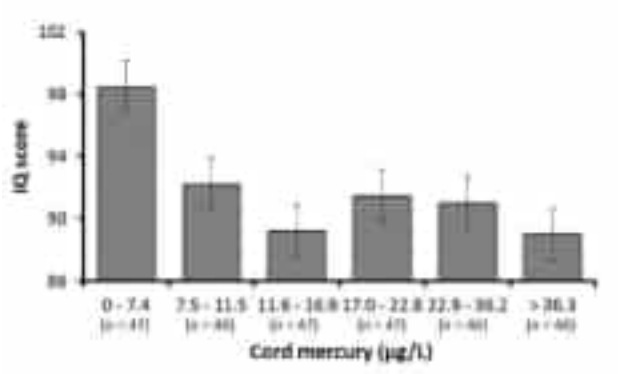
A recent video made by Dr. Bruce Lanphear of Simon Fraser University entitled 'Little Things Matter' (https://www.youtube.com/watch?v=E6KoMAbz1Bw) well describes the impact of very small quantities of toxic substances on children's neurodevelopment. Even **a small decrease in the learning capacity of children in a community has striking repercussions for the community**[1]. For example, an average decrease of 5 IQ points, among exposed children means that, in this community, twice as many children have severe learning difficulties and half as many children are gifted. The effects are amplified if the children have other problems, including poor nutrition, low intellectual stimulation or other toxicant exposures.

In a study of school-age Inuit children from 14 villages in Artic Quebec, children with **cord blood mercury equal to or greater than ≥ 7.5 µg/L were four times as likely to have an IQ score**

[1] Lanphear B. (2015)

below 80, the clinical cut-off for borderline intellectual disability[1], compared to those with lower cord mercury. It is noteworthy that since some of the IQ sub-tests are culturally sensitive, for this study, these tests were modified and validated for this population. The scores ranged from 61 – 125.

Figure 3. Test scores with respect to cord blood mercury in Inuit children 8-14 years old



from Jacobson et al, 2015

6. Developmental impacts of mercury have life-long impacts.

There is increasing evidence that prenatal exposure to mercury has lifelong effects. Subsequent to the Minamata disaster, many children born to asymptomatic mothers with high concentrations of methylmercury during pregnancy, appeared normal at birth but developed a progressive neurological disorder called Minamata fetal disease[2]. At lower levels, prenatal exposure to methylmercury is associated with a decrease in children's later cognitive functions, affecting their learning capacity and success in school and in later life.

Recent studies which have examined long term effect of low-level prenatal exposure on brain activity**,** using electrophysiological or neuro-imaging techniques, have confirmed altered brain activity in children with prenatal exposure to mercury[3,4,5,6]

In the United States, researchers have calculated that neurodevelopmental effects of

[1] Jacobson et al. (2015)
[2] Grandjean et al. (2010)
[3] White et al. (2011)
[4] Ethier et al. (2012)
[5] Yorifuji et al. (2013)
[6] Boucher et al. (2010)

methylmercury in that country accounts for a loss of $8.7 billion dollars annually in earning capacity[1]. The authors of the above-mentioned study of prenatal exposure and cognitive effects in Inuit children point out that intellectual disability on school-age IQ is a measure that is predictive of occupational success in adulthood.

In the above-mentioned study of Inuit children, the adjusted[1] mean IQ of the **lowest exposure group was 4.8 points (5%) higher than the others**. However comparing the percentage below 80, the clinical cut-off for borderline intellectual disability: **only 4.3% of the lowest exposure group** were in this category compared to **17.2% for the more exposed.**

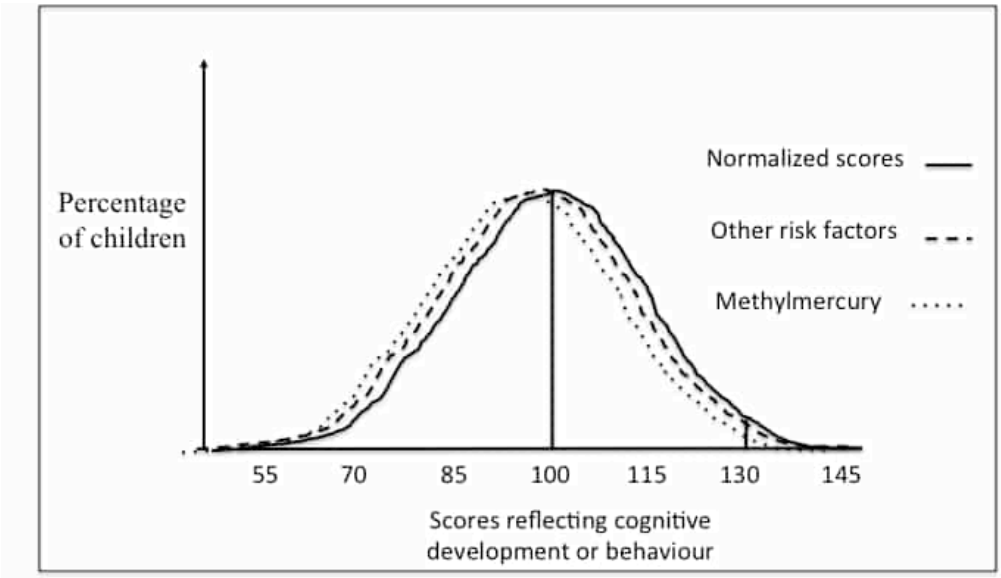
In addition, some studies suggest that there may be associations between attention deficits and/or impulsive or hyperactive behaviour in relation to methylmercury exposure. The birth cohort study of **8 – 14 year old Inuit children** shows that **problems of attention and teacher reported symptoms of attention deficits/hyperactive disorders (ADHD) were associated with higher prenatal mercury concentrations, but not current exposures**[2]. In a study in the United States of 8 year old children living near a contaminated site (superfund site), increased risk for inattention impulsive/hyperactive behaviour for boys, but not for girls, was associated with maternal hair mercury, measured close to child's birth, equal to or above 1µg/g.

Several authors have raised the issue of the combined effects of toxic exposures on children's development in communities with other risk factors, such as poor nutrition and housing, pre-existing diseases and parents' unhealthy lifestyle. Weiss and Bellinger[3] refer to the "social ecology of children's vulnerability to environmental pollutants". The impact of toxic exposures on children who are vulnerable because of other risk factors is greater on the community.

Figure 4 below shows how methylmercury compounds the effects of other risk factors on intellectual capacities. Children's average cognitive capacities or behaviour are influenced by factors such as poor nutrition and housing, pre-existing diseases and parents' unhealthy lifestyle, pushing the normal curve towards the left, with more children suffering from learning difficulties. Methylmercury exposure further pushes the curve towards the left.

[1] In this study, to assess the contribution of mercury, IQ scores were adjusted for cord lead, current PCB153, cord DHA, cord selenium, social environment
[2] Boucher et al. (2012)
[3] Weiss and Belanger (2006)

Figure 4 Estimated distribution of intellectual capacities with methylmercury exposure combined with other factors. The normal curve moves towards the left, towards lower scores.



The impact of exposure may also be passed on from one generation to the next[1], not only through the fetal environment, but also through the care that parents, who function less well because of their exposure, are able to give to their children. It can become a vicious circle, as shown in Figure 5. The way in which boys and girls experience these effects may differ[2]. Boys and girls who drop out of school may occupy poorer jobs or no jobs and act out their dissatisfaction in different ways. For girls, early pregnancy may be a further consequence. Although associations between early pregnancy and school achievement, living conditions and income have been studied in aboriginal and non-aboriginal communities[3], the possible contribution of exposure to contaminants to these situations has not been examined.

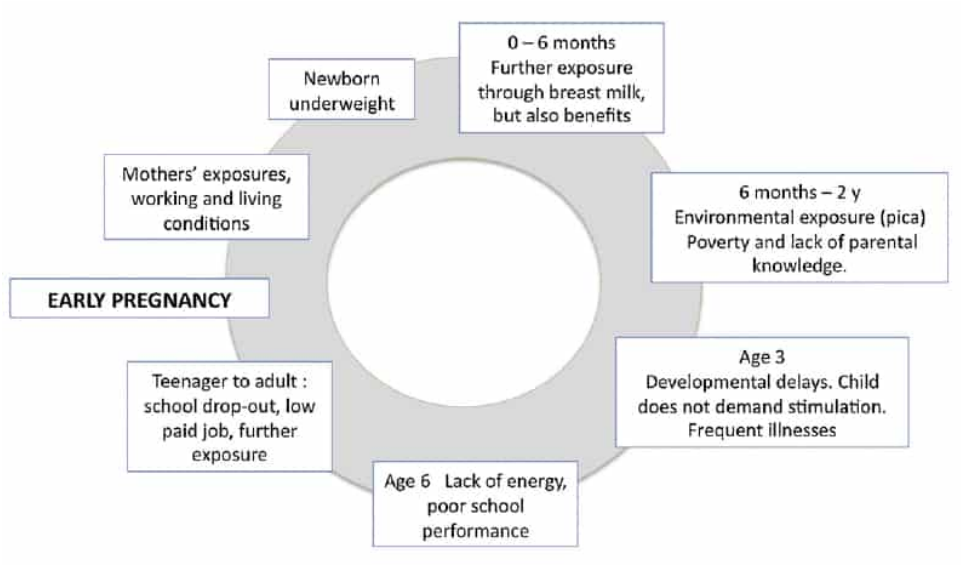
Figure 5 Impact of Environmental Exposure from One Generation to the Next



from Mergler (2012)

7. The health impacts of mercury exposure in adults can take a long time to manifest and can be long lasting and degenerative.

Adverse effects of methylmercury exposure in adults can result from pre-natal and childhood exposure and/or exposure during adulthood. However, the harm may not be immediately evident. Even with high exposures during adulthood, such as those that occurred in Iraq and in Minamata, there was often a delay between exposure and mild to severe neurological effects exposure, varying from weeks to years[1]. A study in Japan[2] compared the subjective complaints and activities of daily living (ADL score) of a randomly chosen sample of 750 persons, classified into three groups with respect to estimated previous exposure to methylmercury; all had lived in their current residence for over 40 years. While no difference was observed between exposure categories for the 40-49 year olds, as they got older there was a strong dose-effect relation, with those in the higher group showing the worst scores. Further data from Minamata and the surrounding areas suggest that, in later life, exposed persons display a higher prevalence of psychiatric problems[3], hypertension[4] and lower urinary tract disorders[5].

[1] Weiss et al. (2002)
[2] Ushijima et al. (2012)
[3] Yorifuji et al. (2011)
[4] Yorifuji et al. (2009)
[5] Hara et al. (2013)

In adult subsistence fish-eaters of the Brazilian Amazon region, hair mercury concentrations have been associated with deficits in visual functions[1] and motor performance[2]. Age-related decrease in near visual acuity and the prevalence of age-related cataracts were higher among those with higher exposures to mercury[3,4]. In a follow-up study of persons in this region, who continued to eat the same amount of fish, but preferentially those with less mercury, the resulting decrease in hair mercury was associated with an improvement in motor functions, but visual functions continued to decrease in relation to their past exposure levels[5].

Studies of non-human primates dosed with methylmercury, the latency period for signs and symptoms increased as the dose decreased[6]. In Figure 6, taken from Weiss (2002), the impact of slight increases in loss of functional capacity with age is illustrated. Like with small decrements in IQ in children, which have a large impact on society, small decrements in functional capacity with age likewise impact the aging process. Again with poor nutrition, living conditions and access to health facilities, the decrease in functional capacities is greater.

Figure 6 Impact of Slight Increases in Loss of Functional Capacity with Age

[6] Weiss (2002)

To better understand the mechanisms involved in adult exposure to methylmercury, researchers have examined the brains of animals chronically exposed to methylmercury over a period of time. These studies show extensive alterations in the cortical regions of the brain[1,2] Autopsies performed on the brains of children and adults from the Minamata disaster show different patterns of mercury related impairment, more diffuse in children and more concentrated in specific areas in adults[3].

Methylmercury from fish consumption has also been associated with chronic conditions in adults although the contribution of previous prenatal and/or postnatal exposure vs. current exposure is difficult to determine. In the study cited above of a Taiwanese population living near a deserted chloralkali plant, there was no historical data and the researchers were unable to determine the contribution of past exposures to their neurologic deficits, which were associated with current exposure concentrations. In this same population, the authors found that current mercury blood concentrations were associated with increased risk of insulin resistance[4].

8. Fish is the most important source of mercury in humans. Other sources of mercury in humans include fish eating wildlife (ducks, otters, etc.), dental fillings, etc. Estimates of mercury impacts based on MeHg or fish alone may underestimate the total impact.

Humans are exposed to both inorganic mercury and organic mercury (usually in the form of methylmercury). Exposure to inorganic mercury is usually through mercury vapours from occupational and industrial sources; mercury amalgams in dental fillings can also be a source of exposure to inorganic mercury. When inhaled or swallowed, this form of mercury passes passively into the blood and is excreted through the urine. Contrary to methylmercury, tissues, such as the brain or the placenta, do not actively take it up and the concentration in mother's blood is similar to that in cord blood[5].

Methylmercury has been used in industrial processes; the methylmercury poisoning disaster in Iraq in the early seventies was due to the methylmercury containing fungicide that was consumed by humans[6]. However, outside of accidental exposures, human exposure to methylmercury is very largely through fish consumption and to a lesser extent through consumption of fish-eating birds and mammals.

To estimate the total intake of methylmercury, one needs to consider the entire diet, including

[1] Dasari et al. (2010)
[2] Kong et al. (2012)
[3] Eto et al. (2010)
[4] Chang et al . (2011)
[5] Morisette et al. (2004)
[6] Grandjean et al. (2010)

fish-eating birds and mammals. The Environment Canada website on mercury in the food chain, updated in 2013 well describes how mercury accumulates through the food chain (https://www.ec.gc.ca/mercure-mercury/default.asp?lang=En&n=D721AC1F-1).

Some salient points are made in this document:

- *Because mercury is a persistent substance, it can build up, or bioaccumulate, in living organisms, inflicting increasing levels of harm on higher order species such as predatory fish and fish eating birds and mammals through a process know as "biomagnification".*
- *In the environment, particularly lakes, waterways and wetlands, mercury can be converted to a highly toxic, organic compound called methylmercury through biogeochemical interactions.*
- *The most important pathway for mercury bioaccumulation is through the food chain. In the water, plants and small organisms like plankton take up mercury through passive surface absorption or through food intake. … Methylmercury biomagnifies through the food chain as predators eat other organisms and absorb the contaminants that their food sources contained.*
- *Over time, an individual who consumes plants or prey contaminated with methylmercury will acquire levels greater than in either its habitat or its food. As a result, top predators acquire greater body burdens of mercury than the fish they consume.*
- *In some cases, methylmercury levels in carnivorous fish, such as freshwater bass, walleye and pike … bioaccumulate up to a million times greater than in the surrounding water.*
- *Piscivorous (fish eating) predators such as loons, merganser ducks, osprey, eagles, herons, and kingfishers, generally have very high concentrations of mercury.*
- *In addition, mercury has been found in predatory mammals such as otters from south central Ontario.*

9. In 1979 the Health and Welfare Canada recommended a limit of 0.2 ppm in fish as a fish consumption limit for Grassy Narrows and White Dog. The limit for possession of fish for sale is 0.5 ppm wet weight.

In 1973, a Task Force on Organic Mercury in the Environment was established by the Minister of National Health and Welfare (currently Health Canada) "in order to respond to the problem of high and unusual mercury levels in relation to the health and well-being of residents of Grassy Narrows and Whitedog, Ontario"[1]. A biomonitoring program was initiated. In 1979, The Health and Welfare Canada recommended a limit of 0.2 ppm in fish for consumption in Grassy Narrows and Whitedog.

[1] cited in Legrand et al. (2010)

The Canadian limit of fish for commercial purposes of 0.5 ppm wet weight is based on the fact that in the general population, fish consumption is not very high. Data from the 2007-2009 Canadian Health Measures Survey (CHMS), which does not include people living on reserves or in remote regions, show that most Canadians eat (82.6%) eat less than three meals of fish and/or shellfish per week. Overall blood mercury levels are low, with median values at 0.81µg/L and the 95th percentile 4.70 µg/L. Blood mercury levels increase with fish consumption. Among pregnant women, 98% are below the Health Canada guideline for blood mercury (8µg/L).

In contrast, a study of diet among 7 Istchee (Cree) communities in the James Bay area showed that blood mercury concentrations 3 – 20 times higher than those reported in the CHMS; blood mercury increased with inland traditional food intake[1]. Another study of persons from the Wapekeka and Kasabonika communities[2] showed hair mercury concentrations 1.5 times higher in persons who ate more than 1 meal of wildlife/week (age adjusted hair mercury concentration (2.96 ± 0.3 µg/g)

10. The Canadian reference dose for preventing fetal neurotoxicity and developmental impacts is double that recommended by US EPA.

In section 2, the different guidelines for mercury exposures are presented. The guidelines were developed to recommend **tolerable daily intake (TDI) or weekly intake (TWI)** of mercury. The Canadian provisional tolerable daily intake for pregnant women, women of reproductive age and infants of 0.2µg/kg body weight/day is twice the US EPA of 0.1µg/kg body weight/day and slightly higher than the proposed revision of the FAO/WHO reference dose (0.19µg/kg body weight/day) (see section 2). The US EPA reference dose is based on **cord blood concentrations**, while the JECFA and Canadian recommendations are based on **hair concentrations**. The Canadian recommendation used a 5-fold uncertainty factor to account for inter-individual variability[3]. The studies that support this recommendation used maternal hair mercury concentrations at birth that are lower than those at the beginning of pregnancy due to placental accumulation (see figure 2 in section 4). All of these reference doses are high for Grassy Narrow since the population has already been exposed to levels that are higher, and in many cases, considerably higher than these.

11. Eating fish has a number of important health benefits. Serious efforts should be made to avoid practices that lead to bio-accumulation of mercury in fish so that the health benefits of fish can be enjoyed while minimizing health impacts from mercury.

Fish is a highly nutritious food, providing a wide variety of nutrients, including omega-3 fatty

[1] Johnson-Down et al. (2015)
[2] Seabert et al. (2014)
[3] Legrand et al. (2010)

acids. In a review of the cardio vascular benefits of omega-3 fatty acids, Mori[1] writes: "Many clinical and epidemiological studies have shown that the polyunsaturated n-3 fatty acids EPA and DHA from fish and fish oils, provide cardiovascular protection, particularly in the setting of secondary prevention. Omega-3 fatty acids beneficially influence a number of cardiometabolic risk factors including blood pressure, cardiac function, vascular reactivity and lipids, as well as having anti-platelet, anti-inflammatory and anti-oxidative actions". Omega-3 fatty acids are likewise positively associated with neuropsychological and neurophysiological outcomes throughout the lifespan.[2,3] Indeed, **today, most studies of mercury toxicity from consumption of fish and fish-eating animals take into account the positive effects of omega-3 fatty acids.**

An article describing a study of myocardial infarction in a Swedish and Finnish cohort well illustrates the benefits associated with omega-3 fatty acids and risks associated with methylmercury from fish consumption[4]. Their model of risk, presented in Figure 7, shows that at lower concentrations of methylmercury, even a small increase in omega-3 fatty acids can have an important impact in reducing the risk of myocardial infarction, but at higher concentrations of methylmercury, the beneficial effects are counteracted.

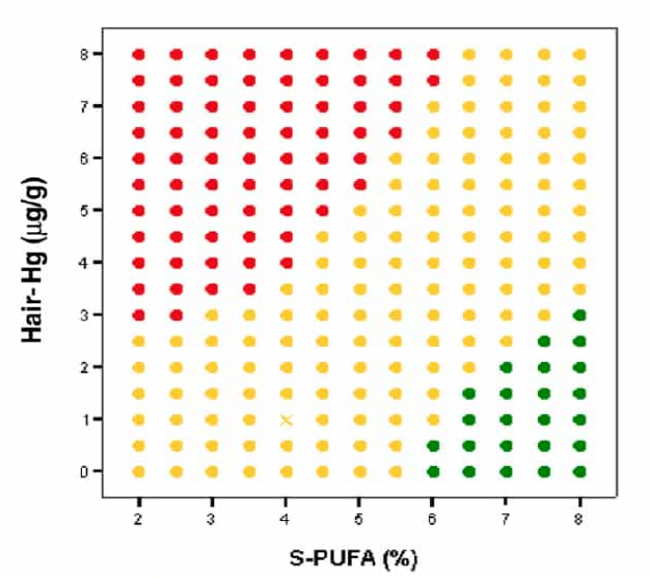

FIGURE 3. Associations of concentrations of long-chain n−3 S-PUFA and Hair-Hg with risk reduction (green circles; upper 95% CI limit for model-based RR <1.0) or increased risk of myocardial infarction (red circles; lower 95% CI limit RR >1.0), with the reference point (RR = 1.0; yellow X) set to S-PUFA = 4.0% and Hair-Hg = 1.0 µg/g; yellow circles denote no statistical evidence of an effect. Hair-Hg, amount of mercury in hair; S-PUFA, PUFAs in serum.

From Wennberg et al. (2012)

Like in many other birth cohort studies, the studies of Inuit children described above, which showed negative effects of prenatal mercury exposure on school-aged children's performance on neurobehavioral tests[1,2], likewise show positive effects of **cord blood DHA**; the benefits and risks are likewise reflected in electrophysiological measurements[3.]

In adult freshwater fish eaters from the Brazilian Amazon, although omega-3 fatty acid concentrations are low compared to consumers of marine fish and mammals, positive effects of omega-3 fatty acids have been observed with better visual functions[4]

The serum omega-3 fatty acids in First Nation inland communities increases with proportion of

[2] Jacobson et al. (2015)
[3] Boucher et al (2011)
[4] Fillion et al, (2011)(2013)

traditional diet meals[1,2]

12. The Ontario Guide for Sport Fish Eaters is not appropriate for Indigenous communities who eat fish as part of their cultural practice. It assumes that fish are eaten relatively infrequently.

The Ontario Guide for Sport Fisher Eaters (2013-2014) indicates: "The advice in this guide is designed for anglers (and their families) who consume moderate quantities of fish. The consumption advice is intended to protect individuals who follow the advice in the guide and consume no more than 8 meals per month of the fish they catch. This maximum recommended consumption frequency was based on the results of surveys indicating that most anglers do not consume sport fish more frequently than 8 meals per month. However, many of these fish can be safely consumed more frequently. Anyone who consumes sport fish more frequently than 8 meals per month is advised to contact the Sport Fish Contaminant Monitoring Program (416-327-6816 or 1-800-820-2716, sportfish.moe@ontario.ca." [3]

The US-EPA developed a guide for subsistence fishing with the collaboration of representatives from Native American tribes. It indicates: "EPA recognizes, however, that Native American subsistence fishers are a unique subsistence fisher population that needs to be considered separately. For Native American subsistence fishers, eating fish is not simply a dietary choice that can be completely eliminated if chemical contamination reaches unacceptable levels; rather eating fish is an integral part of their lifestyle and culture. This traditional lifestyle is a living religion that includes values about environmental responsibility and community health as taught by elders and tribal religious leaders. Therefore, methods for balancing benefits and risks from eating contaminated fish must be evaluated differently than for the general fisher population"[4].

13. People who have already experienced elevated mercury exposure, or are showing symptoms of mercury poisoning, may be more sensitive to further exposure than the general population.

Both animal and human studies have shown long latency effects of methylmercury exposure.[5] Adding further toxic exposure can add further harm to systems that have already been affected. A large number of human and animal studies have shown neuronal and metabolic changes in the absence of manifest signs and symptoms. Persons whose systems have already been altered by previous exposures are more sensitive than the general population.

14. CONCLUSIONS WITH RESPECT TO GRASSY NARROWS

This updated analysis of the scientific literature provides substantial further support and confirm the Chan and Mergler conclusions in the report to the Mercury Disability Board (MDB) in 2009[1]:

14a There is no doubt that at the levels of exposure experienced in Grassy Narrows, many people have suffered and are suffering from mercury poisoning.

- Further scientific knowledge of the past 6 years informs us that damage occurs at concentrations much lower than those previously considered harmless, with important impacts not only for individuals but also on the entire community.
- A growing number of birth cohort studies show that the foetus is particularly sensitive to methylmercury neurotoxicity and even very low concentrations of exposure can affect future cognitive capacity and behaviour.
- In 1996, the Research and Development, Environmental Contaminants, Medical Services Branch of Health Canada presented a report on the mercury and child development research project for the Grassy Narrows Band Council[2]. Although the report has numerous methodological problems as regards data analyses[3] and data presentation is confusing, there is information on children's exposure:
    - For the 139 children included in the study, the authors report that between 1978 and 1990 average cord blood concentrations was 8.67 µg/L, with a maximum value of 78.5 µg/L and 10% above 20 µg/L.
    - One child born in 1979, who was not included in the study, had a cord blood mercury concentration above 120 µg/g, while another born in 1978 had over 80 µg/g.
    - Overall, there was an important decrease in cord blood mercury concentrations between 1978 and 1991, however, in 1992, there appears to be an increase.
    - The mean hair mercury concentration of the participants at the time of the study was 3.90 µg/g with the maximum at 26 µg/g.
    - Figure 8, taken from this report, shows the cord mercury concentrations measured in Grassy Narrows over time.

[1] Chan and Mergler (2009)

[2] Research and Development, Environmental Contaminants, Medical Services Branch of Health Canada (1996)

[3] The analyses that were carried out were insufficient to arrive at any conclusions and particularly the conclusion that there were no effects.

- **At these cord blood concentrations, there is consensus from the current scientific literature that there would be effects on children's neurodevelopment.**

Figure 8 Umbilical cord blood levels/year measured in Grassy Narrows

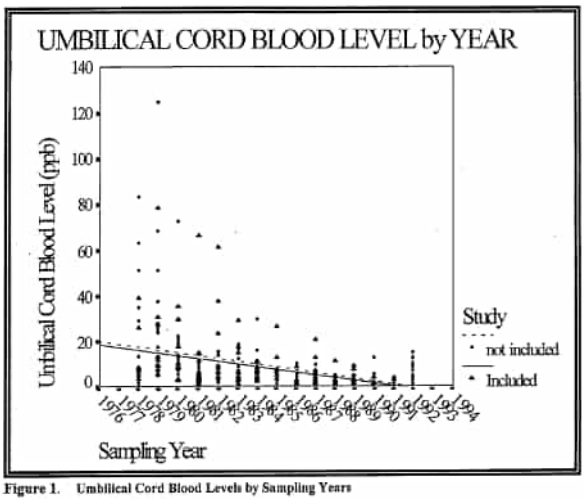

Figure 1. Umbilical Cord Blood Levels by Sampling Years

From the Mercury and Child Development Research Project, Grassy Narrows, Research and Development, Environment Contaminants, Medical Services Branch, Health Canada (1996)

- In a history of Minamata Disease published in 1995[1], Harada describes the diagnosis of the initial cases in 1956. He recounts that by 1960, "while the number of grave cases with acute Minamata Disease in the initial stage was decreasing, the numbers of chronic Minamata patients who manifested symptoms gradually over an extended period of time was on the increase."
- Recent studies from MInamata, supported by findings from animal research, show that methylmercury accelerates the aging process.
- A large number of animal studies and several human electrophysiological and imaging studies are elucidating the mechanistic basis for mercury neurotoxicity.
- While the nervous system is the primary target organ for methylmercury, studies indicate that the cardiovascular system and metabolic pathways may also be affected by methylmercury.

[1] Harada (1995)

14 b. The scientific literature continues to support Dr. Masazumi Harada and colleagues' clinical findings, reviewed by Chan and Mergler for the MDB[1] on the similarities between the neurologic signs and symptoms of persons from Grassy Narrows and White Dog and Minamata Disease in Japan.

- In their early reports[2,3], Harada and colleagues had examined 89 persons from Grassy Narrows and Whitedog and indicated that no one presented all of the classical signs and symptoms of Minamata Disease, although many persons presented one or more classical signs of the disease. Although they did not carry out statistical analyses, they provide evidence of dose-effect relations.

- In 2002[4], the same neurologists examined 57 persons of whom 9 had been examined in 1975. The authors classified 11 of the 57 persons with Minamata Disease, 12 with Minamata Disease and other complications and 22 with "light Minamata Disease".

- None of the persons Harada found with levels over 50 in 1975 survived to be re-tested in 2002. Of the 9 who were re-examined none fell into the Minamata Disease category, but for 7 of the 9, symptoms and signs had worsened.

- In 2004, this team examined 187 persons, among whom they identified 60 of Minamata Disease and 54 cases of the disease with complications. Twenty-seven had participated as well in 1975. In their review of Dr. Harada's follow-up studies (1975 - 2004)[5], the **Chan and Mergler report point outs that the most valuable information of this report was the evolution of neurologic signs and symptoms consistent with mercury poisoning in those that were tested in the two periods.**

- In 2011, Harada and his co-workers[6] wrote a review of the work that they had carried out in Grassy Narrows and White Dog since 1975, including a further study carried out in 2010. In 2010, they performed neurologic assessments of 73 persons from Grassy Narrows and 87 from White Dog over 20 years old. The report indicated that under the diagnostic criteria used in Minamata City, 33.7% of the group that they examined were diagnosed as Minamata Disease patients; and 25.0% as suspected Minamata Disease cases (see more details in answer to question 1.1 c).

[1] Chan and Mergler (2010)
[2] Harada et al. (1976)
[3] Harada et al. (1977)
[4] Harada et al. (2005)
[5] Harada et al. (unpublished report)
[6] Harada et al. (2011)

- Using the findings from the 2010 examinations, Takoaka and coworkers[1] compared the neurologic signs and symptoms of 80 volunteers aged 16 to 76 from Grassy Narrows and Japanese exposed and control groups. From the observed similarities, particularly between the Grassy Narrows older group and the Japanese exposed group, the authors conclude that "clinical signs and symptoms of the residents of Grassy Narrows are almost the same as those recorded for Minamata disease in Japan." (see more details in answer to question 1.1 d)
- It should be noted that Dr. Harada and his team sought to determine whether persons exposed to mercury in Grassy Narrows and White Dog presented a neurological clinical profile similar to Minamata Disease. While they identified cases and possible cases using the Minamata Disease criteria, they did not examine the possible contribution of mercury into other disorders or the impact of more subtle changes of nervous system functions, particularly during fetal exposure and childhood, which occur at lower concentrations of exposure. .
- Both Harada et al (2011) and Takaoka et al (2014) mention that the participants in their studies presented a high prevalence of several health disorders, including hypertension and diabetes among the participants, **but the possible contribution of mercury to these conditions has not been examined.**

14 c. Because of mercury contamination in the region, the people of Grassy Narrows were obliged to reduce their consumption of local fish and wildlife and were thus deprived of healthful nutrients, which have been shown to be beneficial for a large number of physiological functions and to be preventive for many and diseases.

- The historically high mercury concentrations in fish forced the community to greatly decrease their fish and wildlife consumption, depriving them of the nutritional and social benefits[2] of a traditional diet.
- In a 2003 study of 87 persons from Grassy Narrows[3], 61% reported that they currently fish in the surrounding area, 31% reported that they used to but no longer had fished in the area, and 8% reported they have never fished in the area. Of these participants, 9% reported eating more traditional food compared to 10 years ago, 55% reported eating about the same, and 36% reported eating less. Reasons provided for a decrease in the consumption of traditional foods included:
    - changes in the family structure;
    - decreased hunting and fishing practices;
    - decreased availability;

[1] Takaoka et al. (2014)
[2] Wheatley and Wheatley (2000)
[3] Chan (2005)

  - concerns about the safety/contamination of the food;
  - the convenience of market foods.

- Although there has been marked decrease in mercury in fish in the English-Wabigoon River system,[1] recent concentrations of mercury in fish[2] and fish-eating wildlife[3] oblige the community to limit consumption of fish and wildlife.
- Kinghorn et al[4] analyzed fish mercury concentrations in 4 fish species from seven lakes in the Grassy Narrows territory and describe the relation between fish length with respect to mercury concentration. They note that the fish harvested from Grassy Narrows lakes show stronger associations between fish length and mercury compared to those from the Wabaseemong territory. The authors indicate that this may be because "these lakes are closest to the Dryden spill site. Higher levels of mercury in the sediment of these lakes may affect the rate of uptake of mercury in the fish that live predominantly within them."
- For a report in 2005, Chan calculated mercury intake and hair concentrations for 87 persons from Grassy Narrows and 55 from Wabaseemoong measured in 2003. In Grassy Narrows, the average yearly local fish consumption in Grassy Narrows was 20g/day, but in older men (+61 years of age) it averaged 60g/day. When all of the hair segments were analyzed, mean hair mercury was 1.3 µg/g with a maximum of 7.1 µg/g. The highest individual hair segment was 15.5 µg/g. Hair mercury increased with mercury intake from fish consumption. In 2004, Harada reported that one person had a concentration of 25 µg/g and in 2003, Chan reported that persons from the White Dog area had hair concentrations of 60µg/g.
- The 2012 report on fish Contaminant Monitoring near Grassy Narrows First Nation by the Environmental Monitoring and Reporting Branch Ontario Ministry of the Environment[5] shows elevated mercury in the 50 km area around Grassy Narrows in walleye and much lower concentrations in Whitefish. For walleye, with the exception of one site where the report indicates that fish can be eaten with restriction, all the other sites indicate DO NOT EAT. Whitefish present much lower concentrations, which may still pose a risk to subsistence eaters.
- The 2012 above-mentioned report presents separate values for sensitive populations, defined as women of child-bearing age and children under 15 years old, and for the general population. Given the recent information on mercury reviewed above, a population that has already suffered effects from mercury contamination and other harmful risk factors for poor health may also be considered 'sensitive'.

[1] Neff et al. (2012)
[2] Kinghorn et al. (2007)
[3] Sellers et al. (2010)
[4] Kinghorn et al (2007)
[5] Ontario Ministry of the Environment (2012)

Grassy Narrows: a sensitive population

- Prior to the events and poisoning that occurred due to mercury contamination, the Grassy Narrows community had undergone important upheaval that negatively impacted their lives and lifestyle.[1,2,3] The toxic effects of mercury would compound the effects of these stresses on the nervous system and their health status.

- Because of the high prevalence of disease, coupled to mercury intoxication, in the communities of Grassy Narrows and White Dog, in the 2010 MDB report, Chan and Mergler point out " It is paramount that members of the two communities receive the necessary medical care and support. In contrast, residents in Minamata, Japan enjoy superb health care from neurologists and therapists even they had not officially been classified as victims of Minamata Disease".

- It is surprising that although the Japanese neurologists have identified many cases of Minamata Disease in Grassy Narrows and many persons have illness that have been associated with mercury intoxication, there has never been a scientifically sound epidemiologic study of the impact of pre and post natal mercury exposure on the health and well-being of this community.

- There are many sources of mercury contamination. The river and lake systems around Grassy Narrows have been polluted by industrial activities; hydro-electric reservoirs and logging can also contribute to the mercury burden in this ecosystem. Any increase of exposure to this already 'sensitive' community would further compound the harm to the health and well-being of the present and future generations.

Table of Contents

Introduction **5**
Background 5
Major findings 6

Executive Summary **8**
General health and chronic health conditions 8
Mental and emotional health and behaviour 9
Contribution of prenatal fish consumption to children's development 10
Maternal health during pregnancy *10*
Children's physical health *10*
Children's mental health and behaviour *11*
Mercury Disability Board Claims *12*
Intergenerational fish consumption and fishing practices 12
Comparison of Grassy Narrows' children and youth's physical and mental health with other First Nations in Canada *13*
Schooling 14
School performance in comparison with other First Nation communities *15*
Children and youth's activities outside of school 16
Physical activities *16*
Sedentary activities *16*
Community activities *17*
Food consumption 18
Maternal context 18
Children in care of the Child and Family Services 19

Recommendations **21**
Mothers of child-bearing age 21
Children and youth 22
A comprehensive study of the children in Grassy Narrows with intervention components *24*
Conclusion 25

DRAFT - CONFIDENTIAL

Introduction

Background

The present report is the second part of the Asubpeeschoseewagong Netum Anishinabek (ANA; Grassy Narrows First Nation) Community Health Assessment (CHA) survey. The Grassy Narrows CHA stems from a request by Grassy Narrows to better understand the health and wellness of the community and its determinants, with the view to improving the community's wellbeing. All aspects were led by the community. This report presents the results of the Grassy Narrows Child and Youth Survey.

The survey was filled out for 353 children and youth. It included 173 questions for specific age ranges (0 – 3 years of age; 4 – 11 years of age; 12 years and over). Many of the questions were taken from the First Nations Regional Health Survey 2008/2010[1], which allowed us to compare the prevalence of different outcomes in Grassy Narrows with children and youth in First Nation communities in Canada and in Ontario[2]

To extend the statistical analyses and explore the associations between indicators of child health and well-being with respect to the mother's or household situation, we merged the child/youth and the adults' databases. The resulting adult/child database included 327 pairs. From this database, we extracted different sub-groups, depending upon the issue under study. For example, for comparisons with other First Nation communities, only Band member respondents who live in Grassy Narrows were included.

Similar to the adult report, **the health and wellness of the children and youth of Grassy Narrows cannot be understood without considering the impact of the major disaster that occurred in this community,** initiated in the 1960's by the discharge of mercury into Wabigoon-English River system. The resulting loss of culture, livelihood, physical and mental health and a highly nutritious food source greatly impacted the community. Recent evidence has shown that although mercury concentration in fish in the river system has decreased over time, during these children's lifetime, it is still high and has not decreased since the mid 1980's.[3]

The present report clearly shows that **fish consumption, particularly mothers' fish consumption during pregnancy, negatively affects the health and well-being of the children and youth of this community.** The findings are consistent with the large number

DRAFT - CONFIDENTIAL

[2] The data from the FNRHS Canada was analyzed for First Nations in Ontario and published in the report First Nations Regional Health Survey Phase 2 (2008/10) Ontario Final Region Report by the Chiefs of Ontario in 2012 (FNRHS Ontario).

[3] Neff et al, Long-term changes in fish mercury levels in the historically impacted English-Wabigoon River system (Canada). Journal of Environmental Monitoring 2012 ; 14, 2327-2336

of studies that describe the risks associated with prenatal mercury exposure on children and youth's development and health and more recently on behaviour.

The health and well-being of children and youth is also affected by the **intergenerational consequences of mercury contamination of the fish resources in their community, with harmful effects on physical and mental health, behaviour and school performance.**

The young people of Grassy Narrows are nationally known for their ability and persistence in organizing events that seek to further their culture and traditions and improve the well-being of their community. The most well-known are the long-standing blockade against clear-cut logging on their territory and the river runs, but there are many others. The survey shows that more than two-thirds of children/youth participate in community organized cultural events and half of the youth participate in events to recognize Grassy Narrows' rights.

In a recent newspaper article, the young people of Grassy Narrows passionately state: **"We are more than mercury"**[4], and that despite difficulties and hardships, they continue to move forward and **build on the strengths of their community**. By documenting their current situation and demonstrating how mercury poisoning is still affecting their health and wellness, this report serves to identify the physical and mental health care services, schooling, and social and economic conditions, that need to be improved for the health and well-being of the present and future generations.

Major findings

- **Mothers' fish consumption during pregnancy is associated with poorer overall physical health**, notably for specific chronic conditions, such as visual problems, ear infections, speech/language disorders, learning disability and nervous system disorders (Chapter 8 and 9).

- **Mothers' fish consumption during pregnancy is associated with children's poorer mental health**, particularly more emotional and behavioural problems compared to children of the same age and sex, which in turn is associated with a higher prevalence of attempted suicide (Chapter 8 and 9).

- **Mothers' fish consumption during pregnancy is associated with at least one condition that may impact children's school performance** and with more difficulties in school, notably poorer attention span (Chapter 8 and 9).

- Many aspects of Grassy Narrows children and youth's physical health are similar to other First Nation communities in Canada and in Ontario, but **compared to other**

[4] https://www.thestar.com/news/canada/2018/10/21/we-are-more-than-mercury-the-youth-from-a-place-known-for-poisoned-land-and-water-are-sending-a-message.html

DRAFT - CONFIDENTIAL

First Nation communities, they present a higher prevalence of the chronic conditions and emotional and behavioural issues that are associated with maternal fish consumption during pregnancy (Chapter 11).

- **The most striking difference between Grassy Narrows youth and First Nations' youth in Ontario and Canada is attempted suicide rate.** The Band member respondents, living in Grassy Narrows, indicate that 27% of youth have attempted suicide compared to 7% of First Nations' youth in Ontario and 6% in Canada in 2008/2010 (10% in 2015/2016) (Chapter 11)

- The most recent statistics from the First Nations Regional Health Survey (2015-2016)[5] report that the attempted suicide rate among First Nations teenage girls has risen from 10% in the previous survey to 16%. **The Band member respondents, living in Grassy Narrows, report that half (50%) of the girls over 12 years of age have attempted suicide** – three times more than the percentage of girls in other First Nations in Canada. (Chapter 11).

- **Many of Grassy Narrows's children and youth have been in the care of Child and Family Services.** Forty-one children (12% of all children/youth in the survey) were in care of Child and Family Services outside of Grassy Narrows at the time of the survey; 107 children/youth (32%) have at one time been in the care of Child and Family Services (Chapter 10).

- For 22% of the children, who had ever been in care, the person who filled out the questionnaire (respondent) considered that the intervention was **damaging to the child** and 29% felt it was **damaging to the family**. There is an important **gender difference** in the results: for 41% of girls who had ever been in care, the respondent considered that it was damaging to the child, while this was the case for only 16% of boys (Chapter 2).

- **The likelihood of currently or ever being in care of Child and Family Services is higher among children whose maternal grandfather had been a fishing guide**, independently of other factors that are associated with being in care, suggesting intergenerational consequences of the disaster that hit this community.

These findings support the need for urgent action to improve the health and well-being of the children and youth of Grassy Narrows.

DRAFT - CONFIDENTIAL

[5] https://fnigc.ca/news/final-volume-landmark-report-explores-health-care-language-culture-food-security-first-nations

Executive Summary

The Grassy Narrows' Child and Youth Community Health Assessment sought to provide a portrait of the situation of the children and youth of this community. To achieve this, it covered a wide range of aspects: their mental and physical health, their schooling, their physical and sedentary activities, their food consumption and being in the care of Children and Family Services. Questions were likewise asked about factors that could influence these outcomes, such as maternal health and mercury exposure during pregnancy. Merging of the adult and child questionnaires allowed us to examine associations between the parents' and children's situation. The key findings for the chapters are summarized here.

General health and chronic health conditions

Overall, the health of 78% of girls and 70% of boys is rated very good or excellent (thriving). The most prevalent diagnosed chronic health conditions are:

- Visual problems requiring glasses;
- Ear infections;
- Allergies;
- Asthma;
- Eczema or dermatitis;
- Language and/or and speech disorders

In addition, at least 10% of youth (12 years old and more) suffer from:

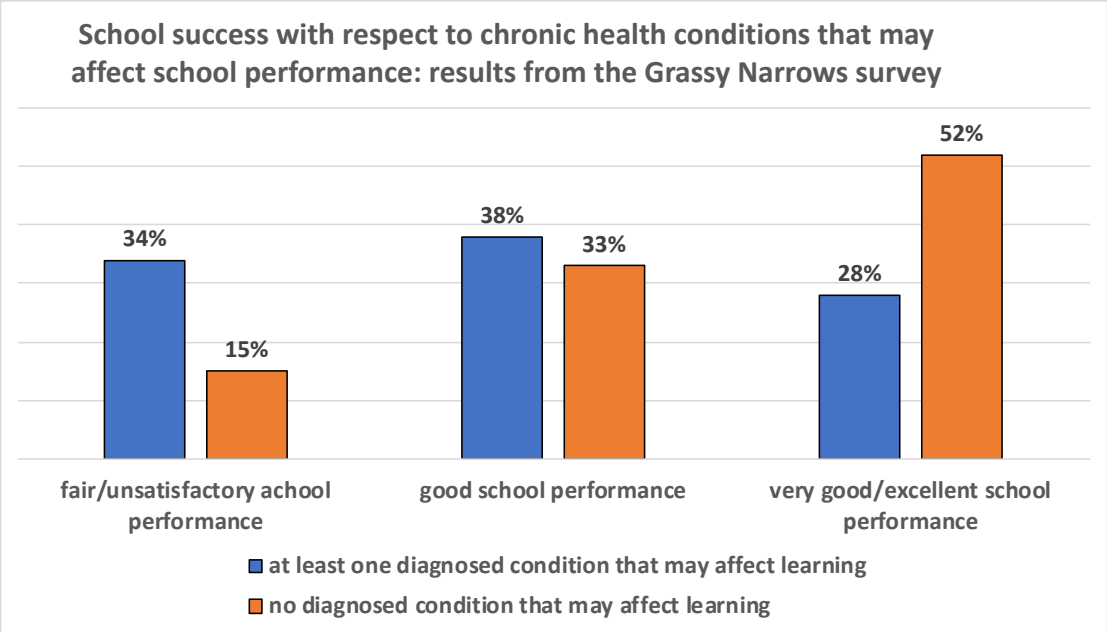
- Anxiety and/or depression;
- Learning disability;
- Attention Deficit Disorder or Attention Deficit Hyperactivity Disorder (ADD/ADHD)
- Anemia

Seven percent (7%) of children and youth have a diagnosed **neurologic disorder.** The details of these findings are in Chapter 6.

The First Nations Regional Health Survey (2008/2010) uses a measure of **diagnosed chronic health conditions that may have a negative impact on learning ability** (having at least one of the following: cognitive or mental disability, a learning disability, ADD/ADHD or speech and language difficulties)[6]. In the present survey, 16% of children and youth between the ages of 4 and 17 fulfill these criteria (Chapter 5). The measure is indeed reflected in school performance of the children and youth in the Grassy Narrows survey as shown in the graph below.

[6] FNRHS, Canada p. 374.

DRAFT - CONFIDENTIAL



DRAFT - CONFIDE

Mental and emotional health and behaviour

Over half of respondents indicate that the child/youth mental health is very good or excellent. Children whose mental and health was reported as very good or excellent were more likely to have very good or excellent physical health.

In answer to the question: ***"Did this child/youth have more emotional or behavioural problems over the past 6 months compared to others of the same age and sex?",*** 28% responded in the affirmative. Among younger children (4 - 12 years of age), the prevalence is higher for boys (27%) compared to girls (17%); for the older children, the prevalence is higher for girls (50%) compared to boys (23%).

The percentage of children/youth who have **attempted suicide** is high. For all respondents, 27 children (10%) between the ages of 4 and 17 have attempted suicide, with proportionally more girls compared to boys.

- For all respondents 12 years of age and over, 39% of girls and 6% of boys have attempted suicide.

- For respondents who are Band members and who live in Grassy Narrows, 27% of youth have attempted suicide; 50% of girls.

Compared to other children of the same age or sex, those who have attempted suicide have more **emotional or behavioural problems over the past 6 months**. Sixty percent (60%) of youth who report **anxiety and/or depression have attempted suicide**.

Three-quarters of children/youth who have **attempted suicide** have been in **the care of Child and Family Services.** Among the children who have been in care, it represents one out of four. For children who have been in the care of Child and Family Services and who have attempted suicide, 50% of respondents indicate that the intervention from Child and Family Services had been damaging to the child and 60% indicated that it had been damaging to the family.

The details of the findings on mental and emotional health and behaviour are in Chapter 7.

Contribution of prenatal fish consumption to children's development

The Grassy Narrows' CHA had a question about mother's fish consumption during her pregnancy with the child: 52% of mothers never or hardly ever ate fish during their pregnancy, 27% ate fish once a month and 21% ate fish at least once a week.

Mothers who lived in Grassy Narrows during their pregnancy (68% of all pregnancies) consumed more fish compared to those who lived elsewhere during her pregnancy. A description of fish consumption and other characteristics during pregnancy is presented in Chapter 2.

Maternal health during pregnancy

Women who ate at least one fish meal a month during pregnancy were twice as likely to have maternal health problems during pregnancy, such as high blood pressure, gestational diabetes. This finding is independent of "drinking a lot or taking drugs during pregnancy", which was also a predictor of gestational and/or birthing difficulties (Chapters 8 and 9).

Children's physical health

Mothers' fish consumption during pregnancy negatively impacts the child's health. The table below indicates the likelihood (Odds Ratio) for children 4 years and over of having a diagnosed health chronic condition with respect to maternal fish consumption during pregnancy. The results are independent of other potential determinants (age and sex of the child, health problems during pregnancy and/or difficulties during childbirth, and drinking a lot or taking drugs during pregnancy) which, in some cases, were also predictors (Chapter 8. Tables 5a and 5b).

The findings in the table below are presented for different levels of fish consumption during pregnancy. The numbers compare **the likelihood for having this problem by comparing the children of mothers who ate fish never or hardly ever, with those who ate fish once a month or once a week or more.** For example, a higher likelihood of visual problems and chronic ear infections is observed among children whose mother ate at least one fish meal a month (both boxes show numbers), while not thriving, learning disability,

DRAFT - CONFIDENTIAL

conditions that may impact school performance and at least one nervous system disorder are observed among children whose mother ate at least one fish meal a week, but not among those who less fish. For these conditions, there was no significant difference between those who ate one fish meal and month and those who hardly or never ate fish during their pregnancy.

The likelihood of child/youth (4 -17 years) having a diagnosed health condition with respect to maternal fish consumption (comparison to those who hardly ever or never ate fish during pregnancy)

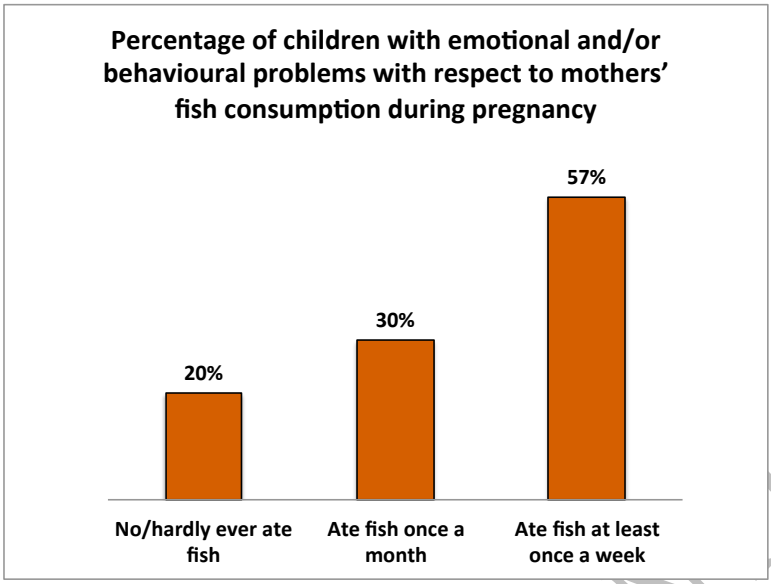
	Maternal fish consumption during pregnancy	
	One fish meal a month	One fish meal a week or more
Visual problems	2x	2x
Chronic ear infections	3x	3x
Health less than very good or excellent (not thriving)		3x
Learning disability		4x
Conditions that may impact school performance		4x
At least one nervous system disorder		4x

DRAFT - CONFIDENTIAL

Children's mental health and behaviour

Among children and youth 4 to 17 years of age, the percentage of children with *"more **emotional or behavioural problems** over the past 6 months compared to those of the same sex and age"*, **increases with increased maternal consumption of fish during pregnancy.**

The table below indicates the proportion of children and youth with emotional or behavioural problems for all the children in the survey and the Grassy Narrows' Band mother/child pairs.



Emotional or behavioural problems is a predictor of **attempted suicide.** Analyses showed that, independently of other child and maternal factors. Behaviour is a mediator for the relation between maternal fish consumption during pregnancy and attempted suicide, that is: **the likelihood of attempted suicide increases with emotional or behavioural problems, which in turn increases with maternal consumption of fish during pregnancy.**

Mercury Disability Board Claims

One or several claims have been made to the **Mercury Disability Board** for a monthly mercury disability benefit for 21 children; half (a total of 11) were accepted. **There is a positive association between maternal fish-eating during pregnancy and a claim being made for the child:** 16% of children whose mother ate fish at least once a week; 6% of children whose mother ate fish once a month and 3% of those whose mother hardly ever/never ate fish.

Intergenerational fish consumption and fishing practices

Fishing and fish consumption have been traditional and cultural practices of the people of Grassy Narrows for hundreds, if not thousands of years. Walleye, a high end predator that bioaccumulates mercury was central to their lives. The discharge of mercury into the river system left the community "to deal with the loss of their traditional economy, unemployment

DRAFT - CONFIDENTIAL

and a mysterious new ailment that was rampant among members of their community – mercury poisoning"[7].

To examine intergenerational fishing practices, we analyzed the responses of mothers who currently live in Grassy Narrows, who lived in Grassy Narrows during their pregnancy with each child, and who answered the question about their fish consumption during their pregnancy. A total of 125 mother/child pairs meet these criteria.

- With respect to fish consumption during pregnancy, there is no difference in the mother's age, the mother's age at birth or the child's age, **indicating that there has been no change in fish consumption during pregnancy since 1999.**
- There is **a positive correlation between maternal fish-eating during pregnancy and mother's father (child's grandfather) being a fishing guide**: 92% of children whose mother ate fish at least once a week had a grandfather who was a fishing guide, compared to 80% of those whose mother ate fish once a month and 54% of those whose mother hardly ever or never ate fish during pregnancy.
- **The positive correlation with mothers' fish consumption during pregnancy is likewise observed for mothers' fish consumption as a child, current consumption of walleye and for practicing fishing.**
    - 90% of children's mothers who report that they ate fish at least once a week during their pregnancy likewise report that they practice fishing.
    - Over half of children of whose mother ate fish at least once a week, practice fishing and ate walleye at least once a month during the past year.

The intergenerational analyses show that from grandfather to mother to child, the tradition and culture of fishing and fish consumption have been passed down from one generation to the next. However, since the 1970's, so, too, has the loss of the traditional economy, unemployment and sickness. Fishing guides and their families were the most highly exposed to mercury[8] and the first to lose their jobs.

Comparison of Grassy Narrows' children and youth's physical and mental health with other First Nations in Canada

The First Nations Regional Health Survey 2008/2010, which surveyed persons from First Nation communities living on reserve, included sections on children and youth. Mothers responded for children 0-11 years of age and youth (12 years and over) responded on their own. For comparison purposes, in this report, for children 0 – 11 years of age, we limited the analyses to mother's responses. (Chapter 11).

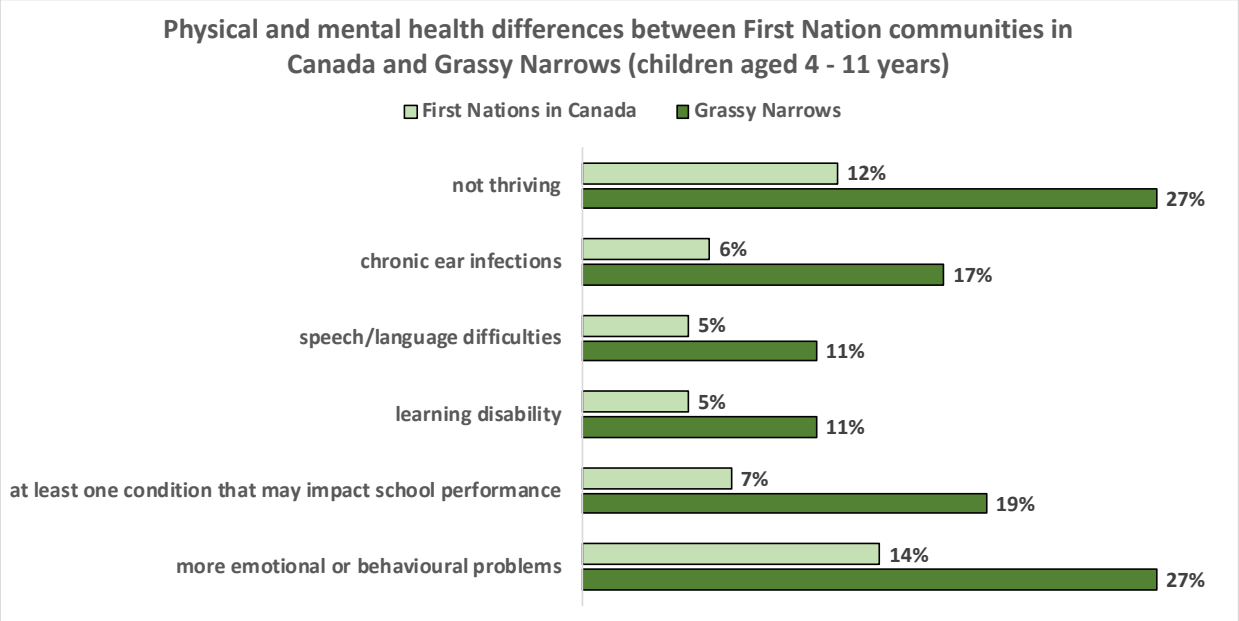
[8] Wheatley B and Paradis S. Exposure of Canadian Aboriginal peoples to methyl mercury. Water, Air and Soil Pollution, 80:3-11; 1995.

DRAFT - CONFIDENTIAL

Although different methods were used with youth for the Grassy Narrows survey (an adult filled out the large majority of the questionnaires) and the First Nations Regional Health Survey 2008/2010, youth survey (youth filled out the questionnaire), we compared the responses for certain outcomes for youth 12 – 17 years of age, living at home.

For the children (0 – 11 years of age), Grassy Narrows children have **a higher prevalence of the diagnosed conditions that are associated with prenatal fish consumption, but not for the other conditions.**



For the youth, the major differences between Grassy Narrows youth and the First Nations Youth Regional Health Survey (2008/2010) were for **chronic ear infections** (23% vs 3%), **dermatitis** (14% vs. 4%) **conditions that may impact school performance** (16% vs 7%) and **attempted suicide** (27% vs 6%).

Schooling

97% of children and 92% of youth attend school; 15% are in pre-kindergarten or kindergarten, 54% in elementary school and 31% in high school (Chapter 5). School success is reported to be better in elementary than in high school; in elementary school 52% are in the very good/excellent category compared to 33% in high school, and 14% are in the fair/unsatisfactory category compared to 34%.

Overall, girls have better success in school compared to boys among both children and youth. With respect to specific difficulties, in elementary school, more boys than girls have difficulty

DRAFT

with mathematics and a short attention span, while in high school, more boys have a short attention span compared to girls and more girls have difficulty understanding the teacher compared to boys.

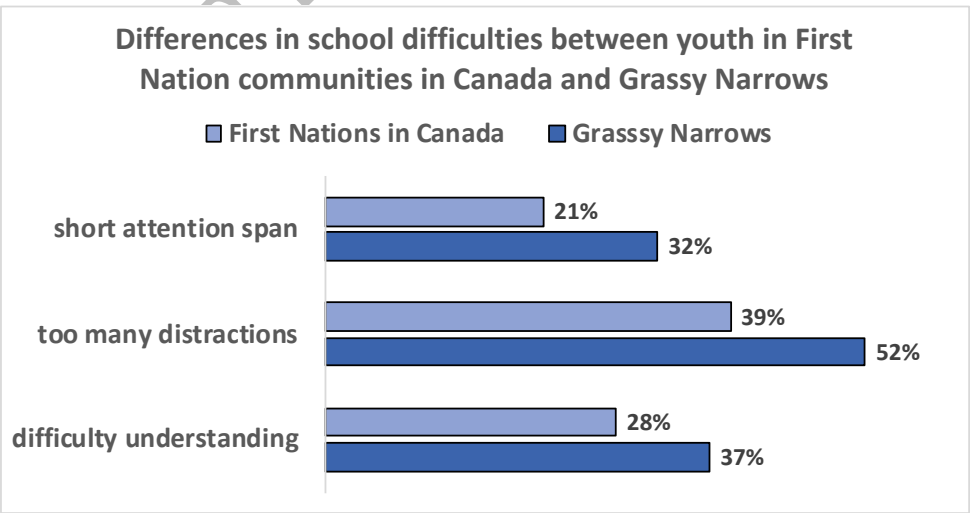
The proportion of children and youth **with poor/unsatisfactory performance in school** is:

- Higher among children and youth with **more emotional and behaviour problems** over the past 6 months compare to others of their age and sex: For boys: 55% vs. 20%; for girls: 29% vs. 9%;
- Higher among those with **neurologic disorders**;
- Higher among children and youth who have **diagnosed health conditions that may impact school performance.**

It is noteworthy that all of the above conditions are associated with maternal fish consumption during pregnancy.

School performance in comparison with other First Nation communities

For children 6 – 11 years of age, there is no difference between Grassy Narrows and other First Nation communities with respect to school performance. For youth, there are **proportionally more who have difficulties in school compared to First Nation communities in Canada** (52% vs. 39%), most notably a short attention span, too many distractions and difficulty understanding.



CONFIDENTIAL

Children and youth's activities outside of school

In these analyses, only children 6 years and older are considered. The details of these findings are in Chapter 3.

Physical activities

The large majority of children (88%) engage in physical activities; the proportion is similar between age categories and sex, with the exception of children 9-11 years of age, with girls more active than boys. Regardless of age, the most popular physical activities are walking, swimming, running or jogging, fishing and bicycle riding/mountain biking.

There was no association between participating in physical activities and being overweight, with the exception of weight-lifting in boys, where no one is overweight.

Compared to other First Nations' children (6-11 years of age), more girls in Grassy Narrows practice swimming and aerobics/fitness; fewer boys walk, cycle, skate, garden or are involved in competitive sports. Fishing is practiced by more girls and boys compared to girls and boys of other First Nation communities. We did not compare the youth because of the differences in the survey methods.

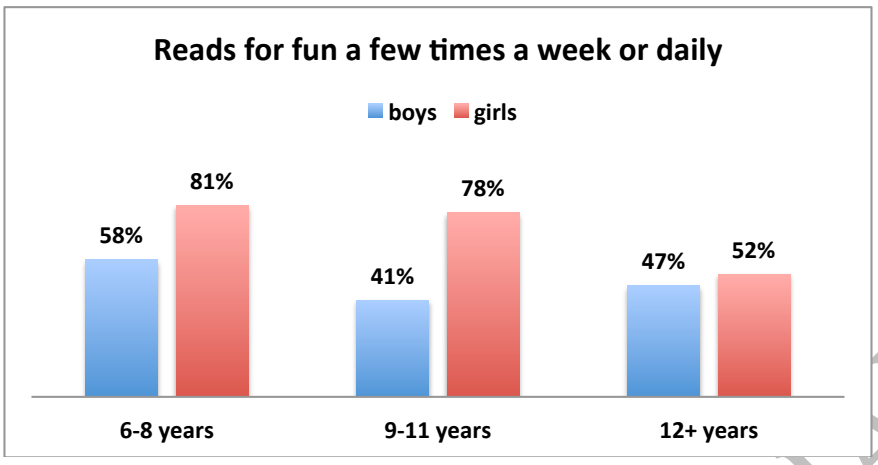
Sedentary activities

With the exception of watching television, the proportion of sedentary activities increases with age; by gender, reading increases with age for girls, and video games and working on computer for boys. Around 60% of boys 6-8 years of age play video games for over one hour a day; for those 12 and over, it is 88%. On the other hand, approximately half of the girls work on computers, for at least one hour a day, at all ages.

Approximately half of the children watch television for one hour or more/day. For boys, watching TV is associated with being overweight for their age.

Overall, for children/youth over 6 years of age, 24% read for fun every day; girls spend more time reading for fun compared to boys. The figure below shows the percentage of girls and boys who read for fun at least a few times a week by age and sex.

DRAFT - CONFIDENTIAL



For children in elementary school, reading for fun is associated with practicing at least one physical activity, working at a computer, not playing video games for over one hour a day, and rated very good or excellent in school.

Compared to other First Nation communities in Canada, in Grassy Narrows, among children (6- 11 years):

- Fewer watch television for more than 1.5 hours/day;
- Four times more work on a computer for more than 1.5 hours/day;
- Twice as many play video games more than 1.5 hours/day.

Community activities

Approximately one third of the children and youth participate in art or music groups or lessons or take part in traditional singing, drumming or dancing groups or lessons.

Regardless of age range, more than two-thirds of children (70%) participate in the community organized cultural events. In the 12 to 17 years of age range, there is a tendency for more girls to participate compared to boys.

For events related to First Nation identity and recognition of rights, one third of children and youth usually participate and there is no difference between age ranges. In the 12 to 17 years of age range, more girls participate compared to boys; 58% of teenage girls participate in activities related to their identity and the recognition of their rights.

DRAFT - CONFIDENTIAL

Food consumption

The ANA-CHA was not designed to evaluate the nutritional status of the children and youth but provides a portrait of the consumption of non-traditional and traditional foods.

Over 75% of children and youth eat milk/milk products, carbohydrates, protein and fruit juice at least once a day. Over 60% of children and youth eat fruit in summer and winter. Less than 60% eat vegetables every day. **Compared to other First Nation communities, fewer 6 – 11 year olds in Grassy Narrows eat vegetables every day** (68% vs. 50%).

The survey questions on traditional food asked about consumption over the previous year. Bannock and walleye, the most eaten traditional foods, is consumed by 2/3 of the children and youth. **Walleye** was eaten at least a few times over the past year by 49% of children and youth, and was eaten often by 14%. Proportionally more children and youth who fish eat walleye; 23% of those who fish ate walleye often over the past year.

There was an inverse relation between eating vegetables every day and body mass: proportionally more **overweight** children **do not** eat **vegetables** at least once a day. Eating **vegetables is positively associated with fewer difficulties in school**, notably in mathematics and too many distractions.

A higher proportion of high school students who eat **walleye often** have short **attention spans** compared to the others (45% vs. 11%).

The details of food consumption patterns are described in Chapter 4 and the comparisons for all foods with other First Nation communities in Chapter 11.

Maternal context

Children's health and behaviour are influenced not only by prenatal conditions, but also by the context in which they live. The ANA-CHA adult survey provided information on parents' socio-economic status, nutrition, community participation and physical and mental health. The child questionnaire provided information on the child's eating habits, success in school, having spent time in the care of Child and Family Services, physical activity, health as well as on possible mercury exposure through current fish consumption.

To explore how home context may affect children's development, we merged the ANA-CHA adult and the ANA-CHA child databases, selecting only those whose mother answered the child questionnaire and those who were 4 years of age or more. In these analyses, we only included Band members. A total of 186 mother/child pairs filled these criteria.

When comparing the maternal and household context of younger (4 – 11 years old) and older children, most indicators (demographics, maternal physical and mental health) are similar, although more mothers of older children understand or speak the Anishinaabe

DRAFT - CONFIDENTIAL

language, indicating that younger children are less exposed to the language. More mothers of older children likewise had a parent who attended a residential school, but there is no difference in the mothers' father being a fishing guide (60%) or living in a smoke-free home (approximately 85%)

However, major differences are observed for indicators of poverty and maternal education indicating that the mothers of younger children are poorer off compared to the mothers of older children. The table below is taken from Table 8 (Chapter 9).

Mothers' situation	**4-11 years old**	**12-17 years old**
Indicators of poverty		
Lowest income adequacy category	30%	20%
Income less than $20,000	50%	39%
Struggle to meet basic needs for food	65%	54%
Severe food insecurity	27%	19%
Maternal Education		
High school diploma	19%	31%
Very good/excellent success in school	33%	46%
Furthered education	53%	66%

Analyses indicate that in addition the associations with fish consumption described above, maternal health, well-being and socio-economic status can likewise contribute to the children's health and wellbeing.

DRAFT - CONFIDENTIAL

Children in care of the Child and Family Services

In a report to the Royal Commission on Aboriginal Peoples Child and Family Wellness in 1994, Joyce Timpson wrote[9] *"The social problems of Grassy Narrows have been immense. Child welfare statistics reflect great suffering. In 1977, 56 children from the community were admitted to the care of the Kenora Children's Aid Society, the highest rate in the Kenora District, an area with the highest rate of children in care in Ontario. The single point rate in January 1977 for children in care from Grassy Narrows was 16.8 percent of the child population."* The author indicates that this high rate has been attributed to the impact of residential schools, relocation and mercury poisoning.

The Grassy Narrows' CHA findings show that there has been little change. In these analyses, which were limited to mother-child pairs, with the mother currently living in Grassy Narrows, 23 children (16%), were in the care of Child and Family Services outside of Grassy Narrows

[9] Timpson J. Aboriginal Families and Child Welfare prepared for the Royal Commission on Aboriginal Peoples Child and Family Wellness, 1994. (http://data2.archives.ca/rcap/pdf/rcap-170.pdf accessed October 18, 2018)

at the time of the survey. The mothers, whose child or children were in care outside of Grassy Narrows, represent 18% of mothers living in Grassy Narrows at the time of the survey.

- All of the **maternal grandfathers were fishing guides**.
- All mothers had an **income of less than $25,000/year.**
- Most (82%) had a **maternal grandmother who attended a residential school**.

Among the Grassy Narrows mothers who are currently living in Grassy Narrows, 34% report that at least one of their children has been in the care of Child and Family Services outside of Grassy Narrows, representing 32% of all children whose mother is a Band member living on reserve. Like for other First Nation communities, the likelihood of ever having been in care is associated with maternal heavy drinking, but it also increased:

- Fivefold if the maternal **grandfather was a fishing guide;**
- Fourfold if the maternal **grandmother had attended a residential school;**
- **Maternal low mastery score**, which represents how much one considers that they have control over their lives.

While the intergenerational negative impact of residential schools on children being in care has been previously studied, the findings of the present survey in Grassy Narrows indicate that the intergenerational impact of the social and economic trauma and illness among fishing guides, and their families, likewise had deleterious effects on raising the next generation of children. The legacy of mercury compounds and exacerbates the legacies of colonialism and residential schools on the health and wellbeing of the next generation.

DRAFT - CONFIDENTIAL

Recommendations

The ANA-CHA child survey provides an overview of the health and welfare of the children of Grassy Narrows Band members and non-Band members living on reserve or spouses of Band members living off reserve.

For these children, born since 1999, the findings that relate to maternal fish consumption during pregnancy and the children's development, health and behaviour, are consistent with the scientific literature on mercury exposure from fish consumption[10].

Although we did not ask what specific fish was eaten during pregnancy, and just asked about fish consumption, our findings are similar to the 2005 report "Our Waters, Our Fish"[11]. Over 90% of fish consumed in Grassy Narrows is walleye and very few other fish species. Walleye is traditional to the culture and wellbeing of the Asubpeeschoseewagong Netum Anishinabek.

The on-going efforts led by the community to remediate the river contamination will take years. There is a need to act immediately to improve the conditions of this and future generations of children.

The following recommendations stem from the results of the Grassy Narrows Child and Youth Health Assessment (CHA) survey:

Mothers of child-bearing age

- Since, early in their pregnancies, women usually do not know whether they are pregnant, a stable **Learning Centre** should be established for women of child-bearing age with secure funding in order to **provide information** to this and future generations about the history of mercury contamination and its effects on the developing foetus and child. Prenatal classes should be offered.

- This **Learning Centre** could also regularly **supply nutritious food** and information for women of child bearing age and special meals for women throughout their pregnancy.

- There should be a **financial incentive** to attend the **Learning Centre**. Generations of people of Grassy Narrows have been directly and indirectly financially impoverished by this major Canadian disaster, for which they have no responsibility. There is a responsibility on the part of governments who allowed this situation to continue for

DRAFT - CONFIDENTIAL

[10] Karagas M et al. Evidence on the human health effects of low-level methylmercury exposure. Environ Health Perspect 120: 799–806 ; 2012

[11] Chan L et al. "Our waters, our fish, our people" Mercury contamination in fish resources of two Treaty #3 communities. Report to Grassy Narrows First Nation. 2005.

several generations to assure that harm to present and future generations is minimized.

- Pregnant women should have access to traditional and professional counseling, access to midwifery and doula services. Access to financial stipends could serve to counter the harmful effects of poverty.

- Training in the **Learning Centre** should be offered to all parents and grandparents so that they better understand how mercury has impacted their community. In the Adult Survey, we showed that there are fewer elders in Grassy Narrows compared to other First Nation communities to pass on traditional and historic information. This could take the form of a living museum.

Children and youth

The health and well-being of children and youth have been affected directly by prenatal exposure to mercury and indirectly by the intergenerational consequences of mercury contamination of the fish resources in their community. To counteract the harmful effects on physical and mental health, behaviour and school performance, the following actions should be taken:

- The findings of this survey strongly support the demands of the Grassy Narrows community for an **emergency and long-term programs for child and youth suicide prevention.** This program should be part of a stable institution (with permanent funding) for children, youth and adults (see Adult ANA-CHA Report and recommendations) that would address suicidal ideation in a way that is relevant to the specific situation and needs of the community[12,13]. Such a program should focus not only on emergency counselling and crisis intervention, but also on the underlying root causes of mental distress. A full-time child psychologist, adequately trained in the impact of colonialism on First Nations and the impact of mercury on mental health and behaviour, is needed for such a program, which likewise requires a traditional counselor/health and elders.

- The type of chronic conditions that were identified in the present study as being associated with fish consumption practices are higher among Grassy Narrows children and youth compared to other First Nation communities. The findings on neurological and neuropsychological disorders, as well as the number of claims that have been made to the Mercury Disability Board for children underline the need for **adequate medical and neuropsychological assessment and therapy** for these children.

[12] Nasir et al. The need for a culturally-tailored gatekeeper training intervention program in preventing suicide among Indigenous peoples: a systematic review. BMC Psychiatry 16(1), 357; 2016.
[13] Toombs et al. First Nations parenting and child reunification: Identifying strengths, barriers, and community needs within the child welfare system. Child & Family Social Work. 23:408–416; 2018.

DRAFT - CONFIDENTIAL

- Primary care physicians need to be cognisant of the potential effects of mercury exposure and be able to refer patients to specialists, particularly in neurology and neuropsychology. Since there are no specialist facilities in Grassy Narrows, financial coverage is needed for travel and expenses not covered by existing programs.

- School principals, teachers, health professionals, counsellors and social workers should be made aware of the long-term consequences of mercury exposure on children. This **awareness program** needs to be repeated every time a person is hired because turn-over is high on reserve and history can rapidly be forgotten.

- There needs to be **resources in the school** that address the children's and youth's specific difficulties, the prevalence of which are higher in Grassy Narrows compared to other First Nation communities and associated with maternal fish consumption during pregnancy. Programs of speech therapy, exercises that can increase attention span and emotion management are just some examples. Children, who require specific help, should be provided with one-on-one support through the Ontario Individual Education Plan (IEP).

- The survey showed that children and youth who do not eat vegetables every day do more poorly in school. Since this may constitute an indicator or nutritional status, it points to the need to set up **community kitchens** with healthful food that is available, in or outside of the school. The adult survey likewise revealed the need for a community kitchen and the finding of the child and youth survey support this recommendation. The community kitchens could use healthy local and traditional foods, such as berries, wild rice, more and deer and fish with low concentrations of mercury harvested from safe locations by local harvesters.

- The percentage of children and youth currently or previously in care of **Child and Family Services** is very high. Many studies have shown the deleterious effects of the child welfare system removing First Nation children and youth from their communities[14]. Although the present survey was not designed to specifically examine this issue, the findings indicate that the multifactorial underlying factors are not addressed. These findings echo the concept in an article by Toombs and co-authors[16]: ***"Heal the community to help the child"***. As in other communities, the mothers of children who are or have been in care live in poverty, have little control over their lives and have parents who were in residential schools. A unique factor in Grassy Narrows is having had a father who was a fishing guide. Further examination of the interventions of the child welfare system with a view to addressing the underlying issues and reducing the number of children in the care of Child and Family Services is severely needed.

[14] Toombs et al. First Nations parenting and child reunification: Identifying strengths, barriers, and community needs within the child welfare system. Child & Family Social Work. 23:408–416; 2018.

DRAFT - CONFIDENTIAL

- The importance of elders passing on traditional knowledge as a deterrent to a high prevalence of children and youth being placed in care of Child and Family Services was identified in the report to the Royal Commission on Aboriginal Peoples Child and Family Wellness[15], In the ANA-CHA Adults report, we, like others have shown that there is a dearth of elders in Grassy Narrows. There is a need for a program that will provide opportunities for children and youth to actively learn traditional knowledge, which contributes to a sense of identity, belonging and pride.

A comprehensive study of the children in Grassy Narrows with intervention components

The situation and needs of the children and youth in Grassy Narrows have never been addressed in a comprehensive study. To improve the situation of the Grassy Narrows community, such a study requires three components: evaluation, intervention and a re-evaluation. It should include a dietary survey, measurement of nutrients and mercury biomarkers, neuropsychological and health assessment, which would drive the intervention (e.g. cognitive stimulation, behavioural therapy, diet, etc.), followed by an evaluation to determine whether there is improvement and the factors that contributed (or did not contribute) to the improvement.

It is noteworthy that fish consumption advisories are unclear and if the information provided in the Chan report of 183 grams of fish/week or two average size portions of walleye every month,[16] is applied to the results from the Grassy Narrows CHA survey, pregnant women who ate fish once a month are within the recommended limits. The present survey shows that even a lower consumption of fish (e.g. once a month during pregnancy) is associated with deleterious effects on children's development.

The findings of this survey suggest that the current guidelines need to be revisited. They are clearly inadequate in this community. The guidelines, which were established on studies of marine fish eaters, and maybe inadequate for freshwater fish eaters. It is also possible that they may be too high for communities, like Grassy Narrows, with known mercury contamination over a long period of time. The guidelines should be applicable to all fish-eating communities.

DRAFT. CONFIDENTIAL

[15] Timpson J. Aboriginal Families and Child Welfare prepared for the Royal Commission on Aboriginal Peoples Child and Family Wellness, 1994. (http://data2.archives.ca/rcap/pdf/rcap-170.pdf accessed October 18, 2018)

[16] Chan, L. Our Waters Our Fish. Report to Grassy Narrows First Nation. 2005; p. 77.

Conclusion

Despite the strong scientific evidence of the harmful effects of prenatal mercury exposure on children's development, this is the first comprehensive survey of the health and wellness of the children and youth of Grassy Narrows. The findings clearly indicate that mercury exposure, particularly *in utero*, compounds the physical and mental health problems that are consistently reported for First Nation communities in Canada.

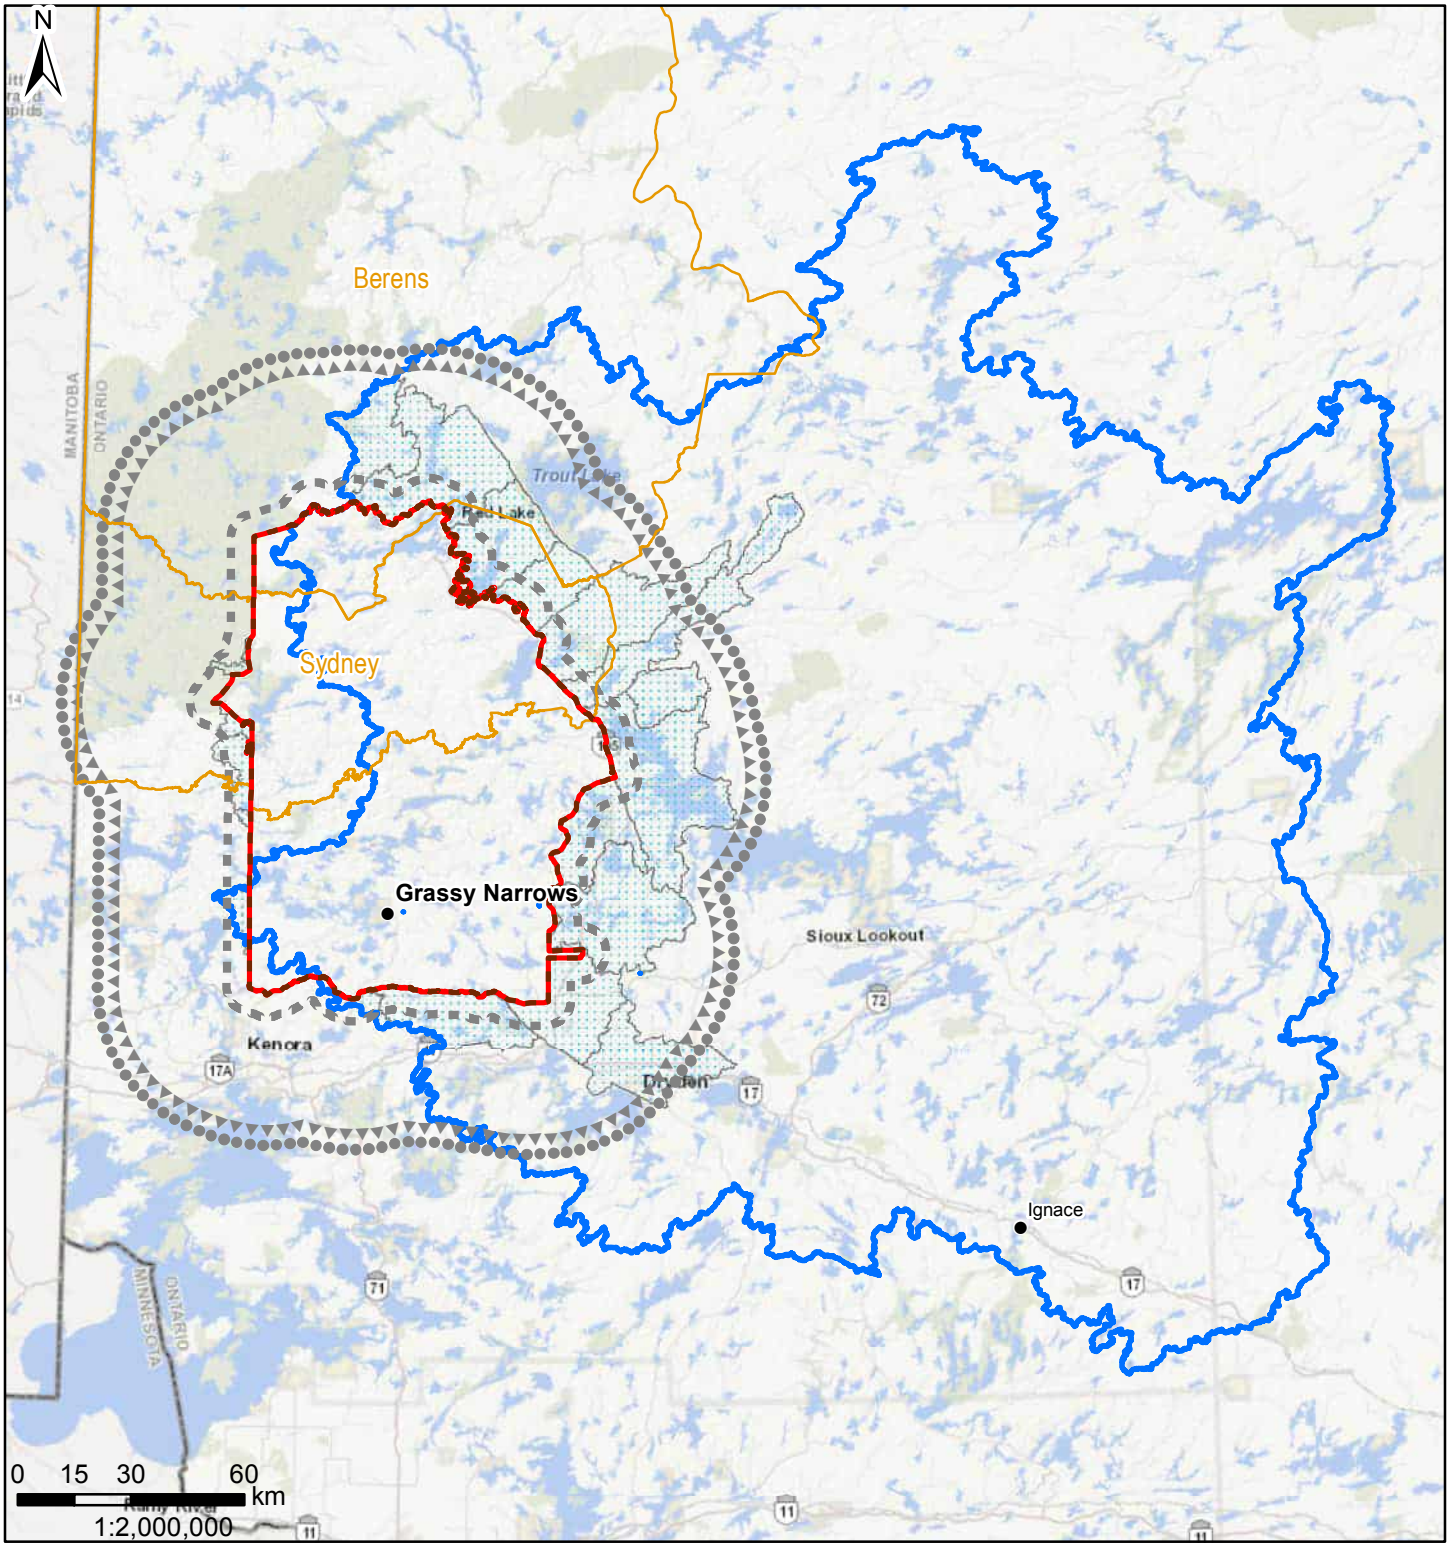
For decades, the Grassy Narrows community has decried the situation. There have been numerous reports, articles, book chapters and books written about Grassy Narrows. But, little has been done to specifically address the hardships created by this environmental disaster. The recommendations that stem from this survey are based on the co-construction of knowledge of the situation of the children and youth. The community's voice needs to be heard and solutions should be developed, refined and implemented under their leadership, with support from relevant professionals, and provincial and federal governments.

The children youth of Grassy Narrows deserve to be "more than mercury".

DRAFT - CONFIDENTIAL

Map Date and Time: 2023-10-26 2:17:10 PM

Asubpeeschoseewagong (Grassy Narrows) Interim Core Area of Interest for Mining



- Interim Core Area of Interest for Mining
- Moose Home Range (6km)
- Wolverine Home Range Area (36km)
- Walleye Migration Area (40km)
- Caribou Range Boundaries
- Nearby Quaternary Watersheds That Flow Into The Core
- English River Watershed at Separation Narrows

N.B. This is an interim product created under duress arising from the escalation of imposed mining activity by the Crown and industry and for the sole purpose of identifying an interim area for negotiations on mining related activity. It is not a complete representation of Grassy Narrows' area of interest. Due to unique circumstances and capacity constraints Grassy Narrows has not completed comprehensive studies required to fully determine its area of interest including, but not limited to, land use and occupancy, ethnohistory, archeaology, biology, and hydrology. For example, rights and interests associated with air quality, migratory birds, travel routes, marten, lake sturgeon, wolves, eastern cougar, landscape intactness, climate resilience, biodiversity, genetic diversity, and many other factors are not reflected here. Also, linear boundaries are an imposed non-Indigenous concept that does not accord with the nature of Grassy Narrows' relationship with the land which includes extensive interconnectedness, reciprocity, travel, sharing, and trade. This map does not limit any claims by Grassy Narrows people to assert their rights and interests throughout their territory and to protect themselves from harm to their health, rights, way of life, livelihood, society, and environment. Grassy Narrows people have Treaty rights, and practice them, throughout the Treaty 3 area. Grassy Narrows people also have inalienable inherent rights given by the Creator, some of which are affirmed in international law and instruments. The Grassy Narrows people are the true experts about their land, rights, and interests.

Past mercury exposure and current symptoms of nervous system dysfunction in adults of a First Nation community (Canada)

Aline Philibert[1], Myriam Fillion[2,1], Judy Da Silva[3], Tanya Suvendrini Lena[4] and Donna Mergler[1*]

Abstract

Background: The watershed in Asubpeeschoseewagong Netum Anishinabek (Grassy Narrows First Nation) territory has been contaminated by mercury (Hg) since 1962, resulting in very high Hg concentrations in fish, central to the community's culture, traditions, economy and diet. Biomarkers of Hg exposure (umbilical cord blood and hair/blood samples), monitored between 1970 and 1997, decreased over time. A recent Grassy Narrows Community Health Assessment (GN-CHA) survey included current symptoms of nervous system dysfunction. The present study aimed to cluster self-reported symptoms and examine their associations with past Hg exposure.

Methods: The GN-CHA included 391 adults. Symptom clustering used a two-step segmentation approach. Umbilical cord Hg and/or yearly measurements of equivalent hair Hg were available for 242 participants. Structural Equation Models (SEM) displayed the associations between Hg exposure and clusters, with Hg exposure modelled as a latent variable or in separate variables (prenatal, childhood and having had hair Hg $\geq$ 5 µg/g at least once over the sampling period). Longitudinal Mixed Effects Models (LMEM) served to examine past hair Hg with respect to clusters.

Results: A total of 37 symptoms bonded into 6 clusters, representing Extrapyramidal impairment, Sensory impairment, Cranial nerve disturbances, Gross motor impairment, Neuro-cognitive deficits and Affect/Mood disorders. Median Hg concentrations were 5 µg/L (1–78.5) and 1.1 µg/g (0.2–16) for umbilical cord and childhood hair, respectively. More than one-third (36.6%) had hair Hg $\geq$ 5 µg/g at least once. In SEM, latent Hg was directly associated with Extrapyramidal and Sensory impairment, Cranial nerve disturbances and Affect/Mood disorders. Direct associations were observed for prenatal exposure with Affect/Mood disorders, for childhood exposure with Extrapyramidal impairment and Cranial nerve disturbances, and for hair Hg $\geq$ 5 µg/g with Extrapyramidal and Sensory impairment. For all clusters, a further association between past Hg exposure and symptom clusters was mediated by diagnosed nervous system disorders. LMEM showed higher past hair Hg among those with higher scores for all clusters, except Affect/Mood disorders.

Conclusion: Our findings provide evidence that in this First Nation community, past Hg exposure from fish consumption was associated with later-life clusters of coexisting symptoms of nervous system dysfunction.

fish resources as far as 250 km downstream [1]. Asubpeeschoseewagong Netum Anishinabek (Grassy Narrows First Nation) and Wabaseemoong Independent Nation (previously known as Whitedog and Islington Bands), for whom walleye *(Sander vitreus)* is central to their traditions, culture, economy and health, were seriously affected by this disaster [2]. Between 1970 and 1997, governmental agencies carried out biomonitoring programs in these communities to assess Hg concentrations in blood and hair [3]. Another program (1970–1992) assessed Hg concentrations in umbilical cord blood collected at the local hospital [3, 4]. Biomarker Hg concentrations from Grassy Narrows First Nation followed a similar pattern to Hg levels in local fish from the contaminated river system, with extremely high concentrations in the early 1970's, a sharp decline until 1977 and a less pronounced decline until 1987, after which, mean concentrations remained relatively stable [5, 6].

In 1975, neurological examinations of 89 residents from the two communities, carried out by Dr. Masazumi Harada and colleagues [7], showed a high prevalence of signs and symptoms, similar to those reported by patients with Minamata Disease. The team revisited the communities in 2002 and 2004 and examined 175 individuals. Sixty (n=60) persons were diagnosed with Minamata Disease, 54 with Minamata Disease with complications due to other diseases, and 25 with "suspicion of Minamata Disease" [7]. Self-reported symptoms included numbness, pain in limbs, joints and back, decreased vision, impaired hearing, cramps in limbs, dizziness, tendency to fall, forgetfulness, impaired finger movement, tremor and speech impairment. For 27 persons who had been examined in 1975, symptoms had worsened [7]. Takaoka and co-authors [8] compared self-reported symptoms of volunteers from the Grassy Narrows First Nation community from examinations performed in 2010, with residents from the Minamata area and a reference group from other areas of Japan. The authors observed that the prevalence of specific and non-specific complaints of older persons from Grassy Narrows was similar to those from the Minamata area, while the prevalence among younger persons from Grassy Narrows was lower, but higher than the Japanese reference group [8]. While signs and symptoms reported in this study are consistent with methylmercury poisoning [9], the findings are limited by the recruitment strategy and the absence of measurements of mercury exposure.

In 2015, Grassy Narrows First Nation undertook a Community Health Assessment survey (GN-CHA), which included a list of 59 symptoms, as well as questions on current and past fish consumption. Although understanding one single symptom is worthwhile per se, people rarely present with one symptom, but rather with an array of multiple coexisting symptoms [10]. Clustering bonds concurrently occurring symptoms [10], whose pattern reflects the nature of the underlying dysfunction [11]. Multidimensional approaches and statistical techniques have been proposed to facilitate the integrated analysis of multiple symptoms [10, 12–15]. Also, a growing body of research has used advanced statistical techniques to examine the contributions of Hg exposure [16–26]. The objective of the present study was to bond GN-CHA reported symptoms of nervous system dysfunction into clusters and to examine their association to long-term and past Hg exposure.

Methods

For the present study, carried out in collaboration with the Grassy Narrows First Nation community, we merged information from the GN-CHA survey and two government biomarker monitoring programs (umbilical cord Hg and blood and/or hair Hg) to examine the associations between current reported symptoms from the GN-CHA survey and past Hg exposure, using cluster analyses, structural equation models (SEM) and longitudinal mixed effects models (LMEM) (Fig. 1).

GN-CHA survey

The GN-CHA survey for adults (18 years old and over), initiated in 2015, included 266 questions that covered many aspects of their life and health: demographics, education, generational attendance of residential school, work and income, food consumption, health status, diabetes care, wellness and mental health, injuries, disability, health care access, physical activity, smoking, drinking and drug use, community wellness and traditional culture. Most questions were taken from the First Nation Regional Health Survey 2008/2010 (FNRHS 2008/2010) [27], which provided a basis for comparison with other First Nation communities in Canada. Specific questions were added about fish consumption at different periods of one's life, as well as illnesses and symptoms consistent with Hg poisoning. The questionnaire was pre-tested with 10 community members in July 2016. A house-to-house survey design was used, with the questionnaire on a web-based platform.

Survey administration was supervised by two field coordinators from Grassy Narrows; nine local interviewers went from house-to-house between December 2016 and March 2017. A total of 213 houses were identified on the reserve; 83.6% of houses were surveyed. Persons living off-reserve were recruited using convenience sampling. The results of the survey were presented to and discussed with community members during several small group and community meetings. The final report was

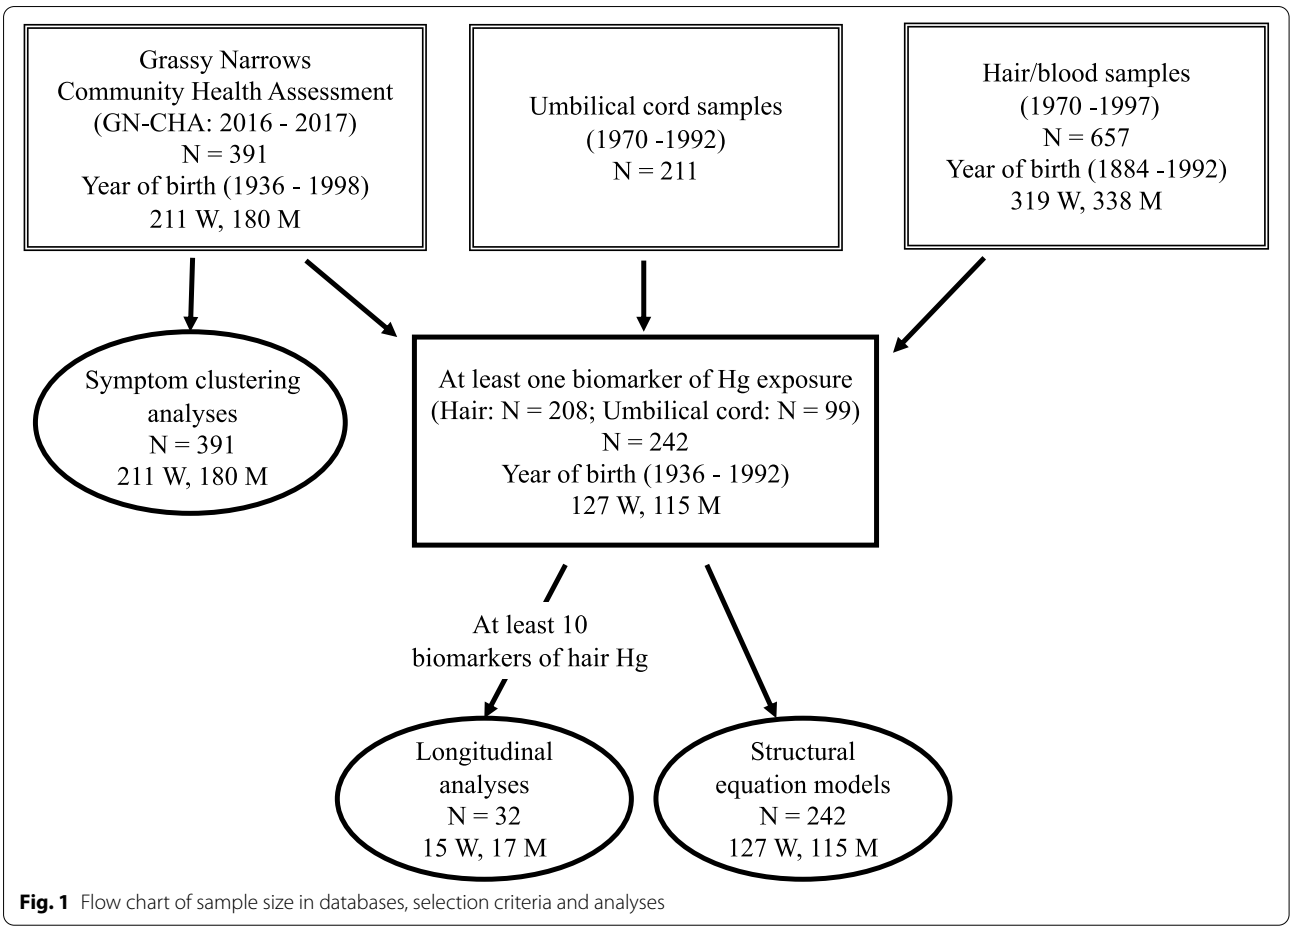

Fig. 1 Flow chart of sample size in databases, selection criteria and analyses

approved by Chief and Council and a summary was made public on May 24, 2018.

A total of 391 Registered Grassy Narrows First Nation members (Band members) participated in the GN-CHA survey. At the time of the survey, 303 were living on-reserve and 88 off-reserve.

For the present study, we used the following variables from the GN-CHA: Demographics: age, sex, living on/off reserve, schooling, generational attendance of residential school in the family. Work: currently working (yes/no), currently looking for work (yes/no), reasons for not working (disability or illness/other). Food security: struggle to pay for food once a month or more in the last 6 months. Fish consumption: childhood fish consumption at 10 years of age (5 categories grouped into once a month or less/at least several times a month); walleye consumption over the past year (not at all/a few times/often). Lifestyle: current smoking (yes/no) and current alcohol consumption (heavy drinking (yes/no), defined in the FNRHS 2008/2010 [27] as 5 drinks in one drinking occasion at least once/month in the past 12 months). Health status: obesity (yes/no) was categorized using Body Mass Index $\geq 30\,kg/m^2$ and at least one reported diagnosed chronic health conditions (yes/no), as listed in the FNRHS 2008/2010 (allergies, arthritis, asthma, cancer, chronic back pain, chronic bronchitis, diabetes, emphysema, heart disease, hepatitis, high blood pressure, liver disease, osteoporosis, rheumatism, stomach or intestinal problems, thyroid problems, and tuberculosis) and at least one diagnosed nervous system disorder (blindness, epilepsy, Bell's palsy, cerebral palsy, muscular dystrophy, Kennedy's disease, Parkinson's diseases, Alzheimer' disease, senile dementia, psychological/nervous disorders, cognitive/mental disorders, Attention deficit hyperactivity disorders (ADHD), learning disability).

The GN-CHA included 59 self-reported symptoms, rated on a 5-point Likert rating scale (*"Never"*, *"Rarely"*, *"From time to time"*, *"Very often"*, *"All the time"*). Higher scores on the Likert rating scale indicate greater frequency of symptoms.

Historic Hg biomarker data

At the request of Chief and Council of Grassy Narrows First Nation, the authors obtained from the First Nations

and Inuit Health Branch (FNIHB) of the Ministry of Indigenous Services Canada and the Ontario Ministry of Health and Long-term Care, archived Band members' historic biomarker data (hair and/or blood Hg concentrations), gathered between 1970 and 1997 and umbilical cord Hg data, collected between 1970 and 1992 at the hospital where Grassy Narrows women gave birth (Fig. 1).

Blood and hair samples were taken as part of a monitoring program of the Medical Research Branch of Health Canada [4]. The objective of the program was to identify persons whose Hg biomarker concentrations surpassed the guidelines of the time. There was no sampling strategy. The program primarily targeted fishing guides and their families, but anyone could volunteer and provide a sample [4]. Some years. The sampling period was longer than others and there was no consistency in the month that sampling was carried out.

Samples were analysed for total Hg at Health Canada laboratories [4, 28, 29]. According to Farant et al. 1981 [28], in the initial years, sample analyses were performed according to the Magos method [29] and later, a more efficient and less time-consuming method used an improved cold-vapor atomic absorption technique. The two methods were highly correlated for blood ($r=0.98$) and hair ($r=0.97$) [28].

Past Hg exposure databases

We created a past Hg exposure database, which included umbilical cord Hg concentrations for 211 newborns from Grassy Narrows, born between 1970 and 1992 (Fig. 2a) and blood/hair monitoring data, collected between 1970 and 1997, from persons born between 1884 and 1992. For the latter, we used the highest measure of equivalent hair Hg concentration for each year sampled; the details are described elsewhere [6]. A total of 3603 year-based equivalent hair measurements were available over the sampling period for 657 persons (Fig. 2b),

For the present study, we selected GN-CHA participants with at least one biomarker measurement: either an umbilical cord Hg measurement ($n=99$) and/or at least 1 year-based hair Hg concentration ($n=208$; 1018 measurements) for a total of 242 persons. The number of year-based hair Hg measurements for each person varied between 1 and 23; 75 persons (36.1%) had 5 or more measurements, while 32 (15.4%) had 10 or more. For childhood Hg exposure, we used the mean hair Hg concentration between 5 and 15 years of age ($n=137$ (56.6%)). Childhood Hg concentrations were significantly higher for persons who reported childhood fish consumption frequency at least several times a month compared to those who ate less (Additional file 1, Fig. 1). Moreover, those who ate fish at least several times a month and had attended a residential school (outside of the community) had lower Hair Hg at 10 years of age (3.8 µg/g [1.7–5.9] ($n=16$) vs. 5.8 µg/g [4.2–7.3] ($n=30$)).

Estimated past Hg exposures

For participants who did not have an umbilical cord Hg measurement, estimated Hg values were predicted from linear regression models using the 211 umbilical cord data (Fig. 2a) on the year of birth for the three periods of Hg exposure (1970–1976, 1977–1987 and 1988–1992). These estimates were then adjusted on where the person's mother had spent her pregnancy and/or gave birth. For those who were born or whose mother spent

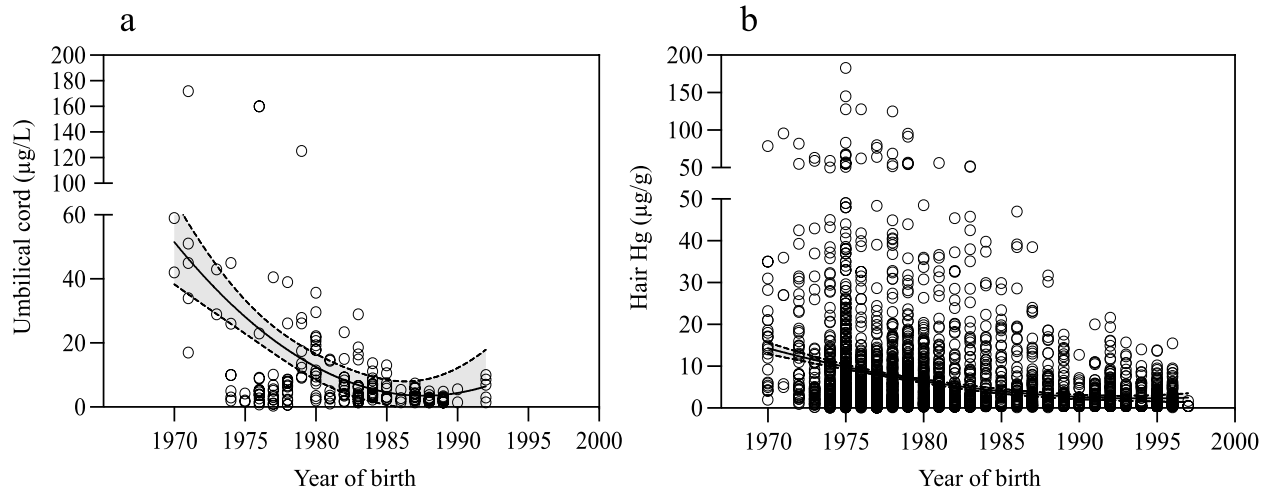

Fig. 2 Distribution of Hg biomarker concentrations over time. **a** Umbilical cord blood Hg (µg/L) collected between 1970 and 1992 ($n=211$). **b** Equivalent hair Hg (µg/g) from samples collected between 1970 and 1997 ($n=657$)

her pregnancy in the Wabigoon-English River region between 1970 and 1992, the mean measured umbilical cord blood Hg for their year of birth was used. For those born prior to the Hg discharge in 1962, we attributed 1.0 µg/L for cord blood Hg, while for those born between 1962 and 1970, mean cord blood Hg in 1970 was used (65.7 µg/L), and for those born after 1992, mean cord blood Hg from 1992 was applied (4.48 µg/L). Finally, for individuals, whose mother spent her pregnancy and delivered elsewhere, cord blood Hg was set at 1.0 µg/L.

For study participants, who did not have childhood hair Hg values, we derived estimates from the yearly-hair Hg database ($n=657$), using the overall mean hair Hg for the year in which they turned 10 years of age. For participants, who were ≥ 10 years old in 1962 (beginning of the discharge) childhood hair Hg was set at 0.1 µg/g. For those who were 10 years of age between 1963 and 1970, the mean measured hair Hg in children in 1970 was used. Since there were few Hg data after 1990 and there appears to be a plateau over this last period (Additional file 1, Fig. 1), we attributed 0.81 µg/g for those who were 10 years of age after 1990. For all those who were 10 years of age after 1962, estimates were then adjusted on reported childhood fish consumption and having attended a residential school. We were unable to estimate childhood hair Hg exposure for 13 persons (5.4%) of the 242 study participants, who were missing hair Hg data between 5 and 15 years old and who did not answer the question about childhood fish consumption in the GN-CHA survey.

To validate the estimated Hg measures, we tested the correlations between measured and estimated values for both umbilical cord and childhood hair Hg, using non-parametric tests (Spearman).

Symptom clustering

Self-reported symptoms from the GN-CHA survey ($n=391$) were clustered based on their Likert scale, using a simultaneous two-step multivariate segmentation approach [30–32]. One is agglomerative and aims at maximising a homogeneity criterion by successively aggregating the variables into clusters using a hierarchical ascendant clustering algorithm. The other is representative and creates a composite variable from a weighted linear combination of symptoms (synthetic variable that can be read as a gradient) for each cluster using a mixed factorial approach (PCAMIX method) [30, 32, 33]. For each composite variable (cluster), all participants received a score based on his/her symptom frequency.

A bootstrap approach was used for maximizing the homogeneity criterion within clusters and determining the suitable number of clusters. The desired number of clusters (K) was determined from the analysis of aggregation levels, stability of the partitions via bootstrapped mean-adjusted Rand Index and boxplots. The mean-adjusted Rand index was based on the generation of 60 bootstrap samples. Each cluster was carefully inspected based on its proportion of variation explained (a minimum of 50% was mandatory) and on degree of "closeness" among the symptoms being clustered (a minimum of 0.6 squared correlation of the variable with its composite variable was required). Some symptoms add noise while providing little or no information in identifying the underlying pattern inherent to the cluster [34]. Finally, we tested for the "driving" symptoms that best reflect the cluster. We validated the cluster results, using the VARCLUS function of the SAS computer application (JMP Professional 15.0 software).

A confirmatory factor analysis (CFA) was conducted to evaluate the construct validity of symptom clustering using a series of fit parameters [35–39], using the following indices: Chi-square divided by the degrees of freedom ($\chi 2/df$), Standardized Root Mean Square Residual (SRMR), Root Mean Square Error of Approximation (RMSEA), Comparative Fit Index (CFI) and Tucker Lewis Index (TLI). Internal consistency (scale reliability) for each cluster was tested using the Cronbach alpha [35, 40–42]. Construct validity for each cluster was also confirmed by the neurologist (T. S. Lena).

Structural equation models

SEM is a comprehensive methodology for representing and simultaneously testing a network of complex relationships. This technique can incorporate observed (measured) and unobserved variables (latent), while traditional techniques only allow for measured variables. The latent variable is an unobservable multidimensional construct that cannot be directly measured [43, 44]. SEM allows for data from multiple exposures and multiple outcomes to be considered simultaneously [45]. It is based on an interrelated system of linear regression equations that extend the possibility of relations between observed and latent variables, as well as direct and indirect (mediation) relations and allows for flexibility in modeling covariance structures [19, 39, 46, 47]. Finally, SEM provides path diagrams that are useful to understand and interpret the contribution of the various variables. The standardized factor loadings allow for pathway comparison.

In the SEM, we used the latent variable for symptom clusters rather than the composite variable because it better reflects the structural concept of co-occurring symptoms. A latent variable was likewise used for Hg exposure at different times (prenatal, childhood and having had ≥5 µg/g hair Hg at least once over the monitoring period). Each cluster was analysed using two SEM,

the first with the latent Hg exposure variable and the second with the Hg exposure variables at the three different times. We tested possible direct and indirect (mediation) associations between Hg exposure variables and the symptom clusters. Age, sex, year of sampling, residence, as well a series of variables representing socioeconomic status (income, struggle to pay for food), drinking, smoking, obesity and medical history (diabetes, hypertension, heart disease, stroke, hypercholesteremia, separately and/or grouped into the variable "at least one diagnosed chronic health condition"), were tested a priori as covariates. We further tested whether sex modified the relation between past Hg exposures and symptom clusters (moderation). Moderated mediation was also tested with age and sex.

Variables with a skewed distribution were log (base 10) transformed. Because latent variables, Hg exposures and covariates, are all on different scales, we used standardized path coefficients to test the magnitude of relations. Standardized coefficients indicate the expected amount of change in standard deviation (SD) in the dependent latent symptoms cluster for an increase of one SD in the predictor, while other predictors (covariates) are kept constant. The adequacy of model fit to the data was determined using multiple indices: χ2/df, CFI, TLI, RMSEA, SRMR and Akaike's Information Criterion (AIC) and Schwarz's Bayesian information criterion (BIC) [35–39]. Diagonally weighted least squares (DWLS) adjustments in SEM were used to take into account the ordinal nature of symptom frequency outcomes. To improve the reliability of the latent construct's scale or the models, we examined residual variances between indicators. Modification indices (MI) were used to assess the addition or deletion of variables and/or associations to improve the goodness of fit of the SEM. The sequence of initial fit, MI and refitting were repeated until the best fit SEM was attained.

To ensure that the database of 242 participants was sufficient to run SEM, two types of power analyses were performed: i) to detect model misspecification and ii) to detect target effect (influence of Hg exposure on the symptom cluster) [48]. A-priori, post-hoc, and compromise power-analyses were run simultaneously to detect model misspecification based on Chi-square likelihood-ratio and RMSEA tests of close and not-close fit, [49–52]. The power for detecting specific target effect was determined with simulated data in SEM [48].

For the SEM, validated prenatal and childhood Hg exposure estimates, described above, were used when there was no measurement, while for GN-CHA variables, missing data were imputed using Multivariate Imputation by Chained Equations (MICE).

To support the SEM, we ran a series of Directed Acyclic Graphs (DAG) for sensitivity analyses. DAG is a visual representation of causal assumptions that makes underlying relations explicit. It is used to detect overt bias, notably through backdoor paths that identify the presence of confounding [53, 54]. Modifications to DAG-implied adjustment sets include conditioning confounding and variables with ambiguous causing roles [55, 56].

Longitudinal mixed effects models

LMEMs were performed using direct measurements of longitudinal hair Hg with respect to the composite variable for each cluster. We chose mixed effects modeling (MEM) as it is robust to missing data and irregularly spaced sampling; it also handles both time-invariant and time-varying covariates [57]. MEM enables multilevel modeling and partitioning of the covariance structure (random effects). We tested a priori the following covariates (age, sex, variables of lifestyle and medical history, age at sampling and sampling season). The normality of residuals was tested using a q-q plot. The most appropriate model was selected using the Akaike Information Criterion (AIC), the Baysian Information Criteria (BIC) and the likelihood ratio (LR) test at $p <= 0.05$.

For the longitudinal approach, LMEM requires repeated measures. Because of the absence of a biomarker sampling strategy, over half (56%) of the 208 persons with hair Hg measurements had 3 repeated measurements or less. Despite the flexibility of MEM with missing data, we preferred not to impute Hg levels for people whose diet and environmental context varied over time, particularly when living off-reserve. For LMEM, we only included persons with at least 10 hair Hg measurements ($n = 32$ (17 men and 15 women)), with a total of 447 hair Hg measurements, covering a period from 10 to 23 years (median 21 years).

To ensure that there were sufficient observations for the analyses, we estimated the minimal required sample size, based on formulas from Hedeker and co-authors [58] and direct calculations using the G*power software [59–61]. Since one centimeter of a hair sample represents an accumulation of Hg during approximately 1 month [62], we used a low correlation of repeated measures between yearly-based samples (rho 0.1 and 0.2). Because the effect size was unknown, 0.25 was chosen. Power analyses were set at 80%, with a two-tailed 5% hypothesis test, 10 time points and up to four fixed factors; the minimum number of participants required was between 29 and 42.

Threshold of statistical significance in all analyses was set at $p \leq 0.05$.

Database management and descriptive statistical analyses were performed using JMP Professional 15.0 (Statistical Analysis Hardware (SAS Institute). LMEM were conducted with Stata 16 software (StataCorp. 2019. Stata Statistical Software: Release 16.0. College

Station, TX: Stata Corporation). All other analyses were computed using the R statistical software version 3.6.1. (R Core Team, 2016). We used the R package ClustOfVar [31] for clustering analyses and the MICE (Multiple Imputation by Chained Equations) package for multiple imputation of missing data in CFA and SEM. PairedData and dplyr packages were used for paired-t tests. CFA and SEM models were computed with the R package Lavaan [39]. The dagitty and ggdag R packages were used for analysing SEM and DAG. A-priori, post-hoc, and compromise power-analyses were computed using the semPower package. To assess power for detecting a target effect in SEM we used an online tool: yilinandrewang.shinyapps.io/pwrSEM/ [63].

Results

Relevant characteristics of the 391 participants in the GN-CHA survey, whose data were used for symptom clustering, are presented by age category in Tables 1 and 2. In this community, age also reflects changes in Hg exposure over time. Almost half of the participants were between 30 and 49 years of age, with no difference in age distribution between women and men. There were important age differences in schooling. Proportionally fewer older persons had attended high school, however, over half of those 30 years and older had furthered their education through post-secondary training programs (data not shown). In Canada, First Nation children were placed, often forcibly, in residential schools, with harmful

Likelihood Ratio Chi-square compares the relative frequency between age categories

effects on themselves and their families [64, 65]. In the present study, no one born after 1978 had attended residential school; for those born prior to this date, 58 persons (50.0%) had been in a residential school, while for their mothers and/or fathers, it was 95.4%. At the time of the survey, 51.1% of women and 43.1% of men were working, excluding persons studying, retired or at home with children ($n=32$). Among participants who reported not working, 78% of those between 18 and 49 years of age were looking for work, while 31 persons (68.9%) of those over 30 years of age, who were not looking for work, reported that it was due to illness or disability.

There was no age difference for difficulty paying for food, which was reported by almost 25% of participants. The prevalence of current smokers and heavy drinkers significantly decreased with age. Obesity was most prevalent among those 30–49 years old, of whom two-thirds were women. Sixty percent of participants reported that a health professional had told them that they had at least one chronic health condition; the prevalence increased significantly with age.

There were no differences between men and women for age distribution, schooling, having attended or having parents who attended residential school, difficulty paying for food, and current smoking. Proportionally more men reported heavy drinking compared to women (62.7% vs 48.7%; Chi-square LR 7.17; $p=0.007$), while women had a significantly higher prevalence of obesity (54.0% vs 38.9%; Chi-square LR: 14.01, $p=0.003$) and at least one chronic health condition diagnosed by a health professional (68.5% vs 49.7%; Chi-square LR: 14.01, $p=0.0001$).

In this community, fish, especially walleye, is the source of Hg exposure [4, 5]. Table 2 contains the responses to the GN-CHA questions on past and current fish consumption frequency. Over half of those 50 years and older (born before 1968) reported that, as a child, they ate fish daily. Childhood fish consumption frequency significantly decreased over time. Fish consumption questions were species specific. Walleye is still the fish the most consumed; 30.6% of persons surveyed in the GN-CHA reported often eating walleye compared to 4.7% for whitefish and 3.2% for northern pike. No differences were observed between women and men for the frequency of childhood or current fish consumption.

For symptom clustering of the GN-CHA, aggregation levels and construct stability are presented in Additional file 1, Fig. 2. Aggregation distances supported a cutting threshold between 5 and 8 clusters (Additional file 1, Fig. 2a), while the bootstrapped mean-adjusted R and criterion suggest 6, 7, 11, or 12 (Additional file 1, Fig. 2b). The boxplots (Additional file 1, Fig. 2c) showed that the highest stability of the partition solution varies between K5 and K9, with K7 showing a slightly higher median value, but a lower dispersion around the mean. After verification of all the above criteria, we kept a total of six clusters. Goodness of fit for CFA was acceptable for the six clusters (CFI = 0.85, TLI = 0.84, RMSEA = 0.08, SRMR = 0.05), with a narrow 90% CI, representing a high degree of precision. The Cronbach alpha (> 0.8) for each cluster confirmed internal consistency (Additional file 1, Supplementary Table 1).

The six clusters included a total of 37 symptoms. Additional file 1, Supplementary Table 1 presents the list of symptoms retained in each cluster with its correlation. Cluster 1 (Extrapyramidal impairment), which

aggregated the highest number of symptoms ($n=9$), included tremors, balance impairment, functional limb weakness and pain in arms and legs, reflecting an extension of extrapyramidal neurological symptoms. Cluster 2 (Sensory impairment) included peripheral neuropathic deficits, notably upper and lower limb sensory impairments including numbness, dullness and tingling. Cluster 3 (Cranial nerve disturbances) included anosmia, ageusia, dysphagia and tingling around the mouth. Cluster 4 (Gross motor impairment) aggregated symptoms that affect carrying, lifting and walking. Cluster 5 (Neuro-cognitive deficits) groups cognitive dysfunction associated with memory loss, hearing impairment and speech disorders. Finally, Cluster 6 (Affect/Mood disorders) included anxiety, irritability, depression and sleeping issues. For each cluster, there was no particular driving symptom. Most symptoms were highly related to their own cluster (Additional file 1, Supplementary Table 1).

For the large majority of symptoms, no significant difference was observed in the proportion of men and women who reported its frequency as very often/all the time (Additional file 1, Supplementary Table 1). Symptom frequency increased significantly with age (data not shown), with the exception of difficulty pronouncing words, forgetting to do things, doing nothing, irritability, anxiety, difficulty falling asleep, waking up at night, depressed, tiredness and difficulty concentrating (Fisher's Exact Test; $p \geq 0.08$).

The descriptive characteristics of the composite variable for each cluster for women and men are presented in Additional file 1, Table 2. A higher score in the composite variable reflects a higher frequency of coexisting symptoms. Scores were significantly higher in women than in men, with the exception of Neuro-cognitive deficits. Scores increased significantly with age (Rho: 0.138–0.409; $p < 0.01$), with the exception of Affect/Mood disorders (Rho: 0.108; $p=0.095$).

Of the original GN-CHA participants ($n=391$) who were used to create the clusters, 242 were selected on the basis of having at least one Hg biomarker measurement (Fig. 1). Umbilical cord, childhood hair Hg concentrations and the percentage of persons with at least one hair mercury concentration ≥ 5 µg/g with respect to age category are presented in Table 3. There was a positive association between childhood fish consumption and measured hair Hg, adjusted for sex and year of sampling (MEM: Wald Chi-square = 96.9; $p=0.003$). Paired t-tests, comparing mean hair Hg at 10 years of age, for each year, between those who reported eating fish during childhood at least several times a month and those who reported eating less, supported the MEM result (Wilcoxon Signed-Rank prob.>|S|, S: 37.5; $p=0.020$).

Persons retained for the SEM analyses ($n=242$) had similar characteristics to the original participants (Tables 1 and 2), although they were slightly older (median: 39 years old; interquartile range: 32–50), with proportionally fewer persons in the 18–29 y old category (13.6%). Compared to the entire cohort (Table 2), more young persons reported eating fish frequently during their childhood (41.6%), and often consuming walleye during the past 12 months (41.9%).

In the SEMs, measured and estimated Hg values were used when measures were missing. Validation of estimated Hg values showed significant associations with direct measurements for both prenatal and childhood Hg exposure ($n=99$; Rho = 0.22; $p=0.023$ and $n=137$; Rho = 0.73; $p<0.0001$, respectively). Most participants ($n=197$ (81.4%)) were born after 1962 (when exposure began) and had both pre- and post-natal exposures. Only 8 of the 242 persons (3.3%) were over 15 years of age in 1962.

For each symptom cluster, SEMs were performed (i) with latent Hg and (ii) with prenatal, childhood and hair Hg ≥ 5 µg/g. Path diagrams, showing the configuration of the different pathways and the one-to-one relation between variables, are illustrated in Figs. 3 and 4 and in Supplementary Figs. 3–12 in Additional file 1. SEM standardized path coefficients, representing the total quantified contribution of significant direct and indirect associations, are presented in Figs. 5 and 6.

Table 3 Measured mercury concentrations by age category

	N	18–29 y Median (min-max)	30–49 y Median (min-max)	50^{+} y Median (min-max)	Total Median (min-max)	Wilcoxon test *p*-value

For all latent Hg-based SEMs, childhood Hg exposure and hair Hg 5 µg/g were the main drivers in the construct of latent Hg (Figs. 3 and 5). Latent Hg showed a direct contribution to most symptom clusters, but not Neuro-cognitive deficits and Gross motor impairment. For all clusters, there was also a pathway mediated through having at least one diagnosed nervous system disorder.

In every SEM with Hg exposure variables for prenatal, childhood and hair Hg ≥ 5 µg/g, there was a significant relation between prenatal and childhood exposure (Figs. 4 and 6 and Supplementary Figs. 8–12, Additional file 1). For Extrapyramidal impairment (Fig. 4) and Cranial nerve disturbances (Supplementary Fig. 9, Additional file 1), standardized path coefficients showed that the contribution of prenatal exposure to the cluster was mediated by childhood exposure.

For Sensory Impairment (Supplementary Fig. 8, Additional file 1), Gross motor impairment (Supplementary Fig. 10, Additional file 1) and Neuro-cognitive deficits (Supplementary Fig. 11, Additional file 1), there was a chain of mediation from prenatal exposure to childhood exposure and from childhood exposure to being

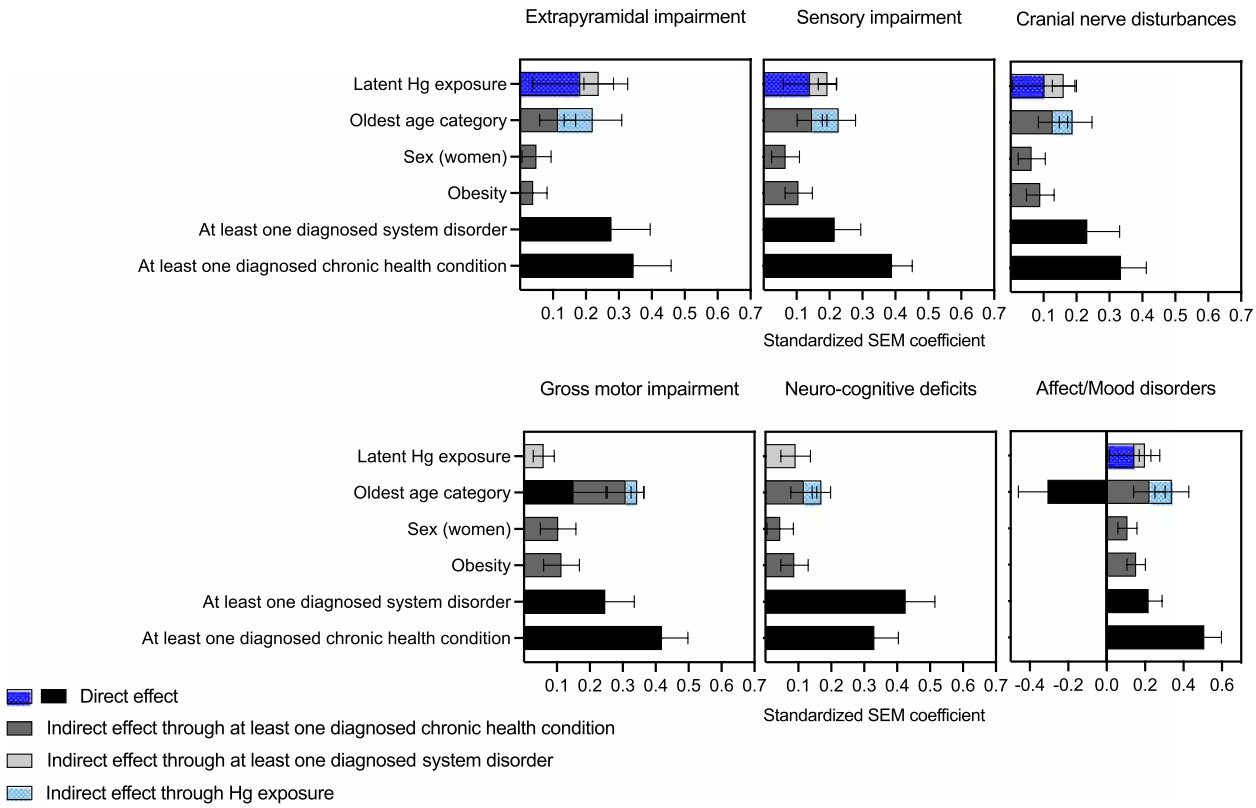

Fig. 5 SEM standardized path coefficients for direct and indirect contributions of latent Hg and covariates on the symptom latent variable for each cluster

diagnosed with at least one nervous system disorder. When the same chain of mediation was modelled for Extrapyramidal impairment and for Cranial nerve disturbances, the models' fit parameters were weaker. In these cases, the direct association of childhood Hg with the symptom cluster was stronger than its indirect association through diagnosed nervous disorder.

Prenatal Hg exposure was directly associated with Affect/Mood disorders (Supplementary Fig. 12, Additional file 1). Hg ≥ 5 µg/g directly influenced Extrapyramidal and Sensory impairment (Fig. 4 and Supplementary Fig. 8 in Additional file 1, respectively).

The best fit models were those that included childhood exposure as mediator for prenatal exposure. Childhood exposure was not a confounding variable in the relation between prenatal exposure, diagnosed nervous system disorder or any symptom cluster. Moreover, there was no moderated mediation with age category or Hg exposure in the SEM.

Although of different magnitudes, age category, sex and obesity, at least one diagnosed chronic health condition and at least one diagnosed nervous system disorder, were directly and/or indirectly associated with symptom clusters in all SEMs. Positive associations were observed with age category with respect to diagnosed nervous system and chronic health conditions, with the exception of Affect/Mood disorders, for which age was both negatively (direct) and positively (indirect) associated with symptom frequency reporting (Supplementary Fig. 12, Additional file 1). Older persons tended to report fewer symptoms of Affect/Mood disorders (direct), unless they suffered from chronic health conditions and/or nervous system disorders (indirect). Past Hg exposure mediated the contribution of age for all clusters, except for Gross motor impairment (Supplementary Fig. 10, Additional file 1) and Neuro-cognitive deficits (Supplementary Fig. 11, Additional file 1).

Longitudinal MEM analyses were performed with all persons who had at least 10 year-based hair measurements ($n = 32$; 17 men and 15 women). Their median age was 54 years (interquartile range: 48–64). The associations between longitudinal hair Hg and the median of the composite variable for each cluster are shown in Table 4. Age, sex and year of sampling were included as fixed factors, and age at time of sampling as a random factor. In these analyses, 5 of the 6 clusters were significantly associated ($p \leq 0.05$) or show a tendency (< 0.10) with longitudinal hair Hg. No association was

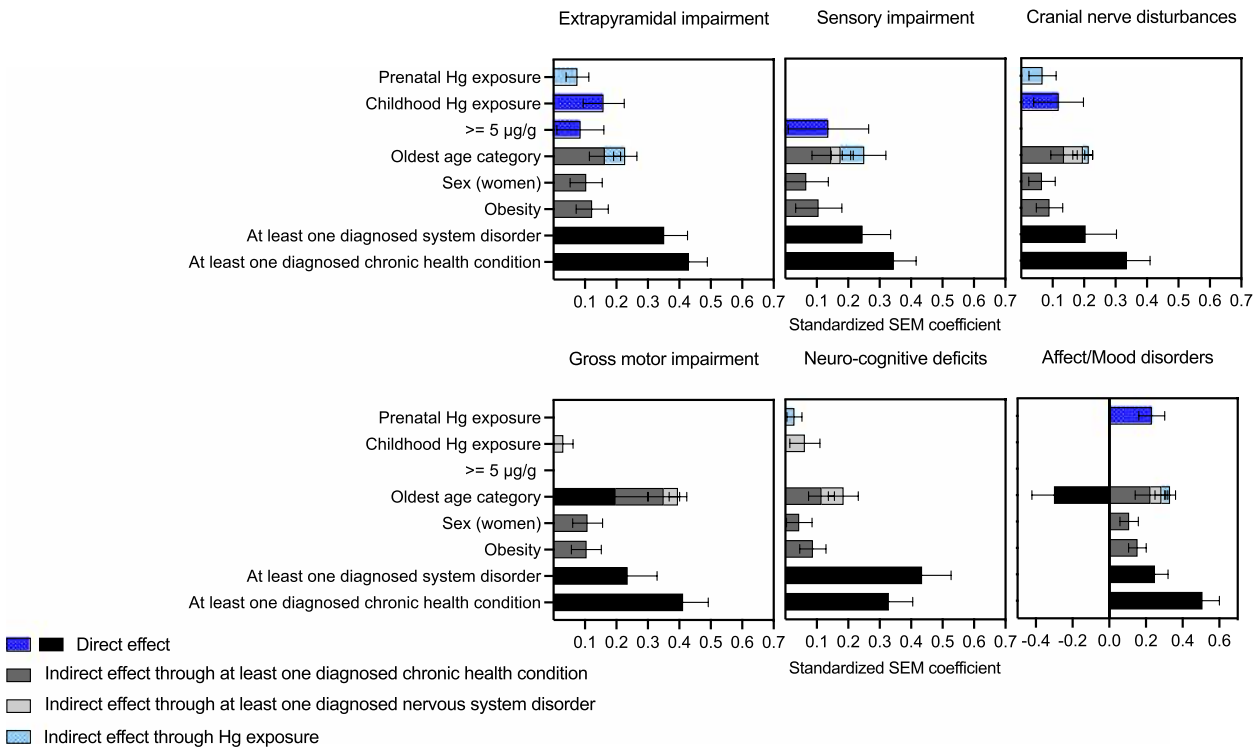

Fig. 6 SEM standardized path coefficients for direct and indirect contributions of prenatal, childhood and ≥ 5 µg/g hair Hg (1970–1997) and covariates on the symptom latent variable for each cluster

observed between longitudinal hair Hg and Affect/Mood disorders.

Discussion

To our knowledge, this is the first study to link past Hg exposure from freshwater fish consumption with clusters of current multiple coexisting symptoms. Clustering analysis enabled us to characterize the various symptom profiles, which constitute the physical and/or mental translation of structural phenomena. The non-random distribution of symptoms and their strong correlation in each cluster suggests a common mechanism or etiology [10, 12, 66]. Here, the six clusters, derived from statistical empirical validation, reflect the involvement of different aspects of nervous system dysfunction, which we classified as representing primarily Extrapyramidal impairment, Sensory impairment, Cranial nerve disturbances, Gross motor impairment, Neuro-cognitive deficits, and Affect/Mood disorders. The symptoms that make up

Table 4 Longitudinal Mixed Effects Model results for estimates of hair Hg concentrations from 1970 to 1997 with respect to the median of the cluster score

Composite cluster variable [a, b]	Hair Hg Estimate[c]	% Confidence Interval	*p* -value
Cluster1 (Extrapyramidal impairment)	1.76	0.0–3.6	0.061
Cluster2 (Sensory impairment)	1.57	−2.7 - 3.4	0.096
Cluster3 (Cranial nerve disturbances)	2.60	1.0–4.2	0.001
Cluster4 (Gross motor impairment)	2.70	0.4–5.1	0.023
Cluster5 (Neuro-cognitive deficits)	2.41	0.6–4.2	0.009
Cluster6 (Affect/Mood disorders)	−0.33	−0.3 - 1.0	0.758

[a] Only participants with 10 measurements and more of hair Hg are included in the analyses (32 persons; 447 Hair Hg measurements)

[b] Significant covariates include age, sex, year of sampling (random effect: age of sampling nested in year of sampling)

[c] Hair Hg estimates represent the difference in hair Hg with respect to cluster scores above and below the median over the sampling period

these clusters were similar to those reported by persons from Grassy Narrows in 2010 [8, 67] and consistent with the many descriptions of methyl Hg poisoning through fish consumption [68–75].

SEM provided the opportunity to simultaneously examine covariance, mediation and moderation between variables through a domino effect of successive pathways from past exposure to current symptoms. The Hg exposure latent variable, which grouped different periods of exposure (prenatal Hg, childhood Hg and hair Hg $\geq 5\,\mu g/g$ at least once), enabled us to examine their combined contributions. Latent Hg exposure variables have been used in other studies. Choi et al. [23] showed that a grouped Hg exposure variable, including current Hg nail and blood concentrations and hair Hg concentration 7 years previously, was associated with adverse cardiovascular outcomes in Faroese whaling men. In a study by Grandjean and co-authors [76], the combined prenatal and childhood Hg exposures were negatively related to children's neurobehavioral outcomes. In the present study, the combined past Hg exposures were, directly and indirectly, associated with all clusters.

Hg biomarker data, collected in Grassy Narrows First Nation between 1970 and 1997 provided a unique opportunity to examine symptom clusters with respect to past exposure over a long-term period and at various time points. The findings of longitudinal analyses, based on participants with at least 10 year-based hair Hg measurements over the sampling period, showed that long-term Hg exposure was associated with higher symptom frequency for all the clusters of nervous system dysfunction, with the exception of Affect/Mood disorders. This is consistent with SEM findings where Affect/Mood disorders showed a significant relation only with prenatal exposure.

Independent Hg exposures may provide insight into the relative importance of exposure at different time periods. While prenatal exposure was directly associated with Affect/Mood disorders, for other clusters, its contribution was mediated by childhood exposure. Fetal Minamata patients present with psychiatric disorders (Harada, 1964 cited in Yorifuji et al. [77]). A re-analysis of 1971 data from Minamata patients showed that psychiatric symptoms peaked at 20 years of age [77]. This may be similar to the present study where young adults ($\leq$ 29 years of age) reported a higher frequency of altered mood symptoms. The importance of prenatal and childhood Hg exposure has been raised by many authors [25, 78]. Children are more vulnerable to toxic exposure than adults because their brains are in a state of rapid growth, with relatively higher absorption rates to body weight; their body systems are not prepared to properly metabolize, detoxify, and excrete toxic substances [79–81].

Although the GN-CHA did not include the age of onset of symptoms, the association between past exposure and later-life symptoms raises the issue of delayed and/or progressive neurotoxicity. Delayed neurotoxicity was reported in 13-year-old monkeys, treated with methyl Hg from birth to 7 years of age [82]. A silent latency period for methyl Hg toxicity has been proposed using examples from the Minamata and Iraq disasters [83]. Newland and co-authors [84] discuss mechanisms by which neuronal development may have long-lasting behavioral consequences that appear in adulthood and, in some cases, may not appear until aging.

The FNRHS 2008/2010 included few nervous system disorders in their list of diagnosed health conditions [27]. The GN-CHA added a series of neurologic disorders which share some of the signs and symptoms of Hg poisoning. These disorders mediated the relation between latent Hg exposure and all symptom clusters and between childhood exposure and Sensory impairment, Gross motor impairment and Neuro-cognitive deficits.

In Canada, chronic health conditions are disproportionately higher among Indigenous communities compared to the non-Indigenous population [85]. The most commonly reported chronic health conditions in the GN-CHA are similar to other First Nation communities across Canada: high blood pressure, allergies, arthritis, diabetes, and chronic back pain [27]. Results of the SEM showed the expected associations of having at least one chronic health condition with age and obesity, with women presenting a higher prevalence compared to men. It is noteworthy that the highest direct contribution to all symptom clusters was having at least one diagnosed chronic health condition and/or nervous system disorder.

SEM remains one of the best approaches to assess simultaneously direct and indirect associations by investigating all relevant regression pathways. Our findings are consistent with follow-up studies of persons that had been affected by Hg pollution from the Chisso Company in Minamata, decades after the company had halted the dumping of methyl Hg into the bay [74, 86–88]. The Japanese studies compared persons who had lived in polluted and non-polluted regions since they did not have actual measures of Hg exposure for the individuals who were evaluated.

Some limitations need to be considered in interpreting the present results. The study reposes on self-reported questionnaire data from the GN-CHA, raising the question of recall bias, and under- or over-reporting. To offset these limitations, the Cronbach alpha and CFA confirmed the construct reliability of the clustered symptoms. Reported diagnosed health conditions and nervous system disorders reflected whether a person had

consulted a health professional who had diagnosed this condition, as well as the accuracy of the diagnosis. Further studies would benefit from clinical assessments in relation to past Hg exposure.

A further limitation is with respect to Hg biomarkers obtained from a government monitoring program [3]. Sampling was not carried out regularly and samples were not collected yearly from everyone, resulting in many missing values. Moreover, there were seasonal and yearly differences in fish consumption frequency [3, 6]. Hg exposure imprecision could also be associated with blood and hair measurements over the sampling years, notably laboratory measurement imprecision and biological variation [89]. Ideally, one would like to have had continuous Hg biomarker measurements over all participants' lifetime, but this was not possible. To address the challenges posed by the biomarker database, for the SEMs, the estimated umbilical cord and childhood Hg values were validated, and we used latent variables of Hg exposure to manage residual error terms between variables. For the longitudinal MEMs, we limited the analyses to persons with a minimum of 10 hair Hg measurements, representing exposure for 10 years or more.

Studies on Minamata Disease have shown differences in fetal, non-fetal infantile and adult Hg damage to the brain [90]. In the present study, the large majority of persons experienced both prenatal and postnatal exposure. The mediated contribution of prenatal exposure on symptom clusters through childhood exposure, observed in most SEMs, suggests that their independent contributions are difficult to assess. While both prenatal and childhood Hg exposures decreased over time, reflecting diminishing fish Hg concentration and changing family dietary patterns, they also represent different stages of neurodevelopment and have potentially different effects. Our data showed that childhood Hg exposure may be a mediator/cumulative effect of prenatal exposure, except for Affect/Mood disorders. We tested childhood exposure alone, but the associations were stronger when prenatal exposure was included in the model.

The Grassy Narrows Hg disaster began in 1962 and after 1970, fish Hg concentration and fish consumption decreased over time, paralleled by a decrease in biomarker Hg concentrations. Associations with Hg exposure, observed in the models, may be partially masked by age. The inverse relation between year of birth and Hg exposure made age an ambiguous variable. Age was a risk factor for the symptom clusters, covaried with Hg exposure, but was not a consequence of Hg exposure.

Conclusions

Since the disaster, Grassy Narrows First Nation has expressed concern about the high rate of symptoms of nervous system dysfunction in their community. This is the first study to demonstrate links between long-term and past Hg exposure and current coexisting symptoms. Given the complexity of the interrelations between the various determinants of chronic health problems in this and other First Nation communities, SEM and LMEM methods were useful to link past Hg exposure with present-day symptoms. Further studies should examine the mechanisms that underlie these manifestations.

Acknowledgements

We thank all of the people of Grassy Narrows who organized and carried out the Grassy Narrows Community Health Assessment (CHA): the community advisory committee, the fieldwork coordinators and the surveyors. A special thank you to the people of Grassy Narrows who participated in the CHA and agreed to share their biomarker data with us. We salute the resilience of the Grassy Narrows community who have fought for mercury justice over the past 50 years.

Authors' contributions

AP created the database, determined the statistical approaches and performed the analyses. She co-wrote the manuscript with DM. JDS is the initiator and organizer of the GN-CHA survey. She provided input for data interpretation. MF participated in the analyses and dissemination of the GN-CHA. She participated in the writing and editing of the manuscript. TSL provided the neurological interpretation of the symptom clusters and verified the manuscript. DM was invited by Grassy Narrows First Nation as scientific advisor for the GN-CHA. She was responsible for over-seeing the fieldwork, analyzing the data and preparing the reports. She is principal investigator on the present research. All authors read and approved the final manuscript.

Funding

The GN-CHA received financial support from Health Canada and the Ontario Ministry of Health and Long-Term Care and technical support from these ministries and the Ontario Agency for Health Protection and Promotion, the Ontario Ministry of Indigenous Relations and Reconciliation and the Northwestern Health Unit of Ontario. The present study was funded by the Canadian Institutes for Health Research (#152882).

Availability of data and materials
Archived mercury biomarker data were obtained from the First Nations and Inuit Health Branch (FNIHB) of the Ministry of Indigenous Services Canada, at the request of Grassy Narrows First Nation. The datasets generated and analysed in the present study are the property of Grassy Narrows First Nation. Permission for use of the data lies with Grassy Narrows Chief and Council.

Declarations

Ethics approval and consent to participate
Ethics approval for the GN-CHA was obtained from the Manitoulin Anishinaabek Research Review Committee (MARRC), who issued an Ethics Certificate on September 1, 2016. Informed consent forms were signed by all participants. Consent included survey participation and the linking of the information from the GN-CHA to data obtained from previous surveillance programs and/or studies of Hg exposure. Ethics approval for the present study was obtained from the ***Université du Québec à Montréal*** (2016_e_1350) and Health Canada Research Ethics Board (REB 2017–0006).

Consent for publication
All participants provided consent for publication. The present study was presented to Grassy Narrows' Chief and Council of, who approved the manuscript for publication on May 12, 2021.

Competing interests
The authors declare that they have no competing interests.

Publisher's Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

Ready to submit your research? Choose BMC and benefit from:

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

At BMC, research is always in progress.

ROLES OF PARTICIPANTS IN CONSULTATION AND ENGAGEMENT DURING THE IMPACT ASSESSMENT PROCESS LED BY THE AGENCY

IMPACT ASSESSMENT PROCESS

Phase 0 – Pre-Planning

Proponent:

- Engages Indigenous groups to present the project
- Learns the views of the groups, including potential effects and how they wish to be engaged, to incorporate them into the **Initial Project Description**

Agency:

- Informs Indigenous groups about the impact assessment process to support them in understanding how they can participate in the process
- Learns the views and contexts of the Indigenous groups, including potential effects and how they wish to be engaged

Indigenous groups:

- Learn about the proponent, proposed project, Agency and impact assessment process
- Share views and values with the proponent and Agency, including potential effects and how they wish to be engaged

Phase 1 – Planning (180 days)

Proponent:

- Engages Indigenous groups to inform the **Detailed Project Description** and responds to issues and concerns identified in the **Summary of Issues**

Agency:

- Seeks input from Indigenous groups on the project, the proponent's **Initial Project Description**, key draft documents for an impact assessment (**Tailored Impact Statement Guidelines**, **Indigenous Engagement and Partnership Plan**), and how they would like to be meaningfully consulted in an impact assessment

Indigenous groups:

- Participate in engagement and consultation activities
- Identify key issues, including potential impacts on rights
- Advise on how they would like to be engaged and provide input and feedback on the **draft Tailored Impact Statement Guidelines** and **draft Indigenous Engagement and Partnership Plan**, if an impact assessment is required

Phase 2 – Impact Statement (up to 3 years)

Proponent:

- Engages Indigenous groups to gather information, identify potential effects and appropriate mitigation, and address concerns
- Prepares the **Impact Statement** based on the **Tailored Impact Statement Guidelines**, considering and including Indigenous knowledge where provided

Agency:

- Supports Indigenous groups and the proponent in understanding the impact assessment process and expectations
- Facilitates engagement with the proponent, Indigenous groups and others, as required
- Leads consultation with Indigenous groups on the proponent's **Impact Statement**

Indigenous groups:

- Undertake community activities to learn about the project and provide input to the proponent and Agency
- Contribute Indigenous knowledge
- Engage with the proponent to co-develop or collect any relevant information and identify potential effects, mitigation and follow-up measures, to inform the **Impact Statement**
- Participate in consultation activities led by the Agency

Phase 3 – Impact Assessment (300 days)

Proponent:

- Participates in Agency-led consultations with Indigenous groups, as appropriate
- Provides comments on potential conditions

Agency:

- Leads ongoing consultation with Indigenous groups on the proponent's impact assessment information, if needed
- Prepares the **draft Impact Assessment Report** and potential conditions
- Leads consultation with Indigenous groups on the **draft Impact Assessment Report** and potential conditions

Indigenous groups:

- Participate in consultation activities, including verifying impacts, mitigation and follow-up measures described in the proponent's impact assessment information and the **draft Impact Assessment Report**
- Contribute Indigenous knowledge
- Provide comment on the **draft Impact Assessment Report** and potential conditions

Phase 4 – Decision-making (30 days)

Proponent:

- Awaits the Minister's **Decision Statement**, which includes enforceable conditions

Agency:

- Posts the **Decision Statement** and **final Impact Assessment Report** on the Canadian Impact Assessment Registry Internet site

Indigenous groups:

- Await the Minister's **Decision Statement**, which includes enforceable conditions

Phase 5 – Post-Decision (ongoing)

Proponent:

- Implements mitigation measures, follow-up programs and, as appropriate, adaptive management plans
- Complies with the **Decision Statement** and corrects any non-compliance

Agency:

- Verifies compliance with the **Decision Statement**
- Provides information on compliance and enforcement

Indigenous groups:

- Work with the proponent on how they wish to be engaged, should the project proceed
- Participate in follow-up and monitoring activities, as may be provided by the **Decision Statement**
- Inform the Agency of potential non-compliance through voluntary reporting

and MINISTER OF THE ENVIRONMENT AND CLIMATE CHANGE (ONTARIO),
and THE ATTORNEY GENERAL OF ONTARIO

Respondents

NOTICE OF APPLICATION TO DIVISIONAL COURT FOR JUDICIAL REVIEW

TO THE RESPONDENTS:

A LEGAL PROCEEDING HAS BEEN COMMENCED by the Applicants. The claim made by the Applicants appears on the following pages.

THIS APPLICATION for Judicial Review will come on for a hearing before the Divisional Court on a date to be fixed by the Registrar at the place of hearing requested by the Applicants. The Applicants request that this application be heard at Osgoode Hall, 130 Queen Street West, Toronto, Ontario, M5H 2N5.

IF YOU WISH TO OPPOSE THIS APPLICATION, to receive notice of any step in the application or to be served with any documents in the application, you or an Ontario lawyer acting for you must forthwith prepare a notice of appearance in Form 38A prescribed by the Rules of Civil Procedure, serve it on the Applicants' lawyer or, where

the Applicants do not have a lawyer, serve it on the Applicants, and file it, with proof of service, in the office of the Divisional Court, and you or your lawyer must appear at the hearing.

IF YOU WISH TO PRESENT AFFIDAVIT OR OTHER DOCUMENTARY EVIDENCE TO THE COURT OR TO EXAMINE OR CROSS-EXAMINE WITNESSES ON THE APPLICATION, YOU OR YOUR LAWYER MUST, IN ADDITION TO SERVING YOUR NOTICE OF APPEARANCE, SERVE A COPY OF THE EVIDENCE ON THE Applicants' lawyer or, where the Applicants do not have a lawyer, serve it on the Applicants, and file it, with proof of service, in the office of the Divisional Court within thirty days after service on you of the Applicants' application record, or not later than 2 p.m. on the day before the hearing, whichever is earlier.

IF YOU FAIL TO APPEAR AT THE HEARING, JUDGMENT MAY BE GIVEN IN YOUR ABSENCE AND WITHOUT FURTHER NOTICE TO YOU. IF YOU WISH TO DEFEND THIS PROCEEDING BUT ARE UNABLE TO PAY LEGAL FEES, LEGAL AID MAY BE AVAILABLE TO YOU BY CONTACTING A LOCAL LEGAL AID OFFICE.

Date: September 1, 2015

APPLICATION

This is an Application for judicial review of a provincial decision approving clearcut logging activities and refusing to order an individual environmental assessment ("IEA") regarding potential mercury contamination and adverse human health effects, arising from the approved activities.

The decision consists of two inter-related stages:

(1) a December 2013 decision by the Minister of Natural Resources and Forestry, or the Minister's designate (the "Natural Resources Minister"), approving a forest management plan ("Plan"), which allows clearcut logging of the Whiskey Jack Forest in northwestern Ontario under section 9 of the *Crown Forest Sustainability Act,* S.O. 1994, c. 25 ("*CFSA*"), and

(2) a December 2014 decision by the Minister of the Environment and Climate Change, or the Minister's designate (the "Environment Minister") refusing, under section 16 of the *Environmental Assessment Act,* R.S.O. 1990, c. E.18 ("*EAA*"), to grant a Part II order (or "bump-up") requested by the Applicants that would have allowed an IEA to be conducted on whether clearcut logging authorized under the Plan could:

(a) release mercury to the watersheds of and adjacent to the English-Wabigoon river system, which system runs through the

Whiskey Jack Forest most of which is part of the traditional territory of the Grassy Narrows First Nation ("Grassy Narrows"),

(b) contaminate fish therein, and

(c) increase the risk of harm to humans consuming the fish.

The Applicants challenge the approval of the Plan and the refusal of their request for a bump-up with respect thereto (collectively the "Decision") on the basis that the exercise of these statutory powers of decision infringe on the rights of their members (1) to life, liberty and security of the person as guaranteed by section 7 of the *Canadian Charter of Rights and Freedoms*, Part 1 of the *Constitution Act, 1982* being Schedule B to the *Canada Act 1982* (U.K.), c. 11 (the "*Charter*"), and (2) to equality under section 15(1) of the *Charter*.

The Applicants also challenge the Decision on other constitutional and administrative law grounds set out below.

1. The Applicants make application for:

***Charter* Remedies**

(a) an order under section 24(1) of the *Charter* declaring that the Decision,

(i) infringes section 7 of the *Charter*, by depriving them of their life, liberty and security of the person in a manner not in accordance with the principles of fundamental justice;

(ii) infringes section 15(1) of the *Charter* by depriving them of their right to equality;

(b) an order under section 24(1) of the *Charter* setting aside the Decision;

(c) an order under section 24(1) of the *Charter* in the nature of mandamus directing the Environment Minister to authorize an IEA as requested by the Applicants;

(d) an interim and permanent order under section 24(1) of the *Charter* prohibiting the Natural Resources Minister from authorizing third parties, by licence or otherwise, from conducting clearcut logging in the Whiskey Jack Forest under authority of the Plan;

(e) an interim and permanent order under section 24(1) of the *Charter* enjoining third parties with a licence or other instrument from the Natural Resources Minister from conducting clearcut logging in the Whiskey Jack Forest under authority of the Plan;

Administrative Law Remedies

(f) an order declaring that:

(i) in failing to ensure that mercury releases would be prevented or mitigated, approval of the Plan by the Natural Resources Minister was without legal authority under the *CFSA* or, in the alternative, unreasonable; and

(ii) the refusal by the Environment Minister to grant a bump-up request so as to assess under an IEA potential environmental and

health impacts from mercury releases was without legal authority under the *EAA* or, in the alternative, unreasonable;

(g) an order quashing or setting aside:

(i) the Decision; and

(ii) any authorizations, licences, permits, or approvals by the Ministers, or their respective ministries, enabling implementation of the Plan to proceed, in whole or in part, before this Application has been heard and determined by this Honourable Court;

Remedies Based on the Federal Paramountcy Doctrine

(h) an order declaring that the Plan, by permitting release of mercury, a deleterious substance, into water frequented by fish, is contrary to, conflicts or is inconsistent with, section 36(3) of the federal *Fisheries Act*, R.S.C. 1985, c. F-14, and is thereby rendered inoperative to the extent of the conflict or inconsistency;

Costs

(i) an order requiring the Respondents to pay the Applicants costs of this Application if requested or, in the alternative, an order that all parties shall bear their own costs;

Other Relief

(j) such further or other relief as counsel may advise and this Honourable Court may permit.

Grounds for the Application

2. The Grounds for the application are:

The Parties

(a) The Applicants are:

(i) Chief Roger Fobister, Senior, the elected chief and a member of Grassy Narrows, and having the status of an "Indian" within the meaning of the *Indian Act*, R.S.C. 1985, c. I-5 ("*Indian Act*"), who is bringing this application on his own behalf and on behalf of all other members of Grassy Narrows;

(ii) Sherry Fobister, William Fobister, Senior, and Simon Fobister, each of whom is a member of Grassy Narrows, having the status of an "Indian" within the meaning of the *Indian Act*, who also bring this application on their own behalf and on behalf of all other members of Grassy Narrows; and

(iii) Grassy Narrows, a First Nation being among the Aboriginal peoples of Canada recognized under s. 35 of the *Constitution Act, 1982*, and having the status of a "band" within the meaning of the *Indian Act*. Members of Grassy Narrows live on and off the English River 21 Reserve (hereinafter the "Grassy Narrows Reserve"), a "reserve" within the meaning of the *Indian Act*. The members of Grassy Narrows, whose ancestors signed Treaty No. 3, are Anishinabe

(Ojibway) men, women, and children many of whom engage in the practice of traditional Anishinabe activities in their traditional territory, which are central to their identity, diet, culture, and economy, including by:

(A) fishing in the English-Wabigoon river system watershed, or adjacent watersheds, in the area that includes the Whiskey Jack Forest; and

(B) consuming fish caught from those waters.

(b) The Respondent Natural Resources Minister is responsible for the *CFSA*, Ontario's primary statute permitting logging of, and development and approval of forest management plans for, the Crown forests of Ontario.

(c) The Respondent Environment Minister is responsible for the *EAA*, Ontario's primary statute for examining the effects of undertakings, such as logging and related forest management activities on Crown lands in Ontario, on the natural environment, human life, and social, economic, and cultural conditions.

Overview

(d) The Applicants rely on fishing in the watershed of the English-Wabigoon river system as a significant part of their way of life, and on the consumption of area fish as a significant part of their diet. Existing

mercury pollution dating from the discharge of mercury by a Dryden, Ontario chlor-alkali plant into the same river system in the 1960s has had, and continues to have, a significant adverse impact, due to the consumption of mercury-contaminated fish, on the health and well-being of members of Grassy Narrows, including some of the individual Applicants who have been diagnosed with, or whose children have been diagnosed with, symptoms consistent with mercury poisoning. The Applicants fear that clearcut logging authorized under the Plan poses a serious risk of additional harm to the health and well-being of community members because it will trigger new releases of mercury to the watershed, increase the accumulation of mercury in the food chain, and prolong and exacerbate the existing mercury problem.

Historical Background: Industrial Discharges of Mercury in the English-Wabigoon River System

(e) Beginning in the 1960s, a chlor-alkali plant at Dryden, Ontario began discharging mercury into the English-Wabigoon river system, eventually discharging approximately 9,000 kilograms of mercury into the river system, which flows into and through the traditional lands and territory of the Applicants;

(f) Once in the water, the mercury was transformed by chemical-biological processes into methyl mercury, a nerve poison capable of bio-accumulating up the food chain, being ingested by fish, and adversely

impacting humans consuming methyl mercury-contaminated fish caught from waters in the aforementioned area;

(g) The consumption of methyl mercury-contaminated fish by members of Grassy Narrows resulted over the decades in serious, and well-documented, neurological harm and other adverse health impacts, many of which continue to afflict many members of Grassy Narrows to this day;

(h) Litigation by Grassy Narrows against the federal and Ontario governments, and the successor company to the original industrial discharger, resulted in a settlement in the 1980s and the payment of some compensation as well as the establishment of a mercury disability board to evaluate and compensate members of Grassy Narrows suffering on-going neurological harm and other adverse health impacts consistent with mercury poisoning arising from the industrial discharges of mercury into local bodies of water;

(i) The watershed of the English-Wabigoon river system where the industrial discharges of mercury took place encompasses most of the Whiskey Jack Forest;

(j) Fish within this watershed continue to have levels of mercury above, or near, the limit for safe human consumption;

(k) Grassy Narrows Reserve is located within the Whiskey Jack Forest itself.

The Whiskey Jack Forest Management Plan

(l) Starting in or about 2010 and continuing to late 2013, the Ministry of Natural Resources and Forestry ("MNRF") gave periodic public notice of its intention to develop a forest management plan that would authorize logging for the Whiskey Jack Forest, and sought from time to time public comment on various stages of what eventually became the approved Plan.

(m) Over this same 2010 to 2013 period, Grassy Narrows and other groups raised publicly through the media, and directly with the provincial government, their concern that the sole method of harvesting trees under the Plan, clearcut logging, would interfere with the rights of the members of Grassy Narrows and risked the release of new, or additional, sources of mercury into the region's watershed system, the potential for increased methyl mercury contamination of fish, and consequential harm, or further harm, to the health and well-being of members of Grassy Narrows consuming the fish.

(n) During the 2010 to 2013 period, and earlier, MNRF also was independently aware, through its own research and investigations, of the mercury problem arising from clearcut logging and the challenge of

preventing or mitigating it. Notwithstanding these concerns, the Natural Resources Minister approved the Plan in December 2013.

The Bump-up Request

(o) The notice of decision approving the Plan indicated that persons objecting to the decision could apply to the Ministry of the Environment and Climate Change ("MOECC") requesting a bump-up under the *EAA* that would, if approved, authorize an IEA to be performed before the Plan would be allowed to go into effect.

(p) Grassy Narrows, in conjunction with an environmental non-governmental organization not party to this application, filed such a request in January 2014 as well as supplementary submissions with supporting material in May, July, September, and November 2014.

(q) The initial request, the supplementary submissions of Grassy Narrows, and the response of MNRF demonstrated the need for an IEA, including:

(i) since the industrial discharges of mercury in the 1960s, clinical evaluations of members of Grassy Narrows show that many have suffered from, and continue to suffer from, a variety of neurological health problems attributable to eating methyl mercury contaminated fish caught in area waters;

(ii) peer-reviewed scientific studies show clearcut logging in boreal forests at latitudes similar to the Whiskey Jack Forest, leads to the presence, or increased presence, of methyl mercury in fish in watersheds where the logging takes place;

(iii) members of Grassy Narrows fear the health risks posed by eating mercury-contaminated fish but continue to do so for a variety of complex reasons, including because fishing and consumption of fish caught has always been part of their traditional way of life, diet, and culture, which they do not wish to lose, and because it is an affordable source of food in an impoverished community;

(iv) MNRF admitted that it makes no claims for the effectiveness of the only measures it proposes for the mitigation of mercury impacts to water from clearcut logging authorized under the Plan;

(v) MNRF personnel involved in preparation of, or comment with respect to, guidance materials for the Plan raised concerns that key measures proposed for use with the Plan would not be enforceable and would not adequately mitigate mercury releases to water and could, in fact, exacerbate them.

(r) Despite the above and related submissions and material filed by Grassy Narrows and admissions by MNRF, the Environment Minister, or his designate, refused the bump-up request of Grassy Narrows in December 2014, allowing implementation of the Plan to proceed. In doing so, the refusal decision specifically relied on the mitigation measures that MNRF disclaimed the effectiveness of in controlling mercury impacts, and simply imposed requirements for monitoring such measures during clearcut logging activity authorized under the Plan.

The Decision Violates the Section 7 *Charter* Rights of the Applicants

(s) Section 7 of the *Charter* declares that everyone has the right to life, liberty and security of the person and the right not to be deprived thereof except in accordance with the principles of fundamental justice.

Depriving Applicants of Right to Life, Liberty and Security of the Person

(t) The Decision violates the section 7 *Charter* rights of the Applicants by:

(i) Depriving them of their right to life guaranteed under section 7 by increasing their risk of death, illness or disease as a result of the approval and anticipated implementation of the Plan and corresponding refusal to examine beforehand, through an IEA, the potential impacts to them posed by consumption of mercury-contaminated fish arising from, or exacerbated by, clearcut logging authorized by the Plan in the Whiskey Jack Forest;

(ii) Depriving them of their right to liberty guaranteed under section 7 by undermining, or seriously compromising, their freedom to choose an environment in which to reside and in which to practice their traditional way of life, including fishing in their traditional territory, due to the serious risks they face, if they stay in the area, of neurological or other harm, or such further harm, as a result of eating fish caught in local waterways contaminated by methyl mercury caused by clearcut logging authorized by the Plan, and not studied beforehand, through an IEA;

(iii) Depriving them of their right to security of the person guaranteed under section 7 by:

(A) increasing the risk to their physical security by exposing them to health damage, or further health damage, including death or disability, due to approval and implementation of the Plan that will permit clearcut logging with known potential to release mercury into the watershed, contaminating fish, and leading to neurological and other harm to those consuming the fish, and not studying the issue beforehand through an IEA; and

(B) increasing the risk to their psychological security because the Decision constitutes serious state-imposed psychological stress arising from their fear that clearcut logging authorized by the Decision, which has been strongly linked in the scientific literature to runoff and bioaccumulation of mercury, will exacerbate the contamination of fish, as well as neurological and other health problems experienced by members of Grassy Narrows consuming the fish.

The Deprivations are not in Accordance with Principles of Fundamental Justice

(u) The Decision also constitutes a deprivation of the section 7 rights of the Applicants by not being in accordance with principles of fundamental justice.

Failure to Respect Sanctity of Human Life

(i) Given the history of mercury impacts on the members of Grassy Narrows, the Decision fails to respect the sanctity of human life, a substantive principle of fundamental justice, by risking further harm to human health and well-being, if not loss of human life, in the community from mercury exposure arising from approval and implementation of the Plan, which authorizes clearcut logging, and failing to examine the risks before hand through an IEA.

Denial of Procedural Protections

(ii) The Decision denies the Applicants procedural protections as it was made without their being able to appear before an independent body that could have considered these matters under three different statutes because:

(A) MNRF failed to promulgate a regulation setting out an appeal process for forest management plans as authorized under section 12 of the *CFSA*;

(B) MNRF and/or MOECC failed to classify by regulation forest management plans as instruments that are eligible for third party appeals under sections 38-48 of the *Environmental Bill of Rights, 1993*, S.O. 1993, c. 28 and O. Reg. 681/94 promulgated thereunder, which could have led to an independent public hearing with respect to the Plan;

(C) as a result of the Environment Minister refusing to grant the bump-up request, the Applicants were denied an opportunity:

(1) to obtain an IEA that could have provided in-depth study and consideration of the issue of mercury release to area waters and resulting health implications thereof, from the Plan's authorization of clearcut logging, matters of vital concern to their life, health, and well-being as consumers of fish from these waters; and

(2) to request an independent public hearing under sections 9.1-9.3 of the *EAA* with respect to the resulting IEA; and

(D) the substitution of a notice, comment, and consultation opportunity offered by MNRF/MOECC to Grassy Narrows was not adequate in the context of this case in comparison to a hearing before an independent body, particularly given the health threats posed by mercury to members of Grassy Narrows arising from clearcut logging authorized under the Plan, and the information known only to MNRF at the time respecting the limitations of its mercury mitigation measures.

Effects Grossly Disproportionate to Objectives

(iii) The effects of the Decision on the life, liberty, and security of the person of members of Grassy Narrows due to potential additional

exposure to mercury and the failure to study same through an IEA before proceeding, are grossly disproportionate to the Decision's objectives of allowing the harvesting of trees in the Crown forest by clearcut logging.

Offends Basic Tenet of Legal System

(iv) The Decision also is not in accordance with principles of fundamental justice because it offends a basic tenet of the legal system by violating the equality rights of the Applicants under section 15(1) of the *Charter*, as set out below.

The Decision Violates the Section 15(1) *Charter* Rights of the Applicants

(v) Section 15(1) of the *Charter* declares that every individual is equal before and under the law and has the right to the equal protection and equal benefit of the law without discrimination and, in particular, without discrimination based on race, national or ethnic origin, colour, religion, sex, age or mental or physical disability.

(w) The Decision violates the section 15(1) *Charter* rights of the Applicants by: (1) creating a distinction based on grounds enumerated in, or analogous to, section 15(1); and (2) creating a disadvantage based on the distinction.

Creating a Distinction

(x) The Decision violates section 15(1) of the *Charter* by creating a distinction that:

(i) disproportionately burdens:

(A) members of Grassy Narrows who live within the watershed and who are identifiable by their Aboriginality, their place of residence, their historical and ongoing practice of traditional Aboriginal activities in their traditional territory, including fishing, all characteristics that are actually or constructively immutable, and which the government has no legitimate interest in expecting the people of Grassy Narrows to change in order to receive substantive equality under the law; and

(B) women of childbearing age in the community who must avoid consumption of methyl mercury-contaminated fish or risk exposing their unborn children to serious adverse health effects; and

(ii) ignores their pre-existing health disadvantage as a result of past consumption of methyl mercury-contaminated fish from local waters.

Creating a Disadvantage

(y) The Decision further violates section 15(1) of the *Charter* by creating a disadvantage on the basis of the above distinction that perpetuates the history of prejudice experienced by Aboriginal peoples in Canada in

general, and the exposure to mercury suffered by members of Grassy Narrows in particular by authorizing, and refusing to examine beforehand through an IEA potential impacts to them posed by, clearcut logging that will trigger new releases of mercury into the local water system, thus effectively putting the members of Grassy Narrows in the position of either:

(i) giving up the fishing and other traditional activities in their traditonal territory that are of significant importance to a band member's personal identity; or

(ii) further exposing themselves and their unborn children to harm due to consumption of fish contaminated by new releases of mercury to area waters.

The Decision is not justified by Section 1 of the *Charter*, or Disproportionately and Unreasonably Interferes with *Charter* Guarantees

(z) The violations of sections 7 and 15(1) of the *Charter* set out above do not constitute a reasonable limit demonstrably justified in a free and democratic society pursuant to section 1 of the *Charter*. The impugned Decision impairs the rights of the Applicants, does not advance a sufficiently important governmental objective and, in any event, fails to meet the proportionality requirements of section 1 of the *Charter*. Alternatively, the Decision, in seeking to meet statutory objectives,

disproportionately and unreasonably interferes with protections guaranteed to the Applicants under sections 7 and 15(1) of the *Charter*.

The Decision Violates Administrative Law Principles

(aa) In making the Decision, the Ministers, or their designates, erred in law and/or acted beyond or without jurisdiction in that:

(i) there was no evidence that the mercury mitigation measures proposed pursuant to, or in conjunction with, the Plan would mitigate mercury impacts to the river system, avoid contamination of fish, or prevent serious risk of harm to members of Grassy Narrows consuming contaminated fish, and there was substantial evidence to the contrary;

(ii) the Natural Resources Minister failed to meet the purposes, duties, and conditions precedent imposed upon the Minister pursuant to sections 1, 2, 9, and 68 of the *CFSA* and various manuals and guides promulgated thereunder, requiring the Minister to only approve a Plan that provides for the sustainability of the Crown forest ecosystem by meeting the social, economic, and environmental needs of present and future generations, as well as minimizing adverse effects to animal life and water;

(iii) the Environment Minister, in refusing to grant the bump-up request and order that an IEA be conducted, failed to meet the purposes and duties imposed by sections 1, 2 and 16 of the *EAA* and declaration orders promulgated thereunder related specifically to forest management on Crown lands, to protect the environment, including human life;

(iv) relevant factors were not taken into account or, in the alternative, irrelevant factors were taken into account.

The Plan Conflicts, or is Inconsistent, with the Federal *Fisheries Act*

(bb) In authorizing the Plan under section 9 of the *CFSA*, which will allow clearcut logging operations causing or permitting the deposit of mercury, a deleterious substance, into water frequented by fish, including the watersheds of and adjacent to, the English-Wabigoon river system, the Natural Resources Minister's decision conflicts or is inconsistent with the prohibition in section 36(3) of the *Fisheries Act* prohibiting such deposits and is thereby, pursuant to the federal paramountcy doctrine, inoperative to the extent of the conflict or inconsistency.

Constitutional and Statutory Provisions

(cc) *Canadian Charter of Rights and Freedoms*, Part 1 of the *Constitution Act, 1982* being Schedule B to the *Canada Act 1982* (U.K.), 1982, c. 11 (the "*Charter*"), sections 1, 7, 15(1), 24(1), 28;

(dd) *Constitution Act, 1982*, being Schedule B to the *Canada Act 1982* (U.K.), 1982, c. 11, section 35;

(ee) *Indian Act*, R.S.C. 1985, c. I-5;

(ff) *Crown Forest Sustainability Act*, S.O. 1994, c. 25;

(gg) *Environmental Assessment Act*, R.S.O. 1990, c. E.18;

(hh) *Environmental Bill of Rights, 1993*, S.O. 1993, c. 28 and O. Reg. 681/94;

(ii) *Fisheries Act*, R.S.C. 1985, c. F-14, section 36(3);

(jj) *Judicial Review Procedure Act*, R.S.O. 1990, c. J.1;

(kk) *Courts of Justice Act*, R.S.O. 1990, c. C.43;

(ll) *Rules of Civil Procedure*, R.R.O. 1990, Regulation 194.

(mm) Such further or other grounds as counsel may advise and this Honourable Court may permit.

Documentary Evidence

3. The following documentary evidence will be used at the hearing of the application:

(a) the record to be filed by the Respondent Ministers pursuant to section 10 of the *Judicial Review Procedure Act*, R.S.O. 1990, c. J.1;

(b) Affidavit of Simon Fobister, affirmed July 30, 2015;

(c) Affidavit of Amber Ellis and David Sone, sworn August 21, 2015;

(d) Affidavit of Chief Roger Fobister, Senior, affirmed August 26, 2015;

(e) Affidavit of Joseph Fobister, affirmed August 26, 2015;

(f) Affidavit of William Fobister, Senior, affirmed July 30, 2015;

(g) Affidavit of Sherry Fobister, affirmed August 26, 2015;

(h) Affidavit of David Sone, sworn August 21, 2015;

(i) Affidavit of Dr. Richard Carignan, to be sworn, _____2015;

(j) Supplementary Affidavit of Dr. Richard Carignan, to be sworn, _____2015;

(k) Affidavit of Dr. Donna Mergler, to be sworn, _____ 2015;

(l) Affidavit of Dr. Anna Willow, to be sworn, _____, 2015;

(m) Affidavit of Dr. Justin Podur, to be sworn, _____, 2015;

(n) Such further or other material as counsel may advise and this Honourable Court may permit.

Forest Management Plan
for the
Whiskey Jack Forest
(Management Unit #490)

Ontario Ministry of Natural Resources (MNR)
Kenora District, Northwest Region

for the 10-year period from April 1, 2012 to March 31, 2022.

I hereby certify that I have prepared this forest management plan, including Silvicultural Ground Rules, to the best of my professional skill and judgement with the assistance of an interdisciplinary planning team in accordance with the requirements of the *Forest Management Planning Manual* and *the Forest Information Manual*.

_____ _____ Date: _____
R.P.F. seal Kurt Pochailo, R.P.F.
Plan Author, Ontario Ministry of Natural Resources

I recommend that this forest management plan be approved for implementation and certify that it has been prepared in accordance with the requirements of the *Forest Management Planning Manual,* the *Forest Information Manual* and relevant policies and obligations (including any relevant MNR agreements with Aboriginal peoples). I also certify that the forest management plan has been prepared using the applicable forest management guides. In this forest management plan, prescriptions that differ from specific direction or recommendations in the applicable forest management guides are identified in the attached List of Exceptions.

Certified and Recommended for Approval By:

_____ Date: _____
Deb Weedon
District Manager, Kenora District
Ontario Ministry of Natural Resources

Approved by: _____ Date: _____
Allan Willcocks
Regional Director, Northwest Region
Ontario Ministry of Natural Resources

DEC 2 2 2014

Mr. Simon Fobister
Grassy Narrows Chief
Grassy Narrows Ontario
P0X 1B0

Dear Mr. Fobister:

Thank you for your interest in the Ministry of Natural Resources and Forestry's (MNRF) proposed Whiskey Jack 2012-2022 Forest Management Plan (Whiskey Jack FMP).

On January 22, 2014, I received your request that MNRF be required to prepare an individual environmental assessment (IEA) for the Whiskey Jack FMP. I am taking this opportunity to inform you that I have decided that an IEA is not required.

Despite my not requiring an IEA be prepared, I understand that concerns were raised in the IEA request with respect to mercury. Therefore, I am imposing conditions on the Whiskey Jack FMP. These conditions will ensure that further monitoring is undertaken and compliance with the most current requirements of the Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (Stand and Site Guide) are assumed by the MNRF.

In making my decision, I have given careful consideration to Whiskey Jack FMP documentation, the provisions of Declaration Order MNR-71, referred to as MNRF's Class Environmental Assessment Approval for Forest Management on Crown Lands in Ontario (Class EA), and the issues/concerns raised in your IEA request. Your concerns together with the reasons for my decision are set out in the attached table.

The Class EA is a process by which MNRF prepares Forest Management Plans (FMPs), including evaluating alternatives, assessing environmental effects, developing mitigation measures, and consulting with the public, without having to obtain approval from me and Cabinet for each individual FMP.

The Class EA has itself been subject to review and approval under the *Environmental Assessment Act* (EAA), which determined, in part, that the application of the Class EA

process would enable proponents to meet the intent and purpose of the EAA. MNRF has demonstrated that it has planned and developed the Whiskey Jack FMP in accordance with the provisions of the Class EA. I am satisfied, therefore, that the purpose of the EAA, "the betterment of the people of the whole or any part of Ontario by providing for the protection, conservation and wise management in Ontario of the environment", has been met for the Whiskey Jack FMP.

The issues/concerns you raised were extensively reviewed. I am satisfied that the issues/concerns have been addressed by the work done to date by MNRF, or will be addressed in future work that is required to be carried out.

With this decision having been made, MNRF can now proceed with the FMP activities set out in the Whiskey Jack FMP, subject to any other permits or approvals required. MNRF must implement the activities in the manner in which they are set out in the Whiskey Jack FMP, and inclusive of all commitments made during the review of the IEA request, mitigation measures, and environmental and other provisions therein.

Again, I would like to thank you for participating in the Class EA process and for bringing your concerns to my attention.

Sincerely,

Agatha Garcia-Wright
Director
Environmental Approvals Branch

c: Mr. Allan Willcocks, Regional Director, Northwest Region, MNR
Mr. Kurt Pochailo, Management Forester, MNR
Mr. Paul Glassford, MNR Senior Advisor, Forest Class EA – Sault Ste. Marie
Mr. John Sullivan, MNR Forest EA Implementation Coordinator
EA File No. 02-07 Whiskey Jack FMP 2012-2022

Whiskey Jack Forest 2012-2022 Forest Management Plan

Ministry's Review of Issues Raised by Grassy Narrows First Nation:

Issues	Response
Clearcut logging and the construction of access roads will disturb the soil causing mercury to travel through the water system, amplifying existing contamination.	The MNRF uses the Stand and Site Guide to develop forest management plans. The Stand and Site Guide provides direction to minimize site disturbance, sediment transport and hydrologic disruption in forest management plans. These reduce the potential for existing mercury mobilization as a result of forest disturbances. The MNRF has informed the Ministry of the Environment and Climate Change (MOECC) that mobilization of mercury following forest disturbance may not be any different than that experienced during natural disturbances. The Whiskey Jack FMP will also mitigate potential adverse effects on the environment including the application of Area of Concern prescriptions, silvicultural ground rules, and best management practices for road construction activities. The MNRF is currently undertaking research to gain further understanding of the potential connection between forestry operations and mercury. This will help inform the development of guidance material used for forest management planning. The MOECC is placing a condition requiring the MNRF to implement forest management planning activities in accordance with the Whiskey Jack FMP and the Stand and Site Guide to ensure that monitoring of the environment, which includes mercury, is undertaken. In addition, a condition requiring the MNRF to follow the most current version of the Stand and Site Guide will be imposed by the MOECC to ensure that the best available guidance is being used for the development of forest management planning. A final condition will be imposed requiring the MNRF to report to the Director, Environmental Approvals Branch, what changes have been made to the Whiskey Jack FMP as a result of any updates to the Stand and Site Guide. I am satisfied that the Stand and Site Guide, used to prepare the Whiskey Jack FMP, provides a methodology to minimize potential mercury contamination in waterways following disturbances such as road construction and clearcut logging.
An increase in mercury will harm fish and terrestrial animals that eat fish, including humans, for a long time period.	The MNRF has followed scientific studies which show that increases in methylmercury concentrations in fish following clearcut operations are generally limited to cases when soils are disturbed. As mentioned above, the Stand and Site Guide provides a methodology for minimizing soil disturbance, such as operating on frozen ground. As the Whiskey Jack FMP has been developed under the provisions of the Stand and Site Guide, the MNRF will minimize soil disturbance, thus minimizing potential mercury movement and contamination in fish and

Issues	Response
	terrestrial animals. The implementation of mitigation measures that the MNRF will be using for the WJFMU, such as emulating natural disturbance patterns, harvesting only in winter on shallow soil sites and reinforcing slopes and bank, will reduce the risk of mercury contamination in animals. I am satisfied that mercury movement and potential mercury contamination in animals will be mitigated using methodologies from the Stand and Site Guide which were incorporated into the Whiskey Jack FMP.
Clearcut logging leads to an increase in mercury, whereas forest fires remove mercury.	The MNRF informed the MOECC that fire intensity is an important factor that influences mercury response. High intensity fires volatilize mercury in the organic soil layer whereas low intensity fires leave this layer undisturbed, with mercury subsequently being mobilized as water tables rise and surface runoff increases. The MNRF has stated that studies conducted by various research groups have found that the highest mercury levels in fish are from watersheds impacted by low intensity fires and lower mercury levels are in fish from watersheds with high intensity fires. The MNRF has indicated that for the 10-year planned renewal and tending operations in the WJFMU, which consists of 745,548 ha of productive forest, prescribed burns will occur during site preparation over an area of 1,069 ha. The MNRF is also planning to undertake natural regeneration which will include clearcut silvicultural system over an area of 25,631 ha. Artificial regeneration will be applied over an area of 27,839 ha and will include planting and seeding. The MNRF claims that harvesting in the WJFMU should emulate natural disturbances (i.e. forest fires). The MNRF also claims that increases in mercury due to clearcut operations would be no different than those experienced for natural occurrences. The requester is suggesting that the production of methylmercury is greater with clearcut operations versus natural forest fires. The Stand and Site Guide acknowledges that mercury dynamics will likely change within the watershed as a result of any type of forest disturbance. MNRF has concluded that the mechanism and magnitude of mercury response differs between burned and harvested watersheds but that some level of mercury response is also found following disturbance by fire. As noted previously, potential mercury movement and contamination is associated with the disruption of soils. To reduce the disruption of soils and the level of mercury movement, the MNRF will implement mitigation measures, such as emulating natural disturbance patterns, harvesting only in winter on shallow soil sites and reinforcing slopes and bank, in the WJFMU.

Issues	Response
	I am satisfied that a combination of forest disturbances will be used during the management of the Whiskey Jack FMP and will include prescribed burns.
The MNRF does not have the science and information to develop prescriptions to mitigate the effect of mercury on terrestrial or aquatic ecosystems.	The Declaration Order stipulates that MNRF shall maintain a program of scientific studies to assess the effectiveness of forest management guides. Results from these studies are used to assist MNRF in the review and revision of forest management guides. The MNRF is currently supporting research projects that are examining patterns in fish mercury bioaccumulation, evaluating the levels of mercury runoff from forest and wetland soils to aquatic systems, and examining the synthesis of land use effects (e.g., mining, hydroelectric, and forest management activities) on watershed mercury cycling and export. The MNRF states that results from its ongoing research will be used during the required periodic reviews of the Stand and Site Guide. Periodic reviews of the Stand and Site Guide are required as part of the adaptive management approach in order to evaluate and improve direction in the guide with respect to minimizing the potential adverse effects of mercury mobilization and subsequent bioaccumulation. The Stand and Site Guide includes a series of predictions or hypotheses. Those with a high degree of uncertainty have been identified as a high priority for testing through an effectiveness monitoring program. The results of the monitoring program, along with other sources of information, are used during periodic reviews of the Stand and Site Guide to ensure the most up to date information is being used when developing forest management plans. The MNRF Stand and Site Guide Background and Rationale for Direction document outlines a mercury response to forest management activities but also identifies mercury export as a priority for effectiveness monitoring. The MOECC is imposing a condition requiring MNRF to conduct monitoring in the Whiskey Jack FMP in accordance with the most current version of the Stand and Site Guide. This will help to ensure that the best available guidance is being used and current research methods to minimize the adverse effects of mercury mobilization and subsequent bioaccumulation are implemented. I am satisfied that the MNRF has prepared the Whiskey Jack FMP in accordance with its Stand and Site Guide and will be subject to any updates based on new research.

Issues	Response
The Whiskey Jack FMP does not contain requirements for ongoing monitoring of mercury levels to determine if approved forest operations will elevate mercury levels.	The MNRF's Declaration Order and the Forest Management Planning Manual contain planning requirements for the monitoring of forest management activities in a forest management plan. The requirements include providing a description of the monitoring of forest operations, with specific provisions for Areas of Concern, to ensure operations are in compliance with the forest management plan. The prevention, minimization and mitigation of the effects of forest management on the environment are addressed through the application of the appropriate guides required by Condition 38 of Declaration Order MNR-71. The development, review and revision of these guides is also mandated by this same condition of the Declaration Order, and directs the MNRF to assess the effectiveness of guides through appropriate scientific research projects and does not implicate ongoing monitoring in the context of individual forest management plans. Concerns such as those identified by the requesters are addressed during the periodic review, and potential revision, of the guides. The Stand and Site Guide acknowledges that mercury dynamics will likely change within the watershed as a result of any type of forest disturbance and that further research and monitoring is required to refine direction in the guide. The MNRF is currently considering the issue of the effects of mercury in the review of the Stand and Site Guide which is scheduled for review in the fall of 2014, with a completion date of December 31, 2015. The MOECC has also established in the Declaration Order a requirement for the formulation and implementation of a Provincial Forest Technical Committee, whose role will be to ensure that Guides are kept current with respect to scientific knowledge and management practices. The committee acts as a review board for proposed changes to existing guides and recommending priorities for new or existing guides. The MOECC is imposing a condition requiring MNRF to conduct monitoring in the Whiskey Jack FMP in accordance with the most current version of the Stand and Site Guide. This will help to ensure that the best available guidance is being used and current research methods to minimize the adverse effects of mercury mobilization are implemented. I am satisfied that the MNRF is considering the effects of mercury in the review of the Stand and Site Guide.
The MNRF did not respond to comments	The MNRF did not receive correspondence during the planning process from the Grassy Narrows First Nation regarding mercury concerns. Concerns regarding honouring the Process Agreement made between

Issues	Response
submitted by you on the mercury issue during the preparation of the Forest Management Plan.	Grassy Narrows First Nation and MNRF, amalgamating the Whiskey Jack and Kenora forests, and being kept informed during the Whiskey Jack FMP planning process were raised by Grassy Narrows First Nation in 2010. The issue of methylmercury was raised by Grassy Narrows First Nation for the first time, prior to the IEA request, in an October 24th, 2013 letter to the Premier, coinciding with Stage 4 of the forest management planning process (review of the Draft Whiskey Jack FMP). The Premier's office responded to Grassy Narrows First Nation on February 11, 2014 and stated that Ontario wanted to continue to work together. The MNRF also received a letter from Grassy Narrows First Nation on October 28, 2013; however, there was no mention of mercury. On April 17, 2014 the MNRF responded to the concerns raised in Grassy Narrows First Nation's October 28, 2013 letter. Earthroots submitted correspondence to the MNRF on October 31, 2013 stating that it was concerned with the impact of clearcutting on mercury levels in fish in local lakes and rivers. The MNRF responded to the concerns identified by Earthroots in a letter dated April 7, 2014, indicating that MNRF applied the direction in the approved Stand and Site Guide to mitigate potential adverse effects of forest management activities on the environment. A more detailed account of the consultation conducted between Grassy Narrows First Nation and the MNRF can be found in the section below. I am satisfied that the MNRF responded to comments submitted by the requesters during the preparation of the Whiskey Jack FMP.
Concerns about the failure to discharge the duty to consult in the development of the Whiskey Jack FMP.	The MNRF informed the MOECC that it followed the public and Aboriginal consultation requirements outlined in the Declaration Order and the 2009 Forest Management Planning Manual for the Whiskey Jack FMP (Phase I). At each stage in the development of the Contingency Plan and Forest Management Plan notification letters were sent to Grassy Narrows First Nation to invite participation in the Forest Management Plan process. Prior to the commencement of the formal public consultation process for the preparation of the Whiskey Jack FMP the MNRF consulted with the Grassy Narrows First Nation. In a letter dated April 20, 2009 the MNRF invited six Aboriginal communities, including Grassy Narrows First Nation, to discuss the development of a customized consultation approach for forest management planning in advance of the formal public consultation. Also in this correspondence, the MNRF offered the Aboriginal communities an opportunity to have a community

Issues	Response
	representative sit on the Forest Management Plan Planning Team and Local Citizens Committee. All of the Aboriginal communities declined the opportunity to develop a customized consultation approach and did not provide representation to the Local Citizens Committee. All of the Aboriginal communities, except for Grassy Narrows First Nation, did provide representatives for the Planning Team. The Invitation to Participate, dated February 3, 2010, was sent by MNRF to the six Aboriginal communities. Grassy Narrows First Nation responded to the invitation on March 17, 2010 in which they outlined their concerns with moving forward with the planning of the Whiskey Jack FMP without a Process Agreement in place. The MNRF responded to Grassy Narrows First Nation's letter on June 22, 2010 and stated that MNRF wanted to work together with Grassy Narrows First Nation. No other formal response was provided by the other five Aboriginal communities; however, representatives from all five communities began attending the Planning Team meetings. A letter was sent on December 14, 2011 inviting the six Aboriginal communities to review and comment on the Long Term Management Direction for the Whiskey Jack FMP. Grassy Narrows First Nation submitted a letter to the MNRF on June 13, 2012 requesting information and providing an overview of their concerns. The MNRF responded on July 6, 2012. The other five Aboriginal communities participated in meetings with the MNRF and continued to participate on the Planning Team. On January 14, 2013 the MNRF sent letters to each of the six Aboriginal communities asking if they would like an information session provided to their communities. On January 31, 2013 the MNRF sent a follow-up letter to the six Aboriginal communities announcing the MNRF's intention to hold public information centres. On April 3, 2013 the MNRF sent another letter to Grassy Narrows First Nation asking if the community would like an information session to be held. The MNRF did not receive a response from Grassy Narrows First Nation.Specific Aboriginal communities, Whitefish Bay First Nation, Wabauskang First Nation and Dalles First Nation, accepted the MNRF's offer of information sessions. An invitation to review the Draft Plan for the Whiskey Jack FMP was sent to the six Aboriginal Communities on July 30, 2013. Grassy Narrows First Nation sent a letter to the Premier of Ontario dated October 24, 2013 outlining their concerns with the undertaking and highlighting mercury concerns. The Premier's office responded on February 11, 2014 and stated that Ontario wanted to continue to work together. A letter was also submitted by Grassy Narrows First Nation

Issues	Response
	to the MNRF on October 28, 2013 and was responded to by the MNRF on April 17, 2014. Whitefish Bay First Nation was the only other Aboriginal community to respond to the MNRF's invitation to review the Draft Plan; however, due to circumstances within the community a meeting was never held. On December 23, 2013 the MNRF invited the six Aboriginal communities to inspect the final Whiskey Jack FMP. Grassy Narrows First Nation submitted an IEA request and no response was received by the MNRF from the other communities. I am satisfied that the duty to consult has been met.

AFFIDAVIT OF SIMON FOBISTER

I, SIMON FOBISTER, of Grassy Narrows, in the District of Kenora, AFFIRM AND SAY AS FOLLOWS:

1. I am one of the applicants in the within application for judicial review, and as such have knowledge of the matters hereinafter deposed to.

2. I am currently the Executive Director for Band Administration of Grassy Narrows First Nation (hereinafter "Grassy Narrows"), an applicant in the within application for judicial review, and I have been working in that capacity since 2014.

3. I am a member of Grassy Narrows and I was its elected Chief during the periods 2002-2014 and 1976-1980.

4. I reside upon property located in Grassy Narrows.

5. I fish in various lakes, streams, and waters that form part of the watershed of the English-Wabigoon river system that runs through the Whiskey Jack Forest, our traditional territory, and I eat fish that I catch from these waterways.

OVERVIEW: GRASSY NARROWS HISTORY, STATUS, AND RELATION TO WATERSHED OF ENGLISH-WABIGOON RIVER SYSTEM AND WHISKEY JACK FOREST

6. The members of Grassy Narrows are Anishinaabe (also referred to as Ojibway). Our ancestors are signatories to Treaty No. 3. I learned from elders in my community that since time immemorial our ancestors and we, their descendents, have hunted, trapped, harvested, and fished in the area that includes the watershed of the English-Wabigoon River System, in northwestern Ontario. I have attached as Exhibit "A" to my affidavit an excerpt from the trial judgment in *Keewatin v. Ontario*. The trial judgment, decided during my tenure as Chief of Grassy Narrows, recognizes our history of engaging in these traditional activities in our traditional territory and their centrality to our identity.

7. Members of Grassy Narrows live both on and off-reserve in the watershed of the English-Wabigoon river system, which flows west past Dryden, Ontario to the Manitoba border. This river system, and its watershed, which I have been taught by elders in my community have always been used and occupied by our people for traditional activities of hunting, trapping, fishing, and harvesting plants for food and medicinal purposes, as well as activities ancillary to these traditional activities, runs through the area where clearcut logging recently was authorized by the Respondents as part of a Forest Management Plan for the Whiskey Jack Forest (the "Plan") for the period 2012 to 2022.

8. I fear that clearcut logging authorized under the Plan will release mercury into the watershed, contaminate the fish we, as a people, consume from those waters, and harm our health and well-being in violation of our legal rights under section 7 and our equality rights under section 15(1) of the *Canadian Charter of Rights and Freedoms*. The history of past industrial discharges of mercury to this river system and the resulting, and on-going, health impacts to our people heighten my concern that clearcut logging will trigger new, and exacerbate existing, mercury-related health problems in the Grassy Narrows community. This is not reasonable. I am concerned that the impact will be especially severe because our community has already suffered greatly, and our capacity to endure has been stretched to its limits.

HISTORICAL BACKGROUND: INDUSTRIAL DISCHARGES OF MERCURY IN THE ENGLISH-WABIGOON RIVER SYSTEM

9. Beginning in the 1960s, a chlor-alkali plant at Dryden, Ontario began discharging mercury into the English-Wabigoon River System, eventually discharging approximately 9,000 kilograms of mercury into the river system. Once in the water, the mercury was transformed by chemical-biological processes into methyl mercury, a neurological poison capable of bio-accumulating in the food chain, being ingested by fish, and adversely impacting humans consuming methyl-mercury contaminated fish caught from area waters. The consumption of methyl mercury-contaminated fish by our people resulted over the decades in serious, and well-documented, neurological harm and other adverse health impacts, many of which continue to afflict members of my community to this day. These observations, based on government documents or peer-reviewed scientific studies, are contained in submissions Grassy Narrows and Earthroots, the latter an environmental non-governmental organization not party to this judicial review application, made to the Respondent Minister of the Environment in January 2014 in support of a request for an Individual Environmental Assessment ("IEA") of the decision of the Respondent Minister of Natural Resources in December 2013 to approve the Plan. A copy of our January 2014 letter that accompanied our submissions is attached as Exhibit "B" to my affidavit. A copy of the full submissions is attached as Exhibit "C" to the affidavit of Amber Ellis and David Sone of Earthroots.

10. Litigation, initiated by Grassy Narrows along with other First Nations during my tenure as Chief in the late 1970s, against the federal and Ontario governments and the responsible companies resulted in the mid-1980s in an out-of-court settlement and the

payment of some compensation as well as the establishment of a mercury disability board to evaluate and compensate the people of Grassy Narrows suffering from neurological and other ill-effects arising from the industrial discharges of mercury. The settlement was confirmed by federal and Ontario legislation that acknowledges that the industrial discharges of mercury to the English-Wabigoon River System, and related river systems, led to the presence of methyl mercury in these ecosystems and that it may have had and may continue to have effects in respect of the social and economic circumstances and the health of present and future members of Grassy Narrows and the other Bands that were parties to the litigation. A copy of the Ontario legislation is attached as Exhibit “C” to my affidavit. A copy of the federal legislation is attached as Exhibit “D” to my affidavit.

THE WHISKEY JACK FOREST MANAGEMENT PLAN

11. In or about February 2010 and continuing to late 2013 the Ministry of Natural Resources and Forestry (“MNRF”) gave periodic public notice of its intention to develop a forest management plan under the authority of the provincial *Crown Forest Sustainability Act* that would allow logging in the Whiskey Jack Forest over the period 2012 to 2022 and inviting participation in the process of developing the plan. The notice indicated that there are over 1.1 million hectares in the Whiskey Jack Forest, with almost 750,000 hectares considered by MNRF to be productive forest lands. Subsequent public notices inviting public participation regarding later stages in the development of what eventually became the approved Plan were issued in December 2011, January 2013, July 2013, and December 2013. A copy of the composite public notices is attached as Exhibit “E” to my affidavit.

12. Due to concerns in our community about earlier government plans to log the Whiskey Jack Forest going back to at least the late 1990s, which concerns were further heightened by the February 2010 notice, members of the Grassy Narrows community and I, as Chief at the time, communicated our concerns to the government directly and through other channels, such as the media, at least twenty times from the late 1990s to late 2013 that the sole method of harvesting trees, clearcut logging, under what eventually became the Plan, would interfere with the rights of members of our community. In particular, as we increasingly became aware of the link between clearcut logging and mercury, our fear grew with respect to the release of new sources of mercury into the region's waterways, the potential for increased methyl mercury contamination of fish, and consequent harm, or further harm, to the health and well-being of community members. These various expressions of concern over the late 1990s to 2013 were listed at pages 10-13 in Exhibit "C" to the affidavit of Amber Ellis and David Sone, referred to above.

13. I know that from an early stage of the development of the Plan, the Premier of Ontario, the Honourable Kathleen Wynne, when she was Aboriginal Affairs Minister, was aware of our concerns about clearcuts deepening the impact of mercury on our community, because she responded to these concerns in a CBC interview in June 2012. The interview is listed at page 11 of Exhibit "C", and summarized at page 11 of Exhibit "H", of the affidavit of Amber Ellis and David Sone.

14. Furthermore, in October 2013, in my capacity as Chief of Grassy Narrows at the time, I sent a letter to Premier Wynne, expressing my concern and that of the Grassy Narrows Band Council respecting the proposed Plan. In this regard, I stated in part that: “You are fully aware that our community continues to struggle with the devastating health impacts from 9,000 kg of mercury that was dumped into our river system in the 1960s with the permission of the government of Ontario. Three generations of our people bear the burden of this degenerative neurological poison. New clearcut logging will bring even more mercury into our river and our food chain, further prolonging and exacerbating this avoidable tragedy. We condemn such processes and plans”. A copy of this letter is attached as Exhibit “F” to my affidavit. The letter is also listed at page 14 of Exhibit “C” of the affidavit of Amber Ellis and David Sone.

APPROVAL OF THE PLAN

15. Despite our expressions of concern, notice of approval of the Plan under the authority of the Respondent Minister of Natural Resources was released in December 2013 as set out in Exhibit “E” of my affidavit, referred to above. The Plan, as approved, indicates that 100 per cent of the 53,471 hectares of the area to be cut over the 10-year (2012-2022) planned harvest in the Whiskey Jack Forest will be cut using clearcut logging as the tree harvesting method. A copy of a summary of the Plan indicating this at page 4 of that document is attached as Exhibit “G” to my affidavit. A copy of the full Plan is attached as Exhibit “B” to the affidavit of Amber Ellis and David Sone.

THE BUMP-UP REQUEST

16. The notice of approval of the Plan, now Exhibit "E" to my affidavit, indicated that persons objecting to the decision could apply to the Ministry of the Environment, now known as the Ministry of the Environment and Climate Change ("MOECC"), requesting a bump-up under the *Environmental Assessment Act* that would, if approved, authorize an IEA to be performed before the Plan would be allowed to go into effect.

17. Grassy Narrows and Earthroots took this opportunity and filed with MOECC a bump-up request in January 2014 seeking an IEA that would examine potential mercury impacts arising from clearcut logging authorized under the Plan. The transmittal letter respecting this request is contained in Exhibit "B" to my affidavit, and the full bump-up request is contained in Exhibit "C" to the affidavit of Amber Ellis and David Sone, mentioned and referred to above.

18. I affirm this affidavit in support of the within application for judicial review, and for no other or improper purpose.

AFFIRMED before me in the City of Toronto, in the Province of Ontario, this 30th day of July, 2015.

Joseph Castrilli
A Commissioner, etc.

Excerpts from trial judgment in *Keewatin v. Ontario (Minister of Natural Resources)*, [2011] O.J. No. 3907 (Ontario Superior Court of Justice)

[475] Lovisek gave evidence that in 1873, the Ojibway were primarily concerned about preserving their way of life, including their right to continue hunting, fishing and trapping as in the past. They valued their seasonal round, the pursuit of their livelihood through traditional harvesting. Their culture and identities were intimately connected with hunting, trapping, fishing and harvesting wild rice as their ancestors had done since time immemorial.

....

[772] The Treaty 3 Ojibway loved their lives and their country (Lovisek, November 16, 2009 at p. 39). They relished their way of life, including their seasonal round of trapping, hunting, fishing and harvesting over the breadth of their territories. They valued their customs and were not prepared to give them up....

...

[773] I accept the evidence of Lovisek...that they were prepared to embrace a Euro-Canadian presence **only** if it would be compatible with their cherished way of life, and would not cause serious interference with their hunting, fishing and trapping – central aspects of their distinctive culture central to their identity.

Ian Parrott
Director of Environmental Assessment and Approvals Branch
Ontario Ministry of Environment
2 St Clair Ave W, Floor 12A
Toronto ON M4V1L5

Dear Mr. Parrott,

Re: Request for Individual Environmental Assessment of Whiskey Jack Forest Management Plan (EBR Registry No. 010-9240)

We are writing on behalf of Grassy Narrows First Nation (Grassy Narrows) and Earthroots to request an Individual Environmental Assessment of the Whiskey Jack Forest Management Plan 2012-2022 (the logging plan) that was approved on December 23, 2013 by the Ministry of Natural Resources.

Earthroots is a grassroots environmental organization dedicated to protecting Ontario's wilderness, wildlife and watersheds through research, education and action.

Asubpeeschoseewagong Netum Anishinabek (ANA) or Grassy Narrows First Nation is an indigenous Anishinabe community located within the Treaty 3 area.

The logging plan fails to adequately deal with the impacts of logging on mercury levels in boreal water and fish. As a result the logging plan fails to protect the environment and to ensure sustainability. In particular the logging plan will harm water quality, fish habitat, wildlife, and the health of people who eat the fish. The logging plan will also impact the inherent Aboriginal and Treaty rights to fish to an extent that precludes the meaningful exercise of those rights.

These shortcomings of the logging plan are in spite of the fact that peer reviewed scientific literature has demonstrated a clear link between clearcut logging and unsafe mercury levels in fish in boreal forest watersheds. While the research in support of this literature generally was not carried out in the Whiskey Jack Forest, the boreal forest conditions examined and logging activities considered in these studies are similar, if not identical, to the conditions and activities expected in Whiskey Jack if the logging plan proceeds as approved.

This failure of the logging plan is particularly grave because of the well-known existing mercury contamination problem in the English and Wabigoon River watersheds, and the well-documented prevalence of methylmercury poisoning arising from the consumption of contaminated fish (Minamata Disease) in Asubpeeschoseewagong (Grassy Narrows) and Wabaseemoong (White Dog).

The history of local mercury contamination, and its ongoing impacts, dictates that the highest level of caution and duty of care must be applied in any action that may deepen and prolong this problem by increasing the levels of mercury in the local food chain. Failure to do so would be a failure to protect the health of the environment and the sustainability of our forests, as well as a failure to uphold the honour of the Crown.

Grassy Narrows has a number of concerns with respect to the Ministry of Natural Resources' decision to approve the Forest Management Plan. These concerns include the failure to discharge the duty to consult, the failure to properly account for treaty rights and traditional use of the land, the failure to ensure that a proper forest inventory has been used to inform the Crown's decision making process, and a concern that the level of logging is unsustainable and unjustifiably infringes our aboriginal and treaty rights. The fact that we do not raise these issues below in relation to our bump-up request should not be taken as in any way suggesting that these concerns are unimportant or will not be raised in other fora.

Grassy Narrows and Earthroots submit that the logging plan warrants a review under an Individual Environmental Assessment because:

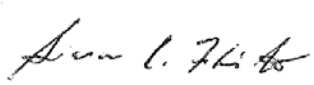
- the outstanding mercury issues (i.e., impacts upon human and ecosystem health) have not been addressed adequately, or at all, under the *Crown Forest Sustainability Act*, or in the forest management planning process, to date;
- similarly, they will not be adequately addressed in any other current or future regulatory or approvals process regarding the logging activities in Whiskey Jack Forest (e.g., in the *Lakes and Rivers Improvement Act* regarding water-crossings);
- these public interest issues raise matters of profound importance both to Grassy Narrows First Nation, and to other stakeholders and the public at large;
- to effectively and thoroughly address these issues it is necessary, as a preliminary step, for the proponent of the logging plan to prepare an Individual Environmental Assessment that fully examines (with public input) all matters listed in section 6.1(2) of the *Environmental Assessment Act*, especially in relation to:
    - the alleged purpose of, or rationale for, allowing clearcutting/logging activities to occur in Grassy Narrows Territory;
    - the alleged purpose of, or rationale for, allowing clearcutting/logging activities in close proximity to fish-bearing waterbodies within the Whiskey Jack Forest despite the risk of additional mercury contamination;
    - alternative sources of wood for the real wood supply needs of local mills;
    - alternatives to the proposed forestry activities and alternative methods of carrying out such activities;
    - the environment affected, and the environmental effects (direct, indirect, and cumulative) of the logging activities;
    - proven mitigation actions to prevent the risk of mercury contamination from logging activities; and
    - systematic evaluation of the advantages and disadvantages of the proposed activities and the alternatives.

The precise nature and scope of the foregoing factors can be developed (with public input) in the Terms of Reference which precede the preparation of the Individual Environmental Assessment. In summary, the potential mercury impacts are significant, adverse, long-lasting, and are

unresolved to date in the forest management planning process. These impacts are best addressed through a process that includes, but is not necessarily limited to, a robust Individual Environmental Assessment.

We go into more detail about the concerns of Grassy Narrows and Earthroots in the appended text. Where possible, we quote directly from peer-reviewed scientific journal articles to avoid misinterpretation of the available facts.

Sincerely,



Simon Fobister,
Grassy Narrows Chief

Amber Ellis,
Earthroots Executive Director

Bill 76

(Chapter 23
Statutes of Ontario, 1986)

An Act to implement the Terms of a Settlement of all Claims arising out of the Contamination by Mercury and other Pollutants of the English and Wabigoon and Related River Systems

The Hon. I. Scott
Attorney General

1st Reading	June 11th, 1986
2nd Reading	June 26th, 1986
3rd Reading	June 26th, 1986
Royal Assent	July 7th, 1986

Printed under authority of the Legislative Assembly by the
©Queen's Printer for Ontario

Bill 76

1986

An Act to implement the Terms of a Settlement of all Claims arising out of the Contamination by Mercury and other Pollutants of the English and Wabigoon and Related River Systems

Preamble

WHEREAS the Government of Canada, the Government of Ontario, Reed Inc., Great Lakes Forest Products Ltd., The Islington Indian Band and The Grassy Narrows Indian Band have entered into a settlement of all claims and causes of action, past, present and future, arising out of the discharge by Reed Inc. and its predecessors of mercury and other pollutants into the English and Wabigoon and related river systems and the continuing presence of any such pollutants, including the continuing but now diminishing presence of methylmercury, in the related ecosystems since its initial identification in 1969;

AND WHEREAS the discharge of such pollutants and governmental actions taken in consequence thereof may have had and may continue to have effects in respect of the social and economic circumstances and the health of the present and future members of the Bands;

AND WHEREAS the Government of Canada and the Government of Ontario have assumed certain obligations under the settlement in favour of the Bands;

AND WHEREAS the settlement provides, among other things, for the payment of certain sums to each Band, for the establishment of The Grassy Narrows and Islington Bands Mercury Disability Board, the establishment of the Grassy Narrows and Islington Bands Mercury Disability Fund, the payment of benefits to Band members and, subject to certain exceptions contained in the settlement, the abolition of all existing and future rights of action of the Bands and of every past, present or future member of the Bands, and the estates thereof, in respect of any claims and causes of action that are the subject of the settlement, in consideration of the rights and benefits set out in the settlement;

AND WHEREAS it is expedient that the Legislature give effect to and implement the terms of the settlement:

Therefore, Her Majesty, by and with the advice and consent of the Legislative Assembly of the Province of Ontario, enacts as follows:

Definitions

1. In this Act,

"administrator" means a person authorized under this Act to administer the Fund in accordance with a plan document;

"applicant" means any member or past member of a Band who makes an application or on whose behalf an application is made and lodged with the administrator, and shall be deemed to include, as if a member of a Band, a registered Indian customarily resident on a reserve before the 1st day of October, 1985;

"application" means a written application, in prescribed form, of an applicant and includes a medical report in prescribed form from an authorized physician;

"authorized physician" means a physician entitled to practice medicine in any jurisdiction in Canada or the United States of America and designated as an authorized physician by the Board;

"award" means a decision of the Board to make available a benefit to an applicant in respect of an application and includes a determination by the administrator which has not been reviewed by the Board;

"Band" means The Islington Band of Indians or The Grassy Narrows Band of Indians and "the Bands" means both of them and includes, for the purposes of sections 36 and 39, a registered Indian customarily resident on a reserve before the 1st day of October, 1985;

"Band Council" means the Council of a Band;

"benefit" means the monetary amounts paid or payable by the administrator pursuant to an award and "maximum benefit" means the maximum monetary amounts payable in accordance with the terms of the settlement;

"Board" means The Grassy Narrows and Islington Bands Mercury Disability Board established by this Act;

"certificate" means a resolution of the Council of the Band of which an applicant is a member, setting forth such matters as the Board may prescribe;

"condition" means an observable medical symptom, sign or condition, or combination of related medical symptoms, signs or conditions which,

(a) is a known condition, or

(b) has been determined by the Board to constitute a condition, on the basis that it is reasonably consistent with mercury poisoning and capable of significantly impairing the quality of life or limiting the activities of an applicant, and "known condition" means any of the conditions specified as known conditions in the settlement;

"costs of the Board" means,

(a) fees and disbursements payable to or incurred by or on behalf of the members of the Board in connection with their duties as members,

(b) the personal expenses of an applicant awarded by the Board under section 29, and

(c) the expenses incurred by the Board in consulting with professionally qualified persons under clause 6 (1) (b),

but does not include the fees and disbursements of a member who is a Band representative or of a member who is an employee of any other party to the settlement;

"depletion" means the total amount of reserves maintained by the administrator;

"disability" means a condition or combination of conditions observed by an authorized physician upon examination of an applicant;

"disbursements" means the costs of travel, accommodation, meals and communications reasonably incurred by or on behalf of members of the Board in connection with their duties as members;

"fiscal year" means the period from the 1st day of April in one year to the 31st day of March in the next year;

"Fund" means the Grassy Narrows and Islington Bands Mercury Disability Fund established by this Act;

"plan document" means the document or documents which define the responsibilities of the administrator and includes an agreement between the Board, or members of the Board, and the administrator, the schedules prescribing criteria for persons who may obtain assistance for disability and the levels of benefits, Neurological Grading Guidelines, Clinical Neurological Examination Protocol and the form of application prescribed by the Board;

"prescribed" means prescribed by the Board;

"reserve" means, as the context requires, the land set aside for the use and benefit of a Band or an amount designated by the administrator according to actuarial principles for the satisfaction of an award;

"settlement" means a settlement made in the public interest with the Bands, as set out in a Memorandum of Agreement signed by the parties thereto in the month of November, 1985, of disputes arising out of the discharge, by Reed Inc. and its predecessors, of mercury and any other pollutants into the English and Wabigoon and related river systems, and the effects which the discharge of such mercury and other pollutants and the continuing but now diminished presence of methylmercury in the related ecosystems may have had and may continue to have upon, and the concerns raised in respect of, the social and economic circumstances and the health of the present and future members of the Bands;

"undepleted balance" means the actual balance of the Fund including accrued income, less depletion.

Purpose of Act

2. The purpose of this Act is to implement, to the extent that the legislative authority of the Legislature extends thereto, the terms of a settlement, subject to certain exceptions contained therein, of all claims, whether past, present or future, arising out of the contamination by mercury and other pollutants of the English and Wabigoon and related river systems, the terms of which settlement are embodied in a Memorandum of Agreement signed by the parties thereto in the month of November, 1985, made between Her Majesty the Queen in Right of Canada as represented by the Minister of Indian Affairs and Northern Development, Her Majesty the Queen in Right of the Province of Ontario, Reed Inc., Great Lakes Forest Products Ltd., The Islington Indian Band and The Grassy Narrows Indian Band.

Board established

3.—(1) A board to be known as "The Grassy Narrows and Islington Bands Mercury Disability Board" is hereby established.

Composition of Board

(2) The Board shall consist of seven members, composed of a chairman and,

(a) two members, one of whom is a representative of one Band and one of whom is a representative of the other Band;

(b) two members, each of whom is a duly qualified physician; and

(c) two members who are not representatives or members of either Band or duly qualified physicians.

Appointment of Board members

4.—(1) The chairman and other members of the Board shall be appointed by a search committee, constituted in accordance with the terms of the settlement, on such terms and conditions as the search committee agrees upon with each Board member.

Appointments or replacements to be unanimous

(2) The chairman and other members of the Board may be replaced from time to time by the search committee, and every appointment or replacement must be the unanimous decision of the search committee and shall be certified in writing by each member of the committee.

Costs of the Board

(3) Pursuant to the settlement, Canada, Ontario, The Islington Indian Band and The Grassy Narrows Indian Band shall each pay 25 per cent of the costs of the Board.

Level of disbursements

(4) Disbursements of the Board or of members of the Board, as the case may be, shall generally be in accordance with the levels from time to time in effect in respect of employees of Ontario.

Collection of costs of Board by administrator

(5) The administrator shall, in accordance with the procedures prescribed by the regulations made under this Act,

(a) collect the costs of the Board from time to time from the parties liable therefor; and

(b) pay the moneys when received to the persons entitled thereto.

Liability of Board

(6) Neither the Board nor any member thereof is liable for any act done or decision made in good faith in relation to any aspect of its proceedings.

Panel for decision of Board

5. The chairman, the two Band representatives and two other members, designated for the purpose by the chairman, constitute a panel of the Board and are sufficient for the exercise of all the jurisdiction and powers of the Board in connection with the making of a decision by the Board.

Powers of Board

6.—(1) The Board may,

(a) consult with and obtain the assistance of any official of the Government of Canada or of Ontario who is able to provide information, advice or assistance to the Board in respect of public health, public health education or any government programs that the Board considers may touch upon the matter of mercury poisoning;

(b) consult with such professionally qualified persons as the Board considers necessary;

(c) make such recommendations as the Board considers appropriate to the Bands or to any minister of the Government of Canada or Ontario;

(d) amend the plan document in accordance with subsection 22 (1);

(e) amend, or with the consent of the Attorney General of Ontario, terminate an agreement with an administrator and enter into an agreement with another administrator;

(f) have regard to the terms of the settlement for the purpose of interpreting and giving effect to this Act,

and shall,

(g) supervise the administration of the Fund and make awards or supervise the making of awards by the administrator in accordance with this Act; and

(h) designate from time to time as authorized physicians two or more physicians that the Board considers,

(i) have expert knowledge in respect of conditions consistent with methylmercury poisoning, and

(ii) will be available and may be required for the purpose of providing medical reports in respect of applicants.

(2) The Board may, Idem

(a) prescribe the form of an application;

(b) prescribe the contents of an affidavit that is to accompany an application;

(c) prescribe the matters that are to be included in a certificate;

(d) prescribe the form of medical report to be submitted with an application;

(e) prescribe any other matter or thing that by this Act is to be or may be prescribed.

(3) The Board may, in its discretion, make an award that takes effect on a day not earlier than the day the application relating to the award was made. Retroactive application of award

7. Where the Board considers that, after the date of the settlement, Where conduct of applicant to be considered by Board

(a) the conduct of an applicant has contributed and is contributing to the continuation or exacerbation of a disability;

(b) the applicant at the time of the conduct had an understanding of its possible effects; and

(c) the conduct occurred under circumstances where the applicant knew or ought to have known that a practical alternative form of conduct without significant disadvantage was available,

the Board,

(d) shall consider the conduct in making or reviewing an award and may establish or vary conditions in the award; and

(e) may, where there are clear clinical grounds for concluding that the conduct has contributed to the continuation or exacerbation of the disability or where the Board finds that any condition attached to an award under clause (d) has been disregarded, make

or vary an award to provide a benefit in such lesser amount than would otherwise be provided as the Board considers appropriate.

Fund to be established

8.—(1) There shall be established and maintained a fund to be known as the Grassy Narrows and Islington Bands Mercury Disability Fund into which shall be deposited by each Band the sum of money set out in the settlement.

Agreement between Board and administrator

(2) The Board shall make use of the services of an administrator in the investment, management and administration of the Fund and shall, subject to the approval of the Attorney General of Ontario, enter into such agreement or agreements with any person as the Board considers necessary for that purpose.

Gifts or bequests

(3) The administrator may,

(a) accept and administer as part of the Fund any unconditional gift or bequest from any person; and

(b) with the approval of the Board, accept and administer in accordance with the conditions attached thereto, any conditional gift or bequest from any person.

When Board not to approve acceptance of gift or bequest

(4) The Board shall not approve the acceptance of any conditional gift or bequest if the Board considers that the conditions attached thereto are not consistent with the objects of this Act or the administration of the Fund.

Income forms part of Fund

(5) The income of the Fund shall form part of the Fund.

Benefits paid out of Fund

(6) Every benefit paid by the administrator under the authority of this Act shall be paid out of the Fund.

Fees and expenses of administrator

(7) The fees and approved expenses of the administrator as provided for in the plan document shall be paid out of the Fund.

Reserves

(8) The administrator shall, in respect of each award, set aside and maintain a reserve, determined and revised from time to time in accordance with actuarial principles, in the amount estimated to be required, together with the income thereon, to provide for the payment of benefits under the award.

When undepleted balance is less than $100,000

(9) In the event that the undepleted balance is less than $100,000 at any time, the administrator shall thereupon give notice thereof in writing to the Bands, the Treasurer of

Ontario and the Board and thereupon the Treasurer shall from time to time as required deposit to the Fund out of the Consolidated Revenue Fund such amount of money as is required to raise the undepleted balance to not less than $100,000.

Audit of Fund

(10) The administrator shall provide for an audit of the Fund annually and at the end of each fiscal year shall provide a copy of the auditor's report to the Bands, the Attorney General of Ontario, the Treasurer of Ontario and the Board.

Application for assistance

9. An applicant may, at any time before the Fund is closed, submit an application in the prescribed form for assistance from the Fund in respect of disability which the applicant believes is caused by mercury poisoning.

Material to accompany application

10. An application shall be accompanied by,

(a) an affidavit of the applicant setting out the matters prescribed;

(b) in respect of the conditions manifested in the disability, a medical report from an authorized physician;

(c) a certificate of the Council of the Band of which the applicant is a member setting out such matters as the Board prescribes; and

(d) such other material as the Board prescribes.

Submission of application to administrator

11. Every application shall be submitted to the administrator and, in the event that an application is submitted by an applicant to the Board or to a member of the Board, the Board or the member shall forthwith transmit the application to the administrator.

Application to be in prescribed form

12. The administrator shall determine whether each application is in the prescribed form and, if it is not, shall provide written notice to the applicant setting out the deficiencies.

Corrections

13. Any deficiencies may be corrected without resubmission of the entire application.

Duties of administrator on receipt of application

14. Upon receipt of an application in the prescribed form, the administrator shall, within twenty-one days,

(a) if the application qualifies in accordance with the plan document and is accompanied by the material set out in section 10, subject to clause (c), advise

the applicant and the Board in writing that the application is accepted and specify the benefit payable in accordance with the plan document;

(b) if the application does not appear to the administrator to qualify in accordance with the plan document or is not accompanied by the material set out in section 10, advise the applicant and the Board in writing of the reason it does not appear to qualify; or

(c) if unable to determine whether the application qualifies, or what is the benefit payable, in accordance with the plan document, or if the administrator believes that there is any reason for the application to be considered by the Board, transmit the application to the Board together with such questions for the Board's decision as the administrator considers appropriate, and advise the applicant in writing that the application has been transmitted to the Board.

Provision of interim benefits to applicant

15. When an application is transmitted to the Board under clause 14 (c), the administrator may, with the consent of the chairman, provide such benefit to the applicant as the administrator considers appropriate pending a decision from the Board and, in the event that the Board subsequently decides that an award should not be made or that a lower benefit should be provided, the amounts or the excess amounts which have been provided shall not be recovered from the applicant.

Where Board required to review decision

16. An applicant or the Board or any member of the Board may, at any time after a determination by the administrator under clause 14 (a) or (b), by notice in writing to the Board or to the applicant or to the Board and the applicant respectively, require that the decision of the administrator be reviewed.

Powers of Board

17. The Board shall, at its next meeting, or in any event within four months or, if more than two years after the coming into force of this Act, eight months after receipt of an application under clause 14 (c) or of notice under section 16, review the application and,

(a) approve the application and make or confirm or vary an award; or

(b) reject the application.

Provision of benefits

18. When an application is subject to review under section 16, the administrator shall, pending receipt of the Board's decision, provide a benefit, or not, in accordance with the

determination made under section 14 and, if the determination is varied by the award of the Board, the administrator shall not give retroactive effect to the award unless expressly so directed by the Board's decision.

Chairman to certify decision of Board

19. The chairman shall set forth and certify in writing every decision of the Board and shall incorporate in the decision the answer of the Board to any question submitted by the administrator under clause 14 (c), and shall provide a copy of the decision to the applicant and to the administrator.

Review by Board

20. The Board may in its sole discretion, at any time after giving notice to the applicant, on its own motion or upon request from an applicant or any member of the Board or the Attorney General of Ontario, review and vary any award.

Decision final

21.—(1) The Board has exclusive jurisdiction to exercise the powers conferred upon it by this Act and to determine all questions of fact and law that arise in any matter before it and, subject to sections 20 and 23, every decision of the Board is final and binding and is not subject to review and, subject to this Act, shall be given effect by the administrator.

Non-application of R.S.O. 1980, c. 484

(2) The *Statutory Powers Procedure Act* does not apply to the Board in its exercise of a statutory power of decision under this Act.

Consent required to amend plan document

22.—(1) The Board shall not amend the plan document, except as provided for in subsection (2), without the consent of the Attorney General of Ontario, the Minister of Indian and Northern Affairs, Canada and the Band Councils.

Addition of further conditions to plan document

(2) The Board may add any further condition to the plan document and assign points in respect of such condition in conformity with the distribution of points then in effect for other conditions.

Award to be based on nature and extent of disability

(3) Notwithstanding anything in this Act, the Board shall make or confirm or vary each award in such amount as it considers appropriate, having regard to the nature and extent of an applicant's disability, but shall not make any award in an amount greater than the maximum benefit.

Procedure

23. The Board shall establish its own procedure including, without limitation, the location of its meetings, and any applicant aggrieved by the procedure, even where the procedure prescribed by this Act has been followed, may request the Board to review an award under section 20.

Evidence

24.—(1) The Board may make any decision without hearing any evidence but may, in its sole discretion, hear evidence under oath and every member of the Board may examine or cross-examine any person.

Applicant may be heard

(2) Any applicant may appear and be heard at any meeting of the Board at which his or her application or award is to be considered or reviewed, and the Board shall provide notice to each applicant accordingly.

Examination of persons

25. No person other than a member of the Board may, except to the extent permitted by the Board in its sole discretion, examine or cross-examine any person at any meeting of the Board.

Report to be considered

26. The Board shall consider, in respect of each condition manifested in the disability, the medical report of an authorized physician before making an award.

What Board may consider

27. The Board shall consider any information, advice, report, evidence or other material or matter which, in its sole discretion, it deems useful for the purpose of deciding any matter including whether it may be appropriate to make or vary any award or awards, and may hear or, subject to subsection 24 (2), not hear any person.

No costs

28. The Board shall not award costs of any application.

Personal expenses

29. The Board may, in its sole discretion, direct payment of all or part of the personal expenses of an applicant in connection with an application, whether or not the Board makes an award.

Quorum

30.—(1) The quorum of the Board shall be four of the panel established under section 5 and the decision of three or more members of the panel is the decision of the Board, and where a decision is not concurred in by three or more members of the Board,

(a) in the case of a review brought under section 16, the decision of the administrator shall be deemed to be confirmed; and

(b) in the case of an application transmitted under clause 14 (c), the application shall be deemed to be rejected.

Use of telecommunications

(2) The Board may, with the consent of the members of the panel established under section 5 and, where applicable, of an applicant, conduct any meeting or make any decision by tele-

communications without the members being physically present in the same place.

Five members only to participate in decision

(3) Other than for the purposes of section 32 and subject to subsection (4) of this section, not more than five members shall participate in any decision of the Board.

Exception

(4) Notwithstanding section 5, the chairman may, if the nature of any decision appears to justify the consequent cost, establish a panel of all members of the Board, in which event the quorum shall be six and the decision of four or more members is the decision of the Board, and where a decision is not concurred in by four or more members of the Board,

(a) in the case of a review brought under section 16, the decision of the administrator shall be deemed to be confirmed; and

(b) in the case of an application transmitted under clause 14 (c), the application shall be deemed to be rejected.

Assistance to applicant by Board member

31. Any member of the Board may assist an applicant in the preparation or submission of an application to the administrator or before the Board and shall not, by reason thereof, be disqualified from participating in the decision of the Board.

Termination of Fund

32.—(1) The Fund may be terminated and closed by the Board after the expiry of three consecutive years from the date of the last award or variation of an award, but in any event not sooner than the 1st day of January, 2001, and with the consent of at least six members of the Board.

Report of Board

(2) The Board shall, before consenting to the Fund being closed, provide to the Minister of Indian and Northern Affairs, Canada, the Attorney General of Ontario and each of the Bands a report in respect of the efficacy of the Fund in achieving the objects of this Act.

Duty of administrator

(3) Upon the Board consenting to the Fund being closed,

(a) the administrator shall, if then possible, purchase from the balance of the Fund for every applicant then in receipt of a benefit a life annuity in the amount of the annual benefit or, if not then possible, do so as soon as it becomes possible, and thereupon advise the Board that the Fund is closed; and

(b) the administrator shall thereupon pay, to the extent of any balance of the Fund remaining, first to the

Treasurer of Ontario the total of any amounts paid by the Treasurer under subsection 8 (9), and then to each Band one-half of any balance remaining.

Board dissolved

(4) Upon the acceptance by the Attorney General of Ontario of the report provided for in subsection (2) and completion of the payments by the administrator provided for in subsection (3), the Board shall be dissolved.

Indemnification of Treasurer of Ontario

33. The Treasurer of Ontario shall be deemed to be and hereafter continue to be indemnified by each of the Bands, to the extent of any amounts paid to each Band under clause 32 (3) (b) together with interest calculated on such payments at a rate equal to the Consumer Price Index for Canada published by Statistics Canada, against liability for any claim by a person who would have been eligible to be an applicant but for the termination of the Fund brought against any party to the settlement in respect of the matters contemplated by the settlement.

Reciprocal legislation by Canada

34. This Act is enacted in contemplation of a reciprocal enactment by the Parliament of Canada for the purpose of giving effect in part to the settlement, and shall be construed accordingly.

Effect of Act

35. This Act shall have force and effect only to the extent that it is within the legislative jurisdiction of the Legislature.

Benefits not treated as income for purposes of other Acts

36.—(1) Notwithstanding any other Act of the Legislature, the benefits paid or payable to a member of a Band under the terms of the settlement shall not be considered or treated as income for the purposes of any other Act of the Legislature and no payment to which that member is entitled under any other Act of the Legislature shall be reduced by reason of the payment or availability of benefits to that member under the terms of the settlement.

Availability of programs or services not diminished

(2) The moneys paid to the Bands in accordance with the settlement and the benefits paid from the Fund to members of the Bands shall be considered as additional to any applicable program or service offered by the Government of Ontario, and the availability to the Bands and the members thereof of such program or service shall not be diminished by reason of the moneys paid under the settlement or the benefits paid from the Fund.

Insured services under R.S.O. 1980, c. 197

37. Every examination, service, test or report provided by, or at the direction of, an authorized physician in respect of an applicant in accordance with a requirement of the plan

document, the administrator or the Board shall be deemed to be an insured service under the *Health Insurance Act*.

Representative action

38. For greater certainty, Ontario Supreme Court Action Number 14716/77 (Judicial District of York) shall be deemed to be a representative action, and its disposition in accordance with the settlement shall not be called into question in any court.

Existing and future rights of action abolished

39. All existing and future rights of action of the Bands and of every past, existing or future member of the Bands, and the estates thereof, in respect of claims and causes of action which are the subject of the settlement are, in consideration of and pursuant to the settlement, abolished.

Limitation on liability in respect of claims

40.—(1) The total liability in respect of any claim by a past, present or future member of a Band or a registered Indian customarily resident on a reserve before the 1st day of October, 1985, brought against any party to the settlement in respect of matters contemplated by the settlement, whether brought before or after the Fund is closed, shall be not more than the cost, at the time of the claim, of a life annuity in the amount of the annual maximum benefit payable from the Fund at the time the claim was brought or immediately prior to the Fund being closed, as the case may be.

Does not contemplate claims may be brought

(2) Section 33 and this section shall not be deemed to contemplate that any claim described in section 33, notwithstanding the other provisions of this Act, may be brought or maintained.

Settlement entire

41. The settlement is entire and the consideration flowing to the Bands and their present and future members therefrom shall be deemed to flow to every such member, and the settlement shall not be deemed to be divided between the Bands and their present and future members by this Act or anything done under the authority of this Act.

Regulations

42. The Lieutenant Governor in Council may make regulations prescribing, for the purposes of subsection 4 (5), the procedures to be followed in the collection of the costs of the Board and in the payment of the moneys received to the persons entitled thereto.

Moneys

43. The moneys required to be paid by Ontario in accordance with the terms of the settlement, including the payment of interest thereon where provided for in the settlement at the rate of 8.52 per cent per annum compounded annually from the 15th day of October, 1985, shall be paid out of the Consolidated Revenue Fund.

Commencement

44. This Act comes into force on a day to be named by proclamation of the Lieutenant Governor.

Short title

45. The short title of this Act is the *English and Wabigoon River Systems Mercury Contamination Settlement Agreement Act, 1986*.

CHAPTER 23

CHAPITRE 23

An Act to approve, give effect to and declare valid certain agreements between the Government of Canada, the Government of Ontario, Reed Inc., Great Lakes Forest Products Ltd., the Islington Indian Band and the Grassy Narrows Indian Band

Loi approuvant, mettant en oeuvre et déclarant valides certaines conventions entre le gouvernement du Canada, le gouvernement de l'Ontario, Reed Inc., Great Lakes Forest Products Ltd., la bande indienne d'Islington et la bande indienne de Grassy Narrows

[*Assented to 17th June, 1986*]

[*Sanctionnée le 17 juin 1986*]

Preamble

WHEREAS the Government of Canada, the Government of Ontario, Reed Inc., Great Lakes Forest Products Ltd., the Islington Indian Band and the Grassy Narrows Indian Band have entered into an Agreement for the settlement of all claims and causes of action, past, present and future, arising out of the discharge by Reed Inc. and its predecessors of mercury and other pollutants into the English and Wabigoon and related river systems and the continuing presence of any such pollutants, including the continuing but now diminishing presence of methylmercury in the related ecosystems since its initial identification in 1969;

AND WHEREAS the discharge of such pollutants and governmental actions taken in consequence thereof may have had and may continue to have effects in respect of the social and economic circumstances and the health of the present and future members of the Bands;

AND WHEREAS the Government of Canada and the Government of Ontario have assumed certain obligations under the Agreement in favour of the Bands;

AND WHEREAS the Agreement provides, among other things, for the payment of certain sums to each Band, the establish-

Préambule

ATTENDU QUE le gouvernement du Canada, le gouvernement de l'Ontario, Reed Inc., Great Lakes Forest Products Ltd., la bande indienne d'Islington et la bande indienne de Grassy Narrows sont convenus de régler toute revendication et tout droit d'action, passés, présents et futurs, découlant du déversement, par Reed Inc. et ses prédécesseurs, de mercure et de tout autre polluant dans le réseau hydrographique English-Wabigoon, y compris tant la présence continue de ces polluants que la présence continue mais en voie de diminution de mercure méthylé dans les écosystèmes connexes depuis qu'on a constaté sa présence en 1969;

ATTENDU QUE le déversement de ces polluants et les mesures gouvernementales prises à cet égard peuvent avoir eu et continuer d'avoir des incidences en ce qui touche la conjoncture économique et sociale, ainsi que la santé, des membres actuels et futurs des bandes en question;

ATTENDU QUE le gouvernement du Canada et le gouvernement de l'Ontario ont, aux termes de la Convention, contracté certaines obligations à l'égard des bandes en question;

ATTENDU QUE la Convention prévoit, notamment, le paiement de certaines sommes à chacune des bandes en question, la consti-

ment of the Grassy Narrows and Islington Bands Mercury Disability Board, the establishment of the Grassy Narrows and Islington Bands Mercury Disability Fund, the payment of benefits to Band members and, subject to certain exceptions contained in the Agreement, the abolition of all existing and future rights of action of the Bands and of every past, present or future member of the Bands, and the estates thereof, in respect of any claims and causes of action that are the subject of the Agreement, in consideration of the rights, privileges and benefits set out in the Agreement;

AND WHEREAS the Government of Canada and the Government of Ontario are obligated, pursuant to section 2.1 of the Agreement, to recommend to Parliament and the Legislature of Ontario, respectively, special legislation to give effect to the Agreement;

NOW, THEREFORE, Her Majesty, by and with the advice and consent of the Senate and House of Commons of Canada, enacts as follows:

SHORT TITLE

Short title

1. This Act may be cited as the *Grassy Narrows and Islington Indian Bands Mercury Pollution Claims Settlement Act*.

INTERPRETATION

Definitions

2. (1) In this Act,

"Agreement" «*Convention*"

"Agreement" means the Memorandum of Agreement between Her Majesty the Queen in Right of Canada as represented by the Minister of Indian Affairs and Northern Development, Her Majesty the Queen in Right of the Province of Ontario, Reed Inc., Great Lakes Forest Products Ltd., the Islington Indian Band and the Grassy Narrows Indian Band, signed by each party thereto in the month of Novem-

tution du Conseil chargé d'apporter de l'aide aux membres des bandes indiennes de Grassy Narrows et d'Islington souffrant d'incapacité due à la pollution au mercure, la création du fonds d'aide aux membres des bandes de Grassy Narrows et d'Islington souffrant d'incapacité due à la pollution au mercure, le paiement d'indemnités aux membres de ces bandes et, sous réserve de certaines exceptions que stipule la Convention, l'annulation de tous les droits d'action présents et futurs de ces bandes, de leurs membres, anciens, actuels ou futurs, ainsi que de leur succession, à l'égard des revendications et des droits d'action qui font l'objet de la Convention et en contrepartie des droits, privilèges et avantages qu'elle prévoit;

ATTENDU QUE le gouvernement du Canada et le gouvernement de l'Ontario se sont, en application de l'article 2.1 de la Convention, engagés à recommander au Parlement et à la Législature de l'Ontario, selon le cas, l'adoption de lois spéciales visant à mettre en oeuvre la Convention en vigueur,

SA MAJESTÉ, sur l'avis et avec le consentement du Sénat et de la Chambre des communes du Canada, décrète :

TITRE ABRÉGÉ

Titre abrégé

1. *Loi sur le règlement des revendications des bandes indiennes de Grassy Narrows et d'Islington (pollution par le mercure).*

DÉFINITIONS

Définitions

2. (1) Les définitions qui suivent s'appliquent à la présente loi.

«bande» La bande indienne d'Islington ou la bande indienne de Grassy Narrows.

«bande» "*Band*"

«biens mobiliers» S'entend des biens personnels visés à la *Loi sur les Indiens*.

«biens mobiliers» *French version only*

«contrat de mise en main tierce» Le contrat de mise en main tierce daté du 16 décembre 1985, conclu entre Great Lakes Forest

ber, 1985, tabled in the House of Commons by the Minister of Indian Affairs and Northern Development on May 21, 1986 and recorded as document number 331-7/43, as amended by the Escrow Agreement;

"Band" «*bande*»

"Band" means the Islington Indian Band or the Grassy Narrows Indian Band;

"Escrow Agreement" «*contrat de mise en main tierce*»

"Escrow Agreement" means the Escrow Agreement between Great Lakes Forest Products Limited, Her Majesty the Queen in Right of the Province of Ontario, Reed Inc. and National Trust Company, the terms of which were approved of and consented to by the Grassy Narrows Indian Band and Islington Indian Band and by Her Majesty the Queen in Right of Canada as represented by the Minister of Indian Affairs and Northern Development, dated as of the 16th day of December, 1985, tabled in the House of Commons by the Minister of Indian Affairs and Northern Development on May 21, 1986 and recorded as document number 331-7/43.

Products Limited, Sa Majesté la Reine du chef de la province d'Ontario, Reed Inc. et National Trust Company, lequel a fait l'objet de l'approbation et de l'assentiment de la bande indienne de Grassy Narrows, de la bande indienne d'Islington et de Sa Majesté la Reine du chef du Canada représentée par le ministre des Affaires indiennes et du Nord canadien, et déposé devant la Chambre des communes par le ministre des Affaires indiennes et du Nord canadien le 21 mai 1986 sous le numéro d'enregistrement 331-7/43.

«Convention» "*Agreement*"

«Convention» Le protocole d'entente conclu entre Sa Majesté la Reine du chef du Canada représentée par le ministre des Affaires indiennes et du Nord canadien, Sa Majesté la Reine du chef de la province d'Ontario, Reed Inc., Great Lakes Forest Products Ltd., la bande indienne d'Islington et la bande indienne de Grassy Narrows, signé par chacune des parties au cours du mois de novembre 1985 et déposé devant la Chambre des communes par le ministre des Affaires indiennes et du Nord canadien le 21 mai 1986 sous le numéro d'enregistrement 331-7/43, compte tenu des modifications apportées par le contrat de mise en main tierce.

Registered Indian deemed member of Band

(2) Any person registered as an Indian pursuant to the *Indian Act* who was customarily resident on a reserve of a Band before October 1, 1985 and who, pursuant to paragraph 1(*b*) of Schedule A to the Agreement, is deemed to be an applicant within the meaning of that paragraph shall, for the purposes of this Act, be deemed to be a member of the Band.

Présomption d'appartenance à la bande

(2) La personne qui, résidant habituellement dans une réserve de la bande avant le 1er octobre 1985, est un Indien inscrit au sens de la *Loi sur les Indiens* et qui, conformément à l'alinéa 1*b*) de l'annexe A de la Convention, est réputée être un requérant au sens de cet alinéa est, pour l'application de la présente loi, réputée être un membre de la bande.

AGREEMENT

CONVENTION

Agreement approved

3. (1) The Agreement is hereby approved, given effect and declared valid.

Approbation

3. (1) La Convention est approuvée, mise en oeuvre et déclarée valide.

Conferral of rights, privileges and benefits

(2) On the abolition of all rights of action referred to in subsection (3), the beneficiaries under the Agreement shall have the rights, privileges and benefits set out in the Agreement.

Octroi de droits, privilèges et avantages

(2) Les bénéficiaires visés par la Convention ont, à compter de l'annulation des droits d'action visés au paragraphe (3), les droits, privilèges et avantages qu'elle prévoit.

Abolition of rights of action

(3) Except as provided in sections 1.16 and 2.3 of the Agreement, all existing and future rights of action of a Band and of every past,

Annulation des droits d'action

(3) Sauf disposition contraire des articles 1.16 et 2.3 de la Convention, est annulé tout droit d'action présent et futur de la bande, de

present and future member of a Band, and of the estates thereof, in respect of any of the claims or causes of action that are the subject of the Agreement are hereby abolished.

ses membres, anciens, actuels ou futurs, ainsi que de leur succession, à l'égard des revendications et des droits d'action qui font l'objet de la Convention.

Exception to *Indian Act*

4. (1) Subject to subsection (2), for the purposes of subsection 90(1) of the *Indian Act*,

(*a*) all moneys paid or payable to a Band pursuant to the Agreement, and any personal property purchased by the Band therewith,

(*b*) all moneys paid at the discretion of a Band in accordance with the Agreement to a trust or corporation, and any personal property purchased by the trust or corporation therewith, and

(*c*) any real or personal property purchased by a Band or by a trust or corporation for the purpose of giving effect to section 2.5 of the Agreement,

shall be deemed to be personal property that was given to the Band under an agreement between the Band and Her Majesty but subsections 90(2) and (3) of the *Indian Act* shall not apply with respect thereto.

Loi sur les Indiens : exception

4. (1) Sous réserve du paragraphe (2) et pour l'application du paragraphe 90(1) de la *Loi sur les Indiens*, sont réputés être des biens mobiliers donnés à la bande aux termes d'une convention conclue entre la bande et Sa Majesté :

a) les sommes payées ou payables à la bande conformément à la Convention, de même que les biens mobiliers que la bande a achetés avec ces sommes;

b) les sommes que la bande, à sa discrétion, verse à une fiducie ou à une personne morale conformément à la Convention, de même que les biens mobiliers que la fiducie ou la personne morale a achetés avec ces sommes;

c) les biens immobiliers ou les biens mobiliers achetés par la bande, une fiducie ou une personne morale afin de mettre en oeuvre l'article 2.5 de la Convention.

Toutefois, les paragraphes 90(2) et (3) de la *Loi sur les Indiens* ne s'y appliquent pas.

Idem

(2) Subsection 89(1) of the *Indian Act* or any enactment of Parliament to the like effect shall not apply

(*a*) in respect of any real or personal property referred to in paragraph (1)(*c*); or

(*b*) for the purposes of paragraph 41(a) of Schedule A to the Agreement, in respect of any amount paid pursuant to subparagraph 40(*c*)(ii) of Schedule A to the Agreement or pursuant to any enactment of the Legislature of Ontario that implements that subparagraph or in respect of any personal property purchased by a Band therewith.

Idem

(2) Ni le paragraphe 89(1) de la *Loi sur les Indiens*, ni les autres dispositions législatives du Parlement ayant un effet semblable ne s'appliquent :

a) aux biens immobiliers ou aux biens mobiliers visés à l'alinéa (1)*c*);

b) en ce qui concerne l'alinéa 41*a*) de l'annexe A de la Convention, aux sommes payées conformément au sous-alinéa 40*c*)(ii) de l'annexe A de la Convention ou conformément aux dispositions législatives de la Législature de l'Ontario destinées à mettre ce sous-alinéa en oeuvre, ainsi qu'aux biens mobiliers que la bande a achetés avec ces sommes.

Exception to *Canada Health Act*

5. Every examination, service, test or report made or provided by a medical practitioner in respect of a member of a Band pursuant to the Agreement shall be deemed for the purposes of the *Canada Health Act* to be an insured health service provided under the health care insurance plan of the Province of Ontario.

Loi canadienne sur la santé : exception

5. Les examens, services, tests et rapports faits ou fournis, selon le cas, par un médecin à l'égard des membres de la bande conformément à la Convention sont réputés, pour l'application de la *Loi canadienne sur la santé*, être des services de santé assurés fournis en application du régime d'assurance-santé de la province d'Ontario.

Benefits not to be treated as income

6. (1) The benefits paid or payable to a member of a Band pursuant to the Agreement shall not be treated as income of that member for the purposes of any other Act of Parliament.

Government programs to continue

(2) No payment or service to which a Band or any member of a Band is entitled under any other Act of Parliament or under any program of the Government of Canada shall be reduced or diminished by reason of the payment or availability of benefits to the Band or any member of the Band pursuant to the Agreement.

REGULATIONS

Regulations

7. The Governor in Council may make such regulations as are necessary for the purpose of carrying out the Agreement or for giving effect to any of the provisions thereof.

APPROPRIATION

Payments out of C.R.F.

8. There shall be paid out of the Consolidated Revenue Fund such sums as may be required to meet the monetary obligations of Canada under the Agreement.

COMING INTO FORCE

Coming into force

9. This Act shall come into force on a day to be fixed by proclamation.

Indemnités et revenus des bénéficiaires

6. (1) Les indemnités payées ou payables aux membres de la bande conformément à la Convention ne constituent pas des revenus de ces membres pour l'application de toute autre loi fédérale.

Maintien des programmes gouvernementaux

(2) Le paiement ou la possibilité de paiement d'indemnités à la bande ou à ses membres conformément à la Convention n'a pas pour effet de réduire ou de diminuer les paiements ou services auxquels la bande ou ses membres ont droit en application d'une autre loi fédérale ou d'un programme du gouvernement canadien.

RÈGLEMENTS

Règlements

7. Le gouverneur en conseil peut prendre les règlements nécessaires à l'application de la Convention ou de telle de ses dispositions.

Paiements sur le F.R.C.

8. Les sommes nécessaires au gouvernement du Canada pour s'acquitter des obligations financières que lui impose la Convention sont prélevées sur le Fonds du revenu consolidé.

ENTRÉE EN VIGUEUR

Entrée en vigueur

9. La présente loi entre en vigueur à la date fixée par proclamation.

This notice is for your information. The Environmental Bill of Rights does not require this notice to be placed on the Environmental Registry, however, section 6 of the Act does allow the Environmental Registry to be used to share information about the environment with the public.

Rationale for Exemption to Public Comment:

This proposal is considered to be a proposal for an instrument under the EBR; however, it is not prescribed by Ontario Regulation 681/94 as a classified proposal for purposes of the EBR. Therefore, MNR is not required to post this proposal on the Environmental Registry.

MNR is voluntarily posting this Notice on the Environmental Registry for information purposes to advise interested parties of the formal public consultation opportunities for this proposal in accordance with the requirements of the Forest Management Planning Manual (FMPM). To participate in that consultation process, the public is invited to submit comments to the contact person identified in this notice.

No formal comment period is established under the EBR through this notice.

Description:

The Whiskey Jack Forest is located Northwestern Ontario, with area in both the Ministry of Natural Resources Administrative Districts of Kenora and Red Lake. The Kenora District office takes the lead role coordinating the administrative and planning activities associated with this forest, including the review of the forest management plan.

Of the over 1.1 million hectares in this forest, almost 750,000 are considered productive forestlands. These productive forestlands can be found in both of the Hill's site regions represented in the Whiskey Jack forest. These include Site Region 5-S which corresponds to the northern limit of the Great Lakes- St. Lawrence Forest and Site Region 4-S which is dominated by Boreal Forest conditions.

Additional Information:

The following government offices have additional information regarding this Notice. To arrange a viewing of these documents please call the Ministry Contact or the Office listed below.

Kenora District
808 Robertson Street
PO Box 5080
Kenora Ontario

Predominant tree species found in this area include jack pine, black spruce, poplar, white spruce, birch and balsam fir. Cedar, larch, ash, red pine and white pine are found intermittently throughout the forest but with a stronger affinity to the southern portions of the area.

The Whiskey Jack forest is a Crown Management Unit with the responsibility of forest management planning held by the MNR, in consultation with the public. Weyerhaeuser iLevel (Kenora) and Kenora Forest Products (Kenora) have wood supply commitments from the forest, as do some smaller mills. Wood fibre from the Whiskey Jack Forest may also go to other mills in Ontario via trades, sales, and other business-to-business negotiations.

Communities within or in close proximity to this forest include Kenora, Sioux Narrows, Redditt, Vermillion Bay, Ear Falls, Grassy Narrows, Wabaseemoong, Wabauskang, and Whitefish Bay.

Decision:

This notice will be updated as new information becomes available.

Purpose of the Notice:

To advise the public that the forest management plan covering forest management activities for the Whiskey Jack Forest for the period 2012-2022 is being prepared. The plan is being prepared in accordance with the Crown Forest Sustainability Act (1994) (CFSA), the Forest Management Planning Manual for Ontario's Crown Forests (2009) (FMPM), and the terms and conditions of the Class Environmental Assessment for Timber Management on Crown Land in Ontario, as extended and amended by MNR's Class Environmental Assessment Approval for Forest Management on Crown Lands in Ontario (MNR-71).

The forest management plan is required to comply with the provisions of the FMPM. The forest management plan will provide for the sustainability of the Crown forest on the management unit, and will outline the long-term strategic direction and objectives for the management related to:

- sustainability of the forest resource;
- biodiversity;
- social and economic matters (including timber harvest levels);
- the provision of forest cover for those values which are dependent on forest cover; and,
- silviculture.

Other Information:

Information about the forest management planning process, information which will be used in the preparation of the plan, and background information about the management unit can be reviewed during normal office hours at the Ministry of Natural Resources Kenora District office. It is recommended that persons make an appointment for viewing. This background information may also be viewed during non-business hours by making an appointment with the government contact person listed in this notice.

kurt.pochailo@ontario.ca

During the Review of the Draft Forest Management Plan, comments are being sought on the background information to be used in the development of the plan. The Ministry of Natural Resources is collecting comments and information regarding this forest management plan under the authority of the Crown Forest Sustainability Act to

P9N 3X9
Phone: (807) 468-2501

assist in making decisions and determining future public consultation needs. Comments and opinions will be kept on file for use during the operating term of the forest management plan and may be included in study documentation which is made available for public review.

Under the Freedom of Information and Protection of Privacy Act, personal information will remain confidential unless prior consent is obtained. However, this information may be used by the Ministry of Natural Resources as public input on other resource management surveys and projects. For further information regarding this Act, please contact Hassan Mohamed, MNR, Kenora, at 807-468-2580.

Other Public Consultation Opportunities:

In accordance with the provisions of the Forest Management Planning Manual (FMPM), formal public consultation is planned to occur at five stages during the preparation, review and approval of this plan. The FMPM sets out that direct written notice is required to be given to certain individuals and organizations, on the mailing list, at each stage of the planning process; individuals and organizations may request to be added to this list, which is updated at each stage. Public notice is also given through advertisements in local newspapers.

The following is a summary of public and Aboriginal consultation:

Stage One – Invitation to Participate: February 3, 2010

Stage Two – Review of the Long Term Management Direction: December 14, 2011 to January 31, 2012

Stage Three – Information Centre - Review of Proposed Operations: March 4, 2013 to May 6, 2013

Stage Four – Information Centre - Review of the Draft Forest Management Plan: August 29, 2013 to October 31, 2013

Stage Five – Public Inspection of approved Forest Management Plan: December 23, 2013 to January 22, 2014

An approved forest management plan is scheduled for implementation commencing April 1, 2014.

All comments and submissions received for Stages One through Four will be considered as part of the decision-making by the ministry. Under the public consultation provisions of the FMPM, a written response will be provided to all written comments and submissions, and upon request, to all verbal comments. All comments and submissions will become part of the public record. Stage Five is an inspection period only. No comments are being sought at that stage.

There is an opportunity during the forest management planning process to seek resolution of issues with the MNR District Manager or the MNR Regional Director in accordance with the process described in Part A, Section 3.4.1 of the Forest Management Planning Manual (2009).

During the 30-day inspection period, commencing December 23, 2013 and ending January 22, 2014 any person may make a written request to the Director of Environmental Assessment and Approvals Branch, Ministry of the Environment, for an individual environmental assessment of specific proposed forest management activities in the forest management plan. A response to a request for an individual environmental assessment will normally be provided after the completion of the 30-day inspection period.

JOSEPH CASTRILLI

JC affirmed

Hon. Kathleen Wynne
Premier
Legislative Bldg
Rm 281
Queen's Park
Toronto ON M7A1A1

October 24, 2013

Dear Premier Wynne,

RE: Forest Management Plan for the Whiskey Jack Forest for the 10-year period April 1, 2012 to March 31, 2022

The Grassy Narrows First Nation Chief and Council reject the Forest Management Plan for the Whiskey Jack 2012-2022 on the basis of failure to consult and infringes on our Aboriginal and Treaty Rights

This document attempts to make plans to clearcut log the lands that we use for our physical, spiritual, and cultural survival. We cannot allow this.

For centuries we have raised our voices to protect our rights and our land. But Ontario and Canada continue to ignore us with devastating consequences for our people and our land. This plan is a violation of our inherent human rights given to us by the Creator, as well as our rights as recognized by Treaty 3, the Constitution of Canada, and the UN Declaration on the Rights of Indigenous Peoples.

Ontario has a long and terrible legacy of imposing decisions on our people and our lands against our will and without consent. The theft of our children to residential schools, the damming of our river, the relocation of our community, mercury poisoning, and clearcut logging have all taken a deep toll on our health, our culture, and our way of life.

Premier Wynne, you came to our community in the summer of 2012 and said that you wanted to rebuild Ontario's relationship with Grassy Narrows. You said that this time you wanted to "get it right." Instead MNR officials have continued to unilaterally pursue clearcut logging plans. These planning processes were and continue to be developed without our participation, knowledge and consent. We are frustrated that these processes are conducted entirely outside of the five year long process we have undertaken in good faith with Ontario to reach a mutually agreeable resolution to these issues.

MNR plan sets out a schedule to clearcut much of what little mature forest remains on our Territory after decades of large scale industrial logging will further erode our ability to sustain our families and to practice our culture through fishing, hunting, trapping, medicine harvesting, ceremony and healing.

Asubpeeschoseewagong Netum Anishinabek

GRASSY NARROWS, ONTARIO P0X 1B0 • PHONE: (807) 925-2201 • FAX: (807) 925-2649

We do not accept any application of this plan to our traditional lands. The Chief & Council along with community Elders stand united on this issue and are determined to protect the community's way of life.

You are fully aware that our community continues to struggle with the devastating health impacts from 9,000 kg of mercury that was dumped into our river system in the 1960's with the permission of the government of Ontario. Three generations of our people bear the burden of this degenerative neurological poison.

New clearcut logging will bring even more mercury into our river and our food chain, further prolonging and exacerbating this avoidable tragedy. We condemn such processes and plans.

We have been repeatedly told that Ontaro cannot undue what was done over forty years ago, but we are deeply concerned that Ontario wishes to repeat further degradation to Grassy Narrows. It is now within your power to ensure that the mistakes of the past are not repeated at the expense of another generation of Grassy Narrows children.

We call on you to ensure that never again will Ontario attempt to force decisions on our people and our lands.

What will your legacy be?

Chief Simon Fobister

Summary of the 2012 to 2022 Whiskey Jack Forest Management Plan

Location

The Whiskey Jack Forest Management Unit (MU) is located within the Kenora District and the Northwest Region of the Ministry of Natural Resources (MNR).

This is Exhibit "5" referred to in the affidavit of SIMON FOBISTER sworn before me, this 30th day of JULY 20 15
Joseph Castrilli
A COMMISSIONER FOR TAKING AFFIDAVITS
JOSEPH CASTRILLI

Public Contacts

The public contacts for the plan are:

Kurt Pochailo, R.P.F.	Plan Author	(807) 468-2597
Deb Weedon	MNR District Manager	(807) 468-2501
Wayne Bruce	LCC representative	

Management Responsibility

The Whiskey Jack Forest (Management Unit #490) has been a Crown Management Unit since Abitibi Company of Canada surrendered the Sustainable Forest Licence in August 2009. The Kenora District MNR administers its forest management planning activities and operations from the MNR District office located in Kenora, Ontario. More details about the administration of the forest can be found in section 1 of the plan. The management unit description is included in section 2 of the plan.

Local Citizen's Committee Participation

A member of the local citizen's committee (LCC) has participated in the preparation of the forest management plan as a planning team member and attended all information sessions. The proposed management strategy, long-term management direction and draft forest management plan were presented to the committee and input was requested on these products as well as the background information.

The LCC has prepared a brief statement of agreement or disagreement with the draft plan. This statement and the full LCC report can be found in the plan electronic submission.

Long-term Management Direction Summary

The Long-term Management Direction (LTMD) for the forest provides guidance for the levels of access, harvest, renewal and tending activities required to achieve the desired future forest and benefits. In the development of the LTMD, management objectives and indicators are identified and analytical methodologies, models and tools regarding forest regulation, social and economic assessment, wildlife habitat supply and landscape management are used. This is discussed in section 3 of the FMP which references supporting details found in the supplementary documentation to the plan.

The long-term management direction provides a means of assessing the sustainability of the management strategy through the measurement and monitoring of indicators that have been developed for each management objective. It is expected that a balanced achievement of the

quantitative and qualitative biological, social and economic objectives, will result in the desired long-term future forest condition and benefits.

Plan Objectives and Indicators

As required by the *Crown Forest Sustainability Act*, management objectives for the Whiskey Jack Forest must be compatible with the sustainability of the Crown forest, and indicators of objective achievement must be identified. In addition, the *Crown Forest Sustainability Act* requires that each FMP contain management objectives relating to:

(a) Crown forest diversity, including consideration for the conservation of natural landscape patterns, forest structure and composition, habitat for animal life and the abundance and distribution of forest ecosystems;

(b) Social and economic factors, including harvest levels and a recognition that healthy forest ecosystems are vital to the well-being of Ontario communities;

(c) The provision of forest cover for those values that are dependent on the Crown forest; and

(d) Silviculture for the harvest, renewal and maintenance of the Crown forest.

Table FMP-9 (located in Section 9.0) summarizes management objectives, indicators, desirable levels and associated targets and presents an assessment of achievement of desirable levels for each objective, for those which can be assessed at this time. The management objectives, indicators, desirable levels and targets were developed with input from the Kenora Local Citizens Committee (through the Desired Forest and Benefits meetings), the planning team, and MNR advisors. Sources of information considered in their development included, but were not limited to: the current FMP; background information; forest management guides and policies; Reports of Past Forest Operations; MNR forest management planning direction and training, and scoping investigations for the 2012 to 2022 FMP.

For each management objective, at least one indicator of objective achievement was developed, along with an associated desirable level(s) and target(s). Some objectives have multiple indicators to measure achievement. A desirable level is a specific number, a range or a trend for an indicator, to be achieved and maintained over time. As with desirable levels, targets are specific numbers, ranges, or trends, with a timeframe for achievement. The establishment of targets for each objective reflected a balancing of objective achievement and considered:

(a) Social, economic and environmental considerations;
(b) The associated indicator and its desirable level;
(c) The current forest condition; and,
(d) The short-term (10 years), medium-term (20 years) and long-term (80-100 years).

The rationale used in setting desirable levels and targets is summarized in section 3.5 of the plan. Modelling with the Strategic Forest Management Model (SFMM) assisted in quantitative scoping investigations and the development of the long-term management strategy (see section 3.6) that balances the achievement of management objectives over time. There are a total of 11 objectives and 30 indicators in this FMP.

The Long-term Management Direction

The Long-term Management Direction (LTMD) is represented by the types and levels of access, harvest, renewal and tending activities required to manage forest cover in a manner that balances the achievement of management objectives over time. The MNR approved Strategic Forest Management Model (SFMM) is used to develop the Long-term Management Direction.

The development of the Long-term Management Direction is an iterative process whereby results are examined and SFMM inputs adjusted as required to improve the model's ability to meet management objectives. This process commonly involves adjusting volume targets, harvest flow policies and targets for the forest diversity indicators – forest unit area, old forest area, mature forest and wildlife habitat. As each investigation is run, the resulting harvest volume, forest diversity indicators, silvicultural expenditures and the silvicultural treatment program are examined. The process continues until the planning team is satisfied that no further significant improvements can be made, that on balance objectives have been achieved, and that the solution is practical and can be implemented. The modelling process that led to the Long-term Management Direction is described in section 3.6 of the plan and the Analysis Package in Supplementary Documentation A.

The outputs of forest modelling for the Long-term Management Direction provide the source for the long-term (100-year) projections of quantifiable objectives and are documented within the plan in the following tables:

(a) Projected Forest Condition for the Crown Productive Forest (Table FMP-5);
(b) Projected Habitat for Selected Wildlife Species (Table FMP-6);
(c) Projected Available Harvest Area by Forest Unit (Table FMP-7); and
(d) Projected Available Harvest Volume by Species Group (Table FMP-8);

These tables can be found in section 9.0 of the FMP.

Planned Forest Operations for the 10-year Plan Period

Silvicultural Systems, Forest Units and Silvicultural Ground Rules

In order to describe the planned forest operations, it is necessary to first explain some forestry terminology:

Clearcutting has long been recognized as a form of management wherein the mature trees are removed in one operation. Clearcutting still involves the removal of the majority of the mature trees, however, the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010) require the retention of residual trees to be left after the harvest and often residual patches of uncut areas are to be left as well. Clearcutting is an appropriate management system in the Boreal Forest for many mixedwood stands and stands to be managed for tree species that are intolerant of shade (e.g. poplar, white birch, jack pine).

Each stand is assigned to a forest unit based on species composition, stocking and history. All stands within a forest unit are managed under the same silvicultural system but may be managed with different treatments (e.g. planting, site preparation, tending) and may have different objectives in terms of different future forest conditions. The management strategy is indicated through the Silvicultural Ground Rule.

Each stand to be harvested is assigned a Silvicultural Ground Rule. Each Silvicultural Ground Rule (SGR) describes the components that make up an individual SGR, including a description

of the current and future stand conditions, renewal treatment options and the regeneration standards that are to be met. Each SGR is intended to describe the harvest, renewal and tending activities that will be carried out on a given stand to allow the current Forest Unit, following harvest, to succeed to the Future Forest Unit, whether it is similar to the pre-harvest stand or a different Forest Unit.

Planned Harvest Operations

Results of the long-term strategic planning were used to plan operations for the ten-year period of this plan. The following table summarizes the harvest operations that are planned (i.e. in detail) for the first five-year term (2012-2017), and those which are proposed (i.e. less detail) for the second five-year term (2017-2022) of the FMP. The planned harvest area and percentage of the total 10-year planned harvest area for each of the three major silvicultural systems is listed below, however as reported, only the clearcut silvicultural system is being implemented on the Whiskey Jack Forest during this plan period (See section 4.3 of the FMP for more details):

Silvicultural System (i.e. Harvest System)	10-year Planned Harvest Area (ha)	% of 10-year Planned Harvest Area
Clearcut	53,471	100 %
Shelterwood	0	0 %
Selection	0	0 %
Total	**53,471**	**100%**

Harvest Area and Volume by Forest Unit and Species Group

The estimated available harvest areas for the 10-year plan period summarized by principal forest units and the harvest volumes (m3) associated with the harvest areas by the principal species groups are listed below:

Forest Unit	Planned Harvest Area (ha)
BFM	1,401
CMX	8,814
HMX	11,360
OCL	-
OTH	-
PJD	3,130
PJM	5,368
POD	11,887
PRW	208
SBL	297
SPD	6,821
SPM	4,186
Total	**53,471**

Species Group	Planned Harvest Volume (m3)
White Pine - Red Pine	20,106
Spruce-Pine-Fir	3,074,828
*** Other Conifer (Cedar, Larch)**	61,959
Poplar	1,756,375
White Birch	401,587
*** Tolerant Hardwood (Black Ash)**	19,862
Total	**5,334,717**

(Net merchantable volumes)

* Volumes for Other Conifer (Larch, Cedar) and Tolerant Hardwood (Black Ash) are reported but are not considered major species groups on the Whiskey Jack Forest.

Planned Road Access

The planned (10 year) road construction summarized for two road classes (primary and branch roads) that are needed to access all harvest and renewal operations over the 10-year period are listed below. Operational (i.e. tertiary) roads are not listed. (See section 4.5 of the FMP for more details).

Road Classification	Planned Road Construction (km)
Primary	30
Branch	19
Total	**49**

The Road Use Management Strategies for each Primary Road are located within FMP Supplementary Documentation G. The proposed Primary Road corridors associated with the 2011 FMP are illustrated on the FMP Summary Map and Composite Map (electronic version of FMP).

The management strategies for each road are consistent with those indicated in the Crown Land Use Policy Atlas.

Planned Forest Renewal and Tending Operations

The planned (10 year) renewal and maintenance activities that are required to meet the plan objectives are listed below by renewal activity type. These renewal activities will be carried out on the current planned harvest areas as well as areas harvested during past plan terms.

Artificial regeneration refers to tree planting and seeding. Supplemental treatment usually refers to an area that is regenerating naturally that needs some supplemental (usually tree planting) treatment to meet the regeneration standards. (See section 4.4. of the FMP for more details).

Renewal Activities	Planned Treatment Area (ha)
Natural Regeneration	25,631
Artificial Regeneration	27,839
Total Regeneration	53,470
Retreatment	0
Supplemental	0
Total Tending	8,065

Area of Concern Prescriptions

The forest provides for many forest values. Some values have the potential to be negatively impacted by forest management. The areas around these values are termed *Areas of Concern*.

An area of concern may be a social value such as an authorized hiking trail or an archaeological site or it may be an ecological or environmental value such as a stream or significant wildlife habitat feature (e.g. a great blue heronry, a hawk nest, deer wintering area, mineral licks or a provincially significant wetland).

The FMP includes Area of Concern prescriptions for many different values. These prescriptions may include a no-cut buffer zone, an area with access restrictions and/or a modified

management area wherein there may be restrictions on timing of harvest or silvicultural activity, method of harvest or types of trees that can be harvested. Some prescriptions are developed from the direction in a forest management guide and others are developed at the planning team level. A few examples of the many Area of Concern prescriptions follow to give the reader a sense of Area of Concern prescriptions:

> ***Example 1 (N01)**. A primary bald eagle nest receives a 200 m radius no cut reserve with no new access roads allowed. Outside this 200 m radius is a further 200 m wide zone in which harvesting may occur (subject to conditions on whether or not nest is occupied and relative potential impact of operations) and it must occur outside the critical breeding period to avoid disturbing the young birds.*
>
> ***Example 2 (M01)**. Mineral licks will receive a 120 m no cut reserve measured from the edge of woody vegetation averaging at least 2 m tall and with ≥25% canopy cover. This reserve is in excess of what is required for water quality and protection of fish habitat, but will provide additional protection and habitat cover for animals using the mineral lick.*
>
> ***Example 3 (TV01)**. Large tourism lakes will receive a 90 m no cut reserve. This prescription may be in excess to what is required to protect the water quality and fish habitat but it will provide a visual buffer from users of the lake.*

Operational prescriptions for areas of concern and silvicultural ground rules for regular operations have been prepared in accordance with the applicable forest management guides. There are no area of concern prescriptions and one silvicultural prescription that are exceptions to the guides. Full tree logging on NWO Ecosites 11 and 12, where total organic matter plus soil depth is less than 20 cm, is designated as a 'not recommended' practice in the *Silvicultural Guide to Managing for Black Spruce, Jack Pine, and Aspen on Boreal Forest Ecosites in Ontario* (MNR, 1997). The shallow soil sites on the Whiskey Jack Forest are, for the most part, productive and, it is felt, that using full tree logging in a careful manner will preserve the sites nutrient capacity. The forest industry is contributing to a comprehensive, region wide initiative to monitor the impacts of this treatment on these site conditions. Operational prescriptions for areas of concern have been prepared consistent with the Endangered Species Act to protect habitat related to species at risk known to exist on the forest.(See section 4.2.1 of the FMP for more detail).

Issues

There are two issues affecting the 2012-2022 Whiskey Jack Forest Management Plan that have the potential to become contentious:

1. The August 2011 Court decision regarding the "Keewatin Lands" (north of the English River system) – Note that as per the stay ordered on consent of the parties, there will be no harvesting of trees for subsequent sale or other commercial purposes other than for firewood within the area of the Whiskey Jack Forest north of the English River, without the consent of Grassy Narrows First Nation.
2. More generally, Grassy Narrows has concerns with the Whiskey Jack Forest that are currently being addressed through the Process Agreement that was signed between ANA and MNR.

Ontario will continue to consult with Grassy Narrows First Nation, Naotkamegwanning First Nation (Whitefish Bay), Ochiichagwe'babigo'inning First Nation (Dalles), Wabaseemoong Independent First Nations (Whitedog), Wabauskang First Nation and Kenora Métis Council and respect any existing obligations in relation to their rights. The Planning Team and LCC will receive public and Aboriginal input via the consultation phases of the forest management plan.

Public Consultation

There are two remaining formal consultation opportunities for the Whiskey Jack Forest Management Plan. There is a 60-day public comment period (Aug. 29, to Oct. 28, 2013) including information centres for Review of the Draft Forest Management Plan. There is an opportunity during this 60-day review period of the draft forest management plan to seek resolution of issues with the MNR District Manager or during the 30 days following the completion of the 60-day review period with the MNR Regional Director (in accordance with the issue resolution process described in Part A, Section 3.4.1 of the Forest Management Planning Manual). Public inspection of the MNR approved Forest Management Plan is tentatively scheduled from December 2013 to January 2014. There is an opportunity during the 30-day period for public inspection of the MNR approved forest management plan for any person to make a written request to the Director, Environmental Assessment and Approvals Branch, Ministry of the Environment for an individual environmental assessment of specific proposed forest management activities in the forest management plan (in accordance with the process described in Part A, Section 3.4.2).

A comment form is attached as Appendix 1.

Summary Map

Proposed harvest, renewal and tending operations, locations of existing and new primary and branch road construction corridors for the 10-year term are shown on the summary map labelled MU490_2012_FMPDP_P1_MAP_Sum. The map also contains an index/grid for identifying specific operational maps.

COMMENTS

The Ministry of Natural Resources is collecting comments and information regarding the forest management plan under the authority of the Crown Forest Sustainability Act to assist in making decisions and determining further public consultation needs. Your comments will be forwarded to the Plan Author and shared with the Kenora Local Citizens Committee (LCC) so that they may consider your concerns. Comments and opinions will be kept on file for use during the forest management plan period and may be included in study documentation which is made available for public review.

Under the Freedom of Information and Protection of Privacy Act (1987) personal information will remain confidential unless prior consent is obtained. However, this information may be used by the Ministry of Natural Resources to seek public input on other resource management surveys and projects. For further information regarding this Act, please contact Stephen Duda, MNR at (807) 468-2543.

There are two remaining formal consultation opportunities for the Whiskey Jack Forest Management Plan. There is a 60-day public comment period (Aug. 29 – Oct. 28, 2013) including information centres for Review of the Draft Forest Management Plan. There is an opportunity during this 60-day review period of the draft forest management plan to seek resolution of issues with the MNR District Manager or during the 30 days following the completion of the 60-day review period with the MNR Regional Director (in accordance with the issue resolution process described in Part A, Section 3.4.1 of the Forest Management Planning Manual). Public inspection of the MNR approved Forest Management Plan is tentatively scheduled from December 2013 to January 2014. There is an opportunity during the 30-day period for public inspection of the MNR approved forest management plan for any person to make a written request to the Director, Environmental Assessment and Approvals Branch, Ministry of the Environment for an individual environmental assessment of specific proposed forest management activities in the forest management plan (in accordance with the process described in Part A, Section 3.4.2).

Comments may be forwarded to the Kenora District Office, Ministry of Natural Resources, 808 Robertson Street, Box 5080, Kenora, ON, P9N 3X9.

AFFIDAVIT OF AMBER ELLIS AND DAVID SONE

WE, AMBER ELLIS AND DAVID SONE, of the City of Toronto, in the Province of Ontario, EACH MAKE OATH AND SAY AS FOLLOWS:

1. I, Amber Ellis, am the Executive Director of Earthroots Coalition ("Earthroots") and, as such, have knowledge of the matters hereinafter deposed to.

2. I have been the Executive Director of Earthroots since 2006. From 1997 to 2006, I was co-director of the organization. Earthroots is a non-profit organization dedicated to the conservation of wilderness, wildlife, and watersheds in Canada, with a focus on Ontario. In this capacity, we work with groups who seek similar goals.

3. I, David Sone, am the Director, Northern Ontario Campaigns at Earthroots and, as such, have knowledge of the matters hereinafter deposed to.

4. I have been with Earthroots since 2010.

FOREST MANAGEMENT PLAN

5. We have worked with the Grassy Narrows First Nation ("Grassy Narrows") concerning the proposal by the Ministry of Natural Resources and Forestry ("MNRF") to develop a forest management plan ("Plan") under the authority of the *Crown Forest Sustainability Act*. The Plan would allow clearcut logging in the Whiskey Jack Forest in northwestern Ontario over the period 2012 to 2022. In this regard I, Amber Ellis, approved on behalf of Earthroots submissions prepared by Mr. Sone that were submitted to the MNRF in late October 2013, during the notice and comment process concerning the Plan. The submissions raised concerns that clearcut logging proposed under the Plan would exacerbate the mercury problem at Grassy Narrows. A copy of the October 2013 submissions is attached as Exhibit "A" to our affidavit.

6. The MNRF approved this Plan in December 2013. A copy of the Plan, consisting of the Plan text, tables, supplementary documentation, analysis package, summary text, summary map, and further map respecting fisheries and wetlands, is attached as Exhibit "B" to our affidavit.

JANUARY 2014 BUMP-UP REQUEST

7. Following the MNRF approval of the Plan, in January 2014 I, Amber Ellis, approved on behalf of Earthroots submissions prepared by Mr. Sone that Earthroots co-filed with Grassy Narrows as a request of the Ministry of the Environment, now the Ministry of the Environment and Climate Change ("MOECC"), for a bump-up under section 16 of the *Environmental Assessment Act*. The request, if granted, would result in an Individual Environmental Assessment ("IEA") being conducted into the potential mercury impacts to the environment and human health arising from clearcut logging authorized under the Plan before the Plan could be implemented. This initial request is mentioned and referred to in the affidavit of Simon Fobister, current Executive Director and former Chief of Grassy Narrows, in respect of the within application for judicial review. A copy of the January 2014 request we filed with Grassy Narrows is attached as Exhibit "C" to our affidavit. A map outlining the geographic location of the specific area of concern of the bump-up request with respect to the Whiskey Jack Forest appears as the last page in Exhibit "C".

8. Exhibit “C” identifies and documents a wide variety of concerns with the Plan, based on government documents and peer-reviewed scientific studies, in support of the bump-up request. These concerns, based on these documents and studies, include:

(a) clearcut logging impacts water quality through mercury contamination; in particular, such logging has been found to raise mercury levels in boreal lakes and rivers, like those found in Grassy Narrows territory, and to raise the levels of methyl mercury, the form of mercury that bio-accumulates in the food chain and acts as a neurotoxin in humans who eat fish;

(b) clearcut logging elevates mercury levels in fish; in particular, such logging has been found to increase the level of mercury in fish often above the safe level for human consumption and that this effect is most pronounced in fish at the top of the food chain like walleye and pike, the primary fish eaten by the people of Grassy Narrows;

(c) fish in Grassy Narrows have critical levels of mercury above, or near, the limit for safe human consumption;

(d) the main effects of mercury exposure to humans are understood to be neurological, renal (kidney), cardiovascular and immunological impacts. Exposure to mercury while in the womb can lead to neurodevelopmental problems in children;

(e) mercury impacts human health in Grassy Narrows; in particular, 35 years of studies by doctors from Japan who have undertaken clinical examinations of members of the community, and published the results, in the years since industrial discharges of mercury ended, confirm that people in Grassy Narrows are suffering neurological harm and other adverse health impacts due to eating fish contaminated with methyl mercury;

(f) the Plan, a document over 400 pages in length, covering the area through which the historically industrially mercury-contaminated English-Wabigoon river system runs, does not mention the word “mercury”, let alone measures for controlling mercury impacts, nor does the primary MNRF manual on forest management planning refer to mercury;

(g) the only guidance document MNRF uses for dealing with mercury impacts arising from clearcut logging, the Stand and Site Guide (“SSG”): (1) mistakenly equates the effects of such logging with natural events, like forest fires, contrary to the scientific literature which concludes that, unlike large fires, clearcut logging will increase mercury levels in fish, (2) relies on measures neither designed for, nor proven to be effective in, mitigating mercury impacts, (3) takes a log now, monitor the results later, approach to determining the effectiveness of mercury mitigation measures, and (4) may make the mercury problem worse than previous government guidelines because it (i) allows logging to the shoreline, and (ii) removes threshold

constraints contained in predecessor guidance documents designed to limit catchment disturbance and, as a result, will increase the release of mercury to water.

APRIL 2014 MNRF RESPONSES TO EARTHROOTS OCTOBER 2013 SUBMISSIONS AND GRASSY NARROWS-EARTHROOTS JANUARY 2014 BUMP-UP REQUEST

9. In April 2014, MNRF responded to our October 2013 submissions on the Plan. MNRF stated that it had "determined that there is sufficient legal, regulatory and policy framework, including guidelines, to ensure that current information and knowledge about mercury dynamics in the Boreal Forest is considered in land-use and resource management decisions". The response also noted that MNRF was reviewing its policies and monitoring protocols, as well as undertaking research to improve the understanding of mercury dynamics in the Boreal Forest. A copy of the MNRF response is attached as Exhibit "D".

10. Also in April 2014, MNRF filed a response to the January 2014 bump-up request with MOECC. In its response, MNRF raised a number of issues that are specific to Grassy Narrows and that are addressed in the affidavit of Chief Roger Fobister, Senior in support of the within application for judicial review. MNRF also stated in its response that (1) work conducted by Quebec researchers Garcia and Carignan is likely the most comprehensive study on the association between watershed disturbances and fish mercury levels and that fish in disturbed watersheds had higher mercury levels than fish in undisturbed watersheds, and (2) in developing the Plan, it complied with the mitigation

measures set out in the SSG and forest management planning manual as required by the *Crown Forest Sustainability Act*. A copy of the MNRF response is attached as Exhibit "E" to our affidavit.

MAY 2014 REPLY TO MNRF RESPONSE

11. In May 2014, I, Amber Ellis, again approved on behalf of Earthroots submissions prepared by Mr. Sone that Earthroots and Grassy Narrows filed with MOECC as a reply to the MNRF response of April 2014 to the January 2014 bump-up request. In our reply to the MNRF response that in developing the Plan MNRF complied with the mitigation measures set out in the SSG and forest management planning manual as required by the *Crown Forest Sustainability Act*, we noted that the MNRF response explicitly conceded that (1) the potential for forest management activities to result in mobilization of terrestrial mercury into aquatic systems is well documented and a serious concern, (2) MNRF was making no claims that the direction in the SSG, or its application, would mitigate or eliminate mercury mobilization into such systems, (3) there are no proven measures to mitigate the harm arising from mercury impacts of clearcut logging, and (4) MNRF was making no further commitments in the Plan to address the concerns raised by Grassy Narrows or Earthroots on this issue beyond following the SSG. A copy of the May 2014 reply is attached as Exhibit "F" to our affidavit.

JULY 2014 SUPPLEMENTARY SUBMISSION IN SUPPORT OF BUMP-UP REQUEST

12. In late May 2014, Earthroots received documentation respecting certain issues pertinent to development of the Plan arising from a request for information we made to MNRF in

or about January 2014 under the *Freedom of Information and Protection of Privacy Act*. Because the documentation from MNRF was relevant to the bump-up request made to MOECC that we had co-filed with Grassy Narrows, we filed this new information with MOECC as a supplementary submission on the joint behalf of Grassy Narrows and Earthroots in late July 2014. A copy of the submission to MOECC, and the documentation, is attached as Exhibit "G" to our affidavit.

13. What we indicated in the submission portion of Exhibit "G" is that the documentation consists of excerpts from comments MNRF received on the SSG, which appear to have been written by two northwestern Ontario MNRF fisheries biologists, at least one of whom was credited by MNRF with having made significant contributions to the writing of individual sections of the SSG itself.

14. The SSG, released by MNRF in 2010, is the guidance document that MNRF relied on for identifying measures for mitigating impacts from clearcut logging arising from the Plan and it was also referenced as such in MNRF's April 2014 response, filed with MOECC, to the Grassy Narrows-Earthroots bump-up request of January 2014.

15. The comments of the MNRF biologists, attached in their entirety in Exhibit "G", stated that the reduction in protection for river, stream, pond and lake shorelines in the SSG needed to be reconsidered for a number of reasons, including (1) mercury is finding its way into water courses from cutovers even with current reserves/AOCs (Areas of

Concern) in place, and (2) this is likely to be exacerbated if complete removal of shoreline vegetation is permitted.

16. The comments of the MNRF biologists went on to state that: “The public and especially First Nations are very sensitive of mercury entering our water systems and they are not going to like the idea that it might be increased”. The MNRF biologists stated further that: “[T]he task team that developed the latest recommendations for protecting aquatic habitat didn’t propose clear cutting entire shorelines so why are we. This task team included some very knowledgeable folks including some of our research scientists”.

17. What we inferred from the observations of the MNRF biologists, and so stated in the submission portion of Exhibit “G”, was that the (1) reserves/AOCs that had been in place prior to the new SSG taking effect were not sufficient to prevent mercury from being released into local water bodies after clearcutting, (2) the new (2010) SSG weakened existing riparian protections (i.e. reserves and AOCs), (3) the amount of mercury entering water bodies is likely to increase as a result of the changes contained in the new SSG, (4) the SSG is not consistent with the limited current science on preventing mercury releases from clearcuts, and (5) the documentation in Exhibit “G” reveals that the MNRF may not have followed the advice of its own fisheries and aquatic habitat experts in developing the SSG as it relates to key concerns respecting the mercury issue.

SEPTEMBER 2014 SUPPLEMENTARY SUBMISSION IN SUPPORT OF BUMP-UP REQUEST

18. In September 2014, I, Amber Ellis approved on behalf of Earthroots further supplementary submissions prepared by Mr. Sone that Grassy Narrows and Earthroots filed with MOECC in support of the bump-up request. These supplementary submissions are attached as Exhibit "H" to our affidavit. The supplementary submissions attached and summarized a 2010 report, publicly released in 2014, prepared for the Mercury Disability Board. The Board was established under Ontario legislation as part of the settlement in the 1980s of the mercury litigation referred to at paragraph 10 of the affidavit of Simon Fobister filed in support of the within application for judicial review. The report, prepared by toxicologists retained by the Board, summarized observations made over the years regarding human health impacts on members of Grassy Narrows, and a neighbouring first nation community, from past industrial discharges of mercury in the English-Wabigoon river system. In particular, the observations of the report included that:

(a) as a result of high mercury exposure in Grassy Narrows in the 1960s and 1970s, there is no doubt that many persons in the community were suffering from mercury-related neurologic disorders; and

(b) follow-up studies by doctors from Japan indicate there is probably still a problem in the Grassy Narrows community due to previous mercury exposure; and

(c) some individuals still exhibit high levels of exposure.

19. The report of the Board, summarized in the Exhibit "H" submissions, also made general observations about the effects of mercury exposure on human health based on a review of studies world-wide. These observations included:

(a) there is a wide consensus that even at low levels, mercury can impact the intellectual and motor development of children, based on observations made in population studies; and

(b) at the sub-clinical and population level, studies in different parts of the world report slower development in newborns, infants, and children exposed to methyl mercury in utero, or during early childhood.

NOVEMBER 2014 SUPPLEMENTARY SUBMISSION IN SUPPORT OF BUMP-UP REQUEST

20. In November 2014, I, Amber Ellis approved on behalf of Earthroots further supplementary submissions prepared by Mr. Sone that Grassy Narrows and Earthroots filed with MOECC in support of our bump-up request. A copy of these submissions is attached as Exhibit "I". These submissions, again largely based on government documents and peer-reviewed scientific studies, noted the following:

(a) an MNRF report on the program designed to monitor the effectiveness of the SSG in mitigating impacts of forest management activities, indicated that it was not sufficient to address aquatic system process uncertainties with respect to mercury, and information on the effectiveness of direction

contained in the SSG should not be expected for several years after the SSG is implemented;

(b) in the late 1970s, 93 percent of the 105 individuals in Ontario with blood mercury levels greater than 100 parts per billion were from Grassy Narrows (56%) and from a neighbouring first nation community (37%); high blood mercury levels contribute to anxiety; physical and mental health effects such as anxiety due to mercury contamination in the English-Wabigoon River System have been borne almost entirely by the native people of Grassy Narrows and another nearby first nation community; the fear and anxiety from knowing that fish were contaminated was debilitating to many people in these communities; the threat of mercury poisoning clearly affected their mental health; a reduction in fish mercury levels could help to reduce anxiety and mental trauma experienced by these people;

(c) MNRF research has documented an increased flux of both mercury and methyl mercury in streams following tree harvesting by clear-cut logging; and

(d) MOECC recognizes that fish consumption patterns in first nation communities are different from those published in the government's guide to eating sports fish; a reduction in mercury contamination in fish could lead to reduced health risk at Grassy Narrows because, according to MOECC, the

people of Grassy Narrows have the most opportunity and inclination to eat fish from contaminated water bodies; the federal government recommends that mercury concentrations in fish should be 0.2 parts per million or lower before the people at Grassy Narrows can safely eat them; the MOECC sport fish guide does not list a fish as "do not eat" for the general population until mercury levels are more than nine times that level.

21. We each swear this affidavit in support of the within application for judicial review, and for no other or improper purpose.

Re: **EBR Registry Number 010-9240** – Forest Management Plan for the Whiskey Jack Forest for the 10-year period April 1, 2012 to March 31, 2022 – Review of Draft Forest Management Plan

Dear Mr. Pochailo,

Please consider this letter an official submission to the public input process for the Draft Forest Management Plan for the Whiskey Jack Forest 2012-2022.

Earthroots is a grassroots environmental organization dedicated to the protection of Ontario's wilderness, wildlife and watersheds – we represent 12,000 supporters across Ontario.

We strongly oppose the draft plan on the grounds that it does not meet the obligation to meaningfully consult, accommodate, and obtain the free, prior and informed consent of the Grassy Narrows First Nation.

Grassy Narrows has rejected the plan, and we join with them. We cannot support any plan for the Whiskey Jack Forest until the conflict with Grassy Narrows has been resolved in a just way.

Earthroots is also deeply concerned about the ecological degradation to the Whiskey Jack Forest that will result if the plan is implemented. We will briefly summarize our concerns re: the potential threats to the area's ecology, however we will reserve a more thorough analysis for a plan that has the support of the Grassy Narrows First Nation.

Past mismanagement of the Whiskey Jack Forest has left a forest that is severely degraded. This has been partially documented in the independent Whiskey Jack Forest Audit 2004-2009.

In particular the audit documented the following impacts:

1) Productive land degraded through soil compaction, rutting, and excessive roads, landings, and slash piles;
2) Conversion of forest away from natural conditions including the replacement of conifer stands with broadleaf and mixed stands;
3) Degradation of wildlife habitat, especially moose, caribou, and martin;
4) Regeneration failure due to cost cutting;
5) Eradication of some tree species;
6) Failure to account for the effects of a major spruce budworm infestation.

These points are elaborated on in our summary and release about the Independent Audit.

The report states that, "[f]orest sustainability… will not be achieved unless corrective measures are immediately taken." [p.iii]

Earthroots believes that the draft FMP does not address the above issues aggressively enough. In many cases the draft FMP exacerbates existing issues while the LTMD plans to improve them only over the course of the following 60 or 80 years. It is unacceptable to delay the remediation of this forest to a theoretical point in the future three generations from now.

The draft FMP proposes to continue a number of disturbing trends:

a) Loss of the few remaining roadless areas in the forest through new road building;
b) Logging targets what little mature forest that remains after decades of intensive logging, insect infestation, blow down, and fire;
c) Near extirpation of caribou, and now moose from the forest. The complete loss of winter caribou habitat and the long term failure to meet martin core targets;
d) Extremely low levels of protected areas (approximately 4%);
e) Return to extensive use of aerial spraying of herbicides in spite of scientific evidence on impacts to amphibians and biodiversity;
f) High volumes of wood for low job intensity products;
g) Failure to account in any way for the scientifically established impact of clearcutting on mercury levels in piscivorous fish in local lakes and rivers already known to contain dangerous levels of mercury;
h) Prioritizing logging over all other landuses and values.

On the longstanding dispute between Grassy Narrows First Nation (GNFN) and the Ministry of Natural Resources (MNR) the auditors reported that fundamental differences "cannot be resolved without… relinquishing significant authority to the First Nation to manage portions of the Whiskey Jack Forest according to the desires of the GNFN community. The audit team further believes that the forest management planning process did not anticipate, nor was it designed to resolve the type of dispute currently being experienced on the Whiskey Jack Forest." [p.5] Earthroots echoes this sentiment.

The cumulative effect of over a century of landuse decisions imposed on the people of Grassy Narrows has had a devastating impact on their health, culture, and livelihood. Ontario should meet Grassy Narrows' demand to restore their control over their territory.

We refer you also to our joint letter to Premier Wynne on this matter with organizations representing over 1 million people in Ontario (attached). Please consider this letter as part of our submission.

It is counterproductive to produce forest management plans against the will of the Grassy Narrows First Nation, especially since the Supreme Court is preparing to hear Grassy Narrows' case which calls into question Ontario's authority to make such plans.

We call on Ontario to finally respect the voice of Grassy Narrows.

Kind regards,

Amber Ellis
Executive Director

Forest Management Plan
for the
Whiskey Jack Forest

Title, Certification and Approval Page

Forest Management Plan
for the
Whiskey Jack Forest
(Management Unit #490)

Ontario Ministry of Natural Resources (MNR)
Kenora District, Northwest Region

for the 10-year period from April 1, 2012 to March 31, 2022.

I hereby certify that I have prepared this forest management plan, including Silvicultural Ground Rules, to the best of my professional skill and judgement with the assistance of an interdisciplinary planning team in accordance with the requirements of the *Forest Management Planning Manual* and *the Forest Information Manual*.

_____ _____ Date: _____
R.P.F. seal Kurt Pochailo, R.P.F.
Plan Author, Ontario Ministry of Natural Resources

I recommend that this forest management plan be approved for implementation and certify that it has been prepared in accordance with the requirements of the *Forest Management Planning Manual,* the *Forest Information Manual* and relevant policies and obligations (including any relevant MNR agreements with Aboriginal peoples). I also certify that the forest management plan has been prepared using the applicable forest management guides. In this forest management plan, prescriptions that differ from specific direction or recommendations in the applicable forest management guides are identified in the attached List of Exceptions.

Certified and Recommended for Approval By:

_____ Date: _____
Deb Weedon
District Manager, Kenora District
Ontario Ministry of Natural Resources

Approved by: _____ Date: _____
Allan Willcocks
Regional Director, Northwest Region
Ontario Ministry of Natural Resources

Forest Information Portal Submission Identifier: _____

The original signed and stamped version of this page is retained at the MNR Kenora district office in Kenora.

List of Exceptions

Forest Management Plan
for the

Whiskey Jack Forest

Ontario Ministry of Natural Resources (MNR)
Kenora District, Northwest Region

for the 10-year period from April 1, 2012 to March 31, 2022.

All silvicultural treatments in the silvicultural ground rules (Table FMP-4) which are exceptions to the recommendations in the silvicultural guides, and all operational prescriptions for areas of concern which are exceptions to the specific direction or recommendations (standards and guidelines) in the applicable forest management guides, are provided in this list of exceptions. The specific section of the forest management plan that provides documentation of the exception is also referenced in this list.

Description of Exception	Specific Section of Plan
The following are exceptions to the *Silvicultural Guide to Managing for Black Spruce, Jack Pine and Aspen on Boreal Forest Ecosites in Ontario (3 volumes, MNR, 1997)*:	Table FMP-4, Section 4.2.2.1: Silvicultural Ground Rules, and Monitoring Section 4.7.2: Exceptions
- Full tree logging on ES 11 and 12 where total soil depth (mineral and surface organic) is less than 20 cm. - Artificial seeding on ES 14. - Natural regeneration of jack pine or spruce on ES 21.

2.2.2 Summary of Demographic Profiles 86
2.2.2.1 Dryden 87
2.2.2.2 Fort Frances 88
2.2.2.3 Kenora 88
2.2.2.4 Sioux Lookout 89
2.2.2.5 Asubpeeschoseewagong Netum Anishnabek First Nation (Grassy Narrows) 90
2.2.2.6 Naotkamegwanning First Nation (Whitefish Bay) 91
2.2.2.7 Wabaseemoong Independent Nations (Whitedog) 91
2.2.2.8 Wabauskang First Nation No.21 92
2.2.2.9 Ochiichagwe'babigo'inning First Nation (Dalles) 92
2.2.3 Industrial and Non-industrial Uses of the Forest 93
2.2.3.1 Timber 93
2.2.3.2 Recreation and Tourism 95
2.2.3.3 Mining, Aggregate and Hydro Generation 101
2.2.3.4 Other Uses 102

2.3 Aboriginal Background Information Report 104

3.0 DEVELOPMENT OF THE LONG-TERM MANAGEMENT DIRECTION 105

3.1 Introduction 105

3.2 Management Considerations 106
3.2.1 Revisions to the Forest Resources Inventory 106
3.2.2 New Forest Management Guides 107
3.2.3 Caribou Habitat Management 107
3.2.4 Species At Risk 109
3.2.5 Aboriginal Interests 109
3.2.6 Climate Change 111
3.2.7 Issues Raised During the Independent Forest Audit 112
3.2.8 Shifts In Markets or Utilization 114

3.3 Base Model for Strategic Analysis 115
3.3.1 Analysis Package 116

3.4 Desired Forest and Benefits 117
3.4.1 Review Confirmation of Objectives from the 2004 FMP 118
3.4.2 Indicators Resulting from New MNR Direction 126
3.4.3 Comments Raised during Desired Forest and Benefits Meetings 130

3.5 Objectives and Indicators 137
3.5.1 General Approach to Determining Desirable Levels for Indicators 137
3.5.2 Management Objectives, Indicators and Desirable Levels 139
3.5.2.1 Objective 1: Landscape Pattern 140
3.5.2.2 Objective 2: Forest Composition 143
3.5.2.3 Objective 3: Wildlife Habitat 148
3.5.2.4 Objective 4: Wood Supply 152
3.5.2.5 Objective 5: Managed Crown Forest 155

TABLE OF CONTENTS

Page No.:

3.5.2.6 Objective 6: Aboriginal Involvement in Planning 156
3.5.2.7 Objective 7: Local Citizens Committee Involvement 157
3.5.2.8 Objective 8: Road Access 158
3.5.2.9 Objective 9: Forest Renewal 159
3.5.2.10 Objective 10: Forest Values 161
3.5.2.11 Objective 11: Soil and Water Resources 162

3.6 Long-term Management Direction 163
3.6.0 Development of the LTMD and Projected Forest Condition 164
3.6.0.1 Scoping Investigations and Development of the LTMD 164
3.6.0.2 Forest Condition for the Crown Productive Forest 169
3.6.0.3 Habitat for Species At Risk and Selected Wildlife Species 178
3.6.1 Available Harvest Area 180
3.6.1.1 Available Harvest Volume By Species Group 182
3.6.2 Selection of Areas for Harvest 185
3.6.2.1 Harvest Area Eligibility Criteria 185
3.6.2.2 Harvest Area Selection Criteria 187
3.6.2.3 Rationale for Planned Harvest Areas by Forest Unit and Age Class 190
3.6.3 Assessment of Objective Achievement 194
3.6.3.1 Objective 1: Landscape Pattern 195
3.6.3.2 Objective 2: Forest Composition 198
3.6.3.3 Objective 3: Wildlife Habitat 204
3.6.3.4 Objective 4: Wood Supply 207
3.6.3.5 Objective 6: Aboriginal Involvement in Planning 209
3.6.3.6 Objective 7: Local Citizens Committee Involvement 210
3.6.3.7 Summary of Indicators Measured After Plan Implementation 211
3.6.3.8 Conclusion on the Assessment of Objective Achievement 213
3.6.4 Social and Economic Assessment 214
3.6.4.1 Timber Value Assessment and Impacts 214
3.6.4.2 Silviculture Value Assessment 216
3.6.4.3 Non-timber Value Impact Assessment 217
3.6.4.4 Summary of Social and Economic Impact Assessment 222

4.0 PLANNED OPERATIONS 223

4.1 Introduction 223

4.2 Prescriptions for Operations 223
4.2.1 Operational Prescriptions for Areas of Concern 223
4.2.1.1 Operational Prescription for Areas of Concern Information Products 227
4.2.2 Prescriptions for Harvest, Renewal and Tending Areas 228
4.2.2.1 Silvicultural Ground Rules (SGRs) 228
4.2.2.2 Conditions on Regular Operations (CROs) 232
4.2.2.3 Silvicultural Treatments of Special Public Interest 248

4.3 Harvest Operations 249
4.3.1 Harvest Areas 249
4.3.1.1 Stand Level Residual in Harvest Areas 253
4.3.1.2 Licensing of Harvest Areas 255
4.3.2 Surplus Harvest Area 255
4.3.3 Completion of On-going Harvest Operations from Previous Plan 255
4.3.4 Planned Clearcuts 256
4.3.5 Harvest Volume 257
4.3.6 Wood Utilization 259

TABLE OF CONTENTS

Page No.:

4.3.7 Salvage 261
4.3.8 Contingency Area and Volume 261

4.4 Renewal and Tending Operations 262
4.4.1 Renewal and Tending Areas 262
4.4.1.1 Eligibility and Selection Criteria for Renewal and Tending Activities 263
4.4.2 Renewal Support 264

4.5 Roads 265
4.5.1 Primary and Branch Roads 265
4.5.1.1 Primary Road Corridors 265
4.5.1.2 Branch Road Corridors 266
4.5.2 Operational Roads 267
4.5.3 Area of Concern Crossings – Primary and Branch Roads 268
4.5.4 Area of Concern Crossings – Operational Roads 269
4.5.5 Existing Roads 269
4.5.6 Forestry Aggregate Pits 270
4.5.7 Conditions on Roads, Landings and Aggregate Pits 271
4.5.8 Decommissioning of New and Existing Roads and Road Networks 279

4.6 Expenditures 280

4.7 Monitoring and Assessment 281
4.7.1 Forest Operations Inspections 281
4.7.1.1 Compliance Goal 282
4.7.1.2 Background 282
4.7.1.3 Compliance Objectives, Strategies and Actions 283
4.7.1.4 Risk Analysis and Management 285
4.7.1.5 Roles and Responsibilities 287
4.7.1.6 Notification of Status 288
4.7.1.7 Prevention, Avoidance, and Mitigation 288
4.7.1.8 Compliance Reporting Areas (CRAs) 288
4.7.1.9 Monitoring Compliance of Forest Operations 289
4.7.1.10 Opportunities for LCC Involvement 289
4.7.2 Exceptions 290
4.7.3 Assessment of Regeneration Success 291
4.7.3.1 Assessment Methods 292
4.7.3.2 Area to be Assessed for Regeneration Success 293
4.7.4 Roads and Water Crossings 294

4.8 Fire Prevention and Preparedness 295
4.8.1 Fire Prevention 295
4.8.1.1 Fire Situation Awareness 295
4.8.1.2 Operational Modifications 296
4.8.1.3 Determining Operational Risk and Fire Danger 298
4.8.2 Fire Preparedness 299
4.8.2.1 Trained and Capable, and Limited Operators 299
4.8.2.2 Fire Suppression Equipment 299

4.9 Comparison of Proposed Operations to the Long-Term Management Direction 301
4.9.1 Comparison of Planned Operations to the LTMD 301
4.9.1.1 Comparison of Planned Harvest Area to the LTMD 301
4.9.1.2 Comparison of Planned Renewal and Tending Area to the LTMD 303
4.9.2 Comparison of Stand Conditions of Planned Harvest Areas to the Eligible Harvest Areas 304

TABLE OF CONTENTS

Page No.:

4.9.3 Effect of Age Class Distribution and Projected Harvest Volumes of Planned Harvest Area on the Achievement of LTMD 305
4.9.3.1 Productive Forest Composition 306
4.9.3.2 Productive Forest by Landscape Class 307
4.9.3.3 Age Class Structure 309
4.9.3.4 Old Forest 309
4.9.3.5 Harvest Volumes Projections 311
4.9.4 Effect of Surplus Area on the Achievement of LTMD 313
4.9.5 Effect of Varied Planned Activities on Objective Achievement and Sustainability 313
4.9.6 Conclusion on the Comparison of Proposed Operations on the LTMD 313

5.0 DETERMINATION OF SUSTAINABILITY 314

5.1 Assessment of Management Objective Achievement 314

5.2 Preliminary Spatial Assessment 317

5.3 Social and Economic Assessment 320

5.4 Prescriptions for the Protection of Values 321

5.5 Conclusion on the Sustainability of the FMP 321

List of Supplementary Documentation

A Analysis Package

B Aboriginal Background Information Reports (retained at Kenora MNR District Office)

C Summary of Aboriginal Involvement (retained at Kenora MNR District Office)

D Social and Economic Description, including community demographic profiles.

E Monitoring Programs for Exceptions

F Monitoring Program for Regeneration Success

G Roads Planning Documentation

H Area of Concern (AOC) Planning Documentation

I Summary of Public Consultation, including:
(i) a summary of all comments received and the consideration of those comments;
(ii) a summary of issue resolution; and
(iii) a summary of each stage of consultation.

J Local Citizens Committee Report

K Final List of Required Alterations,
and a List of Major Changes from the Draft to Final Plans

L Planning Team Terms of Reference

M Statement of Environmental Values (SEV)

N Spatial Analysis Reports, including:
i) Caribou Habitat Analysis
ii) Marten Habitat Analysis
iii) Landscape Pattern (OLT and NDPE indicators)

FMP Maps:
Composite Maps (scale 1:200,000)
- Index Map - Harvest, renewal and tending, roads
- Spatial analysis maps (marten habitat, NDPE landscape pattern)
- Moose emphasis areas and deer emphasis areas (scale 1 :200,000)

Operations Maps by OBM (scale 1:20,000)
Values Maps (scale 1:100,000)

NOTE: Information products for harvest, renewal and tending operations will serve as the stand list.

List of Digital FMP File Names

Electronic FMP packaged into a single compressed file **MU490_2012_FMP_P1.zip**

File Name:	Plan Component:

Note: For the draft plan submission, file names contain "FMPDP" instead of "FMP".

1.0 INTRODUCTION

The *Crown Forest Sustainability Act* and the *Environmental Assessment Act* provide the legislative framework for forest management on Crown lands in Ontario. The *Crown Forest Sustainability Act* requires that each forest management plan provides for the long-term health of the Crown forest and have regard for plant life, animal life, water, soil, air and social and economic values, including recreational values and heritage values. The forest management plan meets these requirements by developing and incorporating a management strategy that balances objectives related to forest diversity, socio-economics, forest cover and silviculture. The Ministry of Natural Resources (MNR) has the ultimate responsibility of sustainable management of the province's Crown forests in order to meet social, economic and environmental objectives of present and future generations.

A Forest Management Plan Summary has been prepared for this forest management plan and is available in English and French.

1.1 Planning Context

The Crown forest of Ontario is subdivided into forests or management units (MUs) for the purpose of forest management. The Whiskey Jack Forest is managed by the Ontario Ministry of Natural Resources as a Crown Management Unit. It is one of two management units administered from the Kenora MNR District Office, one of 21 management units in the MNR Northwest Region, and one of the 45 management units in the Province of Ontario.

The forest management planning requirements and the provisions of the environmental assessment approval are incorporated into the *Forest Management Planning Manual for Ontario's Crown Forests* (MNR, 2009). This manual is referenced in this plan as the "FMPM", "FMP Manual" or the "Forest Management Planning Manual". Forest management plans must also be prepared in accordance with the *Forest Information Manual* (MNR, 2009, FIM).

This Whiskey Jack Forest FMP has been prepared by the Plan Author, a professional forester registered under *Bill 110, the Ontario Professional Foresters Act, 2000* in an open and consultative fashion with the assistance of an interdisciplinary planning team. This team includes professional and technical staff from the MNR and Miisun Integrated Resource Management Inc. as well as members representing First Nation communities, Local Citizens Committees (LCC) from Kenora and Red Lake, and representatives of wood receiving mills. Opportunities for participation by interested and affected stakeholders, organizations, and the general public have been provided during the planning process. The Terms of Reference for the Whiskey Jack Forest Planning Team is included in Supplementary Documentation L.

This forest management plan (FMP) is prepared for the 10-year period from April 1, 2012 to March 31, 2022. The management plan describes forest management activities, such as timber harvesting, road construction and silviculture that will take place during the plan period. The preparation of the plan occurs in two phases. The strategic, long-term planning and the planning of the first five-years of operation are conducted during Phase I. This management plan includes the results of the Phase I planning which covers strategic planning for a ten-year period from April 1, 2012 to March 31, 2022, and details specific operations during the first five-year term from April 1, 2012 to March 31, 2017. Phase II operational planning will commence approximately a year in advance of the second five-year term, subject to Regional Director

endorsement of the Year 3 Annual Report. Detailed operations for the second five-year phase of this plan will be prepared and submitted for approval to guide future operations. This forest management plan supersedes the 2012-2014 Contingency Plan for the Whiskey Jack Forest.

1.2 Statement of Environmental Values

The *Ontario Ministry of Natural Resource's Statement of Environmental Values (SEV), 2008* under the *Environmental Bill of Rights (EBR)* is a document which describes how the purposes of the EBR are to be considered whenever decisions that might significantly affect the environment are made in the Ministry. In the development of this forest management plan, MNR's Statement of Environmental Values has been considered along with direction from Ontario's Crown Land Use Policy Atlas. The plan is intended to reflect the direction set out in the SEV, and to further the objective of managing Ontario's natural resources on a sustainable basis. An SEV consideration document has been prepared by MNR for the plan, and is provided in Supplementary Documentation M. A listing of the environmental assessment components of the forest management plan is located in the plan text immediately following the Table of Contents.

1.3 Management Unit Location and Administration

The Whiskey Jack Forest is located approximately 450 kilometres west of Thunder Bay in the Northwest Region of the Ontario Ministry of Natural Resources (MNR), primarily within the Kenora District, but partially in the Red Lake District to the north. The forest is administered as a Crown Unit by the Kenora District MNR Office (English River Area).

The location of the Whiskey Jack Forest and its proximity to MNR districts and areas within the MNR Northwest Region is illustrated in Figure 1. Figure 2 illustrates the Whiskey Jack Forest at a larger scale, showing boundaries, wood receiving mill locations, administrative boundaries and references the location of the MNR administrative office.

Communities within or adjacent to the Whiskey Jack Forest include the City of Kenora (including the former Keewatin and Jaffray Melick), Sioux Narrows, Redditt, Vermilion Bay, Ear Falls and Red Lake. First Nations communities that are within or adjacent to the Whiskey Jack Forest include Asubpeeschoseewagong Netum Anishinabek (Grassy Narrows First Nation), Wabaseemoong Independent Nations and Ochiichagwe'babigo'inning (Dalles First Nation), Wabauskang First Nation, and Naotkamegwanning (Whitefish Bay First Nation).

The Whiskey Jack Forest was licensed under Sustainable Forest Licence (S.F.L.#542253) effective April 1st, 1997. The Whiskey Jack Forest is the result of the amalgamation of the previous Pakwash Forest (FMA 502100) and Patricia Forest (FMA 502000) Forest Management Agreement areas. The Pakwash Forest was formerly that section of Parcel 1, License 326700 lying north of the English River system. A Forest Management Agreement was signed in 1984 between the Province of Ontario and Boise Cascade Canada Ltd. (now Abitibi-Consolidated) to establish the Pakwash Forest. At that same time forest management agreements were also signed to establish the Patricia Forest and the Lake of the Woods Forest. The Patricia Forest was an amalgamation, as of April 1989, of the East Patricia Forest (FMA 501900) and the Lake of the Woods Forest (FMA 502000). There have not been any changes to the management unit boundary since the signing of the S.F.L.

Note: MNR Kenora District Office located at 808 Robertson Street, Kenora, Ontario.

2.0 MANAGEMENT UNIT DESCRIPTION

2.1 Forest Description

2.1.1 Current Forest Condition

This section of the plan text describes the Crown forest and patent land Crown timber, as described in the forest inventory, and discusses the implications of land type (e.g., large areas of non-productive forest within the management unit) on the development of the forest management plan. The plan text discusses the implications of patent land within the management unit on the development of the forest management plan.

2.1.1.1 Forest Inventory

The planning inventory for the management unit provides information required for forest management planning, including forest modelling, habitat modelling and forest biodiversity analyses. The Forest Resource Inventory (FRI) information is updated annually as a result of forest management activities and natural disturbances. The planning inventory also contains expected or forecasted changes, based on planned operations from the current approved forest management plan (e.g. forest operations which have not yet been implemented during the 2004-2012 terms). The details with respect to updates made to the planning inventory are presented in Supplementary Documentation A - Analysis Package.

The planning composite was developed based on the 2004 Whiskey Jack FMP planning collection inventory (PCOL). The Inventory Task Team considered the 2004 PCOL inventory as the most up to date inventory information available and would require the least amount of update information in order to be usable for planning purposes for the 2012 FMP.

Abitibi surrendered the Whiskey Jack Forest SFL to MNR in 2009. As a surrender condition, Abitibi Bowater Inc. updated the forest polygon coverage to include actual harvest depletion, silviculture and Free-To-Grow information from April 1, 2004 to March 31, 2009. MNR was responsible for all other inventory updates including the creation of a seamless coverage from this inventory. The overall Crown land base decreased by 103 ha as a result of boundary adjustment to match the management unit metes and bounds. As a result of the major inventory update undertaken in 2005, the production land base increased by 7,012 ha. This resulted from some area that was shifted to protection forest (3,352 ha) and a decrease in unclassified land (reduced road right-of-way buffering, 3,660 ha).

For updates to the planning inventory, MNR provided values and ownership information. This information is stored in the Natural Resources Values Information System (NRVIS) and the Land Information Ontario (LIO) Warehouse. Information regarding Free-To-Grow (FTG) was provided from regeneration surveys and depletions records that were created from aerial photography and high resolution satellite imagery.

The composite planning inventory was assembled using the following methodology:

- Updated historical information related to natural and harvest depletions updated to 2009, ownership and roads base coverages;
- Updated values, hydro corridors, and railway beds; and
- Updated stand information based on Free-To-Grow surveys.

Then the planning inventory was used to create the Base Model Inventory using the following methodology:

- Updated inventory format as per the revised *Forest Information Manual* (FIM) and associated technical specifications;
- Updated forest units, development stages and silvicultural intensities;
- Created a Forecast Depletion layer from the approved 2009-2012 Contingency Plan. Estimated depletions were given a year of depletion (YRDEP) of 2012;
- Revised (grew) young forest stand heights through application of an approved algorithm.
- Merged inventory with the MU wide AOC reserves to create the Base Model Inventory (BMI).

The BMI layer was utilized for Table FMP-3 and the Strategic Forest Management Model (SFMM) modelling initial land base. Area summaries in all tables reflect the base model inventory (after the union on the planning inventory and the forecast depletions). This usually results in an over estimation of "recent disturbance" and "below regeneration standards" area due to the full depletion of all forecast clearcut forest unit stands.

As result of a recommendation of the Minister's Council on Forest Sector Competitiveness (June 2005), the Ministry of Natural Resources is assuming the responsibilities for Forest Resource Inventories. Based on recommendations from the Provincial Forest Inventory Advisory Committee, acquisition of new aerial photography was completed in 2009. Follow up calibration plot establishment and photo interpretation work is tentatively scheduled for June 2015 to January 2017, at which time the inventory is tentatively scheduled for delivery in March 2017. These dates are subject to change.

2.1.1.2 Land Ownership and Productivity

The planning inventory can be broadly described in terms of land ownership. Table FMP-1 is a Crown Land Summary, presenting the area (in hectares) of different land types (forested & non-forested), by Crown ownership type for the Whiskey Jack Forest (Managed and Park). Forest management activities are only planned on managed, Crown land; however Crown - Parks (parks, conservation reserves, etc.), may contribute to wildlife habitat and other non-timber objectives. Where appropriate, these ownership and land type classifications are illustrated on maps within this FMP.

A summary of the land types by ownership for the management unit at the beginning of the plan period is provided in Table FMP-1 Management Unit Crown Land Summary. The total Whiskey Jack Forest is 1,063,446 hectares in size, comparable to the land base reported in the previous 2004 FMP. The 2009 Forest Management Planning Manual, used for this FMP, revised the format of Table FMP-1 and now it does not include Patent or Federal lands, only Crown land. Of the total Whiskey Jack Forest land base, 1,053,515 hectares are Crown land (Managed or Park/Conservation reserves, reported in Table FMP-1) and the remainder is Patent Land or Federal Land (not reported in Table FMP-1 and not managed in this FMP).

Provincial Parks and Protected Areas (Ownerships 5 and 7) include several different classifications (all Crown land). Each class and individual area has different objectives and permit different activities within the defined areas. There are six classifications of provincial parks; 1)Wilderness Class Parks, 2) Nature Reserve Class Parks, 3) Cultural Heritage Class Parks, 4) Natural Environment Class Parks, 5) Waterway Class Parks, and 6) Recreational

Class Parks. In addition to parks, there are conservation reserves (considered in combination with Crown park land in the forest inventory and planning).

The Whiskey Jack Forest has seven Provincial Parks surrounded by, or immediately adjacent to the SFL boundaries. Parks within the management unit include the West English River, Eagle-Dogtooth, Tide Lake and the Maynard Lake Parks. Pakwash Provincial Park is located adjacent to the northeast corner of the unit, Rushing River Provincial Park is located in the southern portion of the forest, and Woodland Caribou Provincial Park (and Park Addition) is located in the northwest portion of the unit. All of these parks have either an Interim Management Statement or a park management plan that provides direction. More detail on the parks and protected areas is included in text Section 2.1.3.3.5.

The park and protected areas within the Whiskey Jack Forest encompasses 89,295 hectares (8% of forest) and is 85 hectares greater than the parks land base reported in the 2004 FMP. The provincial parks in and adjacent to the Whiskey Jack Forest are managed by Ontario Parks, while the conservation reserves are managed by Kenora, Sioux Lookout and Red Lake Districts of the Ministry of Natural Resources.

Managed, Crown land (Ownership 1) covers 964,220 hectares (84%) of the Whiskey Jack Forest, a decrease of 188 hectares since the 2004 FMP. This difference is the net difference from revisions for a decrease in reported water, an increase in the non-productive area and protection forest, and an increase in forested area.

The Crown, managed and park areas are used for the strategic planning for this forest management plan.

Patent land – (Ownerships 2, 3, or 4) Approximately 3,066 hectares of patent land (<1% of the production forest) are included within the boundaries of the Whiskey Jack Forest. Provincially, there are three classifications of patent land (other than Crown owned patent land, see note below):

Ownership 2 – Patent land with timber rights reserved to the Crown;
Ownership 3 - Patent land - Fee Simple (private land), no timber reserved;
Ownership 4 – Patent land – Company Freehold.
Note: Patent land owned by MNR, Lands & Forests or other Crown ministries is treated as if it were Ownership 1 – Crown, Managed Land.

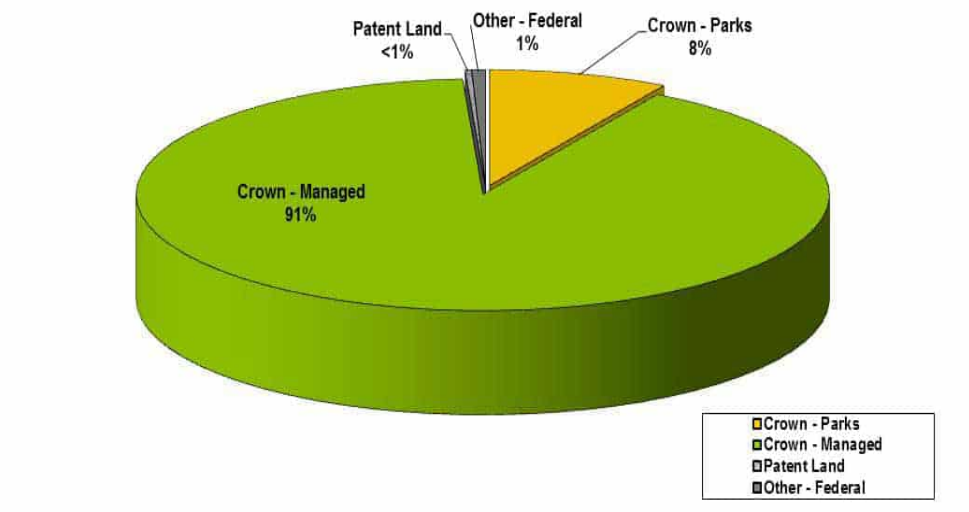
All patent land on the Whiskey Jack Forest is classified as Ownership 3 in the forest resources inventory, though some tracts of patent land do have trees reserved to the Crown. Landowners wishing to harvest trees on patent land should contact the Land Registry Office to confirm if trees are reserved to the Crown.

In accordance with the *Crown Forest Sustainability Act,* all patent land (Ownerships 2, 3, and 4) is excluded from the Whiskey Jack Forest SFL area and is therefore not included in this forest management plan or its associated strategic planning. Patent land is not reported in Table FMP-1. Patent land must be considered as values during forest management planning for the managed, Crown area of the Whiskey Jack Forest. Negotiations with landowners must occur to gain permission if access through patent land is required for harvest or renewal activities. Renewal activities, especially aerial chemical tending, are impacted based on the proximity to patent land where treatment is limited to ground spraying as aerial spraying is considered too great of a liability.

Federal land (Ownerships 6 and 9) accounts for 6,866 hectares (1%) of the Whiskey Jack Forest and is also not included in the management plan strategic planning or operations. Other (federal) land is not reported in Table FMP-1.

The proportion of Crown land (park and managed), patent and other (federal) land are illustrated in Figure 3. Excluding patent and other (federal) land, Managed Crown land accounts for 92% of the Whiskey Jack Forest Crown land, with Crown Park land contributing the remaining 8%.

Figure 3 Land Ownership Summary of the Whiskey Jack Forest



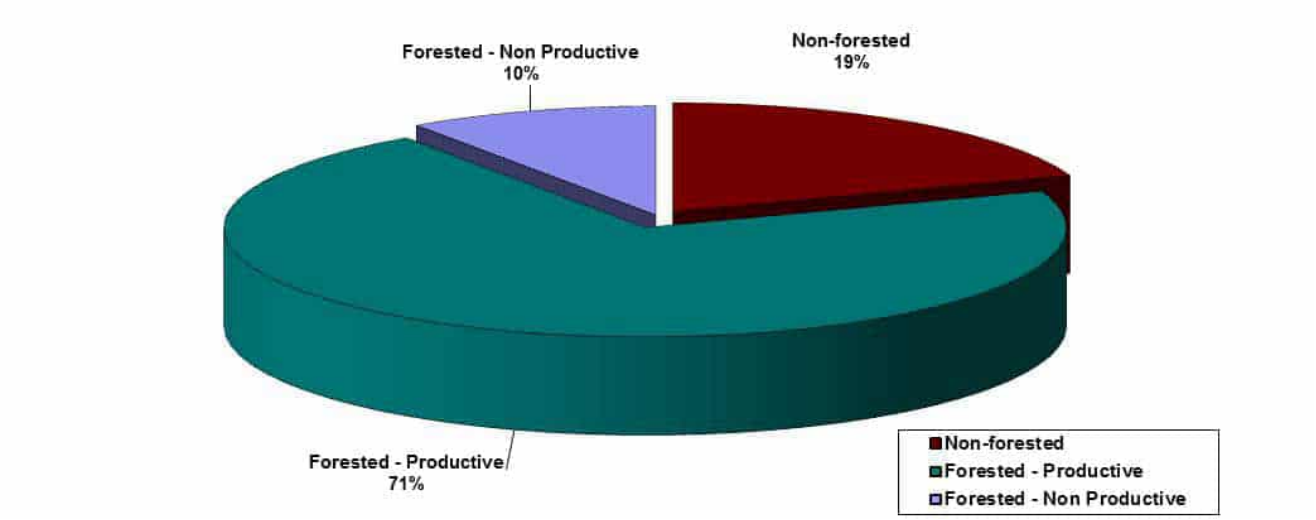
The Whiskey Jack Forest inventory was used as an input to calculate and measure the achievement of Management Objectives (Section 3.5) and Determination of Sustainability (Section 5.0). The forested stands were totalled and categorized into forest units (Section 2.1.2.1). The total land base (Crown managed and park including non-productive) for the Whiskey Jack Forest was calculated to be 1,053,501 hectares in SFMM, which is comparable to the total Crown, Managed and Park land base in Table FMP-1 (14 hectares less, acceptable rounding difference). Patent land (3,066 hectares) and Other (federal) land (6,866 hectares) are not included in the strategic modelling. The reconciliation of the land base of the Whiskey Jack Forest (Table FMP-1) and the SFMM land base used for strategic planning purposes is documented in an optional table located in the table file immediately following Table FMP-3 (also in Supplementary Documentation A – Analysis Package, Section 6.2.1 Land Base Assumptions).

The FMPM (2009) defines the following:

- **Productive Forest** is “all forest areas which are capable of growing commercial trees, irrespective of planning decisions, and which is further sub-divided into “protection forest and production forest”.
- **Protection Forest** is “productive forest land on which forest management activities cannot normally be practiced without incurring deleterious environmental effects because of obvious physical limitations such as steep slopes and shallow soils over bedrock”.
- **Production Forest** is “productive forest land, at various stages of growth, with no obvious physical limitations on the ability to practice forest management”.

For Crown land, the productive forest area is 745,548 hectares (Crown Managed and Parks) or 71 percent of the total Crown area according to the updated Planning Inventory. Water and non-forested land account for 206,541 hectares (19%) of the Crown land base. Non-productive land makes up the balance of the Whiskey Jack Forest with 101,426 hectares (10% of Crown land). The total area of the productive forest is tabulated in Table FMP-1, and depicted graphically in Figure 4.

Figure 4 Crown Land Productivity Summary



Planned harvest depletions for the 2004-2024 forest management plan and 2009-2012 Contingency Plan and actual recent depletions prior to 2012 are classified as "Below Regeneration Standards" forested stands (age class 1-10) in the appropriate forested stand classification for this plan (Forest Unit, Section 3.2.1). Older "Below Regeneration Standards" area, formerly referred to as "true Barren and Scattered" area, is identified in Table FMP-1. More detail on the classification of the forest in the planning inventory is included in Supplementary Documentation A – Analysis Package, Section 4.

It is worth clarifying that area currently classified as being "below regeneration standards" is being reported differently than was done for the 2004 FMP. The older stands (DEVSTAGE equal to LOWNAT, LOWPLANT, LOWSEED, LOWMGMT) are equivalent to the previous "true" Barren and Scattered (B&S) that were reported in the previous FMP. These areas are considered as not being productive in the strategic modelling even though they still provide some benefit for wildlife habitat and forest diversity. The more recently depleted areas, through both harvesting and natural depletions, are now reported on a separate line in Table FMP-1 (NEWNAT, NEWPLANT, NEWSEED and NEWMGMT areas). These "NEW…" areas are not currently meeting regeneration standards but are expected to achieve standards within this plan period either through renewal treatments or natural regeneration. The "NEW…" classified areas are considered as productive forest in the strategic modelling and continue to provide the benefits afforded by forest stands. This "NEW…" area was not reported separately in the 2004 FMP, but was classified as "B&S" in Table FMP-1 and reclassified as young, growing forested stands in the strategic modelling land base.

2.1.2 Forest Classification

This section of the plan text describes the current forest condition and the various means of classifying the land base for forest management planning.

2.1.2.1 Forest Units

Forest stands are aggregated into forest units (FUs) to facilitate management planning. For this plan, the planning team considered the variability of ecosites, management implications and resulting timber yields when determining the forest units for the plan. The forest units represent ecologically based areas of the productive forest land base:

- Have similar species composition;
- Develop in a similar manner (naturally and in response to silvicultural treatments); and
- Are managed under the same silvicultural system.

Forest units provide a foundation for silvicultural ground rules (Table FMP-4), strategic modelling forest dynamics (yield curves, forest succession), analysis of management objective achievement (prediction of forest conditions, available harvest area, biodiversity, managed forest available for timber production, timber volume projections, wildlife habitat potential) and the selection of areas of operations. The development of forest units is an iterative process that must be based on science and are ecologically defensible. Forest unit development occurs within the context provided by management objectives with a link to the desired future forest condition. The development of ecologically based forest units may be constrained by the current forest condition, knowledge or current land base classification.

The first step in the development of plan forest units for this 2012 FMP was agreement that it was a cooperative process with the Kenora Forest 2012-2022 Planning Team and that both forest management plans would be prepared using the same forest unit definitions. Preparing 2012 plans for these adjacent forests utilizing the same forest units was considered a key objective as identical forest units would streamline future planning if there was a potential land base amalgamation and identical forest units would streamline future reporting of forest management activities. Another consideration was that by utilizing the same suite of forest units, there were some efficiencies to be realized in plan development for the 2012 plans (e.g. strategic modelling inputs, plan documentation, etc.). While development of forest units was a joint process between two planning teams, both teams separately demonstrated the appropriateness of the final PLANFUs to each of the two individual management units.

The Forest Resource Inventory parameters used for the development of these forest units were species composition, stocking, site class, age and ecosite (for shallow and wet soils). A number of adjustments were made to the Whiskey Jack Forest 2004 FMP forest units to be more consistent with the Northwest Region Standard Forest Units (SFU). With only very minor exceptions, each standard forest unit fit into a single PLANFU. This strong correlation between PLANFUs and SFUs was important since many forest diversity and forest condition desirable levels and targets were based on science developed for the Ontario Landscape Tool, which utilized inputs documented primarily by standard forest units. Better correlation in forest units to SFUs allowed better analysis of projections to Ontario Landscape Tool Simulated Ranges of Natural Variation (SRNV).

A number of Regional Standard Forest Units were amalgamated to create the 2012-2022 Whiskey Jack Plan Forest Unit. Major ones are the Upland Cedar (**UplCe)** was lumped into Conifer Mixedwood (**CMX)** since Upland Cedar (**UplCe)** is on a much more productive site than Other Conifer Lowland (**OCLow)**, and only makes up 3,545 ha , Hardwood Dominated (**HrDom),** Hardwood Mixedwood **(HrdMw),** White Birch Dominated **(BwDom)** and White Birch Shallow **(BwSha)** was lumped to create Hardwood Mixedwood **(HMX),** Balsam Fir Pure **(BfPur)** was lumped with Balsam Fir Mixedwood **(BfMx1)** to create Balsam Fir Mixedwood **(BFM),** Red Pine Dominant **(PrDom),** White Pine Dominant **(PwDom**) and Red Pine – White Pine Mixedwood **(PrPrMx)** was lumped to create Red Pine – White Pine Mixedwood **(PRW).** These areas were lumped because they represent small area.

Forest units for both the Whiskey Jack Forest 2004-2024 Forest Management Plan (WJ 2004 FMP) and the Whiskey Jack Forest 2012-22 Forest Management Plan (WJ 2012 FMP) were based on the Northwest Regional Standard Forest Units; however the forest units were revised to better amalgamate regional standard forest units and improved to reflect better representation of ecosite classification according to *The Terrestrial and Wetland Ecosites of Northwestern Ontario (MNR, 1996)*. An ecosite is primarily a mapping unit integrating a consistent set of environmental factors and vegetative conditions. They are composed of eco-elements that describe common assemblages of both abiotic (soil depth, texture, moisture regime, hydrology and nutrient regime) and biotic (plant community structure and composition) components.

The relationship between plan forest units from the 2004 and 2012 FMPs and regional standard forest units are summarized in
Figure 5. Table FMP-2 presents summary of the description of forest units including a description of each forest unit, forest types, main ecosites, associated regional forest unit, silvicultural system, and the FRI sort parameters. The development of these forest units is detailed in the Analysis Package Supplementary Documentation A (Section 5.1) including the analysis of the productive Crown, managed land base by Northwest Region standard forest units, ecosites, average species compositions, average stocking and site class. This FMP is prepared based on available information and updates made to the Forest Resource Inventory (FRI) and this information forms the basis for the development of forest units. These forest units have been reviewed and approved as appropriate for the Whiskey Jack Forest by the MNR.

A total of 12 forest units were developed and approved to represent unique stand and site conditions on the Whiskey Jack Forest for the 2012 FMP. The forest units for this plan are outlined below:

Pure Forest Units

The following list represents forest units that are comprised of one dominant tree species:

- PJD - jack pine dominated stands with minimal poplar component;
- POD - poplar dominated stands;
- SPD - upland black (or white) spruce dominated stands with minimal hardwood;
- OCL - larch and cedar dominated lowland stands; and
- SBL - lowland black spruce stands.

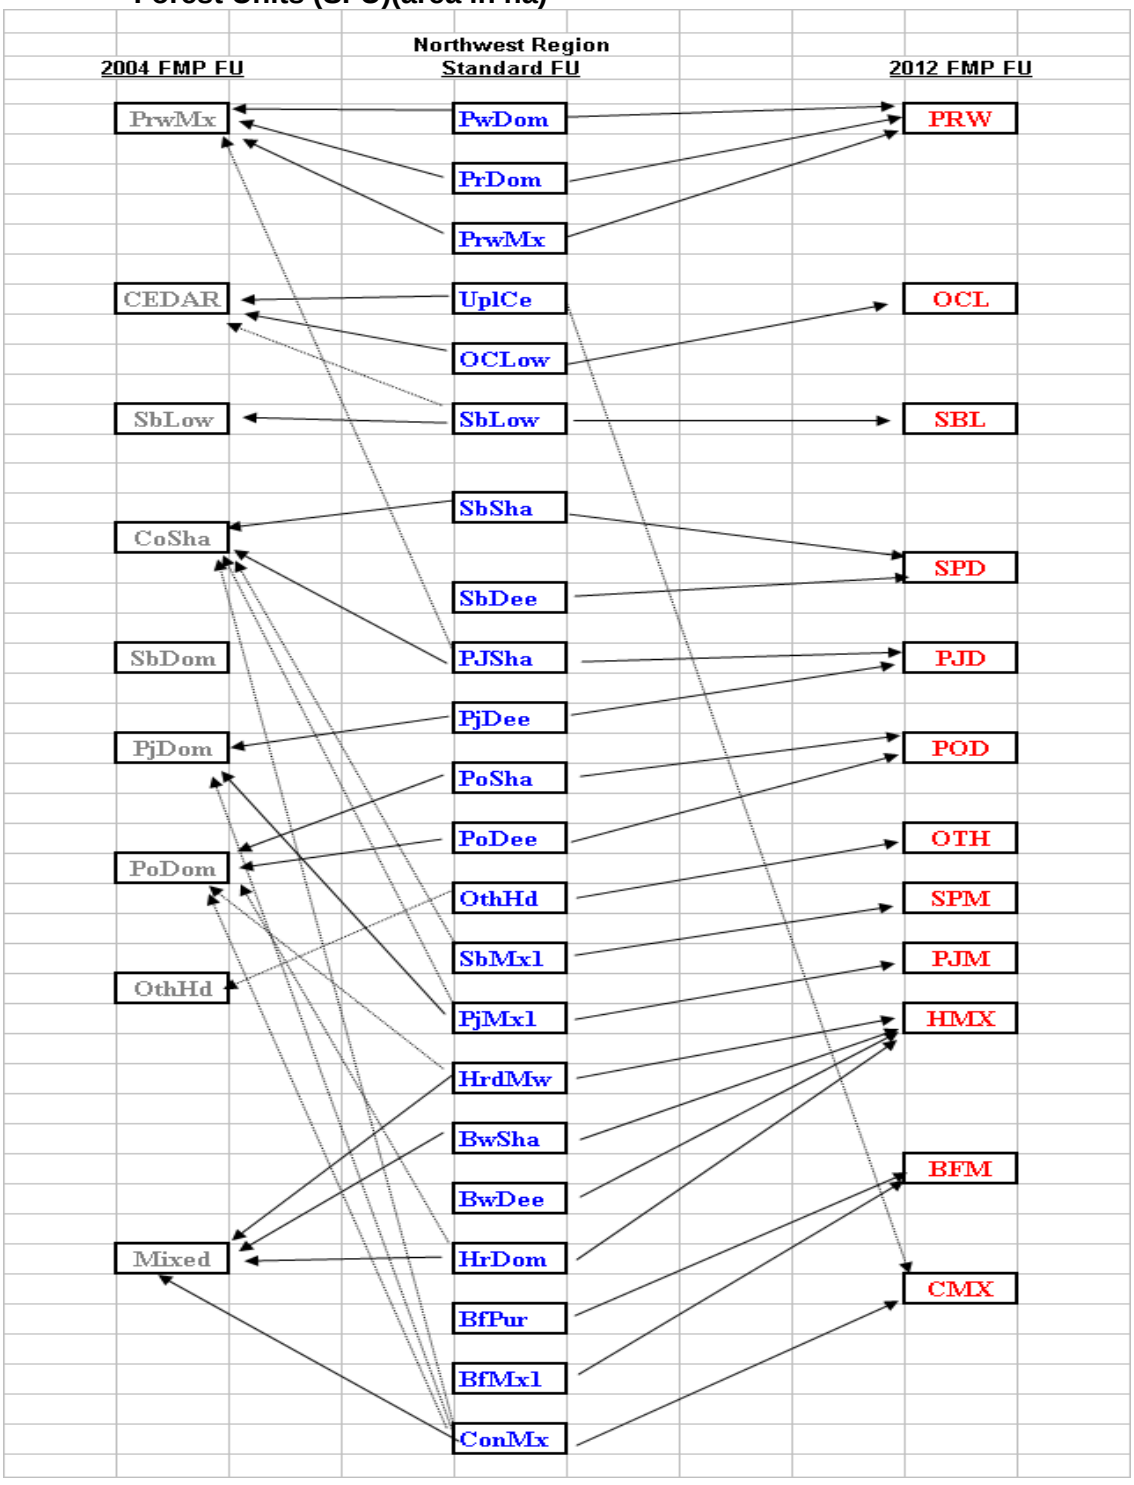
Mixedwood Forest Units

These forest units represent mixed conifer or mixed hardwood stand conditions:

- BFM - balsam fir mixedwood stands;
- CMX - conifer mixedwood stands;
- HMX - mixed hardwood dominated stands;

OTH - other hardwood mixedwood stands;
PJM - jack pine dominated mixedwood stands with minimal hardwood;
SPM - spruce dominated mixedwood stands with minimal hardwood; and
PRW - red pine and white pine mixedwood stands.

Figure 5 Correlation of Plan Forest Units (PLANFU) 2004 and 2012 to Standard Forest Units (SFU)(area in ha)



A summary of the managed Crown productive forest area for the Whiskey Jack Forest is provided in Table FMP-3 by forest unit area, age class and availability for timber production. The productive forest area is also reported by classifications as being production forest or protection forest (classification definitions referenced in Section 2.1.1.2). There are a total of 673,090 hectares of production forest and a total of 32,515 hectares of protection forest on the Crown, managed portion of the Whiskey Jack Forest.

The managed, Crown land within the Whiskey Jack Forest was further classified as available or unavailable according to the *Forest Resources Inventory Technical Specifications (2009)*. The availability indicator identifies which portions of the managed Crown production forest are available for timber production or not. The availability of forest is based on several pieces of information such as access, land use designation, physical operability limitation and managed decisions. Those managed, Crown land stands that are deemed unavailable are considered as reserves for the strategic modelling purposes.

Of the production forest reported in Table FMP-3 (673,090 ha), there are 131,335 hectares estimated to be unavailable for timber production in the inventory, leaving 538,618 hectares estimated to be available for timber production (see Table FMP-3 footnotes). Estimated unavailable area includes forested islands, older LOWNAT area unsuitable for harvest operations, estimated (new) slope-based riparian reserves, nest reserves and tourism reserves.

It should be noted that areas designated as unavailable during this plan, may in fact become available for forest management activities in the future due to advances in timber harvesting technologies, or changes in land use guidelines or their application.

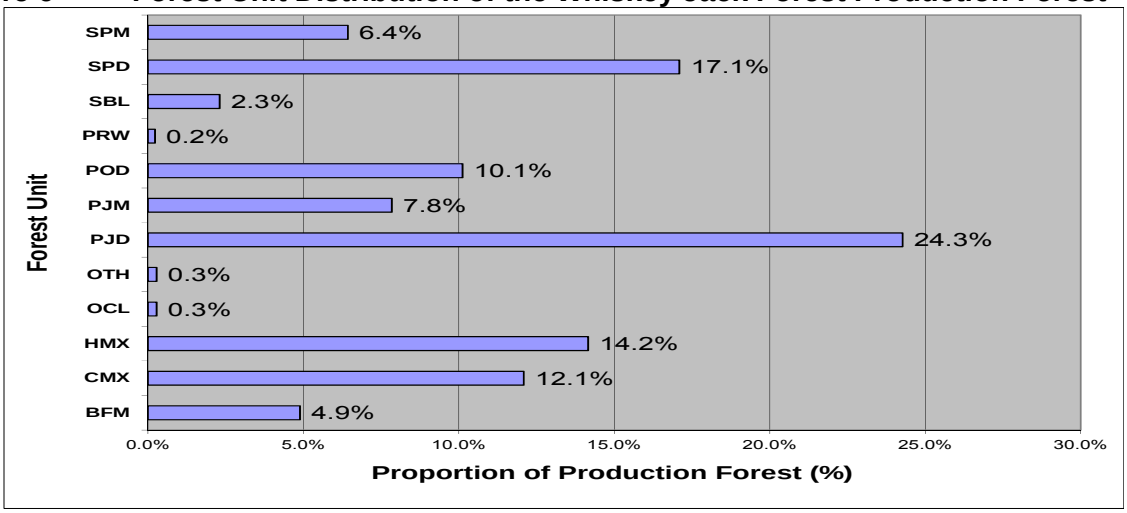
Unavailable area was initially classified in the forest resources planning composite inventory. A further refinement of unavailable area was completed with the Base Model Inventory to identify additional areas projected to be unavailable for operations due to spatial considerations. This total estimate of unavailable area was included in the strategic SFMM modelling data (strategic planning land base reconciled in the table following Table FMP-3, also located in Supplementary Documentation A – Analysis Package, Section 6.2.1 Table 9).

The Whiskey Jack Forest is mostly a conifer dominated forest (64% in PJD, SPD, PJM, SPM, PRW, OCL, BFM and SBL) with 26% mixedwood forest (CMX and HMX) and a slightly lesser proportion of purer poplar dominated forest (10% in POD)(Figure 6).

There is a silvicultural strategy to increase to more pure conifer and hardwood species stands on the Whiskey Jack Forest as would have been created by wildfire (see rationale Section 3.5.2.2 Objective 2: Forest Composition, indicators 2a, 2b, 2e). There is also a provincial and management unit strategy to maintain or increase the area of the red pine and white pine mixedwood (PRW) forest unit area. Red pine and white pine renewal will be encouraged on the Whiskey Jack Forest, but most likely will result in increased red pine and white pine species composition within forest units, with a minimal increase in the PRW forest unit area.

The following is a description of each forest unit and the amount of production forest area available for timber production, as presented in Table FMP-2 and Table FMP-3. Production area by forest unit is described below (listed in order of occurrence on the forest – most common to least common forest units).

Figure 6 Forest Unit Distribution of the Whiskey Jack Forest Production Forest



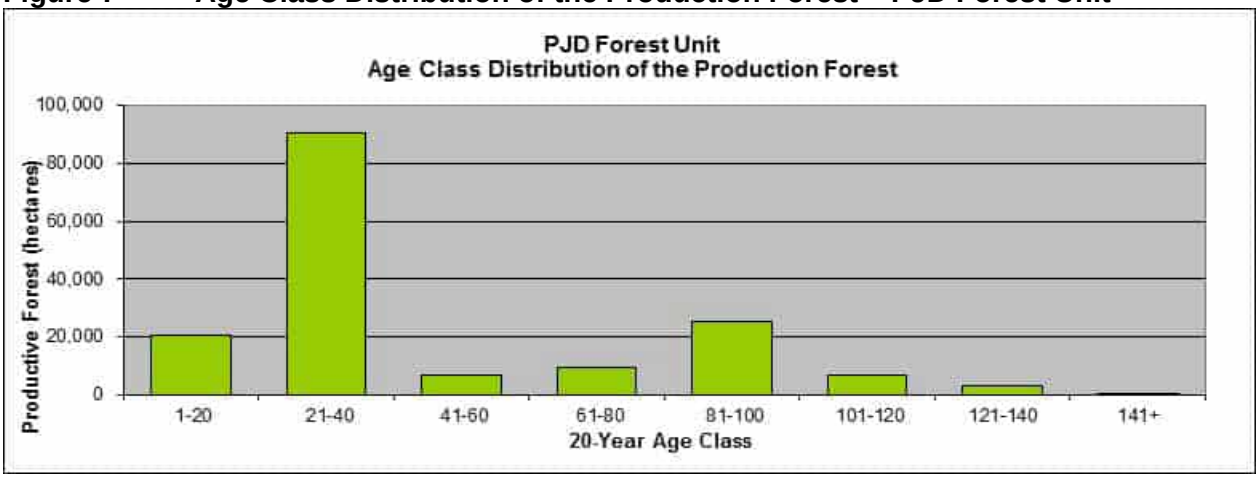
Jack Pine Dominated (PJD) Forest Unit

The PJD forest unit is largest forest unit on the Whiskey Jack Forest and is comprised of jack pine dominated stands (jack pine greater than or equal to 70%) with minimal poplar component. The PJD forest unit includes the Jack Pine Shallow (PjSha) and Jack Pine Deep (PjDee) regional standard forest unit areas.

The PJD forest unit occupies 24% of the production forest land base (163,384 hectares, Figure 7). PJD forest unit stands are located most frequently on Ecosite 12 areas with some occurrences on Ecosite 20. Typical sites are dominated by jack pine, with minor occurrences of black spruce, poplar, white birch and balsam fir. Soils are often very shallow and dry to fresh with fine to coarse sand or coarse loam.

The relatively high level of PJD forest in the 21-40 year age class can be primarily attributed to wildfires that occurred in the 1980s. The relatively low level of conifer in the 41-60 year age class is typical of the northwest region and results from a period when there was minimal investment in conifer regeneration after harvesting (this situation changed in the early 1980s with the signing of the first Forest Management Agreements). The current forest condition does not reflect any significant management implications to be considered in the development of this

Figure 7 Age Class Distribution of the Production Forest – PJD Forest Unit



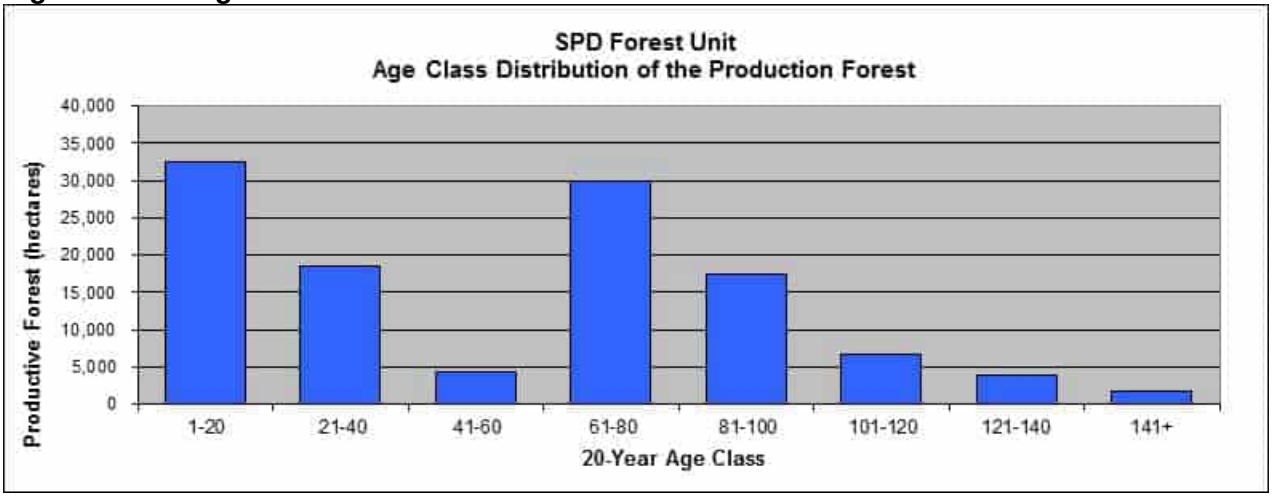
FMP however silvicultural strategies will be implemented to encourage the maintenance of the PJD forest unit area through time while limiting the conversion of area to mixedwoods such as CMX and HMX.

Spruce Dominated Upland (SPD) Forest Unit

The SPD forest unit is the second largest with 17% of the production forest land base (115,053 ha, Figure 8). The SPD forest unit is primarily upland black (or occasionally white) spruce dominated stands with minimal hardwood present. SPD stands are usually associated with Ecosites 12, 20 and 22. Typical sites are dominated by black spruce, with occurrences of jack pine, poplar, white birch and balsam fir. Soils are often shallow and dry to fresh with fine to coarse sand to fine loamy-clayey soils. The SPD forest unit includes area classified as SbSha, SbDee, SbMx1 regional standard forest unit areas.

The relatively high level of SPD forest in the 1-20 year age class can be attributed to significant area not yet free to grow and how forest inventories are interpreted. It is common to classify a stand as SB 100% if the stand is too young to be interpreted on aerial photography. Many of these stands may be in actuality SPM mixed stands containing a component of jack pine. Under current management practices, pure black spruce conditions have a higher level of difficulty to regenerate due to slow growth rate in comparison to other tree competitors. The success of producing SPD forest is much lower and must be considered a priority in increasing area above the current forest level. Many wildlife species prefer mature, conifer (including spruce) dominated forests for habitat which will be a consideration during development of the long-term management direction and setting of desirable levels for indicators of management objective achievement.

Figure 8 Age Class Distribution of the Production Forest – SPD Forest Unit



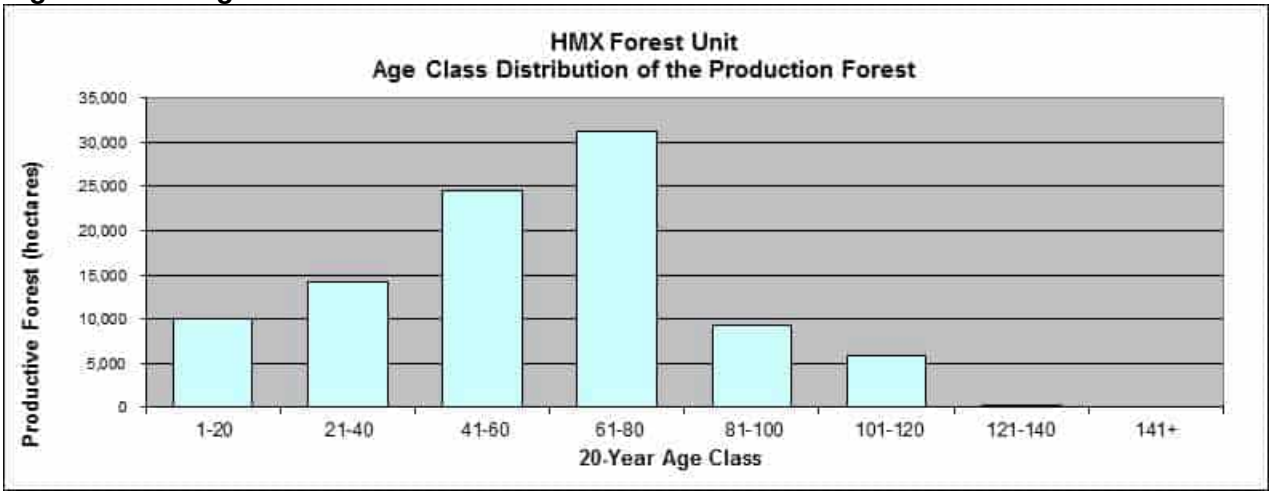
Hardwood Mixedwood (HMX) Forest Unit

The HMX forest unit is the third largest forest unit on the Whiskey Jack Forest comprising 14% of the production forest land base (95,322 hectares, Figure 9). The HMX forest unit is made up of mixed hardwood conifer stands, with 50% or more of the stand composed of hardwoods. The HMX forest unit includes area primarily classified as HrdMx, HrDom regional standards forest units, with some additional area classified as the BwDee and BwSha regional standard forest units.

HMX is most often found on Ecosites 12, 19, 29 and 11 which are frequently very shallow soils over bedrock or fresh, well drained, with coarse loamy to fine sandy soils but this forest unit can also be found on the fine loamy-clayey soils. This forest unit has a predominance of area in the 61-80 year old age class, primarily a result from wildfires 60-80 years ago.

As with the mixed conifer forest unit (CMX), the increase of this forest unit area through time can be attributed to past forest practices and not the historic forest condition. The long-term management strategy for this plan needs to consider the impacts of increasing hardwood and mixed forest type on pure and conifer dominated forest units, and on the provision of wildlife habitat. Silvicultural strategies will be implemented in this plan that will gradually reduce the area of the HMX forest unit area over the next 50 years (approximate timeframe). Most HMX conversion will be to the purer POD forest unit area, and some of the drier sites will be considered for conversion to conifer dominated forest units (Section 4.2.2.1 Silvicultural Ground Rules, Section 3.6.3. Assessment of Management Objectives).

Figure 9 Age Class Distribution of the Production Forest – HMX Forest Unit

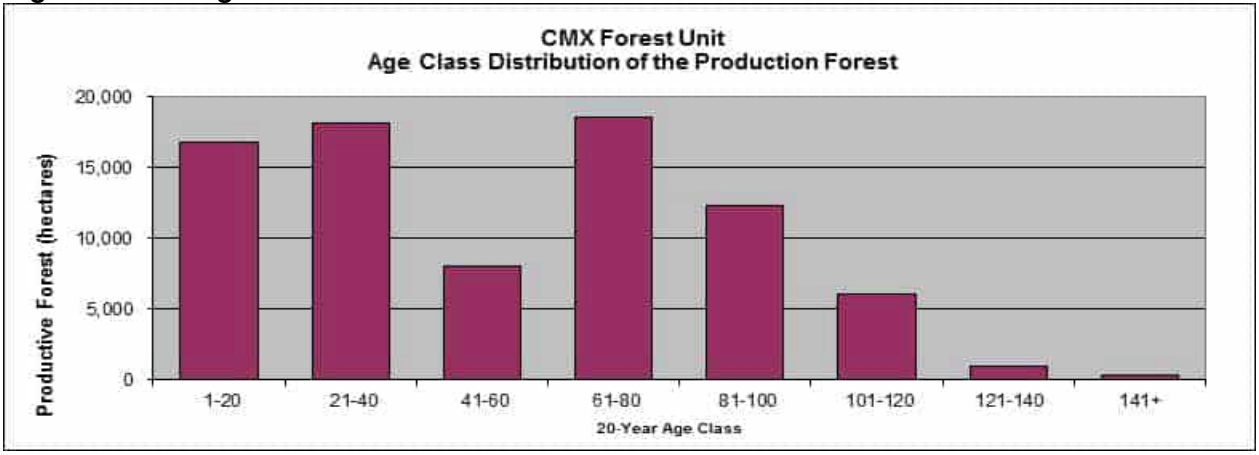


Conifer Mixedwood (CMX) Forest Unit

The CMX forest unit makes up 12% of the production forest, 81,361 hectares. Age class distribution of the CMX forest unit is included in Figure 10. CMX areas are mixed conifer hardwood stands. The CMX forest unit has relatively good representation of area by age class in all but the 41-60 year old class that has proportionately less area. This change is a result of past harvesting techniques that did not encourage hardwood regrowth, followed by renewal strategies in past three decades that limited the amount of herbicide spray that was conducted on the forest. Although this forest unit reflects both pioneer and successional characteristics, its increase must be controlled through silvicultural treatments to mitigate declines in more pure forest unit types.

CMX is predominantly found on Ecosite 12, 21 and 11 areas. Typical sites are dominated by jack pine, white spruce, black spruce and balsam fir with mixtures of trembling aspen and white birch. Coniferous component exceeds 50% of the canopy. Very shallow soils are often dry to fresh with fine to coarse sand or coarse loam but this forest unit can also be found on the fine loamy-clayey soils. These stands are classified in the ConMx and UplCe regional standard forest units.

Figure 10 Age Class Distribution of the Production Forest – CMX Forest Unit



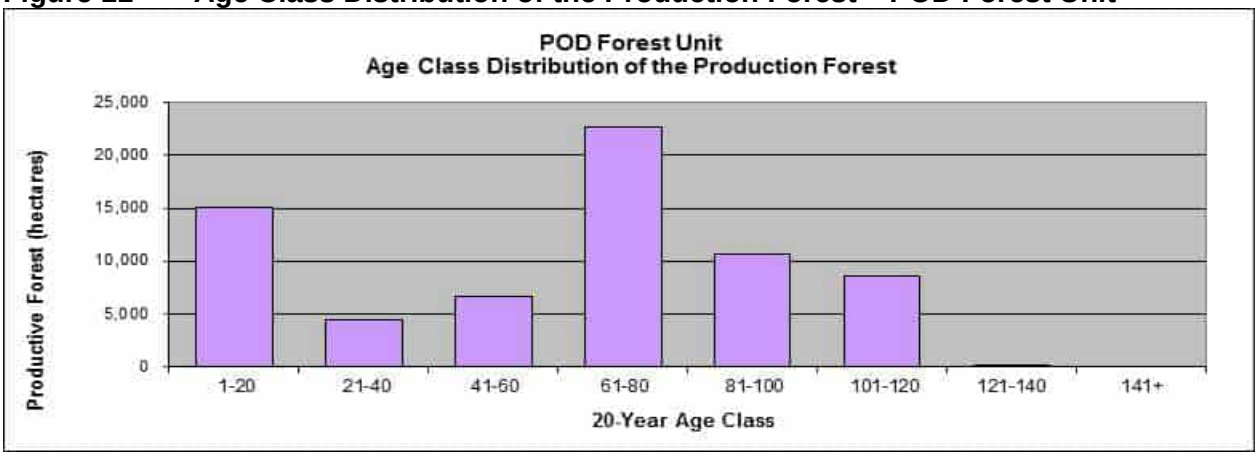
Poplar Dominated (POD) Forest Unit

The POD forest unit is made up of poplar dominated stands with greater than or equal to 70% poplar, including balsam poplar. The POD forest unit areas are also classified as PoSha and PoDee regional standard forest unit areas. The POD forest unit is only 10% of the production forest land base supporting poplar dominated stands (68,089 hectares, Figure 11). The POD stands are often located on fresh, well drained, with sandy-coarse loamy to fine loamy clayey soils, classified as Ecosite 29, 19 and 12 (shallow soils).

The age class distribution is relatively even with larger areas in the 1-20 and 61-80 year old age classes. While there is a natural component of poplar forest on the Whiskey Jack Forest, the occurrence of wildfires 61-80 years ago also contributes to the amount of poplar dominated forest being reported. Natural regeneration of these hardwood dominated stands often resulted in increased poplar composition which increased the area of the POD forest unit.

Poplar regeneration is prolific after harvest and the increase of this forest unit through time can be contributed to recent forest renewal practices including limited herbicide use and an increase in the poplar harvest due to increased local utilization of hardwood volumes. Renewal strategies applied to appropriate sites will allow an increase in the poplar component on many poplar dominated HMX mixedwood areas which will result in an overall increase in the POD forest unit area through time (4.2.2.1 Silvicultural Ground Rules).

Figure 11 Age Class Distribution of the Production Forest – POD Forest Unit

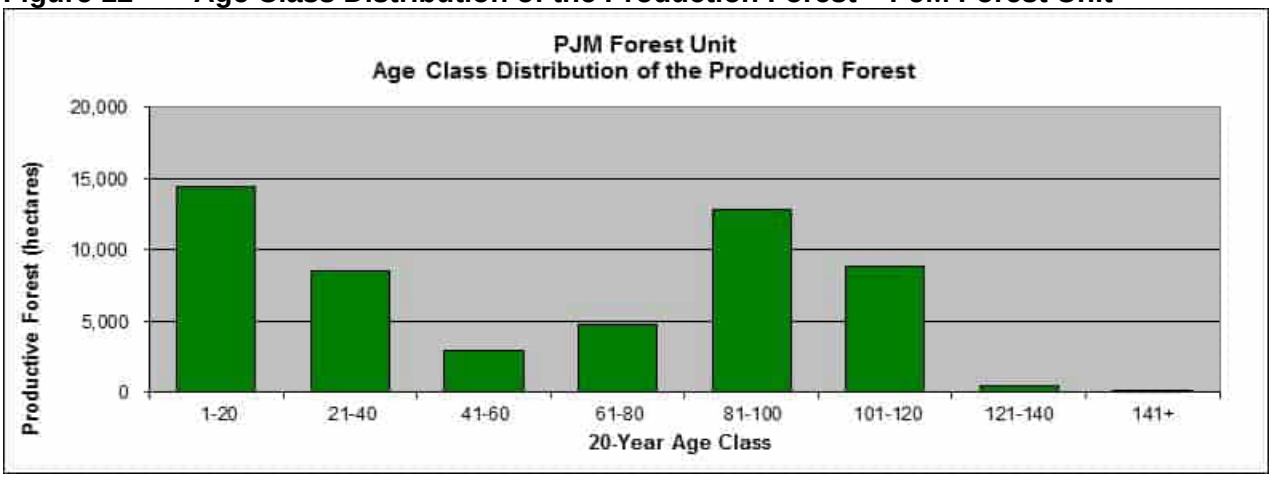


Jack Pine Mixedwood (PJM) Forest Unit

The PJM forest unit occupies 8% of the production forest land base (52,819 hectares, Figure 12). PJM occurs on Ecosites 12 and 21 most often. These shallow sites are characterized by an overstory dominated by jack pine with occurrences of black spruce, poplar, white birch and balsam fir. Poplar and birch make up 20% or less of the stand composition. PJM areas often have dry to dry-fresh moisture regimes, and have frequent occurrence of bedrock. The shallow soils of Ecosite 12 must be considered during harvest operations (SGR Table FMP-4).

PJM forest unit area is classified as the PjMx1 regional standard forest unit. The PJM forest unit has a relatively even age class distribution, with the exception of a lower occurrence in the 41-60 year old age class. This gap in maturing PJM area will be managed through the normal practice of balancing the allocation of eligible harvest stands with other conifer dominated forest unit areas to meet management objectives. No specific management implications are warranted for the PJM forest unit as the silvicultural strategies are similar to those applied to the PJD and SPM forest units.

Figure 12 Age Class Distribution of the Production Forest – PJM Forest Unit



Spruce Dominated Mixedwood (SPM) Forest Unit

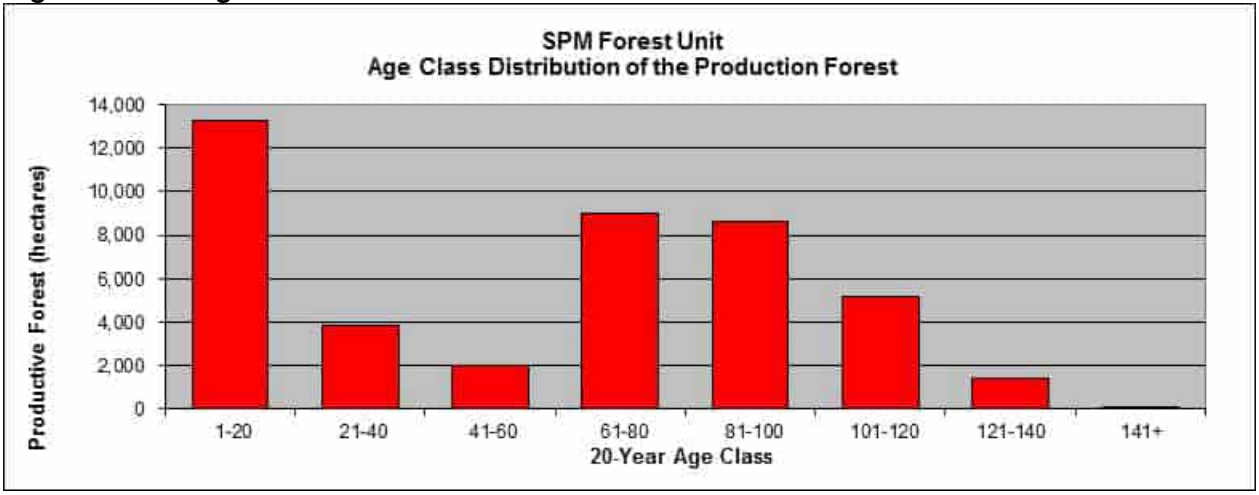
The black spruce mix (SPM) forest unit occurs on 43,285 hectares of the production forest on the Whiskey Jack Forest (6%, Figure 13). SPM occurs most often on Ecosites 12, 21 and 20. These sites are characterized by black spruce, with occurrences of jack pine, poplar, white birch and balsam fir. Poplar and birch are 20% or less of the stand composition. Soils are often dry to fresh with fine to coarse sand or coarse loam, with the very shallow soils occurring on Ecosite 12 areas.

The SPM forest unit includes areas classified as the SbMx1 regional standard forest unit area. The age class distribution reflects lower areas in the 21-40 and 41-60 year age classes. SPM is in many cases a transitional (successional) forest unit and changes in abundance though time as the jack pine component decreases due to natural succession and the spruce becomes more dominant. Silvicultural strategies have more recently favoured SPM renewal to encourage conifer dominated forest with minimal hardwood.

The current forest condition does not reflect any significant management implications to be considered in the development of this FMP. Since SPM forest unit areas tend to naturally

succeed to the SPD forest unit through aging, which causes a decline of the shorter-lived non-spruce tree species, there is a risk of a gradual reduction in the SPM forest unit area through time. Silvicultural strategies will be considered during this plan to maintain area in this forest unit and not allow a continual decrease in SPM forest unit area.

Figure 13 Age Class Distribution of the Production Forest – SPM Forest Unit

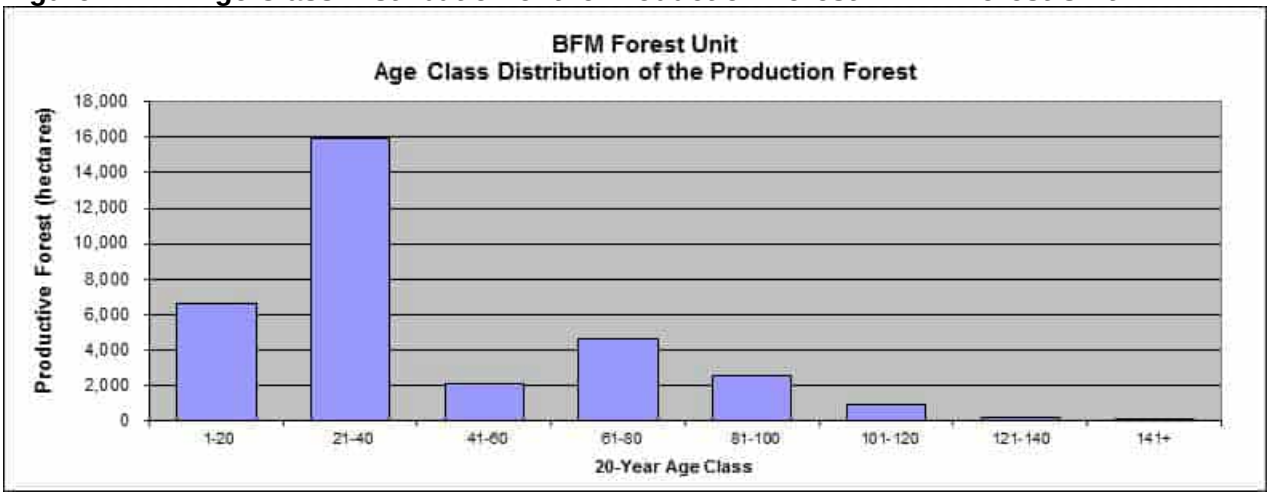


Balsam Fir Mixedwood (BFM) Forest Unit

The Balsam Fir (BF1) forest unit constitutes only 5% of the Whiskey Jack Forest production forest area (32,936 ha, Figure 14). The BFM forest unit is comprised of area classified in the BfMx1, and BfPur regional standard forest units. The majority of BFM area is in the 21-40 year old age class. BFM is typically found on Ecosites 12, 21 and 11 areas.

The area in the BFM forest unit is naturally variable. Small amounts of area transition into the forest unit through old age natural succession and natural disturbances. The natural cycle of spruce budworm infestations and high flammability of balsam fir serve to reduce the area in the forest unit when these events occur. The Whiskey Jack Forest is currently on the lower end of the cycle of occurrence of balsam fir area.

Figure 14 Age Class Distribution of the Production Forest – BFM Forest Unit

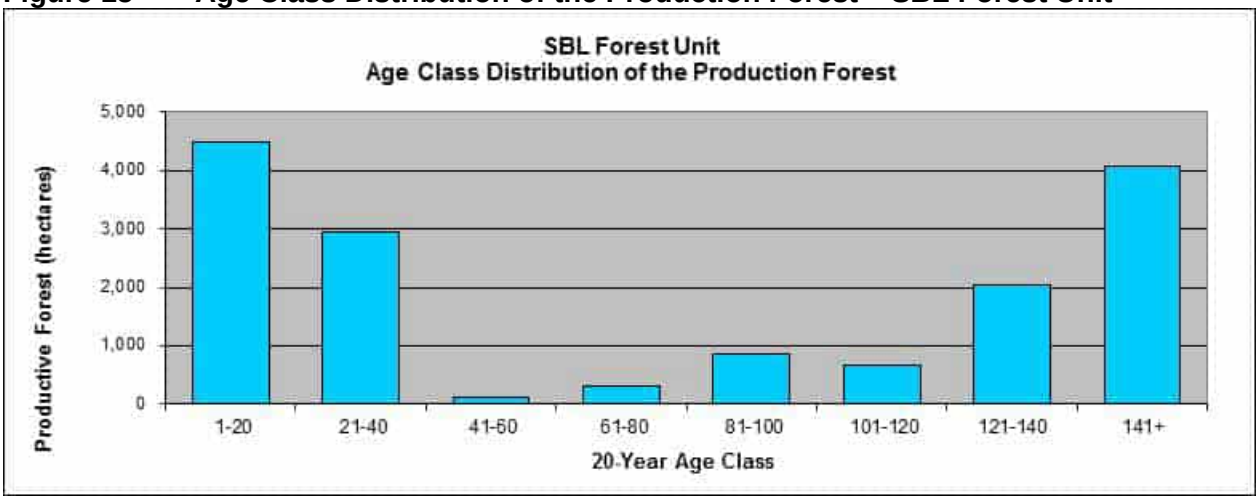


The following four forest units are minor components of the Whiskey Jack Forest and all totaled, comprise the remaining 3% of the production forest.

Black Spruce Lowland (SBL) Forest Unit

The SBL forest unit is made up of lowland black spruce stands, generally on Ecosites 35 and 36. Soils are very wet, nutrient poor organic material. This forest unit has site specific requirements. The SBL forest unit stands fall into the SbLow regional standard forest units. The SBL forest unit found on 2% of the production forest land base, often in smaller stands scattered throughout the forest (15,538 hectares, Figure 15). The site characteristics are limited on the land base as any increase of this forest unit is limited to lowland areas. Management strategies usually target more productive lowland site which are also easier to regenerate to spruce. Consideration must be given to maximum area that can be harvested and treated per year as well as slower growth characteristics on these lowland sites. This forest unit generally occurs as small, scattered stands on the forest and has been under-harvested in the past as is indicated by the age class structure favouring older stands.

Figure 15 Age Class Distribution of the Production Forest – SBL Forest Unit

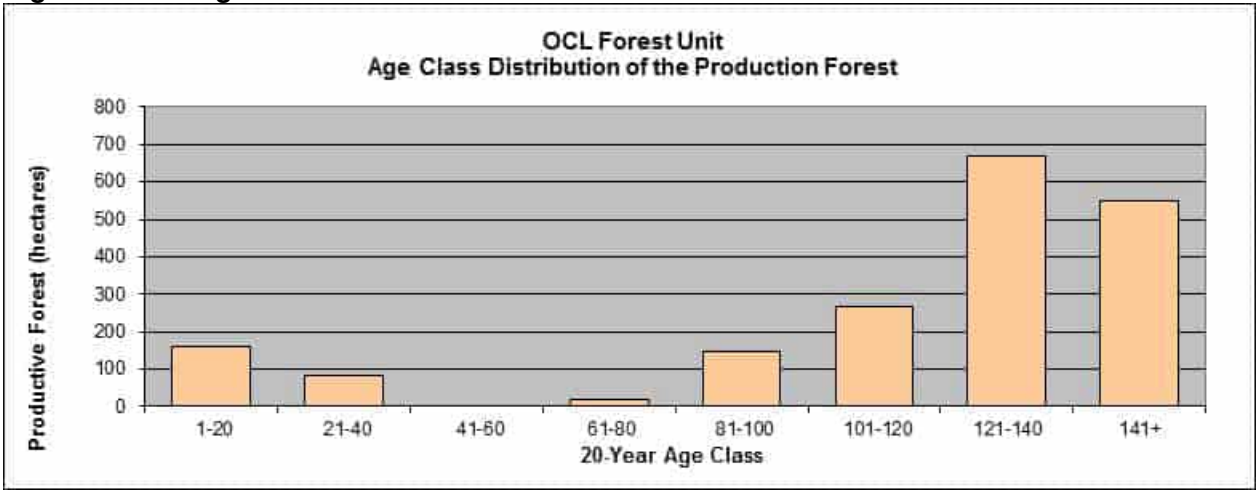


Other Conifer Lowland (OCL) Forest Unit

The OCL forest unit covers only 0.3% of the production forest on the Whiskey Jack Forest (1,895 hectares, Figure 16). OCL occurs primarily on Ecosites 37 and 36 characterized as intermediate swamp with wet, organic soils. Cedar and black spruce are the dominant tree species with occurrences of larch and balsam fir. The black spruce is limited to less than 50% of the stand composition. The OCL forest unit includes area classified as OcLow regional standard forest unit area.

The age class distribution shows an abundance of older (>80 years old) stands. This forest unit occurs in specific site characteristics and is very limited on the land base. Any increase of this forest unit is limited to lowland areas. Decreases in OCL may be contributed to increases in spruce lowlands (by increased black spruce species composition) which can be more productive and economically desirable. Management strategies will have to be considered in maintaining these forest types. However, these areas are usually not harvested which will help maintain current forest levels.

Figure 16 Age Class Distribution of the Production Forest – OCL Forest Unit

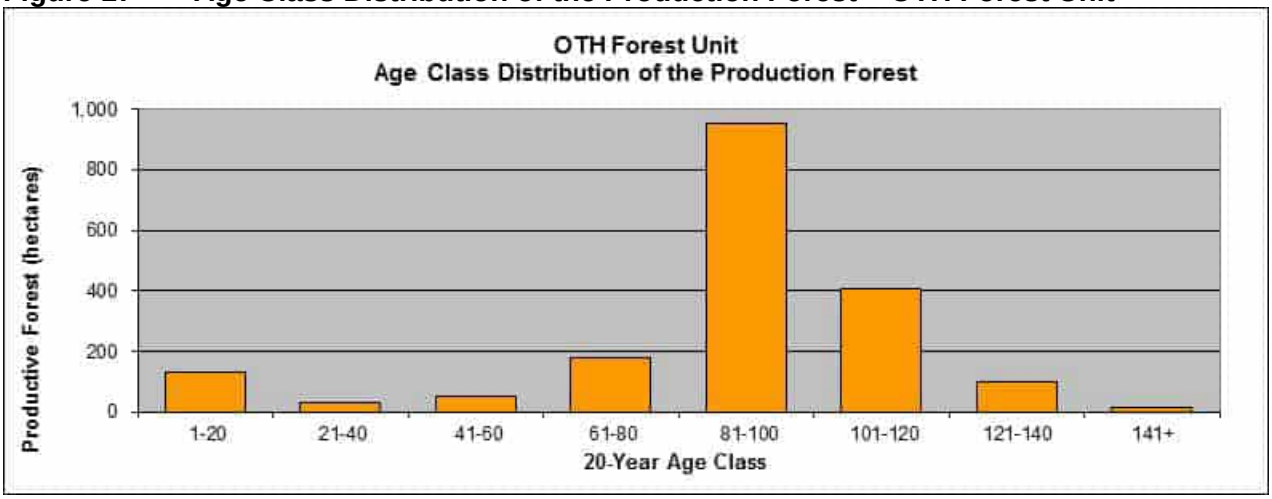


Other Hardwood (OTH) Forest Unit

The Other Hardwood (OTH) forest unit occurs on 0.3% of the production forest (1,880 hectares, Figure 17). OTH stands most commonly occur on Ecosites 38, 33 and 30 areas characterized by forested wetland usually dominated by black ash. OTH stands are classified in the OthHd regional standard forest unit.

There is a greater occurrence of OTH in the 81-100 year old age class. This forest unit occurs in specific site characteristics that are limited on the land base. Management strategies will have to be considered in maintaining these forest types. However, only small areas of OTH are harvested which will help maintain the current OTH forest area.

Figure 17 Age Class Distribution of the Production Forest – OTH Forest Unit

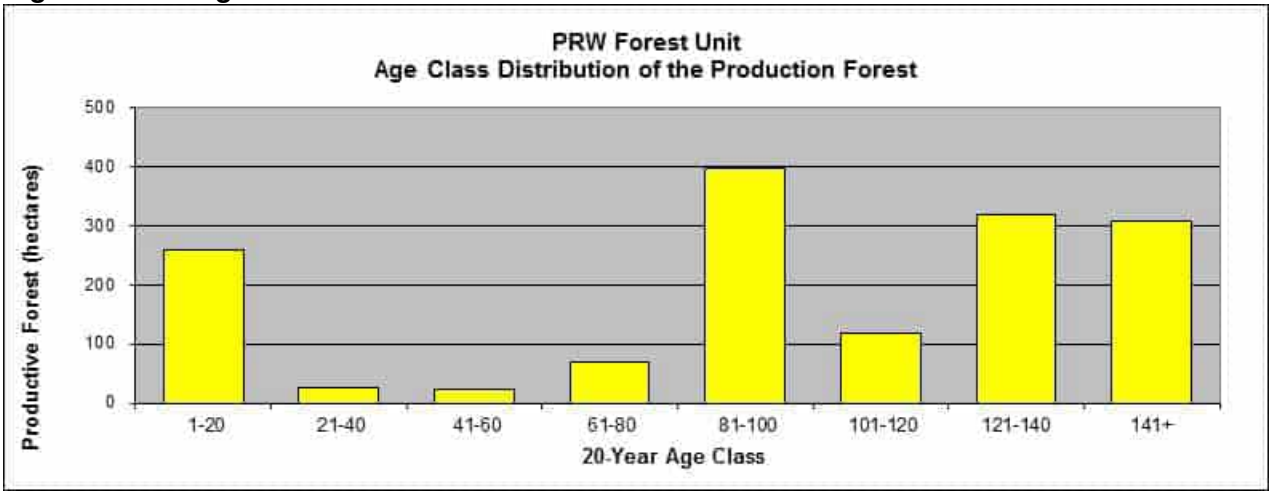


Red Pine and White Pine Mixedwood (PRW) Forest Unit

The PRW forest unit occurs on 1,528 hectares of the production forest (0.2%, Figure 18). The PRW forest unit is found predominantly on Ecosite 11 and 18 sites which are either very shallow soils (11) or fresh, well drained, coarse loam (18). The conifer overstory contains red pine with occurrences of white pine, poplar, white birch and balsam fir. PwDom, PrwMx and PrDom regional standard forest unit areas make up the PRW forest unit area.

The age class distribution reflects the majority of PRW stands being over 80 years of age. The occurrence of the PRW forest unit area is currently lower than was suggested by historical management unit forest inventories. The restoration of red pine and white pine will be encouraged on the sites through the protection of white pine and red pine advanced growth where possible. Red pine is not difficult to regenerate, however, white pine is more difficult to regenerate with survival to maturity due to the white pine weevil and white pine blister rust infection and mortality. Renewal strategies will primarily focus efforts on regenerating red pine mixed with other species in order to increase the occurrence of red pine and to promote a minor increase in the PRW forest unit area in the future. Minimal white pine is expected to be planted in harvest areas due to the challenges in survival to maturity. Management strategies and conservation of existing forest must be considered.

Figure 18 Age Class Distribution of the Production Forest – PRW Forest Unit



2.1.2.2 Forest Landscape Classes

This section of the plan text describes the forest landscape classes and the plan start forest composition, structure and pattern at the landscape level. The plan text also describes any management implications of the plan start forest landscape pattern on the development of the forest management plan.

Provincial Forest Landscape Classes

The *Forest Management Guide for Landscapes* (Landscape Guide) was still being drafted and was not required to be applied to forest management plans in the Boreal Forest at the time of preparation of this 2012 Whiskey Jack Forest FMP. However, the information on biodiversity indicators and the simulated ranges of natural variation for these biodiversity indicators was considered the best available science by the Planning Team and regional advisors. Therefore a management objective indicator related to landscape class area was included in this 2012 FMP in Table FMP-9. This approach was endorsed by the Planning Team and LCC and was consistent with regional and provincial FMP training provided to 2012 FMP Planning Teams.

The amount of area by landscape class is a non-spatial measure of the area, in hectares, of the landscape classified into landscape classes. Seven landscape classes have been developed for assessment in the Northwest Region. These landscape classes incorporate forest type attributes, age and to a limited degree site (e.g. upland / lowland designation for conifer forests).

The assessment of area by landscape class is new for 2012 FMP Planning Teams and has not been included in forest management plans for the Whiskey Jack Forest previously. Landscape classes are measured during strategic modelling analysis and areas are not tagged within the Base Model Inventory. Areas by landscape class have been incorporated into the Ontario Landscape Tool (OLT) to approximate the best estimate of the simulated range of natural variation for the Whiskey Jack Forest. The planning team compared the Plan Start 2012 landscape class areas to the OLT suggested natural range in area and determined an appropriate landscape class objective indicator and desirable levels during development of the Long-term Management Direction. See Section 3.5.2.2 Forest Composition Indicator 2a for Plan Start areas for managed landscape classes and the desired level based on the simulated range of natural variation.

The seven NWR landscape classes are described in Table 1 with reference added for which plan forest units are included in each landscape class (subject to age criteria included in Table 2). The Plan Start 2012 area by landscape class for the Crown forest is presented below in Figure 19. Approximately, 57% of the Whiskey Jack Forest is in the immature development stages, with only 43% being in the mature and late successional landscape classes.

Table 1 Northwest Region Landscape Classes
(excerpt from Ontario Landscape Tool Science and Information Package A with PLANFU column added)

Landscape Class	Northwest Region 3W, 4S, 4W, 3S Landscape Guide Forest Unit	Development Stages	Corresponding Plan Forest Units (PLANFUs)
1 - Presapling & Sapling	All	Pre-sapling, Sapling	All
2 - Immature Conifer	BfDom, ConMX, PjDee, PjMx1, PrwMx, SbDee &SbMx1	Immature	BFM, CMX, OCL, PJD, PJM, PRW, SBL, SPD, SPM.
3 - Immature Hardwood	BwDom, HrdMw, HrDom, OthHd, PoDee,	Immature	HMX, POD, OTH
4 – Mature & Late Balsam Fir	BfDOM	Mature, Late	BFM
5 – Mature & Late Lowland Conifer	OcLow, SbLow	Mature, Late	OCL, SBL.
6 – Mature & Late Hardwood & Mixed	BwDom, HrdMw, HrDom, PoDee	Mature, Late	HMX, POD, OTH
7 – Mature & Late Upland Conifer & Mixed	ConMx, PjDee, PjMx1, PrwMx, SbDee & SbMx1	Mature, Late	CMX, PJD, PJM, PRW, SPD, SPM.

Table 2 Northwest Region Landscape Development Stage Onset Ages by Forest Unit

Onset Age (years) by Stage:	Forest Unit:											
	BFM	CMX	HMX	OCL	OTH	PJD	PJM	POD	PRW	SBL	SPD	SPM
Presapling	0	0	0	0	0	0	0	0	0	0	0	0
Sapling	5	10	5	10	5	10	10	5	10	10	10	10
Immature	10	30	10	30	10	30	30	10	20	30	30	30
Mature	60	70	60	70	60	70	70	60	80	70	70	70

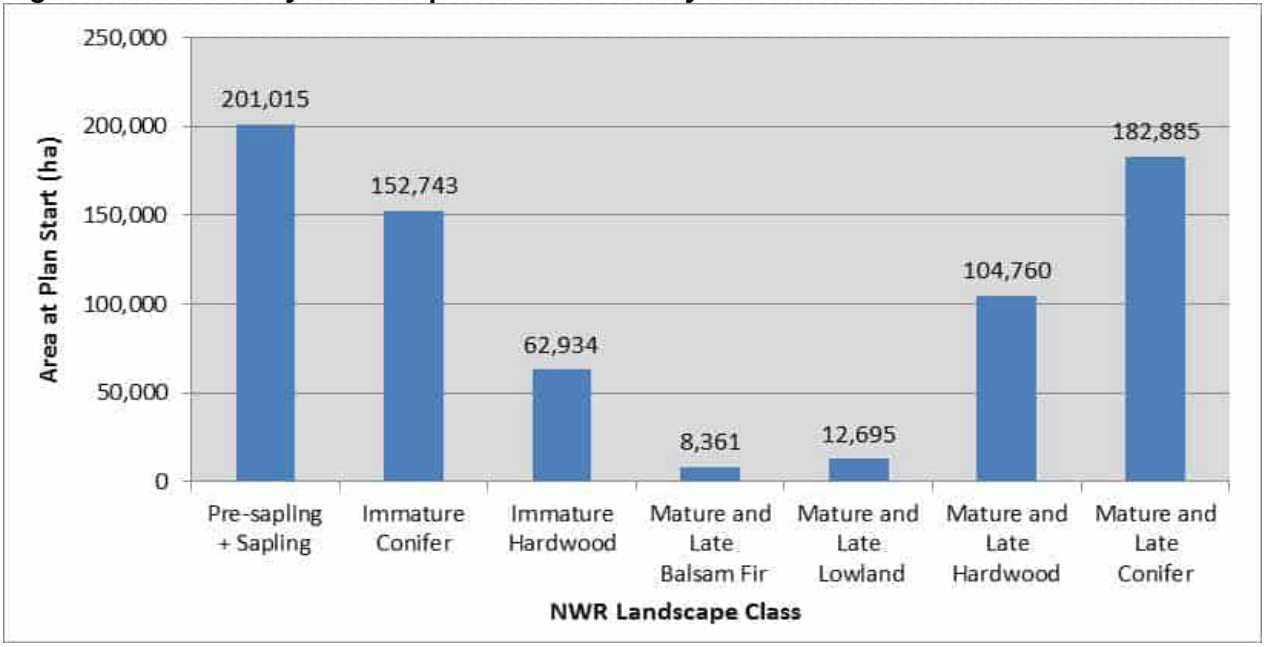
Figure 19 Area by Landscape Class – Whiskey Jack Forest 2012



Forest Type by Age Grouping

In addition to the landscape classes described above, the planning team also used total productive Crown forest area by forest unit groupings as a landscape indicator of forest type. Plan start area by forest unit was discussed in text Section 2.1.2.1.

The final landscape indicator used by the planning team for the purpose of measuring milestones related to forest composition and structure was the old forest indicator by FMP forest unit. The provincial definition was used to establish the age-of-onset. Plan start proportions of old forest by forest unit are reported in Table 3. Old forest red pine and white pine area is also measured and is calculated to be 457 hectares in 2012.

Table 3 Area of Old Forest by Forest Unit Grouping at Plan Start

Old Forest Grouping and Onset Age	Code	2012 (ha)
Balsam Fir > 80 years	BFo	3,707
Lowland Conifer > 100 years	CLo	1,851
Conifer Mixedwood >100 years	CMo	8,730
Hardwood > 100 years	HWo	16,931
Other Hardwood > 90 years	OHo	1,252
Jack Pine > 100 years	PJo	23,267
Spruce Lowland > 160 years	SLo	2,007
Spruce Upland > 110-120 years	SPo	10,155
Red Pine and White Pine > 140 years	PRWo	457
	TOTAL	68,357

Forest Landscape Pattern

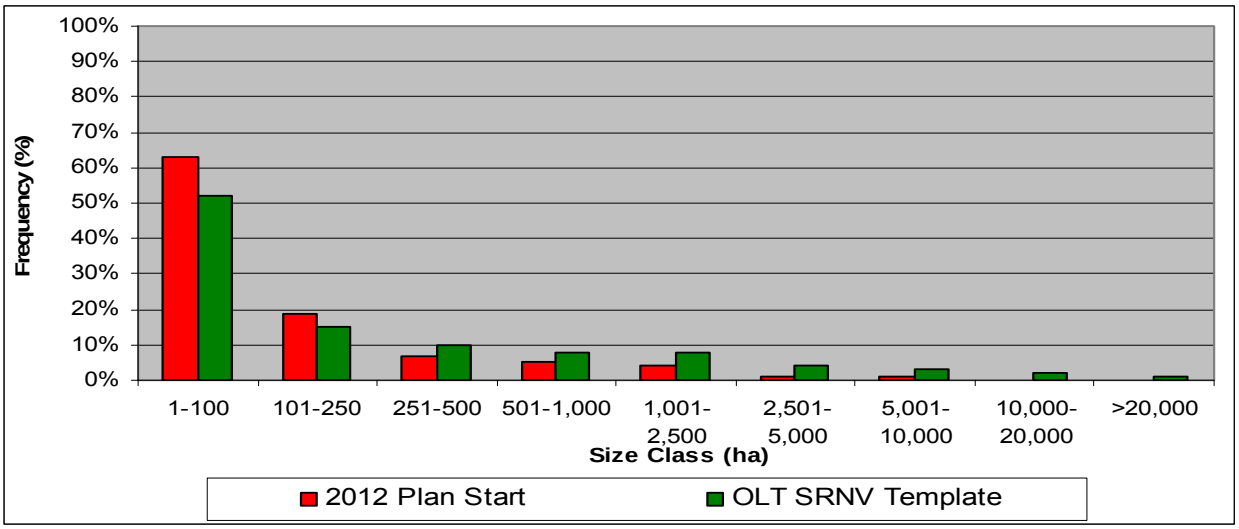
The Forest Management Planning Manual (FMPM), and Natural Disturbance Pattern Emulation Guide (NDPEG) both require the FMP to examine landscape pattern based on the frequency distribution of young forest patches by size class. Landscape level direction from the NDPEG was followed since the *Forest Management Guide for Boreal Landscapes* (Landscape Guide) was still in draft form and did not replace the requirement to follow landscape level NDPEG direction. However, since Science and Information in support of Ontario's Forest Management Guide for Boreal Landscapes contained the most current science and direction for management at the landscape level in the Boreal Forest, this Science and Information in support of Ontario's Forest Management Guides for Landscapes was also incorporated into this 2012 Whiskey Jack Forest FMP.

Patches deal with the *extent* of the homogeneous forest types that make up the landscape mosaic. Patch size can influence the availability of habitat conditions. From the Simulated Range of Natural Variation (SRNV) work done for the Whiskey Jack Forest, young forest patch is classified into stands less than 36 years old. The resulting SRNV estimated natural landscape pattern for young forest is used as the "Template" of the natural forest landscape pattern for the Whiskey Jack Forest.

The young forest frequency by size class of the land base at Plan Start 2012 was compared to the SRNV template for the management unit to determine a baseline distribution of young forest patch size at the start of this planning period. Figure 20 shows the relationship of the current young forest patch size frequency compared to the SRNV. In general, the distribution of young forest patches is similar to the template distribution. Differences are observed in the smaller young forest size patch frequencies where the SRNV developed for the Whiskey Jack Forest

suggests there would naturally be less small disturbances (1-100 and 101-250 ha), and more larger disturbances (> 250 ha) than is evident at Plan Start. This larger proportion of smaller young forest patch at Plan Start 2012 is a result of past forest management, natural disturbance and harvesting practices on the Whiskey Jack Forest, and is typical of the management units in the Northwest Region.

Figure 20 Frequency Distribution of Young Forest by Size Class - 2012 vs SRNV



Management direction in the last 10 years has been to move to larger harvest blocks to emulate natural disturbance patterns more closely. It will take the implementation of several forest management plans with larger harvest area patches to reverse the legacy of small disturbance patches on the Whiskey Jack Forest.

This forest landscape pattern analysis is documented in Supplementary Documentation N – Spatial Analyses: Landscape Pattern (OLT and NDPE). Maps generated during this landscape pattern disturbance analysis are included in the FMP as (MU490_2012_FMP_P1_MAP_LandPat_04.pdf and map 05).

2.1.2.3 Management Zones

In the development of the long-term management direction, the planning team chose to partition the management unit into management zones. A management zone is a geographical area within a management unit that provides spatial context to the long-term management direction, and may influence strategic analysis, and operational planning. Two types of management zones, strategic and operational, were used to represent spatial considerations. Strategic management zones represent areas with distinct ecological characteristics, landscape biodiversity requirements or forest-level harvest and retention considerations.

Management zones may be assigned to differentiate areas such as ecological zones, watershed zones, wilderness zones, industrial working circles etc. For strategic purposes in this 2012 FMP, it was agreed to use wildlife management zones as the primary strategic landscape pattern zones. Strategic management zones are identified in the SMZ field of the spatial planning composite inventory (PCM) information, and operational management zones are identified in the OMZ field. Landscape pattern zones were also classified in the planning composite inventory (identified in the SUBMU field for areas in the caribou habitat management zone) and also serve as a strategic management zone.

Sub-management units were used in the 2004 FMP to split out the areas where caribou habitat management was conducted and general areas outside the caribou management zone where different management objectives were considered and modelled. The 2004 subunits in the caribou zone were included in the inventories for this FMP and were identified in the BMI and PCM spatial forest information layers in the SUBMU field.

The Caribou Conservation Plan (CCP) provides direction to manage the quality, quantity and location of caribou habitat in the area of continuous extent of caribou occurrence. MNR's *Cervid Ecological Framework* also provided direction for which cervid species are managed for on the landscape.

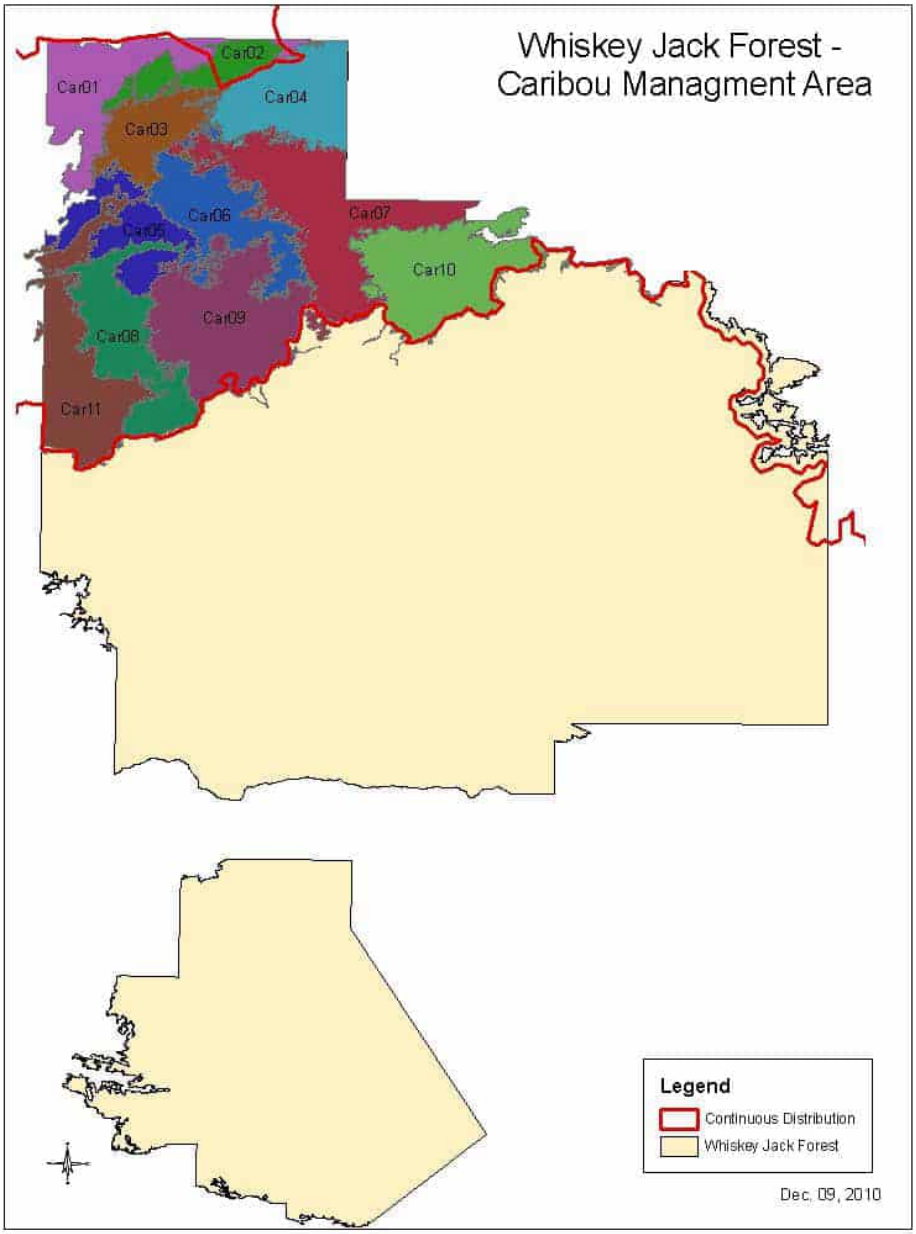
Currently, MNR's delineation of the area of continuous range occupancy for woodland caribou is the primary division of the management zone for caribou (strategic zone) and the rest of the management unit being managed primarily for marten (strategic), moose (operational) and deer (operational).

These wildlife management zones are described in more detail below:

Strategic Management Zone – Caribou Habitat Management Zone

For strategic purposes in this 2012 FMP, it was agreed to continue to implement the existing 2004 FMP sub-management units which represented the caribou habitat mosaic blocks where caribou habitat management was the primary consideration. The caribou zone and the caribou mosaic blocks within the caribou zone are shown in Figure 21. Caribou dynamic habitat schedule blocks (caribou blocks Car01 through to Car11) are strategic management zones and are identified in the SMZ field of the spatial PCM inventory information. Detailed spatial habitat analysis is documented in Supplementary Documentation N – Spatial Analyses: Caribou Habitat.

Figure 21 Caribou Habitat Management Zone on the Whiskey Jack Forest

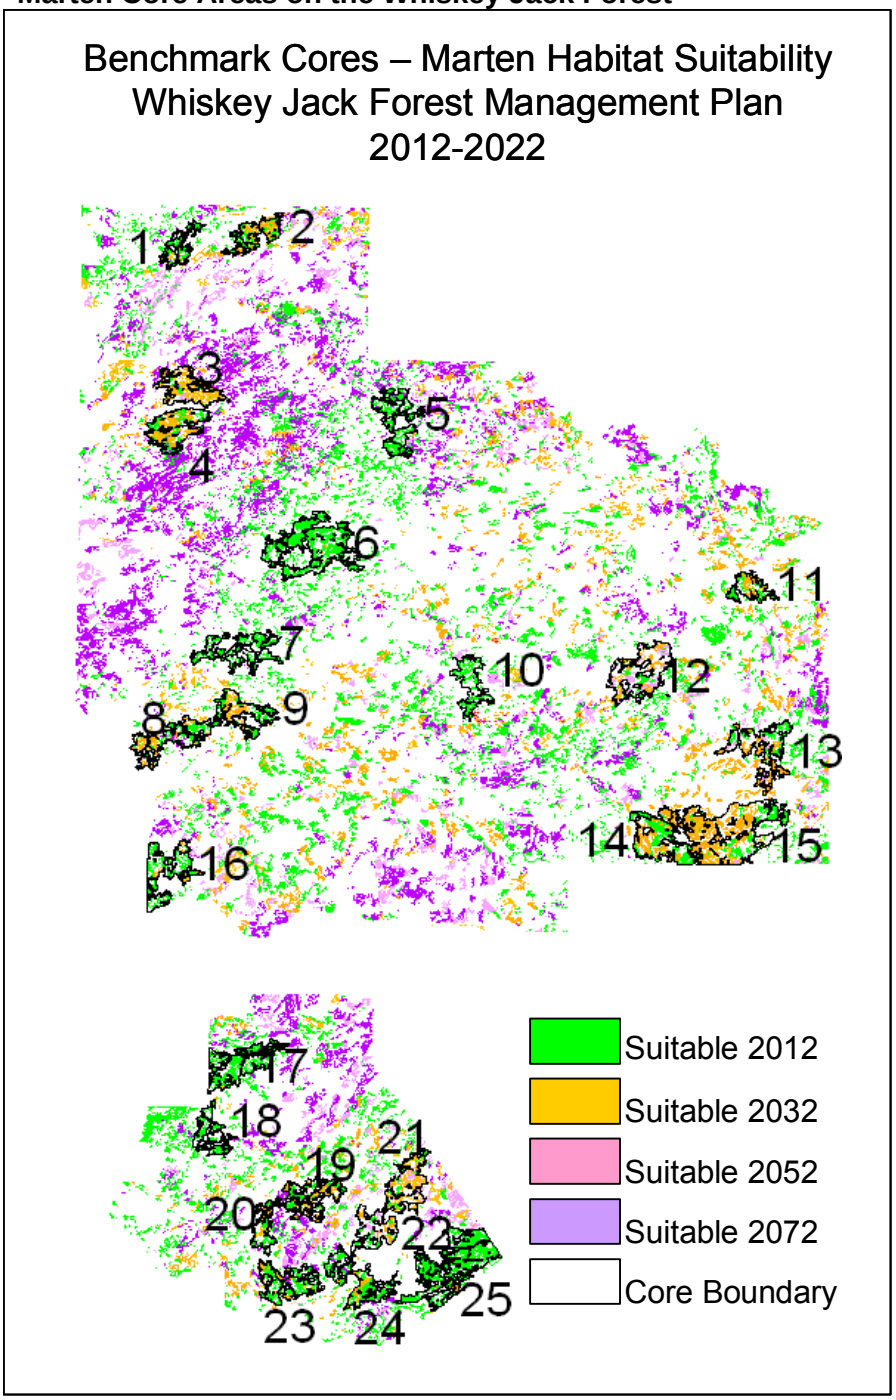


Strategic Management Zone - Marten Core Habitat

The *Forest Management Guidelines for the Provision of Marten Habitat (MNR, 1996)* was applied to the Whiskey Jack Forest for this plan. Spatial analysis was conducted for marten with additional habitat definitions of capable and suitable included. The intent of the marten guideline is to provide large contiguous areas of mature conifer-dominated forest as habitat. The strategic landscape level application of the guidelines directed planning teams to develop core areas of suitable marten habitat in 3,000 to 5,000 hectare blocks to be deferred from harvesting. The planning team applied the strategic landscape level section of the marten guidelines on 25 relatively large contiguous areas (marten core habitat areas or large,

landscape patches) of Crown land on Whiskey Jack Forest (Figure 22). Marten core areas outside of the caribou management zone are strategic management zones and are identified in the SMZ field of the spatial planning composite inventory information. The caribou blocks are the primary SMZ in the caribou management zone, therefore marten cores in the caribou zones Car01 to Car11 are not identified in the SMZ field of the PCM inventory. Detailed spatial habitat analysis is documented in Supplementary Documentation N – Spatial Analyses: Marten Habitat.

Figure 22 Marten Core Areas on the Whiskey Jack Forest



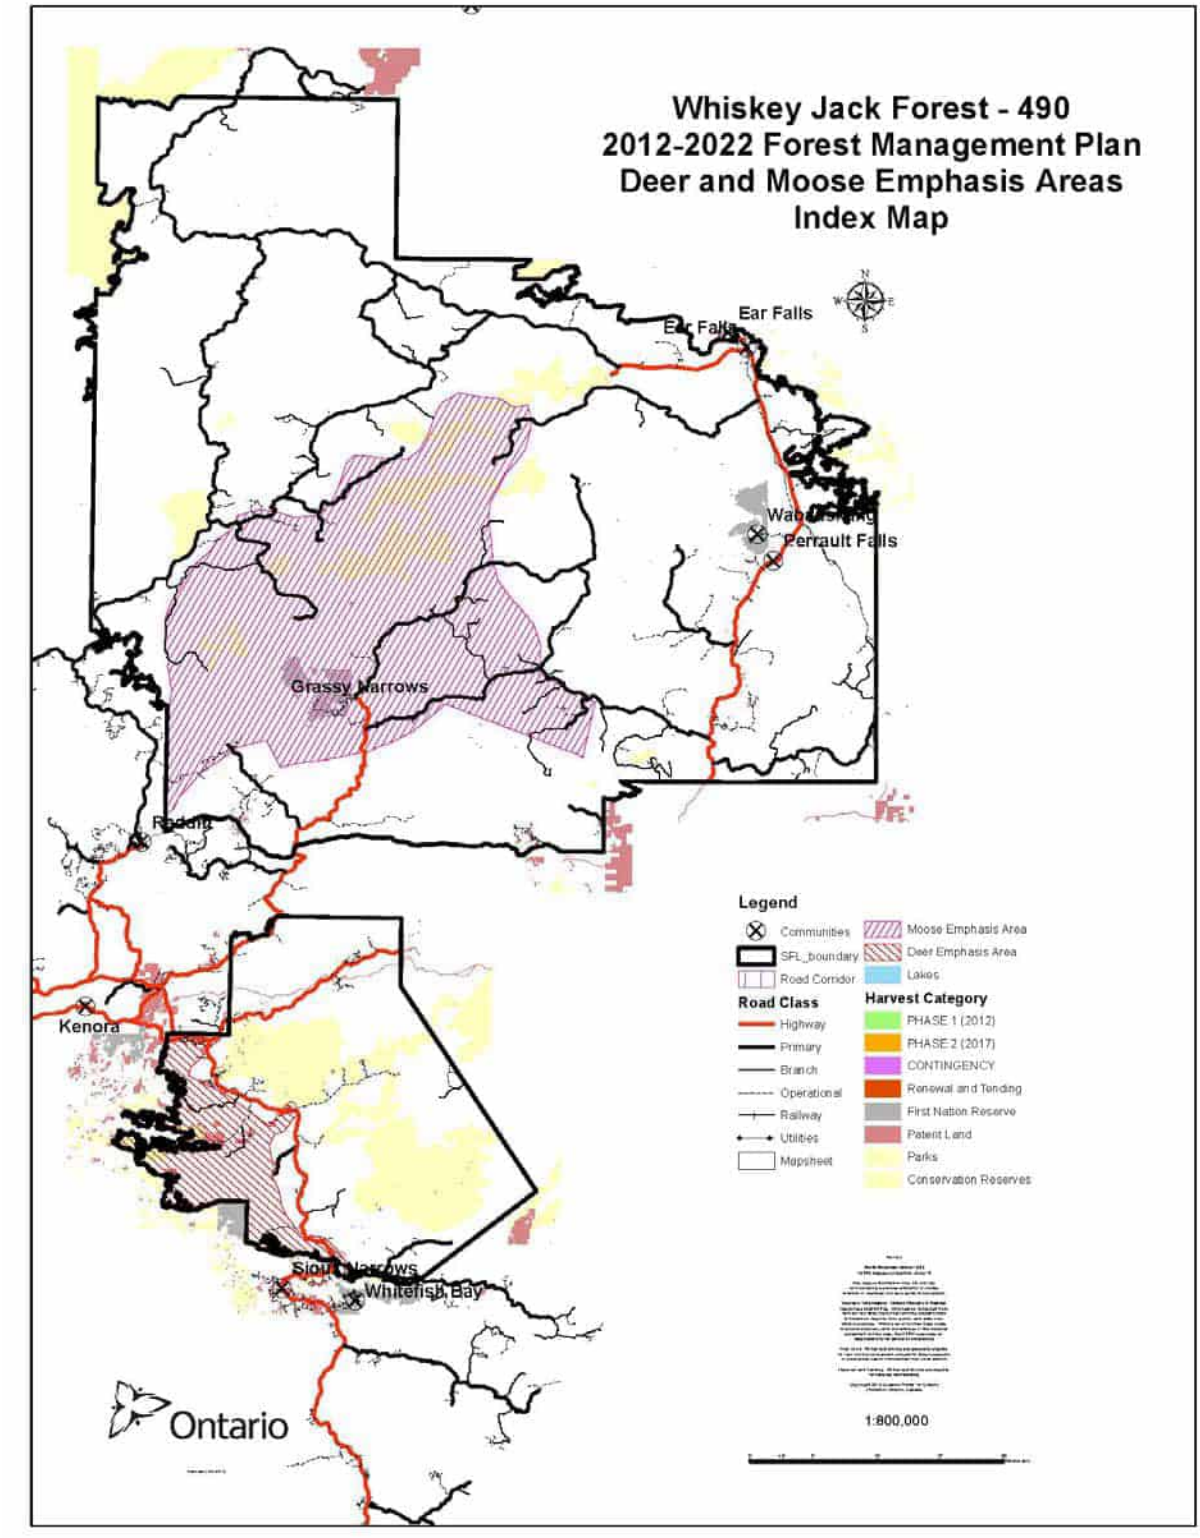
Operational Management Zones – Moose Emphasis Areas and Deer Emphasis Areas

Moose are a habitat generalist and can use a broad range of forest conditions to meet their needs. Although they are habitat generalists, some habitats are preferred over others and habitat preferences change during the year. To achieve forest conditions in a managed forest that are similar to the conditions moose prefer and would encounter in a natural forest ecosystem, areas can be selected for moose emphasis areas (MEAs). Moose emphasis areas are locations where moose habitat will be enhanced through operational forest management practices. Specific MEAs are not managed strategically over the long-term (160 years) but rather considered at the operational planning level for each plan period. The intent of operational management efforts for moose habitat management is to maintain or create through timber management activities the diversity of age classes and species of vegetation that provide habitat for moose. Habitat management efforts focus on seasonal high use areas such as early and late wintering areas and on special areas such as calving sites, aquatic feeding areas and mineral licks, if present. Spatial consideration for moose habitat occurred during the area of concern planning process, before forest management activities were finalized for this plan.

White-tailed Deer - Areas of the management unit with an objective(s) to emphasize white-tailed deer habitat were identified as large landscape patches through application of the Science and Information in support of Ontario's Forest Management Guides for Landscapes. These areas are deer winter concentration areas (or yards) and encompass a single yard or a number of yards. Areas which are not yards and have strategic importance to local deer populations (e.g., large stands or concentrations of mast trees; high-quality summer habitat) are also identified as having an objective for deer habitat.

The forest composition and age structure was analyzed for the Whiskey Jack Forest resulting in Moose Emphasis Areas and Deer Emphasis Areas (Figure 23). MEAs and DEAs are operational management zones and are identified in the OMZ field of the spatial planning composite inventory information.

Figure 23 Moose Emphasis Areas and Deer Emphasis Areas on the Whiskey Jack Forest



2.1.2.4 Other Forest Classifications

This section of the plan text describes the other forest classifications (e.g. forest inventory classifications and habitat for wildlife species) used in the forest management plan. Any management implications concerning the other forest classifications on the development of the forest management plan are also discussed.

2.1.2.4.1 Other Forest Inventory Classifications

There are additional classifications of forest composition, age and function that have been identified in the PCM and BMI forest resource inventories. These classifications are summarized in Table 4**.**

Table 4 Other Forest Inventory Classifications

Inventory Field	Forest Inventory Classification	Code	Description	Analysis Package Reference
SFU	**Standard Forest Units:**	PwDom	White Pine Dominant	AP - Section 5.1.1
	(NW Region)	PrDom	Red Pine Dominant	
		PrwMx	Red and White Pine Mixedwood	
		UplCe	Cedar Dominant Uplands	
		OCLow	Other Conifer Lowlands (Ce/La)	
		SbLow	Black Spruce Lowlands	
		SbSha	Shallow Spruce Dominated Uplands	
		SbDee	Productive Spruce Dominant Uplands	
		PjSha	Shallow Jack Pine Dominated Uplands	
		PjDee	Productive Jack Pine Dominated Uplands	
		PoSha	Shallow Aspen Dominated Uplands	
		PoDee	Productive Aspen Dominated Uplands	
		BwSha	Birch Dominated Shallow Soils	
		BwDom	Productive White Birch Dominated	
		OthHd	Tolerant Hardwoods	
		SbMx1	Spruce Dominant Conifer Mixedwoods	
		PjMx1	Jack Pine Dominant Conifer Mixedwoods	
		BfPur	Balsam Fir Dominated	
		BfMx1	Balsam Fir Dominated Conifer Mixedwood	
		ConMx	Conifer Dominant Mixedwood	
		HrDom	Hardwood Dominant	
		HrdMw	Hardwood Dominant Mixedwood	
		The SFUs are developed regionally to reflect the different forest conditions found across the province and the different forest types. SFUs are sorted along with age to determine landscape classes and were also considered during development of plan forest units.		
SI	**Silvicultural Intensity:**	PRSNT	Present - average natural forest dynamics	AP - Section 5.2.3
		EXTEN	Extensive - managed, natural regeneration	
		BASC1	Basic - managed, prompt renewal after harvest	
		INTN1	Intensive - managed, prompt density regulated renewal (CMX, PJD, PJM, SPD, SPM and PRW only).	
		Silviculture Intensity (SI) indicates forest productivity and the expected growth and development pattern. SI applies only to even-aged forest stands that are managed under the clear-cut silvicultural system.		

2.1.2.4.2 Habitat for Selected Wildlife Species

The Crown Forest Sustainability Act requires the conservation of biological diversity during forest management planning. However, there are hundreds of species of vertebrates and many thousands of species of invertebrates in the boreal forest and it would be impossible to provide for them all using species-specific approaches. Therefore, in the Whiskey Jack Forest, habitat for wildlife is provided using a variety of strategies, including:

i) emulating natural disturbance patterns and residual structure in harvested stands following the *Natural Disturbance Pattern Emulation Guide (MNR, 2001)*;
ii) renewing harvested areas promptly following approved silviculture guides;
iii) utilizing the available information contained in the science package embedded in the Ontario Landscape Tool;
iv) applying area of concern (AOC) prescriptions to protect sensitive sites (e.g., riparian zones, den sites, nest sites);
v) applying habitat guidelines for species at risk and selected species,
vi) applying Conditions on Regular Operations (CROs) around specific wildlife values when they are encountered during operations if not already protected through implementation of AOC prescriptions, and
vii) modelling the supply of preferred habitat over time for species at risk whose habitat can be projected through time (e.g. woodland caribou).

It is thought that by emulating natural disturbance patterns and residual structures in harvested stands and renewing the sites appropriately, the needs of most wildlife will be addressed over the long term (this is “coarse filter management”; see MNR 2001). Additional area-based and species-specific measures (“fine filter management”; MNR 2001) are undertaken for wildlife that are sensitive (e.g., great blue heron and species at risk - caribou, bald eagle), or species of particular public interest (e.g., moose, deer, marten). Finally, the overall effect of the management direction proposed in the FMP on habitat and the sustainability of the forest is assessed by modelling the supply of a broad array of habitat types and seral stages.

The intent of measuring the habitat supply of selected species is to aid in the assessment of the impact of forest management practices on forest sustainability. In consultation with the MNR Regional and District MNR wildlife biologists, the local citizens committee and with reference to forest management planning manuals and guides, the planning team has selected specific wildlife species habitat as indicators of wildlife habitat in northwestern Ontario and the Whiskey Jack Forest. The habitats for the selected wildlife species are used as indicators of objective achievement, and are considered in the overall determination of forest sustainability for the Whiskey Jack Forest. The provision of sustainable wildlife habitat through time must be achieved while balancing the socio-economic benefits from the forest. The selected wildlife species whose preferred habitats are considered during development of the plan and reported in this FMP in Table FMP-6 are listed with their abbreviated code in Table 5.

Table 5 Selected Wildlife Species

Selected Wildlife Species	Species Code Abbreviation
Caribou - refuge	Cr
Caribou - winter used	Cwu
Caribou - winter preferred	Cwp

(Photo Credit: MNR)

Woodland Caribou – Forest Dwelling Population *(Rangifer tarandus caribou*) occur within Northwest Region including the north-northwestern portion of the Whiskey Jack Forest. The forest-dwelling population of woodland caribou in Ontario have been classified as Species At Risk, and their habitat is actively managed in this forest management plan.

The Science and Information in support of Ontario's Forest Management Guides for Boreal Landscapes includes management indicators for caribou habitat (i.e. refuge, winter used and winter preferred) therefore these caribou habitat classifications are included as selected species habitat whose habitat is reported in Table FMP-6. Habitat for the woodland caribou is described in Section 2.1.3.1 Inventories and Information for Species at Risk.

Ontario's Woodland Caribou Conservation Plan provides policy direction for the management and recovery of Woodland Caribou (forest-dwelling boreal population), and will apply to the areas of continuous and discontinuous distribution. Woodland Caribou (forest-dwelling boreal population) are designated as "Threatened" in Ontario under the *Endangered Species Act, 2007*. *Ontario's Woodland Caribou Conservation Plan* was a principle document used by the Planning Team to develop management strategies for current and projected habitat for caribou on the Whiskey Jack Forest.

Currently, MNR's delineation of the area of continuous range occurrence, including area identified for caribou habitat recovery, is the primary consideration for the division of the management zone for caribou habitat management. Caribou habitat management is documented in Supplementary Documentation N – Caribou Habitat Analysis which includes a map of the dynamic caribou habitat schedule (DCHS) areas.

Implication of plan start habitat levels – The caribou zone has been delineated into a dynamic caribou habitat schedule (DCHS) consistent with the Caribou Conservation Plan and with habitat management strategies included in the 2004 FMP for the Whiskey Jack Forest. Strategic planning, including renewal strategies in accordance with Silvicultural Ground Rules, will be considered in this FMP to increase the amount of caribou refuge and winter habitats in accordance to more closely approximate the Simulated Bounds of Natural Variation for caribou habitat on the forest. The Plan Start and desired levels (based on Simulated Ranges of Natural Variation) for the caribou habitat indicators are discussed in Section 3.5.2.3 Wildlife Habitat, Indicators 3a, 3b and 3c.

Additional Wildlife Species with Spatial Habitat Management

Marten *(Martes americana*). The marten is a valuable furbearer which was determined by the Environmental Assessment (EA) Board (April 1994) to be a provincially featured species for timber management in the Boreal Forest of Ontario. MNR's former featured species policy highlighted caribou, moose, deer and pileated woodpeckers, and was thought to provide for the habitat requirements of approximately 70% of the vertebrate species in Ontario. Marten habitat

was selected to represent (a) large tracts of mature and older forest, (b) large, coarse woody material on the forest floor, and (c) wildlife habitat trees to be retained on harvested areas. The stand level requirements for coarse woody material and wildlife trees are now guided by direction from the approved Stand and Site Guide.

(Photo Credit: Larry Colwell, www.bss.sfsu.edu)

The spatial habitat management requirements of the *Forest Management Guidelines for the Provision of Marten Habitat* (i.e. large tracts of mature and older forest) are still in effect for this 2012 FMP, and will continue to be implemented until the draft Boreal Landscape Guide is approved. The featured species approach is being replaced by the landscape level direction in the draft Boreal Landscape Guide (when approved) and requirement for large landscape patches in the approved *Stand and Site Guide*.

The *Forest Management Guidelines for the Provision of Marten Habitat (MNR, 1996)* was applied to the Whiskey Jack Forest for this plan. The marten habitat guidelines influence the supply and spatial configuration of marten habitat on the landscape. Spatial planning of harvest allocations attempts to provide large tracts of contiguous future marten habitat by (a) harvesting blocks in larger disturbance size classes, and (b) harvesting the remaining, smaller areas within previously harvested areas in order to defragment the area and create a larger disturbance pattern for marten future habitat.

Spatial analysis was conducted for marten with additional habitat definitions of capable and suitable included. Core areas are to be spread across the forest and connected by riparian reserves and other unharvested forest. The marten habitat guide suggests that such cores will be large enough to provide high quality habitat for approximately 25 breeding females.

The previous 2004-2024 Forest Management Plan for the Whiskey Jack Forest identified marten cores and in doing so ensured that harvest allocations and road development was restricted from those areas. These areas were deferred from the available land base in the strategic modelling of the selected management alternative. The development of the marten core areas for this 2012 FMP also included deferrals of these areas for 60 years. The Ontario Marten Analyst Model (OMA2) was used for spatial analysis and core area analysis at plan start (Year 2012). The OMA2 model is a spatial analysis program used for the long-term projection of marten habitat levels. Using FRI stand species composition, stocking, age and height, OMA2 classifies the land base into capable and suitable habitat. Capable habitat is defined as those forest types that have the potential to develop into marten habitat. Suitable habitat is defined as those forest stands that have developed certain compositional and structural components (forest stands with greater than 40% spruce, pine, fir, cedar composition, greater than 40% stocking, tree height greater than 15 metres, and age greater than 79 years). OMA2 also estimates the future forest condition based on age and height from the normal yield tables. This "growing of the forest" allows for the spatial projection of suitable marten habitat for 20, 40 and 60 years into the future to aid in the identification of core habitat areas. Ideally, core habitat areas are 3,000 to 5,000 hectares in size and are comprised of 75% suitable forest condition, however lesser quality or smaller sized areas are considered as core habitat areas if locally valuable. The landscape level target is to maintain 10-20% of the capable habitat forest in suitable condition within core areas. Analysis shows that at Plan Start 2012, there is 4.9% of total capable marten habitat in suitable condition in core areas on the Whiskey Jack Forest.

Implications of plan start habitat levels – The marten core area analysis indicated core habitat below the range suggested by the marten guide. While the marten core area deferrals do not allow the Whiskey Jack Forest to meet the minimum 10% suitable marten core habitat objective, the deferrals do provide for the maximum amount of marten core habitat possible on the management unit for the next sixty years. Therefore the Planning Team agreed to continue application of the marten core area deferrals that were included in the 2004 FMP and 2012 Contingency Plan.

A detailed description of how the *Forest Management Guidelines for the Provision of Marten Habitat* were applied in the Whiskey Jack Forest. A description of the classification system and results from the spatial analysis, are provided in Supplementary Documentation N – Marten Habitat Analysis. A map of the marten core areas on the Whiskey Jack Forest is provided in the electronic FMP as MU490_2012_FMP_P1_MAP_MartenBMark_00.

Moose *(Alces alces)* The moose is a highly valued game species in Ontario and is very important to the culture of the local people and to the economic viability of the tourist industry and associated businesses in the Whiskey Jack Forest area. The *Stand and Site Guide* includes current science on moose habitat use and *Stand and Site Guide* direction was applied for this FMP. Because moose have diverse habitat requirements, providing habitat for moose also provides habitat for many other wildlife species. Moose range in Ontario encompasses a wide variety of physiographic site conditions. Moose tend to prefer forests with much edge, with older, more mature stands in close proximity to young deciduous stands. Such areas provide food and shelter from weather and predators. Moose also show a preference for areas where aquatic plants can be fed upon in spring and summer. Mineral licks are also used, although they may not occur at all in any given forest. The best moose habitat are forests with an abundance of these elements intermixed over large areas (e.g., > 10,000 ha).

(Photo Credit: MNR)

Forest management, that produces irregularly shaped and sized cuts with scattered shelter patches and a high diversity of age classes and species of vegetation, can and has been beneficial to moose numbers in the Kenora area. Timber cutting has been one of the major producers of moose habitat in the Province of Ontario, and without this disturbance, moose populations would be lower.

The intent of management efforts for moose habitat management is to maintain or create through timber management activities the diversity of age classes and species of vegetation that provide habitat for moose. Habitat management efforts focus on seasonal high use areas such as early and late wintering areas and on special areas such as aquatic feeding areas and

mineral licks, if present. Spatial consideration for moose habitat has occurred during the area of concern planning process before forest management activities were finalized for this plan.

As mentioned in Section 2.1.2.3 Management Zones, to achieve forest conditions in a managed forest that are similar to the conditions moose prefer and would encounter in a natural forest ecosystem, areas can be selected for moose emphasis areas (MEAs). Moose emphasis areas are locations where moose habitat will be enhanced through forest management practices. Moose habitat will exist across the forest, while the moose emphasis areas will just enhance the habitat quality in the designated areas. There are also many other factors that impact moose populations aside from habitat, and moose emphasis areas are only relevant to habitat planning. With that being said, habitat planning improves the habitat for moose populations.

Implications of plan start habitat levels – The Planning Team considered the quality and abundance of moose habitat at Plan Start and decided to identify and manage Moose Emphasis Areas for target species composition at the operational level. The analysis was done for the Whiskey Jack Forest resulting in the identification of one large Moose Emphasis Area in the northern portion of the forest, south of the area of the dynamic caribou habitat schedule.

It should be noted that even with an abundance of good to excellent moose habitat, moose populations may become depressed. Over the past decade, moose numbers in the Whiskey Jack Forest have declined substantially, and although a decline in habitat quality is likely a contributing factor, evidence suggests that disease and parasites, weather, predation and other factors are also implicated. Over time, though, moose populations should recover if habitat conditions are suitable.

White-tailed Deer *(Odocoileus virginianus)*

The white-tailed deer prefer foraging habitat which includes the pre-sapling and sapling stages of mixedwood balsam fir-spruce stands and lowland hardwood stands. The presence of suitable grasses and forbes (any herb that is not grass or grass-like) can enhance summer range by prolonging the longevity of openings and providing early spring and late fall browse for deer. Winter deer habitat must provide cover from snow and be located in association with browse species. Cedar is usually the best interceptor of snow and often grows in association with preferred browse. Arboreal lichens, where available, may provide a portion of the required food supply. In the absence of cedar, a mixture of spruce, pine and/or balsam fir may be used for deer yarding purposes, also referred to as winter concentration areas. Deer winter concentration areas tend to be a part of learned behaviour, so areas that are preferred can be of lasting significance. Winter concentration areas have been identified in the Whiskey Jack Forest through approved aerial survey techniques. This information was used to determine where deer habitat would be emphasized in deer emphasis areas (DEA). One DEA is located in the southern portion of the forest. (Photo Credit: www.duke.edu)

The Whiskey Jack Forest supports many areas that provide both deer and moose habitat. Winter severity is a major factor in controlling deer populations on the Whiskey Jack Forest.

Spatial consideration for deer habitat has occurred during the area of concern planning process before forest management activities were finalized for this plan. As mentioned in Section 2.1.2.3 Management Zones, to achieve forest conditions in a managed forest that are similar to the conditions deer prefer and would encounter in a natural forest ecosystem, suitable area was selected as a deer emphasis areas (DEA).

Implications of plan start habitat levels – The Planning Team considered the quality and abundance of deer habitat at Plan Start and decided to identify and manage Deer Emphasis Areas for target species composition at the operational level. The analysis was done for the Whiskey Jack Forest resulting in the identification of one Deer Emphasis Area in the southern Lake of the Woods portion of the Whiskey Jack Forest.

2.1.3 Forest Resources

2.1.3.1 Inventories and Information for Species at Risk

Ontario's *Endangered Species Act, 2007* (*ESA*) (Government of Ontario 2007) came into effect on June 30, 2008 to protect and recover the province's species at risk. MNR is the lead provincial government agency responsible for the management of species at risk in Ontario.

A "*species at risk*" is any naturally-occurring plant or animal in danger of extinction or of disappearing from the province. Therefore, recognition of potential significant negative conditions to species at risk or the known locations of their habitat have been considered by the Planning Team and where necessary, forest management operations were planned to mitigate any such potential adverse conditions.

Species at Risk are defined as *species that are at risk of extinction, extirpation or becoming endangered globally or within a jurisdiction or region*. Managing forested landscapes on a sustainable basis will help to contribute to the stability of special concern, threatened or endangered species that are either resident or transient in this area. In addition site conservation planning is also required for species at risk as they are often limited in numbers and/or location, necessitating in some cases Area of Concern prescriptions.

Forest management and the resulting harvesting operations alter forest conditions (tree species, age class, and structure) and the available habitat, reducing habitat supplies temporarily for some species and creating new opportunities for other species. It is important to have a sense of the potential for impact on the other forest resources that are dependent upon the range of forest cover and conditions.

The *Forest Management Planning Manual* (FMPM) requires that each FMP must identify and discuss any forest dependent Species at Risk (special concern, threatened or endangered) that inhabit the Whiskey Jack Forest and the contribution and importance of habitat for those species.

There are two separate Species at Risk lists: the provincial Species at Risk in Ontario (SARO) list which is developed by the Committee on the Status of Species At Risk in Ontario (COSSARO) and the federal Species at Risk Act (SARA) list which is developed by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). The provincial list of species must be considered during development of forest management plans however it should be noted that all species federally listed as endangered or threatened are also recognized as provincially featured species in Ontario's forest management planning process.

MNR's Natural Heritage Information Centre is the source of information on species of flora, fish and wildlife listed as endangered or threatened, and species of special concern.

The known locations of occurrences of flora and fauna Species at Risk were reviewed in the Whiskey Jack Forest in order to determine if operations would impact these values. The provincially listed species (SARO) were identified by MNR as having the potential to occur in the Whiskey Jack Forest and are identified in Table 6.

The following Species At Risk are also found within the Whiskey Jack Forest, but are not considered forest-dependent and/or forestry-related and therefore are not specifically managed in the FMP: American White Pelican, Golden Eagle, Bobolink, Horned Grebe, Shortjaw Cisco.

The history and habitat requirements of the forest-dependent species at risk with the potential to occur on the Whiskey Jack Forest are discussed in more detail following the table (in same order as listed in Table 6.

All known forest dependent Species at Risk (SAR) have their habitat managed in the plan using species specific guidelines and/or by recognizing specific habitats as values and developing appropriate area of concern (AOC) prescriptions. If in the future, any SAR is thought to exist near areas proposed for forest operations, the area will be surveyed and mapped by a qualified individual, and an appropriate area of concern prescription will be developed and applied.

The Species At Risk whose preferred habitat was strategically considered during development of the plan and reported in this FMP in Table FMP-6 is the woodland caribou (three habitat types: refuge, winter preferred and winter used). Caribou habitat management is documented in Supplementary Documentation N – Caribou Habitat Analysis which includes a map of the dynamic caribou habitat schedule (DCHS) areas.

Table 6 Forest Dependent Species At Risk (SARs) on the Whiskey Jack Forest

PROVINCIAL STATUS (SARO list)	SPECIES (Common Name)	SPECIES (Latin Name)	FOREST CONTEXT
Endangered	Eastern Cougar	*Puma concolor*	Public reports of observations of transient animals. No known den locations. Protection: see AOC D03 in FMP-10/FMP-19.
Endangered	Western Silvery Aster	*Symphyotrichum sericeum*	Highly restricted range. Known sites within a conservation reserve, not subject to forest management activities.
Endangered	Northern Bat	*Myotis septentrionalis*	Forest dependent. No known hibernacula on the Whiskey Jack Forest. Protection: see AOC NO08 in FMP-10/FMP-19.
Endangered	Little Brown Bat	*Myotis lucifugus*	Forest dependent. No known hibernacula on the Whiskey Jack Forest. Protection: see AOC NO08 in FMP-10/FMP-19.
Threatened	Woodland Caribou	*Rangifer tarandus caribou*	Dynamic Caribou Habitat Schedule planning in the northern part of the forest. No operations near calving/nursery values, though if a new value was identified near an area of operations, an AOC prescription would be develeoped and applied.
Threatened	Wolverine	*Gulo gulo*	No known denning sites. Large tracks of mature forest planned for through the caribou DCHS and marten core areas. Protection: see AOC D05 in FMP-10/FMP-19.
Threatened[2009]	Whip-poor-will	*Caprimlugus vociferus*	Forest dependent, particularly lands with a combination of open areas and woodlands. Though not on the Whiskey Jack Forest, the Dixie Lake Road area seems to be a regionally important 'hot-spot' in Red Lake District. Protection: see AOC NO04 in FMP-10/FMP-19.
Threatened	Least Bittern	*Ixobrychus exilis*	Wetland species - currently no known locations within forest. Protection: see AOC WW01 in FMP-10/FMP-19.
Threatened	Lake Sturgeon	*Acipenser fulvescens*	Lake of the Woods,Winnipeg River, English River System - Water crossings are considered as part of ESA. No crossings included in the FMP that affect known Lake Sturgeon areas.
Threatened	Showy Goldenrod	*Solidago speciosa*	Highly restricted in range – confined to one Crown parcel not subject to forest management activities.
Threatened	Barn Swallow	*Hirundo rustica*	Forest dependent (cleared and young forest stages). Protection: see AOC BS02 in FMP-10/FMP-19.
Threatened	Flooded Jellyskin	*Leptogium rivulare*	Seasonally flooded wetlands, particularly those including black ash. Flooded jellyskin grows below the high-water mark, usually on tree bark – but has been found growing on rock (Sandy Lake area). Protection: see AOC WW02 in FMP-10/FMP-19.
Special Concern	Eastern Wolf	*Canis lupus lycaon*	Hybrids occur throughout area. Protection: see AOC D04 in FMP-10/FMP-19.
Special Concern	Bald Eagle	*Halieetus leucocephalus*	Breeds throughout area. Protection: see AOC N01, N02, N03, N04 in FMP-10/FMP-19.
Special Concern	Black Tern	*Chlidonias niger*	Wetland bird, restricted range. Not forest dependent.
Special Concern	Olive-sided Flycatcher	*Contopus cooperi*	Breeds throughout area. Protection: see AOC NO06 in FMP-10/FMP-19.
Special Concern	Short-eared Owl	*Asio Flammeus*	No known breeding locations. Habitat is large open fields associated with agriculture. Protection: see AOC NO03 in FMP-10/FMP-19
Special Concern	Canada Warbler	*Euphagus carolinus*	Breeds throughout area. Protection: see AOC NO07 in FMP-10/FMP-19.
Special Concern	Common Nighthawk	*Chordeiles minor*	Breeds throughout area. Protection: see AOC NO05 in FMP-10/FMP-19.
Special Concern	Rusty Blackbird	*Euphagus carolinus*	No known locations. Typically observed near wet areas in conifer-dominated forests. Protection: In the event a nest is discovered and confirmed on the forest, an AOC prescription will be developed in consultation with MNR staff.
Special Concern	Snapping Turtle	*Chelydra serpentina*	Southern portion of unit. Breeds throughout area. Usually found in shallow water. Protection: see AOC NE10 in FMP-10/FMP-19.

STATUS: ENDANGERED

Cougar (*Puma concolor*) - The cougar is considered to be "endangered" in Ontario. It has been confirmed to occur in southern Manitoba but there have been no confirmed observations in the Northwestern Ontario. The cougar is a habitat generalist and deer are its preferred prey.

MNR tracks cougar reports and may respond with follow-up investigation of public reports depending on the circumstances. These reports to date have been of a transitory nature. MNR and partners also attempt to gather information using remote cameras and through the collection of DNA samples.

Should a cougar den be discovered, Table FMP-10 AOC prescription D03 will be applied, and if possible the area will be avoided during the denning period. This prescription is accordance with the *Stand and Site Guide*. . (Photo Credit: MNR)

STATUS: ENDANGERED

The **Western Silvery Aster** (*Symphyotrichum sericeum*) has daisy-like flowers that come in various shades of bright pink to deep purple. Leaves of this plant are covered with silky hairs, giving it a silvery appearance. They are found in well-drained soil. The Western Silvery Aster inhabits open habitats that are susceptible to succession from other vegetation. In Ontario, it is known to grow in two areas in the Rainy River district on the south shore of Lake of the Woods, and on an island in the lake. These areas are not subject to forest management activities, and continue to be monitored by MNR.

Western Silvery Aster is protected by Ontario's Endangered Species Act and the federal Species at Risk Act. The habitat of Western Silver Aster is regulated under the ESA, 2007. Cottage development is a potential threat to the Western Silvery Aster. The risk of impact through forest management activities is low given the locations of the known sites. Should Western Silvery Aster be discovered at a new location on the unit, the site conditions, as defined in the regulation, would be avoided or a permit sought through the ESA, 2007. . (Photo Credit: Bill Crins_www.rom.on.ca)

STATUS: ENDANGERED

Northern Bat (*Myotis septentrionalis*), better known simply as the Northern Long-eared Bat, is a small to medium sized bat, best recognized by its long rounded ears, which extend beyond the tip of the nose when laid forward. It has a comparatively longer tail and larger wing area than other Myotis species of similar size (7-8 cm in length). This bat has dull to light brown fur on the back, and yellowish fur on the underside.

Northern Bat
(Photo Credit: http://en.wikipedia.org)

STATUS: ENDANGERED

The **Little Brown Bat** (*Myotis lucifugus*) has uniformly glossy, dark brown fur on the back and upper parts with slightly paler, greyish fur underneath. Mature Little Brown Bats reaches a body length of 7-10 cm.

Little Brown Bat
(Photo Credit: mens-news.com)

General Bat Information:

Ontario bats have small eyes and poor vision and use 'echolocation', a series of high pitched sounds through its nose or slightly opened mouth, to navigate and identify prey. These sounds are very high pitched, too high for humans to hear.

All of Ontario's bat species are insectivores. Most foraging occurs over lakes, ponds, streams, wetlands, associated riparian habitats, other open habitats, or along roads, trails, and other forest edges; some foraging also occurs below, within, or above forest canopies, especially in older forest with irregular canopy structure. All species use forested habitats for roosting and/or reproduction. Some species simply roost in tree foliage but most species roost under the loose bark of dead or declining trees or in tree hollows or cavities. Most nursery colonies are reported from human dwellings, but trees with large hollows or cavities are likely used in natural situations.

The Northern Bat and the Little Brown Bat hibernate in Ontario, typically using caves or abandoned mines that provide above freezing air temperature and high relative humidity. Suitable hibernacula may be a limited resource; individual sites may be used by large numbers of bats drawn from an area of several thousand km2 around the hibernaculum. Disturbance of hibernating bats is a major mortality factor. COSSARO (May 2012) reported that Canadian bats that hibernate underground are dying from White Nose Syndrome (WNS), caused by a fungus, Geomyces destructans, that was inadvertently imported from Europe to North America. WNS has not been documented west of Wawa yet but appears to be spreading rapidly.

General direction that maintains a diversity of forest types and ages (including old forest), a range of potential roost and nursery sites within stands (cavity trees), and the integrity of aquatic and shoreline habitats largely addresses the basic habitat requirements of bats.

There are no known bat hibernacula on the Whiskey Jack Forest, however if one is identified the AOC NO08 prescriptions in Tables FMP-10 and FMP-19 will be implemented. It is unlikely that forest management operations would disturb a hibernaculum located underground, but if avoidance is not possible and disturbance is likely, an ESA permit may be sought in consultation with the MNR Species at Risk Biologist.

STATUS: THREATENED

Woodland Caribou – forest-dwelling population (*Rangifer tarandus caribou*) are native to Ontario's northern forests. They are an important indicator of the healthy boreal forest ecosystem on which they rely. As one of several jurisdictions responsible for managing the northern boreal forest, Ontario has an important role in Woodland Caribou stewardship.

(Photo Credit: MNR)

All caribou in Canada, including the barren-ground caribou, are of the same species and reported to be the most abundant ungulate in Canada (Canadian Cooperative Wildlife Health Centre 2005). A review by Sleep (2007) concluded there are perhaps 2 million or more caribou of all types in Canada. Ontario's caribou are all members of the woodland caribou subspecies, but two "ecotypes" have been identified: forest-dwelling and forest-tundra ecotypes. These ecotypes differ mainly in their behaviour (the tendency to migrate from the forest to the tundra or to remain within the forest). Only the forest-dwelling ecotype is considered to be "threatened". A status report produced by Thomas and Gray (2002) for COSEWIC estimated about 1.28 million of Canada's caribou belong to the woodland caribou subspecies, and about 184,000 of those belong to the forest-dwelling ecotype or sub-population.

In a status report on the woodland caribou prepared for MNR, Harris (1999) provided population estimates. The status report stated that in 1996 there were about 21,000 caribou in Ontario (all of the "woodland caribou" subspecies). This population included about 5,000 of the threatened "forest-dwelling ecotype" (listed as "at risk" federally in 2002 and provincially in 2004), with the remainder (about 16,000) being the forest-tundra ecotype (Harris 1999), which has not been listed by COSSARO or COSEWIC as "at risk".

The geographic range of caribou in Ontario has receded northward since the late 1800s. Several factors have been hypothesized to have had a role including hunting, forest fires, land clearing, logging, and increased predation by wolves due to increased populations of moose and deer. Hunting of caribou by non-Aboriginal people has been banned in Ontario since 1929. Another influence on caribou is a parasitic nematode (*Parelaphostrongylus tenuis*) commonly

called the "brain worm" that is carried by deer. Although deer are not seriously affected, the parasite can cause death to infected caribou and moose. When deer invade moose and caribou habitat, the frequency of transmission of this parasite is increased.

Specific management actions have been undertaken for caribou in this forest since a draft version of the "*Forest Management Guidelines for the Conservation of Woodland Caribou – a Landscape Approach*" (Racey et al.1999) was first applied. The 2012-2022 FMP will be the third plan for this forest to address caribou habitat explicitly. Since the forest-dwelling woodland caribou has been classified as a "species at risk" in Ontario, it is more important than ever for the FMP to consider caribou habitat management.

In winter, caribou use open coniferous forest with abundant terrestrial or arboreal lichens (Racey et al. 1999). Refuge habitat, consisting of a variety of ages of conifer-dominated stands, is also important for caribou (Racey et al. 1999). Refuge habitat is habitat unlikely to support large numbers of alternate prey species suitable for large predators. It consists of immature and older ConSh, CuPjk, SbMix (spruce-dominated mixedwood), and all ages of SbLow.

(Photo Credit: MNR)

The objective of the spatial components of the guide was to provide a sustainable supply of connected, suitable year round caribou habitat and to protect sensitive sites, such as calving sites. To apply the caribou habitat guide spatially, MNR identified calving sites and ecologically-based caribou habitat tracts across the northern portion of the Whiskey Jack Forest and across the entire portion of the Area of the Undertaking in northwestern Ontario in which caribou occur. Habitat mosaic blocks that complement the habitat tracts have also been identified to assist in scheduling forest harvesting, and to maintain a continuous supply of connected habitat in suitably large patches.

Ontario's Woodland Caribou Conservation Plan provides policy direction for the management and recovery of Woodland Caribou (forest-dwelling boreal population), and will apply to the areas of continuous and discontinuous distribution. In this FMP, the caribou habitat guidelines are used to assess caribou habitat spatially through application of the dynamic caribou habitat schedule (DCHS, previous referred to as the caribou mosaic), and habitat relationships defined in the guidelines are also used in non-spatial habitat supply modelling performed within the Strategic Forest Management Model (SFMM). The supply of caribou habitat was measured non-spatially in SFMM, treating habitat as an ecological constraint and a test of the sustainability of the overall Long-term Management Direction. Both preferred winter habitat and refuge habitat were modelled over a 150-year period for the Long-term Management Direction (see Table FMP-6 and Section 3.6.0.3 Habitat for Species At Risk and Selected Wildlife Species).

One of the key directions in the 2009 *Forest Management Planning Manual* (FMPM) is to develop an FMP with the best available science and information, new legislation, regulation and policy, and changes to forest conditions and land base (FMPM A-29). The expectation was to

utilize the *Forest Management Guides for Boreal Landscapes* (hereafter called the draft Boreal *Landscape Guide*) in development of the 2012 Whiskey Jack FMP. Since the landscape guide was not approved for implementation during the development of this FMP, regional advice has been to utilize the draft *Boreal Landscape Guide* science package as a reference for the estimated natural forest condition. The science packages used in the development and prepared for the support of the *Landscape Guide* were prepared by science teams.

There are several new management objective indicators included in Science and Information in support of Ontario's Forest Management Guides for Landscapes that have been incorporated into this 2012 FMP related to caribou habitat management: young forest patch size by size class, mature and old forest area (amount and pattern), old forest area, caribou refuge and winter habitat (amount and pattern) and the simulated ranges of natural variation used to set desirable levels for these indicators was considered the best available science by the Planning Team and regional advisors. The direction identifies and helps to set landscape mosaic goals and targets for forest composition (forest tree species groups and age classes) and structure (pattern) in forest management plans. Spatial and non-spatial indicators of caribou habitat amount and pattern/texture (refuge and winter habitats) were analyzed through use of the Ontario Landscape Tool (OLT) with the forest inventory for the Whiskey Jack Forest. This methodology was used to set desirable levels and analyze spatial and non-spatial results. This analysis was a significant step forward in forest management as compared to previous FMPs.

Finally, a General Habitat Description under the *Endangered Species Act, 2007* was approved June 2013. MNR has developed a draft Range Management Policy that is currently on the Environmental Registry for public comment. Any required additions or changes to caribou habitat management in Ontario dictated by the Range Management Policy will be included or amended into the forest management plan.

Caribou habitat is spatially managed in the northern part of the Whiskey Jack Forest through the Dynamic Caribou Habitat Schedule, in accordance with the Caribou Conservation Plan. Consideration for other values (ie. calving and migration) occurs through AOC and operational planning (i.e. timing restrictions). Prescriptions that consider Section 9 of the ESA (harm and harass) have been developed. Several survey flights have occurred in the last three years to determine and/or confirm winter habitat use. A summer survey was conducted on Sydney Lake in 2009 (partnership with Wabaseemoong through the SAR Stewardship Fund). Best Management practices for forestry operations in caribou country are currently being developed in accordance with the General Habitat Description.

Details of the spatial analysis of habitat supply are provided in Supplementary Documentation N – Caribou Habitat Analysis, and in Supplementary Documentation N – Landscape Pattern OLT.

STATUS: THREATENED

The **Wolverine** (*Gulo gulo*) has been described as resembling a compact, strongly built, small bear in general appearance except for its bushy tail and shorter legs (Hash, 1999). The wolverine is a "scavenging predator" that depends to a large extent on carrion, but will also eat berries, fish, small to medium-sized mammals, birds, and any other prey it can catch. Individual wolverines occupy very large home ranges (generally much larger than 10,000 hectares), which they cover in search of carrion and live prey. Denning habitat is critical for the persistence of the wolverine in disturbed landscapes.

Recently, wolverines have been studied extensively in the Red Lake District, north and northeast of the Whiskey Jack Forest. Ontario has the most easterly viable wolverine population in Canada, believed to be concentrated in northwestern Ontario, roughly from Red Lake-Sioux Lookout to Fort Severn-Peawanuck. There have been wolverine observations within the northern parts of the Kenora District. Incidental harvest of wolverine by trappers has been documented and addressed through the ESA, 2007.

Because of their very large home ranges, opportunistic nature, and affinity for a wide variety of habitat types (Hash 1999), management strategies that emulate natural disturbances, maintain a supply of forest types in approximately natural amounts, and protect denning sites should provide for wolverines over the long term. Therefore, at this time, the management approach for the Whiskey Jack Forest is: (i) to provide large patches of suitable habitat in the caribou zone through application of the *Forest Management Guidelines for the Conservation of Woodland Caribou – a Landscape Approach* (Racey et al.1999), (ii) to protect wolverine denning sites if identified in accordance with direction in the *Stand and Site Guide*, and (iii) to ensure the supply of all forest types present in the Whiskey Jack Forest reflects natural levels under the Long-term Management Direction (see Section 3.0 of the FMP).

As a species listed as threatened on the Species at Risk in Ontario List, and with the implementation of the new Endangered Species Act (2007), wolverine will be provided habitat protection under the General Definition (SAR Policy 4.1) of habitat in 2013 (within the timeframe of this plan). This general habitat protection will be applied until such a time when a habitat regulation will be developed specifically for the protection of wolverine habitat. The wolverine recovery plan is currently in draft phase and is expected to be completed in the near future. Once these recommendations are made to the Ontario government, they will have the opportunity to produce a government response statement which will further detail the management approach to be taken with respect to the protection of wolverine and their habitat. If wolverine habitat values (den sites) are identified in the Whiskey Jack Forest, area of concern D05 will be implemented as stated in Table FMP-10.

STATUS: THREATENED

The **Whip-poor-will** (*Caprimlugus vociferus*) is a medium-sized bird (22-26 centimetres long) with mottled brown and grey feathers that help it blend in with its surroundings. Since the whip-poor-will becomes active at dusk and rests during the day, it is more commonly heard than seen. Whip-poor-wills are most vocal during bright, moonlit nights when they can be heard singing their name "Whip-poor-will". (Photo Credit: Mark J M Wilson)

The Whip-poor-will is usually found in areas with a mix of open and forested areas, such as savannahs, open woodlands or openings in more mature, deciduous, coniferous and mixed forests. It forages in these open areas and uses forested areas for roosting (resting and sleeping) and nesting. It lays its eggs directly on the forest floor, where its colouring means it will easily remain undetected by visual predators.

Whip-poor-will have been reported many times in the Lake of the Woods area according to the Atlas of the Breeding Birds of Ontario, but no known nesting sites have yet been confirmed. The Whip-poor-will was announced as Threatened in the fall of 2009. In 2010 Aboriginal Traditional Knowledge (ATK) was collected for sites around Lake of the Woods.

There are no known nesting sites at this time, however should a nesting site be identified during the course of implementation of this FMP, protection of the area will be achieved through application of Area of Concern prescription NO04. (Facts: http://www.mnr.gov.on.ca/276687.pdf)

STATUS: THREATENED

Least Bittern (*Ixobrychus exilis*) is more likely heard than seen, as it "coo"s softly from deep in a cattail marsh. This species is the smallest of the North American herons. Least Bitterns generally require medium to large, quiet marshes and as marshes decrease in size and human recreation increases, the population declines in an area. (Photo Credit: Mark Peck, www.rom.on.ca)

Because of its secretive nature breeding locations are likely underrepresented. The Atlas of the Breeding Birds of Ontario (ABBO) has a possible Least Bittern breeding site listed for the Lake of the Woods area. Though there are no identified breeding locations in the Kenora District, it mostly likely that Least Bitterns breed within the southern portion of the Whiskey Jack Forest. Surveys for this species have not yet been undertaken in the Kenora District but rather have been focused on areas with reports and areas that appear to have high habitat suitability (areas in southern Lake of the Woods).

The main threat to Least Bitterns is draining of wetlands for conversion to farmland and urban development. This species is not forest-dependent. If a nesting site is found, Table FMP-10, AOC prescription WWO1 will be applied, and if avoidance is not possible an ESA permit will be sought in consultation with the Species at Risk Biologist.

STATUS: THREATENED

Lake Sturgeon *(Acipenser fulvescens)* is unlike any other fish found in Ontario. This unusual fish has five rows of bony plates arranged along the back and sides; the skin is covered with tiny toothlike projections that give it the feel of fine sandpaper; and the dorsal fin is fairly large and located just forward of the tail, which is unequally lobed like that of a shark. Like catfish, the Lake Sturgeon is a specialized bottom feeder. The Lake Sturgeon is Canada's largest freshwater fish species: past records exist of specimens exceeding 2 metres in length and 136 kg in weight, although most mature specimens seen today are much smaller. It usually inhabits the bottoms of shallow areas of large freshwater lakes and rivers, but migrates each year from early May to late June to swift-flowing water to spawn. Individuals usually return to the same spawning rivers year after year. The decline in numbers witnessed today partially reflects human over-exploitation in the latter half of the nineteenth century. At present, it is likely that over-harvesting for meat and caviar forms a significant threat to the Lake Sturgeon. Additional threats include the construction of dams, which may disrupt habitat and interrupt spawning movements and timing; habitat degradation resulting from human activities; habitat contamination caused by chemicals, toxins, and fertilizers; and the introduction of non-native species that include competing and predatory fish, and plants that may modify habitat. (Photo Credit: MNR)

Lake Sturgeon are found throughout Lake of the Woods, the Winnipeg River and the English River systems. Lake sturgeon values are considered when planning for water crossings. Most recently there have been discussions with Weyerhaeuser surrounding a bridge crossing that has the potential to impact lake sturgeon spawning habitat (e.g. Caribou Falls crossing of the English River on the adjacent Kenora Forest). As more information becomes available regarding the Lake Sturgeon recovery strategy, it will be incorporated into FMP planning. Lake sturgeon monitoring and assessment has been ongoing since 2007 with partnerships with Ontario Power Generation, Wabaseemoong First Nation, Dalles First Nation and the Department of Fisheries and Oceans).

Forestry operations on the Whiskey Jack Forest are not expected to impact Lake Sturgeon habitat directly, however road construction in the vicinity of any known Lake Sturgeon spawning areas is considered during road planning. MNR District and regional wildlife biologists and Species At Risk Biologists are consulted for direction on the acceptable construction design to ensure there is no negative impact on spawning habitat. If negative impacts cannot be avoided, an ESA permit may be required for activities at these sites.

STATUS: THREATENED

Showy Goldenrod *(Solidago speciosa)* belongs to the distinctive group of wildflowers which produce showy, yellow flowers in late summer and early fall. In Canada, it grows in prairies, particularly under oaks in a habitat called the oak savannah. It prefers sandy soils and does not tolerate disturbance.

(Photo Credit: MNR)

Showy Goldenrod is protected by the federal Species at Risk Act and Ontario's Endangered Species Act. It receives general habitat protection under the ESA, 2007. This species is restricted to one location and is not subject to forest management. The site is monitored by MNR staff. Should new populations be discovered an AOC will be developed or an ESA permit sought.

STATUS: THREATENED

Barn Swallow *(Hirundo rustica)* is the most widespread species of swallow in the world. It is a distinctive passerine bird with blue upperparts, a long, deeply forked tail and curved, pointed wings. It is found in Europe, Asia, Africa and the Americas.

The preferred habitat of the Barn Swallow is open country with low vegetation, such as pasture, meadows and farmland, preferably with nearby water. This swallow avoids heavily wooded or precipitous areas and densely built-up locations. The presence of accessible open structures such as barns, stables, bridges or culverts to provide nesting sites, and exposed locations such as wires, roof ridges, abandoned buildings or bare branches for perching, are also important in the bird's selection of its breeding range. This is a species which has greatly benefited historically from forest clearance, which has created the open habitats it prefers, and from human habitation, which have given it an abundance of safe man-made nest sites. It builds a cup nest from mud pellets in barns or similar structures and feeds on insects caught in flight.

At this time this there are no known sites within the management unit and the likelihood of its occurrence is low. Barn Swallow nests should be considered when planning maintenance or replacement of bridges. Should Barn Swallow nests be discovered within the Whiskey Jack Forest during the course of implementation of this FMP, protection of the area will be achieved through application of Area of Concern prescription BS02 in Table FMP-10.

(Facts and Photo Credit: en.wikipedia.org)

STATUS: THREATENED

Flooded Jellyskin *(Leptogium rivulare)* is a leaf-like lichen that grows at the base of trees growing around vernal ponds that fill with meltwater in spring, then dry up in summer. The lichens, which are bluish-grey when dry, swell up and become translucent when they are submerged (hence the name "jellyskin"). Lichens are compound organisms consisting of a fungus co-existing with an algae or bacteria. Lichens grow slowly – perhaps one millimetre per year. Individual lichens grow to about 6 cm, but lichens cluster and can form larger encrustations half a metre across trees. Flooded Jellyskin has always been rare throughout its range. While it has an extremely restricted range, there are likely thousands of individuals present at ponds in Ontario. Ponds are being threatened by recreational use and housing development. One of the main tree species around the vernal pools that the lichens live on is Black Ash, which is threatened by a recent invader, the Emerald Ash Borer. Forestry operations on the Whiskey Jack Forest are not expected to impact Flooded Jellyskin habitat. There are no known woodland pools supporting Flooded Jellyskin at this time, however should a site be identified, protection of the area will be achieved through application of AOC prescription WW02.

STATUS: SPECIAL CONCERN

(Photo Credit: MNR)

The **Eastern Wolf** *(Canis lupus lycaon)* a distinct form of the Grey Wolf, lives in southern Ontario and Quebec. The Eastern Wolf differs from other subspecies of Grey Wolf in Canada: it is smaller, fawn-coloured with long black guard hairs on the back and sides, and the back of the ears are reddish. It is estimated that there are about 2,000 Eastern Wolves in Ontario and Quebec. Eastern Wolves live in groups called "packs," which typically number from 3-6 adults. Each pack has a home range that is loosely defended from neighbouring packs and may be as big as 500 km2. Eastern Wolves prey primarily on White-tailed Deer and Moose.

The Eastern Wolf has disappeared from all of southern Ontario largely as a result of forest clearance and farmland development, and the subsequent loss of habitat. The wolf is classed as a furbearer under the Fish and Wildlife Conservation Act (1997) and there is a regulated hunting season in Ontario. A grey wolf-eastern wolf hybrid occurs across the northwest and is included in the Species At Risk designation. All known denning locations are recognized as values in the FMP planning process. Appropriate area of concern (AOC D04) prescriptions are applied in accordance with the approved forest management plan (Table FMP-10) and direction from the *Stand and Site Guide.*

STATUS: SPECIAL CONCERN

Bald Eagle (*Halieetus leucocephalus*) - COSSARO down listed the bald eagle from "endangered" to "special concern" in northern Ontario in 2006 due to improvements in densities observed in this region of Ontario. The Kenora District MNR has a good database of the locations of past and presently used Bald Eagle nesting sites, containing over 450 recorded nest locations for the Whiskey Jack Forest. Nest locations are collected through a variety of means, including aerial surveys targeting stick nests, compliance flights for other values, as well as other flights that occur for forest management. Values are also provided by the public and forest industry staff. (Photo Credit: Mark Peck, www.rom.on.ca)

Habitat of Bald Eagles (nesting sites) could potentially be affected by forestry operations, but this is mitigated through Area of Concern planning. A combination of reserves and timing restrictions on operations is applied around all nests. The preferred nest trees are large, supercanopy poplar, white pine and red pine on or near the shorelines of productive lakes. Prescriptions for identified nests were developed with information gathered from flights, carry-over from previous FMP, and assessment of potential impact.

The recovery of Bald Eagle in northern Ontario is a combination of population increases in all areas, including the Whiskey Jack Forest. Bald Eagle nesting habitat is protected through implementation of prescriptions and conditions outlined in this FMP that were developed using the *Stand and Site Guide* (AOC prescriptions N01, N02, N03 and N04 in Table FMP-10).

STATUS: SPECIAL CONCERN

The **Black Tern** (*Chlidonias niger*) is a small tern that has a black head and underparts during the breeding season. They are mainly insect predators, hovering just above the water as they pick their prey off the surface. They build floating nests in loose colonies in shallow marshes, especially in cattails. In winter they migrate to the coast of northern South America.

Black Terns are largely associated with wetland complexes and nest in colonies in wetland marshes associated with lakes, ponds, and rivers. Hemi-marsh, an interspersion of emergent vegetation (i.e. cattails, bulrushes, burreed, and reeds) and open water appear to be a critical factor in nest habitat selection. (Photo Credit: Mark Peck, www.rom.on.ca)

Traditional nesting areas of Black Tern have been largely provided by the public and are tracked through the Natural Heritage Information Centre. Specific Black Tern Surveys are not conducted by MNR for the purpose of Forest Management Planning. There are 13 reports of Black Terns in the Lake of the Woods area, though none are on the Whiskey Jack Forest.

Sensitive breeding habitat for the Black Tern is not forest-dependent. Black Terns are Special Concern and are not afforded protection under the ESA 2007. However, a prescription is applied through the application of the *Stand and Site Guide* (AOC WW01 in this FMP). Roads can impact black tern nesting habitat if water crossings cause changes in water flow to an area. This factor will be considered when roads are planned on the Whiskey Jack Forest.

STATUS: SPECIAL CONCERN

Olive-sided Flycatcher *(Contopus cooperi)* are often found perched on top of a large tree or snag in the boreal forest and are often heard in large wetlands, riparian zones and burns. It will use early successional forests that have been logged or burned, if there are ample tall snags and trees to use for foraging perches and nearby wetland complexes. Olive-sided Flycatchers' breeding habitat usually consists of coniferous or mixed forest adjacent to rivers or wetlands. The Olive-sided Flycatchers commonly nest in conifers such as white and black spruce, jack pine and balsam fir. This species captures all of its meals in flight, specializing in bees, wasps, large flies, beetles and dragonflies.

(Photo Credit: Brian Small, www.mnr.gov.on.ca)

They perform one of the longest migrations of the Nearctic migrants, and are typically known as late arrivals in the spring and early migrants in the fall. Although their breeding range is quite expansive, their low density and significant declines over the past 30 years have caused them to be listed by COSSARO.

There have been many confirmed and probable sightings of Olive-sided Flycatchers in the Lake of the Woods area according to the Atlas of the Breeding Birds of Ontario. Minimal other information is available for the Kenora District. There are no known nesting sites at this time, however should a nest be identified during the course of implementation of this FMP, protection of the area will be achieved through application of Area of Concern prescription NO06.

STATUS: SPECIAL CONCERN

The **Short-eared Owl** (*Asio flammeus*) is a medium-sized owl that lives in open areas such as grasslands, marshes and tundra where it hunts for small mammals, especially voles. Short-eared Owls nest on the ground. These owls have been observed to the east in the Dryden Forest but there are no known nesting sites in the Kenora District. Records from the recent Atlas of Breeding Bird in Ontario (ABBO, 2001-2005) suggest the Short-eared Owl is a possible or probable nester in the Lake of the Woods area and vicinity. The Short-eared Owl was probably more common and widespread in southern Ontario when there were larger areas of prairie and savannah, their preferred habitat. The creation of new grasslands with the clearing of forests for farmland may have initially benefited the species, but as agricultural methods became more intensive, these areas became unsuitable for the species. Current threats include loss of marshes.

There are no known nest locations in the Whiskey Jack Forest. If a nest is discovered during the course of forest management operations, MNR will be consulted and AOC prescription NO03 will be implemented which is consistent with *Stand and Site Guide* direction for Short-eared Owl nests.

(Photo Credit: Mark Peck, www.rom.on.ca)

STATUS: SPECIAL CONCERN

The **Canada Warbler** *(Euphagus carolinus)* is a small, brightly coloured songbird. Males are more brightly coloured than females, with bluish-grey upperparts and tail and bright yellow underparts. The head is bluish with a black forehead and "sideburns," which join to form a distinctive necklace of black stripes across its chest. In the spring, males can be heard singing a distinctive song of clear, liquid notes ending emphatically.

The Canada Warbler breeds in a range of deciduous and coniferous, usually wet forest types, all with a well developed, dense shrub layer. Dense shrub and understory vegetation helps conceal Canada warbler nests that are usually located on or near the ground on mossy logs or roots, along stream banks or on hummocks. It winters in South America. The Canada warbler is one of the last migratory songbird species to arrive on Canadian nesting grounds in the spring and is also one of the first species to leave at the end of summer. A reduction in forests with a well-developed shrub-layer has likely impacted Canada Warblers throughout their breeding range. The Atlas of the Breeding Birds of Ontario (ABBO) reports many possible sightings of Canada warblers in the Lake of the Woods area, but no confirmed nesting sites.

There are no known nesting sites at this time, however should a nesting site be identified during the course of implementation of this FMP, protection of the area will be achieved through application of Area of Concern prescription NO07. (Photo Credit: Brenda Carroll)

STATUS: SPECIAL CONCERN

The **Common Nighthawk** (*Chordelies minor*) is a medium-sized bird, active at night or at twilight. It has cryptic plumage, long wings, short legs, and a very short bill. Its wide mouth scoops up large insects on the wing, and its flight is very agile, silent and erratic. Common Nighthawks build no nest, laying their eggs instead on the bare ground. Traditional Common Nighthawk habitat consists of open areas with little to no ground vegetation, such as logged or burned-over areas, forest clearings, rock barrens, peat bogs, lakeshores, mine tailings.

This species is found throughout the Whiskey Jack Forest and is frequently associated with cutover areas. No specific surveys are undertaken, however public reports are recorded. The ABBO lists possible and probable nesting sites for the common nighthawk in the Lake of the Woods area. There are no known nesting sites at this time, however should a nest be identified during the course of implementation of this FMP, protection of the area will be achieved through application of Area of Concern prescription NO05. (Photo Credit: Mark Peck, www.rom.on.ca)

STATUS: SPECIAL CONCERN

The **Rusty Blackbird** (Euphagus carolinus) was listed by COSEWIC as a bird of "special concern" in Canada. The OBBA suggests it has declined by about 30% in northern Ontario since the first atlas 20 years ago. This bird nests in immature coniferous trees in open shoreline forests and scrubby habitat adjacent to wetlands such as beaver meadows, marshes, ponds, swamps, and bogs (COSEWIC 2006). The rusty blackbird forages by walking along shorelines searching for invertebrates. Forest management that results in some harvesting and coniferous regeneration along shorelines would benefit this species. The recent OBBA does contain records of possible and probable nesting for the rusty blackbird in the region, though no confirmed nesting sites are identified for the Whiskey Jack Forest. If a rusty blackbird nesting site is found, appropriate AOC prescriptions will be developed and applied. (Photo Credit: Mark Peck, www.rom.on.ca)

STATUS: SPECIAL CONCERN

The **Snapping Turtle** (*Chelydra serpentina*) is Canada's largest freshwater turtle, reaching an average length of 20-36 cm and a weight of 4.5-16.0 kg. Snapping turtles have large black, olive or brown shells typically covered in algae. Their tails, which can be longer than their body, "dinosaur-like" triangular crests along their length. Hatchlings are about the size of a loonie and are smaller and darker than adults, with pronounced ridges along the length of their shell.

Snapping Turtles spend most of their lives in water. They prefer shallow waters so they can hide under the soft mud and leaf litter, with only their noses exposed to the surface to breathe. During the nesting season, from early to mid-summer, females travel overland in search of a suitable nesting site, usually gravely or sandy areas along streams. Snapping turtles often take advantage of man-made structures for nest sites, including roads (especially gravel shoulders), dams and aggregate pits.

(Facts: http://www.mnr.gov.on.ca/276686.pdf, Photo Credit: Wasyl Bakowsky, NHIC)

Snapping turtles are known to nest on the Whiskey Jack Forest. Information on nest sites has been collected through Aboriginal Traditional Knowledge as well as public reports. Information on occurrences is tracked through NHIC. Snapping Turtle is a Special Concern species and is not afforded protection under the ESA, 2007. If a snapping turtle nesting site is found during implementation of this FMP, AOC NE10 in Table FMP-10 will be applied.

2.1.3.2 Fish and Wildlife Inventories

This section of the plan text describes fish and wildlife resources on the Whiskey Jack Forest, excluding those species already discussed as selected species (Section 2.1.2.4.2) or species at risk (Section 2.1.3.1). A summary of available information on the occurrence of fish and wildlife species follows and is based on fish and wildlife inventory and habitat information. The quantity and quality of habitat for these species are not likely to be affected by forest operations. Information is presented for fisheries resources in the following subsection.

There are a variety of wildlife species that occur on the unit, and limited information is gathered on the abundance and distribution of these species using inventory techniques. Inventory techniques primarily include aerial surveys for bird nesting sites, which provides some information on species with nests that can be viewed from the air (e.g. bald eagles, osprey, great blue heron). There are over 600 known nest locations in the Whiskey Jack Forest.

In 2000 and 2001, 104 elk were released in the Lake of the Woods restoration area; specifically near Cameron Lake in the Kenora Forest. Following their release, research and monitoring efforts suggest elk numbers declined, but have recently stabilized and may be increasing. Presently, the population in the core area (approximately a 40 km radius from the release site) is estimated to be about 40 animals, with a similar or smaller number of animals in small groups scattered over a much wider area extending into the Whiskey Jack Forest.

There are two Black Bear Population Index Network (BBPIN) lines that pass through the Whiskey Jack Forest. The lines were designed to provide a broad-scale view of the bear population trends in Ontario. Although informative for managing black bear population, this information is not used for forest management planning; there is however an AOC for bear dens if one is identified within a harvest block.

Moose aerial inventories are conducted to estimate abundances of moose however; they are not on the same scale as a forest management unit. Although these surveys are not always developed for the intention of inventory for a FMP, the information may be useful to some degree when choosing Moose Emphasis Areas.

Deer winter concentration areas are regularly mapped using approved and standardized inventory techniques. This information is used to aid in the delineation of deer emphasis areas. The management of moose and deer emphasis areas will follow guidance provided by the *Stand and Site Guide*.

2.1.3.2.1 Fisheries Resource

The fisheries resource on this unit is diverse as many lakes, rivers and streams are found throughout the Whiskey Jack Forest. Stream and pond values are divided into High, Medium or Low Potential Sensitivity (HPS, MPS and LPS) to forest management activities. Lakes and rivers are High Sensitivity to forest management activities. Sites inventoried as HPS sites have one or more of the following characteristics;

- Known to contain fish species that are highly sensitive to perturbations (e.g. lake trout),

- Known to provide components of fish habitat for which there is a high degree of species dependence,
- Known to contain a rare habitants or fish that are species at risk
- Low habitat resiliency
- Identified as significant habitat by specific fisheries management plans.

MPS sites have one or more of the following characteristics;

- Known to contain fish species that are moderately resilient to perturbations (e.g. walleye, northern pike)
- Known to provide components of fish habitat for which there is a moderate degree of species' dependence
- Known to contain habitats or fish that have a limited distribution
- Moderate habitat resiliency

LPS streams or ponds are those sites that do not meet the criteria for an HPS or MPS stream or pond.

There are over 1,700 lakes with a total surface area of approximately 500,000 hectares within the boundaries of Kenora District. There are over 200,000 hectares of water in the Whiskey Jack Forest. Lake of the Woods and three major river systems, the English River, Wabigoon River and Winnipeg River systems, which encompass 50% of the total water area of Kenora District.

The major sport and commercial species sought by anglers, tourist industry, commercial and subsistence fishers are: yellow pickerel (walleye), sauger, northern pike, muskellunge, black crappie, smallmouth bass, largemouth bass, yellow perch, lake trout, lake whitefish, and lake sturgeon. In addition to the major commercial and sport species, other species include ling (burbot), bullheads, cisco (lake herring), white sucker, and redhorse suckers.

Unregulated forest management activities can have detrimental effects on fisheries resources by degrading, harmfully altering, disrupting or destroying fish habitat. The most common negative impacts occur with improper road water crossings which can remove or alter physical cover critical to fish habitat (spawning, rearing habitats) and/or block the migration of fish. To ensure this does not occur on the Whiskey Jack Forest, harvest block design and water crossings will follow the prescriptions and conditions outlined in this FMP that were developed using the *Stand and Site Guide*. For example, water bodies will be assigned AOC prescriptions based on type of water body (i.e. lake, river or stream), potential sensitivity to forest management activities (i.e. high, moderate or low) and slope of surrounding land. Water crossings will be located away from critical fish habitats and appropriate crossings structures (bridge, culvert etc.) will be used to ensure fish migration.

Kenora District also possesses a number of water bodies inhabited by two locally and provincially significant fish species: muskellunge (57 lakes) and lake trout (119 lakes). Kenora District possesses approximately 15% of the province's muskellunge waters. This species is managed for trophy opportunities and is afforded water quality protection similar to lake trout. Due to the increasing concern with the survival of lake trout, both within the MNR and internationally, and the fact that MNR is the trustee of 20% of the world's lake trout resource, every lake trout lake is important and needs protecting in Ontario (*Kenora District Land Use Guidelines 1983*).

The *Kenora District Fisheries Management Plan* is a background document used in the preparation of this forest management plan, and should be referenced for additional detail on the fisheries resource.

Implications of Fisheries Resources - Fisheries Resources will be considered during area of concern planning for operations adjacent to riparian zones as well as during roads planning. The initial land base available for timber production used for the Strategic SFMM modelling was reduced to not include estimated riparian zones in the calculation of the available harvest area for this 10-year period. The quantity and quality of these fisheries resources are not likely to be affected by forest operations.

2.1.3.2.2 Rare Species

The Natural Heritage Information Centre (NHIC) database was searched to identify rare species, that are known occur on the Whiskey Jack Forest. Rare species are classified as those with rankings of S1, S2 and S3. These classifications are defined as:

S1 (Extremely rare) in Ontario; usually 5 or fewer occurrences in the province or very few remaining individuals;

S2 (Very rare) in Ontario; usually between 5 and 20 occurrences in the province or with many individuals in fewer occurrences; and

S3 (Rare to uncommon) in Ontario; usually between 20 and 100 occurrences in the province; may have fewer occurrences, but with a large number of individuals in some populations; may be susceptible to large-scale disturbances.

Rare species confirmed to exist on the Whiskey Jack Forest at one time, according to NHIC are listed in Table 7. A note on whether they are forest dependent and if so, what protection is afforded them in the FMP is listed. A record in NHIC means that species was observed in a particular area at one time, and many records are more than 20 years old. Additional rare species may be present but are currently unknown in the area.

Implications of Rare Species – When a rare species (on the S1 to S3 species list) is identified in an area of operations, encountered during forest operations, or confirmed during the duration of the plan, the occurrence will be addressed using an appropriate area of concern prescription, or through the creation of a Condition on Regular Operations, developed from the appropriate MNR guide or a prescription will be developed by the planning team where the species is not covered by an MNR guide.

Table 7 List of Rare Species on the Whiskey Jack Forest

Scientific Name	English Name	S-Rank	Plan Protection
Spermophilus franklinii	Franklin's Ground Squirrel	S3	Not forest dependent
Podiceps grisegena	Red-necked Grebe	S3B	Water quality AOC's apply
Limosa fedoa	Marbled Godwit	S3B	Water quality AOC's apply
Xanthocephalus xanthocephalus	Yellow-headed Blackbird	S2B	Not forest dependent
Coenagrion angulatum	Prairie Bluet	SH	Water quality AOC's apply
Aeshna interrupta lineata	Variable (Lineate) Darner	S2	Water quality AOC's apply
Arigomphus comutus	Horned Clubtail	S3	Water quality AOC's apply
Gomphus graslinellus	Pronghorn Clubtail	S3	Water quality AOC's apply
Stylurus notatus	Elusive Clubtail	S2	Water quality AOC's apply
Somatochlora focipata	Forcipate Emerald	S3	Water quality AOC's apply
Sympetrum corruptum	Variegated Meadowhawk	S3	Water quality AOC's apply
Allium cernuum	Nodding Onion	S2	Not forest dependent
Amorpha canescens	Downy Indigobush	S1	Not forest dependent
Anemone patens	Prairie Crocus	S1	Not forest dependent
Artemisia dracunculus	Dragon Wormwood	S1	Not forest dependent
Artemisia frigida	Prairie Sagebush	S3	Not forest dependent
Asclepias ovalifolia	Dwarf Milkweed	S2	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Bouteloua curtipendula	Side-oats Grama	S2	Not forest dependent
Calamovilfa longifolia var. longifolia	Prairie Sand Reed	SX	Not forest dependent
Caltha natans	Floating Marsh Marigold	S2	Water quality AOC's apply
Carex assiniboinensis	Assiniboia Sedge	S2	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Carex conoidea	Field Sedge	S3	Water quality AOC's apply
Carex obtusata	Blunt Sedge	S2	Water quality AOC's apply
Carex saximontana	Rocky Mountain Sedge	S2	Not forest dependent
Carex torreyi	Torrey's Sedge	S2	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Chenopodium leptophyllum	Slim-leaved Goosefoot	S1	Not forest dependent
Corispermum americanum	American Bugseed	S1S3	Not forest dependent
Corispermum villosum	Hairy Bugseed	S1S3	Not forest dependent
Cuscuta cephalanthi	Bottonbush Dodder	S2	Water quality AOC's apply
Cyperus schweinitzii	Schweinitz's Flatsedge	S3	Not forest dependent
Cypripedium arietinum	Ram's-head Lady's-slipper	S3	Water quality and woodland pool AOC's apply
Cystopteris laurentiana	Laurentian Bladder Fern	S3	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Dalea candida	White Prairie Clover	SX	Not forest dependent
Dalea purpurea	Purple Prairie Clover	S1	Not forest dependent
Dichanthelium leibergii	Leiberg's Panic Grass	S2	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Dichanthelium perlongum	Long-stalked Panic Grass	S2	Not forest dependent
Elatine rubella	Long-stemmed Waterwort	SH	Water quality AOC's apply
Eurybia schreberi	Schreber's Wood Aster	S2S3	Not forest dependent
Festuca hallii	Plains Rough Fescue	S1	Not forest dependent
Galium brevipes	Limestone Swamp Bedstraw	S2S3	Not forest dependent
Glycyrrhiza lepidota	Wild Licorice	S3	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Hesperostipa comata	Needle and Thread Grass	S1	Not forest dependent
Heuchera americana	American Alumroot	S2	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Hudsonia tomentosa	Woolly Beach-heath	S3	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Juncus vaseyi	Vasey's Rush	S3	Not forest dependent
Lechea stricta	Strict Pinweed	S1	Not forest dependent
Lithospermum canescens	Hoary Puccoon	S3	Not forest dependent
Micranthes pensylvanica	Eastern Swamp Saxifrage	S1	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
hispidissimum	Soft-hairy False Gromwell	S2	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Opuntia fragilis	Brittle Prickly Pear	S3	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Pascopyrum smithii	Western Wheat Grass	S2	Not forest dependent
Quercus ellipsoidalis	Northern Pin Oak	S3	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Schoenoplectus heterochaetus	Slender Bulrush	S3	Not forest dependent - Water quality AOC's apply
missouriensis	Leonard's Small Skullcap	S3	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Senecio eremophilus	Desert Ragwort	S2	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Solidago missouriensis	Missouri Goldenrod	S2	Not forest dependent
longipetiolata	Gray-stemmed Goldenrod	S1S2	Not forest dependent
Sporobolus heterolepsis	Prairie Dropseed	S3	Not forest dependent
pansum	Prairie White Heath Aster	S2	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Viola novae-angliae	New England Violet	S3	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Woodsia scopulina	Mountain Woodsia	S3	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.
Rhizomnium gracile	A Moss	S1	When a specific location is identified that may be impacted by forest operations, an AOC prescription will be deveopled with MNR staff.

2.1.3.3 Natural Resource Features, Land Uses and Values

This section of the plan text identifies the information portrayed on the values maps (Section 2.1.3.3.1), and how it was used in the preparation of the forest management plan. The text also includes a list of sources of the information on the values map(s) or otherwise available in the values database and identification of those subjects for which data is recognized as being incomplete or missing.

The management implications of natural resource features, land uses and values, on the development of the forest management plan is included in Sections 2.1.3.3.2 through 2.1.3.3.9.

Land use policy areas that are documented in the Crown Land Use Policy Atlas (CLUPA) are referenced in Section 2.1.3.3.5 Parks and Protected Areas. The CLUPA also contains fifteen general use areas in addition to the parks and protected areas. While there are no provincial-level policy restrictions to forest management in the general use areas, it should be recognized that there are some general use areas with local-level policy restrictions. Of the 15 general use areas in the Whiskey Jack Forest, 10 (67%) contain qualifying land use direction that denotes that forest operations will recognize the importance of tourism and recreational use in the area, and will be conducted so as to have minimal impact on such. Four of the other general use areas identify the importance of recreation and tourism in the Land Use Intent for the area, but do not contain specific direction related to commercial timber harvest.

Other uncommon or notable natural resource features (e.g., significant old growth stands, large wetland complexes) which occur on the management unit are also to be discussed in this section however there are no other uncommon or notable natural resource features on the Whiskey Jack Forest.

2.1.3.3.1 Values Information and Maps

Values are features, benefits, or conditions of the forest that are linked to a geographic area, that are of interest from various points of view, and that must be considered in forest management planning. The values maps are intended to be used primarily as background information for planning, and will also be used for display purposes and to solicit additional information about natural resource features, land uses and values. Any person or party can provide values information at any time. Information about values normally comes from the MNR or other government staff; SFL holders, other forest resource licence holders and their operators; non-government organizations, third parties, other resource users, or the public; and Aboriginal communities. Values Maps are included in the supplementary documentation of the plan (see FMP Maps – Values Maps).

The public consultation process described in the *Forest Management Planning Manual* (FMPM, MNR, 2009) supports the collection and provision of information about values at any time during the development and implementation of a forest management plan.

Values can be classified into two groups based on the requirements to provide information for forest management planning: timber values and non-timber values. Timber values include such features as growth and yield plots, research plots, and seed orchards. The FRI is not considered as a timber value for purposes of prescribing requirements for values information.

Non-timber values include such features as cultural heritage sites, Aboriginal values, and critical wildlife and fisheries habitat areas, such as mineral licks, raptor nests, or spawning areas. Non-timber values also include various uses such as wild rice production areas, recreational areas, trails, Aboriginal use areas, and traditional use areas.

Values maps provide a summary of the geographic location(s) of *known* natural resource features, land uses and values which must be considered in forest management planning and about which further inventory information is available. A value is considered to be a *known* value when there is sufficient information to describe its geographic location and its basic features. Known values must be considered in forest management planning. The MNR shall determine if a value can be treated as a known value based on the available information and in consideration of standards described in the *Forest Information Manual* (FIM, MNR, 2009).

MNR values information is stored in the *Natural Resources Values Information System* (NRVIS). The *Natural Resources and Values Information System* is a Geographic information System (GIS) based system for managing the storage of the Ontario Ministry of Natural Resources' (MNR) digital land related information in a standardized manner. It provides the ability to store, maintain and access over 600 different geographic feature types.

Information about certain values such as, the location and description of Aboriginal values, cultural heritage sites, sites of Species at Risk, rare vascular plants, fish spawning areas, etc. may be considered as “sensitive information” that, if released or portrayed on maps may pose a threat to the existence, integrity, or health of those values. Sensitive information about values shall not be made available or accessible to the public. Where the availability of information could be considered as potentially detrimental to the existence of a value, the MNR shall determine whether or how the value can be depicted on a values map.

Values Maps - For each forest management plan, MNR produces a series of values maps. The *Forest Information Manual* (FIM, MNR, 2009) and the FMPM require the production of a series of maps depicting specific values on the Whiskey Jack Forest that are used for forest management planning purposes. This series of maps is identified as follows;

- 4.1a Natural Resources Features Values Map – Wildlife, Areas of Natural and Scientific Interest (ANSI) and Forestry Values;
- 4.1b Natural Resources Features Values Map – Fisheries and Wetlands;
- 4.2 Resource Uses Values Map;
- 4.3 Land Values Map;
- 4.4 Bear Management Areas Values Map;
- 4.5 Trapline Areas Values Map;
- 4.6 Resource-Based Tourism Values Map; and
- 4.7 Cultural Heritage Values Map.

(Note: the Cultural Heritage map identifies Archaeological Potential Areas (APAs) which have already been portrayed on Areas of Operations maps in the FMP supplementary documentation. Therefore a separate Cultural Heritage Values map was not prepared for this FMP.)

Known values and land uses on the Whiskey Jack Forest are documented on the Values Maps. Technical requirements and information to be portrayed on values maps are detailed in the *Forest Information Base and Values Technical Specifications*. More detailed information on

certain land uses is included in the Social and Economic Description in Supplementary Documentation D.

Sources of Values Information - The principle source of values information for display was the Natural Resources Values Information System (NRVIS) compiled and maintained by MNR – Kenora District. NRVIS values data was originally obtained from a number of sources, including:

- fisheries habitat and population surveys
- protected area regulation plans
- protected areas inventories
- protected area management direction documents
- wildlife habitat inventories
- MNR staff, forest industry and public reporting
- Aboriginal reports and/or cultural heritage values studies
- forest compliance reports
- water crossing and road corridor inspections
- Ministry of Northern Development, Mines and Forestry (MNDMF)
- Ministry of Tourism and Recreation (MTR)
- Ontario Base Map (OBM) features
- Land Use Permit System (LUPS), control maps and survey plans
- Boat cache inventory
- Natural Heritage Information Centre
- Forest Resource Inventory (FRI)

A number of methodologies were used to collect the various data for compilation in NRVIS. Wildlife habitat values were generally provided from public/MNR/industry reports and from standardized inventories conducted by MNR according to the *Selected Wildlife and Habitat Features: Inventory Manual (MNR, 1998)*. Specific survey designs included the identification and/or ranking of:

- Moose aquatic feeding areas and mineral licks,
- Identification of early and late winter moose habitat,
- Bald eagle, or other stick nests, and
- Locating other provincially and locally featured species habitats.

Most of these surveys are conducted using rotary-wing aircraft, and occasionally fixed-wing aircraft.

Fisheries habitat values (spawning, nursery and migration areas) were often obtained in conjunction with aerial surveys of wildlife habitat; field inspections or aerial observations of proposed road corridors and water crossings; Aquatic Habitat Inventories (AHI) or lake surveys; and public reports. Fish species occurrence and thermal regime were largely determined from the AHI database or from more detailed fish population surveys on specific water bodies.

There are no identified provincially significant wetlands on the Whiskey Jack Forest.

Locations of significant communities of flora and fauna, in particular rare vascular plants, were obtained through field inspections by the Natural Heritage Information Centre (NHIC) and District MNR staff and from site specific investigations by contractors or consultants.

The locations of recreational, commercial and resource user boat caches were derived from formal MNR boat cache authorization agreements and control maps. Additional infrastructure, such as commercial outpost camps, land use permits (LUPs) and resource user (trapper, baitfish) cabins were identified in LUPs, lands control maps and actual survey plans on file at the MNR District office.

Missing or Incomplete Data - In general, the lands and waters within the Whiskey Jack Forest have been surveyed over the past several years and during previous FMP planning processes. Values information is updated continuously as new values are identified, or it is confirmed that previously identified values no longer exist (e.g. stick nests). Values information must be considered the "best available" at the time of plan preparation however values information is continually being updated. Timing of the area surveyed to update local values is often affected by the available MNR funding for surveys.

MNR data collection efforts have followed standard methodologies as outlined in the *Selected Wildlife and Habitat Features: Inventory Manual (MNR, 1998)*. District staff, Natural Heritage Information Centre (NHIC), environmental consultants and the general public have also obtained data on Species at Risk and rare species.

FMP Management Implications - Where a known value may be affected by forest management activities, the *Forest Management Planning Manual (2009)* requires that a defined geographic area adjacent to the feature be established. The defined geographic area is called an "area of concern" (AOC). An operational prescription is developed for each AOC or group of AOCs to prevent, minimize or mitigate adverse effects of forest management operations on the value. Operational prescriptions for AOCs may be reserves (e.g. prohibition of operations), modified operations (e.g. specific conditions or restrictions on operations) or regular operations (i.e., in accordance with the silvicultural ground rules), individually or in combination. Modified operations may be regular operations with conditions (e.g. timing, equipment), or unique prescriptions that are developed to protect or manage specific values or land uses. Areas estimated to be impacted by reserves were incorporated in the strategic modelling for the Long-term Management Direction (LTMD) in order to calculate the most realistic available harvest area for this plan and to assess long-term objective achievement.

Operational prescriptions were developed for an individual AOC or groups of AOCs using the forest management guides identified by MNR as applicable to the forest (e.g. the *Stand and Site Guide*). An operational prescription may also be proposed from another planning exercise for inclusion in the FMP (e.g., Resource Stewardship Agreements (RSAs)). In some situations, the planning team will develop an operational prescription (e.g., prescription for operations adjacent to private land). Additional information regarding the development of operational prescriptions for AOCs associated with known values on the Whiskey Jack Forest is provided in Section 4.2 Prescriptions for Operations.

Where a new value is identified during implementation of the plan, the AOC prescription associated with the geographic area of the value (Table FMP-10) will be implemented or conditions on regular operations (Section 4.2.2.2) for the value will be implemented. Conditions on regular operations (CROs)(prescriptions for harvest, renewal, and tending) have been developed through application of MNR's forest management guides relating to conserving biodiversity at the stand and site scales (*Stand and Site Guide*).

2.1.3.3.2 Old Forest Red Pine and White Pine

The Whiskey Jack Forest includes the transition forest zones between the Boreal Forest to the north and the Great Lakes-St. Lawrence Forest in the south. Conditions are favourable in this transition zone for red pine and white pine. The red pine and white pine forest unit area (PRW) represents less than 1% of the productive forest area. While this area is not large, it does present opportunities for the management of these tree species for sawlogs as well as for the old forest characteristics required by certain cavity nesting species such as the pileated woodpecker. Mature pines are also the favoured nesting habitat of the bald eagle.

The *Old Growth Policy for Ontario's Crown Forests (MNR, 2003)* guides the maintenance or restoration of old forests on the Whiskey Jack Forest. Old forest red pine and white pine forest communities are portrayed on Map 4.1b Natural Resource Features Values – Wildlife and Forestry. There are 309 hectares of old forest red pine and white pine at the start of this plan (all PRW forest unit area greater than 140 years old).

Old forest in all forest units were incorporated into the Management Objectives, associated indicators, desirable levels, and the strategic modelling based on definitions and criteria outlined in the *Old Growth Policy for Ontario's Crown Forests* (MNR 2003), *Old Growth Forest Definitions for Ontario* (MNR 2003), and the *Old Growth FMP Interpretation Note No. 1* (MNR, 2003). Based on results from the strategic modelling, old forest communities on the Whiskey Jack Forest will continue to be represented across the landscape at levels within or exceeding the desirable levels endorsed in the Long-Term Management Direction.

Not all old forest red pine and white pine forest communities will be managed for old forest condition values. Old forest red pine and white pine stands may be planned for harvest if their harvest is in accordance with the Long-term Management Direction (Section 3.0), achievement of management objectives and harvest eligibility criteria (Section 3.6.2).

2.1.3.3.3 Resource-based Tourism Areas

The Resource-Based Tourism Values Map (Map 4.6) was produced locally during the forest management planning process. The map only displays the properties, facilities, or the land-based amenities of tourism operators who are Resource-based Tourism Establishments. The information displayed on the values map includes:

- Recognized RBT Main Base Lodges (remote, semi-remote, drive-in);
- Recognized RBT Outpost Camps (remote, semi-remote, drive-in);
- Recreation Access Points; and
- Boat Caches (commercial)
- Recreation Trails

Depending on the resource-based tourism values, the maps may include camping sites, hunting stations, swimming beaches, fish and wildlife viewing sites, scenic lookouts, identification of navigable waterways, picnic sites and RBT access routes. The information portrayed on the Resource-based Tourism Map was taken into consideration during Resource Stewardship Agreement negotiations during plan development.

There are approximately 362 tourist operators in Kenora District, of which 219 are associated with the Whiskey Jack Forest (identified on Values Map 4.6 Resource-Based Tourism Values Map). The tourism industry has been an important component in the Kenora area for a long time. Lodges and cottages were in operation by 1905. At that time the activities were based on hunting, fishing and canoeing opportunities. The Whiskey Jack Forest has attracted recreation-based tourism since the late 19th Century due to its variety of natural values. The area continues to be a desired recreational destination for canoeing, boating, fishing, hunting, hiking, snowmobiling, camping and cottaging.

MNR was committed to maintaining the viability of the tourism industry by protecting tourism values in the forest management planning process through the application of the *Management Guidelines for Forestry and Resource-Based Tourism* .

The *Tourism and Forest Industry Memorandum of Understanding (MOU)* is an agreement between the government, the tourism industry and the forest industry on the development of Resource Stewardship Agreements (RSAs) and related matters. A Resource Stewardship Agreement is an agreement negotiated between two legal entities: a Resource-Based Tourism Establishment (RBTE) operator; and the Sustainable Forest Licensee. Essentially, the parties agree, through negotiations of an RSA, to apply forest management operational prescriptions to protect specific tourism values and roads planning and/or related conditions on new and existing roads that affect forest management that will be approved by the MNR and included in the FMP under the Crown Forest Sustainability Act. The RSA may also include other provisions the parties agree to that are not part of the FMP.

Since the Whiskey Jack Forest is managed by the Ministry of Natural Resources, not an SFL company, there are no Resource Stewardship Agreements for this forest. However tourism values and natural resource features are considered during forest management planning through the application of the Area of Concern process. Any forest management prescriptions developed by MNR with resource-based tourist operators are carried forward in this FMP and applied to any relevant planned operations in this forest management plan. These prescriptions are included in Table FMP-10 Operational Prescriptions for Areas of Concern or Table FMP-19 Road Crossings, Landings and Aggregate Pits in Areas of Concern. Tourist operators are contacted several times throughout development of the forest management plan to ensure any known concerns are discussed and if warranted, operations planned in the FMP are adjusted to mitigate the concern and adequately protect identified values.

2.1.3.3.4 Mineral, Aggregate and Quarry Pits

Historically, mining and mineral exploration have been an important activity in this management unit and historically gold, silver and copper were the predominant commodities mined. Currently there are four granite producers in operation which have been and continue to be a significant contributor to the economy of the area. The value of total granite production was not available at the time of writing. Historical metal production occurred within the management unit between 1893 and 1951 and totaled 68,513 ounces gold, 14,762 ounces silver and 1.89 million pounds of copper valued at $49.73 million CDN at current metal prices.

In addition to historical and current mineral production there are significant concentrations of gold, nickel, copper, silver and uranium contained within documented mineral deposits throughout the management unit. The total estimated value of metals contained within these deposits at current commodity prices is in excess of $158 million CDN.

There are an estimated 1,605 active mining claim units recorded throughout this management unit, as indicated on MNDM's CLAIMaps website (MNDM, 2006). These claims represent an investment in the management unit of approximately $400,000 CDN for claim staking, which directly relates to its mineral potential. In addition there is an estimated dollar expenditure of nearly $650,000 CDN per year related to mineral exploration work required to keep the claims in good standing. Current claim staking targets areas with potential for uranium, rare-metals, zinc and gold. Historically, several areas within the management unit have seen extensive staking and mineral exploration.

There are 12 aggregate sites located in the Whiskey Jack Forest, all of which are operated by MNR.

The FMP Values Maps provide detail for active aggregate permit areas, unrehabilitated aggregate sites, land use permit locations and Crown lease locations.

There are few implications of mineral, aggregate and quarry pits on forest management activities. Annually, mining claim holders must be notified of forest management activities scheduled on their respective mining claims. Harvest and silviculture activities must not damage or destroy claim posts. Obtaining good sources of aggregate on Crown land is a consideration during roads planning and identification of operational road boundaries. Lack of suitable aggregate sources for forest access roads can result in long aggregate haul distances for road building, or the increase use of winter access for timber extraction.

2.1.3.3.5 Parks and Protected Areas

The purpose of Ontario's Provincial Parks and protected areas is to permanently protect a system of provincial parks and conservation reserves that includes ecosystems that are representative of all of Ontario's natural regions, protects provincially significant elements of Ontario's natural and cultural heritage, maintains biodiversity and provides opportunities for compatible, ecologically sustainable recreation. Ontario's provincial parks and conservation reserves are dedicated to the people of Ontario and visitors for their inspiration, education, health, recreational enjoyment and other benefits with the intention that these areas shall be managed to maintain their ecological integrity and to leave them unimpaired for future generations.

The following are important benefits and help to demonstrate how provincial parks support our quality of life:

- Protection and contribution to ecological functions (air quality, water quality, flood control, soil stabilization),
- Biodiversity contributions (genetic material, protection of species at risk),
- Protection of resource integrity (some of the last green spaces left in the province),
- Health effects from use of parks (mental, physical, spiritual benefits),
- Worker productivity (healthy and happy workers tend to be more productive - a visit to a provincial park can contribute),
- Educational benefits (young and old learning about our environment),
- Scientific benefits (research in provincial parks),
- International responsibilities to protect natural settings, features and wildlife,
- Business location decisions (quality of life/business) and community cohesion.

There are several different classifications of parks and protected areas. Each class and individual area has different objectives and permit different activities within the defined areas. There are six classifications of provincial parks; 1)Wilderness Class Parks, 2) Nature Reserve Class Parks, 3) Cultural Heritage Class Parks, 4) Natural Environment Class Parks, 5) Waterway Class Parks, and 6) Recreational Class Parks. In addition to parks, there are conservation reserves that not only provide protection to representative ecosystems, biodiversity and provincially significant elements of Ontario's natural and cultural heritage, but also allow opportunities for ecologically sustainable land uses, including traditional outdoor heritage activities and associated economic benefits.

There are seven provincial parks or protected areas adjacent to or surrounded by the Whiskey Jack Forest. Parks in the management unit include the West English River, Eagle-Dogtooth, Tide Lake and the Maynard Lake Parks. The Pakwash Provincial Park is located adjacent to the northeast corner of the unit, Rushing River Provincial Park is located in the southern portion of the forest, and Woodland Caribou Provincial Park (and addition) is located in the northwest portion of the unit. All of these parks have either an Interim Management Statement or a park management plan that provides direction.

Scattered throughout or adjacent to the Whiskey Jack Forest there are nine Conservation Reserves including Campfire River, Clay Lake, Dryberry Lake, Lac Seul Islands, Lake of the Woods CR, Scenic Lake, Scotty Lake, Solitary Lake and Twilight Lake Conservation Reserves. Additional social and economic information on parks and protected areas is included Section 2.2.3.2 and in Supplementary Documentation D - Social and Economic Information.

PROVINCIAL PARKS

A description of each provincial park follows. The number associated with each area corresponds to the Crown Land Use Policy Atlas (CLUPA) area number

West English River (P2345), a non-operating waterway class park of 22,923 hectares, was regulated in 2003. The area includes that portion of the English River from Barnston Lake to Tide Lake. The waterway contains old growth red and white pine at the northern extent of its range, wilderness environments and tourism attributes, and is an historic travel corridor. Two provincial nature reserves, Maynard Lake and Tide Lake, abut the park. Motor boating, canoeing, sport fishing, hunting and camping are popular activities, although the actual use is unknown.

Eagle-Dogtooth (P2363), a non-operating waterway class park of 41,128 hectares, was regulated in 2003. It provides a waterway linkage between Eagle Lake and nearby protected areas (e.g., Rushing River, Winnange). It is an important recreational waterway. The site contains regionally significant moraines, wetlands, pine forest ecosystems, eagles, waterfowl and is an important recreation and tourism area. Motor boating, canoeing, sport fishing, hunting and camping are popular activities, although the actual use is unknown.

Tide Lake (P2614), a non-operating nature reserve class park of 51 hectares, was regulated in 1997. It consists of the peninsula between Ball and Tide lakes. The park provides representation/protection of an atypical old growth white pine stand (age class + 160 years) at the northern limit of the species' range. It is surrounded by West English River Provincial Park on three sides. Camping, day-use, hunting and most other recreational activities are prohibited because of the classification of the park. The actual amount of use is unknown.

Maynard Lake (P2698), a non-operating nature reserve class park of 25 hectares, was regulated in 1997. It consists of a peninsula with deep soils on the east shore of Maynard Lake. It provides representation/protection of an atypical old growth white pine stand (age class + 160 years) at the northern limit of the species range. It is surrounded by West English River Provincial Park on three sides. Camping, day-use, hunting and most other recreational activities are prohibited because of the classification of the park. The actual amount of use is unknown.

Pakwash (P2528) is a staffed natural environment class provincial park of 3,993 hectares. The park was established in 1967 and was regulated in 1989 as a natural environment class Provincial Park. The park provides representation/protection of Site District 4S-2, specifically the Hartman Moraine. Pakwash provides opportunities for car-camping and day-use. The park is operated by Friends of Pakwash.

Rushing River (P2615), a staffed recreation class provincial park of 340 hectares was established in September 1958. Natural features include jack pine uplands, wetlands and a lush river valley. The park has a popular campground, day-use area and interpretive facilities/trails.

Woodland Caribou (P2370e), an operating wilderness class park of 450,000 hectares, was regulated in 1983. It protects representative earth and life science features of Site District 4S-1, such as the Eagle-Finlayson Moraine, prairie-boreal vegetation and habitat for Woodland Caribou, a threatened species.

Woodland Caribou recommended park additions (P2370) were established during Ontario's Living Legacy – Land Use Strategy. There are four additions to the existing park (Douglas Lake, Peisk Lake, Anchor Lake and Sydney Lake areas) although only Sydney Lake is within the FMU. The Sydney Lake addition includes a significant white elm site. A primary forest access road crossing between Rowdy and Sydney Lakes will be permitted as determined through previous forest management planning processes. This addition is in the most popular backcountry canoeing area of the park.

CONSERVATION RESERVES

A description of each conservation reserve follows. The number associated with each area corresponds to the Crown Land Use Policy Atlas (CLUPA) area number.

Campfire River Conservation Reserve (C2368), a protected area of 4,180 hectares is located approximately 73 kilometers north of the City of Kenora, immediately west of South Pakwash Road. The reserve contains extensive representation of wetland vegetation, including deep and shallow marshes, graminoid marshes, wet meadows, low shrub fens, and thicket swamps. Coniferous, deciduous and mixed forests are all represented within the reserve. The reserve is used for fishing, hunting and trapping. The traditional harvesting of wild rice is practiced in Paintpot Lake. Winter activities include ice fishing and snowmobiling.

Clay Lake Conservation Reserve (C2594), a protected area of 89 hectares. The CR contains an old growth red and white pine community at northern fringe of its range; a core area of 27 hectares of 70% red pine and white pine aged at 121+ years; known to contain very large trees; other stands contain up to 40% white pine as well as some scattered red pine. The reserve is made up of lacustrine deposits.

Dryberry Lake Conservation Reserve (C2357), a protected area of 21,850 hectares of land and water, with Dryberry Lake itself forming half of this total. It is located approximately 25 kilometres southeast of the City of Kenora and 20 kilometres north of Sioux Narrows. This reserve incorporates Dryberry Lake, Point Lake and several smaller unnamed lakes located east of Northwest Bay and west of Point Lake. This site contains representative landform and vegetation types including mixed conifer, sparse forest and burn on weakly and moderately broken bedrock, and vegetated bedrock. There are also several red and white pine stands in excess of 75 years old. Dryberry Lake provides a world class lake trout, smallmouth bass, northern pike, and muskellunge fishery. There are a number of identified bald eagle nests within the boundary. There are also several identified archeological values within the area.

Lac Seul Islands Conservation Reserve (C2317), a protected area of 14,723 hectares. The vast waterway system of Lac Seul extends from Sioux Lookout westward to Ear Falls and abuts the communities of Whitefish Bay, Keesic Bay and Frenchman's Head of the Lac Seul First Nation Reserve. The conservation reserve includes over 1000 islands found within the Lac Seul waterway system. There are several established access points found within the Sioux Lookout area that provides easy access to Lac Seul. This conservation reserve contains sand dune complexes, historical, cultural and archaeological sites and offers excellent tourism, recreational and educational experiences. The forest cover of the islands primarily consists of balsam fir, black spruce, white birch and white spruce. The area includes a significant old growth red and white pine stand located on Eagle Island.

Lake of the Woods Waters Conservation Reserve (C2501) is a protected area of 1,984 hectares. The conservation reserve is water-based, consisting of open waters and wetlands. It is located 15 kilometers northwest of the Town of Rainy River. The area provides continuity of protection for the water between the mainland and the offshore barrier-islands of the Sable Islands Provincial Nature Reserve. The reserve contains significant wetland communities and shallow open water lagoon areas that provide productive habitat for an array of fish and wildlife species. The conservation reserve represents part of a very large sand barrier island – lagoon complex, a unique feature to the Canadian Shield.

Scenic Lake Conservation Reserve (C2365), a protected area of 1,890 hectares is located approximately 53 kilometres north of the City of Kenora. This reserve incorporates Scenic Lake, all islands within the lake, Moose Lake, and a 200 metre buffer zone around the lake shores. The reserve contains representation of several forest types, including aspen, white birch, balsam fir, white and black spruce, and jack pine. Fishing opportunities exist for northern pike and smallmouth bass. There are also boating opportunities, as well as snowmobiling, and hunting opportunities for moose, deer, black bear, small game, and waterfowl.

Scotty Lake Conservation Reserve (C2361) is a protected area of 775 hectares. The original Scotty Lake Conservation Reserve (encompassing 53 hectares) had been identified as an area containing old growth White Pine on moderately broken ground moraine and was regulated on January 7, 1995. Resulting from *Ontario's Living Legacy* (*OLL*) natural heritage program, an additional 722 hectares adjacent to the original reserve was selected for protection due to the representative landform and vegetation types (primarily mixed and sparse forests on weakly broken ground moraine and burn) existing within the area. The Scotty Lake Conservation Reserve Addition (C2361) is the first expansion to a previously established conservation reserve in the Province of Ontario. Scotty Lake Conservation Reserve is located approximately 69 kilometres north of the City of Kenora and includes two unnamed headwater lakes located

southeast of Little Mountain Lake. Aboriginal interests in the area are primarily those of Grassy Narrows First Nation.

Solitary Lake Conservation Reserve (C2362), a protected area of 257 hectares is located approximately 85 kilometres north of the City of Kenora. The reserve incorporates the area adjacent to the northeastern shoreline of Solitary Lake and the peninsula on the west shore of the lake. It also includes the small island between these two areas, as well as the large island found in the southern basin of Solitary Lake. Mixed stands of aspen, birch, spruce, fir and some jack pine dominate the reserve. The majority of wetland vegetation is comprised of graminoid meadows and fens, low shrub bogs, shrub-rich treed bogs, and red alder thicket swamps.

Twilight Lake Conservation Reserve (C2430), a protected area of 396 hectares and is located approximately 85 kilometres northeast of the City of Kenora. The reserve primarily incorporates: Twilight Lake; a 200 metre buffer along the north and west shores of the lake; an area extending from 200 metres southeast of the creek intersecting the south end of Twilight Lake, to Evening Lake in the northeast; and a portion of Evening Lake's west shoreline, which borders the reserve in the northeast. Aboriginal interests in the area are primarily those of Grassy Narrows and Wabauskang First Nations. The reserve contains representation of several forest types: Aspen hardwoods, mixed stands of White Birch, Aspen/Spruce mixedwoods, and Jack Pine/Spruce stands on shallow soils on bedrock. Also existing here are Red Pine (along the western extremity of the reserve), a small stand of Black Ash (in the southeast portion), and wetland communities

Implications of Parks and Protected Areas –
During forest management planning, the area within provincial parks and conservation reserves, within the boundaries of the Whiskey Jack Forest are used in the contribution to wildlife habitat and for the establishment of core habitat areas for marten habitat or large landscape patches. Similarly, these areas contribute to meeting "old forest" targets and preferred wildlife habitat levels, but are not included in the area of the forest available for harvest operations.

Conducting forest management operations adjacent to parks and protected areas requires consideration of the values and potential access, tourism and recreation concerns. Parks staff (parks) and district staff (conservation reserves) will be consulted regarding boundary layout prior to commencement of adjacent harvest operations. During plan development, parks managers are consulted and can influence FMP development as it relates to access, noise and aesthetics in proximity to parks and protected areas.

2.1.3.3.6 Crown Land Recreation and Cottaging

In addition to the commercial activity described above, there is significant social and economic benefit derived from Crown land recreation and cottaging on the Whiskey Jack Forest. The various values or activities are described below with discussion of the implications of the activities or value on the development of the FMP.

The Whiskey Jack Forest has attracted recreation-based tourism since the late 19th Century due to its variety of natural values. The area continues to be a desired recreational destination for canoeing, boating, fishing, hunting, hiking, snowmobiling, camping and cottaging for the following reasons:

- There is a high concentration of interconnected lakes, rivers and portages.
- The rugged topography including cliffs, low wetlands, viewpoints and island-dotted lakes provide excellent scenery for summer and winter travelers.

- The area is traversed by numerous trails providing winter recreation opportunities by snowmobile, cross-country ski, or dog sled. In the summer, canoeist and hikers can access remote locations.
- There are numerous cultural heritage values including very old native heritage sites and more recent logging and mining heritage sites.

The large variety of lakes and rivers, some of which are remote while others are easily road accessible, provide a wide range of angling opportunities. Whiskey Jack Forest has excellent natural lake trout lakes and walleye fishing is also popular in hundreds of small lakes along with larger lakes such as Lake of the Woods.

The Whiskey Jack Forest has portions of Fisheries Management Zones (FMZs) 4 and 5. FMZs reflect certain ecological factors and angler use patterns, such as climate zones, watersheds, fishing pressure and road access. In general FMZ 4 has less access with less fishing pressure and being more northerly, its waters are somewhat less productive with fisheries that are not as diverse as those of FMZ 5.

In addition to the FMZ's, Whiskey Jack Forest includes the Specially Designated Waters (SDWs) Lake of the Woods and Winnipeg River. SDWs are managed and monitored separately to reflect their unique and important fisheries.

The Whiskey Jack Forest is comprised of five Wildlife Management Units (WMU); zones 2, 3, 5, 6, 7B and 8. This represents a significant portion of these wildlife units that are utilized extensively for hunting and fishing. Hunting continues to be an important recreational activity in the Whiskey Jack Forest area. Big game is the primary activity although ruffed grouse, black bear, migratory waterfowl and snowshoe hare are also hunted. Hunting is either carried out adjacent to access roads created by the forest industry, by use of water based transportation to remote roadless areas, or by fly-in outfitters to backcountry locations. A large proportion of big game hunters are non-resident hunters who contribute to the local economy depending on how many local services they utilize. More than 90% of the bear hunters are nonresidents. There are a wide variety of trails in the Whiskey Jack Forest that are used (depending on the nature of the activity and the Land Use designation) by hikers, cross country skiers, dog sledders, snowmobilers, and ATV operators. In addition to prepared trails, there are opportunities to travel on ungroomed areas such as snowshoeing along lakes and portages or snowmobiling along ungroomed lakes or unploughed roads.

Rushing River Provincial Park, and a few other private campgrounds along Highway 17 and Highway 71 corridor, provides camping opportunities. Approximately 65,000 people visit or use the many canoe routes around the park. Canoe trippers and anglers that are flown into backcountry sites use most of the remote sites. Many cottages were established after the railroad arrived in 1888 and made access to the Whiskey Jack Forest area easier. There are abundant cottages on Lake of the Woods are primarily located on the many islands on the lake, since shoreline development is limited. The building of what is now known as Hwy 17 made it easier to access additional lakes in the area.

Implications - Forest management within the Whiskey Jack Forest is planned with consideration for the effects of forest operations on various natural and man-made values associated with Crown land recreation and cottaging. Examples of this consideration include:

- Natural features, such as water bodies, canoe routes and portages, bird nests or colonies, and furbearer dens, are considered through the Area of Concern planning process (Table FMP-10 Prescriptions for Areas of Concern).
- Certain man-made features are also specifically considered through the Area of Concern planning process (e.g. growth and yield plots, railways, cultural heritage values, highway corridors, natural gas transmission pipelines).
- Trails - Where possible, trails are left clear of debris from harvesting operations and in many cases, previous forest access roads are used as snowmobile trails. Access to snowmobile trails is typically addressed during FMP development through communication and agreements between the snowmobile club and the SFL to address club use of SFL roads.
- Access points are specifically designed for public access to lakes or to support camping and other activities. There are also numerous access points, camp sites, and recreational areas that have been informally developed and not all of these are known and therefore are not identified as values. On the Whiskey Jack Forest, there are 73 designated MNR public access points, 147 designated camping sites, and 23 identified picnic area. These areas are considered during operational planning for harvest areas and road development. Roads to access points are retained to allow continued public access. Harvest operations near camp sites and recreational areas may be modified to limit operations to the off season. Camp sites generally are located in areas of concern adjacent to water bodies.
- On the Whiskey Jack Forest, there are an extensive number of MNR issued boat caches, which allow the holder the right to freely cache a boat on Crown Land adjacent to a designated water body. On the Whiskey Jack Forest, there are 418 commercial boat caches, 223 private boat caches and 99 resource harvest boat caches. All boat caches are identified as values and normally fall within Area of Concerns of a shoreline reserve therefore additional modifications on planned operations are not usually required.

2.1.3.3.7 Commercial Fur Trapping

Trapping provides seasonal employment for 89 registered traplines in the Whiskey Jack Forest. Additionally, there are approximately 17 First Nation Community traplines located with the Whiskey Jack Forest. The major fur bearing animals that are of economic importance are beaver, fox, muskrat, lynx, otter, mink, fisher, and marten. Registered trap lines cover the entire Whiskey Jack Forest.

All primary trappers are on the FMP mailing list and have had the opportunity to review and provide comments on proposed forest operations in the Whiskey Jack Forest. Individual trap line boundaries, as well as known trapline cabins and trails are considered values and mapped. Where identified values are adjacent to or within areas proposed for forest operations, Area of Concern planning may be initiated to mitigate any negative impacts on the value. Typically, AOC prescriptions that may include strategies such as timing restrictions, notification requests and/or road decommissioning may be applied to protect trails and trapline cabins and address additional concerns brought forth by trappers.

All primary trappers on the FMP mailing list are kept informed of changes to the planned operations on an annual basis through the notification associated with the Annual Work Schedule.

Implications - Wildlife habitat was considered during development of the Long-Term Management Direction for the FMP. Spatial and non-spatial habitat analysis was analyzed for marten to ensure the provision of adequate habitat now and into the future. Harvest eligibility criteria include the consideration for harvest deferrals in marten core habitat areas for up to 60 years.

2.1.3.3.8 Private Land

Patent land comprises a very small portion (less than 1%) of the Whiskey Jack Forest as described in Section 2.1.1.2 Land Ownership and Productivity. In accordance with the *Crown Forest Sustainability Act,* Patent Land is not included in this forest management plan. Patent Land was not included in the strategic modelling for this plan, nor is any forest operations proposed in this FMP on any Patent Land.

Implications - Where patent land is adjacent to areas proposed for forest operations, Area of Concern PL01 was applied, unless a prior agreement with the land owner was been reached. Road building, road-use and forest operations adjacent to patent land are also planned to ensure no negative impact on these areas.

2.1.3.3.9 Strategic Forest Access

Early logging of the Whiskey Jack Forest began over 100 years ago with the harvest of red and white pine trees on the shores of Lake of the Woods. Pulp wood operations started in the 1920s with the construction of the Kenora paper mill. Within the next four decades, pulpwood and saw log harvest continued, moving north towards the Jones Road area. The northern area of the Whiskey Jack Forest was accessed only in the early 1970s and the majority of harvesting operations were centred in this area in the 1980s and 1990s. The advent of salvage operations in the 1990s added an extensive number of roads to an already existing strong road network created during the 1980s. The Whiskey Jack Forest road network was expanded slightly over the past twenty years and has resulted in a well-accessed forest as we enter the 2012 planning period.

There are no areas on the Whiskey Jack Forest designated as roadless. Unless access controls or road decommissioning is identified in this forest management plan (Table FMP-18 Road Construction and Use Management), it is expected that existing roads will remain open for public use during the 10-year period of this plan. Strategic road access is considered in this 2012 FMP through an objective indicator for road density of primary and branch roads with desirable levels set for the caribou zone (decrease road density) and the non-caribou zone which is used extensively for public recreation. Road construction and decommissioning has minimal impacts on the amount of productive forest area (negatively and positively respectively); however it has a greater impact on the accessibility of the future wood supply and the provision of recreational opportunities. Decommissioning will occur when roads are no longer required for future forest access and the MNR or a third party are not interested in maintaining the road infrastructure. (Note: Roads may be decommissioned to enhance caribou habitat regardless of whether a third party is interested in maintaining the road.)

2.2 Social and Economic Description

2.2.1 Overview of Social and Economic Context

Communities that have been impacted by forest management activities on the Whiskey Jack Forest over the last five years include Dryden, Fort Frances, Kenora and Sioux Lookout.

The communities of Kenora, Dryden and Fort Frances have the majority of wood volume from the Whiskey Jack Forest over the past years. Wood deliveries over the last several years have been redirected due to indefinite closures of certain sawmills and the closure of the Abitibi-Bowater paper mill in Kenora. The planned wood supplies from the Whiskey Jack Forest are directed towards: Weyerhaeuser – Kenora LSL mill and Kenora Forest Products (Kenora) (Table FMP-15). Other volumes will be sold on the open market. The volumes delivered over the last several years can be viewed in tabular format in Section 2.2.3.

Aboriginal Communities within or adjacent to the Whiskey Jack Forest whose interests of traditional uses may be affected by forest management activities include:

1. Asubpeeschoseewagong Netum Anishnabek First Nation (Grassy Narrows)
2. Naotkamegwanning First Nation No. 32A (Whitefish Bay)
3. Wabaseemoong Independent Nations (Whitedog)
4. Wabauskang First Nation No.21
5. Ochiichagwe'babigo'inning First Nation (Dalles)
6. Kenora Métis Council

2.2.2 Summary of Demographic Profiles

This section contains a summary of community profiles that receive significant social and economic benefit from the Whiskey Jack Forest. The profiles contain information on populations, labour force, community characteristics and household prosperity indicators. Population information includes gender, age, ethnicity, languages and education levels. Prosperity information reflects household characteristics and income. Community employment and dependency (on the forest industry sector) ratios are included to reflect the state of the labour force.

The main source of information for these profiles is derived from 2006 Statistics Canada census data. First Nations information from census data is often limited due to low return information. Additional information related to First Nation community profiles is derived from Department of Indian Affairs and Northern Development and Grand Council of Treaty 3. The individual community profile datasheets are located in Supplementary Documentation D, PART B.

It should be noted that the available information presented relating to the community dependency on forestry was based on 2006 Statistics Canada information and does not reflect the fact that forest products processing facilities in some of these communities have been closed permanently or shut down indefinitely resulting in spin off effects from the loss of employment.

The following communities are affected by forestry activity occurring on the Whiskey Jack

Forest within the Kenora MNR District. The list includes communities that host forestry facilities; supply labour to the forest industry; and Aboriginal communities. Details for each community are summarized in the following subsections:

2.2.2.1 Dryden
2.2.2.2 Fort Frances
2.2.2.3 Kenora
2.2.2.4 Sioux Lookout
2.2.2.5 Asubpeeschoseewagong Netum Anishnabek First Nation (Grassy Narrows)
2.2.2.6 Naotkamegwanning First Nation (Whitefish Bay First Nation)
2.2.2.7 Wabaseemoong Independent Nations (Whitedog)
2.2.2.8 Wabauskang First Nation No.21
2.2.2.9 Ochiichagwe'babigo'inning First Nation (Dalles)

2.2.2.1 Dryden

The town of Dryden is located on Highway 17, centrally located in the Dryden Forest. With a population of 8,195, Dryden is made up of 3,285 dwellings. The population in Dryden is stable and has increased slightly in the past 10 years. It is predicted that the population will decrease if the forest industry continues to struggle. The 2006 Census may not totally capture the full effect of the closure of the Weyerhaeuser sawmill and definitely does not reflect the impact of the closure of the paper production at the Domtar Pulp Mill. The average annual income in Dryden is $37,246, with a total labour force of 4,290 people. Average household size is 2.4, with an average household income of $72,443. The average value of a home in Dryden is approximately $171,993. Rent in Dryden on average $653 per month which is approximately 22% lower than the provincial average.

Dryden has a 94% employment rate. A significant 35% of the population has moved within the last five years. Only 5% of the population of Dryden was born outside of Canada, having immigrated from Europe and the United States.

Dryden's population is represented by 95% being Canadian born and 10% of the population being Aboriginal. Migration is referred to as how many people have moved into or locally in the community over the last five years. Migration over five years was 36%. The official language is English spoken by 93% of the population (English only) and the remaining 7% speak both English and French. 39% of the population continued post-secondary studies in college, university or trades while 34% did not continue studies after graduating from high school.

The Aboriginal population in Dryden includes 792 people with a labour force 415 of whom 390 are employed as part of the local workforce. The average income for Aboriginal men is $42,528 and $18,574 for women. Approximately 2% of the Aboriginal population in Dryden has limited knowledge of an Aboriginal language while 15% primarily speak an Aboriginal language and use the language at home.

Approximately 17% of the labour force is employed by the forestry sector (705 people), making an average annual income of $69,645, far above the local average. Dryden's employment dependence ratio (EDR) for forestry is approximately 1:16, which is very high. The majority of those working in the forestry sector are employed at forest nurseries, the local pulp and paper mill, support activities and logging.

2.2.2.2 Fort Frances

Fort Frances is located west of Rainy Lake at the International Falls, Minnesota, United States of America border. One Resolute Forest Products mill (formerly AbitibiBowater Inc.) is located in Fort Frances, which may receive wood from the Whiskey Jack Forest. Fort Frances district historically has not received large amount of wood volume from the Whiskey Jack Forest. The current forecast of wood flow suggests Fort Frances District to be the third highest dependency on Whiskey Jack Forest wood.

Fort Frances has a population of 8,103 people with a work force of 4,165. The population was stable for the past 20 years, but has been decreasing since 1996.

Employment in Fort Frances is at a rate of 93% with individuals earning an average of $35,087 annually. Men tend to make 32.2% more than women annually on average with incomes of $42,167 and $28,613 respectively. Dependency on the forest industry in Fort Frances is 14.6 times higher than the provincial average with the forest industry employing approximately 610 people (17% of the total labour force). Forestry in Fort Frances provides an average income that is 38% higher than the average community income as a whole ($56,379 as to $35,087).

Fort Frances contains approximately 3,445 households, with an average of 2.3 persons per household. The average value of a household is $138,127 and has an income of $63,556. Rent in Fort Frances is an average of $618 per month which is 30% below the provincial average.

A large portion of Fort Frances residents graduated from a secondary institute, approximately 32%. Post-secondary education was pursued by 44% of the graduating population. The remaining percent of the population completed their education at a primary school level. English is the official language used in Fort Frances (94%) while an additional 6% can speak both English and French. Only 7% of the Fort Frances population was born outside of Canada, and 87% of these people immigrated to Canada prior to 1991.

Fort Frances has an Aboriginal population of 1,362 people; including a workforce of 625 people who earn an average of $28,980 per year. An Aboriginal male earns an average annual income of $26,491, while the average annual income of an Aboriginal female is $31,361. Less than 6% of Fort Frances' Aboriginal population speaks their traditional language. Almost half of the Aboriginal population in Fort Frances is Métis.

2.2.2.3 Kenora

The City of Kenora is located on the north shore of the Lake of the Woods, on the Trans-Canada Highway. Kenora has a population of 15,177 people, of which 2,400 are Aboriginal. The Kenora labour force is 8,225 workers. Of the total labour force 485 people are employed in the forest industry. Population levels in Kenora have been relatively consistent since 1981 until the present census in 2006.

Kenora has a relatively diverse economy, relying upon a number of sectors, including forestry, tourism, mining and metals, equipment manufacturing, high technology and agriculture.

The closure of both the Devlin Timber Company sawmill and the AbitibiBowater pulp and paper mill in 2005 negatively affected the Kenora population and forestry related employee figures that

may not be reflected in the 2006 Census. Likewise the indefinite closure of the Kenora Forest Products sawmill would not be reflected in the census figures.

The AbitibiBowater pulp and paper mill in Kenora closure resulted in the layoff of approximately 300 people. Prior to the mill closure, approximately 7% of the labour force was employed by the forestry sector (560 people; dependency ratio of ~1:6) (based on 2001 census data); these workers were earning considerably more than the local average and were employed as loggers or at the pulp and paper mill. The mill closure leaves Kenora with approximately 485 people employed in forestry. A person currently employed in the forest industry in Kenora tends to make an annual income of $53,756 which is about 35% higher than the community average as a whole.

The Weyerhaeuser laminated strand lumber mill in Kenora receives the majority of hardwood fibre from the Whiskey Jack Forest.

Kenora has an employment rate of 93% and individuals make an average annual income of $35,252. On average men make $42,474 annually and women on average make $14,000 less. Of the non-aboriginal communities who receive wood from the Whiskey Jack Forest, Kenora has the lowest dependency ratio of only 5.8 times higher than the provincial average. Since Kenora is located on Lake of the Woods, the second largest inland lake in Ontario, and is relatively close to Winnipeg there is a much higher dependency on hunting and fishing recreation.

Kenora has 6,250 dwellings with the average value of each dwelling being approximately $172,060. Households on average in Kenora have an income of $67,773 and individually house 2.4 people. Rent in Kenora is an average of $633 per month and is still lower than the provincial average.

Ninety-five percent of the population of Kenora was born in Canada, most of whom are third generation or greater. The official language in Kenora is English. Approximately 29.6% of the population ended their schooling following high school, 13% attending college, 16% attended university, and 12.9% were trained in trades.

The Aboriginal population in Kenora has a knowledge of their traditional language with approximately 9% identifying an Aboriginal language as their first language, and approximately 9% speaking their Aboriginal language at home. Slightly less than half of the Aboriginal population in Kenora is Métis. The Aboriginal community has a labour force of 1,115 with an average income of $28,885. Aboriginal women make slightly less ($26,698) than Aboriginal men ($30,798).

2.2.2.4 Sioux Lookout

Sioux Lookout is located north of Minnitaki Lake and south of Lac Seul, at the junction of the Canadian National (CN) railway line and Highways 72, 516, 642 and 664. Hudson is west of Sioux Lookout along Highway 664, south of Lost Lake, and is included in the demographic profile for Sioux Lookout. The Mackenzie Forest Products Inc. mill is located in Hudson.

Sioux Lookout is home to 5,183 people, living in 1,925 dwellings, with a labour force of 3,190 earning an average of $38,971 per year. The incomes earned by men are approximately $10,000 per year higher than those earned by women ($33,942) per year. Aboriginal men earn approximately $9,000 more per year than Aboriginal women, although both are lower than the

local average (an average of $27,401 per year). The population of Sioux Lookout is generally stable, having increased slightly over the past 20 years. The average dwelling in Sioux Lookout costs approximately $184,898. Average monthly rent is $743 in Sioux Lookout. Household income, based on an annual income, is in the order of $79,374. Approximately 49% of the households have combined incomes of over $100,000 per year.

Approximately 18% of Sioux Lookout's population attended university, 11% attended college and 11% studied a trade. Also, 27% of the population graduated from secondary school while 32% completed primary school.

Approximately 11% of the workforce in Sioux Lookout is employed in the forestry sector (335 people), earning an average of $47,889 per year. The majority of these workers are employed in logging operations and at the Hudson sawmill. Forestry is the main employment sector for Sioux Lookout, with a economic dependency ratio (EDR) of 1:10, followed by health with an ERD of approximately 1:2. These figures do not reflect fact that the Hudson sawmill was shutdown indefinitely in 2008. Newspaper articles in April 2010 suggest there is a possibility that the mill may start up on a scaled back level.

The Aboriginal population in Sioux Lookout includes 1,457 people, 765 of whom are part of the local workforce. Approximately 35% of the Aboriginal population in Sioux Lookout has knowledge of an Aboriginal language, with 35% speaking an Aboriginal language at home.
Over 91% of the people living in Sioux Lookout were born in Canada. Of those born outside of Canada, over 91% have been in Canada for more than 15 years, and 57% of those born outside of Canada are originally from the United States, with the remainder arriving from Europe.

2.2.2.5 Asubpeeschoseewagong Netum Anishnabek First Nation (Grassy Narrows)

The Grassy Narrows First Nation (Asubpeeschoseewagong Netum Anishinabek) occupies the English River No. 21 reserve. The reserve is located 80 kilometres north of Kenora (Jones Road, also known as Highway 671). The Grassy Narrows First Nation is affiliated with the Bimose Tribal Council and Grand Council Treaty #3.

The community of Grassy Narrows has an approximate population of 633 people, 52% of which is male and 48% female. The age demographic reflects a younger population the majority of the population under 30 years of age. No information is available of population trends. The majority of the population speaks Ojibway with 51% of the population describing Aboriginal Language as first learned and 60% speak it in the home. 100% of the population is reported to speak English.

Grassy Narrows had approximately 185 private dwellings. The median income in 2006 for all private households was $25,580 per year. Average individual income is $11,599 per year.

The education level within the community appears to be increasing. The census suggests 60% of people over 15 have only primary educations, 9% of people completed secondary school, and 31% completed post-secondary education (university, college or trades).

The overall labour force for the community is 235 with and employment level of 66%. Occupations vary with sales leading at 52%, followed by trades with 19% of the workforce, management at 11%, finance at 11% and primary industries with 7% of the workforce.

Grassy Narrows is not dependent on the forest industry, but is more dependent on government employment (5 times more), education (4 times more) and health care (3 times more) than the provincial average.

2.2.2.6 Naotkamegwanning First Nation (Whitefish Bay)

The Naotkamegwanning First Nation has three reserves:

1. The community settlement is at the Whitefish Bay No. 32A site, located approximately 8 kilometres east of Sioux Narrows accessible via Gaudry Road off Highway # 71.
2. Sabaskong Bay No. 32C, located 65 kilometres southeast of Kenora on Lake of the Woods.
3. Yellow Girl Bay No. 32B located 32 kilometres southeast of Kenora on Lake of the Woods.

Whitefish Bay No. 32A can be accessed via Highway 71. This First Nation is affiliated with the Bimose Tribal Council and Grand Council Treaty #3.

The Naotkamegwanning First Nation has approximately 622 people with 51% male population and 49% female. The age profile for the community is mostly a younger demographic with a median age of 23 years. The primary language of the community is English with 100% of the population speaking English, and 48% of the population also speaking Aboriginal languages. Thirty-nine percent of the community describes Ojibway as first learned language. The average education level within the community is low with only 27% of people with post secondary education and 51% with only primary education. No information is available on population trends.

The average individual income is $14,061 per year with little difference between males and females average income. The labour force is 235 people and an employment rate of 83%. The main occupations are in sales (53%), trades (20%), management (10%), finance (10%) and primary industries (7%).

2.2.2.7 Wabaseemoong Independent Nations (Whitedog)

The Wabaseemoong Independent Nations (sometimes referred to as Whitedog) has three Reserves:

1. Islington No. 29, which is located 13 kms east of the Manitoba border and 77 kms northwest of Kenora.
2. One Man Lake No. 28, which is located on the north shore of One Man Lake, 100 kms northwest of Kenora.
3. Swan Lake No. 29, which is located on the east shore of Swan Lake, 36 kms northwest of Kenora.

Most of Wabaseemoong's on-reserve population lives at the main community of Whitedog located on Islington No. 29 Reserve and accessible via Highway 596. Swan Lake is road accessible and has a few families that live there on an infrequent basis. One Man Lake has no road access. Kenora is the nearest service centre.

The Wabaseemoong Independent Nations has approximately 785 people with 50% male population and 50% female. The age profile for the community is mostly a younger demographic with a median age of 24 years. The primary language of the community is English with 100% of the population speaking English, and 52% of the population also speaking Aboriginal languages. Forty-four percent of the community describes Ojibway as first learned

language. The average education level within the community is low with only 3% of people with post-secondary education and 10% with only primary education. No information is available on population trends.

The average individual income is $14,516 per year with little difference between males and females average income. The labour force is 505 people and an employment rate of 41%. The main occupations are in government services (18%), sales (15%), trades (9%), and primary industries (4%).

2.2.2.8 Wabauskang First Nation No.21

The Wabauskang First Nation occupies the Wabauskang No. 21 reserve. The reserve is located 67 kilometres northwest of Dryden off of Highway #105. Ear Falls is the closest urban centre which is approximately 27 km north of the community. The Wabauskang First Nation is affiliated with the Bimose Tribal Council and Grand Council Treaty #3.

The Wabauskang First Nation has a total registered population of 85. This is an increase of 40% from the 2001 census. The population on-reserve is approximately 53% male, 47% female. Based on the 2006 census, the majority of the population is under 50 years of age. The median age of population is 25 with 77% of the population over the age of 15 years. There are 30 private households housing approximately 2.8 people each. The majority of the population use English as their mother tongue. No income related values are available through Statistics Canada.

The educations background of the community reflects approximately 27% of the people over 15 years of age have post-secondary education, 13% graduated from secondary school and 60% completed primary education.

Forestry employs 10 people in Wabauskang which is enough to push the dependency ratio to 37 times greater than the provincial average. Actual income for residents of Wabauskang is unknown.

2.2.2.9 Ochiichagwe'babigo'inning First Nation (Dalles)

The Ochiichagwe'babigo'ining First Nation (sometimes referred to as The Dalles) is located within 50 Km north of Kenora to which it has year-round road access on Highway 658. Most of the Ochiichagwe'babigo'ining on-reserve population lives at the main community.

The Ochiichagwe'babigo'ining First Nation has approximately 156 people with 54% male population and 45% female. The age profile for the community is mostly a younger demographic with a median age of 26 years. The primary language of the community is English with 100% of the population speaking English, and 45% of the population also speaking Aboriginal languages. Thirty-three percent of the community describes Ojibway as first learned language. The average education level within the community is low with only 0% of people with post-secondary education and 13% with only primary education. There was a 34% reduction in population since 2001.

There is no information on the individual income of the community. The labour force is 110 people and an employment rate of 38%. The main occupations are in sales (18%), management (18%), government services and trades (9%).

2.2.3 Industrial and Non-industrial Uses of the Forest

This section of the forest management plan includes a summary of the industrial and non-industrial uses of the forest organized by sector. The sectors include:

Section 2.2.3.1	Timber;
Section 2.2.3.2	Recreation and Tourism;
Section 2.2.3.3	Mining, Aggregate and Hydro Generation; and
Section 2.2.3.4	Other Uses.

The complete description of industrial and non-industrial uses of the forest is included in Supplementary Documentation D – Social and Economic Information, Part A.

2.2.3.1 Timber

Communities that have received significant volumes of wood from the Whiskey Jack Forest over the last nine years prior to plan production include Kenora, Dryden and Fort Frances. The amount delivered changes from year to year as impacted by mill closures and market conditions. The following table (Table 8) is a summary of the wood deliveries that is also presented in more detail in Supplementary Documentation D.

Table 8 Summary of Mill Deliveries from the Whiskey Jack Forest 2004-2013

Whiskey Jack Forest
Timber Use
2004/05 to 2012/13

Company Name	Mill Destination	Product	Species Sector	2004/2005	2005/2006	2006/2007	2007/2008	2008/2009	2009/2010	2010/2011	2011/2012	2012/2013	Total	Share
Abitibi Consolidated	Kenora	Paper	Conifer	194,257	71,138								265,395	11%
Kenora Forest Products	Kenora	Sawmill	Conifer	154,721	155,265	131,192	80,766						521,944	22%
Weyerhaeuser	Kenora	Composite	Poplar / White Birch	152,768	204,695	120,908	100,110	19,071		5,334	4,060	18,175	625,120	26%
Abitibi Consolidated	Fort Frances	Pulp	Conifer	49,358	34,835	26,132	99,227	2,195					211,746	9%
Abitibi Consolidated	Fort Frances	Paper	Conifer	33,250	48,209	71,565	44,519	702					198,245	8%

1423 1358807 Ontario Ltd.	Perrault Falls	Sawmill	Conifer						1,959	335			2,294	0%
Misc.	Kenora	Building	Conifer	5	0	0	0	0					5	0%
Misc.	Kenora	Building	Poplar / White Birch	125	0	0	0	0					125	0%
Misc.	Kenora	Fuelwood	Poplar / White Birch	0	38			52					90	0%
Misc.	Kenora	Sawmill	Red Pine / White Pine Category 1	0	1,433	0	0	0					1,433	0%
Misc.	Kenora	Fuelwood	Conifer	0	26	454	634	78	1,000				2,192	0%
			Total	601,365	531,602	358,219	327,003	31,130	119,889	101,556	135,002	185,720	2,391,486	

The community of Kenora receives the greatest amount of timber, chips or other forest resources from the Whiskey Jack Forest due to the proximity of the Whiskey Jack Forest in relation to the Weyerhaeuser laminated strand lumber mill situated in Kenora. Over the nine year period reported, the Weyerhaeuser - Kenora mill received 26% of the delivered fibre from the Whiskey Jack Forest, the vast majority being poplar and birch. The Abitibi-Consolidated mill in Kenora received 11% of wood deliveries, and the Kenora Forest Products sawmill in Kenora received 22%, however Abitibi-Consolidated mill closed permanently in November 2005 and the Kenora Forest Products sawmill is indefinitely shut down.

Deliveries to Fort Frances have been fairly consistent at around 17% of Whiskey Jack Forest fibre being delivered the Resolute Forest Products (formerly AbitibiBowater Inc.) Pulp and Paper mill (all conifer pulp and paper fibre).

While the number of employees varies from the large laminated strand lumber or pulp and paper mills to the smaller numbers required to operate sawmills, the economic importance of the wood processing facilities on the community is still high as the sawmills are often in smaller communities, where the pulp mills are located in larger population based communities.

The Aboriginal communities who both benefit from the forest management activities on the Whiskey Jack Forest are the same ones whose interests or traditional uses may be affected by forest management activities. The identification and protection of Aboriginal values has been addressed in this plan.

2.2.3.2 Recreation and Tourism

Tourism Industry

There are numerous tourist operators in the Whiskey Jack Forest. The recreational activities provided by these outfitters include options for fishing, hunting, camping and other eco-tourism opportunities. The number of individuals, residents and non-residents, procuring services from these tourist establishments are numerous, and they contribute a significant amount of economic resources to local communities.

It is estimated that 500,000 people visited Kenora district in 2001 which was made up of travellers from Ontario (20%), other Canadian provinces (25%), United States (55%) and Others (1%). The Sunset Country Economic Study reports that in 2001, 443 operators provided employment to 3,785 persons of which 1,221 were located in the Whiskey Jack Forest. The operator survey also indicated that there were 758 First Nations employed in Sunset Country of which 80% were seasonal or part time employees.

Although a variety of outdoor recreation activities are provided by these tourism businesses, the primary activities offered at the Resource-Based Tourism (RBT) lodges and outposts in the Whiskey Jack Forest are fishing and hunting opportunities. In addition to the RBT outfitters, there are a significant number of fishing and hunting opportunities offered by operators on the forest that are not classified as RBT.

Crown Land Recreation

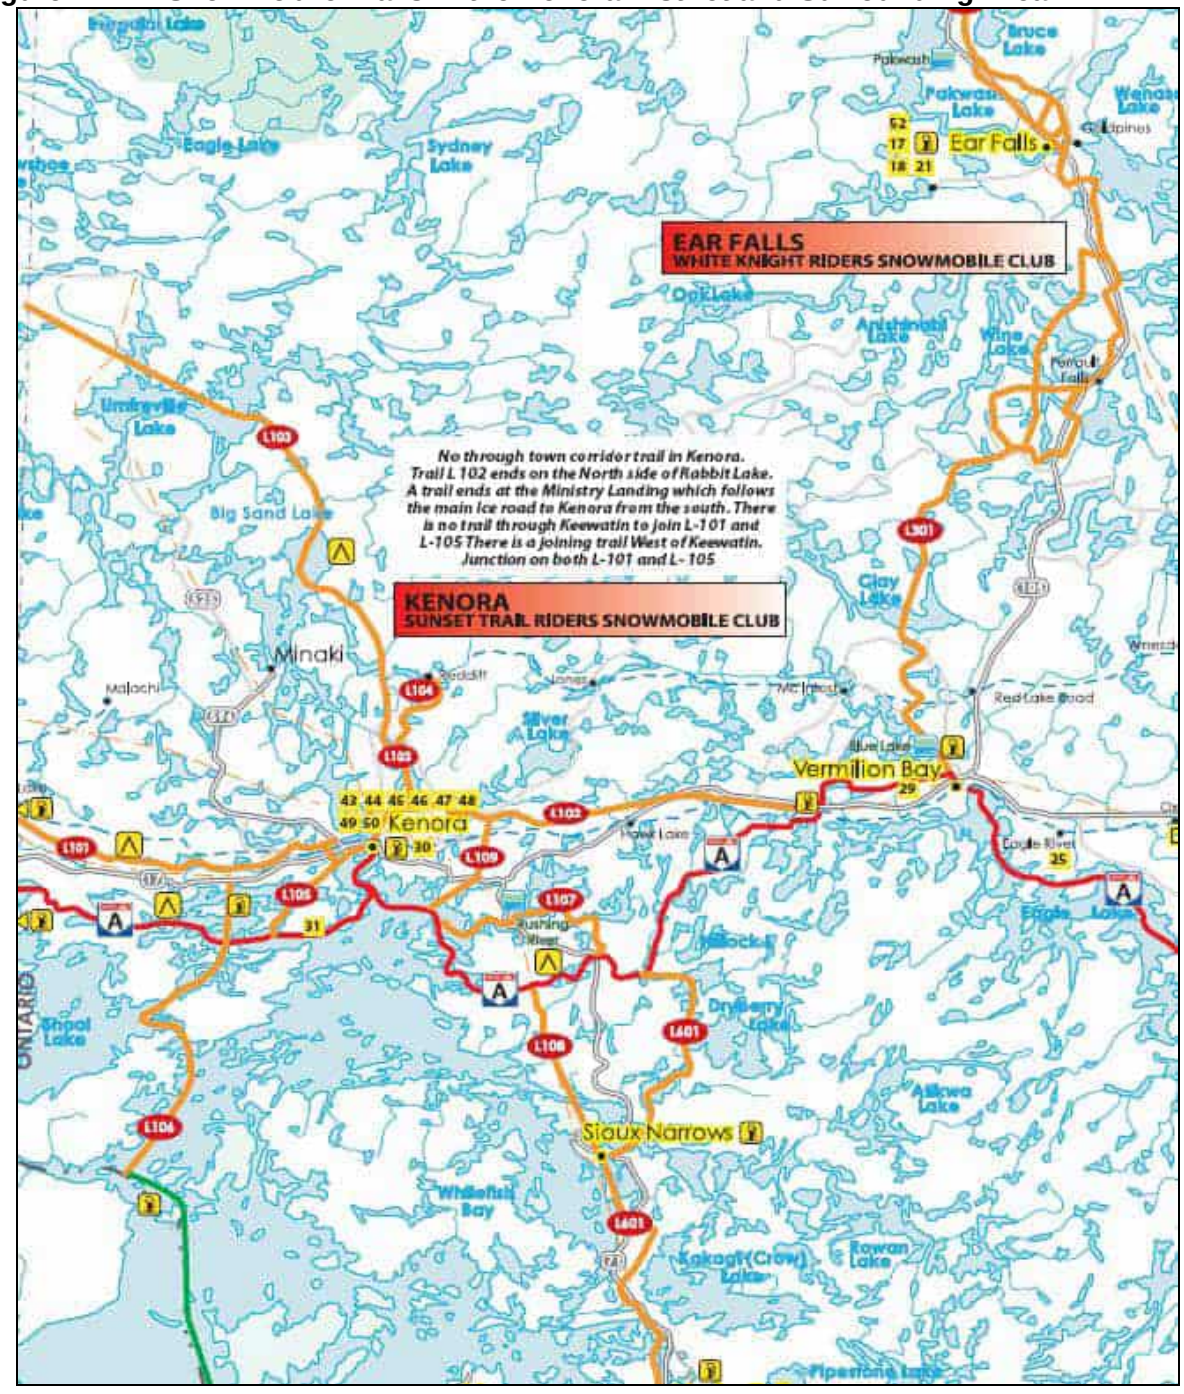
In addition to the commercial activity described above, recreationalists derive great benefit from the Whiskey Jack Forest. There are approximately 960 kilometres of active primary and branch forest access roads and additional 10,000 km of inactive and operational roads, providing opportunities such as hunting, camping, berry picking, fuelwood collection, bird watching, trails and access to small lakes for angling. Additional recreational opportunities are provided through canoe routes, snowmobile trails and various public access points. There are numerous private homes and recreational camps on the Whiskey Jack Forest.

Cottages - Area values associated with patent cottage lots are not presently available. However, there are abundant cottages on Lake of the Woods, which are primarily located on the many islands on the lake, since shoreline development is limited. The building of what is now known as Hwy 17 made it easier to access additional lakes in the area. Local and out of the area cottage owners spend thousands of dollars a year in the local communities. The economic influence of cottages in the area varies from basic food and building supplies to recreational purchases.

Trails – The Whiskey Jack Forest contains a large network of trails and canoe routes associated with the Crown land and waterways. There are also thousands of kilometres of mapped and unmapped trails of various types on Crown land within the Whiskey Jack Forest. In the summer months many of these trails are used as ATV, cycling, horseback riding and hiking trails.

Snowmobiling is a popular sport on the Whiskey Jack Forest and surrounding area. The trail guide produced by the Ontario Federation of Snowmobile Clubs and the Kenora Sunset Trail Riders Snowmobile Club shows an established network of main and feeder trails throughout the Kenora District (Figure 24). The thousands of snowmobilers that use the vast trail systems in the areas contribute economically to a variety of businesses in the local area. Forest management within the area considers the effects of forest operations of trail systems and access issues. Where possible, trails are left clear of debris from harvesting operations and in many cases, harvest roads are used as snowmobile trails.

Figure 24 Snowmobile Trails in the Kenora District and Surrounding Area



There are access points specifically designed for public access to lakes and some that support camping and other activities. There are also numerous access points, camp site, and recreating areas that have been informally developed and not all of these are known and therefore are not identified as values.

On the Whiskey Jack Forest, there are an extensive number of MNR issued boat caches, which allow the holder the right to freely cache a boat on Crown Land adjacent to a designated water body.

The total amount of camping, snowmobiling, ATVing, hiking, mountain biking and cross-country skiing trails and activity that takes place within the forest boundaries cannot be fully identified at this time. Similarly, no information on the revenue generated by recreation (i.e. tourism not associated with a tourism lodge or outfitter) is available at this time.

Angling and Hunting Opportunities - The Forest contains a variety of sport fishing lakes, as well as overlapping with several wildlife management units. Thousands of hunting and fishing licenses are sold across the province to both resident and non-resident hunters and anglers. Local hunters and fisherman contribute significant amount of economic spin off in the form of purchasing of fuel, equipment and general needs to support their activities. Other residents of the province, that are not local and non-residents contribute even larger economic input to the areas by sustaining lodges and purchasing supplies for their activities.

People travel long distances to hunt and fish in the remote and semi-remote forested areas in the region, either through tourism operators or on their own. The sale of food, lodging, outdoor equipment and supplies related to hunting and fishing contributes millions of dollars annually to the provincial economy, much of which is potentially generated in the north. As noted earlier, the Whiskey Jack Forest is the base for over 140 tourism operations, suggesting that the economic impact of recreational tourism in this area is significant.

Hunting continues to be an important recreational activity in the Whiskey Jack Forest area. Hunting is either carried out adjacent to access roads created by the forest industry, by use of water based transportation to remote roadless areas, or by fly-in outfitters to backcountry locations. A large proportion of big game hunters are non-resident hunters who contribute to the local economy depending on how many local services they utilize. More than 90% of the bear hunters are non-residents. There are a wide variety of trails in the Whiskey Jack Forest that are used (depending on the nature of the activity and the Land Use designation) by hikers, cross country skiers, dog sledders, snowmobilers, and ATV operators. In addition to prepared trails, there are opportunities to travel on ungroomed areas such as snowshoeing along lakes and portages or snowmobiling along ungroomed lakes or unploughed roads.

Sport Fishing - The area contains numerous lakes, wetland areas, rivers and streams that provide fishing opportunities for both resident and non-residents. The major sport fishing species sought by anglers are: yellow pickerel (walleye), sauger, northern pike, muskellunge, black crappie, smallmouth bass, largemouth bass, yellow perch, lake trout, lake whitefish and lake sturgeon.

Parks and Protected Areas - The purpose of Ontario's Provincial Parks and protected areas is to permanently protect a system of provincial parks and conservation reserves that includes ecosystems that are representative of all of Ontario's natural regions, protects provincially significant elements of Ontario's natural and cultural heritage, maintains biodiversity and provides opportunities for compatible, ecologically sustainable recreation. Ontario's provincial

parks and conservation reserves are dedicated to the people of Ontario and visitors for their inspiration, education, health, recreational enjoyment and other benefits with the intention that these areas shall be managed to maintain their ecological integrity and to leave them unimpaired for future generations.

There are several different classifications of parks and protected areas. Each class and individual area has different objectives and permit different activities within the defined areas. There are six classifications of provincial parks; 1) Wilderness Class Parks, 2) Nature Reserve Class Parks, 3) Cultural Heritage Class Parks, 4) Natural Environment Class Parks, 5) Waterway Class Parks, and 6) Recreational Class Parks. In addition to parks, there are conservation reserves.

There are seven provincial parks or protected areas adjacent to or surrounded by the Whiskey Jack Forest. Parks in the management unit include the West English River, Eagle-Dogtooth, Tide Lake and the Maynard Lake Parks. The Pakwash Provincial Park is located adjacent to the northeast corner of the unit, Rushing River Provincial Park is located in the southern portion of the forest, and Woodland Caribou Provincial Park (and addition) is located in the northwest portion of the unit. All of these parks have either an Interim Management Statement or a park management plan that provides direction.

Scattered throughout or adjacent to the Whiskey Jack Forest there are nine Conservation Reserves including Campfire River, Clay Lake, Dryberry lake, Lac Seul Islands, Lake of the Woods CR, Scenic Lake, Scotty Lake, Solitary Lake and Twilight Lake Conservation Reserves. Some of the social contributions of parks and protected areas are previously described in Section 2.1.3.3.5.

Ontario Parks reports on the following indicators of economic impact:

- Value Added
- Provincial Gross Sales (or Provincial Gross Output)
- Wages & Salaries
- Provincial Person Years of Employment

Economic impacts are based on expenditures such as those made by the park on operations and capital improvements, as well as average visitor trip expenditures (camper and day visitor).

As well, the public and municipal officials should be aware that provincial parks help to make their communities attractive for business as well as for tourists and retirees. The retirement community brings in pension income, which is often indexed to inflation and is recession proof. Communities with attractive waterfronts, low crime, recreational activities and healthy environments are sought out by the retirement community. The park budget (operating and capital) represents a grant or transfer payment from the government to their community. Not all communities have this transfer. The community may also receive grants in lieu of taxes.

The provincial parks in and adjacent to the Whiskey Jack Forest are described in section 2.1.3.3 (Natural Resource Features, Land Uses and Values).

Woodland Caribou (P2370e), an operating wilderness class park of 450,000 hectares, was regulated in 1983. It protects representative earth and life science features of Site District 4S-1, such as the Eagle-Finlayson Moraine, prairie-boreal vegetation and habitat for Woodland Caribou, a threatened species. The park provides opportunities for backcountry canoeing,

camping and outpost camp and main base lodge fishing. The park had 4799 camper-nights and 4799 days-use visitors in 2007. For 2005/06, the economic impact of Woodland Caribou Provincial Park was: Initial expenditure: $503,938; Value Added: $709,902; Wages and Salaries: $505,559; Person-years employment: 28. Only a portion of the Whiskey Jack Forest abuts Woodland Caribou, so the entire economic impact of the park does not affect the Forest.

Woodland Caribou recommended park additions (P2370) were established during Ontario's Living Legacy – Land Use Strategy. There are four additions to the existing park (Douglas Lake, Peisk Lake, Anchor Lake and Sydney Lake areas) although only Sydney Lake is within the FMU. The Sydney Lake addition includes a significant white elm site. A primary forest access road crossing between Rowdy and Sydney Lakes will be permitted as determined through previous forest management planning processes. This addition is in the most popular backcountry canoeing area of the park. It is unknown how much of the economic impact of Woodland Caribou Provincial Park (see above) can be assigned to the Sydney Lake recommended park addition.

Maynard Lake (P2698), a non-operating nature reserve class park of 25 hectares, was regulated in 1997. It consists of a peninsula with deep soils on the east shore of Maynard Lake. It provides representation/protection of an atypical old growth white pine stand (age class + 160 years) at the northern limit of the species range. It is surrounded by West English River Provincial Park on three sides. Camping, day-use, hunting and most other recreational activities are prohibited because of the classification of the park. The actual amount of use is unknown.

Tide Lake (P2614), a non-operating nature reserve class park of 51 hectares, was regulated in 1997. It consists of the peninsula between Ball and Tide lakes. The park provides representation/protection of an atypical old growth white pine stand (age class + 160 years) at the northern limit of the species' range. It is surrounded by West English River Provincial Park on three sides. Camping, day-use, hunting and most other recreational activities are prohibited because of the classification of the park. The actual amount of use is unknown.

West English River (P2345), a non-operating waterway class park of 22,923 hectares, was regulated in 2003. The area includes that portion of the English River from Barnston Lake to Tide Lake. The waterway contains old growth red and white pine at the northern extent of its range, wilderness environments and tourism attributes, and is an historic travel corridor. Two provincial nature reserves, Maynard Lake and Tide Lake abut the park. Motor boating, canoeing, sport fishing, hunting and camping are popular activities, although the actual use is unknown.

Eagle-Dogtooth (P2363), a non-operating waterway class park of 41,128 hectares, was regulated in 2003. It provides a waterway linkage between Eagle Lake and nearby protected areas (e.g., Rushing River, Winnange). It is an important recreational waterway. The site contains regionally significant moraines, wetlands, pine forest ecosystems, eagles, waterfowl and is an important recreation and tourism area. Motor boating, canoeing, sport fishing, hunting and camping are popular activities, although the actual use is unknown.

Pakwash (P2528) is a staffed natural environment class provincial park of 3,993 hectares. The park was established in 1967 and was regulated in 1989 as a natural environment class Provincial Park. The park provides representation/protection of Site District 4S-2, specifically the Hartman Moraine. Pakwash provides opportunities for car-camping and day-use. The park is operated through a partnership with Ear Falls 2000 Inc. The park had 8,523 camper-nights

and 476 days-use visitors in 2007. For 2005/06, the economic impact of Pakwash Provincial Park was: Initial expenditure: $178,746; Value Added: $205,386; Wages and Salaries: $124,866; Person-years employment: 3.2. Only a portion of the Whiskey Jack Forest abuts Pakwash, so the entire economic impact of the park does not affect the Forest.

Rushing River (P2615), a staffed recreation class provincial park of 340 hectares was established in September 1958. Natural features include jack pine uplands, wetlands and a lush river valley. The park has a popular campground, day-use area and interpretive facilities/trails. The park had 47,804 camper-nights and 14,960 days-use visitors in 2007. For 2005/06, the economic impact of Rushing River Provincial Park was: Initial expenditure: $3,896,802; Value Added: $4,815,843; Wages and Salaries: $3,771,395; Person-years employment: 118.3. Only a portion of the Whiskey Jack Forest abuts Rushing River, so the entire economic impact of the park does not affect the Forest.

2.2.3.3 Mining, Aggregate and Hydro Generation

Mining, Mineral Exploration and Aggregates

Historically, mining and mineral exploration have been an important activity in this management unit and historically gold, silver and copper were the predominant commodities mined. Currently there are four granite producers in operation which have been and continue to be a significant contributor to the economy of the area. The value of total granite production was not available at the time of writing. Historical metal production occurred within the management unit between 1893 and 1951 and totaled 68,513 ounces gold, 14,762 ounces silver and 1.89 million pounds of copper valued at $49.73 million CDN at current metal prices.

In addition to historical and current mineral production there are significant concentrations of gold, nickel, copper, silver and uranium contained within documented mineral deposits throughout the management unit. The total estimated value of metals contained within these deposits at current commodity prices is in excess of $158 million CDN.

There are an estimated 1,605 active mining claim units recorded throughout this management unit, as indicated on MNDM's CLAIMaps website (MNDM, 2006). These claims represent an investment in the management unit of approximately $400,000 CDN for claim staking, which directly relates to its mineral potential. In addition there is an estimated dollar expenditure of nearly $650,000 CDN per year related to mineral exploration work required to keep the claims in good standing. Current claim staking targets areas with potential for uranium, rare-metals, zinc and gold. Historically, several areas within the management unit have seen extensive staking and mineral exploration.

There are 12 aggregate sites located in the Whiskey Jack Forest, all operated by MNR.

Hydro Generation

A number of hydro-electric facilities are located within or adjacent to the forest. These facilities are on the English River between Lac Seul and the Manitoba border and on the Winnipeg River between Lake of the Woods and the English River.

Four facilities are located within Kenora district and supply power to the area. Two of these are owned by Ontario Power Generation and the other two (both in Kenora) are owned by Resolute Forest Products (formerly AbitibiBowater Inc.).

1. Caribou Falls - Caribou Falls consist of three power generating units built in 1958 on the English River at the outlet of Umfreville Lake. The Caribou station was the third plant built along the English River which represented just a fraction of the widespread program undertaken to meet the challenge of expansion in mining and also pulp and paper industries.
2. Whitedog Falls - This facility consists of three power generating units built in 1958 on the Winnipeg River at Whitedog Falls.
3. Kenora Power House and Norman Dam - These generating stations are owned by Resolute Forest Products (formerly AbitibiBowater Inc.). The Kenora Power House is located on the

Winnipeg River in Kenora at the outlet of Lake of the Woods. The Norman Dam generating station is located on the Winnipeg River in Kenora.

Two additional sites owned by Ontario Power Generation are located within the district:

4. Ear Falls - There are four power generating units at Ear Falls located on the English River at the outlet of Lac Seul. The first unit began operating in 1930. Additional generating capacity is being developed at the Ear Falls GS by adding a new 12.5 MW generating unit capable of generating approximately 52 million kilowatt hours of hydroelectricity per year.
5. Manitou Falls - This facility is located on the English River where it enters Barnston Lake downstream of Ear Falls. There are five operating units located at this facility. Construction on this facility began in 1953.

2.2.3.4 Other Uses

Summary of First Nation Use of Other Resources - First Nation community members actively use portions of the Whiskey Jack Forest for many resource-based activities, many providing social and/or economic benefits.

Fishing - Several First Nation communities hold commercial fishing licences on Lake of the Woods and inland lakes. Lake of the Woods and surrounding lakes are used for subsistence fishing by community members. Surrounding tourist lodges provide some employment opportunities for First Nation residents as guides in the sport fishery.

Trapping - First Nation community individuals hold registered trap lines located all or partially within Kenora District.

Wild Rice - Wild rice is harvested annually by community members for personal use and re-sale from various lakes throughout the area.

Cultural and Social, other Wildlife - Special sites within the forest are used for traditional cultural purposes such as fasting, vision quests and offerings. The specific location of these sites are known to community members, and the community is encouraged to participate in the forest management planning process to ensure these values are considered in proposed forest management activities. Certain wildlife species, such as the bald eagle, have a cultural and social significance to First Nation people. The protection and management of these species and their habitats is important.

While the subsistence hunting, fishing, and gathering of resources from within the forest are an integral part of community existence, there are no accurate records of the level of such harvest. The harvest of deer, moose, waterfowl, rabbits and grouse provides an important source of food to community members.

Trapping and Traplines - Trapping provides seasonal employment for 89 registered traplines in the Whiskey Jack Forest. Additionally, there are approximately 17 First Nation Community traplines located with the Whiskey Jack Forest. The expected average resources value per trapline is estimated at $2,440. Since all the trappers work out of their home it would not be appropriate to identify their names in this document The

major fur bearing animals that are of economic importance are beaver, fox, muskrat, lynx, otter, mink, fisher, and marten. Registered trap lines cover the entire Whiskey Jack Forest (Values Map 4.4).

Baitfish - In 2009-2010, the Whiskey Jack Forest had licensed baitfish individuals of which all are camp operators operating in 95 harvest areas. Baitfish is consumed locally by the angling industry. Since the majority of baitfish operators' work as individuals out of their home, it would not be appropriate to identify their name in this document. The baitfish industry provides supplemental income to these people and complements the local angling industry.

Commercial Bear Management - There are approximately 124 commercial bear management areas on the forest operated by 76 tourist operators. All of these areas are accessible from the existing road network on the unit. The bear management areas are distributed throughout the unit except for the areas close to populated centres. Registered bear management areas cover all of the Whiskey Jack Forest as seen on the 2012 Values Map 4.4.

Other - Local residents use the forest for fuelwood cutting; primarily white birch and poplar.

2.3 Aboriginal Background Information Report

The Aboriginal Background Information Report summarizes, for each Aboriginal community, past and current resource use and recent forest management-related concerns, and includes an Aboriginal values map. Specifically, the report will contain:

(a) a summary of the use of natural resources on the management unit by Aboriginal communities, in particular hunting, fishing, trapping and gathering;

(b) forest management-related problems and issues for those Aboriginal communities;

(c) an Aboriginal values map which identifies the locations* of natural resource features, land uses and values which are used by, or of importance to, those Aboriginal communities. In particular, the following features, land uses and values will be mapped:

(i) areas of significance to local Aboriginal communities, such as areas used for traditional or recreational activities;
(ii) boundaries of trapline management areas of those Aboriginal communities (i.e., all registered trapline areas associated with individual Aboriginal communities);
(iii) Reserves and Aboriginal communities;
(iv) areas that have been identified as being required as Reserve lands or for economic or capital development projects of those Aboriginal communities;
(v) areas used by those Aboriginal communities for fuelwood or building materials;
(vi) sites of local archaeological, historical, religious, and cultural, significance to those Aboriginal communities, including Aboriginal cemeteries, spirit sites and burial sites; and
(vii) areas identified by Aboriginal communities during the archaeological predictive modelling process as having archaeological potential; and

(d) a summary of the involvement of Aboriginal communities in the preparation of the Aboriginal Background Information Report.

** Publicizing the location of certain values may be detrimental to conservation, in which case information would not normally be shown on the Aboriginal values map(s).*

The *Forest Management Planning Manual (2009)* requires agreement from each Aboriginal community for the inclusion of their Aboriginal Background Information Report in the forest management plan. No Aboriginal communities affected by this Whiskey Jack Forest FMP provided such agreement. Therefore the Aboriginal Background Information Reports prepared during plan development are retained at the Kenora District Office of the Ministry of Natural Resources and do not form part of this forest management plan.

3.0 DEVELOPMENT OF THE LONG-TERM MANAGEMENT DIRECTION

3.1 Introduction

The long-term management direction (LTMD) for the forest provides guidance on levels of access, harvest, renewal and tending activities required to achieve a balance of objectives over time and meet the desired future forest and benefits. In the development of the LTMD, management objectives and indicators were developed/established and target levels identified through various analytical methodologies (models and tools) with regard to forest guidelines, social and economic assessment, wildlife habitat, and landscape management over time. The overall goals are to provide for biological diversity, sustainable forest management, social and economic benefits/development, and protection of natural resources and the forest ecosystem condition on the Whiskey Jack Forest.

The long-term management direction provides a means of assessing the sustainability of the management strategy through the measurement and monitoring of indicators that have been developed for each management objective. These management objectives, both quantitative and qualitative are based on the desired future forest and benefits.

The Long-term Management Direction was prepared for the Whiskey Jack Forest 2012-2022 Forest Management Plan and received preliminary endorsement by the Kenora District Manager and Regional Director (Northwest Region) on March 22nd, 2012. The Summary of the Long-term Management Direction is included in Supplementary Documentation O.

Development of the Long-term Management Direction is discussed in detail in Sections 3.2 through 3.6:

Section 3.2	Management Considerations during LTMD development;
Section 3.3	Development of the Base Model for strategic planning;
Section 3.4	Determining Desired Forest and Benefits
Section 3.5	Management Objectives and Indicators (including determination of appropriate desirable levels for indicators); and
Section 3.6	Long-term Management Direction.

The Available Harvest Area (AHA) for the 10-year period of this forest management plan is presented by forest unit in Section 3.6.1, as well as the criteria used for the selection of areas for harvest operations (Section 3.6.2). Management objective achievement is determined by the overall achievement of the established desirable levels and targets (Section 3.6.3). The socio-economic impacts associated with implementation of the long-term management direction are summarized in Sections 3.6.4.

Primary road corridors proposed for the next twenty-year period are discussed in Section 4.5.1 of this plan text.

3.2 Management Considerations

Management considerations are changes to the forest condition (e.g. large natural disturbance) or social, economic or environmental concerns that will be considered in the development of the long-term management direction. Management considerations are also considered in the planning and implementation of operations.

Some management considerations were identified from Section 1.2.3 of the *Forest Management Planning Manual*, and other management considerations were identified during development of the Long-term Management Direction by the Planning Team. Sources of information on the management considerations included previous direction from the 2004 FMP, new MNR policies and guides, results of consultation efforts, previous forest inventories and the process to update the 2012 forest resources inventory, the Independent Forest Audit, planning team discussions on primary road access, and Aboriginal negotiations with the provincial government that resulted in the Keewatin Decision.

The Planning Team discussed the following management considerations that may influence the development of the long-term management direction:

Section 3.2.1 Revisions to the Forest Resources Inventory;
Section 3.2.2 New Forest Management Guides;
Section 3.2.3 Caribou Habitat Management;
Section 3.2.4 Species at Risk;
Section 3.2.5 Aboriginal Interests;
Section 3.2.6 Climate Change;
Section 3.2.7 Issues Raised During the Independent Forest Audit; and
Section 3.2.8 Shifts in Markets or Utilization.

Many management considerations may affect the development of the long-term management direction. The following subsections summarize the management considerations and how information was used to confirm or change past management direction.

3.2.1 Revisions to the Forest Resources Inventory

There have not been any significant revisions to the land base since the preparation of the 2004 FMP. The forest resources inventory was updated to reflect actual attribute changes since 2004 (planning inventory) and additional estimated attribute changes to April 1, 2012 (base model inventory). The inventory attribute changes were a result of actual harvest areas, surveyed free-to-grow renewal areas, actual silvicultural treatments applied to specific sites, road construction and mapped natural disturbances. There have not been any major natural disturbances on the Whiskey Jack Forest since the 2004 FMP was approved.

Considerations in FMP: The revised planning inventory (including ownership and forest stand attributes) is included in the initial strategic modelling land base and reported in forest management plan land base Tables FMP-1 and FMP-3. Details of the updates to the inventory are included in Supplementary Documentation A – Analysis Package, Section 4: Development of the Planning Inventory, and Section 6: Base Model Inventory and Base Model.

3.2.2 New Forest Management Guides

The *Forest Management Guide for Boreal Landscapes* (Landscape Guide) was in production and was not approved for implementation for forest management plans in the Boreal Forest at the time of preparation of this 2012 Whiskey Jack Forest FMP. The Ontario Landscape Tool (OLT) developed to support the Landscape Guide (when approved) was available for use by planning teams. The science package embedded into OLT included the most current science and analysis on the simulated natural forest condition and the range of natural variation for a multitude of forest attributes. The OLT information on landscape class areas, young forest patch size by size class, mature and old forest area (amount and pattern), old forest area, caribou refuge and winter habitat (amount and pattern) and the simulated ranges of natural variation (SRNV) was used to set desirable levels for these indicators and was considered the most current available science by the Planning Team and regional advisors. Therefore the Science and Information in support of Ontario's Forest Management Guides for Landscapes management objective indicators (Table FMP-9) related to landscape composition and pattern were included in this 2012 FMP. This approach was endorsed by the Planning Team and LCC and was consistent with regional and provincial FMP training provided to 2012 FMP Planning Teams. The use of the OLT model represented an improvement in the estimation of the natural forest condition and natural ranges of variation of indicators as compared to previous forest management plans.

The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (Stand and Site Guide) was new for this 2012 FMP and was also followed for the 2012-2014 Contingency Plan. Overall, the application of the Stand and Site Guide was challenging as the description of forest values has changed from previous management guides (i.e. cool and cold water lakes are now classified as High Potential Sensitivity (HPS) or Moderate Potential Sensitivity (MPS) to forest management activities). The Planning Team feels the Stand and Site Guide direction was incorporated successfully into the area of concern planning, conditions on regular operations, conditions on roads, landings and aggregate pits, and planned operations.

3.2.3 Caribou Habitat Management

Woodland Caribou are native to Ontario's northern forests. They are an important indicator of the healthy boreal forest ecosystem on which they rely. As one of several jurisdictions responsible for managing the northern boreal forest, Ontario has an important role in Woodland Caribou stewardship.

Ontario's Woodland Caribou Conservation Plan provides policy direction for the management and recovery of Woodland Caribou (forest-dwelling boreal population), and will apply to the areas of continuous and discontinuous distribution. Woodland Caribou (forest-dwelling boreal population) are designated as "Threatened" in Ontario under the *Endangered Species Act, 2007*.

Ontario's Woodland Caribou Conservation Plan was a principle document used by the Planning Team to develop management strategies for current and projected habitat for caribou on the Whiskey Jack Forest.

The purpose of *Ontario's Woodland Caribou Conservation Plan* (CCP) is to:

- Provide broad policy direction regarding Woodland Caribou conservation and recovery;
- Summarize the actions the Government of Ontario intends to take in response to recommendations in the Ontario Woodland Caribou Recovery Strategy and the government's priorities in taking those actions (Government Response Statement)1; and
- Outline initiatives to support Woodland Caribou recovery.

The CCP requires that forest management plans provide for caribou habitat, including silviculture, scheduling of harvesting and deferrals, science-based modeling, precautionary planning in the face of natural uncertainty such as wildfire, and a requirement for caribou habitat provision objectives and a dynamic caribou habitat schedule. Forest management plans will demonstrate how planning decisions provide for an uninterrupted supply of year-round caribou habitat within the limits of natural forest variability, recognizing the influence of both forest harvesting and wildfire.

Currently, MNR's delineation of the area of continuous range occurrence, including area identified for caribou habitat recovery, is the primary consideration for the division of the management zone for caribou habitat management. A review of the caribou habitat analyses from the previous 2004 and draft 2009 FMPs did not identify any significant changes in habitat or assumptions therefore the application of caribou habitat management was agreed to be continued for this plan. For strategic purposes in this 2012 FMP, it was agreed by the Planning Team and Plan Advisors to continue to implement the existing 2004 FMP sub-management units which represented the caribou habitat mosaic blocks where caribou habitat management was the primary consideration. Dynamic caribou habitat schedule blocks (DCHS blocks Car01 through Car11) were accepted as strategic management zones for this FMP. Analysis of caribou habitat management for this FMP is included in Supplementary Documentation N.

As previously identified in Section 3.2.2 New Forest Management Guides, there are several new management objective indicators included in this 2012 FMP related to caribou habitat management: young forest patch size by size class, mature and old forest area (amount and pattern), old forest area, caribou refuge and winter habitat (amount and pattern) and the simulated ranges of natural variation used to set desirable levels for these indicators was considered the best available science by the Planning Team and regional advisors.

The CCP requirement for consideration of silviculture for the provision of future caribou habitat is included as management indicators for conifer forest unit dominance within the caribou zone, and also occurrence of jack pine and spruce species composition (conifer purity) within conifer forest units in the caribou zone. Through effective implementation of Silvicultural Ground Rules (Table FMP-4, text Section 4.2.2.1), the maintenance of or increase in conifer dominated forest in the caribou zone should provide for future caribou habitat should any harvest occur within the area. There are limited operations planned in the DCHS blocks (only Car06-Car10) during the term of this FMP.

The road density management indicator required by the FMPM has been divided into two to report road densities within and outside of the caribou management zone. This split in the indicator allowed for the setting of a desirable level for the caribou zone that specifically addressed the intent to minimize linear features that negatively impact functional habitat for woodland caribou.

Finally, a General Habitat Description under the *Endangered Species Act, 2007* was approved June 2013. MNR has developed a draft Range Management Policy that is currently on the Environmental Registry for public comment. Any required additions or changes to caribou habitat management in Ontario dictated by the Range Management Policy will be included or amended into the forest management plan.

3.2.4 Species At Risk

The Forest Management Plan must discuss any forest dependent Species at Risk (SAR) that may inhabit the Whiskey Jack Forest and the contribution and importance of habitat for those species. Since the 2004 FMP was approved, the Endangered Species Act was passed in 2007 with several habitat protection regulations for Endangered Species being draft for future implementation. The known locations of occurrences of flora and fauna Species at Risk were reviewed on the Whiskey Jack Forest in order to determine if operations would impact these values. Forest dependent Species At Risk that have been known to occur or have the potential to occur in the Whiskey Jack Forest were identified in Section 2.1.3.1.

> **Considerations in FMP:** Habitats for Species at Risk are documented in text Section 2.1.3.1. All known Species at Risk have their habitat managed in the plan using species specific guidelines and/or by recognizing specific habitats as values and developing appropriate area of concern (AOC) prescriptions (Table FMP-10). The woodland caribou is the only forest-dependent Species At Risk present on the Whiskey Jack Forest that has their habitat modelled strategically through time. Other forest dependent Species At, Common Nighthawk nests, Risk may be present on the Whiskey Jack Forest, but their habitat is not suitable for long-term strategic modelling. AOC prescriptions are included in Table FMP-10 for cougar dens, wolf dens, wolverine dens, bald eagle nests, short-eared owl nests, whip-poor-will nesting areas, Canada Warbler nests, Olive-sided Flycatcher nests, bat hibernacula and wetlands occupied by breeding black terns, and least bitterns. If in the future, any species at risk are thought to exist near areas proposed for forest management operations, the area will be surveyed by a qualified individual, mapped, and an appropriate area of concern prescription will be developed and applied.

3.2.5 Aboriginal Interests

Aboriginal interests may be expressed both as the interests of Aboriginal communities and the interests of aboriginal individuals and organizations. There are five First Nation communities and one Aboriginal community within or adjacent to the forest that may be directly affected by forest operations within the Whiskey Jack Forest:

Asubpeeschoseewagong Netum Anishinabek (Grassy Narrows First Nation),
Wabaseemoong Independent Nations,
Ochiichagwe'babigo'inning (Dalles) First Nation,
Wabauskang First Nation,
Naotkamegwanning First Nation No. 32A (Whitefish Bay), and
Kenora Métis Council.

Wabaseemoong Independent Nations recently signed a Stewardship Protocol Agreement with the Ministry of Natural Resources which establishes a process for engagement with the First Nation on resource development within an area defined as the Wabaseemoong Stewardship Area.

Aboriginal individuals (outside of their community), who trap, hunt, fish, collect wild rice, collect forest products and work in the forest may also be influenced by forest operations on the Whiskey Jack Forest.

Considerations in FMP:

Direction from past Whiskey Jack FMPs was confirmed and was enhanced for this plan. The forest management planning process directs specific involvement for Aboriginal Communities and Representatives of those communities are invited to participate as members of the Planning Team.

- MNR contacted the Kenora Metis Council and all five Aboriginal First Nations located on or adjacent to the Whiskey Jack Forest and offered them the opportunity to decide if they wished to participate in the Whiskey Jack Forest planning process. This approach allowed the communities to decide on 'adjacency' and desired level of involvement. This participation was intended to assist MNR in its understanding and consideration of Aboriginal Community interests and traditional uses on the Whiskey Jack Forest.
- The Aboriginal Communities were also invited to select a Representative to sit as part of the FMP Planning Team. Each Aboriginal Planning Team member was also designated as a member of the Aboriginal Task team to ensure opportunity for discussion of FMP topics and to share ideas on topics outside the scope of Forest Management Planning.

The forest management planning process directs specific involvement for Aboriginal Communities in the identification of Aboriginal values and input and review into the Aboriginal Background Information Reports.

- The communities were invited to participate in the identification of Aboriginal Values. The Planning Team encouraged the identification of values important to the community, regardless of whether the values are shared with MNR. This was promoted through the provision of tailored maps with a Community focus and the opprotunity for ad-hoc community meetings. It was up to each Community to determine how much information about values would be shared with the Planning Team and MNR.
- The Communities were also invited to participate in the development of their Aboriginal Background Information Report. Communities were encouraged to write all or portions of the report. If that was not successful, they were encouraged to review the MNR-prepared reports. If the MNR-prepared reports were used, the Aboriginal Background Information Reports used from the 2004 Whiskey Jack Forest FMP, 2006 Kenora Forest FMP and the 2011 Dryden Forest FMP served as the starting points for these reports. Red Lake, Sioux Lookout and Dryden Districts were asked to provide background information for those Communities located outside of the Kenora District.

The forest management planning process directs specific involvement for Aboriginal Consultation.

- The Communities were invited to determine an appropriate consultation approach for their community. Timing of the approach was left to each community. MNR repeatedly re-iterated their offers to participate in tailored consultation throughout all stages of FMP development.

- When requested by specific Aboriginal Communities, the Planning Team presented plan information at community meetings at various times during plan development. Each presentation was tailored to the topics and level of detail that was requested by each community.

The forest management planning process provides direction with regard to notification about the planning process.

- All five Aboriginal Communities and the Kenora Metis Council received notification at each stage of Public Consultation.
- Aboriginal Community Representatives (from communities identifying such) received all Planning Team agendas and minutes, as well as notification at each stage of Public Consultation.
- Direct mailout at each stage of Public Consultation was sent to all known values-holders and those requesting to be on the mailing list. Aboriginal values-holders typically include individuals or organizations that are licensed trappers, commercial and/or bait fishermen, camp operators, as well as collectors of wild rice and collectors of forest products.
- Newspaper notices at each stage of Public Consultation were placed in Wawatay News, the local Aboriginal newspaper.

3.2.6 Climate Change

The Kenora Local Citizens Committee expressed its concern with how climate change will affect the local forest and also suggested that a climate change adaptation option should be included in this plan.

The planning team discussed the issue of potential impacts of climate change and whether there were changes in management strategies that needed to be included in the forest management plan to mitigate negative impacts. Scientists continue to monitor and analyze the occurrence and impacts of climate change. Research work on seed zones and climate change has been inconclusive for this area about how climate change may affect suitability of tree growth in different seed zones.

To date, no specific direction has been provided by MNR to FMP planning teams on specific strategies to be implemented to mitigate potential impacts of climate change. In future forest management plans, if supported by specific policies and scientific data, applicable management strategies may be incorporated into development of the LTMD.

3.2.7 Issues Raised During the Independent Forest Audit

Independent Forest Audits (IFA) are required to occur on the Whiskey Jack Forest at least every five years. The last IFA was conducted in 2009 resulting in recommendations, some of which were relevant during preparation of this forest management plan. A general summary of issues and how they were considered during development of this plan follows:

i) Update the forest resources inventory with free-to-grow information and barren and scattered survey information.

Considerations in FMP: The planning composite inventory was updated by MNR with all recent free-to-grow information and barren and scattered survey results. This update was approved in Progress Checkpoint #1 of the planning process.

ii) Use silvicultural survey information to develop the silvicultural program.

Considerations in FMP: The planning composite inventory was updated by MNR with recent free-to-grow and silvicultural effectiveness monitoring information. Silvicultural effectiveness monitoring results were also used in the development of post-renewal forest succession assumptions for the strategic modelling component of LTMD development (what forest units are expected to result from various regeneration treatments). A discussion of silvicultural treatments that are successful on the Whiskey Jack Forest is included in FMP Section 4.2.2.1 Silvicultural Ground Rules and documented in Table FMP-4.

iii) Silvicultural strategies are reflected in the operational renewal program.

Considerations in FMP: For each forest unit, the Silvicultural Ground Rules (Table FMP-4) identify broad silvicultural strategies and specific acceptable operational treatments in accordance with approved provincial silvicultural guides. The strategic renewal assumptions are included in the strategic SFMM modelling during development of the Long-term Management Direction. The linkage between strategic and operational silviculture and the application of the LTMD projected renewal program is discussed in FMP Section 4.4 Renewal and Tending Operations and Table FMP-17. Projections from the LTMD are considered during operational planning of the renewal program. Confirmation that the implementation of the operational silvicultural program will support the LTMD is included in FMP Section 4.9 Comparison of Proposed Operations to the LTMD, the SFMM modelling Final Test of Sustainability (plan supplementary documentation), and Section 5.0 Determination of Sustainability.

iv) The natural condition be considered in development of indicator desirable levels.

Considerations in FMP:

The support tool for the draft Boreal Landscape Guide, the Ontario Landscape Tool (OLT), provides Simulated Ranges Natural of Variation (SRNV) for the indicators included in the model. These SRNV s are based on the best available science and reflect the estimated natural forest condition. These SRNV s will be incorporated into desirable levels for many FMP indicators, and assessed during development of the Long-term Management Direction.

v) Moose habitat shelter patches.

Considerations in FMP:

Moose management strategies are discussed in text Section 2.1.2.3 Management Zones. The Stand and Site Guide directs the consideration of forest cover for moose habitat. Planned and mapped residual forest patches are identified on the geospatial

information layer (MU490_12PRP00.E00) submitted in the FMP. During harvest operations, some patches of mapped residual may be moved as long as the patches are designated as being acceptable to move (e.g. not required in a certain specific location for habitat) and the same amount of residual forest area is retained as was approved in the FMP.

vi) Operations on fine-textured soils.

Considerations in FMP:

This is an operational consideration related to implementation of planned operations. Conditions on Regular Operations (Section 4.2.2.2) are included in the FMP to direct operations on sensitive sites, and conditions to minimize erosion, rutting and compaction.

vii) Quality of site preparation results.

Considerations in FMP:

This is an operational consideration related to implementation of the silvicultural program, including site preparation, as forecast in Table FMP-17. Site preparation quality standards are included in work contracts issued for site preparation to ensure payment for a good quality result, suitable for subsequent planting or seeding treatments. Monitoring and assessment of regeneration (Section 4.7.3) to confirm that Silvicultural Ground Rule (Table FMP-4, Section 4.2.2.1) regeneration standards are met that will contribute to the achievement of management objectives (Section 3.6).

viii) Less common species planted on appropriate sites.

Considerations in FMP:

This is an operational consideration related to implementation of the silvicultural program. Silvicultural Ground Rules (Table FMP-4 and Section 4.2.2.1) identifies acceptable species and regeneration standards for each ground rule on specific ecosites. Forest Operations Prescriptions are prepare annually and confirm specifically what SGR and what acceptable treatments will be carried out on what area during that operating year. Planned silvicultural treatments must conform to approved SGRs.

ix) Slash management in harvest areas.

Considerations in FMP:

Slash pile management and limited loss of productive land to landings and slash piles is included in Conditions on Regular Operations (Section 4.2.2.2).

x) Survey silviculturally treated areas and identify any areas requiring retreatment or tending.

Considerations in FMP:

The monitoring procedures for the assessment of regeneration success are documented in Section 4.7.3 of the forest management plan. Survey methodology will include the timing of assessments and survey for the identification of areas requiring additional treatments. The Silvicultural Ground Rules (Table FMP-4) include reference to regeneration standards used to determine regeneration success.

xi) Adequate tree seed for implementation of the regeneration program.

Considerations in FMP:

Renewal support including tree seed and planting stock required for the five-year term of the plan is discussed in Section 4.4.2.2 Cone Collections and Planting Stock Procurement. Implementation of the identified renewal support activities will ensure

adequate tree seed and planting stock to carry out the forecast renewal program (Table FMP-17).

xii) Road decommissioning strategy.

Considerations in FMP:

Table FMP-18 Road Construction and Use Management identifies all roads to be decommissioned during the plan period. Road use management strategies (Section 4.5.8 and Supplementary Documentation 14) outline use management strategies, including decommissioning and rehabilitation options, when the roads are no longer required for forest management purposes. Road decommissioning is included as a silvicultural strategy in the caribou zone.

xiii) Water crossing monitoring strategy.

Considerations in FMP:

Water crossing monitoring and assessment is discussed in the FMP in Section 4.74 Roads and Water Crossings and in Table FMP-18 (component of road use management strategies) and the associated road Supplementary Documentation. Conditions on water crossings in areas of concern are detailed in Table FMP-19 and supplementary Documentation 13.

xiv) Forestry aggregate pit rehabilitation.

Considerations in FMP:

Forestry Aggregate Pits are discussed in FMP Section 4.5.6 and include operational standards accordance with the FMPM (2009) Appendix VII.

3.2.8 Shifts In Markets or Utilization

The forest management plan is developed to regulate the supply of forest products through time, in addition to strategically planning for the achievement of non-timber objectives over time. The quantity of wood harvested from the Whiskey Jack Forest and where the wood is processed is variable from one year to the next in the 10-year forest management plan period. The uncertain economic times that are being experienced by the forest industry in general were considered by the Planning Team. While shifts in markets or wood utilization may be on-going, it was considered important to provide a supply of timber from the Whiskey Jack Forest in order to provide continued local and regional socio-economic benefits.

Considerations in FMP: Harvest volumes are estimated in the strategic modelling through forest unit yield curves. The planning team analyzed regional and business plan wood supply targets during strategic planning scoping analyses to determine potential and sustainable timber production levels from the Whiskey Jack Forest. The Long-term Management Direction includes specific timber volume targets balanced with other management objectives for the Whiskey Jack Forest. Operational planning resulted in allocated harvest areas with associated volumes related to the projected mill utilization.

3.3 Base Model for Strategic Analysis

The Strategic Forest Management Model (SFMM) was used as the primary analysis tool for the strategic analysis. This tool is used to track the entire Whiskey Jack Forest land base through time, and produce projections of changes to the forest structure and composition for 160 years into the future. SFMM also allows for the evaluation of forested areas and their contribution to forest diversity, timber production, old forest area and wildlife habitat through time. The Base Model serves as the common starting point for all scenarios investigated during development of the long-term management direction.

The first step in development of the Base Model for the management plan LTMD was development of a Base Model Inventory (BMI) used to classify the initial forest land base within the Strategic Forest Management Model. For the BMI, the planning forest resources inventory for the Whiskey Jack Forest was updated to March 31st, 2012.

Secondly, a suite of SFMM modelling inputs for natural forest dynamics, silvicultural options and management options were developed that would provide structure to the projected natural and human-influenced changes projected within the SFMM model.

During development of the Base Model, it was important to correlate the SFMM natural forest dynamics (without fire suppression) to the Simulated Ranges of Natural Variation (SRNV) incorporated into the Ontario Landscape Tool (OLT), so that both models projected similar future natural forest conditions. If this correlation was not completed, there could be a situation where planning teams could not achieve desirable target results, no matter what was projected for harvest and renewal in the Long-term Management Direction. This correlation ensured that OLT SRNVs are achievable, or in fact may identify where certain OLT projections are not reasonable for the FMP considering the planning inventory used. In this latter situation, differences would be identified and desirable levels for management objective indicators would need to be developed from sources other than the OLT model. The first step in this correlation was the development of a SFMM run to simulate the natural forces of change in the forest, which are disturbance (principally fire disturbance with no fire suppression) and old age succession (stands convert to different species composition through time, or stands break up to form younger stands from understory trees). The Natural Scenario (Nature12) is this simulation using the Strategic Forest Management Model (SFMM) of how the forest might develop in the absence of human intervention. The result of the correlation of SFMM natural forest projections (no fire suppression or harvesting) was that natural (old age) succession and fire disturbance (cycles and transitions) were reviewed and refined in SFMM as necessary to align with the OLT SRNV projections using Boreal Forest Landscape Dynamics Simulator (BFOLDs) inputs. This was an iterative process and resulted in the two models generally being comparable for the forest composition classes being reviewed: landscape classes, caribou habitat, old forest area, forest unit area.

Strategic silviculture options were developed to represent the broad renewal treatments appropriate for the forest. Various renewal treatment options (e.g. extensive, basic and intensive silvicultural treatments) were incorporated into the Strategic Forest Management Model for each forest unit (as appropriate), and included assumptions about how the forest will develop after these general treatments are applied, their associated costs, success rates and future forest conditions. Strategic silvicultural options are reflected in the Silvicultural Ground Rules Table FMP-4 and correspond to current or future forest units as described in Section 2.1.2.1 Forest Units. The broad silvicultural assumptions are in accordance with the Silvicultural

Ground Rules (Section 4.2.2.1).

An analysis package was developed, documenting assumptions pertaining to the strategic modelling inputs and the Base Model. The analysis package is included as Supplementary Documentation A to the forest management plan, with Section 6.0 detailing the development of the Base Model Inventory, the Base Model and associated modelling assumptions.

3.3.1 Analysis Package

The outputs of the forest modelling for the Long-term Management Direction are summarized in the Analysis Package for the plan (Supplementary Documentation A, in Appendices 2 and 3). Digital files are included in electronic FMP plan folder (**MU490_2012_FMP_P1_MODEL**) in MU490_2012_FMP_SFMM_inputs.zip and electronic case files are included in MU490_2012_FMP_SFMM_cases.DAT). The decisions made in the development of the LTMD are documented in the Analysis Package.

The strategic silviculture inputs assumptions used to develop the Base Model Inventory and Base Model related to the land base, forest dynamics (forest succession, growth and yield), available silvicultural options, biological limits, and other model assumptions identified by the planning team are included in Supplementary Documentation A – Analysis Package, Section 6.2.3. Also included in the Analysis Package are the results of the key investigations and the details leading to the development of the Long-term Management Direction.

A summary of how the management objectives were represented in the analysis is included in Supplementary Documentation A - Analysis Package (Section 9.1 Management Objective Representation and Interpretation of Results in the Analysis). The Analysis Package also includes a summary of changes made to the base model, and how the achievement of objectives was interpreted from the model results. The modelling results, conclusions of the analysis, and a digital copy of the key model runs evaluated in the scoping analysis (including the LTMD) are also included in file MU490_2012_FMP_SFMM_cases.DAT.

3.4 Desired Forest and Benefits

As part of the forest management plan objective setting process, it is necessary to have an understanding of the forest structure and composition, and the goods and services, which are desired from the forest to achieve a balance of social, economic and environmental needs. The desired forest and benefits are developed considering the background information available, and include the benefits identified locally by the planning team and the Local Citizens Committees, with input from the public. Some desired forest and benefits are inherently suggested by the *Crown Forest Sustainability Act (CFSA)*, the *Forest Management Planning Manual*, MNR guides (e.g. Draft *Forest Management Guide for Boreal Landscapes*); provincial policy (e.g. *Old Growth Policy for Ontario's Crown Forests*) or other direction.

The Planning Team, the Kenora Local Citizens Committee (LCC) and the Red lake District Resource Management Advisory Committee (LCC) were involved in the development of the desired forest and benefits for the 2012-2022 Whiskey Jack Forest FMP. The desired forest and benefits are the forest structure and composition and goods and services, which are desired from the forest to achieve a balance of social, economic, and environmental needs from the forest over time.

Multiple meetings were held from March to October 2010 with representatives from the Local Citizens Committee and the Planning Team. These meetings were held to provide participants with background information on the forest, an overview of landscape level guidelines, and to develop a list of desired forest and benefits and associated desirable and target achievement levels.

The following subsections document the process used to refine the objectives for this 2012 FMP:

- Section 3.4.1 Review and Confirmation of Objectives from the 2004 FMP;
- Section 3.4.2 Indicators Resulting from New MNR Direction;
  - Aboriginal Involvement
  - Local Citizens Committee Effectiveness
  - Habitat for Species At Risk (SARs)
  - Landscape Biodiversity Indicators
  - Various planning and compliance monitoring indicators to be assessed during plan implementation.
- Section 3.4.3 Comments Raised During Desired Forest and Benefits Meetings.

The participation in the Desired Forest and Benefits Meetings by Local Citizens Committee and Planning Team members is documented in the Supplementary Documentation – Summary of Public Consultation.

The final plan objectives and indicators are detailed in Section 3.5 with rationale for desirable levels. The best balance of achievement of plan objectives is discussed in the development of the Long-term Management Direction (Section 3.6). The LTMD was developed to achieve the desired forest conditions and goods and services from the Whiskey Jack Forest as identified by the Local Citizens Committees, Planning Team and the public.

3.4.1 Review Confirmation of Objectives from the 2004 FMP

The Planning Team and Local Citizens Committees (Kenora and Red Lake) reviewed and discussed objectives from the 2004-2024 forest management plan to confirm which objectives were still desired forest and benefits applicable to the 2012 FMP. The following desired forest and benefits from the 2004 FMP were confirmed as being important to include in this forest management plan.

Each 2004 FMP management objective is noted below with reference to the decision to include or not include the objective in this 2012 FMP. Several 2004 FMP objectives are not carried forward as management objectives in this FMP, but will continue to be considered through operational planning or plan implementation strategies.

1. Forest Structure Objective:

The objective is to maintain or move toward a natural age class structure that is within the estimated bounds of natural variation for the Whiskey Jack Forest through management planning and silviculture.

Targets: - Maintain old forest area;
- Forest age class distribution.

Consideration in 2012 FMP:

- Area of old forest assessment required by FMPM and included in the Science and Information in support of Ontario's Forest Management Guides for Landscapes. Old forest indicator carried forward and included in Objective 2 Forest Composition by area of old forest and area of mature and late successional landscape classes.

2. Forest Composition Objective:

The objective is to maintain or move toward a range of forest units and age classes within the bounds of natural variation as developed for the Whiskey Jack Forest.

Targets: - Area of each forest unit by age class;
- Maintain or increase the amount of PRWMX forest unit.

Consideration in 2012 FMP:

- Forest type (forest unit) and age grouping indicators carried forward and included as indicators in Objective 2. Forest Composition as required by the FMPM.
- Red pine and white pine forest (PRW) area indicator carried forward as required by FMPM(2009) and in Science and Information in support of Ontario's Forest Management Guides for Boreal Landscapes.

3. Natural Disturbance Pattern Emulation Objective:

The objective is to emulate natural disturbance patterns, characteristic of the Whiskey Jack Forest.

Targets: - Maintain or move toward a pattern of natural forest disturbance;
- Disturbance size class and frequency distribution;
- Percentage of planned clearcuts >260 ha;
- Amount of peninsular and insular residual forest retained; and
- Retention of wildlife trees.

Consideration in 2012 FMP:

- Natural disturbance pattern (originally required by the *Natural Disturbance Pattern Emulation Guideline)* was initially replaced by mandatory biodiversity indicators as the Science and Information in support of Ontario's Forest Management Guides for Boreal Landscapes (see Section 3.4.2: Indicators Resulting from New MNR Direction). Incorporated into Objective 1: Landscape Pattern. During LTMD development, the Planning Team was informed that the Landscape Guide would not be approved in time for full implementation for 2012 FMPs, therefore the landscape disturbance frequency by size class indicator from the NDPE guide and 2004 FMP was added back into the suite of indicators for the 2012 FMP.
- The stand level residual component from the NDPE guide is now required as per the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales.* Residual and wildlife tree requirements are related to operational practices and are included in the forest management plan as Conditions on Regular Operations (Section 4.2.2.2) and are not included as objectives or indicators.

4. Sustained Wood Supply Objective:

The objective is to provide a predictable and continuous supply of wood to the forest products industry from the Whiskey Jack Forest.

Targets: - Maintain specific minimum annual harvest volume by species group (spruce-pine-fir, poplar and white birch)

Consideration in 2012 FMP:

- Long-term annual harvest volume carried forward as a mandatory FMPM (2009) indicator in Objective 4: Wood Supply.
- Variance of projected harvest volumes between 10-year terms will be assessed during development of the Long-term Management Direction for acceptability to the Planning Team of projected harvest volumes in the short-term and long-term in relation to the balanced achievement of all management objectives.

5. Working with Aboriginal Peoples Objective:

The objective is to work with local Aboriginal peoples, whose communities are situated in or adjacent to the Whiskey Jack Forest, to identify and implement forest operations (harvest, access, renewal, maintenance and protection) that will maintain or enhance social and economic benefits to Aboriginal peoples.

Targets: - Provide opportunity to harvest 10,000 cubic metres, on an annual basis, to members of Grassy Narrows First Nation (Asubpeeschoseewagong Netum Anishinabek).

Consideration in 2012 FMP:

- Harvest area allocations and assignment of licensees will occur during development of the forest management plan. All licensee commitments will be incorporated into the planned operations and reported in Table FMP-14 Planned Harvest Volume and Wood Utilization.

6. Forest Resources for Personal and Commercial Use Objective:

The objective is to make available incidental volumes of timber for other uses such as fuelwood, building logs, furniture and other materials. (These incidental volumes will come from areas

allocated within this FMP).

Targets: - Provide opportunities for the public to obtain fuelwood; and
- Provide opportunities for the public to obtain incidental quantities of timber for a variety of uses including building logs.

Consideration in 2012 FMP:

- Delete as a management objective. Harvest area allocations, including the identification of public fuelwood collection areas, will occur during operational planning for the forest management plan. Provision of fuelwood areas is carried forward and included in harvest area and volume included in Objective 4: Wood Supply. Fuelwood areas are specifically discussed in the FMP text Section 4.2.2.3 Silvicultural Treatments of Special Public Interest.
- Harvest of specific incidental quantities of timber will be considered either during planned harvest allocation development by the SFL (if known) or by MNR after plan implementation through regular incidental harvest volume permits.

7. Tourism, Commercial and Non-Commercial Forest Users Objective:

The objective is to select and prescribe forest operations (harvest, renewal, maintenance, protection and access) that consider the requirements of other forest users, allowing continued use of the forest while minimizing conflict between forest operations and other forest users.

Targets: - Maintain a system of active forest access roads available for public travel;
- Contact licensed tourism operators for RSA negotiations; and
- Minimize conflict between forest industry and all other users.

Consideration in 2012 FMP:

- Delete as a separate forest users management objective. Communication with tourism and other forest users and consideration for values is a requirement of forest management planning in Ontario and does not require a separate objective in order to be implemented. Maintenance of an active road network is a component of Objective 8: Road Access and includes an indicator for road density (See Section 3.5.2.8).
- It is required that all resource-based tourism operators must be contacted early in the planning process and offered the opportunity to negotiate Resource Stewardship Agreements.
- The planning process requires that known stakeholders and identified values be considered during operational planning for harvest, renewal and tending activities and for road access planning. Conflict between the forest industry and other users will be minimized through implementation of this requirement.
- Mandatory consideration for stakeholders and known values are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern, text Section 4.2.2.2 Conditions on Regular Operations, text Section 4.5.3 to 4.5.4 Area of Concern Crossings – Roads, and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).
- Maintenance of road access is a component of the mandatory road density indicator required by the FMPM(2009)(Objective 8: Road Density). See new mandatory

indicators Section 3.4.2, FMPM (2009).

8. Other Land Uses Objective:

The objective is to conduct forest management activities in a manner that considers private land, parks and other land designations or values.

Targets: - Protect known values through implementation of the area of concern prescriptions approved in the forest management plan.

Consideration in 2012 FMP:

- Delete as a separate Other Land Uses management objective.
- The planning process requires that known stakeholders and identified values, including land ownership and management status, be considered during operational planning for harvest, renewal and tending activities and for road access planning.
- Consideration for stakeholders and known values are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern, and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).

9. Cultural Heritage Values Objective:

The objective is to protect identified, registered, or high potential archaeological and cultural heritage sites from conditions that could potentially damage or cause an increase in rates of deterioration.

Targets: - No negative impacts on identified archaeological or cultural heritage values resulting from forest management activities;
- Minimal fibre loss and archaeological mitigation costs through value protection

Consideration in 2012 FMP:

- Delete as a separate Cultural Heritage Values objective.
- The planning process requires that cultural heritage values, including archaeological potential areas, be considered during operational planning for harvest, renewal and tending activities and for road access planning.
- Mandatory consideration for known values, including cultural heritage values, are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).

10. Wildlife Habitat Objectives

10(a) Selected Wildlife Species Objective:

The objective is to provide suitable/preferred habitat within the bounds of natural variability for the selected wildlife species within the Whiskey Jack Forest.

Targets: - Maintain habitat for selected species within a specified range; and
- Avoid any significant reductions in habitat available for selected species.

Consideration in 2012 FMP:

- Modelled wildlife non-spatial preferred habitat is not required for species other than the Species At Risk (carried forward in Objective 3). Habitat for selected species are accounted for in the multiple forest biodiversity, forest composition and structure indicators that are indicators of various habitats (Objectives 1-3).

10(b) Caribou Objective:

The objective is to maintain or improve contribution of the Whiskey Jack Forest to continued range occupancy and healthy populations of woodland caribou in Northwestern Ontario.

Target: - NWEST portion of the forest to contribute to the habitat range for woodland caribou.

Consideration in 2012 FMP:

- Consideration for woodland caribou habitat (a Species At Risk) is carried forward in the 2012 plan in Objective 3: Wildlife Habitat. This consideration is required by the Endangered Species Act 2007 and is in accordance with the Caribou Recovery Plan 2009.
- Management zones were identified, one of which is the area of the forest to be management primarily for woodland caribou habitat. These management zones are discussed in text Section 2.1.2.3.
- The draft *Forest Management Guide for Boreal Landscapes (Landscape Guide)* suggested two new indicators that relate to caribou habitat in the caribou zone.
  - Amount of woodland caribou habitat (refuge, winter)(Objective 3); and
  - Texture (arrangement) of woodland caribou habitat (refuge, winter)(Obj. 3).
- The FMPM(2009) requires an indicator for habitat for forest-dependent Species At Risk. Therefore the Landscape Guide indicator for amount of woodland caribou habitat (first bullet above) also satisfies the FMPM requirement.

10(c) Marten Objective:

The objective is to maintain or move toward having 10-20% of capable marten habitat area in suitable conditions arranged in core areas of 3,000 to 5,000 hectares.

Target: - Maintain specific portion of suitable forest land base in marten core habitat areas.

Consideration in 2012 FMP:

- Marten core areas were required by the *Forest Management Guidelines for the Provision of Marten Habitat* for the 2004 FMP. This habitat management guide is still in effect as the Landscape Guide has not been approved in time for full application for 2012 FMPs. The Science and Information in support of Ontario's Forest Management Guide for Boreal Landscapes also suggests direction and indicators for forest diversity, including landscape forest composition, pattern and texture. The Stand and Site Guide requires the provision of large landscape patches. Therefore, marten core areas are carried forward in the 2012 FMP in Objective 3: Wildlife Habitat, as well as consideration in the new landscape indicators in Objective 1: Landscape Pattern.

10(d) Moose Objective:

The objective is to retain a year round supply of suitable habitat (including foraging and winter habitat) for moose on the Whiskey Jack Forest.

Target: - Amount of preferred habitat for moose foraging and moose winter habitat.

Consideration in 2012 FMP:

- Consideration for moose habitat is carried forward in the 2012 plan.
- Management zones were identified, one of which is the area of the forest to be management primarily for moose habitat. These management zones are discussed in text Section 2.1.2.3.
- Habitat for selected species, including moose, are accounted for in the multiple forest biodiversity, forest composition and structure indicators that are indicators of various habitats.
- The Science and Information in support of Ontario's Forest Management Guide for Boreal Landscapes includes suggested biodiversity indicators for mature and late successional forest and for young forest distribution (see Section 3.4.2: Indicators Resulting from New MNR Direction). These indicators are incorporated into Objective 2: Forest Composition and in Objective 1: Landscape Pattern and will measure some components of moose habitat.
- The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* provides direction for the consideration of Moose Emphasis Areas (MEAs). If MEAs are warranted for the management unit, discussion is included in text Section 2.1.2.3 Management Zones, with detailed analysis of the MEAs included in plan supplementary documentation. Operational planning of harvest areas must consider proportion of area in specific forest composition classes with MEAs if MEAs are identified for a FMP.

10(e) Stick Nest Objective:

The objective is to provide for the protection of nest sites and associated habitat of bald eagle, osprey, great blue heron and other locally significant forest dwelling raptors.

Target: - Minimize negative impacts on stick nests (i.e. bald eagle, great blue heron, osprey, and forest dwelling raptors).

Consideration in 2012 FMP:

- Delete as a separate stick nest management objective.
- The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* provides mandatory direction for prescriptions for the protection of nests for many bird species, including stick nests.
- Mandatory consideration and appropriate prescriptions for the protection of stick nests are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern, text Section 4.2 Prescriptions for Operations, text Section 4.2.2.2 Conditions on Regular Operations, text Section 4.5.3 to 4.5.4 Area of Concern Crossings – Roads, and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values, including stick nests, is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).

11. Soil Objective:

The objective is to minimize any possible adverse effects of forest practices on soil quality.

Targets: - No forest operations in areas where forest practices threaten the long-term site productivity;
- No Forest Operations Compliance Information System (FOCIS) reports with non-compliances related to site damage; and
- Limit area of roads and landings to 1% of area proposed for forest operations.

Consideration in 2012 FMP:

- Delete as a separate forest users management objective.
- The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* provides direction for management practices that prevent, minimize or mitigate site damage, and practices to mitigate erosion, hydrological impacts, loss of productive land, and nutrient retention on shallow soil sites.
- Consideration for sensitive sites is documented in text Section 4.2.2.1 Silvicultural Ground Rules, Section 4.2.2.2 Conditions on Regular Operations, and Section 4.7.2 Monitoring and Assessment for Exceptions.
- The success in implementation of management practices that prevent, minimize or mitigate site damage is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).
- Maintenance of sustainable amounts of Crown managed forest available for timber production is carried forward as it is a mandatory indicator required by the FMPM (2009) in Objective 5: Managed, Crown Forest. This indicator is directly affected by the quantity of productive land converted to roads and landings.

12. Fisheries and Water Quality Function Objective:

The objective is to maintain riparian habitat, water quality and to prevent the harmful alteration, disruption or destruction of fisheries habitat where forest management activities occur.

Targets: - Minimize impact to riparian areas from harvest through the application of no-cut reserves; and
- To implement forest practices that do not create the harmful alteration, disruption or destruction of fisheries habitat without Department of Fisheries and Oceans consent.

Consideration in 2012 FMP:

- Delete as a separate fisheries and water quality management objective.
- The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* provides mandatory direction for the protection of fisheries and water quality values.
- The planning process requires that identified values be considered during operational planning for harvest, renewal and tending activities and for road access planning.
- Mandatory consideration and appropriate prescriptions for the protection of known values are documented in the Table FMP-10 Prescriptions for Areas of Concern, Table FMP-19 Road Crossings, Landings, and Forestry Aggregate Pits in Areas of Concern, text Section 4.2 Prescriptions for Operations, text Section 4.2.2.2 Conditions on Regular Operations, text Section 4.5.3 to 4.5.4 Area of Concern Crossings – Roads, and associated supplementary documentation for areas of concern and road planning.
- The success in implementation of area of concern prescriptions for the protection of values, including aquatic values, is included in the FMP in Objective 10: Forest Values (see new mandatory indicators Section 3.4.2, FMPM (2009)).

13. Silviculture Objective:

The objective is to apply the most appropriate level of silviculture that will ensure the long-term forest sustainability while consistent with all other objectives of this plan.

Target: - Assess and silviculturally treat depleted areas to achieve the level of forest cover and wood supply required to sustain the forest resources of the Whiskey

Jack Forest.
- Lowest achievable silviculture costs per cubic metre.
- Maximize yield and product quality.

Consideration in 2012 FMP:

- Maintenance of sustainable amounts of Crown managed forest available for timber production is carried forward as it is a mandatory indicator required by the FMPM (2009) in Objective 5: Managed, Crown Forest.
- Consideration for silvicultural treatment costs is included in the development of silvicultural option assumptions in the strategic modelling during development of the Long-term Management Direction, therefore the target for lowest silvicultural costs was not specifically carried into this FMP. Projected LTMD silvicultural treatments are determined after consideration for the achievement of management objectives, treatment costs and estimated available funding from the Forest Renewal Trust Fund.
- The FMPM(2009) requires three new indicators of regeneration success (achieve free-growing status), silvicultural success (free-growing to projected forest unit) and strategic silvicultural planning (area treated by planned silvicultural treatment intensity) (see Section 3.4.2: Indicators Resulting from New MNR Direction). These three indicators are incorporated into Objective 9: Forest Renewal.

Successful regeneration (three indicators above) will contribute to the maximization of timber yields through time (Objective 4: Wood Supply).

3.4.2 Indicators Resulting from New MNR Direction

Since the approval of the 2004 FMP, several major MNR guidance documents have been revised or prepared that are being implemented on the Whiskey Jack Forest for the first time for this 2012 forest management plan. These documents contain new (and some previously measured) indicators of forest sustainability to be included in forest management plan development. Where new indicators are prescribed by new MNR direction, the indicators may be assessed in association with existing, confirmed management objectives from the 2004 FMP (if appropriate), or be included with new objectives for the 2012 FMP. The documents containing new MNR direction include:

1. Forest Management Planning Manual for Ontario's Crown Forests (Dec. 2009)

The Forest Management Planning Manual prescribes the requirements for Ontario's forest management planning system including a detailed description of the planning process and the products. The forest management planning cycle, established by the manual, consists of planning, implementation, monitoring and reporting. Since preparation of the 2004 FMP, the FMP manual was revised twice: once in 2004 for implementation by 2007-2011 FMP planning teams, and again in late 2009 for implementation by 2011+ FMP planning teams.

The FMPM(2009) requires certain new indicators of forest sustainability be included in each forest management plan. Indicators that were previously included in the 2004 FMP and are being carried forward into this plan (Section 3.4.1) are not duplicated in the following bullets:

New Indicators Assessed During Plan Preparation:

- Indicator for Aboriginal community involvement in plan development (Obj. 6);

  The Aboriginal communities and MNR recognized that information in previous FMPs on Aboriginal values and background community information have not been as complete or accurate as they could have been with information reviewed or supplied by the communities themselves. Additional indicators have been added to the 2012 FMP (Objective 6) to ensure better communication with Aboriginal communities and input throughout the forest management planning process. These indicators reflect opportunities for involvement provided to, and involvement of Aboriginal Communities in the plan development process. The indicators include:
  (a) Number of Aboriginal communities in or adjacent to the Whiskey Jack Forest with representation on the planning team;
  (b) Number of Aboriginal communities (that are in or adjacent to the Whiskey Jack Forest) that contribute information to the planning process.

- Indicator for Local Citizens Committee self-evaluation of its effectiveness in plan development (Objective 7);

  This is a new objective for this plan included for the associated mandatory indicator from the *Forest Management Planning Manual (2009)* required for this

FMP. This indicator will relate to both the Kenora LCC and the Red Lake LCCs. While involvement of the LCCs has been encouraged and well received during preparation of past plans, the quality and effectiveness of the LCCs involvement will now form one of the indicators by which forest sustainability is measured.

(a) Local citizens committee's self-evaluation of its effectiveness in plan development.

Specific desired forest conditions and goods and services discussed with the Local Citizens Committees are included in Sections 3.4.1 to 3.4.3. The management objectives and indicators are detailed in Section 3.5 with rationale for desirable levels.

- Indicator for habitat for species at risk (Objective 3):

The importance of considering the forest dependent species at risk has been discussed in Section 2.1.3.1. In recognition of this importance, the FMPM (2009) requires the inclusion of an objective indicator related specifically to the non-spatial habitat estimated for Species at Risk (Objective 3).

(a) Area of habitat for forest-associated species at risk.

The only Species at Risk on the Whiskey Jack Forest that have habitat that can be effectively modelled non-spatially through time in the strategic modelling is the woodland caribou. Reporting will occur at the time of Long-term Management Direction and in Year Seven and Year Ten Annual Reports.

New Indicators assessed after plan implementation:

- Actual conifer caribou habitat - % of Conifer Dominated Forest Units in the Caribou Zone (Objective 3);
- Actual conifer purity of caribou habitat - % of Jack Pine and Spruce Species Composition by Forest Unit in the Caribou Zone (Objective 3);
- Actual harvest area by forest unit (% of planned)(Objective 4);
- Actual harvest volume by species group (% of planned)(Objective 4);
- Kilometres of SFL roads per square kilometre of Crown forest (Objective 8);
- Regeneration Success: Percent of harvested forest assessed as free-growing by forest unit (Objective 9);
- Silvicultural Intensity: Planned and actual percent of harvest area treated by silvicultural intensity (Objective 9);
- Silvicultural Success: Planned and actual percent of area successfully regenerated to the projected forest unit by forest unit (Objective 9);
- Percent of forest operation inspections in non-compliance by activity and remedy type (Objective 10);
- Compliance with management practices that prevent, minimize or mitigate site damage (% of inspections in non-compliance, by remedy type)(Objective 11); and
- Compliance with management practices that protect water quality and fish habitat (% of inspections in non-compliance, by remedy type)(Objective 11).

2. Ontario's Woodland Caribou Conservation Plan (Oct. 2009)

The Caribou Conservation Plan provides broad policy direction regarding woodland caribou conservation and recovery. This plan states that in areas licensed for forest management within the continuous extent of caribou occurrence, Ontario will ensure that forest management practices fully consider both current and future Woodland Caribou habitat needs, reflecting natural forest conditions and dynamics. The plan requires that all management plans include:

(a) Provision for caribou habitat during forest management planning by requiring the development of a "dynamic caribou habitat schedule" for each forest management plan.
(b) A caribou-based objective for silviculture to be included in all forest management plans within the geographic distribution of caribou.
(c) Use of the Silvicultural Effectiveness Monitoring to assess the effectiveness of forest renewal for caribou, provide recommendations for improvements, and monitor how successfully logged areas are tracking toward a suitable future habitat condition.
(d) Determination of densities (thresholds) of roads to support caribou persistence.

The Planning Team has considered these requirements and included a dynamic caribou habitat schedule (formerly referred to the "caribou mosaic" in the previous FMPs) in the management zones and strategic planning for the management plan. The following objective indicators are included in the plan and address points (b) to (d) above.

New Indicators:

- Indicator for % of upland conifer dominated forest units in caribou zone. (Objective 3);
- Indicator for % of conifer species composition in caribou zone. (Objective 3);
- Indicator for density of SFL road per square kilometre of Crown forest, specifically in the caribou zone of the forest (Objective 8).

3. (DRAFT) Forest Management Guide for Boreal Landscapes

This draft guide may be considered by 2012 Planning Teams as a guide for maintaining or enhancing natural landscape structure, composition and patterns that provide for the long term health of forest ecosystems in an efficient and effective manner. When approved, the Landscape Guide will replace existing landscape, stand and site scale direction previously found in several other documents. In the meantime, the science package developed to support the Landscape Guide is the most current science and information for many of the landscape related indicators.

The Landscape Guide suggests several new indicators of forest biodiversity be included in each forest management plan. The Planning Team reviewed these suggested indicators and decided to include them in the 2012 FMP:

New Indicators Assessed After Plan Implementation:

- Landscape class area for mature and older age classes (Obj. 2);
- Old forest by appropriate grouping (plan forest unit or landscape guide forest unit)(Obj. 2);
- Red pine and white pine forest unit areas (grouped)(Obj. 2);

- Upland spruce and jack pine dominated forest areas (grouped)(Obj. 2);
- Texture (arrangement) of the mature and old forest (all forest units combined)(Obj. 1);
- Young forest patch size (Obj. 1);
- Amount of woodland caribou habitat (refuge, winter)(Obj. 3); and
- Texture (arrangement) of woodland caribou habitat (refuge, winter)(Obj. 3).

4. Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (March 2010)

The Stand and Site Guide provides direction on various aspects of conserving biodiversity, including aquatic and wetland habitats and shoreline forests, special habitat features (e.g. bird nests, dens, bat hibernacula), and habitat for species at risk. It also addresses topics like road and water crossing construction and maintenance, forestry aggregate pits, and soil and water conservation (e.g. rutting, erosion, nutrient loss), and salvage and biofibre harvest operations. The Stand and Site Guide replaces existing stand and site scale direction previously found in numerous forest management guides.

While most direction in the Stand and Site Guide is "operational direction" at the stand and site level, the guide contains some landscape level direction that may be applicable in the Long-term Management Direction of a forest management plan. Each planning team will determine if any direction from this guide warrants an indicator in the strategic planning of the FMP. No indicators have been included in the Whiskey Jack Forest FMP that relate to Stand and Site Guide direction.

5. Landscape Direction from Existing MNR Guides

Landscape direction from the following guides was included in the 2012 FMP. (Note: These guides would have been replaced by the Landscape Guide, but it was not approved in time for development of this FMP.)

Forest Management Guide for Natural Disturbance Pattern Emulation (2001)

- Landscape pattern (Objective 1), disturbance frequency and planned clearcuts.
- Note: the approved *Stand and Site Guide* replaces stand level direction from the NDPE guide.

Forest Management Guidelines for the Provision of Marten Habitat (1996)

- Marten core habitat (Objective 3).
- During development of the LTMD, it was thought that the marten guide was going to be replaced by the Landscape Guide for use in the FMP. The Planning Team decided to include one additional indicator to approximate the landscape pattern of concentrated (>60%) mature and old conifer (Objective 1) in addition to the other indicators suggested by the Science and Information in support of Ontario's Forest Management Guide for Boreal Landscapes. There was concern that the combination of indicators for mature/old landscape pattern (spatial), mature/late conifer landscape class (non-spatial), and upland pine and spruce (non-spatial) may not cover all the area currently assessed according to the marten habitat guide. This concentrated conifer indicator area is similar to marten core habitat but allows a greater range in sizes and distribution of this older conifer area. This

- indicator is measured through use of the OLT Model. This concentrated conifer landscape pattern indicator was retained in the Whiskey Jack plan after the provincial decision was made to continue use of the marten habitat guide.

3.4.3 Comments Raised during Desired Forest and Benefits Meetings

This section summarizes the main comments or issues raised by the LCC or Planning Team during Desired Forest and Benefits meetings as recorded and synthesized by the Kenora District MNR. The Planning Team response to how this issue was addressed (if possible) within development of the forest management plan is also noted in this table.

Input from Desired Forest and Benefits meeting, Kenora LCC, and Red Lake District Resource Management Advi
Notes synthesized by MNR Kenora District.

FMPM - Forest Management Planning Manual;
LG - Landscape Guide;
SSG - Stand and Site Guide.

Theme		Input	Synthesis	Tracked to Where Used	Phase of Planning Addressed
Forest Management	General	Sustainable forest management/harvest Sustainable, predictable, consistent wood supply	- Sustainable forest management with predictable wood supply	Included in **Objective 4** Wood Supply with mandatory (FMPM) long-term harvest volume indicator.	LTMD-FMP-9-Obj. 4
		No net loss in productive forest land	- No net loss in productive forest land (to roads, chipper piles)	Included in **Objective 5**: Managed Crown Forest with mandatory (FMPM) available land base indicator (desirable level to be determined) Plan text (Section 4.2.2.2) includes **Condition on Regular Operations (Section 4.2.2.2)** to mitigate loss of productive land.	LTMD-FMP-9-Obj. 5
		Less fire supression where silviculturally beneficial	- Less fire prevention	MNR fire suppression policy for designated areas incl KF and WJF. Identify priority areas for surpression during times of escalated fire activity and/or limited resources.	
		Use Boreal Mixedwood Guide	- Use Boreal Mixedwood Guide	May consider for Silvicultural Ground Rules (SGRs) **FMP-4** on limited areas. Manage for mixedwood anyway, but generally want less mixedwood on forest as per OLT. Mandatory (LG) indicator (**Objective 2**) for landscape class area.	LTMD-FMP-9-Obj. 2
		Forest composition and structure similar to pre-mill/natural condition*	- Forest should consist of variable age classes - Produce a healthy, more natural, mixed forest	Mandatory FMPM/LG indicators for forest composition and age included in Objective 2: Forest Composition. Desirable levels based on simulated natural condition from Ontario Landscape Tool (OLT). - pre-harvest, natural condition related to OLT Simulated Natural Range of Variation (SRNV) projections.	LTMD-FMP-9-Obj. 2
		Variable age classes			LTMD-FMP-9-Obj. 1& 2
		Forest should consist of various age harvested areas, older growth			LTMD-FMP-9-Obj. 1& 2
		Increased conifer component/regeneration	- Increase conifer component in forest, esp. Pr/Pw		LTMD-FMP-9-Obj. 2
		Increase Pr/Pw component of forest			LTMD-FMP-9-Obj. 2
		Healthy forest			
		More natural/mixed forest			
		Historic disturbance sizes		Mandatory indicators (LG) for young forest frequency by size class and also for mature/old forest landscape pattern (texture) included in **Objective 1**: Landscape Pattern.	LTMD-FMP-9-Obj. 1
	Harvesting	Pre-harvest inspections for values confirmation, cultural consideration and cost verification	- Conduct pre-harvest planning and site inspections	Operational planning strategy to conduct pre-harvest inspections and mandatory AOC planning to consider identified values (**FMP Section 4.2 Prescriptions for Operations**).	
		Increase red pine harvest	- Increase red pine harvest	Specific harvest area/volume targets could be considered in Long-term Management Directon (LTMD) development while balancing all objectives. Included in text **Section 3.5 Objectives and Indicators and strategic modelling**.	LTMD-FMP-9-Obj 4
		Accessible fuelwood areas	- Fuelwood areas	Areas available for fuelwood collection identified on **planned harvest area maps**. Discussed in text **Section 4.3.1.4 Fuelwood Collection Areas**.	
		Increased old growth	- Increase old forest area	Mandatory (FMPM/LG) indicator for amount old forest included in Objective 2: Forest Composition. Desirable level expected to be related to natural forest SRNV range.	LTMD-FMP-9-Obj. 2
		Cut old growth - selective cut	- Cut old growth - selective cut	Old forest will not be excluded in harvest eligibility criteria (**text Section 3.6.5 Selection of Areas for Harvest**), however harvest of old forest could only occur to the extent that the retention of old forest indicator is still achieved.	

1

Theme	Input	Synthesis	Tracked to Where Used	Phase of Planning Addressed
Clearcut	No clearcutting	- No clearcutting	Clearcutting is an appropriate silvicultural system for the Boreal Forest (**SGRs FMP-4**). All harvest areas will include retention of residual forest patches and individual wildlife trees, so clearcuts are not "cut clear"(**Section 4.2.2.2 Conditions on Regular Operations**). Also operational prescriptions for retention of forest area for protection of other values (e.g. tourism values, aquatic values, wildlife incuding Species At Risk values, etc.) will occur adjacent to harvest areas. Areas suitable for a Boreal mixedwood trial will be identified during plan implementation.	
	Mix of clearcut and other harvest practices	- Use other harvest practices as well as clearcutting		
	Examination of other harvesting techniques (besides clearcutting)			
	Protect advanced growth when clearcutting	- Protect advanced growth during harvest	Silviculturally appropriate for some areas (SGRs FMP-4). Age and species of advanced growth for protection is dependent on the site being harvested. All harvest areas will have residual forest retained and wildlife trees (**Section 4.2.2.2 Conditions on Regular Operations**).	
Buffers	Harvesting to shorelines (where appropriate)	- Harvest to shorelines (where appropriate)	Stand and Site Guide allows harvest to shorelines in certain circumstances (**Table FMP-10 Operational Prescriptions for Areas of Concern**). Application of harvesting of shorelines will be limited to appropriate areas with consideration for other values. **FMP Section 4.2 Prescriptions for Operatrions**	
	No shoreline harvest	- Do not harvest to shorelines		
	Less use of buffers*	- Leave fewer buffers (esp. roadside to reduce accidents)	The SSG dictates some reserve distances (aquatic values/wildlife habitat), other reserves are planning team decisions (road buffers).**FMP Section 4.2 Prescriptions for Operatrions**	
	Buffers between Reserve and Crown Land	- Leave more buffers (FN's, waterbodies, moose corridors)		
	Buffers around larger lakes and streams			
	Cut blocks should be connected via uncut corridors		Wildlife travel corridors planned where needed for caribou zone. SSG mandatory retention of residual forest in and around harvest areas (**Section 4.2.2.2 Conditions on Regular Operations - Residual**).	

1

Theme		Input	Synthesis	Tracked to Where Used	Phase of Planning Addressed
	Silviculture	Utilize prescribed burn	- Use prescribed burns for regeneration and forest health	Available silvicultural tool if (a) is recommended in provincial silvicultural guides for the specific site/species, (b) is warranted on specific sites (SGRs FMP-4) and c) is in accordance with district fire management policy. If appropriate, prescribed burns will be identified in the plan text and forecast renewal **Table FMP-17**. *(will require further Planning Team discussion)*	
		Use of fire in harvested/insect damaged areas for forest health			
		Chemical-free forest	- Do not use any pesticides in the forest	Chemical tending will be considered if the treatment is recommended in provincial silvicultural guides, and is warranted on specific sites. Chemical tending is an important tool for the manipulation of forest cover and will assist in moving toward simulated natural forest condition (OLT conifer targets). *(mayrequire further discussion)*	
		Use of herbicide spray to meet objectives	- Use herbicides to promote conifer regeneration		
		Increase in extensive (intensive?) silviculture	- Increase intensive silviculture	Acceptable treatments in **SGRs FMP-4.** Balance of intensive/extensive treatments relates to the achievement of indicators for forest composition (type) for the LTMD.	LTMD-FMP-4
		Limited treatments	- Increase extensive silviculture		
		Plant areas that were left unplanted		Assessment of Regeneration Success (discussed in text **Section 4.7.3** and related to regeneration standards in **SGRs FMP-4**) will determine if areas require retreatment.	
Access/Roads		Mixture of roaded and remote areas	- Keep some areas of forest remote	Mandatory (FMPM) indicator for road density (**Objective 8**). Consideration during road planning, caribou mosaic, retention of Large Landscape Patches, Resource Stewardship Agreements, **FMP-18 Road Constructon and Use Management**, primary road planning for LTMD, road use management strategies.	LTMD-FMP-9-Obj. 8
		Decreased roads/no excessive road networks			
		Retain Remote Tourism Area			
		Roads closed after harvest in remote areas to protect wildlife	- Close some roads to protect wildlife & remote tourism		
		Rehabilitate/abandon all unused water crossings	- Make forest more accessible (for hunting, firewood, etc.)		
		Increased/maintained road accessibility (for hunters/trappers)			
		Accessible lakes and hunting areas		Roads planning is completed with consideration for road use and other values. Road density will determine quantity of accessible roads, however the location of the roads may change through time as roads are built and others decommissioned. Planning will have consideration for road density by large landscape area (e.g. caribou zone)	
		Fewer restrictions-maximized residential use (hunt, fish, ATV, cottage)			

1

Theme		Input	Synthesis	Tracked to Where Used	Phase of Planning Addressed
Wildlife		Managed for optimal wildlife habitat for benefit of users	- Manage wildlife habitat to benefit users (hunters, outfitters)	FMP will identify Management Zones (**Section 2.1.2.3**) to guide strategies for wildlife habitat management. - Landscape Guide and Stand and Site Guide both provide direction on manipulation of forest cover for the provision of wildlife habitat.	
		Create a variety of habitats	- Manage for multiple species		
		Increased/maintained presence of wildlife			
		Some specific areas managed for moose/deer			
		Increased moose habitat			
		Manage for moose vs. caribou	- Manage for moose vs. caribou		
		Sustainable caribou habitat	- Manage for caribou (specific locations)		LTMD-FMP-9-Obj. 3
		Caribou reoccupation to area near English River			
		Caribou areas should be north of AOU, highways and people			
		Wildlife habitat consistent with guideline recommendations	- Wildlife habitat consistent with guideline recommendations		
		Define wildlife species with forest type		Plan text (**Section 2.1.3 Forest Resources**) will describe main species and habitat (Species At Risk, other reported species and rare species).	
		Less marten core	- Less marten core areas	Large, landscape patches required by LG. No marten guide implementation of core habitat areas with new LG. (note: in the absense of an approved Landscape Guide default will be to the existing approved marten guide - indications are that the large landscape patches (LG) will correspond closely to the marten cores.	
		Identify appropriate wildlife trees	- Identify wildlife trees	SSG requires retention of wildlife trees based on species and flamability (**text Section 4.2.2.2**).	
		Less chemical tending - increased browse	- Increase browse by reducing chemical tending	SGRs in **FMP-4** will identify if tending acceptable. Implement based on wildlife management strategies (**FMP-17 forecast renewal**).	
		Indication of number of wolverine and caribou in forest		FMP manages and discusses wildlife habitat not populations. District does surveys on wildlife populations. *(note out of scope)*	
		Proper assessment of wildlife population and wildlife habitat	- Better idea of wildlife populations (i.e. caribou, wolverine)		
Economics		Maximize industrial benefit	- Maximize industrial use & provide employment - locally	Plan operations in accordance with LTMD to provide sustainable economic opportunities. Intent is to identify long term predictable and sustainable wood supply. - Implement Area of Concern prescriptions in planned operations to protect other identified values. - Social and Economic Description has non-timber users as well as timber users identified as well, support for other forest users are considered in other non-timber objectives. - Social and economic indicators included in FMP for Long-term harvest area and volume **(Obj. 4 Wood Supply)**. - Ecological sustainability indicators included for **Forest Values (Obj. 10) and Soil and Water Resources (Obj. 11).**	LTMD-FMP-9-Obj. 4
		Healthy forest industry			
		Adapt to changes in Forest Industry			
		Employment			
		Keep economic benefits locally (i.e. do not sell to US, other Districts)			
		Maximize forest resources			
		Sustainable, predictable, economic wood supply	- Sustainable, predictable, economic wood supply		LTMD-FMP-9-Obj. 4
		Support all users of forest			
		Managed for other traditional users			

Theme	Input	Synthesis	Tracked to Where Used	Phase of Planning Addressed
Stakeholders	Equal opportunity for all user groups (not forestry first)	- Equal opportunity for all stakeholders	Opportunity for consultation throughout plan production through contact with the planning team, task teams, individual stakeholder communication, several formal public consultation opportunities, comments through LCCs, issue resolution process.	
	Consideration given to active traplines	- Consider active traplines and impacts over lifetime of trapper	Values, including traplines, considered during the AOC planning process and trappers notified as part of the public consultation process.	
	Consider trapline/habitat impacts over lifetime of trapper			
	Stakeholder acceptance of FMP	- Stakeholder acceptance of FMP	Planned operations, Area of Concern planning and Roads planning presented twice to public for comment. RSA contact made with all RBTOs. All known stakeholders notified for comment during public consultation opportunities. (Note: when Whiskey Jack Forest reverted to a Crown unit, RSAs were not applicable, therefore none signed.) All known comments will be recorded for the public consultation summary and must be considered during development of the FMP. Kenora and Red Lake local citizens' committees actively involved in FMP production and informed on a regular basis of progress towards completion and opportunities for involvement.	
	Plan for fire resistant areas around communities	- Plan for fire resistant areas around communities	not specifically an FMP issue - focus is on community (FireSmart) and fire breaks / specific regeneration adjacent to communities. Refer communities to OMNR Fire and Aviation.	
	Roads closed after harvest in remote areas to protect remote tourism		RSA process is implemented (if applicable) and any negotiated prescriptions affecting the forest are included in the FMP. Road use strategies (**FMP-18**) will address road decommissioning after forest management activities completed.	
	Resource Stewardship Agreements	- Maintain RSAs		
	Value of Tourism industry considered in planning		RSA contact made with all RBTOs (if applicable), offer to include formula provided by LCC Tourism Contact to identify tourism value, MNR available for participation in RSA discussions (upon request of RBT operator and/or forest industry. Target of industry interests appropriately addressed as demonstrated by no issue resolution or bump up requests.	

1

Theme		Input	Synthesis	Tracked to Where Used	Phase of Planning Addressed
First Nations		Increased Aboriginal involvement	- Increased Aboriginal participation/involvement	FMP process requires opportunities for Aboriginal consultation and representation on the planning team. - Planning Team has also organized an Aboriginal task team to aid communication and discussion and the Terms of Reference include opportunities for Aboriginal Input to be developed by the Aboriginal Team members and communities and have this included as part of the plan. - Input into Aboriginal reports on values and community background information is also requested by the Planning Team and forms an indicator in **Objective 6**. - Mandatory FMPM indicator for Aboriginal Involvement in Planning included in **Objective 6**.	LTMD-FMP-9-Obj. 6
		Increased Aboriginal participation in forest management planning			
		Increased cooperation between industry and First Nations	- Increased cooperation between industry and First Nations		
		First Nation employment			
		Aboriginal leading studies of traditional use and values	- Aboriginal-led studies of traditional use and values	Terms of Reference include opportunities for Aboriginal Input to be developed by the Aboriginal Team members and communities and have this included as part of the plan.	
		Protect medicinal herbs, natural medicines	- Protect medicinal herbs, sacred/historic sites		
		Protect sacred/historic sites			
Other		Adaptable to climate change (genetic modifications)	- Adaptable to climate change	Provincial acknowedgement, but no clear direction on operational strategies to be included in FMPs.	
		Clear running rivers/streams	- Clean lands and waters	SSG direction for protection of aquatic values incorparated in **Table FMP-10,** Conditions on Regular Operaitons (**Section 4.2.2.2**) and operational planning.	
		No garbage on site after logging/mining		Standard Operating Practice to remove garbage from forest operation's work sites when finished. Compliance and Enforcement item (not planning)	

1

3.5 Objectives and Indicators

The desired forest conditions and goods and services from the Whiskey Jack Forest as discussed by the Planning Team and Local Citizens Committees were reviewed and resulted in the management objectives to be strategically planned for and assessed for achievement in this 2012-2022 FMP. The process of finalizing management objectives and assigning appropriate desirable and target levels for objective indicators are described in the following subsections:

1. Finalize plan management objectives and assign relevant indicators of objective achievement (included in Section 3.5.2 documentation);
2. General approach to determine desirable levels for indicators (Section 3.5.1); and
3. Document desirable and target levels for objective indicators and provide rationale for choice of these levels (Section 3.5.2).

A summary of the specific management objectives for this plan is included in Section 3.5.2. For each objective, an indicator or multiple indicators are identified including the actual "measure" for each indicator, timing of assessment, the general rationale for desirable levels for each indicator, and references where scoping investigation results influenced the setting of desirable and target levels for indicators.

The Analysis Package documents strategic modelling inputs (Parts 1, 2, 3), results and conclusions for the development of management objectives and scoping investigations (Parts 4, 5). The Analysis Package is Supplementary Documentation A and is included as FMP file: MU490_2012_FMP_P1_TXT_AnPack.PDF.

3.5.1 General Approach to Determining Desirable Levels for Indicators

The Forest Management Planning Manual (2009) (FMPM) requires objectives for natural landscape patterns, forest structure and composition, and distribution and abundance of forest ecosystems. For these objectives, the FMPM requires indicators of landscape pattern, area by forest unit and development stage, and amount and distribution of old growth forest to be included in a forest management plan (FMP). The FMPM refers to forest management guides for the specific indicators and desirable levels for which a target will be established. In addition to the forest management guides, when developing objectives for the amount and distribution of old growth forest, planning teams are to follow direction in the Old Growth Policy for Ontario's Crown Forest (2003).

For this Whiskey Jack Forest FMP, the desirable levels for certain indicators of objective achievement were determined after analysis of a simulated natural forest scenario, which estimated how the forest might develop in the absence of human intervention. The Regional Science and Information Packages and Ontario Landscape Tool include the most current science-based estimates of the natural forest condition. The Simulated Range of Natural Variation (SRNV) estimates in the OLT are forest management unit specific and are both area and landscape pattern based. For each of the indicators required by the FMPM, the planning team used the Regional Specific Science and Information Packages and/or Ontario's Landscape Tool to identify specific indicators for their plan, and used the associated SRNV to identify desired levels. The current levels on the management unit for each indicator were also considered when developing targets. The planning for a future forest condition that is

comparable to OLT natural forest condition projections was the primary consideration for development of the LTMD.

The OLT SRNV replaces the Strategic Forest Management Model (SFMM) based natural benchmark approach. The estimates of landscape pattern, area by forest unit and development stage, and amount and distribution of mature and old forest found in the Science and Information Packages are based on current science. The SRNV estimates are robust but it is not appropriate to compare them to SFMM natural benchmarks and wildlife habitat models that were used to develop desired levels and targets in previous forest management plans.

Indicators of forest composition and structure, proportion of old forest and wildlife habitat are examples of indicators with desirable levels determined in relation to the simulated ranges of natural variation. During development of the LTMD, SFMM results were compared to the SRNV for relevant indicators and reviewed to see if the estimated SRNVs were reasonable desirable levels for these indicators for the FMP.

Some of the indicators are not based on strategic modelling; e.g., road density, compliance, Aboriginal involvement. Desirable levels for other indicators were determined after analysis of the quantity that was currently or historically available from the forest, or the amount that can be sustainably produced while considering the achievement of all objectives (e.g. harvest area, harvest volumes) or the quantity that was expected to be achieved through implementation of the plan (e.g. compliance with area of concern prescriptions, actual harvest area, harvest volume and deliveries to mill, areas renewed to free-growing status, road density).

Spatial analyses were used to assess the potential of the Whiskey Jack Forest to produce marten core habitat and landscape pattern by specific planned clearcut size classes. Scoping investigations for various indicators of forest composition, structure and pattern were conducted early in the development of the LTMD and were considered in the determination of desirable and target levels for the desired forest and benefits from the Whiskey Jack Forest (documented in Section 3.5.2).

3.5.2 Management Objectives, Indicators and Desirable Levels

The list of desired forest and benefits, past management plans for the Whiskey Jack Forest, and MNR sources of direction (including Figure A-3 from the *Forest Management Planning Manual for Ontario's Crown Forest, 2009*) and forest management guides were used to develop plan objectives, indicators of objective achievement, desirable levels, and targets for the 2012 Whiskey Jack FMP.

As per direction in the 2009 FMPM, objective categories, criteria and indicators from the Crown Forest Sustainability Act (CFSA) objective categories were developed. A total of 30 indicators of objective achievement were developed by the Planning Team for the long-term management direction for this plan.

A management objective was developed for each desired forest and benefit indicator (or group of related indicators) identified for the plan. A desirable level and the timeframe for achievement were also developed for each indicator of objective achievement. Only indicators that could be quantified were selected for the management plan.

The Strategic Forest Management Model (SFMM) was used to develop a Long-term Management Direction that balances the achievement of certain management objectives over time (those that can be modelled non-spatially through time). The objectives considered in the Long-term Management Direction include forest composition and age class structure, proportion of old forest areas, areas of red pine and white pine, available forest area, habitat for woodland caribou (Species At Risk), harvest areas, and harvest volumes.

A process of repetitive analyses was conducted to balance the achievement of management objectives while developing a Long-term Management Direction for the Whiskey Jack Forest. Results or findings of the strategic scoping analyses were used to guide the balancing of management objectives. During LTMD development, the Planning Team was forced to make trade-offs for conflicting management objectives or where the land base of the Whiskey Jack Forest did not allow achievement of desirable levels in the short or medium-term between multiple indicators. Trade-offs were also required when the achievement of certain desired forest conditions conflicted with the provision of desired goods and services, or vice versa. If desirable levels could not be reached in this 10-year plan period, short-term compromises were reached, and targets for this plan period were established to allow movement towards the desirable levels for the indicator.

A summary of the plan objectives, indicators of objective achievement, desirable levels, targets and timing of assessment follows in this text section and is included in Table FMP-9. The following text also described the rationale for desirable and target levels for each indicator and references where scoping investigation results influenced the setting of desirable and target levels for indicators.

3.5.2.1 Objective 1: Landscape Pattern

Objective 1: Landscape Pattern:
"To emulate natural disturbance and landscape patterns characteristic of the management unit."

This objective is carried forward from the 2004 FMP in accordance with the *Forest Management Guide for Natural Disturbance Pattern Emulation (2001*) and also addresses a landscape pattern indicator from the *Forest Management Planning Manual (2009)* required for this FMP.

Indicator: (1a) % of polygons with >60% mature and old forest

Timing of Assessment: Completion of proposed LTMD,
Completion of Phase I Ops Planning, and
Year 10 Annual Report.

How Measured: Spatial measurement in OLT model at 500 ha and 5,000 ha scales.

Desirable Level: The desirable level is to have the landscape pattern consistent with OLT percentage projections for mature/old forest established for the forest (Table 9).

Table 9 Desirable Level for Percent of Polygons with >60% Mature or Old Forest

Analysis Scale	Plan Start 2012 Percentage	Minimum Desirable Percentage
Scale: 500 ha hexagon	27%	35%
Scale: 5,000 ha hexagon	18%	28%

Target Level: Movement towards desirable level during this plan period.

Rationale for Desirable and Target Levels:
This landscape pattern indicator is assessed to determine whether the proposed plan activities will create a landscape pattern consistent with historic natural disturbances. The minimum desirable level for proportions of mature and old forest were calculated by the Ontario Landscape Tool and accepted by the Planning Team as the best estimation of the natural forest condition. The target level (movement towards desirable level) recognizes that it is almost impossible to change a current landscape pattern to match desirable levels in one 10-year plan period given the starting point or pattern of the forest at Plan Start.

Indicator: (1b) Young Forest Patch Size by Size Class

Timing of Assessment: Completion of proposed LTMD,
Completion of Phase I Ops Planning, and
Year 10 Annual Report.

How Measured: Spatial measurement in OLT model.

Desirable Level: The desirable level is to have young forest landscape pattern consistent with OLT projections by size class calculated for the forest (Table 10).

Table 10 Young Forest Frequency Percentage by Size Class

Young Forest Patch Size Class	Plan Start Percentage	Desirable Percentage
1 - 100 ha	63%	52%
101 - 250 ha	19%	15%
251 - 500 ha	7%	10%
501 - 1,000 ha	5%	8%
1,001 - 2,500 ha	4%	8%
2,501 - 5,000 ha	1%	4%
5,001 - 10,000 ha	1%	3%
10,000 - 20, 000 ha	0%	2%
> 20,000 ha	0%	1%

Target Level: Movement towards desirable level during this plan period.

Rationale for Desirable and Target Levels: This indicator for natural disturbance pattern of the forest is measured by the young forest landscape pattern. The Plan Start and Plan End young forest frequency distribution is measured using the OLT model with the updated forest inventories and is compared to the natural disturbance frequency template supplied by MNR. This natural template was derived using the best current available information which comes from the science information built into the OLT model. Achievement of the template frequency distribution of young forest by size class is the desirable level. The target level (movement towards desirable level) recognizes that it is almost impossible to change a current landscape pattern to match desirable levels in one 10-year plan period given the starting point or pattern of the forest at Plan Start. The timeframe in which the desirable level can be achieved is also limited by the layout of the planned harvest allocations that must adhere to the standard that 80% of planned clearcuts are to be <=260 hectares in size (NDPE Guide), the same size classes that should be reduced to reach the desirable level for this indicator.

Indicator: (1c) % of polygons with >60% mature and old conifer forest

The Planning Team decided to include one indicator to approximate the landscape pattern of concentrated (>60%) mature and old conifer in addition to the other indicators suggested by the Science and Information in support of Ontario's Forest Management Guide for Boreal Landscapes. There was concern that the combination of indicators for mature/old landscape pattern (spatial), mature/late conifer landscape class (non-spatial), and upland pine and spruce (non-spatial) may not cover all the area currently assessed according to the marten habitat guide. This concentrated conifer indicator area is similar to marten core habitat but allows a

greater range in sizes and distribution of this older conifer area. This indicator was retained in the Whiskey Jack plan after the provincial decision was made to continue use of the marten habitat guide.

Timing of Assessment: Completion of proposed LTMD,
Completion of Phase I Ops Planning, and
Year 10 Annual Report.

How Measured: Spatial measurement in OLT model at 500 ha and 5,000 ha scales.

Desirable Level: The desirable level is to have the landscape pattern consistent with OLT percentage projections for mature/old conifer forest established for the forest (Table 11).

Table 11 Desirable Level for Percent of Polygons with >60% Mature or Old Conifer Forest

Analysis Scale	Plan Start 2012 Percentage	Minimum Desirable Percentage
Scale: 500 ha hexagon	4%	19%
Scale: 5,000 ha hexagon	1%	9%

Target Level: Movement towards desirable level during this plan period.

Rationale for Desirable and Target Levels:
This landscape pattern indicator is assessed to determine whether the proposed plan activities will create a landscape pattern consistent with historic natural disturbances. The minimum desirable level for proportions of mature and old conifer forest were calculated by the Ontario Landscape Tool and accepted by the Planning Team as the best estimation of the natural forest condition. The target level (movement towards desirable level) recognizes that it is almost impossible to change a current landscape pattern to match desirable levels in one 10-year plan period given the starting point or pattern of the forest at Plan Start.

3.5.2.2 Objective 2: Forest Composition

Objective 2: Forest Composition:
"To maintain or move towards a natural range of forest composition and age distribution."

This objective combines several objectives carried forward from the 2004 FMP and includes indicators to address two indicators from the *Forest Management Planning Manual (2009)* required for this FMP (area by forest unit and age grouping, amount and distribution of old forest).

Indicator: (2a) Crown Productive Forest by Landscape Class

This indicator contributes to the assessment of forest composition and development stage as required by the FMPM as previously noted, but more specifically this indicator was included to address the indicator for assessment of landscape class that is included in the draft *Forest Management Guide for Landscapes* (Landscape Guide). While this guide is not approved for implementation in the Boreal Forest, the Planning Team decided that the inclusion of an indicator for landscape class area was pro-active and would provide valuable information for reference and determination of trends for the next forest management plan. Mature and late successional landscape classes were considered for this indicator in accordance with regional FMP training direction and the milestones table prepared and considered according to Science and Information in support of Ontario's Forest Management Guide for Boreal Landscapes during preparation of Table FMP-9.

Timing of Assessment: Completion of proposed LTMD, and
Year 7 and Year 10 Annual Reports.

How Measured: SFMM Crown productive area by mature/late successional provincial Landscape Class projected through time.

Desirable Level: The desirable level is to maintain the mature and late successional landscape class areas at or above the minimum of the lower interquartile hectare range (Simulated Range of Natural Variation)(SRNV) for each mature and late successional landscape as projected by the Ontario Landscape Tool for the Whiskey Jack Forest (Table 12).

Table 12 Minimum Desirable Area by Landscape Class

Landscape Class	Plan Start Ha.	Minimum Desirable Ha.
Mature/Late Balsam	8,361	8,706
Mature/Late Lowland	12,695	12,845
Mature/Late Hardwood	104,760	43,021
Mature/Late Conifer	182,885	178,461

Target Level: Same as desirable level measured in the medium term (Terms 4-8).

Rationale for Desirable and Target Levels: The Ontario Landscape Tool (OLT) provides an analytical projection of the range of forest types/age class structure for the Whiskey Jack Forest. The minimum SRNV for mature/late successional landscape classes was adopted as the

desirable level and was considered to be the best available science on the natural forest structure. Target levels were kept the same as desirable levels for each of the landscape classes in this indicator and are measured in the medium term (Terms 3-8). While two of the landscape classes achieved desirable levels with Plan Start conditions, the two smallest landscape classes (ML Balsam, ML Lowland) decreased slightly in area in Term 2, contrary to desirable levels, therefore a short-term target timeframe corresponding to this 10-year plan period was not feasible for this indicator's target timeframe. All desirable and target levels can be achieved in the medium term.

Indicator: (2b) Crown Productive Forest by Forest Unit and Age Grouping

Timing of Assessment: Completion of proposed LTMD, and Year 7 and Year 10 Annual Reports.

How Measured: SFMM Crown productive forest unit area grouped by (a) young/immature and (b) mature and late successional age groupings projected through time.

Desirable Level: The desirable level is to achieve and maintain productive forest area by forest unit and age grouping at or above the minimum SRNV area projected by OLT (Table 13**Table 25**).

Table 13 Minimum Desirable Area by Forest Unit and Age Grouping

Forest Unit / Age Grouping	Plan Start Ha.	Min. Desirable Ha.
BFM - Young/Immature	18,788	1,948
- Mature/Late	8,361	8,361
CMX - Young/Immature	57,387	11,696
- Mature/Late	31,106	24,197
HMX - Young/Immature	51,632	21,591
- Mature/Late	55,608	19,993
OCL - Young/Immature	187	465
- Mature/Late	2,029	1,499
OTH - Young/Immature	162	448
- Mature/Late	1,833	1,240
PJD - Young/Immature	133,098	106,124
- Mature/Late	49,734	52,493
PJM - Young/Immature	29,870	36,541
- Mature/Late	31,975	27,435
POD - Young/Immature	26,658	12,670
- Mature/Late	47,319	12,933
PRW - Young/Immature	635	635
- Mature/Late	2,677	1,367
SBL - Young/Immature	6,945	3,667
- Mature/Late	10,666	10,078
SPD - Young/Immature	67,038	6,479
- Mature/Late	45,748	34,643
SPM - Young/Immature	24,292	17,441
- Mature/Late	21,645	21,733

Target Level: The target level is the same as the desirable level to be measured in the medium term (30-80 years).

Rationale for Desirable and Target Levels: The minimum Simulated Range of Natural Variation area by forest unit and age grouping summarized from the OLT model was adopted as the desirable level for this indicator. The target level was the same as the desirable level but measured in the medium term.

Many forest unit/age grouping areas achieve desirable levels with Plan Start conditions, however some forest unit/age grouping areas are projected to need more time to achieve desirable levels. The medium-term timeframe for target achievement is needed to stabilize the majority of forest unit – age grouping classes. With 12 forest units each having two age groupings, there is considerable variation in movement towards or away from the desirable levels in any given 10-year term. Therefore, a medium-term target was selected since shorter term assessment for overall forest condition achievement would be problematic (how to assess if several of the 24 forest unit – age combinations were not at desirable levels at various times) and this indicator was considered less critical to achieve in the short or medium term as compared to landscape classes (Indicator 2a), old forest area (Indicator 2c) or upland pine and spruce forest area (Indicator 2e).

Indicator: (2c) Amount and Distribution of Old Forest

This indicator is required by the FMPM and the *Old Growth Policy for Ontario's Crown Forests.*

Timing of Assessment: Completion of proposed LTMD, and
Year 7 and Year 10 Annual Reports.

How Measured: SFMM old forest grouping area projected through time. Old forest groups and definitions are based on late successional (old) forest classification from the OLT model summarized into forest unit old forest groupings.

Desirable Level: The desirable level is to achieve and maintain old forest area by forest unit group at or above the minimum desirable hectares (Table 14).

Table 14 Minimum Desirable Percentage by Old Forest Group

Forest Unit Group / Onset Age (years)	Plan Start Level (ha)	Minimum Desirable Level (ha)
OLD - BFo >80 years	3,707	5,315
OLD - CLo >100 years	1,851	1,328
OLD - CMo >100 years	8,730	20,665
OLD - HWo >100 years	16,931	7,050
OLD - OHo >90 years	1,252	992
OLD - PJo >100 years	23,267	20,800
OLD - SLo >160 years	2,007	3,319
OLD - SPo >110-120 years	10,155	25,840
OLD - PRW >140 years	457	457

Target Level: Overall movement towards desirable level as projected for the end of the plan period.

Rationale for Desirable and Target Levels: The Ontario Landscape Tool (OLT) provides an analytical projection of the range of forest types/age class structure for the Whiskey Jack Forest. The desirable level was set be a minimum of the SRNV by old forest grouping. Red pine and white pine forest area is not well represented in the OLT model. Therefore the desirable level for PRW Old Forest was set to maintain a minimum of area as existed at Plan Start. The target level allows overall movement towards the desirable level within this 10-year plan period, with allowance for minor deviations by individual old forest groupings.

Indicator: (2d) Amount of Red Pine and White Pine Forests

This indicator addresses the *Old Growth Policy for Ontario's Crown Forests*.

Timing of Assessment: Completion of proposed LTMD, and
Year 7 and Year 10 Annual Reports.

How Measured: SFMM PRW productive forest unit area (all ages) projected through time.

Desirable Level: The desirable level is to maintain a minimum of the Plan Start area of the PRW forest unit (3,312 ha).

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: The Planning Team investigated the estimated amount of red pine and white pine forest that would occur in the natural forest through use of the Ontario Landscape Tool natural simulation. The PRW Plan Start value from the OLT Tool was reported to be 856 hectares, significantly lower than our inventory data. The current forest inventory has 3,312 hectares of PRW forest unit area at Plan Start, an amount thought by the Planning Team to be less than historically occurred. The discrepancy between PRW estimates in the inventory and OLT model were discussed and the conclusion was that the OLT model did not accurately define the PRW land base. Therefore, unlike other forest condition indicators, the OLT SRNV was not used as the desirable level for this indicator and the Planning Team developed a different approach.

The Planning Team recognized the need to maintain the current area of red pine and white pine forest and preferably increase the PRW forest area through time. Strategic modelling over the next 100+ years suggested the desirable level was achievable and therefore the target level was the same as the desirable level. Since strategic modelling is less reliable the farther into the future that is projected, achievement of this indicator beyond 100 years was not forced in the LTMD through modelling constraints.

Indicator: (2e) Amount of Upland Pine and Spruce Forest

While not required, this indicator is suggested by the Science and Information in support of Ontario's Forest Management Guide for Boreal Landscapes and was endorsed by the Planning Team for inclusion in the plan.

Timing of Assessment: Completion of proposed LTMD, and
Year 7 and Year 10 Annual Reports.

How Measured: SFMM productive forest unit area projected through time for the PJD, PJM, SPD and SPM forest units.

Desirable Level: The desirable level is to maintain a minimum of 457,260 ha upland pine and spruce as per OLT minimum SRNV projections for upland conifer.

Target Level: Movement towards the desirable level in this 10-year plan period.

Rationale for Desirable and Target Levels: The Ontario Landscape Tool (OLT) provides an analytical projection of the range of forest types for the Whiskey Jack Forest including the estimated range upland conifer in the natural forest. OLT projected a minimum of 457,260 hectares of upland conifer (jack pine and spruce) which was adopted as the desirable level. Strategic modelling confirmed that this desirable level was achievable, though the Planning Team was very aware that this magnitude of increase in upland conifer as compared to the Plan Start level (403,400 ha) would be a significant consideration during development of Silvicultural Ground Rules (Section 4.2.2.1, Table FMP-4) and Operational Planning (harvest Section 4.3 and Renewal and Tending Section 4.4). Therefore, movement towards the desirable level in this plan period was adopted as the target level.

3.5.2.3 Objective 3: Wildlife Habitat

Objective 3: Wildlife Habitat:
"To maintain forest function for wildlife habitat in the management unit."

This objective is carried forward from the 2004 FMP and also addresses an indicator of non-spatial wildlife habitat from the *Forest Management Planning Manual (2009)* required for this FMP. The indicator for marten core habitat area management is carried forward from the 2004 FMP in accordance with the *Forest Management Guidelines for the Provision of Marten Habitat (MNR, 1996)* and also is a landscape pattern indicator for this plan.

Indicator: (3a) Area of Habitat for Forest-dependent Species At Risk

This indicator is required by the FMPM (2009) and recognizes the special consideration for Species At Risk and their habitat as mandated by the Endangered Species Act (provincial) and Species At Risk Act (federal). Woodland caribou habitat is the only Species at Risk habitat measured for this indicator. The successful implementation of prescriptions for the protection of Species At Risk habitat values will be assessed in Indicator 10a.

Timing of Assessment: Completion of proposed LTMD, and
Year 10 Annual Report.

How Measured: SFMM model includes extra "species" in yield curves to track area by caribou habitat type (3 types: refuge, winter used and winter preferred). Non-spatial caribou habitat is measured for the caribou zone only (not the entire forest).

Desirable Level: The desirable level is to achieve and then maintain preferred habitat for Species At Risk (woodland caribou) at or above minimum SRNV level (Table 15).

Table 15 Minimum Desirable Habitat for Species At Risk

Wildlife Habitat in caribou zone	Plan Start Level (ha)	Minimum Desirable Level (ha)
Caribou - refuge	103,969	147,605
Caribou - winter used	45,055	26,809
Caribou - winter preferred	20,581	36,912

Target Level: Movement towards desirable level over next 30 years.

Rationale for Desirable and Target Levels: The Ontario Landscape Tool (OLT) provides an analytical projection of the range of forest types and age structure for the Whiskey Jack Forest including the estimated range caribou habitat within the caribou zone. OLT projections were reviewed and SFMM investigations confirmed these minimum SRNV levels were achievable and sustainable. Therefore the desirable level was accepted by the Planning Team. The target level was adjusted to allow a 30 year timeframe for achievement of the desirable level since caribou refuge and winter preferred habitats are projected to not move towards the desirable level in Term 2 (both) or Term 3 (winter preferred only), but do achieve and maintain the target levels from Term 4 onwards.

Indicator: (3b) % of Polygons with >60% Caribou Refuge Habitat in Caribou Zone

Timing of Assessment: Completion of proposed LTMD, and Year 10 Annual Report.

How Measured: Spatial measurement in OLT model at 6,000 ha and 30,000 ha scales.

Desirable Level: The desirable level is to have the landscape pattern consistent with OLT percentage projections for caribou refuge habitat in the caribou zone established for the forest (Table 16).

Table 16 Desirable Level for Percent of Polygons with >60% Caribou Refuge Habitat

Caribou refuge habitat in caribou zone	Plan Start (%)	Minimum Desirable Level (%)
Scale: 6,000 ha hexagon	36%	87%
Scale: 30,000 ha hexagon	25%	92%

Target Level: Movement towards desirable level during this plan period.

Rationale for Desirable and Target Levels: This indicator is assessed to determine whether the proposed plan activities will create a landscape pattern consistent with the natural forest condition. The minimum desirable level for proportions of caribou habitat in the caribou zone were calculated by the Ontario Landscape Tool and accepted by the Planning Team as the best estimation of the natural forest condition. The target level (movement towards desirable level) recognizes that it is difficult to change a current landscape pattern to match desirable levels in one 10-year plan period given the starting point or pattern of the forest at Plan Start.

Indicator: (3c) % of Polygons with >60% Caribou Winter Habitat in Caribou Zone

Timing of Assessment: Completion of proposed LTMD, and Year 10 Annual Report.

How Measured: Spatial measurement in OLT model at 6,000 ha and 30,000 ha scales.

Desirable Level: The desirable level is to have the landscape pattern consistent with OLT percentage projections for caribou winter habitat in the caribou zone established for the forest (Table 17).

Table 17 Desirable Level for Percent of Polygons with >60% Caribou Winter Habitat

Caribou winter habitat in caribou zone	Plan Start (%)	Minimum Desirable Level (%)
Scale: 6,000 ha hexagon	0%	45%
Scale: 30,000 ha hexagon	0%	40%

Target Level: Movement towards desirable level during this plan period.

Rationale for Desirable and Target Levels: This indicator is assessed to determine whether the proposed plan activities will create a landscape pattern consistent with the natural forest condition. The minimum desirable level for proportions of caribou habitat in the caribou zone were calculated by the Ontario Landscape Tool and accepted by the Planning Team as the best estimation of the natural forest condition. The target level (movement towards desirable level)

recognizes that it is difficult to change a current landscape pattern to match desirable levels in one 10-year plan period given the starting point (0%) or pattern of the forest at Plan Start.

Indicator: (3d) Landscape Pattern - Interior, Marten Core Habitat

This indicator is required by the *Forest Management Guidelines for the Provision of Marten Habitat (1996).*

Timing of Assessment: Completion of proposed LTMD, and Year 7 and Year 10 Annual Reports.

How Measured: % suitable of capable marten habitat in core areas as measured in Marten Analyst2 according to marten suitable and capable habitat definitions applied to the updated planning inventory.

Desirable Level: The desirable level is to retain 10-20% of capable marten habitat area in suitable conditions in core areas of 3,000 to 5,000 ha.

Target Level: The target level acceptable in this plan is 10-20% of capable marten habitat area in suitable conditions in core areas of greater than 1,000 ha moving towards the desirable level measured in 2072.

Rationale for Desirable and Target Levels: Investigations for wildlife habitat, including marten core areas, was conducted both spatially and non-spatially. Initially, the spatial distribution of marten core habitat areas were compared to the 2004-2024 FMP marten core areas and suitable marten habitat was assessed for this plan period through to the next 60 years. Marten cores were also compared to the dynamic caribou habitat subunits and schedule to ensure consistency. This scoping confirmed continuation of the marten cores from the 2004 FMP which set the marten habitat deferrals for the strategic modelling. The proposed spatial layout of the marten core areas was recommended by the Planning Team and reviewed by regional Plan Advisors and the Local Citizens Committees. All parties were in favour of the recommended spatial distribution of the marten core habitat areas.

Percentage suitable in cores of total capable habitat measured spatially using OMA2. Desired level reflects marten habitat guideline. Initial analysis was completed to determine a favourable core deferral scenario with respect to marten habitat and spatial distribution. Marten cores were developed to meet guideline levels and to incorporate the best concentrations of suitable habitat, spatially distributed across the forest for the next 60 years.

The target level was varied by Planning Team decision and review of core achievement analysis. The target level was reduced to allow consideration of suitable habitat in core areas of greater than 1,000 ha suitable habitat where additional core areas were spatially important on the forest. Target % levels include some smaller, higher quality cores that will provide functional marten habitat for the next 60 years. Since marten core area analyses use 20 year increments for the projected suitable habitat percentages, the timeframe for the target was extended to 60 years to coincide with the analysis time periods and projected increase in suitable core habitat through time.

Indicator: (3e) % of Conifer Dominated Upland Forest Units in Caribou Zone

This indicator contributes to the silvicultural objective requirement of *Ontario's Woodland Caribou Conservation Plan (2009)*.

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: This indicator is calculated from an updated Base Model Inventory. In the caribou zone, total productive forest area of targeted conifer forest units (only PJD, PJM, SBL, SPD and SPM forest units) divided by the total productive area, expressed as a percentage. Information is reported by forest unit, but indicator is for combined total percentage of the targeted forest units in the caribou zone (not individually).

Desirable Level: The desirable level is to maintain or increase percentage of upland conifer dominated forest units in the caribou zone.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: The specific targeted forest units are the purer conifer forest units which have the capability of producing better caribou habitat than mixedwoods do. Conifer forest composition is critical to woodland caribou habitat (Species At Risk) therefore a reduction in hardwood and mixedwood forests in the caribou zone is desirable and will result in an increase in preferred caribou habitat. The desirable and target levels are to maintain or increase the percentage of specific conifer dominated forest unit area in the caribou zone at or above the Plan Start level of 75%.

Indicator: (3f) % of Conifer Species Composition in Caribou Zone

This indicator contributes to the silvicultural objective requirement of *Ontario's Woodland Caribou Conservation Plan (2009)*.

Timing of Assessment: Year 7 and Year 10 Annual Reports.
Note: This assessment is short-term but reporting will continue over future planning periods. The assessment of conifer purity at Year 7 and 10 provide trends through time.

How Measured: Forest composition to be derived using the Base Model Inventory with the species composition string parsed out. Indicator calculated for only PJD, PJM, SBL, SPD and SPM forest units within the caribou zone: the combined species composition percentage for jack pine, black spruce and white spruce (only) is calculated, based on the area weighted average tree species composition by forest unit.

Desirable Level: The desirable level is to maintain or increase percentage of conifer species composition in the caribou zone.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: Conifer forest composition is critical to woodland caribou habitat (Species At Risk) therefore a reduction in hardwood and mixedwood species composition in the caribou zone is desirable and will result in an increase in preferred caribou habitat. It is important to maintain the purity of conifer species composition within the targeted

forest units in order to maintain high quality caribou habitat. The desirable and target levels are to maintain or increase the percentage of jack pine, black spruce and white spruce species composition in the caribou zone at or above the Plan Start levels of:

PJD Forest Unit – 97%
PJM Forest Unit – 92%
SBL Forest Unit – 95%
SPD Forest Unit – 92%
SPM Forest Unit - 89%.

3.5.2.4 Objective 4: Wood Supply

Objective 4: Wood Supply:
"To provide a predictable and continuous supply of wood products to the forest products industry from the management unit."

This objective was included in the 2004 FMP and with similar wording in many previous forest management plans. A predictable future wood supply from the Whiskey Jack Forest was discussed by MNR, the Planning Team and LCCs as a desired forest and benefit. In recognition of the need to address short-term as well as long-term projected wood supply, an additional indicator was added to specifically measure and report achievement of wood supply for this 10-year plan period (short-term). The long-term harvest area and volume indicators are required by the *Forest Management Planning Manual (2009).*

Indicator: (4a) Long-term projected available harvest area

Timing of Assessment: Completion of proposed LTMD.

How Measured: SFMM projected available harvest area.

Desirable Level: The desirable level is to maintain an average total available harvest area above 4,100 ha/year.

Target Level: Same as desirable level measured over the long-term (100 years).

Rationale for Desirable and Target Levels: This desirable level was determined through scoping and development of the Proposed Long-term Management Direction. The target level was left the same as the desirable level as results from scoping and the LTMD supported achievement while balancing other plan objectives. The FMPM dictated that this indicator have a long-term time frame (100 years).

Indicator: (4b) Long-term projected available harvest volume by species group

Timing of Assessment: Completion of proposed LTMD.

How Measured: SFMM projected annual harvest volumes by species group.

Desirable Level: The desirable level is to achieve the highest possible long-term annual harvest volumes by species group while maintaining a balance of objective achievement.

Target Level: Same as desirable level measured over the long-term (100 years). The FMPM dictated that this indicator have a long-term time frame (100 years).

Rationale for Desirable and Target Levels: The desired benefit is to maximize a sustainable harvest from the forest while balancing the achievement of other non-timber objectives. Therefore the desirable and target levels are to maximize volumes through time.

Scoping investigations and development of the LTMD provided indication that the forest would be able to increase Spruce-Pine-Fir harvest volume from the current 279,000 cubic metres per year to sustainable levels of approximately 340,000 cubic metres per year (with a few terms higher, up to as much as 400,000 cubic metres per year). Projected poplar harvest volume decreased from the short-term (200,000 cubic metres per year) to the medium-term (90,000 – 100,000 cubic metres per year). The rate of decrease in poplar volume was managed in the LTMD while balancing achievement other management objectives.

Indicator: (4c) Short-term Projected Harvest Volume Per Year

Timing of Assessment: Completion of proposed LTMD.

How Measured: SFMM projected total annual harvest volume for Term 1.

Desirable Level: The desirable level is to maintain harvest volume (all species combined) at or above 510,000 cubic metres per year for this plan (2012-2022).

Target Level: Same as the desirable level measured for this plan period.

Rationale for Desirable and Target Levels: A minimum annual volume of 510,000 cubic metres (net merchantable cubic metres, all species combined) is desirable for the short-term to ensure positive socio-economic benefits and non-timber objective achievement through this plan period. Through scoping investigations and development of the LTMD, it was confirmed by the planning team that current harvest levels could be sustained through the long-term at 450,000-500,000 cubic metres per year (therefore the target level is the same as the desirable level).

Indicator: (4d) Actual Harvest Area, by Forest Unit (% of planned harvest area)

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: Actual harvest area by forest unit reported in annual reports divided by the forecast harvest areas by forest unit in the FMP, expressed as a percentage.

Desirable Level: The desirable level is to achieve the 80-100% or 90-100% of the planned harvest area by forest unit actually harvested the 10-year plan period (2012-2022) based on Table FMP-11.

Target Level: Same as desirable level measured at Plan End.

Rationale for Desirable and Target Levels: The desirable level of a minimum of 80% or 90% harvest (after reductions for inoperable, residual, etc.) is a goal, however uncertain economic times may limit markets for some harvest volumes and inoperable areas may limit some harvest areas. It was expected that the forest units with larger available harvest areas (HMX, CMX and POD) would achieve a minimum 90-100% harvested area. However forest units with smaller available harvest areas would have more variable harvest area term to term dependent on demand to harvest or markets for specific volumes and the scheduling of allocated stands in one five-year term or another. Since there is no available harvest area projected for the OCL or OTH forest units, the desirable and target levels for OCL and OTH are “not applicable”.

NOTE: Planned harvest area includes internal areas to be left unharvested during operations (inoperable, residual, etc.) therefore the desirable and target levels for actual harvest area reflect the anticipated reductions for unharvested areas (will never achieve 100% harvest).

Indicator: (4e) Actual Harvest Volume, by Species Group (% of planned harvest volume)

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: Actual harvest volume reported in annual reports summarized by species group divided by the forecast harvest volumes by species group in the FMP, expressed as a percentage.

Desirable Level: The desirable level is to have 80-100% or 90-100% of the planned harvest volume by species group actually harvested during the 10-year plan period (2012-2022) based on FMP-13.

Target Level: Same as desirable level measured at Plan End.

Rationale for Desirable and Target Levels: The desirable level allowed a range of achievement to acknowledge the variability in the forest industry today. As discussed with the indicator for harvest area, the uncertain economic times we are experiencing may make it impossible to plan markets for all timber, therefore a desirable and target level range of a minimum of 80-100% by species group for the smaller species groups (White Birch and Red Pine-White Pine) with the expectation that the larger species groups (Spruce-Pine-Fir, Poplar) would achieve 90-100% harvest.

3.5.2.5 Objective 5: Managed Crown Forest

Objective 5: Managed Crown Forest:
"To provide continuous social benefits resulting from the managed, Crown forest available for timber production on the management unit."

This objective is associated with a mandatory indicator from the *Forest Management Planning Manual (2009)* required for this FMP.

Indicator: (5a) Managed Crown Forest Available for Timber Production

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: Plan Start available area measured from SFMM initial land base at LTMD. Annual Report (Table AR-14 Assessment of Objective Achievement) measurements based on updated the area of productive, managed Crown forest available for timber production, in hectares, at the end of the plan period recorded and compared to the area of managed Crown forest available for timber production as projected in the forest management plan. Available area does not include parks, conservation reserves (e.g. land use decisions, non-managed ownership classifications) or unavailable production forest (e.g. actual and estimated shoreline, tourism or nest reserves). Available forest area is measured from the Base Model Inventory.

The BMI is constructed from the Planning Inventory updated for actual depletions, FTG survey results, long-term losses to non-productive land, etc. with additional forecasts for depletion and estimated reserve (unavailable) areas. The updated BMI measured for the indicator assessment includes the same classification of available area as incorporated into the SFMM model for strategic modelling for the forest management plan.

Desirable Level: The desirable level is to maintain a minimum of 570,000 hectares of Managed, Crown forest available for timber production through time.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: Used SFMM scoping analysis to determine desirable and target levels. Desirable level is achievable as the forest is reasonably well accessed now which will minimizes further losses of available forest to roads and landings (classified as non-forest).

3.5.2.6 Objective 6: Aboriginal Involvement in Planning

Objective 6: Aboriginal Involvement:
"To work with local Aboriginal peoples, whose communities are situated in or adjacent to the management unit, to identify and implement forest operations (harvest, access, renewal, maintenance and protection) that will maintain or enhance social and economic benefits to Aboriginal peoples."

For this plan, the *Forest Management Planning Manual (2009)* required a new mandatory indicator to be assessed concerning Aboriginal involvement in plan development. The Planning Team translated this requirement into two indicators associated with Aboriginal representation on the Planning Team and Aboriginal input in the planning process. These new indicators were added to address identified issues with the effectiveness of Aboriginal consultation and the quality of Aboriginal community background information prepared for the FMP.

Indicator: (6a) Representation on the Planning Team

Timing of Assessment: Draft plan (Table FMP-9).

How Measured: Review of planning team minutes and the final FMP Terms of Reference for Planning Team membership.

Desirable Level: The desirable level is to have five Aboriginal Communities located in or adjacent to the Whiskey Jack Forest with representation on the planning team, measured during plan development.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: Aboriginal involvement on the planning team is greater than was experienced for the 2004 FMP. This is considered a significant step in engaging Aboriginal communities. There are currently five Aboriginal communities located in or adjacent to the Whiskey Jack Forest with representation on the planning team.

Indicator: (6b) Aboriginal Communities that Contribute Information to the Planning Process

Timing of Assessment: Draft plan (Table FMP-9).

How Measured: Review of planning team minutes, Community Representative meetings, the final FMP Terms of Reference for Planning Team membership and consultation records.

Desirable Level: The desirable level is to have a minimum of five Aboriginal Communities located in or adjacent to the Whiskey Jack Forest that contribute information to the planning process, measured during plan development.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: It is desired for all affected Aboriginal communities participate in the planning process and provide input into Aboriginal reports, it is recognized that the communities that are in or adjacent to the Whiskey Jack Forest will be more engaged and should provide more input. The desirable and target levels reflect that there may be a few communities not directly impacted by operations on the Whiskey Jack Forest that do not choose to provide input. MNR efforts were directed at all affected communities to get the best response possible.

3.5.2.7 Objective 7: Local Citizens Committee Involvement

Objective 7: Local Citizens Committee Involvement:
"To have the Local Citizens Committee effectively participate in the development of the management plan."

This is a new objective for this plan included for the associated mandatory indicator from the *Forest Management Planning Manual (2009)* required for this FMP. While LCC involvement has been encouraged and well received during preparation of past plans, the quality and effectiveness of the LCC involvement will now form one of the indicators by which forest sustainability is measured.

Indicator: (7a) Local Citizens Committee's Self-evaluation of its Effectiveness in Plan Development

Timing of Assessment: Draft plan (Table FMP-9).
How Measured: Analysis of LCC completed effectiveness survey.

Desirable Level: The desirable level is to have both the LCC Effectiveness Survey results indicate at least 60% effectiveness in the development of the management plan.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: A 50% effectiveness ranking implies neither effectiveness nor ineffectiveness. Therefore a 60% effective ranking was determined to be the minimum desirable and target level, however more favourable results (80%+) are expected.

3.5.2.8 Objective 8: Road Access

Objective 8: Road Access:
"To provide road-based access, land use and recreational opportunities through road maintenance and development of access to areas planned for harvest and renewal within the plan period."

This indicator is a new mandatory indicator of road density from the *Forest Management Planning Manual (2009)* required for this FMP. The separation of desirable levels for road density in the caribou zone and non-caribou zone are in accordance with *Ontario's Woodland Caribou Conservation Plan (2009)*.

Indicator: (8a) Kilometres of SFL Road per Square Kilometre of Crown Forest.

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: The length (km) of primary and branch SFL responsibility road on the forest is measured and divided by the area of Crown productive forest (in km2).

Desirable Level: The desirable level is maintain SFL primary and branch forest access road density in the non-caribou zone at a minimum of 0.11 km/km2 productive Crown area (Plan Start density) and to maintain SFL primary and branch forest access road density in the caribou zone at a maximum of 0.13 km/km2 productive Crown area.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: Forecasted road density at plan start for this 2012 FMP is 0.11 km/km2 in the non-caribou zone and 0.12 km/km2 in the caribou zone. Habitat management strategies suggest limited roads and trails where caribou and marten core habitat management is in effect therefore a maximum level of 0.13 km/km2 was set for the caribou zone. More road access can be created elsewhere on the management unit so as to maintain or enhance the overall access for other forest users. While different areas of the non-caribou zone will have decreased or increased road densities, the Planning Team decided to include a minimum road density for the non-caribou zone at no less than the Plan Start road density of 0.11 km/km2.

3.5.2.9 Objective 9: Forest Renewal

Objective 9: Forest Renewal:
"To successfully regenerate harvest areas to Free-Growing status in a manner that is consistent with the regeneration standards outlined in the Silvicultural Ground Rules."

This objective is related to objectives carried forward from the 2004 FMP. This objective is associated with new mandatory indicators from the *Forest Management Planning Manual (2009)* required for this FMP.

The achievement of these forest renewal indicators will demonstrate that the silvicultural strategies implemented in the FMP (Section 4.2.2.2 Silvicultural Ground Rules) are on track to achieve the desired future forest condition as projected in the LTMD. These silvicultural strategies include treatments that attempt to increase conifer dominated stands and minimize the hardwood mixedwood component as suggested by caribou habitat management (caribou zone) and suggested by the indicators for forest composition by landscape class and upland conifer (Objective 2).

Indicator: (9a) Regeneration Success: Percent of Harvested Forest Area Assessed as Free-Growing by Forest Unit

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: Identify hectares harvested by term from previous Annual Reports and Year 7 and 10 Annual Reports. Identify declared successfully regenerated area by term and determine % success by forest unit. Compare to target % by forest unit.

Desirable Level: The desirable level is to achieve 95-100% of harvest area successfully regenerated to free-growing status within 10 years of harvest.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: On the Whiskey Jack Forest, nearly 100% of harvest area assessed reaches free to grow (regeneration success) within 10 years of treatment. The range in desirable and target levels (95-100%) recognizes that spruce plantations may require a little longer than 10 years to reach FTG height therefore desired level is 95-100% success in 10 years.

Indicator: (9b) Silviculture Intensity: Planned and Actual Percent of Harvested Area Treated by Silvicultural Intensity

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: Planned (target): Identify silvicultural intensity for planned harvest areas by term from the composite planning inventory, express as a percent of total harvest area. Actual: Identify hectares treated by silvicultural intensity from Annual Reports and express as percent of total harvest area.

Desirable Level: The desirable level is to achieve a minimum of 80-90% of area treated by planned silvicultural treatment intensity for each 5-year plan term (2012-2017, 2017-2022).

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: It is important that renewal treatment efforts match the level of intensity projected by the LTMD and these levels were determined to be necessary to achieve the long-term management objectives for the forest. However, variation may be acceptable if similar results can be achieved through less intensive or less costly methods, or if in fact an area requires more intensive treatment to achieve desirable results. Where one intensity level is overachieved, another is underachieved compounding the variance from planned when this indicator is reported. Therefore it was considered that a desirable level of a minimum of 80-90% treatment to planned intensities was reasonable.

Indicator: (9c) Silvicultural Success: Planned and Actual Percent of Harvested Forest Area Assessed as Free-Growing and Successfully Regenerated to the Projected Forest Unit

While regeneration success of free-growing stands is expected, there may be some areas that regenerate to forest units other than those originally planned. This indicator is a measure of silvicultural success and planning.

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: Planned (target): Percentages used in strategic modelling by forest unit. Actual: Identify hectares harvested by term by forest unit from previous Annual Reports and Year 7 and 10 Annual Reports. Identify hectares declared successfully regenerated by term and forest unit and determine % of harvested area by forest unit. Compare to planned rates by forest unit.

Desirable Level: The desirable level is 70-100% of harvest area successfully regenerated to free-growing status and to the projected forest units within 10 years of harvest.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: The desirable and target levels recognize that regeneration to forest units other than originally planned is not silvicultural success but may still result in acceptable future forest conditions that are consistent with the strategic post-renewal forest succession transitions in the LTMD. With 12 forest units on the Whiskey Jack Forest, it is usual that a 10% variance in a stand's species composition may cause an area to be classified as one forest unit rather than another. This forest unit definition variance is reflected in a minimum desirable achievement of 70% silvicultural success. It was acknowledged that there would be no strategic impact in failure to successfully regenerate area if the area was PJD versus PJM, or was SPD versus SPM therefore the choice of 70% minimum success was considered reasonable. Lower silvicultural success does not mean that the forest is not being regenerated effectively, but it does reflect the change in forest units on certain sites through time.

3.5.2.10 Objective 10: Forest Values

Objective 10: Forest Values:
"To implement forestry operations in a manner that minimizes negative impacts on all identified resource users, and protects all identified values."

This objective is associated with a new mandatory compliance indicator from the *Forest Management Planning Manual (2009)* required for this FMP.

Indicator: (10a) % of Forest Operation Inspections in Non-Compliance, By Activity and Remedy Type (i.e. severity)

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: Analysis of compliance reports.

Desirable Level: The desirable level is to have a maximum 5% of forest inspections reported in non-compliance reported for each 5-year plan term (2012-2017, 2017-2022).

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: A desirable and target level of a maximum of 5% of forest operations inspections in non-compliance is an important level to achieve as this level of non-compliance is caused by activities that were not documented in the Forest Management Plan and which negatively impact upon the objectives and strategies on the Forest Management Plan. Although operations will strive for 0% non-compliance, a desirable and target level of a maximum of 5% is acceptable as generally most occurrences of non-compliances are less severe and have no long-term effect on the forest ecosystem or environment.

3.5.2.11 Objective 11: Soil and Water Resources

Objective 11: Soil and Water Resources: "To maintain productivity of soil function, and to protect water quality and fisheries habitat where forest management activities occur in the forest."

Targets for soils, fisheries and water quality objectives from the 2004 FMP are carried forward in this objective. This objective addresses required compliance indicators from the *Forest Management Planning Manual (2009).*

Indicator: (11a) % of Forest Operations Inspections in Non-Compliance with Management Practices that Prevent, Minimize or Mitigate Site Damage (by remedy type)

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: Analysis of compliance reports.

Desirable Level: The desirable level is to have a maximum 5% of inspections related to prescriptions in the FMP that were developed using the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* reported as not in compliance.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: The desirable and target levels recognize that while not desirable, an incidence of non-compliance may occur. The desirable level of no more than 5% of inspections not in compliance is a reasonable level given the importance of preventing, minimizing or mitigating site damage.

Indicator: (11b) % of Forest Operations Inspections in Non-Compliance with Prescriptions Developed for the Protection of Water Quality and Fish Habitat (by remedy type)

Timing of Assessment: Year 7 and Year 10 Annual Reports.

How Measured: Analysis of compliance reports.

Desirable Level: The desirable level is to have a maximum of 5% of inspections related to water quality and fish habitat protection prescriptions not in compliance.

Target Level: Same as desirable level.

Rationale for Desirable and Target Levels: The desirable level of no more than 5% non-compliance annually with AOC prescriptions recognizes that while not desirable, an incidence of non-compliance may occur. The maximum desirable level of 5% non-compliance is a reasonable level given the importance of protecting water quality and fish habitat.

3.6 Long-term Management Direction

A long-term management direction (LTMD) is represented by the types and levels of access, harvest, renewal and tending activities required to manage forest cover and balance the achievement of management objectives.

The Strategic Forest Management Model (SFMM) was used to develop a management strategy that balanced the achievement of all the management objectives and desirable levels as presented in Table FMP-9.

A process of repetitive analyses was conducted to balance the achievement of management objectives while developing a LTMD for the Whiskey Jack Forest. Results or findings of the scoping analyses were used to guide the balancing of management objectives. The LTMD represents a balance in the achievement of management objectives. The final digital LTMD model run (27d-OLTMS.cas) was provided for review to MNR district and region. Development of the LTMD and modelling outputs, showing how the forest is expected to develop over time in terms of forest composition and structure, and the projected types and levels of activities required to achieve management objectives are summarized in Supplementary Documentation A - Analysis Package in Section 9.0 and Appendix 3. The projected results of the LTMD are documented in FMP text sections and tables as follows:

Section 3.6.0 Development of the LTMD and Projected Forest Condition
- Section 3.6.0.1 Scoping Investigations and Development of the LTMD

Section 3.6.3 Assessment of Objective Achievement (FMP-9)

Section 3.6.4 Social and Economic Assessment

Summaries of the desired forest and benefits, plan objectives, indicators of objective achievement, desirable levels, and targets were included in Table FMP-9 and discussed in Section 3.5. Table FMP-9 was not finalized until scoping investigations were conducted and potential desirable levels for indicators were discussed with the Local Citizens Committees (LCC)(Kenora and Red Lake).

The Long-term Management Direction was presented to and endorsed by the Planning Team, Local Citizens Committees and the Regional Director, MNR Northwest Region. Public review of the LTMD during FMP production included opportunities at Stage Two - Review of Proposed Long-Term Management Direction, and Stage Three – First Information Centre Review of Proposed Operations.

3.6.0 Development of the LTMD and Projected Forest Condition

3.6.0.1 Scoping Investigations and Development of the LTMD

Strategic analysis is an iterative process used to determine the types and levels of access, harvest, renewal, and tending activities required to balance the achievement of management objectives associated with the management of forest cover, and to develop achievable targets in the proposed long-term management direction.

Desirable levels that were not provided directly by guides or other sources of direction were refined through scoping analysis. Scoping analysis is an iterative process that involves a series of investigations to provide insight to what the forest is capable of producing in order to develop realistic and feasible desirable levels for objective indicators. Scoping investigations consider implications on wood supply, forest composition and age structure, wildlife habitat, and other non-timber resources for the short- term, medium-term, and long-term. These values were also considered throughout the 160-year planning horizon. All strategic modelling was conducted and reviewed co-operatively between the Strategic Task Team and MNR district staff, with valued input and advice from the plan advisors including regional MNR staff.

The FMP Manual requires that the establishment of targets for each indicator will consider:

(a) the current forest condition;
(b) a balance of social, economic and environmental considerations;
(c) the associated indicator and the desirable level;
(d) the potential achievement for the short term (10 years), medium term and long-term; and
(e) projections from past forest management plans and historical levels of objective achievement.

In addition, for harvest level indicators, the targets will also consider:

(a) historic wood utilization;
(b) Ontario Forest Accord Advisory Board benchmark harvest levels, as identified in the *Regional Wood Supply Strategies*; and
(c) maximum even-flow harvest volume by major species group.

The above listed forest condition, desired forest and benefits, projected achievement and harvest related investigations were all considered during scoping investigations during development of the LTMD.

The base model was used as the starting point for the development of the proposed long-term management direction. For all scoping investigations, unless specifically noted otherwise, the following management decisions were consistently included in each investigation as per the Base Model:

- management decisions for caribou management (SUBMUs and operational timing);
- large landscape patch deferrals (includes marten core habitat management);
- estimated reserve areas as per the Stand and Site Guide (riparian, nests) and estimates of known tourism reserves;
- crude control of projected TOTAL harvest volumes of +/- 20% variance allowed between 10-year terms; and

- execution of SFMM for the greatest volume of timber harvested over the entire planning period.
  Note: Volume groups are referenced as TOTAL – all species, SPF – Spruce-Pine-Fir, PO – poplar, and BIRCH – White Birch. "Terms" in the SFMM modelling are 10-year terms. All volumes are reported in net merchantable cubic metres.

Specific SFMM model inputs varied for each investigation and projected results are documented in a standardized 3-Page Summary for all documented investigations in Supplementary Documentation A – Analysis Package, Appendix 2. The Analysis Package includes additional detail on the summary and conclusions of scoping investigations (Section 8.3) and development of the LTMD (Section 9.2).

Summary of Scoping Investigation Conclusions

The following summary of scoping investigations and significant conclusions were considered in the development and rationalization of desirable levels for management indicators.

(a) An investigation into the ability of the forest to meet forest diversity and forest cover desirable levels (based on current forest condition and forest dynamics);

Based on results, it was investigated when the Simulated Range of Natural Variation (SRNV) achievement for OLT investigations could occur (e.g. in 70 years, or in 50 years).

CONCLUSION: There was no reason to not meet OLT suggested minimum levels within 50-60 years (e.g. versus not meeting levels until 70-100 years in the future) for all OLT landscape classes, old forest, upland conifer area and non-spatial caribou habitat except MLI (mature and late successional intolerant hardwood). Desirable levels for mature/late landscape class area (Indicator 2a), old forest class area (Indicator 2d), upland conifer (Indicator 2e) and caribou habitat (Indicator 3a) were agreed to be the minimum OLT SRNV levels.

CONCLUSION: It was concluded that constraints to force the general achievement of projected forest unit area by age grouping (young versus mature/late) to OLT minimum SRNV levels could not be utilized in the absence of OLT desirable level constraints. In isolation, forest unit age groupings had reasonable projections but the achievement of landscape class areas and old forest areas were negatively impacted.

CONCLUSION: Constraints for the mature age groupings by forest unit from Term 8 (70 years) were considered acceptable for forest unit / age grouping desirable levels for Indicator 2b. Control of forest unit area for the young age grouping was not considered as significant to manage as was the need to ensure sufficient area in the mature and older age grouping. The LTMD Task Team and Planning Team also agreed that the achievement of desirable levels for landscape class area was a higher priority as compared to total forest unit area through time, or forest unit by age grouping (young versus mature/late).

CONCLUSION: The total area of the PRW forest unit was consistently above the range projected by OLT (SFMM 2012 = 3,312 ha versus OLT 2012 = 856 ha at Plan Start). It was recognized that OLT does not adequately simulate the forest dynamics for red pine and white pine regeneration and natural succession. Therefore a desirable level of

maintaining a minimum of the Plan Start PRW value (no decrease) was adopted rather than a lower level prescribed by the OLT model.

CONCLUSION: The LTMD Task Team and Planning Team agreed that spatial indicators for landscape pattern/texture and caribou habitat would have desirable levels as projected by the OLT model. This represented the best science and information on natural landscape pattern. This related to Indicators 1a, 1b, 1c, 3b and 3c.

The management objectives, indicators, desirable levels and the timing of assessment for each indicator are documented in Table FMP-9.

(b) An investigation and assessment of the ability of the forest to continue to supply forest benefit levels associated with the current forest management plan;

Several items related to wood supply, forest condition and age, and wildlife habitat were reviewed to complete this assessment.

Wood Supply - First, a SFMM investigation was completed that incorporated wood supply by species group from the 2004 FMP, with the objective of sustaining 2004 wood supply levels for as many terms as possible. Targets were included for PWR (1.6 Mm3/year), SPF (400 Mm3/year), PO (265 Mm3/year) and BW (25 Mm3/year) species groups. **CONCLUSION**: The Spruce-Pine-Fir and the Red Pine-White Pine wood supplies were projected to be met for 40 years (Terms 1-4). Hardwood volumes (Poplar, Birch) were limited after Term 2 or 3 respectively. Wood supply can be comparable to the 2004 FMP for this plan period, but without added constraints to force the projected increase in hardwood volumes in Terms 3-7, future hardwood will be less than were projected in the 2004 FMP.

Productive Area by Forest Unit – This comparison is a reflection of the forest condition that contributes to other desired forest and benefits such as wildlife habitat, forest diversity and harvest area. Habitat for selected wildlife species are no longer measured in the strategic modelling, rather the combination of landscape class area, old forest groupings and landscape pattern/texture indicators are considered as better measure of forest condition. Forest units from the 2004 FMP are aligned to roughly correspond to the 2012 FMP PLANFUs, though it must be noted that this is a rough comparison only. The differences were partially due to refined forest unit definitions and should not compromise the Whiskey Jack Forest's ability to continue to provide forest benefits associated with the productive forest.

Old Forest Area – Next, the quantity of old forest was compared for Plan Start 2004 and 2012. The comparison utilizes the PLANFUs and old forest definitions used in each of the plans with 2004 PLANFUs organized and grouped to roughly align with the 2012 FMP old forest groupings. It is evident that through aging of the forest over the past eight years, significantly more area has now aged enough to be classified as old forest (2004: 19,649 ha versus 2012: 68,801 ha). Therefore, while this increase in area of old forest may be detrimental to future wood supply and provide a greater fire hazard in some portions of the forest, it does provide more of the inherent benefits associated with older forest structure (e.g. wildlife habitat for those species preferring old forest, forest diversity).

Caribou Habitat – A similar dynamic caribou habitat schedule was spatially applied for both the 2004 and 2012 forest management plan land bases. Therefore it is expected that the projected benefits to caribou are comparable for both plans.

Marten Habitat – a similar spatial distribution of marten core areas was incorporated into both the 2004 and 2012 FMPs. Plan Start achievement of % suitable of total capable % was 3.7% for the 2004 FMP (13 cores) and 4.9% for the 2012 FMP (17 cores or Large Landscape Patches). These results support the forest's ability to continue to supply spatial marten core area.

CONCLUSION: Based on the comparison of projected wood supply, productive forest area, old forest area, caribou habitat and marten habitat, it is expected that the 2012 Whiskey Jack Forest will continue to be able to supply forest benefit levels associated with the 2004 forest management plan.

Summary of LTMD Development Investigations and Conclusions

Upon completion of the investigation of the types and levels of activities and setting of desirable levels (Section 3.5.1 and 3.5.2) and conducting broad and specific scoping investigations, the Planning Team began developing a Long-term Management Direction (LTMD). This task was iterative in that various objectives were included in the strategic model and refined in multiple steps to results in a strategic option that provides a balance of achievement of all modelled management objectives. Through all iterations, the impacts of constraints/changes were reviewed with respect to forest condition (forest unit areas, caribou habitat, old forest), projected harvest areas and volume, and the projected renewal program. The results for forest condition were repeatedly compared to those projected by OLT Simulated Ranges of Natural Variation (SRNV) for the Whiskey Jack Forest, with adjustments to constraints through time added to improve consistency of results to the SRNV.

The following summary of investigations and significant conclusions were considered in the development of the Long-term Management Direction and indicator target levels.

(a) Ontario Forest Accord Advisory Board (OFAAB) benchmark harvest levels, as identified in the Regional Wood Supply Strategies.

CONCLUSION: OLT landscape indicator targets achievement was good due to the constraints added to all LTMD development scenarios. OFAAB Benchmark volume targets for PWR (0.6 Mm3/year), SPF (354 Mm3/year), PO (149 Mm3/year) and BW (4 Mm3/year) were able to be met in all terms. The PO (poplar) species group benchmark level was projected to be met in all terms except Terms 4-6.

The OFAAB historic harvest area and volume investigations are documented in text Section 3.6.1 Available Harvest Area and Section 3.6.1.1 Available Harvest Volume by Species Group.

(b) Maximum even-flow harvest volume by major species group.

The even flow (flat line) harvest volume investigations gave ballpark estimates of how much volume by species group (PWR, SPF, PO and BW) could be sustained through time if there was the same volume projected in every term. Additional information was derived

from the even-flow runs to see what volumes were projected if volumes could increase, but not decrease, between terms. This information was recorded as the non-declining volumes by species group but are not saved investigations. The non-declining information gave an indication of what terms limited the projected harvest volumes for each species group.

Results	Even Flow Volumes (m3 /year)	Non-declining volumes: (Information point only, not saved cases.)
06-Flat-PWR	1,290 m3	1,290 increases to 1,431 in T9 and then 2,178 in T13 and 2,200 in T15.
07-Flat-SPF	392,370 m3	389,174 then increases to 474,804 T7 to end.
08-Flat-PO	110,507 m3	110,051 limited to T6, then incr to 117,878 in T7. Incr to 134,591 in T15.
09-Flat-BW	17,467 m3	Same as even flow, so limited by last term.
09-Flat-TOTAL	551,399 m3	546,319 m3 to T6, then incr to 616,460 m3 in T7-T14, then incr to 705,091 m3 for T15.

CONCLUSION: Increased volumes can be realized by allowing increases in volumes between terms or by adjusting the OLT achievement targets or timeframe for achievement. Poplar volumes were confirmed to be a challenge that needed to be addressed in the LTMD, particularly for the short-term. Spruce-Pine-Fir projected volumes were generally at an acceptable level.

Various LTMD refinement runs were conducted which included additional constraints to improve projected LTMD results and operational feasibility of the LTMD:

- to balance wood flow through time;
- to optimize caribou habitat and landscape class areas through time;
- to balance the funding available for forest renewal treatments to the projected Forest Renewal Trust Fund;
- to maintain the area in the PRW forest unit;
- to fine-tune SFMM deferral timing for marten core areas, large landscape patches and operational deferrals to the dynamic caribou habitat schedule;
- to improve projected forest unit area by age grouping;
- correction of the classification of 16,000 ha SBL forest unit area (erroneously classified as SPD in the BMI) which resulted in a better correlation between strategic SFMM modelling and the OLT model, and achievement of SRNV targets, and
- reclassification of estimated previous bypass area from the available forest to reserve forest or deferrals in SFMM to better approximate the area actually feasible for allocation in this plan period. Refinement of SPF targets was also done at this time to better balance projected volumes through time.

CONCLUSION: The resulting scenario, 27d_OLTMS, was reviewed at length by the Strategic Task Team, regional advisors and Planning Team and considered a viable LTMD option. It provided a good balance of objective achievement and included forest management activities of harvest and renewal that were reasonable for the forest and had the potential to be successfully implemented.

Scenario 27d_OLTMS was selected as the Proposed Long-term Management Direction.

The following sections describe the projected forest condition, social and economic benefits and objective achievement related to LTMD 27d_OLTMS.

3.6.0.2 Forest Condition for the Crown Productive Forest

The forest condition for the Crown Productive Forest projected in the LTMD is documented in Table FMP-5 by forest unit and age class. The productive Crown forest includes managed area as well as parks and protected areas. The productive forest at 2012 Plan Start is 745,534 hectares in size. It is projected to decrease only 0.2% over 100 years to 744,231 hectares. This overall minor decrease in productive forest area is a result of projected conversion of harvested area to new (non-productive) roads and landings, and also involves an adequate program to offset needed new roads by the reclamation of unnecessary existing roads, landings, and slash/chipper debris areas (Section 4.5.8).

The Long-term Management Direction projects an increase in proportion of conifer versus hardwood leading forest units through time (ratio of 75:25 conifer to hardwood at Plan Start, and increased conifer of 81:19 at Year 100). This minor increase in conifer dominated forest unit area is consistent with movement towards the desirable level of increased conifer forest in accordance with OLT simulated range of natural variation projections. There is also a shift in forest unit areas to purer forest units with a decrease in mixedwood forest units. The CMX and HMX forest units are projected for the most significant decrease in the LTMD (33 and 57% decreases over 100 years respectively).

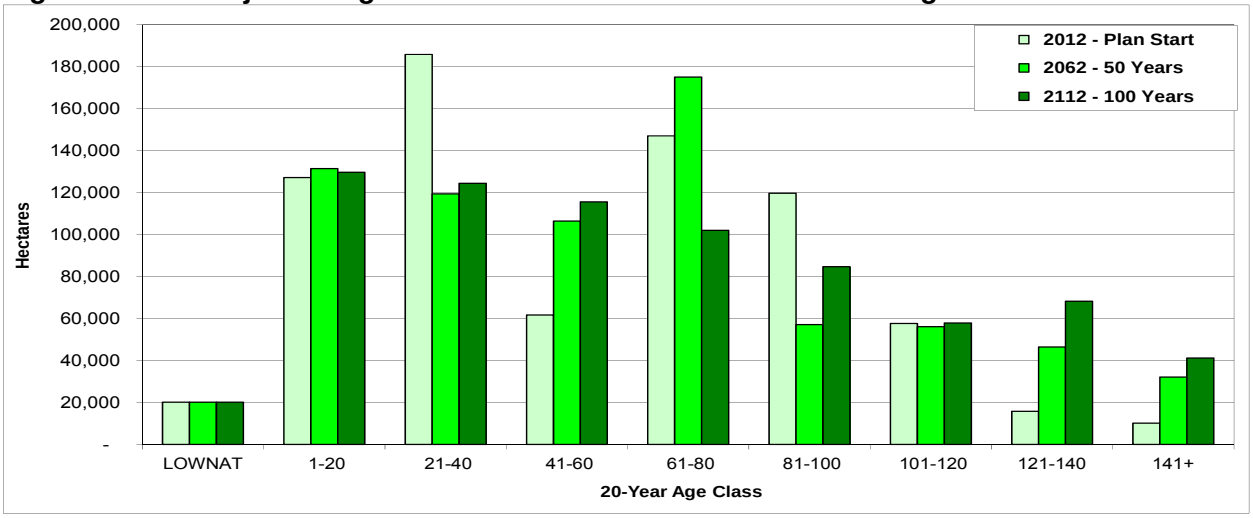
Significant increases are projected for SPM, PJM, POD and SPD forest units as a result of shifting forest composition after harvest from mixedwoods to purer forest units. This change in forest composition through time is consistent with management objectives and OLT simulated natural forest condition projections. It also is in keeping with silvicultural strategies developed by the Planning Team (Section 4.2.2.1 Silvicultural Ground Rules).

The age class distribution of the productive forest is illustrated in Figure 25 for 2012 (Plan Start), 2062 (50 years in the future) and 2112 (100 years). At Plan Start there is a disproportionately large amount of area in the 21-40 (primarily PJD resulting from 1976-1983 burns) and 61-100 year old age classes, primarily located in the HMX and CMX forest units. Through implementation of the LTMD, the age class distribution of the Whiskey Jack Forest is projected to become more normalized, with less area in the age classes below 40 years old, a gradual decrease in areas 61-100 years, and an increase in older forest area greater than 120 years old. This projected age class distribution allows for the achievement of management objectives for forest composition, age structure and provision of wildlife habitat (Section 3.5.2 and Section 3.6.3) within the simulated range of natural variation.

A discussion of changes in each forest unit area projected over the next 100 years, including a comparison between the Long-term Management Direction (LTMD)(SFMM run 27d_OLTMS) and the Simulated Range of Natural Variation (SRNV Lower Limit and SRNV Upper Limit) follows. The desirable level for indicator achievement is to maintain area by forest unit equal to or above the lower Simulated Range of Natural Variation through time. The upper SRNV is illustrated for comparison purposes, but does not form a binding target limit.

Projections for individual forest units are summarized alphabetically below and illustrated in Figure 26 (four groups of three forest units located after the forest unit summaries). LOWNAT area contributes to the productive forest area, but is considered to be constant at 20,140 hectares (all forest units combined) through time in the LTMD. LOWNAT area is not discussed in the forest unit summaries below and was also added into Table FMP-5 separate from the forest unit projected areas.

Figure 25 Projected Age Class Distribution of the LTMD Through Time



BFM Forest Unit

2012 Productive Area – 27,150 ha (4% of the total productive land base).
2112 Productive Area – 17,056 ha (2% of the total productive land base).
Trend over Time – Plan Start above SRNV range with decrease of 37% to within SRNV over 100 years.
Impact - Potential positive management implications as a reduced amount of BFM may reduce extent or duration of future spruce budworm infestations, and BFM stand harvest volumes are often lower on average than other stands. Projected BFM area closer to SRNV median through implementation of LTMD than at Plan Start.

CMX Forest Unit

2012 Productive Area – 88,492 ha (12% of the total productive land base, 2nd largest forest unit).
2112 Productive Area – 59,516 ha (8% of the total productive land base, 3rd largest forest unit).
Trend over Time – Plan Start above SRNV range with decrease of 33% to within SRNV in 80 years and sustained near SRNV median level thereafter.
Impact - Implementation of the LTMD improves the forest unit composition relative to the OLT simulated natural forest condition median level. The silviculture strategy is to direct these stands to more pure species stands. It is recognized that there are increased treatment cost implications related to hardwood vegetative control and conversion to, or maintenance of, conifer dominated forest areas. Stands with a high probability of naturally regenerating to hardwood will be left for natural regeneration, those more suitable for conifer will be regenerated to jack pine or spruce based on suitability of sites. The majority of this forest unit will be maintained in a conifer dominated condition and will still available for wildlife habitat for those species favouring conifer dominated forest types.

HMX Forest Unit

2012 Productive Area – 107,239 ha (15% of the total prod. land base, 3rd largest forest unit).
2112 Productive Area – 46,480 ha (6% of the total productive land base).

Trend over Time – Plan Start above SRNV range with decrease of 57% to within SRNV in 30 years and sustained within SRNV thereafter, trending to the lower SRNV level.
Impact - Implementation of the LTMD improves the forest unit composition relative to the OLT simulated natural forest condition. The silviculture strategy for the HMX forest unit will be to cut and naturally regenerate healthy hardwood stands to more pure hardwoods and to regenerate poor and off site hardwood stands to more suitable conifer species. There are no negative management implications related to the decrease in HMX area as the majority will be converted to poplar dominated stands.

OCL Forest Unit

2012 Productive Area – 2,217 ha (<1% of the total productive land base).
2112 Productive Area – 2,205 ha (<1% of the total productive land base).
Trend over Time – Plan Start level remains stable above the lower SRNV. This forest unit is forest composition and ecosite-based therefore it is not expected to have any changes to the area occupied by OCL.
Impact - The silviculture strategy for the OCL forest unit will be to primarily leave for natural regeneration or plant to black spruce if the site is suitable. There are no specific management implications for the OCL forest unit as the change in area through time is projected to be minimal.

OTH Forest Unit

2012 Productive Area – 1,995 ha (<1% of the total productive land base).
2112 Productive Area – 1,995 ha (<1% of the total productive land base).
Trend over Time – Plan Start within lower SRNV range and remains stable throughout planning horizon.
Impact - Black ash reproduces vegetatively very well after harvesting and fire, therefore the forest unit area is expected to remain stable through time with no impacts of implementing the LTMD.

PJD Forest Unit

2012 Productive Area – 182,832 ha (25% of the total productive land base, largest forest unit).
2112 Productive Area – 171,417 ha (24% of the total productive land base).
Trend over Time – Plan Start above the lower SRNV range and remains relatively stable through time.
Impact – There are no expected impacts due to the stability of area in the PJD forest unit within the OLT SRNV. The primary silviculture strategy for the PJ1 forest unit will be to regenerate it back to jack pine primarily through aerial seeding. This management strategy will ensure a future supply of jack pine harvest volumes and maintained provision of habitat in the future for those species favouring jack pine dominated habitat (e.g. moose favouring young seral stages of jack pine, and all other selected species (except deer) favouring mature and late seral stages of jack pine).

PJM Forest Unit

2012 Productive Area – 61,845 ha (9% of the total productive land base).

2112 Productive Area – 84,655 ha (12% of the total productive land base).
Trend over Time – Forest unit area at Plan Start starts marginally below the lower SRNV, then increases during this plan period to within the SRNV. Long-term trend is a gradual increase of 37% over 70 years, then remaining stable at this level within the SRNV.
Impact - The increase and maintenance of the PJM forest unit area is in accordance with the SRNV. The primary silviculture strategy for the PJM forest unit will be to regenerate it back to jack pine through aerial seeding. There may be some sites with heavier competition or finer soils that will be more suitable for planting black spruce. The maintenance of this forest unit area provides a stable future supply of timber and habitat for those many species that prefer upland conifer habitat (e.g. moose favouring young seral stages of jack pine, and all other selected species (except deer) favouring mature and late seral stages of jack pine).

POD Forest Unit

2012 Productive Area – 73,977 ha (10% of the total productive land base).
2112 Productive Area – 92,120 ha (13% of the total productive land base).
Trend over Time – Plan Start POD area is above the upper SRNV and increases 25% over 100 years.
Impact – The POD forest unit after harvest will generally be left for natural poplar regeneration. The increase in purer poplar dominated stands will produce more economical harvest opportunities to supply poplar markets in the future as there are less secondary tree species harvested that need to be marketed in small quantities. Poplar harvest volume is expected to be fully utilized regardless if it is harvested from the POD forest unit area (increases through time), or if it is harvested from the CMX and HMX forest unit areas (decrease through time). The stand structure of POD stands is less diverse than HMX or CMX. The provision of wildlife habitat is similar for these forest units with no significant negative implications on wildlife habitat expected through implementation of the poplar renewal strategies and reduction in area of mixedwood forest in this LTMD, consistent with the OLT simulated natural forest condition for those forest units.

PRW Forest Unit

2012 Productive Area – 3,312 ha (<1% of the total productive land base).
2112 Productive Area – 3,923 ha (1% of the total productive land base).
Trend over Time – PRW area increases slightly over the next 100 years (18%, 600 ha). The OLT SRNV did not correlate well to the PRW forest unit land base therefore the projection is not compared to the SRNV.
Impact – The strategic modelling for the LTMD was constrained to ensure that there was no decrease in the PRW forest unit area from the Plan Start level in order to maintain of the forest unit area through time. The silviculture strategy will be to plant sites that have a component of white pine and/or red pine in the parent stand and sites that are suitable to increase the presence of this forest unit over time. Red pine is not difficult to regenerate, however, white pine is more difficult to regenerate with survival to maturity due to the white pine weevil and white pine blister rust infection and mortality. Renewal strategies will primarily focus efforts on regenerating red pine mixed with other species in order to increase the PRW forest unit area in the future. Minimal white pine is expected to be planted in harvest areas due to the challenges in survival to maturity. Management strategies and conservation of existing forest must be considered including the retention of any white pine trees encountered in harvest areas. The retention of these white pine trees will aid the maintenance and restoration of this forest unit.

SBL Forest Unit

2012 Productive Area – 17,611 ha (2% of the total productive land base).
2112 Productive Area – 17,620 ha (2% of the total productive land base).
Trend over Time – SBL forest unit productive area is stable within the SRNV from Plan Start throughout the entire planning horizon.
Impact – The SBL forest unit is defined by lowland ecosites dominated by black spruce therefore there is minimal conversion of harvest area into or out of the SBL forest unit through time. By harvesting lowland sites, water tables can increase and convert these areas to non-forest if trees are not promptly regenerated. The silvicultural strategy for the SBL forest unit will be to leave these stands for natural regeneration after harvest unless there are some suitable areas for planting to black spruce. It is expected that on most sites black spruce will promptly naturally regenerate or will have sufficient advance growth to re-establish productive stands, with minimal increase in the level of the water table.

SPD Forest Unit

2012 Productive Area – 112,785 ha (16% of the total prod. land base, 2nd largest forest unit).
2112 Productive Area – 136,698 ha (19% of the total productive land base).
Trend over Time –SPD productive area is above the upper SRNV at Plan Start and continues to increase (21%) over the next 100 years.
Impact – OLT SRNV related plan objectives, particularly for upland conifer dominated forest and caribou habitat, contribute to the significant increase projected for the SPD forest unit area. The amount of reserved forest area (e.g. parks, protected areas, riparian reserves, nest reserves) through time with natural forest succession contribute to the increase in SPD area. The silviculture strategy for the SPD forest unit will be to plant to spruce unless the sites are coarse and dry and more suitable for regeneration to jack pine. Herbicide will be necessary where hardwood regeneration threatens to inhibit spruce growth and development. An increase in spruce composition through renewal treatments will convert some SPM sites to the SPD forest unit after treatment. Older SPD area is a preferred wildlife habitat for many wildlife species in the Boreal Forest. The increase in SPD forest unit area may have a moderately positive impact on wildlife habitat as most of this increase in SPD area is a result of conversion of SPM to a more pure forest unit.

SPM Forest Unit

2012 Productive Area – 45,937 ha (6% of the total productive land base).
2112 Productive Area – 90,406 ha (12% of the total productive land base).
Trend over Time – Plan Start productive area is at the lower SRNV. SPM area increases 80 years to the upper SRNV level. At that time it is projected to increase slightly and stabilize above the upper SRNV.
Impact – The silviculture strategy for the SPM forest units will be to plant these areas after harvest to black spruce unless the sites are coarse and dry and more suitable for regeneration to jack pine. The increase of this SPM forest unit area is projected to contribute to the desirable levels for upland conifer forest and caribou habitat on the forest. Implementation of the LTMD to increase the SPM and SPD forest unit areas is consistent with the OLT simulated natural forest condition.

3.6.0.3 Habitat for Species At Risk and Selected Wildlife Species

The projected habitats for the Species At Risk (SARs) and selected wildlife species for this FMP are documented in Table FMP-6. FMP-6 documents habitat from Plan Start through the 100-year projections. The following text describes the changes in habitat levels over the next 100 years, and any implications of the projected habitat level changes. The projected area of habitat for species at risk and selected wildlife species (FMP-6) is portrayed graphically in this section of the plan.

The woodland caribou is the only species at risk with habitat managed at the landscape level and modelled strategically through time in the LTMD. Habitat reported in this FMP for the woodland caribou includes caribou refuge habitat and caribou winter habitat (both used and preferred classifications reported). Caribou habitat through time is discussed below in relation to the desirable level which is the OLT Simulated Range of Natural Variation (SRNV).

Caribou Refuge Habitat – Whiskey Jack Forest caribou refuge habitat at Plan Start is lower than the OLT SRNV lower limit, however through implementation of the LTMD, projected caribou refuge habitat reaches and sustains SRNV levels throughout the rest of the 160-year planning horizon (Figure 27). Strategic modelling inputs were included to ensure desirable results for caribou refuge habitat through time.

Caribou Winter Habitat – Caribou used winter habitat at Plan Start is at the upper SRNV and increases above the SRNV throughout the 160-year planning horizon as projected in the LTMD (Figure 28). Caribou preferred winter habitat at Plan Start is below the SRNV and is projected to increase over 30-40 year to within the desirable SRNV level, and remain within the SRNV throughout the planning period (Figure 29). Since caribou is a threatened species, the Planning Team agreed to not force a reduction in caribou winter used habitat in the LTMD, just to match the SRNV. In this case, overachievement of caribou habitat through time was considered a positive LTMD outcome and supported by the Planning Team, MNR and the LCC.

Implementation of the LTMD is projected to improve and sustain desirable levels of caribou refuge and winter habitat through time.

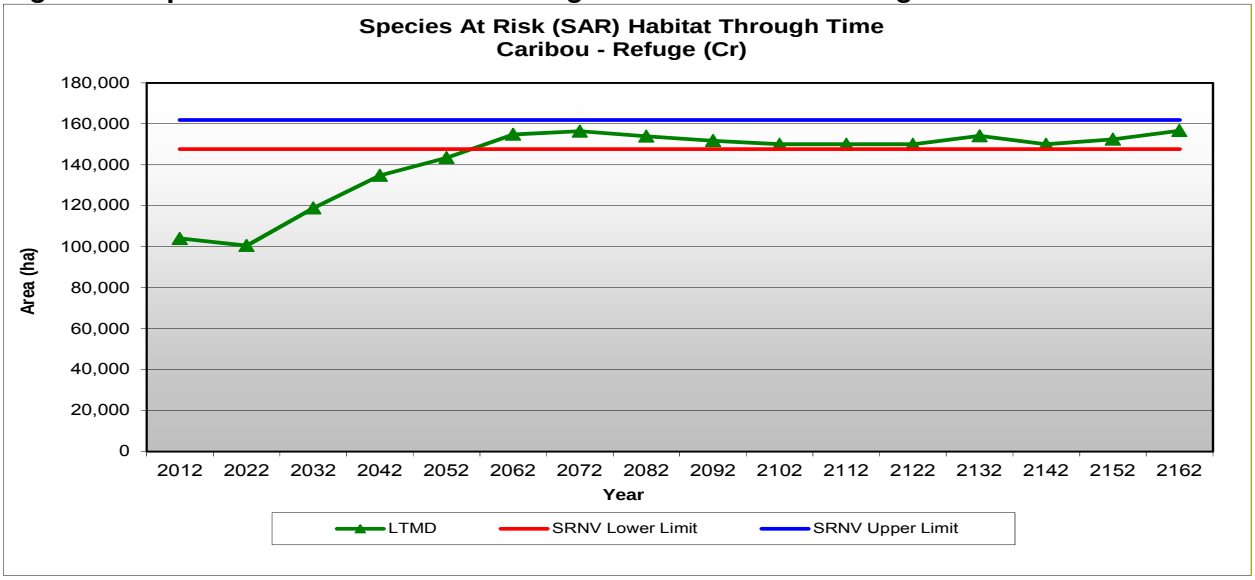

Figure 28 Species At Risk Habitat Through Time – Caribou Winter Used

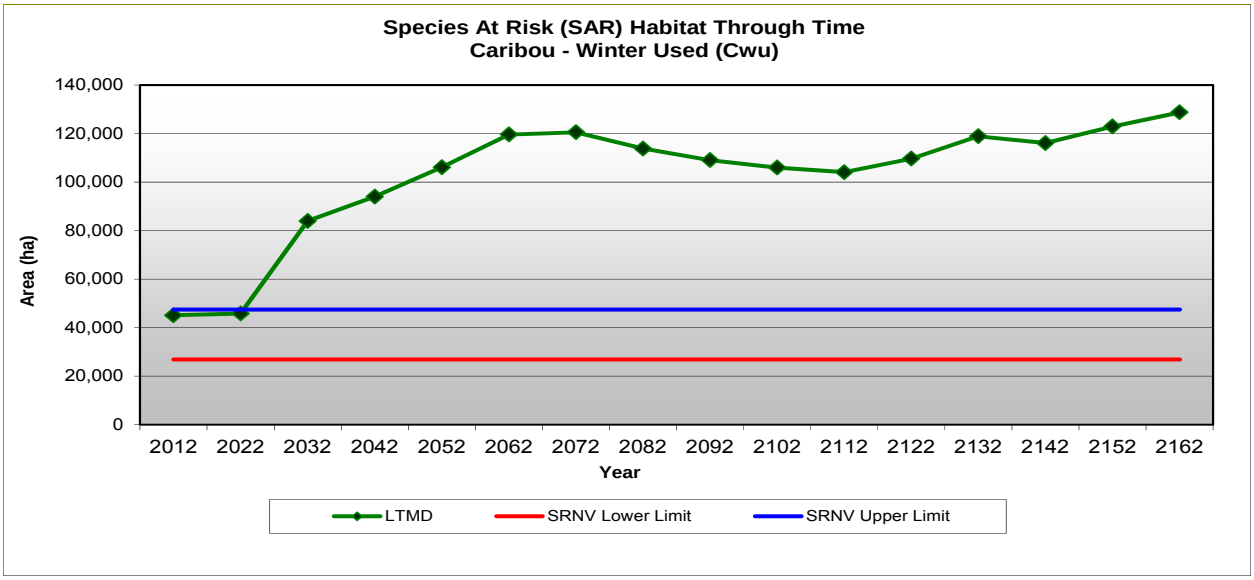

Figure 29 Species At Risk Habitat Through Time – Caribou Winter Preferred

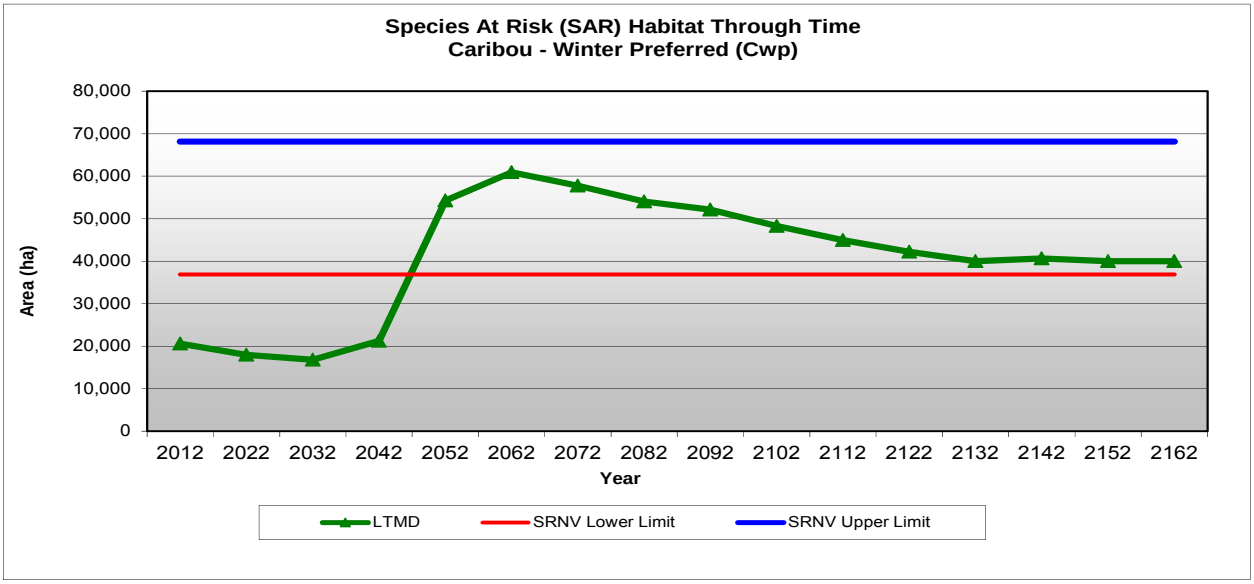


3.6.1 Available Harvest Area

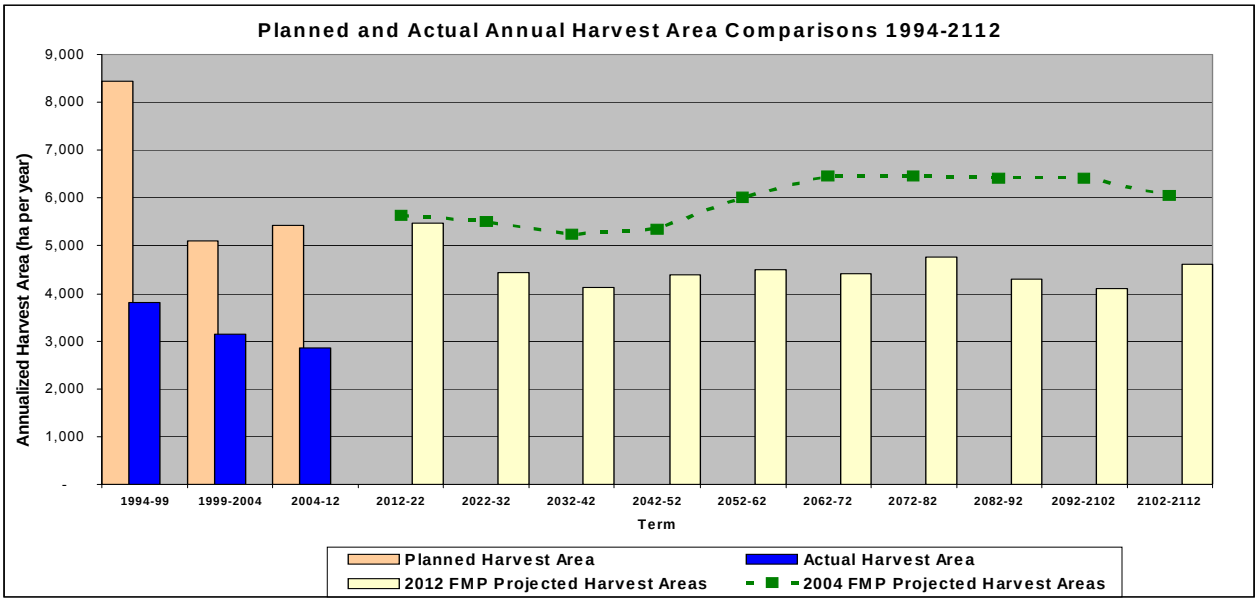
The Long-term Management Direction (27d_OLTMS) projects a harvest of 5,483 hectares per year from 2012-2022. The projected available harvest area over the next 100 years is documented in Table FMP-7.

The projected annual harvest area in the LTMD was compared to the historical planned and actual total harvest areas for 1994 through to 2112 (Figure 30). The total available harvest area planned for 2012-2022 (5,483 ha per year) is comparable to the total available harvest area projected in the 2004 FMP (5,657 ha per year), and slightly lower than the available harvest area approved in the previous 1999 forest management plan (6,692 ha per year). This level of harvest for the 2012-2022 plan period was determined in response to identified management considerations for short-term harvest volumes (Indicator 4c) while balancing long-term objective achievement and forest sustainability.

Long-term Harvest Areas 2022-2112

The total annual harvest area (AHA) is projected to average approximately 4,500 hectares per year for the next 100 years, lower than projections in the 2004 FMP (average of 5,950 ha per year over 100 years). The lower long-term projected harvest area in this plan is a result of (a) a major revision to the objective indicators and desirable levels based on the OLT model simulated ranges of natural variation and (b) the balancing of socio-economic benefits from the Whiskey Jack Forest within the context of overall forest sustainability.

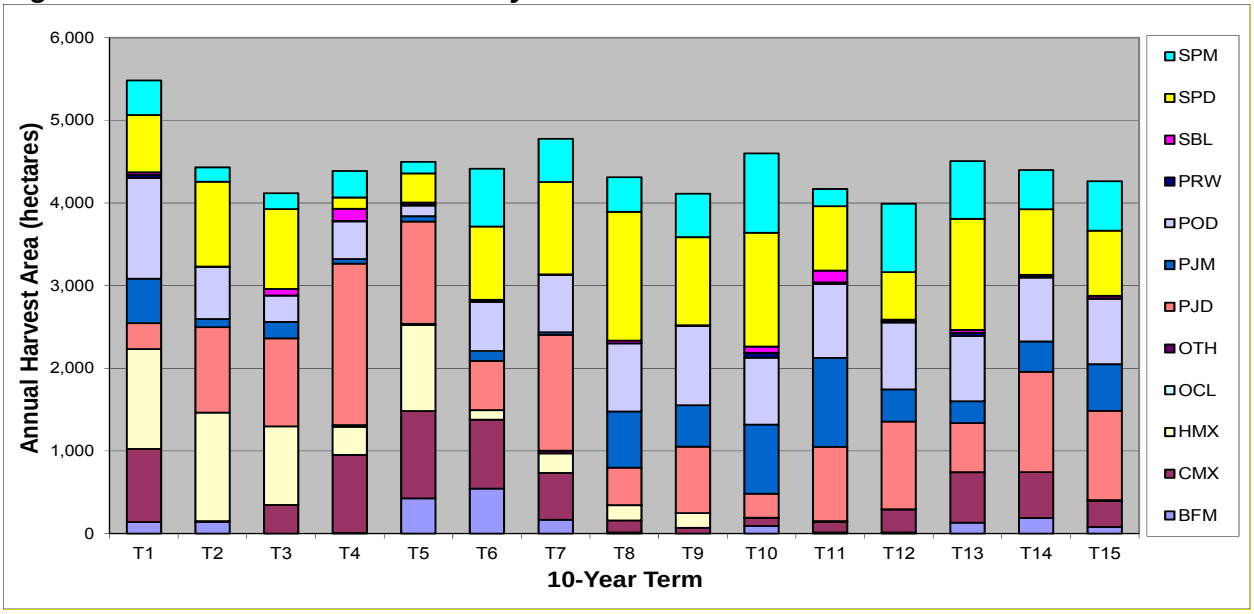
Figure 30 Planned and Actual Annual Harvest Area Comparisons 1994-2112



The available harvest area through the 160-year planning horizon is portrayed graphically by forest unit in Figure 31. The harvest area by forest unit varies from term to term as the projected harvest volume and total harvest area was considered by the Planning Team to be more important than consistent areas between terms for individual forest units. In keeping with movement towards the Simulated Range of Natural Variation for forest composition objective indicators for forest unit, age groupings (including old forest) and future caribou habitat, the short-term harvest area is projected to be primarily in the HWD, POD and CMX forest units. This proportion of harvest by forest unit facilitates a reasonably quick conversion of some areas

to purer conifer forest units, or purer hardwood (POD) which creates the best balance of objective achievement for the long-term.

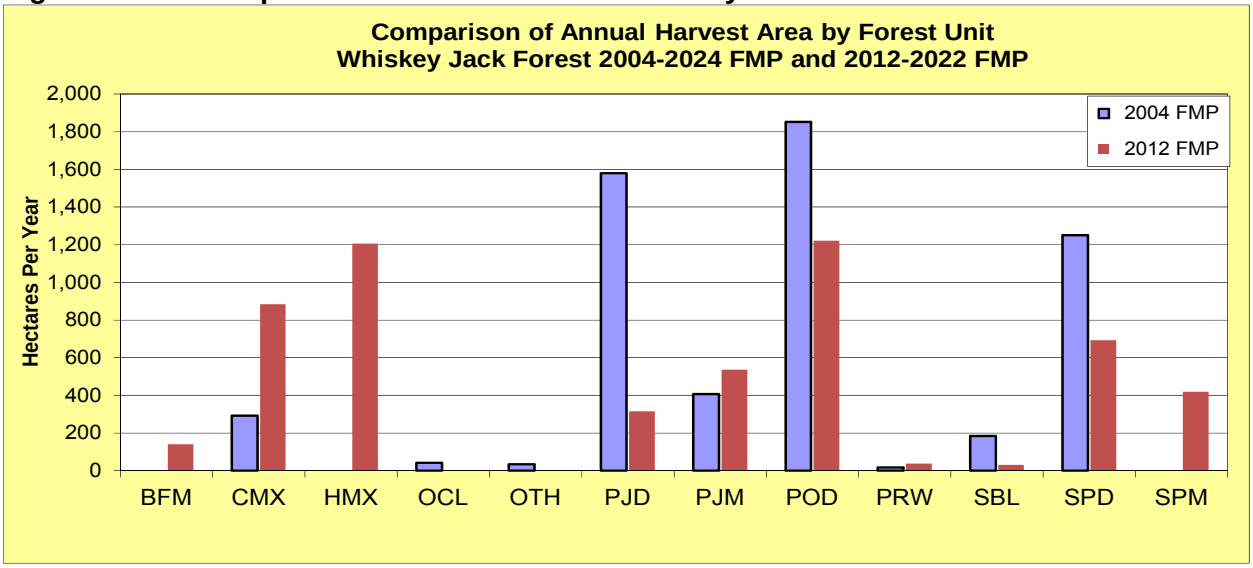
Figure 31 Annual Harvest Area by Forest Unit 2012-2112



The annual available harvest areas by forest unit from the 2004 and 2012 FMPs are compared in Figure 32. The change in numbers of forest units between plan (reduced from 9 to 12 for 2012 plan) and the change in definitions, particularly in the mixedwood forest units, prohibits a meaningful comparison of AHA by forest unit between plans.

The PJD, SPD and POD forest units appear to have decreased in harvest area, but again, this is a result of forest unit definition changes and some areas previously classified as these forest units are now classified as SPM, PJM, CMX and HMX which appear to have increased in AHA area.

Figure 32 Comparison of Annual Harvest Area by Forest Unit 2004 to 2012



3.6.1.1 Available Harvest Volume By Species Group

Short-term Harvest Volume 2012-2022

The 2012-2022 Long-term Management Direction annual harvest area is projected to yield approximately 574,000 cubic metres of timber each year from 2012-2022 (TOTAL, Figure 33). This is comprised of 340,000 cubic metres of Spruce-Pine-Fir (SPF), 190,000 cubic metres of Poplar (PO), 33,000 cubic metres White Birch (BW) per year and 4,000 cubic metres per year of Red Pine and White Pine (PWR). Incidental species (cedar, larch and black ash) total approximately 7,000 cubic metres per year but are not considered major species groups.

The annual total harvest volume level in the LTMD for the 2012 Whiskey Jack FMP (574,600 cubic metres) is 20% lower than the harvest volumes projected in the selected management alternative for the 2004-2024 FMP (718,300 cubic metres per year). The decrease in harvest area and associated harvest volume is a result of desired forest and benefits while balancing other socio-economic indicators and forest sustainability. The Planning Team carefully considered the impact of the 2012-2022 projected harvest area on long-term harvest area/volume and future desired forest and benefits. The Planning Team supports this balance of long-term objective achievement.

Associated with the available harvest volumes are additional potential volumes of defect volume (branches, twigs, leaves, bark) and undersize volumes (top wood). These defect and undersized volumes were estimated through use of a MNR NW Region spreadsheet calculation based on the available harvest volume in the Long-term Management Direction. As reported in Table FMP-8, there are an estimated 104,400 m3 per year of defect volume and 20,700 m3 per year of undersized volume potentially available through harvest of the full available harvest area during this 10-year plan period. The total of available harvest volume, defect and undersized volume is estimated to be 6,997,400 m3 for this plan period 2012-2022 (699,700 m3 per year).

Long-term Harvest Volume 2022-2112

The LTMD projects that the total harvest volume will be sustained at 501,000 m3 per year from 2022-2032, later decreasing to approximately 477,000 m3 per year from 2032 through to 2112. Strategic total harvest volumes projections are lower in this FMP as compared to the 2004 forest management plan. Spruce-Pine-Fir volume is projected to be comparable for 2012-2052 period as was projected in the 2004 FMP but then volumes are projected to be lower than the 2004 FMP for the following 60 years to 2112. Poplar volumes are projected to be significantly lower than 2004 projected levels. This variance is attributed to the refinement of the growth and yield curves and revision of modelling assumptions for the 2012 FMP and also due to the maximization of harvest area and total volumes, rather than forcing constant levels for any particular volume species groups. White Birch harvest volume is projected to be variable in this 2012 FMP but is on average comparable to 2004 FMP volume projections for the next 50 years.

OFAAB Benchmark Levels

The projected volume in the LTMD was compared to the historical and benchmark levels identified in the Ontario Forest Accord Advisory Board (OFAAB) report. The following graphs show the historical and benchmark harvest levels which have occurred on the Whiskey Jack Forest from 1994 to the present. The planned and actual harvest volumes are also illustrated by 10-year FMP term from 1994 to 2012 (includes three additional years for 2009-2012 Contingency Plan period), and planned volumes from 2012 to 2112. Volume comparisons are included for all volumes (TOTAL, Figure 33), Spruce-Pine-Fir (Figure 34), Poplar, (Figure 35, White Birch (Figure 36) and White Pine and Red Pine, (Figure 37).

LTMD projections for Spruce-Pine-Fir harvest volumes are above the OFAAB level in this plan period, but then are projected to be comparable or marginally lower than the benchmark level through the long-term. Poplar harvest volumes are projected to be greater than the OFAAB benchmark level for this plan period, then are projected to be lower than the benchmark through the long-term. The fluctuation in poplar volume is a result of revised modelling assumptions and yield curves and the maximization of short-term harvest volume (not by species group) noted above. White Birch projections are consistently above the OFAAB benchmark. Red Pine – White Pine is also projected to exceed the OFAAB benchmark level for this 10-year plan period, then to be comparable to the benchmark over the following 80 years (except 2032-2042 when no PWR is projected to be harvested). Total harvest volume (not a provincial species group, but informative) is projected to be sustainable at a level slightly below the OFAAB total volume benchmark level.

3.6.2 Selection of Areas for Harvest

A set of criteria was developed in order to identify the areas that could reasonably be harvested during the 2012-2022 period of the Whiskey Jack Forest Management Plan. The Available Harvest Area (AHA) by forest unit (which was derived from the Strategic Forest Management Model outputs for the LTMD) was the primary criterion for the selection of preferred and optional harvest areas. The Ministry of Natural Resources' *Forest Management Guide for Natural Disturbance Pattern Emulation*, *Forest Management Guidelines for the Conservation of Woodland Caribou: A Landscape Approach, Forest Management Guidelines for the Provision of Marten Habitat* and other guides and decisions provided additional direction. The criteria used for the selection of preferred and optional harvest areas are found in the following Sections 3.6.2.1 and 3.6.2.2.

Based on these eligibility and selection criteria, 51,971 hectares of planned harvest areas were identified for the 10-year plan period during for Stage Four of plan production.

3.6.2.1 Harvest Area Eligibility Criteria

The Long-Term Management Direction provides the strategic, long-term direction for management of the Whiskey Jack Forest. In order for the LTMD to be successfully implemented, areas eligible for harvest operations during the ten-year period of the plan are identified. These eligibility criteria are consistent with the strategic modelling for the LTMD using the SFMM model.

All eligible areas that were not identified as preferred areas for harvest were considered to be optional harvest areas. The eligibility maps represent the stands eligible for harvest during the 10-year period of the plan.

The allocated areas for harvest for the 10-year plan period have been portrayed on a composite summary map located in the electronic version of the FMP. This summary map includes a breakdown of the harvest area for each of the two five-year terms. The summary map also includes optional harvest areas during the ten-year period. Further refinements to the planned harvest allocation required for subsequent stages of plan development (Stage Three and Stage Four) are discussed in Section 4.3.

For this forest management plan, areas eligible for harvest operations during the ten-year period must meet the following eligibility criteria:

a) The first, and most important criterion is that the area must be managed, Crown land ownership. While the possibility of harvest is somewhat unlikely, all shoreline reserves and areas previously classified as bypassed or inoperable are considered eligible for harvest.
b) The second eligibility criterion was to have harvest allocations from areas located outside marten core habitat areas.
c) The third consideration was to ensure stands eligible for harvest are in the active subunits, including active subunits in the Dynamic Caribou Habitat Schedule (for 2012-2022 these active subunits are LOW, PAK, PAT, Car06, Car07, Car08, Car09 and Car10).

d) All eligible areas should meet the lower operability age limits by forest unit during the ten-year period (Table 18).
e) Younger stands are considered eligible for harvest where they are spatially associated with older stands and their harvest at the same time as the rest of the area is beneficial for landscape pattern or operational reasons (harvest, road access or consideration for other forest uses); and
f) All areas in which timber has been damaged by blow down, insects, or disease.

Lower harvest operability limits have been set by forest unit to guide planning of operations and are applied consistently to all subunits. Ages are measured at the beginning of 10-year plan periods. The lower harvest operability limits are as follows in Table 18:

Table 18 Lower Harvest Eligibility Ages for 2012 FMP

Forest Unit	Lower Operability Age
BFM	60 years
CMX	55 years
HMX	55 years
OCL	90 years
OTH	70 years
PJD	55 years
PJM	60 years
POD	55 years
PRW	65 years
SBL	90 years
SPD	70 years
SPM	60 years

The operability limits were set in order to maximize volume while the blocks are available for harvest. This has been done taking into consideration that a 10-year planning horizon will provide some opportunity for the younger wood to grow for a period of time before harvest occurs in the second five-year term of the plan. In most cases, the younger wood has been scheduled for harvest in the second five years to maximize the size and yield from these stands.

These operability ages were included in the base model and were consistent throughout the SFMM investigations that involved harvest operations. Generally, the minimal volume yield was considered to be 80 cubic metres per hectare for a stand to be operational. These minimum volume requirements were related to yield curves for each forest unit and estimated product piece size to determine the minimum operability limits for the SFMM modelling and eligibility criteria. The minimum operability age of certain forest units were increased above the age which would produce 80 cubic metres per hectares to reflect the desire to harvest larger piece sizes and volumes in some of the conifer forest units. The minimum operability age was reduced slightly for BFM, CMX and SBL to allow greater flexibility in clean-up and spatial harvest allocations for these forest units.

3.6.2.2 Harvest Area Selection Criteria

The preferred harvest areas were selected and separated into the first 5-year term (Phase I) and the second 5-year term (Phase II), for the 10-year plan period. Contingency areas have been identified from the optional harvest areas and have received detailed area of concern planning.

The areas for harvest operations were selected from within the areas that passed through the eligibility criteria filter. The stands deemed eligible had to meet specific stand characteristics. The application of this set of selection criteria aided the application of sustainable forest management and enhanced plan continuity from the previous term to the current plan term. It is important to recognize that the following selection criteria were applied after the potential harvest stands met the eligibility criteria based on harvest timing according to the dynamic caribou habitat schedule and the marten core habitat area harvest deferral criteria.

The following are the selection criteria that were used to direct the harvest allocation from within the eligible areas (geographic and time). The order in which these criteria are presented represents a general ranking of importance.

1) Maturity of forest stands.
   a) Allocate the full available harvest area for each forest unit as projected by SFMM in order to align with the Long-term Management Direction (approximate age class projections as much as is operationally possible) (i.e. SFMM Annual Available Harvest Area by forest unit by age class).
   b) Stand age at plan start should meet minimum harvest operability age.
   c) Avoid allocating stands less than 15 metres tall unless they are associated with adjacent operable stands.

2) Operability of the area.
   a) Allocate areas that can be reasonably accessed within the plan period.
   b) Select all merchantable timber in active caribou subunits.
   c) Schedule harvest allocations associated with Grassy Narrows First Nation (Asubpeeschoseewagong Netum Anishinabek) in the second five-year term.

      Note: The 2012-2022 Forest Management Plan identifies access, harvest, renewal and tending activities in the “Keewatin Lands” (north of the English River system). An earlier court decision held that Ontario could not authorize land uses in the Keewatin Area that would significantly impact the ability of Treaty 3 beneficiaries to exercise their Treaty-protected rights, without First Nation consent or Federal Authorization. On March 18, 2013, the Ontario Court of Appeal reversed that earlier decision. The appeal court’s decision is subject to an appeal to the Supreme Court of Canada to be heard in Spring 2014. In areas closest to the community of Grassy Narrows, south of the Keewatin Lands, the majority of the allocations have been scheduled for Phase 2 to provide for the final court decision and further consultation.

   d) Utilize geographical boundaries such as patent land, streams, lakes, non-productive areas, topography and stand boundaries to define the boundaries of the harvest area.
   e) To ensure harvest areas are economical, the average harvest block size is preferred to be at least 70-100 ha.

f) Haul distances must be balanced in an attempt to control fibre costs. The harvest blocks must be made accessible with a road construction and maintenance program that will be balanced annually.
g) Isolated harvest areas less than 40 hectares in size are not generally economical in which to operate. Avoid allocating areas that leave less than 40 ha. patches in a geographical area (i.e. bordered by lakes, streams, patent land etc.) to avoid 'orphaning' future harvest areas.
h) Where stands are 50% or lower in stocking, increase economic feasibility by ensuring that these stands do not make up of more than 30% of the area in a harvest block.
i) Where access is remote or costly, design larger harvest areas to increase operational feasibility and utilize opportunity to create larger disturbance sizes to emulate natural disturbance patterns.
j) Create a balance of summer and winter wood to provide continuous year round harvest opportunities, and volume and delivery requirements of destination mills.
k) Attempt to reasonably balance harvest allocations equally between the two 5-year phases of the ten-year period.
l) Allocate harvest area to meet the area and volume needs of specific harvest operators and overlapping licensees.
m) Allocate areas of natural disturbance for salvage harvest operations where feasible.
    a. Salvage operations will consider strategic landscape objectives.
    b. When finalizing boundaries of a salvage operation that results from wildfire, the area of undisturbed forest included in the salvage operation will be minimized.
    c. When finalizing boundaries of a salvage operation that results from blowdown, insect infestation, or other factors (e.g., ice storms), the area of the salvage operation can include undisturbed forest.
    d. When salvage operations include undisturbed area, the direction for residual forest retention during regular operations will apply to the maximum extent possible given the undisturbed forest present.

3) Emulation of natural disturbance patterns
a) Allocate harvest areas in size classes that indicate movement towards the landscape pattern frequency distribution as determined in the natural disturbance template for the forest.
b) Allocate areas that have previous depletion (< 20 yrs. old) and look for opportunities to complete the harvest in an area in order that the area has the potential to become future large, landscape patches or caribou habitat subunits.
c) Follow direction in the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* in regards to leaving mapped residual patches.

4) Wildlife Habitat
a) Within designated Moose Emphasis Areas (i.e. Large Landscape Patches) allocate harvest areas that show movement towards meeting moose habitat management objectives.

5) Visual Aesthetics
a) When allocating near large high usage lakes attempt to minimize the visibility of the harvest area.

6) Tourism Agreements
a) Allocate in accordance with agreements with tourist operators.

7) Fuelwood Opportunities
   a) Allocate fuelwood opportunities accessible to the public.

The balancing of these selection criteria does not always follow the same order depending on location, access, agreements with tourist operators, and balancing forest units and age classes. While determining harvest allocations, the relative proportion of winter and summer wood was considered important for the two five-year terms, as well as road access and planned clearcut sizes (the NDPEG standard for planned clearcuts states that 80% of the total number of planned clearcuts in the Boreal Forest are to be equal to or less than 260 ha in size).

The description of the achievement of the natural disturbance pattern template as required by the FMPM is discussed in Section 3.6.3.1 as natural disturbance pattern is an indicator of objective achievement.

The selection criteria for contingency areas are:
   a) Maximum of two years available harvest area to be allocated as contingency area.
   b) Areas must be accessed or expected to be accessed in a reasonable timeframe.
   c) Areas must be able to be harvested year-round.

Harvest areas were selected as closely as possible to match the available harvest area for the 10-year period by forest unit as projected by the Long-term Management Direction (Table **19**). Overall, 50% of the 10-year planned harvest will occur in the first five-year term, with the remaining 50% occurring in the second five-year term. During planning for Phase 2 operations when areas of concern are planned and reserves finalized, the total of the Phase 1 harvest area and the planned harvest area for Phase 2 will be equal to the full available harvest area for the 10-year period. Any areas allocated in Phase 1, but not yet harvested, will remain approved for harvest during the second five-year term. By forest unit, the breakdown of harvest area by five-year term is as recorded in Table **19.** The distribution of harvest area by forest unit between the two five-year terms is variable between forest units and their geographic location. The smaller forest units tend to have less balanced harvest area between the two five-year terms (i.e. PRW, SBL) as full stands are allocated in one term or the other. Additional rationale on the harvest allocations is detailed in Section 3.6.2.3.

Table 19 Summary of Planned Harvest Area by Forest Unit and Five-Year Term

Forest Unit	LTMD 10-YEAR TOTAL	Planned Allocations 10-YEAR TOTAL	Variance to LTMD	Planned Allocations 1st Term, 2012-2017		Proposed Allocations 2nd Term, 2017-2022

3.6.2.3 Rationale for Planned Harvest Areas by Forest Unit and Age Class

During the selection of harvest areas, consideration was given to projected available harvest area by forest unit from the Long-Term Management Direction, current forest conditions, desired forest and benefits, stakeholder comments, fish and wildlife habitat, water quality, cultural heritage values, tourism values, caribou habitat, retention of old forest area, marten core area deferrals and overall natural disturbance pattern. A comparison of planned harvest to the projected LTMD harvest areas by forest unit and age class are included in Table 20.

The comparison of the planned harvest area to the available harvest area shows good correlation with projected age classes however there is some age class substitution in certain forest units. The allocated harvest area that does not exactly match the LTMD projected age classes shows a minor trend to stands younger (0% of harvest area) or older (3% of the planned harvest) than the projected LTMD age classes by forest unit. Only 14 ha of SBL are allocated in an age class lower than projected in the LTMD. All other planned harvest area meets or exceeds the ages projected in the LTMD. The LTMD projected 22% of harvest area in stands less than 80 years of age. The planned allocations project 42% of harvest area to be less than 80 years old.

Table 20 Comparison of Harvest Allocations to the LTMD by 20-year Age Class

Forest Unit	10-Year Available Harvest Area (ha)	Age Class	Planned Harvest Area (10-year period, ha)
BFM	-	0-20	-
	-	21 - 40	-
	-	41 - 60	-
	20	61 - 80	31
	876	81 - 100	834

Effort was made during the allocation process to minimize the amount of forest stands allocated

for this plan that are younger than LTMD projections, though all these stands do meet the harvest eligibility and selection age criteria (Section 3.6.2.1 and 3.6.2.2). This younger timber was not specifically targeted during allocation selection but was considered logical to incorporate into operating blocks. The younger aged harvest area in the POD and SPD forest units were allocated to create operationally feasible blocks and to clean up areas from previous operations.

All eligible stands for harvest in this plan were reviewed to determine operability, access concerns, seasonal wood flow, maturing adjacent stands (younger wood coming on line) and stakeholder concerns and commitments. In addition most of the selected harvest areas were visually inspected through the use of a helicopter or were ground checked by MNR staff. Most areas are in close proximity to previous harvest areas. The selection/allocation of stands was not performed by a generic computer/GIS exercise of those stands SFMM generated, rather a specific site related approach to allocations, was utilized. This resulted in a level of confidence in the suitability of allocated areas and will form an operational foundation critical during successful implementation of the plan.

When age class substitution was necessary, the allocation of stands older than the SFMM LTMD projected age was considered more favourable than a trend to allocate younger stands. There were a variety of reasons why age class substitution in the planned harvest occurred. These reasons include:

1) Interested stakeholders were engaged in the planning process and changes were made through negotiations and/or minor changes to protect resource values, and increasing lakeshore buffers. Interested stakeholders (who made their concerns known) were consulted on several occasions throughout the planning process, to discuss concerns with access, view aesthetics and harvest scheduling. These concerns have been addressed through AOC planning or harvest scheduling. Appropriate prescriptions were applied to protect fisheries and water quality, wildlife and tourism values and adjusted road use strategies. Other public correspondence was received that required detailed review of certain areas of interests, which resulted in minor changes to the selection of harvest areas.

2) For a harvest block to be economically feasible a minimum size of 70 hectares is generally preferred. The economic feasibility of harvest areas depend on a number of factors, such as proximity to a road, the quality of the fibre, age of adjacent stands, etc. Harvest blocks are then created around stands that meet the age classes preferred in the LTMD. However what occurs frequently is there are younger, yet operable stands adjacent to the older stands that if not allocated become “orphaned” in the future. In order to not fragment the forest, these younger stands are generally allocated before the ideal scheduling projected in the LTMD. In some areas the opposite occurs, where stands older than projected by the LTMD are allocated in association with other eligible stands.

3) The *Forest Management Guide for Natural Disturbance Pattern Emulation (MNR, 2001)*, requires that 80% of the planned clearcuts by frequency are less than 260 hectares in size. This has an effect of spatially limiting areas of older wood that are adjacent to existing ‘planned clearcuts’ that are slightly less than 260 ha. in size. In the assessment of the “80% under 260 hectares” standard, the assessment has identified 76% of planned clearcuts to be equal to or under 260 hectares in size, leaving 24% of planned clearcuts greater than 260 ha. This result is lower than the 80% standard, but is

acceptable to the Planning Team as it results from strategic landscape pattern direction (e.g. dynamic caribou habitat schedule, marten core areas, moose / deer emphasis areas) and projected harvest allocations that balance consideration for all desired forest and benefits and operational challenges.

4) Small allocations such as SPL (300 ha.) are considerably fragmented. Although there were larger older eligible stands that could have made an operable block, the AHA was totally utilized by picking up small "orphan" stands adjacent to stands made up of other forest units.

5) Negotiations with several stakeholders have resulted in the delayed harvest of some mature stands that they utilize as part of their recreational activities (i.e. contain recreational trails therefore no harvest will occur in this plan period).

6) Some stands are mistyped and resulted in not being allocated. Generally, the mistyped stands fall in two categories: Younger than FRI indicates or should have been reclassified as 'protection forest'.

Reasons for the age class substitution can be attributed to many factors. Certain factors apply broadly to the forest and its landscape pattern (i.e. road access, geographic location of concentrations of mature eligible forested stands), and other factors apply specifically to individual operating areas. The combination of these factors has been reviewed in detail and supported by the Whiskey Jack Forest 2012 FMP Strategic Task Team and Operations Task Team and it is felt that based on environmental and operational considerations, harvest allocations have been selected in conjunction with provincial guides and direction, consultation with the public, and sound operational logistics.

Preliminary harvest allocations were determined prior to the First Information Centre (Public Review of Proposed Operations). Harvest allocations were again refined between the information centre and the draft plan submission. Several new factors influenced a minor change in planned harvest areas. For example, as a result of public and stakeholder consultation, several shoreline reserves were increased to enhance protection of tourism values. The reduction of allocated harvest area in these tourism areas had to be balanced with new allocations elsewhere. Some of this replacement harvest area was in younger or older age classes (but still eligible for allocation as per Section 3.6.2.1 and 3.6.2.2). This age class substitution was considered reasonable as the protection of tourism values was considered more important than the age class distribution of harvest areas.

The analysis of harvest allocations by forest unit and age class show that of the 51,971 hectares of harvest area allocated for this 10-year plan period, 0% (14 ha) is in age classes lower than projected in the LTMD and 3% (approx. 1,400 ha) is in age classes older than the LTMD projections. It is important to note that the younger allocated harvest areas still do meet all the harvest area eligibility and selection criteria, but are younger than the suggested age classes projected in the LTMD.

The potential impact of this level of age class substitution in the harvest allocations was analyzed through a "Final Test of Sustainability" by including the actual planned harvest, by forest unit and 10-year age class, into the SFMM model with the same constraints and assumptions as the Long-term Management Direction run. The Final Test analysis confirmed that 'the planned allocations do not negatively impact upon overall objective achievement, definition of the desired future forest condition, nor do they compromise the long-term

sustainability of the Whiskey Jack Forest'. Results of this analysis are detailed in Section 4.9. Given the specific rationale discussed with MNR district staff, and the confirmation of forest sustainability (Section 4.9), this level of age class substitution was considered acceptable to MNR given the varied issues to be considered. The concept, and amount, of age class substitution was presented to the Planning Team and no concerns were noted.

In general there are many constraints in matching the age class specific allocations generated through the LTMD. However the constraints are valid as they are based on economic, environmental and societal values that are important to a balanced forest management plan.

The impact of implementation of the planned harvest areas, including age class substitution compared to the LTMD, was analyzed and documented in Section 4.9 Comparison of Proposed Operations to the LTMD, and in Section 5.0 Determination of Sustainability. Analysis results support that implementation of the 10-year planned harvest, including variances in area by age classes, does not negatively impact objective achievement or the long-term sustainability of the Whiskey Jack Forest.

3.6.3 Assessment of Objective Achievement

The long-term management direction (LTMD) for the forest provides guidance on levels of access, harvest, renewal and tending activities required to achieve a balance of objectives over time and meet the desired future forest and benefits. In the development of the LTMD, management objectives and indicators were developed/established and target levels identified through various analytical methodologies (models and tools) with regard to forest guidelines, social and economic assessment, wildlife habitat, and landscape management over time. The overall goals are to provide for biological diversity, sustainable forest management, social and economic benefits/development, and protection of natural resources and the forest ecosystem condition on the Whiskey Jack Forest.

This section of the forest management plan documents the results of the assessment of objective achievement for each of the management objectives and indicators, scheduled for assessment during the preparation and approval of the forest management plan. Objective achievement and the relationship to desirable levels and targets, including any differences, are also documented. If the level of objective achievement is outside of the desirable level for an objective, rationale is provided. A summary of the projected objective achievement, desirable levels and targets in the long-term management direction is recorded in Table FMP-9.

The achievement of individual management objectives was assessed using the results of the forest modelling for the Long-term Management Direction, the results of the preliminary spatial assessment, and other plan components developed during preparation of the plan.

The assessment of objective achievement was based on the extent to which the established desirable levels for each indicator have been satisfied within the 10-year plan period. The management objective information and an assessment of objective achievement are documented in Table FMP-9.

Of the 30 indicators included in Table FMP-9, 18 of the indicators can be assessed during plan development. The remaining 12 indicators (and reassessment of some of the original 18 indicators) will be assessed in the future: after plan implementation as appropriate (specific indicator timing of assessment is noted in Table FMP-9 and in plan text Section 3.5.2).

Of the 30 plan indicators assessed:

- 11 indicators ACHIEVE desirable and target levels in this 10-year plan period;
- 6 indicators are projected to ACHIEVE target levels in a target timeframe longer than this 10-year plan period;
- 1 indicator is projected to NOT ACHIEVE desirable or target levels at some point in the 100-year strategic planning horizon; and
- 12 indicators will be assessed in the FUTURE after plan implementation.

30

The following is a brief discussion of the objectives, indicators and achievement of desirable and target levels for each indicator with a summary of the assessment and relevant detail provided.

3.6.3.1 Objective 1: Landscape Pattern

Indicator: (1a) % of polygons with >60% mature and old forest

This landscape pattern indicator for mature and old forest is assessed to determine whether the proposed plan activities will create a landscape pattern consistent with simulated natural disturbances. This objective is carried forward from the 2004 FMP in accordance with the *Forest Management Guide for Natural Disturbance Pattern Emulation (2001*) and also addresses a landscape pattern indicator from the *Forest Management Planning Manual (2009)* required for this FMP. This indicator is intended to influence the supply and arrangement of mature and older conifer-dominated forest across the forest. Mature and old forest indicator is used to provide habitat for certain song birds and wildlife habitat that requires this seral stage.

Desirable and Target Levels: The desirable level is to have the landscape pattern consistent with minimum OLT percentage projections for mature/old forest established for the forest Table 21) and the target level is to show movement towards these levels by Plan End. The minimum desirable level for proportions of mature and old forest was derived from the Ontario Landscape Tool for the Whiskey Jack Forest and accepted by the Planning Team as the best estimation of the natural forest condition.

The following table reports the projected percentage of mature or old forest polygons at Plan Start 2012 and Plan End 2022, as analyzed at the 500 ha and 5,000 ha hexagon scales.

Table 21 Analysis for Percent of Polygons with >60% Mature or Old Forest

Analysis Scale	Plan Start 2012 Percentage	Minimum Desirable Percentage	Projected Plan End 2022 Percentage
Scale: 500 ha hexagon	27%	35%	29%
Scale: 5,000 ha hexagon	18%	28%	24%

ASSESSMENT - Indicator 1a – Mature and Old Forest Landscape Pattern:
Desirable level not achieved in this plan period. Target level is projected to be **ACHIEVED** during the plan period with movement towards the minimum desirable percentages.

Spatial assessment using the OLT model showed that implementation of planned operations would result in a landscape pattern of mature and old forest that is moving towards desirable level from plan start level during this plan period.

Indicator: (1b) Frequency Distribution of Young Forest Patches by Size Class

Desirable and Target Levels: The desirable level is to have young forest landscape pattern consistent with OLT projections of young forest patches by size class calculated for the forest (Table 22). The target level is adjusted to recognize movement towards desirable level during this plan period. This target flexibility considered that achievement of the template distribution during the next 10-years was limited by the current landscape pattern, other considerations related to short-term landscape pattern management (e.g. caribou habitat management, marten

core habitat management, frequency of planned clearcuts <260 hectares in size), and operational considerations or timing limitations to road access and harvest allocations during the plan period.

Additional operational consideration was given to the reduction in the number of larger patches of young forest in response to concerns of the Kenora LCC.

The percentage distribution of young forest patches by size class is presented for plan start (2012); forecasted for plan end (2022) with only ageing of the forest (no harvest); forecasted for plan end (2022) with ageing and planned harvest operations; and for the "natural" forest template, as derived from the Ontario Landscape Tool model specifically for the Whiskey Jack Forest. This information is presented graphically in Figure 38 and in tabular form in Table 22 including an assessment of movement towards the desirable level of natural template distribution.

Figure 38 Frequency Distribution of Young Forest Patches by Size Class

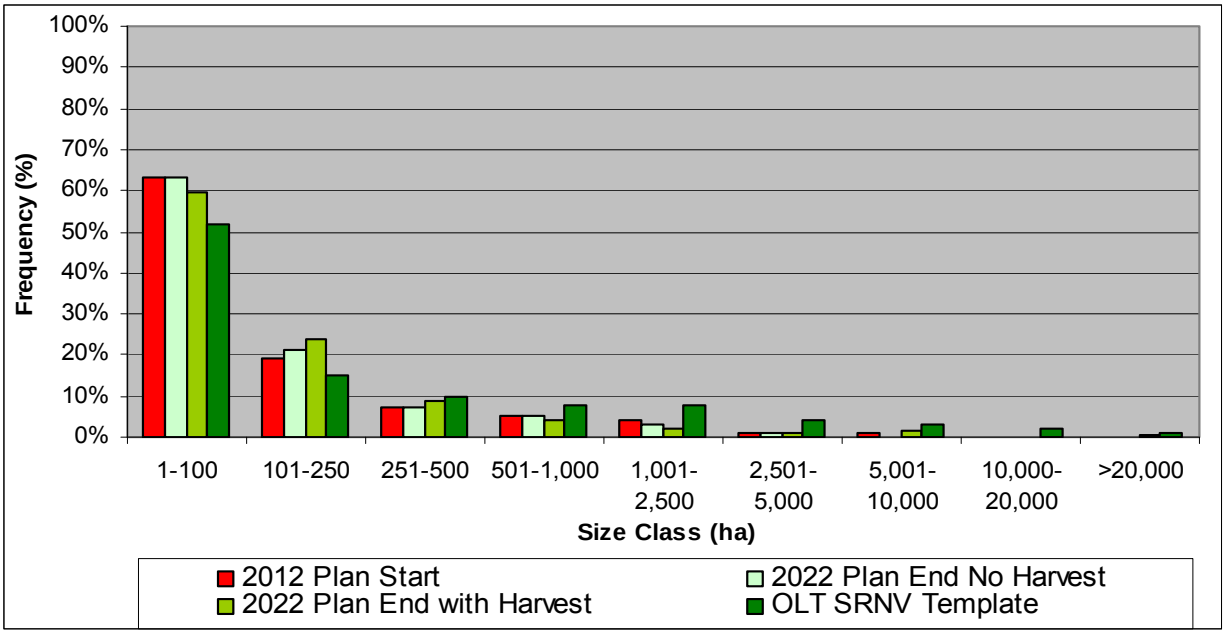

Table 22 Young Forest Frequency Percentage by Size Class

	As a Percent				Assessment
Size Class (ha)	2012 Plan Start	2022 Plan End No Harvest	2022 Plan End with Harvest	OLT SRNV Template	Assessment of Movement Towards Natural SRNV Template
1-100	63%	63%	60%	52%	Movement towards
101-250	19%	21%	24%	15%	Movement away
251-500	7%	7%	9%	10%	Movement towards
501-1,000	5%	5%	4%	8%	Minor movement away
1,001-2,500	4%	3%	2%	8%	Minor movement away
2,501-5,000	1.0%	1.0%	1.1%	4.0%	Towards - but no significant change
5,001-10,000	1.0%	0.0%	1.3%	3.0%	Towards - but no significant change
10,000-20,000	0.0%	0.0%	0.2%	2.0%	Towards - but no significant change
>20,000	0.0%	0.2%	0.3%	1.0%	Towards - but no significant change
Total					

Six of nine young forest patch size classes project movement from Plan Start distribution towards the Simulated Range of Natural Variation (SRNV) through implementation of planned harvest areas for this plan period. Four of these size classes that show movement towards the SRNV do not change significantly from the Plan Start frequency. Three size classes project movement away from the SRNV at the end of this plan period. The 101-250 ha class increases in frequency from 19% to 24% whereas the template suggests a reduction to 15%. The 501-1,000 and 1,001-2,500 ha class frequencies decrease slightly at Plan End compared to higher desirable levels, but only change by 1-2%.

There are several areas of young forest that have resulted from past natural disturbances, including the large 1991 blowdown (114,000 ha). This blowdown is now 21 years old and the OLT model counts all young forest less than 36 years of age. As this blowdown and other pre-NDPEG harvest areas age there will be a significant change in the distribution of young forest by size classes. Therefore the current distribution of young forest is considered socially acceptable for this plan period.

Overall assessment is that while it will take many future plan periods to reach the desirable level, the target level for this indicator is achieved in this plan period, as the movement toward the template frequency distribution is greater than the minor shortfalls in 3 classes.

Additional documentation of the landscape pattern spatial analysis is included in Supplementary Documentation N – Spatial Analysis: Part 3: Landscape Pattern OLT.

ASSESSMENT - Indicator 1b – Frequency Distribution of Young Forest Patches by Size Class:
Desirable level not achieved in this plan period. Target level is projected to be **ACHIEVED** during the plan period.

The desirable level could not be achieved within the 10-year period of this plan therefore the target level was determined to allow movement towards the template distribution in this plan period. Five of nine size classes demonstrated movement towards the desirable frequencies, and the remaining four size classes remained constant at 0%, the same as the Plan Start values for these four size classes.

Indicator: (1c) % of polygons with >60% mature and old conifer forest

The Planning Team decided to include one additional indicator to approximate the landscape pattern of concentrated (>60%) mature and old conifer in addition to the other indicators suggested by the Science and Information in support of Ontario's Forest Management Guide for Boreal Landscapes. There was concern that the combination of indicators for mature/old landscape pattern (spatial), mature/late conifer landscape class (non-spatial), and upland pine and spruce (non-spatial) may not cover all the area currently assessed according to the marten habitat guide. This concentrated conifer indicator area is similar to marten core habitat but allows a greater range in sizes and distribution of this older conifer area. The conifer dominated forest is composed of PJD, PJM, SPD and SPM forest unit areas.

Desirable and Target Levels: The desirable level is to have the landscape pattern consistent with minimum OLT percentage projections for mature/old conifer forest established for the forest (Table 11) and the target level is to show movement towards the desirable level by Plan End. The minimum desirable level for proportions of mature and old conifer forest was derived from the Ontario Landscape Tool for the Whiskey Jack Forest and accepted by the Planning Team as the best estimation of the natural forest condition.

The following table reports the projected percentage of mature or old conifer forest polygons at Plan Start 2012 and Plan End 2022, as analyzed at the 500 ha and 5,000 ha hexagon scales.

Table 23 Analysis for Percent of Polygons with >60% Mature or Old Conifer Forest

Analysis Scale	Plan Start 2012 Percentage	Minimum Desirable Percentage	Projected Plan End 2022 Percentage
Scale: 500 ha hexagon	4%	19%	6%
Scale: 5,000 ha hexagon	1%	9%	1.3%

For the 500 hectare hexagon, the plan start is at 4% moving to 6% at plan end. The SRNV for this indicator is 19% therefore there is some movement towards the SRNV. For the 5,000 hectare hexagon, the plan start is at 1% moving to 1.3%, again showing very marginal movement towards the desirable SRNV level of 9%. The limited movement towards the desirable level was not negatively influenced by harvest allocations. The Planning Team planned for the maximum amount and arrangement of conifer-dominated marten core areas that the Whiskey Jack Forest is currently capable of supporting; planned harvest areas spatially to defragment (clean up) previously harvested areas and to not fragment any new large areas. It will take several more 10-year planning terms for the forest to age and create more mature and old forest, which will result in the desirable level being achieved in the future. So while this indicator is technically achieved for this plan period with some movement toward the desirable level being measured, more time is needed for the forest to grow older and more significantly achieve this indicator.

ASSESSMENT - Indicator 1c – Mature and Old Conifer Forest Landscape Pattern:
Desirable level not achieved in this plan period. Target level is projected to be **ACHIEVED** during the plan period with some demonstrated movement towards the minimum desirable level.

3.6.3.2 Objective 2: Forest Composition

Indicator: (2a) Crown Productive Forest by Landscape Class

Desirable and Target Levels: The desirable level is to achieve and maintain the mature and late successional landscape class areas at or above the minimum of the lower interquartile hectare range (Simulated Range of Natural Variation)(SRNV) for each mature and late successional landscape class as projected by the Ontario Landscape Tool for the Whiskey Jack Forest (Table 24). The target level is the same as the desirable level, measured at the end of the plan period.

The projected productive forest area by landscape class at the end of this FMP period (2022)

and through the long-term (2112) are reported in the following table. Minimum desirable and target levels for the mature/late successional landscape classes are met or exceeded for two classes at Plan Start, and with the other two classes (smallest landscape classes) having projected areas approximating the desirable levels within 40-80 years.

ASSESSMENT - Indicator 2a – Crown Productive Forest by Landscape Class:
Desirable level is not met for all classes in this plan period. The desirable and target levels are **ACHIEVED** and maintained within the 100-year planning horizon.

Two mature/late (ML) landscape classes achieve minimum desirable and target levels at Plan Start. Remaining two classes are the smallest of ML classes and achieve and sustain desirable levels in medium-term (40-80 years) and sustain levels through long-term. Some achievement was increased to improve trends closer to OLT medians rather than minimums. Target levels ACHIEVED in the medium term indicator timeframe.

Table 24 Projected Area by Landscape Class

(2a) Productive Area by Landscape Class (ha)							
Ha	PreSap +Sap	Imm Conifer	Imm Hwd	Mature and Late Successional:			
				Balsam	Lowland	Hardwood	Conifer

T11	160,000	177,997	77,266	13,212	12,850	49,208	233,558
T12	160,000	177,323	73,300	14,617	12,850	48,631	237,310
T13	160,000	180,100	71,180	16,350	12,948	47,318	236,136
T14	160,000	181,572	69,777	15,794	12,850	45,228	238,812
T15	160,000	174,065	70,528	14,287	12,850	43,100	249,202
T16	160,000	167,768	69,660	13,731	12,850	43,100	256,923
OLT Max.	263,084	228,782	63,469	16,237	16,276	65,739	269,185
OLT Min.	143,268	103,333	36,052	8,706	12,845	43,021	178,461

Where projections fall below the min. target, the data is shaded yellow;
where projections exceed max. targets, the data is shaded green.

Indicator: (2b) Crown Productive Forest by Forest Unit and Age Grouping

Desirable and Target Levels: The desirable level is to achieve and maintain productive forest area by forest unit and age grouping at or above the minimum SRNV area projected by OLT (Immature in Table 25, Mature+ in Table 26). The target level is the same as the desirable level to be measured in the medium term (40-80 years). Where projections in the following tables fall below the minimum range (desirable level), the data is shaded yellow; where projections exceed the upper simulated bounds of the range, the data is shaded green (still within desirable level).

While the desirable level for every forest unit – age grouping combination were not met during the plan period, most groupings (19 of 24) achieved desirable levels with Plan start conditions. All other groupings achieve desirable levels within the planning horizon. The young BFM and HMX groupings underachieve the SRNV for several terms 120-160 years in the future, however these groupings do achieve the desirable level from Plan Start for the next 120 years so these projections are acceptable.

On average, the desirable level and target level are projected to be achieved for this objective. Overall indicator achievement of area by forest unit and age grouping is projected to be very good while managing for landscape class area and old forest area.

ASSESSMENT - Indicator 2b – Crown Productive Forest by Forest Unit:
Desirable level and target level projected to be **ACHIEVED** over the target time frame of 40-80 years (medium term).

Table 25 Desirable and Projected Area by Forest Unit and Age Grouping – Immature

Immature Productive Forest

Mature Onset Age:		60	70	60	70	60	70	70	60	80	70	70	70

Indicator: (2c) Amount and Distribution of Old Forest

Desirable and Target Levels: The desirable level is to achieve and maintain old forest area by forest unit group at or above the minimum desirable hectares in accordance with the Ontario Landscape Tool (OLT) projected range of forest types/age class structure for the Whiskey Jack Forest (Table 27). After review, the Planning Team determined that the area in the red pine and white pine forest area (PRW) is not well represented in the OLT model. Therefore the desirable level for PRW Old Forest was set to maintain a minimum of area as existed at Plan Start. The target level allows overall movement towards the desirable level within this 10-year plan period, with allowance for minor deviations by individual old forest groupings.

Desirable and targets levels of old forest are achieved and maintained from Term 6 onwards (or earlier) for all forest unit groupings. Some achievement was improved to trend closer to OLT medians. All old forest groups move towards SRNV in this plan period except BFo and SPo that decrease for 10 years then increase again T3-T6 to the SRNV. The deviation is acceptable given the overall improvement for this indicator.

ASSESSMENT - Indicator 2c – Amount and Distribution of Old Forest:
Desirable level is not projected to be achieved within the plan period. Desirable level of old forest is **ACHIEVED** (or higher achievement) and maintained from Term 6 onwards (or earlier) for all forest unit groupings.

The target level is **ACHIEVED** with overall old forest area for the old forest groupings moving toward the desirable level in the plan period, except BFo and SPo (noted above) that decrease for only Term 2 (acceptable in short-term to planning team).

The projected achievement of old forest by forest unit group is also documented in Table FMP-9. The availability of a reasonable amount of old forest was considered important to the Planning Team, LCC and the public.

Indicator: (2d) Amount of Red Pine and White Pine Forests

Desirable and Target Levels: The desirable level is to maintain a minimum of the Plan Start area of the PRW forest unit (3,312 ha)(OLT SRNV not used for PRW. See Section 3.5.2.2 2d for further rationale). The Planning Team recognized the need to maintain the current area of red pine and white pine forest and preferably increase the PRW forest area through time. Strategic modelling suggested the desirable level was achievable and therefore the target level was the same as the desirable level.

The desirable level is sustained through the planning horizon at a level greater than the Plan start level of 3,312 ha (
Table **28**). The desirable level of the Plan Start amount of red pine and white pine forest area is increased for the next 100 years.

Table 28 Desirable and Projected Amount of Red Pine and White Pine Forests

2d Productive Area (ha):		
Term	Total	PRW
T1	725,394	3,312
T2	724,845	3,500

T15	724,032	3,395
T16	724,032	3,312

ASSESSMENT – **Indicator 2d - Amount of Red Pine and White Pine Forests**:
Desirable level and target level are **ACHIEVED** with the Plan Start condition.

Indicator: (2e) Amount of Upland Pine and Spruce Forest

Desirable and Target Levels: The desirable level is to maintain a minimum of 403,400 ha upland pine and spruce as per OLT minimum SRNV projections for upland conifer. Strategic modelling confirmed that this desirable level was achievable, though the Planning Team and plan advisors were very aware that the magnitude of the increase in upland conifer as compared to the Plan Start level (403,400 ha) would be a significant consideration during development of Silvicultural Ground Rules (Section 4.2.2.1, Table FMP-4) and Operational Planning (harvest Section 4.3 and Renewal and Tending Section 4.4). The target level is to move towards the desirable level during this 10-year plan period.

ASSESSMENT – **Indicator 2e - Amount of Upland Pine and Spruce Forest**:

Desirable level is not ACHIEVED in the plan period however the target level is **ACHIEVED** through a projected increase in upland pine and spruce forest area.

The desirable level is achieved in Term 7 and sustained throughout the remainder of the 160-year planning horizon (Table 31).

Table 29 Desirable and Projected Amount of Upland Pine and Spruce Forest

3.6.3.3 Objective 3: Wildlife Habitat

Indicator: (3a) Area of Habitat for Forest-dependent Species At Risk

Desirable and Target Levels: The desirable level is to achieve and then maintain preferred habitat for modelled Species At Risk (woodland caribou) at or above minimum OLT SRNV level (Table 30). The target level is to move towards the desirable level over the next 30 years.

Projected habitat and desirable levels for caribou refuge habitat (Cr), caribou winter used habitat (Cwu) and caribou winter preferred habitat (Cwp) are presented in Table 30. Minimum desirable levels of used caribou winter habitat (Cwu) are sustained through the planning horizon. Caribou refuge habitat (Cr) and caribou winter preferred (Cwp) achieves the desirable levels by Term 6, and sustains the desirable levels thereafter.

Caribou habitat generally increases from Plan Start to exceed min. desirable levels by Term 6 onwards. During this plan period, there is clean-up occurring in 4 caribou blocks which accounts for the short-term reduction in refuge and preferred winter habitat. Increased habitat is then projected from T3-6 to within SRNV levels to ACHIEVE target levels of movement within the 30-year target timeframe.

ASSESSMENT – Indicator 3a – Area of Habitat for Forest-dependent Species At Risk:
Desirable level **ACHIEVED** for caribou winter used habitat with Plan Start levels for Cwu. Desirable level for Cr and Cwp projected to be ACHIEVED by Term 6 (50 years), therefore target level of movement towards SRNV is assessed as ACHIEVED in the 30-year target timeframe.

Table 30 Minimum Desirable Habitat for Species At Risk

(3a) Caribou Habitat Through Time:			
Term	Cr	Cwu	Cwp
T1	103,969	45,055	20,581
T2	100,503	45,782	17,975

T8	153,900	113,803	54,020
T9	151,766	109,010	52,131
T10	150,000	105,966	48,294
T11	150,000	104,075	44,972
T12	150,000	109,674	42,243
T13	154,070	118,882	40,000
T14	150,000	116,052	40,619
T15	152,438	122,894	40,000
T16	156,614	128,719	40,000
OLT Max.	161,804	47,453	68,169
OLT Min.	147,605	26,809	36,912

Where projections fall below the min. target, the data is shaded yellow;
where projections exceed max. targets, the data is shaded green.

Indicator: (3b) % of Polygons with >60% Caribou Refuge Habitat in Caribou Zone

Desirable and Target Levels: The desirable level is to have the spatial landscape pattern consistent with OLT percentage projections for caribou refuge habitat in the caribou zone established for the forest (Table 31). The target level is to show movement towards desirable level during this plan period.

Table 31 Desirable and Projected Levels for Percent of Polygons with >60% Caribou Refuge Habitat

Caribou refuge habitat in caribou zone	Plan Start (%)	Minimum Desirable Level (%)	Projected Plan End 2022 (%)
Scale: 6,000 ha hexagon	36%	87%	37%
Scale: 30,000 ha hexagon	25%	92%	24%

Spatial assessment shows 1% movement towards the desirable level for analysis at the 6,000 ha scale. The second analysis shows 1% movement away from the desirable level which is not considered significant. There is clean-up occurring in four caribou blocks which accounts for the reduction in refuge habitat at the 300 km2 scale over this plan period.

While implementation of the dynamic caribou habitat schedule is expected to result in improved caribou habitat in the future, there are several other factors that affect the provision of caribou habitat in the short- and medium-term (approx. 50 years). The time needed to age a significant portion of the forest into suitable habitat conditions is a major factor – one that cannot be accelerated through management strategies (i.e. not conducting harvesting in the caribou zone). The Planning Team did utilize an expanded caribou management and recovery zone as compared to the 2004 FMP. The Planning Team considered the projected results for this plan period to be acceptable due to the spatial results achieved, the expanded caribou management and recovery zone, the past disturbance history on the Whiskey Jack Forest, the time needed to age the forest into older patches of mature and old forest, and the fact that "doing nothing" in this plan period would not improve caribou habitat.

ASSESSMENT - Indicator 3b –
% of polygons with >60% caribou refuge habitat in caribou zone:
Desirable level NOT ACHIEVED during the 10-year plan period, but target level is **ACHIEVED** during the plan period.

Indicator: (3c) % of Polygons with >60% Caribou Winter Habitat in Caribou Zone

Desirable and Target Levels: The desirable level is to have the landscape pattern consistent with OLT percentage projections for caribou winter habitat in the caribou zone established for the forest (Table 32). The target level is to show movement towards desirable level during this plan period.

This indicator measures the caribou winter habitat pattern in the caribou management zone of the forest at two analysis scales. Spatial assessment shows movement towards the desirable level for analysis at the 6,000 ha scale. Second analysis at the 30,000 ha scale shows no movement (toward or away) from the Plan Start 0% level (constant). Implementation of the dynamic caribou habitat schedule is expected to improve caribou habitat in the future, therefore projected results for this plan period are acceptable. Overall target assessed as ACHIEVED in this plan period.

As discussed for Indicator 3b, the Planning Team considered the projected results for this plan period to be acceptable due to the spatial results achieved, the expanded caribou management and recovery zone, the past disturbance history on the Whiskey Jack Forest, the time needed to age the forest into older patches of mature and old forest, and the fact that "doing nothing" in this plan period would not improve caribou habitat.

Table 32 Desirable and Projected Levels for Percent of Polygons with >60% Caribou Winter Habitat

Caribou winter habitat in caribou zone	Plan Start (%)	Minimum Desirable Level (%)	Projected Plan End 2022 (%)
Scale: 6,000 ha hexagon	0%	45%	4%
Scale: 30,000 ha hexagon	0%	40%	0%

ASSESSMENT - Indicator 3c –
% of polygons with >60% caribou winter habitat in caribou zone:
Desirable level NOT ACHIEVED during the 10-year plan period. Overall target is **ACHIEVED** during this plan period.

Indicator: (3d) Landscape Pattern - Interior, Marten Core Habitat

Desirable and Target Levels: The desirable level is to retain 10-20% of capable marten habitat area in suitable conditions in core areas of 3,000 to 5,000 ha. The target level acceptable in this plan is 10-20% of capable marten habitat area in suitable conditions in core areas of greater than 1,000 ha moving towards the desirable level measured in 2072.

Marten cores were developed to meet guideline levels and to incorporate the best concentrations of suitable habitat, spatially distributed across the forest for the next 60 years. The percentage suitable habitat in cores of total capable habitat is measured spatially using OMA-2. The Whiskey Jack Forest currently lacks sufficient concentrations of conifer forest to meet the desirable level.

The percentage of capable habitat in suitable condition in core areas is 4.9% in 2012 at the start of this FMP. It is expected that the deferral of these 25 cores for the next 60 years, providing there is no natural disturbance, will provide for an increase of suitable marten habitat to 9.1% capable) by 2072. While this scenario does not meet the 10-20% marten habitat objectives, it does represent the best case scenario for the Whiskey Jack Forest. Preliminary assessment indicates that the minimum target of 10% should be available in 60-80 years. Overall, the selected marten cores provide adequate spatial distribution of marten habitat over the forest.

ASSESSMENT – Indicator 3d - Landscape Pattern - Interior, Marten Core Habitat:
Desirable level **NOT ACHIEVED** but target level is projected to be **ACHIEVED** through the 60-year target timeframe).

A more detailed analysis of marten core habitat areas is included in the Supplementary Documentation N – Spatial Analysis: Part 2: Marten Habitat Analysis. A map of the marten core areas management for this plan is included in Section 2.1.2.3, Wildlife Habitat Management Zones.

3.6.3.4 Objective 4: Wood Supply

Projected harvest volumes are discussed in Section 3.6.1.1 in text and associated graphs. The discussion in Section 3.6.1.1 includes comparisons to the planned and actual volumes from the three previous forest management plans including the 2004 FMP, the Ontario Forest Accord Board (OFAAB) benchmark harvest levels, recognized industrial volume demand and the Long-term Management Direction. Projected wood supply by species group associated with the LTMD is documented in Tables FMP-8 and FMP-9.

Indicator: (4a) Long-term projected available harvest area

Desirable and Target Levels: The desirable level is to maintain an average total available harvest area above 4,100 ha/year. Target level is the same as the desirable level measured over the long-tem (100 years).

ASSESSMENT - Indicator 4a – Long-term Projected Available Harvest Area:
Desirable level and target level projected to be **ACHIEVED** (achieved with the plan start level and maintained through 100-year target timeframe).

Desirable and target levels are projected to be achieved in all terms. Harvest area decreases from 5,483 hectares per year in 2012 to 4,168 hectares per year in 2112 and stays above 4,100 hectares per year in all terms over the next 100 years. The comparison of these harvest area levels to historic levels and the past management plan is included in Section 3.6.1 Available Harvest Area.

Indicator: (4b) Long-term projected available harvest volume by species group

Desirable and Target Levels: The desirable level is to achieve the highest possible long-term annual harvest volumes by species group while maintaining a balance of objective achievement. Target level is the same as the desirable level measured over the long-term (100 years).

Scoping investigations and development of the LTMD provided indication that the forest would be able to increase Spruce-Pine-Fir harvest volume from the current 279,000 cubic metres per year to sustainable levels of approximately 340,000 cubic metres per year (with a few terms higher, up to as much as 400,000 cubic metres per year). Projected poplar harvest volume decreased from the short-term (200,000 cubic metres per year) to the medium-term (90,000 – 100,000 cubic metres per year). The rate of decrease in poplar volume was managed in the LTMD while balancing achievement other management objectives.

An acceptable balance of volume by species group is projected to be achieved in all terms, which projects the meeting of the desirable and target levels for this indicator (Table 33). SPF and PO species groups were considered a higher priority than volume by other species groups or total volumes. Spruce-Pine-Fir volumes are projected to remain over 450,000 cubic metres per year over the next 100 years. Poplar volumes decrease from 190,000 to 90,000 cubic metres per year over the next 30 years then stabilize at that level for 50 years before increasing again. White Birch volumes are generally limited on the Whiskey Jack Forest and are projected to decrease from 33,000 to 7,000 cubic metres per year over the next 100 years.

Table 33 Projected Annual Harvest Volumes by Major Species Groups

Annual Harvest Volumes by Major Species Groups (1,000s net merchantable cubic metres)					
Term	TOTAL	SPF	PO	BW	PRW
T1 (4c)	574.6	340.0	190.0	33.6	3.8
T2	501.6	340.0	130.0	27.8	0.6
T3	456.2	340.0	90.0	21.8	0.0
T4	482.5	369.9	90.0	15.4	0.6
T5	466.5	340.0	90.0	28.4	0.7
T6	449.4	340.0	90.0	15.2	0.8
T7	494.5	385.1	90.0	13.6	0.5
T8	483.3	370.4	100.0	10.7	0.0
T9	464.7	340.0	112.6	10.4	0.1
T10	518.8	399.0	100.0	11.5	6.2
T11 (4b)	451.9	340.0	100.0	7.0	1.5
T12	450.9	340.0	100.0	8.0	1.2
T13	459.1	340.0	100.0	11.0	4.9
T14	454.3	340.0	100.0	9.5	2.1
T15	452.2	340.3	100.0	9.1	0.5
Average	477.4	351.0	105.5	15.5	1.6

ASSESSMENT - Indicator 4b – Long-term Projected Available Harvest Volume by Species Group: Desirable level and target level **ACHIEVED** (achieved with the plan start level and maintained through 100-year target timeframe).

Indicator: (4c) Short-term Projected Harvest Volume Per Year

Desirable and Target Levels: The desirable level is to maintain harvest volume (all species combined) at or above 510,000 cubic metres per year for this plan (2012-2022).

The desirable and target level of a minimum of 510,000 cubic metres per year was achieved in the LTMD with 574,600 cubic metres per year from 2012-2022 (Table 33). This target was specifically addressed during strategic modelling and during development of the LTMD.

The planned net merchantable harvest volume (Table FMP-13, Section 4.3.5 Harvest Volume) for this 10-year plan period averages 538,000 net merchantable cubic metres per year for all tree species combined. Therefore desirable and target levels were achieved with the planned operations.

ASSESSMENT - Indicator 4c – Short-term Projected Harvest Volume Per Year: Desirable level and target level **ACHIEVED** in this 10-year plan period.

3.6.3.5 Objective 6: Aboriginal Involvement in Planning

Indicator: (6a) Representation on the Planning Team

Desirable and Target Levels: The desirable and target levels are to have five Aboriginal Communities located in or adjacent to the Whiskey Jack Forest with representation on the planning team, measured during plan development.

ASSESSMENT - Indicator 6a – Aboriginal Representation on the Planning Team:
Desirable level and target level **ACHIEVED** during the target timeframe of plan development with participation and or representation of the planning team by five Aboriginal communities.

Five communities have representation on the planning team. Participation at planning team meetings and information centres varied based upon each representatives schedule and availability. The Aboriginal involvement on the planning team is greater than was experienced for the 2004 FMP. This is considered a significant step in effectively engaging Aboriginal communities.

Indicator: (6b) Aboriginal Communities that Contribute Information to the Planning Process

Desirable and Target Levels: The desirable and target levels are to have five Aboriginal Communities located in or adjacent to the Whiskey Jack Forest contribute information to the planning process, as measured during plan development.

ASSESSMENT - Indicator 6b – Aboriginal Communities that Contribute Information to the Planning Process:
Desirable level and target level **NOT ACHIEVED** during the target timeframe of plan development, though multiple opportunities were offered to all affected Aboriginal communities.

Three communities accepted the offer to review detailed operational plans at the LTMD stage and community information sessions were held. The Aboriginal Background reports were available for review by community members at the information sessions.

During plan development, FMP information was provided by MNR and the planning team to all affected Aboriginal communities. Aboriginal Communities that are in the Whiskey Jack Forest were generally more engaged and provided more input throughout the planning process. Regular communication between MNR and Aboriginal communities facilitated the exchange of information. MNR efforts were directed at all affected communities to get the best response possible.

3.6.3.6 Objective 7: Local Citizens Committee Involvement

Indicator: (7a) Local Citizens Committee's Self-evaluation of its Effectiveness in Plan Development

Desirable and Target Levels: The desirable level is to have the LCC Effectiveness Survey results indicate at least 60-80% effectiveness in the development of the management plan.

ASSESSMENT - Indicator 7a – Local Citizens Committee's Self-evaluation of its Effectiveness in Plan Development:
Desirable level and target level **ACHIEVED** during the target timeframe of plan development.

Desirable and target level assessment occurred during plan development at the draft plan stage. The individual members of the LCC completed a self-evaluation survey regarding their effectiveness in plan development prior to draft plan submission (survey results included in Supplementary Documentation J – LCC Report).

Areas being assessed included the functioning of the LCC, their involvement, their influence, representation of their opinions, functioning of the LCC and overall satisfaction with opportunities for public involvement in the forest management planning process. Results of this survey are summarized in Table 34. Overall, the LCC members indicated a very good level of involvement and effectiveness in the development of the FMP with an average 82% positive satisfaction response.

Table 34 Summary of Local Citizens Committee Effectiveness Self-Evaluation Survey

3.6.3.7 Summary of Indicators Measured After Plan Implementation

The following indicators are measured after the forest management plan implementation. See Section 3.5.2 for details on the desirable and target levels. The planned harvest, renewal, tending, and road construction and decommissioning activities for this FMP period have been planned to aid in the achievement of these objective indicators.

Objective 1: Landscape Pattern

Indicator: (1a) % of Polygons with >60% mature and old forest
Timing of Assessment: Year 10 Annual Report.

Indicator: (1b) Frequency Distribution of Young Forest Patches by Size Class
Timing of Assessment: Year 10 Annual Report.

Indicator: (1c) % of Polygons with >60% mature and old conifer forest
Timing of Assessment: Year 10 Annual Report.

Objective 2: Forest Composition

Indicator: (2a) Crown Productive Forest by Landscape Class
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (2b) Crown Productive Forest by Forest Unit and Age Grouping
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (2c) Amount and Distribution of Old Forest
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (2d) Amount of Red Pine and White Pine Forests
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (2e) Amount of Upland Pine and Spruce Forest
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Objective 3: Wildlife Habitat

Indicator: (3a) Area of Habitat for Forest-dependent Species At Risk
Timing of Assessment: Year 10 Annual Report.

Indicator: (3b) % of Polygons with >60% Caribou Refuge Habitat in Caribou Zone
Timing of Assessment: Year 10 Annual Report.

Indicator: (3c) % of Polygons with >60% Caribou Winter Habitat in Caribou Zone
Timing of Assessment: Year 10 Annual Report.

Indicator: (3d) Landscape Pattern - Interior, Marten Core Habitat
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (3e) % of Conifer Dominated Forest Units in the Caribou Zone
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (3f) % of Jack Pine and Spruce Species Composition by Forest Unit in the Caribou Zone
Timing of Assessment: This assessment is long-term and will continue over future planning periods. The assessment of conifer purity at Year 7 and 10 provide trends through time.

Objective 4: Wood Supply

Indicator: (4d) Actual Harvest Area, by Forest Unit (% of planned harvest area)
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (4e) Actual Harvest Volume, By Species Group (% of planned harvest volume)
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Objective 5: Managed Crown Forest

Indicator: (5a) Managed Crown Forest Available for Timber Production
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Objective 8: Road Access

Indicator: (8a) Kilometres of SFL Road per Square Kilometre of Crown Forest
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Objective 9: Forest Renewal

Indicator: (9a) Regeneration Success: Percent of Harvested Forest Area Assessed as Free-Growing by Forest Unit
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (9b) Silviculture Intensity: Planned and Actual Percent of Harvested Area Treated by Silvicultural Intensity
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (9c) Silvicultural Success: Planned and Actual Percent of Harvested Forest Area Assessed as Free-Growing and Successfully Regenerated to the Projected Forest Unit
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Objective 10: Forest Values

Indicator: (10a) % of Forest Operation Inspections in Non-Compliance, By Activity and Remedy Type (i.e. severity)
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Objective 11: Soil and Water Resources

Indicator: (11a) % of Forest Operations Inspections in Non-Compliance with Management Practices that Prevent, Minimize or Mitigate Site Damage (by remedy type)
Timing of Assessment: Year 7 and Year 10 Annual Reports.

Indicator: (11b) % of Forest Operations Inspections in Non-Compliance with Prescriptions Developed for the Protection of Water Quality and Fish Habitat (by remedy type)
Timing of Assessment: Year 7 and Year 10 Annual Reports.

3.6.3.8 Conclusion on the Assessment of Objective Achievement

Based on the assessment of objective achievement documented in Table FMP-9, the majority of the indicators of objective achievement that could be assessed in the forest management plan were within or exceeded minimum desirable levels. For any indicators that had targets for this plan period established below desirable levels, the reason for the variance was documented in Section 3.5.2. Certain desirable levels could not be reached in specific terms due to incompatible management objectives or where the land base of the Whiskey Jack Forest did not allow achievement of desirable levels in the short or medium-term such as Landscape Pattern.

Of the 30 indicators included in Table FMP-9, 18 of the indicators can be assessed during plan development. The remaining 12 indicators (and reassessment of some of the original 18 indicators) will be assessed in the future: after plan implementation as appropriate (specific indicator timing of assessment is noted in Table FMP-9 and in plan text Section 3.5.2).

Of the 30 plan indicators assessed:

11 indicators ACHIEVE desirable and target levels in this 10-year plan period;
6 indicators are projected to ACHIEVE target levels in a target timeframe longer than this 10-year plan period;
1 indicator is projected to NOT ACHIEVE desirable or target levels at some point in the 100-year strategic planning horizon; and
12 additional indicators (not already assessed in this FMP) will be assessed in the FUTURE after plan implementation.

Total: 30

The indicator that is not achieving desirable and target levels is the indicator for Aboriginal Communities that Contribute Information to the Planning Process (6b). All affected Aboriginal communities were contacted for comment on products during development of the plan, however some communities chose to not comment on information products or Aboriginal values. This resulted in one indicator “not achieving” desirable levels because the goal is to have five Aboriginal communities contribute information or comments on the plan and only three communities contributed. Multiple opportunities for input were offered and will continue to be offered to all affected Aboriginal communities.

3.6.4 Social and Economic Assessment

A component of forest sustainability is provision for the needs of the people who receive benefits from the forest. Decisions in a forest management plan have significant impacts on the local economy, as well as the regional and provincial economies. Therefore it is important to be knowledgeable about the social and economic impacts, which can result from decisions that are made in forest management plans.

The *Forest Management Planning Manual* (2009) requires that a Social & Economic Assessment (SEA) be prepared to identify the expected social and economic impacts of implementing the Long-term Management Direction included in the forest management plan (FMP). The assessment examines how the quantity of timber supplied to the wood-processing facilities, and the silvicultural investment requirements for the LTMD may affect the communities identified in the Social & Economic Description. The Social & Economic Assessment of timber volumes and silvicultural expenditures is based on a comparison of the annual planned levels for the 2004 FMP and the annual levels shown in the Long-term Management Direction for the 2012 FMP.

The implementation of the long-term management direction of the forest management plan affects the social and economic environments associated with several communities that receive benefit from forestry operations on the Whiskey Jack Forest. This section attempts to measure some of the impacts the implementation of this forest management plan may have on the areas social and economic values.

This social and economic assessment has been prepared for the LTMD by the MNR. This assessment summarizes the expected social and economic impacts associated with the LTMD. The Social and Economic Assessment evaluates the social and economic impacts associated with respect to:

Section 3.6.4.1	Timber Value Assessment and Impacts,
Section 3.6.4.2	Silviculture Value Assessment, and
Section 3.6.4.3	Non-timber Value Impact Assessment.

3.6.4.1 Timber Value Assessment and Impacts

The Socio-economic Impact Model (SEIM) was used by MNR to evaluate the socio-economic impacts of the preferred forest management scenario. The basis of the analysis was the quantity of timber harvested and supplied to the various wood-processing facilities and the silvicultural investments required to support that level of harvest.

The intent of the socio-economic analysis is to account for as many forest users as possible. It attempts to predict the impacts of computer simulated forestry operations over the ten-year implementation period of the FMP. While the model cannot provide an in-depth socio-economic analysis for every business sector and community in the district, it does provide resources managers with a sense of the relative benefits and/or disadvantages that various management strategies could have in the local, regional and provincial economies. The Socio-economic Impact Model provides the multi-dimensional framework through which the extensive socio-economic impact can be identified, at least in part, and quantified. This framework supports informed decision making based on a holistic perception of the forest management undertaking,

providing insight into the possible trade-offs associated with the proposed long-term management direction. A comparison of the 2012 SEIM output is then made to the 2004 FMP to see if the trend has shifted.

In general, socio-economic model results indicated that the less the volume of wood harvested from the Whiskey Jack Forest, the less the positive socio-economic impact that the forest industry had on the Kenora District. Decreased harvest volumes resulted in lower industry output, person years of employment and gross domestic product (GDP). These same indicators for the Northwest Region and Province of Ontario were also decreased proportionately with decreased wood volumes.

The economic impacts, provincially and regionally, associated with the proposed long-term management direction were analyzed by MNR using the Socio-economic Impact Model (SEIM).

Compared to the 2004 Whiskey Jack Forest Management Plan SEIM output, there was a general downward trend to the economic impact at the District and Regional scale. This trend is also observed in the environmental impacts, most notably the Green GDP Cost which had a reduction of 86%. The impacts on the social scale were either positive e.g. Average Wages increased by 53% compared to the 2004 output even with the reduction of volume harvested, or negative trends e.g. Pulp & Paper Sector Dependency 100% due to the closure of the Abitibi-Bowater Inc. facility in Kenora. The decision to implement a long-term management direction that results in lower economic activity is related partly to the time scale over which the two models, namely SFMM and SEIM operate and partly to the measures used to determine sustainability. The SFMM projects outcomes and identifies levels of objective achievement at scales of ten years as the first operating term of the FMP plan period, roughly 50-100 years as the point in time where the desirable levels for future forest condition are achieved and finally 150 years for the full strategic modelling planning horizon. The SEIM model on the other hand operates on a scale of five years. Effectively the SEIM considers the specific volumes to be harvested annually, the silviculture costs annually and the industrial outputs annually for the first five-year term of the 10-year FMP. The difficulty with these different time scales is that management strategies or the long-term management direction are developed and chosen on the basis of long-term objective achievement (usually 100 years) and the outputs from SEIM in terms of objective achievement cannot be ranked on the same scale.

The ‘measure of sustainability’ as applied to different objectives and therefore the long-term management direction varies based on the measurable variables of the objective. The socio-economic objectives in the FMP begins with wood supply to meet the initial identified target, which is usually based on past history and current industrial demand, and then considers how well that target can be met through time in the context of balancing other objectives.

When the overall achievement of plan objectives and the full measure of sustainability is considered, SFMM LTMD run 27d_OLTMS projects the best balance and has been confirmed as the Proposed Long-term Management Direction.

The second part of the assessment of sustainability of wood supply considers whether the supply is ‘continuous and predictable’. If the LTMD cannot achieve the strategy level for wood supply through all future terms then the second measure is whether the supply is continuous and predictable. The choice to rank any given management strategy based on wood supply then must consider both parts of the sustainability measure.

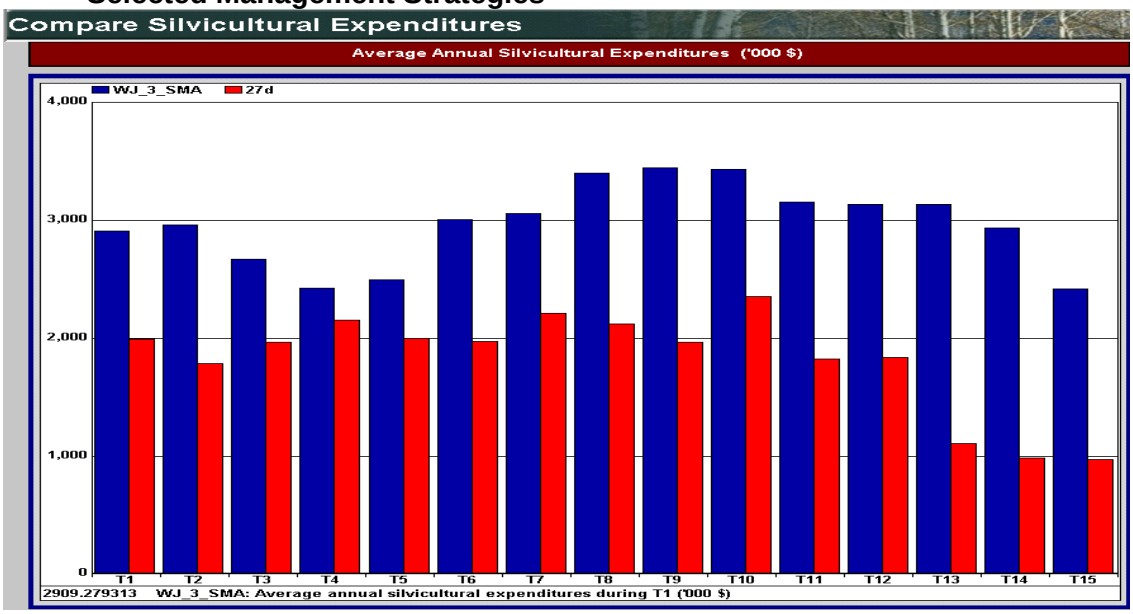
None of the scenarios provided sufficient wood to fully meet the regional strategy in the wood supply objective in the short to mid-term. The planning team decided upon a scenario which ensured long-term forest health and identified the best continuous and predictable wood supply available from that forest. The LTMD provides the best wood supply while lessening the impact that sudden, significant declines in projected harvest volumes would have on the communities which depend upon wood from the Whiskey Jack Forest.

The LTMD will have significant positive socio-economic impacts on the communities directly receiving timber from the Whiskey Jack Forest. The relationship between the economic activity engendered through the forest management expenditures and the manufacture of the timber into processed products creates a chain of events which have an extensive positive impact on the social and economic dimension of the community, the region and the province.

3.6.4.2 Silviculture Value Assessment

The silvicultural renewal and tending impacts of the Long-term Management Direction also have social and economic impacts on contractors doing the work. The projections from the 2004 FMP suggest 926 ha per year would be treated extensively (cut and walk away treatments) and 4,673 ha per year would be treated either basically or intensively (cut with some form of renewal and potentially tending). The 2012 FMP revised the level of renewal and tending to reflect 3,126 ha/year be treated extensively and 2,298 ha/year be treated basically or intensively. This increase in extensive treatment is appropriate given the increased level of harvest of HMX and POD since the 2004 plan (in keeping with plan objectives, Section 3.5) and the projected success of natural regeneration of poplar on the Whiskey Jack Forest. The projected renewal expenditures reflect an overall decrease in spending to $913,000 per year for the next ten years; an average decrease in silviculture spending of 46% between plans. Of that difference in silviculture expenditures is a representative decrease in employment to complete the work and the spin off impact of reduced purchase of products.

Figure 39 Silviculture Expenditure Comparison for the 2004 (blue) and 2012 (red) Selected Management Strategies



The main impact of the decreased silvicultural program is on the community of Kenora. The main concentration of people performing the work is located in Kenora with some of the other spin offs such as consulting, tree seed extraction, tree seedling production, etc. being from the Thunder Bay area, other locations in Ontario and outside the province (mainly Manitoba).

3.6.4.3 Non-timber Value Impact Assessment

Due to the nature of the non-timber values in the area and no existing approved model to evaluate the impacts of forestry and forest operations on these values, it was decided that a qualitative assessment would be used to assess the impacts on non-timber values. This qualitative assessment will look at different classes of values and identify potential impacts (positive and negative). Where forest operations are identified in proximity to certain values or directly impact these non-timber values, the potential impacts will be identified specifically for that value.

Summary of First Nations Use of Other Resources

First Nation community members actively use portions of the Whiskey Jack Forest for many resource-based activities.

i) Fishing
Several First Nation communities hold commercial fishing licences on Lake of the Woods and inland lakes. Lake of the Woods and surrounding lakes are used for subsistence fishing by community members. Surrounding tourist lodges provide some employment opportunities for First Nation residents as guides in the sport fishery.

ii) Trapping
First Nation community individuals hold registered trap lines located all or partially within Kenora District.

iii) Wild Rice
Wild rice is harvested annually by community members for personal use and re-sale from various lakes throughout the area.

iv) Cultural and Social, other Wildlife
Special sites within the forest are used for traditional cultural purposes such as fasting, vision quests and offerings. The specific location of these sites are known to community members, and the community is encouraged to participate in the forest management planning process to ensure these values are considered in proposed forest management activities.

Certain wildlife species, such as the bald eagle, have a cultural and social significance to First Nation people. The protection and management of these species and their habitats is important.

While the subsistence hunting, fishing, and gathering of resources from within the forest are an integral part of community existence, there are no accurate records of the level of such harvest. The harvest of deer, moose, waterfowl, rabbits and grouse provides an important source of food to community members.

Recreation and Tourism

The impacts of forest management and operations on recreation and tourism are dependent on the value (Table 35). Some values benefit from increased access to previously un-accessed areas whereas others that rely on remoteness can be negatively impacted. Similarly, harvest areas may be desirable to improve certain opportunities such as hunting or berry picking, but may also be temporarily detrimental to the natural aesthetics or carrying capacity for certain wildlife species that favour mature forest habitat. Harvesting operations tend to be noisy which most recreationalists and the tourism industry do not approve of, particularly during certain times of the year.

These activities have significant impacts on the local Kenora economy. There are 362 tourist operators in Kenora District, of which 143 are associated with the Whiskey Jack Forest. These tourism operations offer activities such as hunting, fishing and ATV riding. See Table 35 for impacts of the forestry on the tourism industry. Qualitative analysis suggests that forestry has a **net neutral impact** on the tourism industry, specifically when recent initiatives, such as Resource Stewardship Agreements (RSAs) are developed coupled with an open and transparent forest management planning process.

There are seven provincial parks or protected areas adjacent to or surrounded by the Whiskey Jack Forest. These parks include the West English River, Eagle-Dogtooth, Tide Lake and the Maynard Lake Parks. The Pakwash Provincial Park is located adjacent to the northeast corner of the unit, Rushing River Provincial Park is located in the southern portion of the forest, and Woodland Caribou Provincial Park is located in the northwest portion of the unit.

Table 35 Summary of Recreation and Tourism Impacts

Value	Positive Impacts	Negative Impacts
Non-Remote Tourist Outfitters	• New road access to be used for accessing fishing, hunting and other recreational activities.	• Harvest operations are noisy and can affect the natural experience outfitter offer. • Aesthetics and noise levels are affected when harvest activities occur adjacent to lakes utilized by tourism operators.
Remote Tourism Outfitters	• Reduced road densities would have a positive impact on remote based ecotourism.	• New road access in proximity to camps and outfitters affect the selling points of their business.
Fishing	• New access may open up previously inaccessible areas which would be desirable to road based fishing	• Decreased road densities could potentially lead to over fishing in some areas due to less roads and fishing efforts being concentrated. • Potential shoreline disturbances due to logging activities. • Greater potential of reducing fish population levels due to higher water temperatures, destruction of spawning areas resulting from road construction and increased sedimentation in water courses.
Hunting	• Moose and deer hunting opportunities increase for the short term after an area is	• Decrease in road densities will mean less opportunities for road-based hunting and efforts may become

Value	Positive Impacts	Negative Impacts
	harvested. • Habitat protection and/or improvement due to implementation of forest management guides.	concentrated. • Increased access may result in higher hunting pressures on wildlife populations resulting in population decline. • Harvest operations in the fall may disrupt hunting opportunities.
Cottagers	• Decreased road densities could mean less non owner traffic in vicinity of cottages. • Increased road access may increase recreational opportunities for cottagers. • Regeneration of forest in proximity to cottages may temporarily reduce forest fire risk.	• Reduced road densities may limit recreational opportunities for cottagers and may limit access to their cottages. Transfer of road responsibility to the cottagers is an option but will expensive for the cottagers to maintain roads. • Aesthetics and noise levels are affected when harvest activities occur adjacent to cottages. • Increased road access could reflect higher traffic and increase potential for vandalism.
Recreation, Ecotourism and Natural Adventure	• Increased road access may increase recreational opportunities. • Decommissioning of roads may increase the opportunities to create trails for other users. • Change in forest cover may change the wildlife viewing opportunities.	• Aesthetics and noise levels are affected when harvest activities occur adjacent to values • Existing trails can be destroyed or aesthetic values may be altered by forest operations. • Additional road access reduces the remoteness aspect of backcountry tourism and recreation activities.
Berry Picking and Wild rice picking	• Increased road access may increase opportunities to access natural food harvest areas. • Removal of forest cover may improve berry production potential in an area.	• Change in forest cover may reduce the abundance and potential for certain types of plant production • Application of herbicide may reduce the areas of potential berry production. • Decommissioning of roads can limit access to recent harvest areas that yield good blueberry crops

Mining and Mineral Exploration

Historically, mining and mineral exploration have been an important activity in this management unit and historically gold, silver and copper were the predominant commodities mined. Currently there are four granite producers in operation which have been and continue to be a significant contributor to the economy of the area. In addition to historical and current mineral production there are significant concentrations of gold, nickel, copper, silver and uranium contained within documented mineral deposits throughout the management unit.

The impacts of forest management on mining and mineral exploration are mainly positive. The maintaining of exiting road systems allow for continue access to the forest. The creation of new roads can open new areas to possible mineral exploration and tends to expose sediment and rock formation for prospectors to investigate for mineralization. Negative effects consist of the potential to decommission a road which may affect exploration opportunities in the area.

Impacts of road construction are mitigated by consultation. Plan development allows the MNR to transfer road responsibility to mining parties prior to decommissioning.

With more roads, increased access for timber harvesting can clear areas for mining sampling and mapping, but potentially it would increase the chance or removing mining survey lines, and destruction of claim posts could occur. The disruption of existing mining survey monuments are mitigated by consulting MNDM area office and the CLAIMS website prior to operations and training for operator to identify these values.

There are 54 aggregate sites located in the Whiskey Jack Forest. Forest operations, such as timber harvesting and construction of forest roads, increase the chance of finding aggregates. More road network ultimately increases access to aggregates.

Hydro Electricity Generation

The implementation of this forest management plan is not expected to have any impacts on current hydro-electric generation stations. The potential impact is a temporary increase in water deposited into the generation stations watershed area due to lower levels of evapotranspiration as result of removing portions of forest cover in the watershed. These areas generally recover within a few years after harvest. Only small amounts of harvest are expected in the vicinity of these watersheds therefore not having any significant effect.

Trappers and Traplines

The overall harvest area levels have little impact on trappers. Of more significance is the location of forest operations, type of renewal and locations of roads. The land base is occupied by traplines. Forest operations will directly affect certain traplines and not others. These operations may have both a positive and negative impact to one or more trappers and their traplines. The strategic allocation of some larger harvest blocks has the potential of completely eliminating the mature forest of a trapline. This will eliminate the potential for trapping of certain species that desire older forest in that area, such as marten. However, other trapped species that prefer young forest may increase in population. Also, new guidelines around harvesting near shorelines may improve beaver habitat and populations in certain areas, however no cutting to the shoreline is proposed in this plan period. The partial harvest of a trapline can be beneficial to trappers. The combination of mature and immature forest can diversify trapping opportunities or increase populations of certain species. These increased opportunities can be translated in higher trapping success and economic benefit to the trapper.

Associated with harvesting is road access. Road management can create or remove access to trap lines. However, it is likely that many trappers use ATVs and snow machines to access their lines and this will continue to be possible, even following road decommissioning, subject to conditions which may be negotiated between the trapper, the SFL and MNR. Trap cabins are also protected by Area of Concern prescriptions. All trappers were invited to public information centers and informed that forestry operations may have an impact on their business and were encouraged to comment. Trappers that feel they may be affected by road management strategies can have their concerns addressed during the public consultation opportunities.

Baitfish Operators

Similarly to trappers, the overall harvest levels of the plan have little impact on the baitfish operator. The harvest operations and roads are more of an impact on baitfish operators. With increased road access created to extract timber, these roads may also increase access to new baitfish lakes and ponds that baitfish licensees did not have previously. This may decrease the cost of accessing these ponds or open up higher productive baitfish areas. This translates into higher production levels and profits.

Improved access to some of these areas may also increase pressure on baitfish blocks by other users, such as anglers. It may also increase the potential of introducing invasive species to these newly accessed areas.

Bear Management Area Operators

Bear Management Area (BMA) operators may be affected by both the harvest operations and road access. Road access may be increased or decreased in the area of a BMA. The improved access may result in higher pressure on bear populations through more opportunities for public hunting access. However, the creation of more access may improve the BMA operators access to an area that was previously inaccessible.

The removal or decommissioning of roads should have little impact on most BMA operators as many operator use trails and ATVs to access bait stations and hunting stands. BMA operators also have the opportunity to assume responsibility for a road should the road be considered for decommissioning through the public consultation process.

Forest cover changes and harvesting operations can also impact the BMA operator by increasing or decreasing habitat. Denning areas can be destroyed or created through harvesting operations. The removal of mature forest cover may affect the potential for creating hunting stands and bait stations. The change in forest cover can also influence the population of bears in an area. The creation of a desirable habitat and food source such as blueberries may increase the populations of bears in a given area. However, the changing of forest cover to a less desirable condition may reduce the population of bears in an area. This can considerably affect the BMA success. Harvest operations and silviculture in the fall season may also affect hunting. The disruption in the vicinity of the BMA may reduce hunting success. The operator should negotiate seasonal restrictions when necessary with the plan author to mitigate any impacts to the hunt.

3.6.4.4 Summary of Social and Economic Impact Assessment

The overall social and economic impacts of implementing the 2012 FMP as compared to the 2004 FMP are generally good. The social and economic assessment for this FMP indicates that current levels of social or economic benefits are projected to be generally maintained or increased for the 2012-2022 plan period, in comparison with the 2004-2009 FMP.

The LTMD will have significant positive socio-economic impacts on the communities directly receiving timber from the Whiskey Jack Forest. The relationship between the economic activity engendered through the forest management expenditures and the manufacture of the timber into processed products creates a chain of events which have an extensive positive impact on the social and economic dimension of the community, the region and the province.

Compared to the 2004 Whiskey Jack Forest Management Plan SEIM output, there was a general downward trend to some of the economic and environmental impacts at the District and Regional scales. Positive or negative social impacts were projected, depending on the indicator being measured. When the overall achievement of plan objectives and the full measure of sustainability is considered, SFMM LTMD run 27d_OLTMS projects the best balance of achievement and has been confirmed through this analysis as the Proposed Long-term Management Direction.

The impacts of forest management and operations on recreation and tourism are not dependant on the harvest level but rather how the specific value has been addressed. Some values benefit from increased access to previously un-accessed areas whereas others that rely on remoteness can be negatively impacted. The impacts of forest management on mining and mineral exploration and baitfish operations are mainly positive. Forest operations will directly affect certain traplines and not others depending on where harvest allocations are planned. These operations may have both a positive and negative impact to one or more trappers and their traplines. Bear management area (BMA) operators may also be affected by both the harvest operations and road access. Stakeholder involvement during plan development will allow consideration for other values and users to be incorporated in the FMP to minimize potential negative impacts from forest operations.

4.0 PLANNED OPERATIONS

4.1 Introduction

This section of the plan describes the planned harvest, renewal and tending for this 2012-2022 forest management plan. Also summarized is a description of the prescriptions for operations, planned clearcuts, harvest volumes, wood utilization, forest access and road use management, road maintenance, road decommissioning, forestry aggregate pits, and monitoring and assessment activities.

The plan text describes the areas planned for operations for the first and second five-year terms (2012-2017 and 2017-2022) including area of concern planning. The planned operations for the second five-year term will be reviewed, updated as required, and approved for operations during Phase II Planned Operations.

Contingency harvest areas and associated contingency harvest volumes are also discussed in this section. There is no second-pass harvest planned in this FMP.

All planned operations are provided in digital format as per the requirements of the *Forest Information Manual (2009)*. The information products for harvest, renewal and tending operations will serve as the stand listing.

4.2 Prescriptions for Operations

4.2.1 Operational Prescriptions for Areas of Concern

An “area of concern” (AOC) is defined as a geographic area associated with an identified natural resource feature, land use or value that may be affected by forest management activities. A detailed prescription is developed for the area of concern in order to prevent, minimize or mitigate adverse effects of forest management operations on the value. MNR guidelines, site inspection by ground or air, regular and supplementary aerial photographs, contour and elevation maps, slope analysis, and local knowledge of trappers, Aboriginal groups, tourist operators and forestry workers were used to develop area of concern prescriptions in order to consider and protect identified values.

The area of concern prescriptions for this FMP have been prepared by the Operations Task Team to address identified values that may be affected by planned operations. Prescriptions have also been prepared in advance for values not currently identified on the forest, but which may be encountered during the course of operations (e.g. previously unidentified stick nests, or low potential sensitivity (LPS) streams).

Operational prescriptions for areas of concern within the areas of operations are documented in Table FMP-10. Table FMP-10 presents for each AOC, among other things, the unique identifier which is illustrated on maps, a description of the value, the operational prescription, the source of the prescription, and identifies if there are conditions on roads, landings and forestry aggregate pits. AOC operational prescriptions related to roads, landings and aggregate pits

within the areas of operations are documented in Table FMP-19. Where required, AOC operational prescriptions are documented in Supplementary Documentation Section H.

The spatial locations of areas of concern are included in the FMP in two information formats: illustrated on maps and included in the digital coverages of electronic information to be viewed with the planned harvest layer of information.

Some of the AOC prescriptions associated with the protection of tourism values were based on previously negotiated Resource Stewardship Agreements (RSAs). The RSAs are no longer in effect due to the Whiskey Jack Forest reverting to a Crown Unit. However, the planning team is still committed to maintaining the viability of the tourism industry by protecting tourism values in the areas of operations through the application of the *Management Guidelines for Forestry and Resource-Based Tourism* as one method of protecting and sustaining these values.

The selection and planning of harvest, renewal, tending operations and road locations was conducted in consideration of all currently identified values. Phase II planning will include refinement of area of concern prescriptions, updating of values information and implementation of relevant direction provided by any new or updated forest management guides. While Phase II estimated areas of concern are portrayed on operations maps in this FMP, they are not approved prescriptions. Complete AOC planning will occur prior to approval of Phase II operations and any Phase II prescriptions currently shown are subject to change.

The AOC prescriptions were applied to known values and common prescriptions from the previous FMP were used where possible and relevant. New prescriptions were created based on new direction in new forest management guides and new values found on the forest. Prescriptions can be one of the following:

- Reserve – no harvest, renewal or tending operations.
- Modified – modified forest management activity – timing, operational conditions.
- Regular – no conditions on harvest, renewal or tending operations.

Discovery of Cultural Heritage Values During Forest Operations

If a cultural heritage value is discovered during operations then operations must immediately stop and the district MNR staff is to be contacted. The value class of the discovery will determine who of the following will be contacted: Ontario Ministry of Culture staff, the local Aboriginal community, Registrar of Cemeteries, and/or the provincial cultural heritage specialist.

As per the Guide, if human remains are discovered, operations at the site must stop immediately. Contact will be made with MNR district staff, the local or Ontario Provincial Police, and the Registrar of the Cemeteries Regulation Section of the Ministry of Consumer and Business Services at (416) 326-8393 as soon as possible. The police will investigate the report to determine if the human remains are of forensic interest or represent a burial site as defined by the Cemeteries Act. All involved parties must act to safeguard the location until the police attend the site, and to limit media contact or display. In addition, if the protection measures for an area of archaeological potential are not complied with, operations must immediately cease within the area of concern and a Stage 2 archaeological assessment per the Ontario Ministry of Culture's current standards and guidelines for consultant archaeologists shall occur.

The following is related to some of the values as documented in Table FMP-10. Refer to Table FMP-10 for the actual prescriptions that apply:

Archaeological Potential Areas (AOC A01)

Forest management activities are to be planned and carried out in a manner to prevent adverse effects on cultural heritage values. Area of concern planning for cultural heritage values will be carried out in accordance with the *Forest Management Guide for Cultural Heritage Values (2007)*.

Archaeological Potential Areas (APAs) for the Whiskey Jack Forest were determined through the use of an archaeological potential area modelling tool. The model predicts areas where archaeological sites are likely to exist based on the presence of specific landscape features that resemble the location and site conditions of known sites on the forest management unit. Each archaeological potential area on the Whiskey Jack Forest is an area of concern. The APA areas of concern are identified on maps as AOC A01 and their prescription is found in Table FMP-10.

Furbearer Dens (AOCs D01 to D05)

In accordance with the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010), prescriptions for the protection of furbearer dens have been included in Table FMP-10 as AOCs D01 to D05. These prescriptions apply to identified black bear, grey fox, cougar, wolf and wolverine dens. In general, regular harvest, renewal, and tending operations are permitted within the AOC outside the denning period (varies by species) and are subject to the general direction for the protection of dens of furbearing mammals (text Section 4.2.2.2 Conditions on Regular Operations).

Mineral Licks (AOC M01)

In accordance with the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010), a prescription has been included in Table FMP-10 (AOC M01) to protect known mineral licks.

Bird Nests (AOC numbers starting with N, ON, BH, BG, HO, or NO)

Bird nests that have been identified are recorded in the current Natural Resource Values Information System (NRVIS) values information. Each nest has a unique identifier as per NRVIS numbering system and NRVIS maps (not shown on FMP maps). Other bird nests will be identified during forest operations as encountered.

In accordance with the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010), prescriptions have been included in Table FMP-10 to protect identified bird nests. The level of protection around the nests are based on many factors: the bird species associated with the nest(s), location of the nest (trees or ground), whether the nest is a primary, alternate or inactive nest, the nest occupancy, the timing since the nest was known to be occupied, timing of identification of the nest (before or during operations), timing of the critical breeding period (varies by bird species), and the relative impact of harvest, renewal or tending operations on the birds and their nests.

Of note is the AOC prescription for whip-poor wills (AOC NO04) which are classified as a "threatened" species. When the habitat description under the Species At Risk Act becomes available these conditions may be updated prior to plan approval if this is necessary to address the habitat description. If the habitat description becomes available after final plan approval, a plan amendment for this AOC may be submitted if necessary to address the habitat description.

Growth and Yield Plot (AOC PGP01)

The FESC PGP Growth and Yield Trial Plot is a value that has an associated prescription in Table FMP-10 for adjacent harvest, renewal or tending operations.

Land Ownership or Non-timber Use Values (AOCs FL01, PL01, NG01, RR01, HB01)

Areas were identified that were not owned by the Crown (patent land, federal land) or Crown land with management uses other than or in addition to timber production (e.g. provincial parks, railway right of way, natural gas transmission pipelines, highway corridors). Where these land ownership/management use areas were in proximity to planned operations on the Whiskey Jack Forest, area of concern prescriptions were developed to protect the values. Prescriptions included in Table FMP-10 include precautions to identify the location of the land value, slash management adjacent to railway right of ways, communication with natural gas pipeline staff prior to operations on pipelines and delay of harvest adjacent to highway corridors until adjacent forest is a minimum height.

Tourism Values (AOC numbers starting with TV)

Prescriptions for the enhancement of tourism values were developed through consultation with the affected stakeholders and tourist outfitters, either as a component of Resource Stewardship Agreement negotiations or through regular communication with stakeholders during area of concern prescription development.

The Operations Task Team, with input from interested tourist outfitters and/or the public, applied varied prescriptions around various tourism values. These prescriptions included increased riparian reserves in specific locations to enhance shoreline aesthetics, conditions on operational roads to address access concerns, seasonal restrictions on harvest, road construction or mechanical site preparation.

All the tourism areas of concern prescriptions have followed the direction and recommendations provided in the *Management Guidelines for Forestry and Resource-Based Tourism* as well as direction from the *Ontario's Crown Land Use Policy Atlas*.

All negotiated areas of concern are included in the Area of Concern (AOC) Planning Supplementary Documentation H.

Lakes, Ponds, Streams and Rivers (AOCs starting with WL and WS)

Values associated with lakes, ponds, streams, and rivers were identified in accordance with definitions included in the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010). The values are classified based on the type of water body, as well as the relative potential impact from forest management activities (low, moderate or high potential impact from operations).

Areas of concern are identified adjacent to the specific aquatic values. Depending on the value being protected, some AOCs are of a fixed dimension (e.g. 15 metres from ponds with low potential sensitivity to forest management operations) or are variable width based on shoreline slope (e.g. 30-90 metres AOC on lakes with high potential sensitivity to forest management operations).

Within the AOC, the width of the reserve or permitted harvest, renewal or tending activities will be dependent on the value being protected and the potential sensitivity of the value to forest management operations.

Wetlands Occupied by Breeding Black Terns and Least Bittern (AOC WW01)

Specific restrictions are identified for wetlands occupied by breeding black terns and Least Bittern (Species At Risk).

4.2.1.1 Operational Prescription for Areas of Concern Information Products

The spatial locations of areas of concern are included in the forest management plan in two information formats: illustrated on maps and included in the digital coverages of electronic information to be viewed with the planned harvest layer of information.

In both formats, the (a) area of concern identifier, and (b) the area of concern type are identified. The spatial location of the area of concern when cross referenced with the operation prescription for the area of concern (Table FMP-10) identifies the operational prescriptions for harvest, renewal and tending to be applied to the specific AOC.

For bridging areas originally approved in the 2012-2014 Contingency Plan, the appropriate AOC prescription from this 2012 FMP Table FMP-10 has been applied.

There is no second-pass harvest planned in this FMP.

4.2.2 Prescriptions for Harvest, Renewal and Tending Areas

Prescriptions for harvest, renewal and tending operations are discussed in the following sub-sections:

Section 4.2.2.1 Silvicultural Ground Rules
Section 4.2.2.2 Conditions on Regular Operations
Section 4.2.2.3 Silvicultural Treatments of Special Public Interest

Digital spatial information products for harvest, renewal and tending operations that are included with the FMP will serve as the stand list for forest operations. The information product for the harvest, renewal and tending areas is the SGR field in the planning composite (PCM) coverage and linked information for the planned harvest is in the PHR coverage.

4.2.2.1 Silvicultural Ground Rules (SGRs)

Silvicultural Ground Rules (SGRs) are defined as "Specifications, standards, and other instructions, that direct silvicultural activities on a management unit during the period of the forest management plan" (FMPM, 2009).

SGRs were developed to reflect planned silvicultural intent and are consistent with the development information used in the LTMD strategic model projections. SGRs are not included for unplanned future forest conditions (e.g. resulting from unintentional treatment failures), though the impact of estimated failures was factored into the calculation of the available harvest area in the Long-term Management Direction.

Silvicultural ground rules which identify a unique combination of current forest unit/ecosite and future forest unit, are documented in Table FMP-4. Silvicultural Ground Rules were established to specify the silvicultural systems, types of harvest, renewal and tending treatments that will be used to manage forest cover on the Whiskey Jack Forest.

The prescriptions for harvest, renewal and tending presented in Table FMP-4 will serve as the prescriptions for operations, including naturally depleted areas that are salvaged, for the ten-year period of the forest management plan.

Table FMP-4 includes renewal and forest development information for native tree species to the Whiskey Jack Forest. Exotic tree species, not naturally found on the forest, will not be planted or otherwise encouraged through renewal efforts.

The silvicultural ground rules identify the type of forest that is expected to develop over time and the regeneration standards used to measure renewal success (see Section 4.7.3 Assessment of Regeneration Success).

Regeneration Standards:

- MNR report NWSI TM-009 was used to assist in the development of renewal standards and to ensure that provincially consistent terminology was used.
- It is expected, with a reasonable level of confidence that achievement of the regeneration standards will result in the stated future forest conditions at maturity (Forest Unit, Stand Characteristics, Silvicultural Intensity, and Projected Yields) in Table FMP-4.

- Acceptable tree species are compatible with the stand objectives, and where competitive tree species are considered acceptable, they are limited to a specific proportion of the stand's species composition to align with the forest conditions represented in the stated stand characteristics and projected volume yields at maturity.
- Balsam Fir has not been included as an acceptable species, unless it is stated in the future stand characteristics.
- Regeneration standards include a minimum target of 80% of site occupancy (target and acceptable species).
- Regeneration standards include a measure of tree distribution. The use of density versus stocking targets depends on the type of treatments employed. Areas that receive extensive or basic treatments will receive regular free-to-grow or ocular surveys and contain an estimate of tree stocking. Areas treated intensively and are density regulated will receive a well-spaced free-growing survey or survey with Large Scale Photography and Photo Interpretation (methodology in Supplementary Documentation F).

The planned SGR represents the best estimate of the proposed operations at the time of FMP preparation, and will not limit the selection of any of the acceptable alternative silvicultural treatments in the silvicultural ground rules at the time of implementation of operations. For each forest unit, the most common silvicultural treatment package in Table FMP-4 is considered to be the package of treatments most likely to be used that will reflect the silviculture strategy for each forest unit. The most common treatment packages are the most likely treatments to be applied (summarized in Table 36). Overall the most common silvicultural treatment packages are designed to meet the Long-term Management Direction strategy of moving the forest to a more natural (pre-fire suppression) state where there are fewer mixedwood stands and more pure conifer and hardwood stands.

Acceptable alternative treatments are also identified in the silvicultural ground rules. It is recognized that individual treatments within a silvicultural treatment package or alternate identified acceptable treatments are implemented in succession, and therefore it may take longer than a five-year phase of the FMP for an entire silvicultural treatment package to be implemented.

As harvested areas are regenerated, operational roads, where in accordance with the use management strategy for the road, will also be regenerated where possible. Site preparation will cross ungravelled roads and they will be planted or seeded. Those roads that cannot be site prepared will be planted tightly to the edge.

All 1:20,000 maps (FMP Maps) show ecosite type and proposed silvicultural ground rule (for each stand planned for harvest or renewal). The information products (i.e. PHR & PRT layers) for harvest, renewal and tending operations will serve as the stand listing. Silvicultural Ground Rules are found in the field "SGR" in the Planning Composite inventory (PCM) coverage.

There are some silvicultural treatments that are of special public interest (also discussed in Section 4.2.2.3 Silvicultural Treatments of Special Public Interest). These activities include the aerial application of herbicides. The aerial application of herbicide as a tending operation is proposed in this plan, with the location of eligible areas identified on renewal and tending maps in FMP Maps – Composite Maps. The identification of areas for aerial chemical tending will be approved annually by MNR in the Annual Work Schedules. Approvals by the Ministry of the Environment (MOE) will be required prior to the aerial application of registered herbicides on the Whiskey Jack Forest.

Table 36 Most Common Silvicultural Treatment Packages by Forest Unit

Forest Unit		Most Common Silvicultural Treatments	
Forest Unit	**Stand Description**	**SGR Code ***	**SGR Description**
BFM	balsam fir mixedwood stands	BFM-BA1-PJM	(No BFM area planned for harvest in this plan.) Conventional harvest, followed by mechanical site preparation and planting, resulting in a jack pine dominated mixedwood (includes a spruce component).
CMX	conifer mixedwood stands	CMX-BA1-PJM	Conventional harvest, followed by mechanical site preparation and jack pine seeding, resulting in a jack pine dominated mixedwood.
HMX	mixed hardwood dominated stands	HMX-EXT-POD	Conventional harvest, followed by natural regeneration, resulting in a poplar dominated stand.
OCL	larch and cedar dominated lowland stands	OCL-EXT-OCL	(No OCL area planned for harvest in this plan.) Conventional harvest, followed by natural regeneration, resulting in a larch and cedar dominated lowland stand.
OTH	other hardwood mixedwood stands	OTH-EXT-OTH	(No OTH area planned for harvest in this plan.) Conventional harvest, followed by natural regeneration, resulting in an other hardwood mixedwood stand.
PJD	jack pine dominated stands with minimal hardwood component	PJD-BA1-PJD	Conventional harvest, followed by mechanical site preparation and jack pine seeding, resulting in a jack pine dominated stand.
PJM	jack pine dominated mixedwood stands with minimal hardwood	PJM-BA1-PJD	Conventional harvest, followed by mechanical site preparation and jack pine seeding, resulting in a jack pine dominated stand.
POD	poplar dominated stands	POD-EXT-POD	Conventional harvest, followed by natural regeneration, resulting in a poplar dominated stand.
PRW	red pine and white pine mixedwood stands	PRW-BA1-PRW	Conventional harvest, followed by mechanical site preparation and planting, resulting in a red pine and/or white pine dominated stand.
SBL	lowland black spruce stands	SBL-EXT-SBL	Conventional harvest, followed by natural regeneration, resulting in a lowland black spruce stand.
SPD	upland black (or white) spruce dominated stands with minimal hardwood component	SPD-BA1-SPD	Conventional harvest, followed by mechanical site preparation and planting, resulting in a spruce dominated stand.
SPM	spruce dominated mixedwood stands with minimal hardwood	SPM-BA1-SPD	Conventional harvest, followed by mechanical site preparation and planting, resulting in a spruce dominated stand.

* **SGR CODE** reflects the [current forest unit] - [silvicultural intensity] - [future forest unit]

4.2.2.1.1 Exceptions

Any silvicultural ground rules involving treatments that are “not recommended” (NR) in the approved silvicultural guides are documented as “exceptions” in Table FMP-4 and in the List of Exceptions following the Title, Certification and Approval page for this plan. “Not Recommended” activities cannot be implemented until the associated rationale and effectiveness monitoring plan is approved in an FMP.

Any silvicultural ground rule involving treatments that are “conditionally recommended” (CR) in the approved silvicultural guides are identified in Table FMP-4. The conditions under which these guideline recommendations apply, and any associated conditions or best management practices that must be applied during the implementation of the silvicultural treatment are identified for each silvicultural ground rule included in Table FMP-4. Through implementation of any stated conditions, the treatments for the specific sites are not considered “exceptions” to approved guides.

Monitoring of Silvicultural Treatments Not Recommended in Guides

The following activities are not recommended in the *Silvicultural Guide to Managing Black*

as exceptions: artificial seeding of black spruce on ES 14 and 21, aerial seeding of jack pine on ES 14 and 21, and natural regeneration of jack pine on ES 21. Results will be submitted as part of the Annual Report.

Areas receiving treatments considered “exceptions” in table FMP-4 would be monitored for the effectiveness of the treatment to the site on which it was applied. In the event that any exceptions to the silvicultural guides do occur, they will be monitored as required with the results documented. Inspections will involve a visual evaluation of indicative sites by experienced foresters to evaluate whether the effectiveness of the respective renewal treatment is satisfactory. If the silvicultural results are in question, a regeneration survey will be conducted in accordance with corresponding Forest Operations Prescriptions.

The assessment of these surveys will be documented in the annual report under AR-13 with a discussion on the progress toward completing the forecast assessments of regeneration success (comparison to Table FMP-21).

Full Tree Logging on Ecosites 11 and 12

“Full tree logging on NWO Ecosites 11 and 12, where total organic matter plus soil depth is less than 20 cm, is designated as a ‘not recommended’ practice in the *Silvicultural Guide to Managing for Black Spruce, Jack Pine, and Aspen on Boreal Forest Ecosites in Ontario (MNR, 1997).*

The forest industry and MNR are contributing to a comprehensive, region wide initiative to monitor the impacts of this treatment on these site conditions. As part of this monitoring program these shallow soil sites have been identified in this plan and operations will be conducted in accordance with the Best Management Practices approved for these conditions' as per the letter from the NWR Regional Director of 3 Oct 2007:*Full Tree Harvesting of Ecosites 11 & 12 in Northwestern Ontario: Monitoring Procedures and Best Management Practices April 1, 2001* (Supplementary Documentation E - Monitoring Programs for Exceptions).

Ecosites in the Whiskey Jack Forest are identified in the forest resources inventory and are identified within the planned operations digital information associated with the FMP. Actual Ecosite 11 and 12 areas scheduled for activities will be identified on the Annual Work Schedule maps.

The rationale for using full tree harvesting on these sites is that it is currently the common method of harvest and it would be uneconomical to bring in specialized equipment to harvest scattered areas of shallow soils. The shallow soil sites on the Whiskey Jack Forest are, for the most part, productive and, it is felt, that using full tree logging in a careful manner will preserve the sites’ nutrient capacity.

Artificial seeding on ES 14 is listed as an exception. This site is prone to draught which will limit the success of seeding.

Natural regeneration of jack pine or spruce on ES 21 is an exception. Advance black spruce growth is not of sufficient distribution to regenerate this site and jack pine does not regenerate under a closed canopy.

4.2.2.2 Conditions on Regular Operations (CROs)

This section of the plan documents conditions on regular operations that have been developed through application of the Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales (MNR, 2010). Where these conditions on regular operations apply to a specific management zone, the text identifies the management zone where the condition is applied. For example, Moose Emphasis Areas are such management zones and the associated CROs for these zones are included in the following table.

MNR has not identified any S1, S2, or S3 Natural Heritage Information Centre vegetation communities or other uncommon vegetation communities identified which are likely to occur in areas of planned operations. Therefore CROs as per page 13 of the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales, 2010* have not been developed. If any of these communities are identified in the future, the MNR Species At Risk and Regional Biologists will be consulted to develop CROs (or an AOC if determined appropriate). See Section 2.1.3.2.2 Rare Species and Section 2.1.3.2 Species At Risk for additional species information.

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

Biofibre Harvest:

Forest biofibre refers to forest resources from Crown lands that are not being utilized for other forest products and that are made available under an approved FMP, forest biofibre is comprised of:

1. Unmerchantable timber such as undersized wood, cull trees or portions of trees,
2. Individual trees and stands of trees that are merchantable, and
3. Trees that may be salvaged as a result of a natural disturbance.

Biofibre may be the primary (e.g., otherwise unmarketable stand of low-grade hardwoods) or secondary (e.g., undersized material after optimizing recovery of pulpwood, veneer and/or sawlog) product of a planned harvest operation.

- Direction applies to all planned harvest areas regardless of the product derived.
- Stumps and all below ground portions of a tree are not available for utilization as a forest product; movement or removal associated with normal operations (skid trails, renewal and tending, slash piling, etc., including incidental movement or removal during harvest operations), is permitted but will be minimized to that required for efficient operations; removal for forest health purposes is permitted.
- Organic matter that is not part of a harvested tree (including boles, branches, roots, bark, leaves, needles, debris, soil carbon, etc.) will remain on site; movement of such material for silvicultural purposes is permitted.

Salvage Harvest:

The direction in this section will apply to all salvage operations, regardless of the origin or type of natural disturbance that led to the decision to engage in salvage operations.

- Consistent with direction in Wildlife Trees – Clearcut Silviculture System, salvage harvest will normally retain a minimum average of ≥25 stems/ha ≥3 m in height and ≥10 cm dbh. This is the minimum average for the harvest block (or minimum average per 20 ha if the harvest block ≥20 ha) contingent upon sufficient numbers and types of standing stems being available and in a condition suitable for retention.
- In fire salvage areas, preferably retain conifers such as jack pine and black spruce as wildlife trees.
- Salvage operations will consider strategic landscape objectives.
- When finalizing boundaries of a salvage operation that results from wildfire, the area of undisturbed forest included in the salvage operation will be minimized.
- When finalizing boundaries of a salvage operation that results from blowdown, insect infestation, or other factors (e.g., ice storms), the area of the salvage operation can include undisturbed forest. When salvage operations include undisturbed area,

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

conditions on residual forest retention, wildlife trees, and downed woody material apply.

- The trees retained following salvage operations will have a range of distribution patterns (relatively even-spaced to some clumping), recognizing operational limitations, and subject to the availability of standing trees.
  - Whenever possible, the trees retained following harvest will be the same species and size classes as trees that would have been retained following normal harvest (as per direction below 'Wildlife Trees – Clearcut Silviculture System').
- Adjust the timing of entry and/or other operational factors to minimize unnecessary site disturbance that could potentially result in ecological damage (e.g., avoid salvaging a swamp in the frost-free period).
- Reasonable efforts will be made to avoid windrowing or crushing of downed woody material.

Downed Woody Material:

Material that was traditionally referred to as downed woody debris.
Downed woody material refers to wood above the soil and on the ground: coarse woody material refers to sound and rotting branches, boles, logs, and stumps, generally ≥7.5 cm in diameter at the small end; fine woody material refers to stems and twigs generally <7.5 cm in diameter at the small end.

- Stems retained as wildlife trees that fall down, or are felled for worker safety reasons, become downed woody material and will be left on site; moving such trees for silvicultural purposes is permitted.
- Dead trees present prior to harvest, including those lowered to the ground for safety considerations should be left on site.
- Downed trees (or pieces of trees) present prior to harvest will be left on site; moving such trees for silvicultural purposes is permitted.
- Trees leaning and downed by a recent disturbance (windstorms or other natural events e.g. snow, ice), which normally would have been available for harvest, may be harvested and utilized.
- Minimize the windrowing of downed woody material; where long windrows do occur, breaks should be provided to allow animals, other forest users and operations unobstructed access routes across the right of way e.g. a 10 m break for every 100 m of windrow.
- Where compatible with logging methods, unmerchantable logs, or portions of logs, should be left on site, at the stump.
- Dead trees present prior to harvest, including those lowered to the ground for safety considerations, should be left on site (only safe dead trees will remain standing).

Erosion:

Erosion can be defined as the overland movement of soil particles by water, wind or gravity.
Erosion can be the result of either natural causes or human site alterations.

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

- Skid trails will avoid steep slopes (>30% slope) where possible.
- Shallow soil sites that are particularly susceptible to erosion (i.e. moderate to steep slopes) will be harvested in winter.
- Wood will be winched or reached with a feller buncher on areas where the skidder operator feels the slope is unsafe for operations.
- Forest operations will not be conducted on extremely steep slopes.
- Green wildlife trees, organic matter and surface vegetation will be preserved on steep slopes (>30% slope).
- Stable slopes will be maintained on ditch lines, road fills and cuts.
- Slopes and banks will be reinforced (re-vegetate or use logging debris).
- Site disturbance associated with forest operations will be minimized on shallow soil sites.
- Skid trails will be kept to a minimum, with an emphasis on the protection of advanced regeneration.
- Post-harvest prescriptions and renewal efforts will be carried out as quickly as possible on shallow soil sites to encourage full site occupancy. This will minimize problems with erosion and loss of nutrients.
- Heavy mechanical site preparation (i.e. blading, heavy drags or continuous disc trenching with down pressure) will not be used on shallow soil sites.
- Harvest and site preparation will be scheduled for the appropriate season for the site. Sensitive sites will be cut in winter (or drier periods in summer).
- Decommission main skid trails constructed on steep slopes by installing water bars, diversion ditches, straw bales, etc. at appropriate intervals or critical landform junctures to filter runoff water through surrounding vegetation.
- Minimize mineral soil exposure to that required for efficient operations and effective silviculture (consistent with SGR for the site).
- Mitigate or rehabilitate areas of significant erosion that are transporting, or are likely to transport, sediment into a water feature.

Forest Composition

- Harvest, renewal and tending treatments to maintain existing tree species composition at forest unit level unless strategic direction to do otherwise.
- Forest unit conversion within moose emphasis areas to move towards desired forest composition ranges.

Furbearing Mammal Dens(other than red foxes, skunks, wolves, wolverines) – in caves, excavated burrows, under large piles of coarse woody material or other **enduring features** – known to have been occupied at least once within the past 5 years:

- Harvest, renewal, and tending operations are not permitted within 20 m of the den entrance.

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

Furbearing Mammal Dens (other than red foxes, skunks, wolves, wolverines) – in tree cavities, hollow logs, brush piles, other **transitory features** – known to be occupied: • Known occupied dens encountered during operations will not be destroyed; in this context, destruction means the complete or partial damage of the den structure or its contents (i.e. adults or young). • To minimize disturbance harvest, renewal, and tending operations will be avoided within 3 metres of dens known to be occupied that are encountered during operations; this will include the following: retaining trees within 3 m (patch may be counted as a clump of wildlife tees), not felling trees into the area within 3m, heavy equipment will not travel within 3m.
Hydrological Impacts: • Based on local conditions, take reasonable precautions to ensure harvest, renewal, and tending operations will not result in disturbance of the forest floor that impedes, accelerates, or diverts water movement within recognizable ephemeral streams, springs, seeps, and other areas of groundwater discharge connect to lakes, ponds, rivers, or streams. • Based on local conditions, explore reasonable alternatives to crossing organic and saturated mineral soils during the frost-free period. • Minimize the potential for hydrological disruption when crossing during the frost-free period cannot be avoided (See conditions listed under the section titled “Rutting and Compaction” found in this table.). • Train field staff, especially equipment operators, in the recognition and significance of disruption of hydrological function. • On very dry sites, careful logging practices that retain some trees, shrubs, advanced growth, and slash can reduce overall ground temperature and reduce excess drying. • Where possible, locate roads and landings so skidding and forwarding does not have to cross natural drainage patterns. • Regenerate susceptible sites as quickly as possible to restore transpiration and moderate hydrological changes.
Large Landscape Patches – Deer Emphasis Areas (DEAs) The following direction will apply to areas of operations in DEAs: • If practical and feasible, the block will be scheduled for harvest in the winter season • All bur oak will be retained except where required to be cleared for road right-of-way • Operations will preferentially retain mature white spruce, white pine and cedar as wildlife trees, priority given to retaining small clumps of trees, as opposed to individual trees, if they occur. • All blocks were reviewed by the District Biologist. Locations of the DEAs are portrayed on the MU490_2012_FMP_P0_MAP_MEA_DEA_00 index map.

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

Large Landscape Patches – Moose Emphasis Areas (MEAs)

The following direction will apply to areas of operations in MEAs:

- Residual shoreline forest (see FMP-10, WS and WL AOCs) (see Section 4.3.1, the operations maps and Residual, Mapped and Residual, Unmapped in this table) should be retained preferentially when it:
  - is adjacent to higher quality moose aquatic feeding areas (MAFAs) (i.e., class 4 MAFAs or class 3 MAFAs),
  - is adjacent to larger MAFAs (i.e., MAFAs > 8 ha are better than MAFAs 4-8 ha which are better than MAFAs < 4 ha),
  - is adjacent to MAFAs without features that restrict access such as steep terrain,
  - will provide screening from roads,
  - connects MAFAs to other residual forest (especially identified patches of summer thermal shelter and/or travel corridors), or
  - minimizes the distance between the aquatic vegetation and cover.
- Residual patches required to meet residual forest guidelines (see Section 4.3.1, the operations maps and Residual, Mapped and Residual, Unmapped in this table) can be used to manage for summer cover in areas where forest operations are planned, using the following criteria:
  - Size and Distribution: minimum 2 ha
  - Location: Summer cover habitat will normally be adjacent to MAFAs moose are most likely to use (i.e., ≤ 200 m, measured from the edge of the MAFA to the nearest edge of the patch of summer cover). If high quality MAFAs (Class 3 or 4) are not present, suitable summer cover will be adjacent (≤ 200 m) to other MAFAs, or natural openings (e.g., beaver meadows). Link summer cover to immature, mature, old, or residual forests, particularly shoreline forests. Linkages are considered adequate when the distance from the edge of a patch of summer cover to immature, mature or residual forests is ≤ 200 m and the terrain is traversable by moose (e.g., the terrain is relatively flat).
  - Characteristics: Maintain or retain the best summer cover habitat available. In general, lowland conifer > upland conifer > lowland or upland>hardwood > mixed woods.
- Location of the afore-mentioned unmapped residual patches required to meet residual forest guidelines will be determined in consultation with the MNR district biologist at the AWS submission stage. This will include either mapping them on the AWS operations maps or providing more specific direction in the AWS text on a block by block basis.
- Silvicultural prescriptions will be consistent with moose habitat management objectives.
- Locations of the MEAs are portrayed on the MU490_2012_FMP_P0_MAP_MEA_DEA_00 index map.

Loss of Productive Land:

Loss of productive land can be described as the conversion of previously productive forest land to a long-term or permanently non-forested condition as a result of forest management operations. Some loss of productive land through the conversion to other land

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

types (e.g., permanent roads) is inevitable.

- Sites will normally be regenerated within three years of harvest and FTG by the age of FTG in the SGR.
- Minimize the amount of area being converted to non-forest (e.g., roads and landings) to the minimum required for efficient operations.
- Placement of landings should consider bedrock or other existing non-productive land and the creation of landings will be minimized.
- Pile unutilized fibre on non-productive rock or use in the production and/or reclamation of roadways where possible.
- Exposure of bedrock should be minimized.
- Ponding created by operations and roads will be mitigated where possible.

Slash and Chip Debris Piles:

- Slash and chip debris piles will not accumulate through time or result in a permanent loss of production land.
- The production land base will be recovered from new slash and chip piles (and existing piles as noted below) and these areas will be renewed except where they were not part of the production land base originally (e.g. rock outcrops).
- Operations will be conducted in a manner to prevent or minimize the creation of slash debris piles where full tree and/or tree-length logging is identified as an acceptable logging method in the SGRs.
- Operations will be conducted to remove slash and chip debris piles and recover the production land base from these areas (e.g. biofibre harvest, slash pile burning, spreading, site preparation, or planting/seeding).
- Slash/chip treatment operations are planned to be completed while equipment is still within the harvest area with renewal planned to be completed within one year of slash/chip pile treatment. Slash/chip treatment operations will be completed no later than two years following the completion of harvest operations and renewal will be completed no later than three years following the completion of harvest operations.
- The most applicable SGR will be applied to renew the area, based on the specific site conditions of areas formerly occupied by slash and/or chip piles, and the renewal including regeneration treatments should complement the treatments on the adjacent treated areas.
- Existing slash and chip piles (three years old or less) will be treated and regenerated as noted above usually within three years of the completion of harvest operations.
- Older existing slash and chip piles (more than three years old) will be reviewed and where practical treated and regenerated as noted above using the most applicable SGR unless a different rehabilitation strategy including regeneration standards have been documented in Section 4.2.2.1 Silvicultural Ground Rules.

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

Slash Piles:

- Unutilized woody material, which accumulates at roadside and is expected to remain unutilized, will be piled, redistributed, or otherwise treated to increase the area available for regeneration.
- Avoid piling unutilized fibre on productive non-forest cover types (e.g., brush, alder or wet areas).
- Pile unutilized fibre on non-productive rock where possible.

Chip Debris:

- Suitable chipping pads and landings will be selected prior to the commencement of operations.
- Bedrock and/or non-productive areas are preferred locations for chipper pads.
- Windrowing and piling of chip debris on productive land must be limited in application (extraordinary circumstances).
- Piles are to be located to maximize skid distance and minimize the number of chipper pads.
- Piles will be no larger than 3 metres by 3 metres and a maximum of 3 metres high;
- Piles will be located at least 30m from standing timber or previously regenerated areas to reduce the fire hazard.
- When the skidder is returning to the harvest area for the next bundle, the operator will distribute logging debris back into the cutover. The debris will be dropped in front of the next bundle of trees and the bundle will be dragged over the newly dropped debris pile.
- In all other cases debris is to be carried as far as possible back into the harvest area.
- Mechanical site preparation through chipper pads will be done with the intent of exposing down to mineral soil for follow-up regeneration treatment.
- Incorporate debris into road construction or brush matting for crossing swamps, in accordance with the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales*.
- Rehabilitate gravel pits, borrow pits, and blow sand areas with chipper debris. Debris thickness should not exceed 15 cm.
- Use chipper debris as fill for road construction, landscape material for aggregate site rehabilitation, and road bank or ditch stabilization as appropriate.
- Use of chipper debris to prevent rutting and compaction.
- Renew area following most appropriate SGR.
- For any chip debris remaining at chipping site the following measures may be taken following discussion with a representative of the forest manager:
  - Pile unutilized fibre on non-productive rock where possible.
  - Push up clean piles of remaining chipper debris for use by grinding operation or for burning.
  - For areas scheduled to receive site preparation, spread out any remaining chipper debris on the landing to a

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

depth of 15 cm or less.
- For areas not scheduled for site preparation, pile all clean debris for burning and distribute the remaining dirty debris back into the cut over.
- Windrow the remaining chipper debris with a minimum 2.5 metre distance between rows.
- Pile all the clean debris for grinding operations or burning and windrow the remaining dirty debris with a minimum 2.5 metre distance between rows.
- After grinding operations are complete on each landing, spread out any remaining debris on the landing to a maximum depth of 15 cm. to prepare the landing for site preparation. Alternatively, windrow the remaining debris to prepare site for renewal.
- All chipper debris management must be completed before the harvest operation leaves the block. This will prevent the accumulation of backlog areas, especially for winter operations and improve the sequencing of harvest, debris management and silviculture. The FRL holder will notify the MNR contact, **10 days prior** to the cessation of operations.

Roundwood Slash:
- Slash piles will be aerated (or "fluffed") and piled for burning. Soil mixing will be minimized during the piling process.
- Pushed or fluffed piles will be in a location that is suitable for fall burning (away from wet ponds, drainage, or standing timber) and free of soil/foreign materials.
- Roundwood slash will not be placed on or near chipper pads so that burning operations will not be hampered.
- Use slash for brush mates to prevent rutting or compaction when available.
- Incorporate slash into road operational road sub-grades during construction where possible.
- Use slash to create access restrictions, consistent to road use strategies.
- Carry out prescribed burn plan.
- Renew area following most appropriate SGR.

Note: It is understood some of the above listed methods are dependent on weather or proximity to heavy equipment. Although completion within 3-years is expected, the ability to complete these procedures within this time frame is not always feasible. In the event that unplanned circumstances arise, and debris management activities are not practical (unplanned loss of access, or new area of concern prescription implement), the following will apply:

- The location of the logging debris will be tracked.
- A follow-up silvicultural assessment will be carried out and once the debris has undergone sufficient decomposition to permit

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

a follow-up silviculture treatment and renewal. Existing regeneration success will be a consideration.
Nests – Inactive Nest - **great grey owl, northern goshawk, red-shouldered hawk**: nests not known or suspected to have been occupied at least once within the past 5 years that are >400m from a primary nest, or <=400m from a primary nest but in poor repair; primary and alternate nests within nesting areas where all nests within the nesting area have been documented as unoccupied for >=3 consecutive years • If the nest is in good repair, harvest is not permitted within 20m (the patch may be counted as residual forest); otherwise, the nest tree will be retained as a wildlife tree. • There is no timing restriction on harvest, renewal, and tending activities.
Nests - Unoccupied Stick Nests known or suspected to have been built or used by **broad-winged hawk, merlin, sharp-shinned hawk,** unknown species **small** stick nest <75cm diameter • The nest tree will be retained as a wildlife tree if the nest is in good repair or the nest tree contains a good fork. • There is no timing restriction on harvest, renewal, and tending activities.
Nests - Unoccupied Stick Nests known or suspected to have been built or used by **barred owl, Cooper's hawk, common raven, great horned owl, long-eared owl, red-tailed hawk**, unknown species **large** stick nest >=75cm diameter • The nest tree will be retained in an unharvested residual patch ≥20 m radius if the nest is in good repair (the patch may be counted as residual forest); otherwise, the nest tree will be retained as a wildlife tree. • There is no timing restriction on harvest, renewal, and tending activities.
Nests - Unoccupied Nests in cavities known or suspected to have been used by **American kestrel, boreal owl, eastern screech-owl, northern hawk owl, northern saw-whet owl** • The nest tree will be retained as a wildlife tree if not a safety concern. • There is no timing restriction on harvest, renewal, and tending activities.
Nests – Unoccupied Nests/communal roosts in cavities known or suspected to have been used by **barred owl, great horned owl, chimney swift** • The nest/communal roost tree will be retained in an unharvested residual patch>=20m radius (the patch may be counted as residual forest). • There is no timing restriction on harvest, renewal, and tending activities.

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

Nests – waterfowl, grouse – known nests containing eggs encountered during forest management operations • Known nests will not be destroyed; in this context, destruction means the complete or partial damage of the nest structure or its contents (i.e., attendant birds, eggs, or young). • To minimize disturbance harvest, renewal, and tending operations will be avoided within 10 metres of known nests containing eggs; this will include the following: retaining trees within 10 m (patch may be counted as a clump of wildlife tees), not felling trees into the area within 10 m, heavy equipment will not travel within 10 m.
Nests – Song Birds or other small birds – known nests containing eggs or young encountered during forest management operations • Known nests will not be destroyed; in this context, destruction means the complete or partial damage of the nest structure or its contents (i.e. attendant birds, eggs, or young). • To minimize disturbance harvest, renewal, and tending operations will be avoided within 3 metres of nests known to contain eggs or young; this will include the following: retaining trees within 3 m (patch may be counted as a clump of wildlife tees), not felling trees into the area within 3 m, heavy equipment will not travel within 3 m.
Nutrient Retention on Shallow Soil Sites • All ES11 & ES12 areas greater than 8 hectares will be identified in the Annual Work Schedule. • Harvesting of shallow soil sites is preferred in the winter. • Avoid harvesting and skidding on steep slopes with shallow soils and modify skidding patterns (i.e. along the contour) where possible. • Site disturbance associated with forest operations will be minimized on shallow soil sites. • Mechanical site preparation will not be used if there is adequate disturbance of the site for renewal purposes. Heavy mechanical site preparation (i.e. blading, heavy drags or continuous disc trenching with down pressure) will not be used on these sites. Planting or aerial seeding without site preparation may be an alternative to mechanical site preparation. • Careful Logging Around Advance Growth (CLAAG) will be used where applicable. • Wildlife trees will be left favouring green hardwood trees. • Renewal efforts will be carried out as quickly as possible to encourage full site occupancy. This should also help to prevent problems with erosion and loss of nutrients. • Establish lower nutrient demanding trees (i.e. jack pine) on nutrient poor sites where appropriate. • The application of chemical aerial tending will be carefully assessed on shallow soil sites prior to use to determine if appropriate

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

for the site.
Residual Forest – definition Residual Forest is defined in the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR 2010) as: • 35 years old or > 10 m tall • >= 0.1 ha in size • >= 30% crown closure, unless harvested with in the last 20 years, then >=50% crown closure
Residual, Mapped – movement of mapped residual (note that there are currently no mapped residual areas required to meet the 25 ha in 500 ha Stand and Site Guide rule in this forest management plan, areas where moveable residual required to meet the 0.5 ha in 50 ha requirement are shown on the operations maps, but the residual patches are not mapped specifically – see next row in this table re Residual, Unmapped) • Mapped residual that is not serving any other purpose (e.g. AOC, specific habitat function, etc.), and would otherwise be available for harvest, can be moved during operational implementation as long as: o The residual requirements from the Stand and Site Guide are still met after the residual is moved (i.e. 25 ha. residual in 500 ha. circle, or 0.5 ha. residual in 50 ha. circle); o The planned harvest area is not exceeded; o The mapped residual polygon is specifically identified in the FMP as eligible for movement; o The Annual Work Schedule will identify eligible residual areas for movement.
Residual, Unmapped - for areas where residual is not mapped in advance. (see the operations maps, Section 4.3.1 and Large Landscape Patches – Moose Emphasis Areas (MEAs) in this table) • Implementation of the harvest plan will ensure that any point within a new clearcut harvest area will have at least 0.5 ha of residual within a 50 ha circle about that point. • When locating unmapped residual forest, preference will be given to locations connected to habitat features encountered during operations such as bird nests, furbearer dens, woodland pools, MAFAs, etc. When additional habitat features are not encountered, give preference to uncommon forest types, locations connected to known values (water, nests, etc.), or located consistent with expected disturbance behaviour.
Rich Lowland Hardwood-Dominated Forest (black ash) – mapped and unmapped pockets greater than or equal to 0.5 ha.

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

encountered during operations • Harvest will follow direction for rich lowland hardwood-dominated forest found in FMP-4 Silvicultural Ground Rules (Forest Unit: OTH). • No harvest, renewal or tending is permitted that: does not meet the 'rutting and compaction' conditions outlined in this table or that disrupts hydrological function (see above). • Extraction trail crossings are not permitted during the frost-free period. During winter conditions extraction trails will be minimized and will follow the conditions listed under the section titled "Rutting and Compaction" found in this table to minimize potential site damage and effects on hydrological function.
Rutting and Compaction: • No more than 50% of any 0.1 ha circle is permitted in ruts. • No ruts permitted that channel water into, or within 15 m of lakes, ponds, rivers, streams, woodland pools, or those portions of mapped non-forested wetlands dominated by open water or non-woody vegetation. • Shallow soils (<30cm): No more than 5% of any 20 ha area (or the operating block if less than 20 ha) is permitted in ruts. • All other soils: No more than 10% of any 20 ha area (or the operating block if less than 20 ha) is permitted in ruts. • The area of rutting and compaction will be minimized. • In advance of any operations, MNR and industry staff will agree to an approach to measuring the percent coverage, depth and length of a rut, definition of roadside work area, and percent coverage of extraction trails. • Harvest and site preparation will be scheduled for the appropriate season for the site. Sensitive sites will be cut in winter (or drier periods in summer). • During spring break-up, operations will be limited to frozen or dry ground conditions. • In large complex blocks where a return winter cut is planned, organic and wet lowland areas will be harvested after freeze-up. • There will be no mechanical site preparation of organic sites in summer conditions. • Where advanced regeneration is a significant contributor to future forest development (e.g. CLAAG, white pine advanced regeneration) the area in extraction trails will be minimized. On sites susceptible to rutting, achievement will be balanced against the increased rutting that may occur when extraction is concentrated on fewer trails. • Skid trails will be planned in advance. Where conditions warrant due to a high potential of compaction or rutting, skidding will be limited to main trails to reduce the overall disturbance across the block. • Main skid trails will be located on upland areas, wherever possible. Non-productive areas such as rock outcrops shall be selected for skid trails. • Log loading areas, and turn-around areas should be located on high ground to avoid rutting and blocking of drainage paths.

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

- Brush mats, slash, or corduroy maybe be placed on heavy traffic areas such as main skid trails and organic sites to reduce rutting.
- If damage occurs, operations will shift to less sensitive areas.
- High floatation tires or other low impact equipment will be used on organic sites, during the spring and fall.
- Drainage will be maintained in areas with sub-surface water flow.
- The size of skidder loads will be decreased to prevent breaking through of the organic mat.
- Advanced regeneration will be protected, wherever possible, to minimize the area travelled by harvesting equipment.

Wetlands – mapped permanent non-forested (polygon types OMS, TMS, and BSH) (See FMP-19 WW01 and FMP-10 WW01 and FMP Section 4.5)

- No harvest, renewal, or tending operations are permitted that will result in significant damage to wetland vegetation or disruption of hydrological function.
- Operations specifically prohibited include:
    - Machine travel during the frost-free period within 3 m of those portions of the wetland dominated by open water or non-woody vegetation (i.e., vegetation communities with <25% canopy cover of trees, tall (≥1 m high) woody shrubs such as alder or willow, or low (<1 m high) woody evergreen shrubs such as Labrador tea or leatherleaf);
    - Excessive removal or damage of sapling-sized trees (<10 cm dbh) and shrubs within 3 m of those portions of the wetland dominated by open water or non-woody vegetation;
    - Felling of trees during the frost-free period into, or within, 3 m of those portions of the wetland dominated by open water or non-woody vegetation; trees accidentally felled into those portions of the wetland dominated by open water or non-woody vegetation will be left where they fall;
    - Operations that leaves ruts, a significant area of exposed mineral soil, or disrupt hydrological function within the wetland itself or within forest that is within 15 m of those portions of the wetland dominated by open water or non-woody vegetation. Ruts or significant patches of exposed mineral soil will be promptly rehabilitated.
- No contamination of wetlands by foreign materials is permitted.
    - The use and storage of fuels will be carried out in accordance with the Liquid Fuels Handling Code;
    - No equipment maintenance (e.g., washing or changing oil) is permitted within 15 m of non-forested wetlands.
- Extraction trail crossings are not permitted during the frost-free period. During winter conditions, crossings will be minimized and will follow the appropriate operating practices described in rutting and compaction to minimize potential site damage and effects on hydrological function.

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

Wildlife Trees – Clearcut Silvicultural System

The following is required in any given 20 ha area within a block where harvest has occurred or for the entire block when the block is less than 20 ha:

- Because trees or stems desirable as wildlife trees may not always be present, all requirements below include the provision 'when available'; in situations where wildlife tree requirements cannot be achieved because trees are too small, requirements will be considered to be met if suitable types of trees are retained from the largest size class available.
- Wildlife trees must be >=10cm dbh and >=3m in height unless 'large' wildlife trees/stubs or cavity, veteran trees or supercanopy trees are to be retained in which case the minimum dbh is >=25cm.
- Retain an average of ≥ 25 stems/ha; wildlife trees will generally be well dispersed; retain an average of at least 15 individual stems/ha; the remaining stems may occur in clumps.
- Retain an average of ≥ 10 large stems/ha with a minimum of 5 large living trees on each ha; large wildlife trees must be a minimum of >=25 cm dbh and ≥ 38 cm dbh are preferred, however supercanopy trees will generally be >=60cm dbh; the 10 large trees/ha will be a mix of living cavity trees, stubs, supercanopy trees, veteran trees, mast trees, diversity trees, and safe dead trees.
- Large hollow trees and those providing existing nesting or denning sites are preferred as cavity trees.
- When the number of large wildlife trees averages < 25/ha, additional wildlife tree requirements may be met by retaining small safe standing dead trees, small stubs or any other living trees.
- Stubs may be left on shallow sites (ES11/12) or on sites that are susceptible to windthrow. Prior to stubbing MNR Kenora District must be contacted.
- Do not stub or knock down trees retained to meet specific wildlife functions such as cavity trees, mast trees, veteran trees and supercanopy trees (preferred trees for stubbing are jack pine and black spruce).
- Do not stub trees being relied upon as a seed source.
- When stubbing, stub to a minimum height of ≥ 3 m (5 m is preferred) and have stubs scattered throughout the harvest area.

1

Conditions on Regular Operations

NOTES: Conditions on regular operations apply to all harvest, renewal and tending operations.
Additional conditions may apply as documented in Table FMP-10 Operational Prescriptions for Areas of Concern and Table FMP-4 Silvicultural Ground Rules.
Conditions on roads, landings and aggregate pits are documented in Table FMP-19 (within AOCs) and FMP Section 4.5.7 (all areas of operations).

1

Woodland Pools – encountered during operations

- No harvest, renewal, or tending operations are permitted that will result in deposition of sediment within, or reduction of the water-holding capacity of, woodland pools
- Operations specifically prohibited include:
    - Machine travel within 3 m of the high-water mark of pools during the frost-free period.
    - Excessive removal or damage of sapling-sized trees (<10 cm dbh) and shrubs within 3 m of the high-water mark of pools.
    - Felling of trees into pools or within 3 m of the high-water mark of pools during the frost-free period; trees accidentally felled into pools will be left where they fall.
    - Disturbance of the forest floor that leaves ruts or a significant area of exposed mineral soil within 15 m of the high-water mark of pools; ruts or significant patches of exposed mineral soil will be promptly rehabilitated.
- Unmapped residual patches required to meet the direction outlined above [Residual – for areas where residual is not mapped in advance] will preferentially be connected to pools; when connecting residual patches to pools, trees will be retained in and within 3 m of the high-water mark to provide overhead shade and residual forest will be retained within at least 15 m of the high-water mark to provide amphibian cover.
- No contamination of pools by foreign materials is permitted.
- The use and storage of fuels will be carried out in accordance with the Liquid Fuels Handling Code.
- No equipment maintenance (e.g., washing or changing oil) is permitted within 15 m of the high-water mark of pools.

4.2.2.3 Silvicultural Treatments of Special Public Interest

There are some silvicultural treatments that are of special public interest. These activities include the aerial application of herbicides for vegetation management, the application of insecticides for pest management, and the areas available for fuelwood.

The **aerial application of herbicides** as a tending operation is proposed in this plan. The locations of eligible areas are identified on the MU490_2012_FMP_P1_MAP_Herb_Comp_00 index map. The identification of areas for chemical tending will be approved annually by MNR in the Annual Work Schedules. Approvals by the Ministry of the Environment (MOE) will be required prior to the aerial application of registered herbicides on the Whiskey Jack Forest.

Areas available for Fuelwood - Fuelwood is available at any approved FMP block. Fuelwood from these areas includes cull wood brought to roadside or wood in slash piles. The public is to obtain personal use fuelwood licences from the MNR prior to harvesting fuelwood.

Fuelwood will only be available if timber was not left on site for a specific reason. In all blocks, timber will be left standing intentionally to enhance wildlife habitat and natural disturbance patterns and will be unavailable for fuelwood. No fuelwood will be considered available within a block once renewal activities have commenced, or after a period of two years after harvest operations have ended. This strategy is intended for the protection of regenerating trees, whether they were initiated naturally or artificially.

There are no areas planned for **candidate high complexity prescribed burns** or **insect pest management**.

If any new operations of special public interest were to be required on the unit during this plan period, an amendment would occur to the FMP where affected stakeholders would be consulted.

4.3 Harvest Operations

This section of the FMP describes the planned harvest operations for the first five-year term (2012-2017) and those planned for the second five-year term (2017-2022) of the ten-year period of the plan. Although the strategic level planning has been conducted for this FMP for the ten-year period (2012-2022), the approval and implementation of harvest operations is divided into two Phases:

- Phase I of the forest management planning process facilitates the "approval" of the first five-year term (2012-2017) forest operations. Term 1 forest operations are referred to as "planned" operations. Area of concern planning has been completed for these planned harvest areas.
- Phase II of the forest management planning process facilitates the "approval" of the second term (2017-2022) forest operations following MNR Regional Director Endorsement of the Year 3 Annual Report. Term 2 forest operations are selected and form part of the 10-year total planned harvest operations in this FMP. They will be confirmed and changed if necessary when Phase II planning and the associated public consultation is completed. Preliminary area of concern planning has been done for these second term harvest areas in this FMP, however all Term 2 areas of concern prescriptions are not approved until Phase II planning is complete and approved. This Phase II planning process will include the review and AOC planning consideration for all updated values identified at that time.

Surplus harvest areas, bridging or second-pass harvest areas (completion of on-going harvest operations from the previous plan), salvage and contingency harvest areas are discussed in Sub-sections 4.3.2, 4.3.3, 4.3.7 and 4.3.8 respectively.

4.3.1 Harvest Areas

There were a number of management considerations and variables influencing operational planning on the Whiskey Jack Forest (as discussed in detail in Sections 3.2 and 3.4). MNR conducted its operational planning with the following considerations:

- Adherence to harvest eligibility and consideration for selection criteria (Sections 3.6.2.1 and 3.6.2.2);
- Adherence to the dynamic caribou habitat schedule areas and timing;
- Adherence to marten core habitat area deferrals;
- Selection of harvest areas to be consistent with the ten-year LTMD available harvest area by forest unit, with secondary consideration for age class;
- Consideration of all currently identified values through area of concern planning, including the implementation of no harvest reserve area of concern prescriptions;
- Consultation and negotiation with the public and other stakeholders;
- Consideration for residual forest pattern requirements and natural disturbance pattern emulation, wildlife habitat and cover to cover distances, etc.; and
- Identifying other operational considerations and conditions for specific harvest areas.

The areas planned for harvest operations for the first five-year term, and the areas proposed for harvest operations for the second five-year term are identified on the operations maps (FMP

Maps – Operations Maps). No areas were identified for harvest as a result of an insect pest management strategy at this time.

The FMPM stand listing requirement has been met through the provision of a spatial Planned Harvest Layer (PHR) and the Planning Composite inventory (PCM).

The available harvest area and the planned harvest area for the ten-year period, and the planned harvest area for the first five-year term is documented in Table FMP-11 by forest unit and age class. Minor deviations or under allocation between the planned 10-year harvest area and the Available Harvest Area (AHA) will be addressed during the planning of operations for the second five-year term. Slight variation in harvest area between five-year terms occurs for all forest units since harvest areas are allocated in operational patches. Depending on stand size and location, allocated harvest area may be below or above the projected five-year total available harvest area by forest unit in order to avoid needless splitting of stands in order to mathematically match the AHA.

The total available harvest area (AHA) for the ten-year period projected by the Long-term Management Direction is 54,834 hectares. The total planned harvest area for the ten-year plan period is under the total available harvest area (53,471 ha, Table FMP-11, 97.5% of LTMD AHA). The majority of the planned harvest for this 10-year period is in the POD forest unit (11,887 ha), followed by the HMX (11,360 ha), CMX (8,814 ha) and SPD (6,821 ha) forest units.

The planned harvest area for the first five-year term is 27,306 hectares, and the proposed harvest area for the second 5-year term is 26,164 hectares, for a total planned harvest area of 53,471 ha for the ten-year period of the plan. Term 1 and Term 2 planned harvest areas are well balanced with 51% and 49% of the 10-year planned harvest allocated for each of the five-year terms respectively.

The actual planned harvest area by forest unit generally approximates five-years of annual available harvest area by forest unit, except for the PRW and SBL forest units that have significantly less or more than half (50%) of the 10-year planned harvest area projected for the first five-year term (34% and 66% respectively). This split of harvest scheduling between the two five-year terms of the FMP period reflects several considerations:

- Allocation of full stands for forest units with small available harvest areas is logical and economical, but creates a percentage area imbalance of allocations between the two five-year terms (small areas involved).
- To provide flexibility in harvest scheduling. Allocations that are not harvested in the first 5-years will remain available in the second 5-year term.

The average harvest area associated with the 10-year plan period and each 5-year term is compared to the average 10-year and 5-year Available Harvest Area (AHA) in Figure 40 And Figure 41. Forest units have been split alphabetically into two groups of six forest units in order to more simply portray graphed data. These figures illustrate the average annual harvest area split between plan terms for each forest unit(s), and that the areas selected for operations in each five-year term are generally balanced with the average annual available harvest area for the ten-year period. It must be noted once again, that the area of concern planning for the second five-year term has not been finalized or approved at the time of FMP approval.

Allocations for the second five-year term are not approved for implementation until after MNR Regional Director Endorsement of the Year Three Annual Report and Phase II of the forest management planning process is completed and approved.

The comparison of the ten-year available harvest area and planned harvest area by 20-year age class is illustrated in Figure 41. During operational planning, minimal age class variance by forest unit occurred as compared to the age classes projected for harvest from the Strategic Forest Management Model LTMD (27d_OLTMS). In general, there was very little age class substitution into stands younger than those projected for harvest by the strategic modelling. More stands 81-100 years old are planned for harvest compared to the LTMD, and fewer younger 61-80 year old stands. A discussion of this variance and associated rationale is detailed in Section 3.6.2.3.

Figure 40 Comparison of 10-Year Harvest Area by Forest Unit (Group 1)

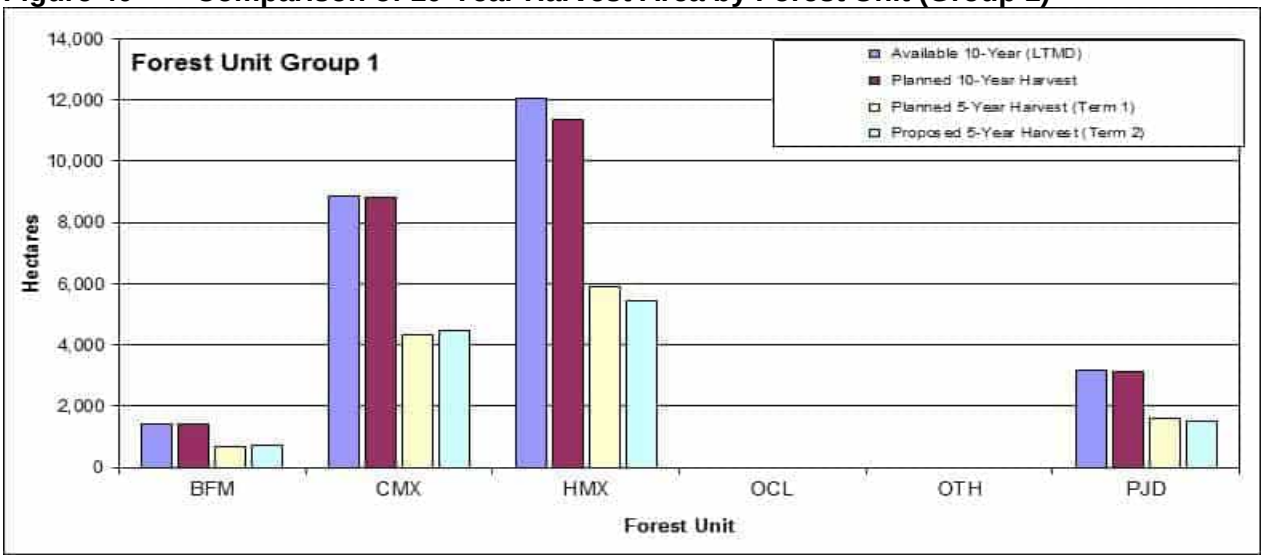


Figure 41 Comparison of 10-Year Harvest Area by Forest Unit (Group 2)

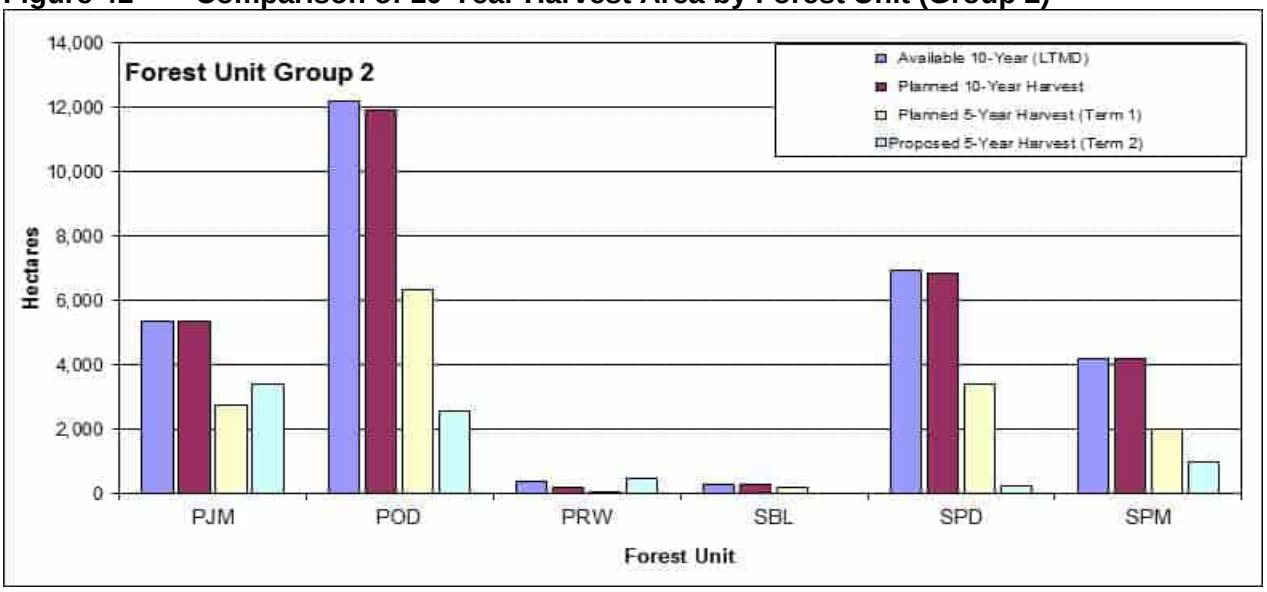

Figure 42 Comparison of 10-Year Harvest Area by 20-Year Age Class

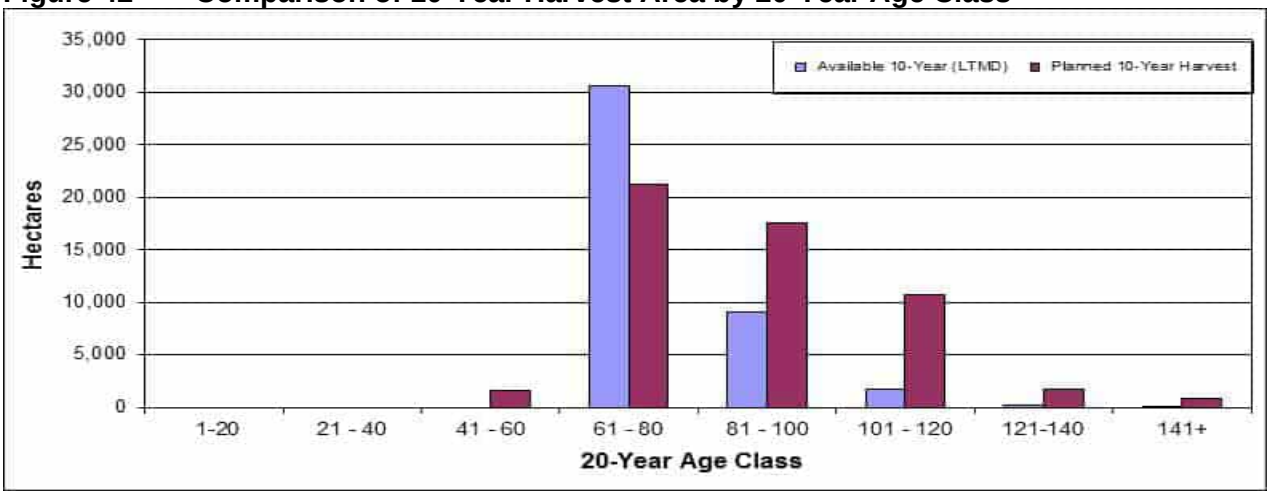


The effect of planned harvest on objective achievement was assessed. A detailed summary of LTMD objective assessment is documented in Section 3.6.3. A comparison of the planned operations to the LTMD is documented in Section 4.9, including the effect of age class distribution and projected harvest volumes of planned harvest area on the achievement of LTMD. It was confirmed that implementation of the planned harvest will aid in the achievement of objectives related to future forest composition and age structure, harvest areas and volumes.

4.3.1.1 Stand Level Residual in Harvest Areas

MNR Forest Policy Section has developed a series of guiding documents to assist forest managers in the planning and implementation of forest management activities so that forestry activities are consistent with direction contained within the Crown Forest Sustainability Act.

The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* is one of such documents, and has been developed to provide forest management planning guidance to forest managers at the stand and site level. Of particular relevance to this section of the forest management plan is the requirement to maintain residual forest within clearcut harvest areas. The *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* directs the amount and distribution of stand level residual.

NOTE: *The residual requirement from the Stand and Site Guide does not apply in the caribou emphasis area, which is the area covered by the Dynamic Caribou Habitat Schedule (caribou mosaic area). Wildlife tree requirements, detailed in the Conditions on Regular Operations (CROs, Section 4.2.2.2), still apply, but not the patch sized residual requirements detailed below in this section. In the caribou emphasis area, caribou habitat management strategies take precedence over other landscape pattern strategies.*

MNR analyzed the amount of stand level residual associated with the planned harvest for first five years of the 10-year plan period through the use of an MNR-developed computer spatial analysis program.

The Stand and Site Guide states that residual forest will be retained as follows:

- **"25 in 500 ha Analysis"** - Operational planning will ensure that any point within a planned clearcut harvest area will have at least 25 ha of mapped residual forest within a 500 ha circle (or hexagon) about that point (results discussed in Section 4.3.1.1.1).
- **"5 of 25 ha Analysis"** - A minimum of 5 ha of the mapped residual (minimum 25 ha) within any 500 ha circle (or hexagon) will belong to a patch greater than 5 ha (results discussed in Section 4.3.1.1.2).
- **"20% Residual Analysis"** - Operational planning will ensure the area of residual forest averaged over all planned clearcut harvest areas outside of large landscape patches for habitat management, using a 500 ha moving window assessment, is greater than or equal to 20% of the Crown forested area (results discussed in Section 4.3.1.1.3).
- **"0.5 in 50 ha Analysis"** - Implementation of the harvest plan will ensure that any point within a new clearcut harvest area will have at least 0.5 ha of residual within a 50 ha circle (or hexagon) about that point. This residual may or may not be mapped in advance of operations (results discussed in Section 4.3.1.1.4). The conditions on residual, unmapped in Section 4.2.2.2 CROs table apply.
- **Mapped residual** that is not serving any other purpose (AOC, specific habitat function, etc.), and would otherwise be available for harvest, can be moved during operational implementation. Refer to Section 4.2.2.2 CROs table for conditions that apply to movement of Residual, mapped (documents general direction from guide, however , as noted below, there are no mapped residual patches in this FMP).

There were no mapped residual patches required for the planned harvest operations, therefore no associated map product was required or included in the FMP.

4.3.1.1.1 25 in 500 ha Analysis Results

Requirement: *Operational planning will ensure that any point within a planned clearcut harvest area will have at least 25 hectares of **mapped** residual forest within a 500 hectare circle (or hexagon) about that point.*

Results: MNR ran the Evaluate Forest Residual Tool (EFRT) on the Phase 1 allocations, resulting in no planned harvest areas being identified as requiring additional residual forest. Since there are no blocks requiring additional ***mapped*** residual, the associated map and digital file were not produced.

4.3.1.1.2 5 of 25 ha Analysis Results

Requirement: *A minimum of 5 hectares of the mapped residual within any 500 hectare circle (or hexagon) will belong to a patch greater than 5 hectares.*

Results: MNR ran the Evaluate Forest Residual Tool on the Phase 1 allocations and there were no planned harvest areas identified as requiring additional residual greater than 5 hectares (therefore no mapped residual shown on operations maps).

The Operations Task Team discussed that the Residual Tool was designed to include lakes in its assessment (i.e. consider lake area as though it were land) in order to put more weight in leaving residual near water as this is considered to be valuable habitat. However as a consequence, the Residual Tool includes patent land/First Nations reserves next to small parcels in its assessment and treats it like a lake (i.e. not classified as residual). The Operations Task Team felt that adjacent patent land/First Nations do provide residual stands in most cases and should not be treated the same as a lake. However, this situation was not evident in the actual planned harvest allocations for this FMP period.

The residual patches or locations of the range of residual movement within each block are identified on the 1:20,000 scale operations maps.

4.3.1.1.3 20% Residual Analysis Results

Requirement: *Operational planning will ensure the area of residual forest averaged over all planned clearcut harvest areas where Section 3.2.2.2 of the Stand and Site Guide applies, using a 500 hectare moving window assessment, is greater than or equal to 20% of the Crown forested area.*

Results: The Evaluate Forest Residual Tool run by MNR calculated that the area of residual forest averaged over all planned clearcut harvest areas is 38%. This exceeds the minimum average residual requirement by 18%.

4.3.1.1.4 0.5 in 50 ha Analysis Results

Requirement: *Implementation of the harvest plan will ensure that any point within a new clearcut harvest area will have at least 0.5 hectare of residual within a 50 hectare circle (or hexagon) about that point.*

Results:

MNR ran the Evaluate Forest Residual Tool on the Phase 1 allocations and identified the planned harvest areas (129 records) that require a minimum 0.5 hectare patch of residual to be retained during operations.

The designated areas where the 0.5 hectare patch of residual are required to be left are identified on 1:20,000 scale operations maps by a polygon, somewhere in which the required residual patch(es) will be left during operations.

The 0.5 hectare patches will **not** be in the Planned Residual Patches layer (MU490_12_PRP00) as they are **unmapped**. Before harvest operations begin, the operators will be given a map showing the above identified areas where a 0.5 hectare residual patch will be required to be placed during operations.

The operators must follow the conditions on regular operations (Section 4.2.2.2) for "residual, unmapped", and "Large Landscape Patches – Moose Emphasis Areas (MEAs)" in determining the location of unmapped residual within the designated boundary.

4.3.1.2 Licensing of Harvest Areas

Forest Resource Licensees are allocated 100% of the planned harvest area as the Whiskey Jack Forest is a Crown Unit. Based on the allocation of planned harvest blocks for the ten-year period, FRL licensees can harvest the full 53,471 hectares during the ten-year term of the plan.

4.3.2 Surplus Harvest Area

The Whiskey Jack Forest available harvest area is planned to be fully utilized over this ten-year period. The full ten-year and five-year planned harvest areas were classified to be harvested therefore there is no surplus area.

4.3.3 Completion of On-going Harvest Operations from Previous Plan

Areas of bridging operations are identified to allow for the completion of harvest operations from the previous forest management plan to the next FMP. Since operations from 2012-2014 (first two years of this plan period) were conducted under the approved 2012-2014 Contingency Plan, there are no bridging areas being identified in this forest management plan.

Second pass harvesting is not carried out on the Whiskey Jack Forest.

4.3.4 Planned Clearcuts

The disturbance frequency by size class analysis was conducted during development of the Long-Term Management Direction. The analysis was updated for the draft and final plans. The analysis is described in Section 3.6.3.1 Assessment of Objective Indicators (Objective 1: Natural Disturbance and Landscape Pattern).

Consistent with the requirements of the *Forest Management Guide for Natural Disturbance Pattern Emulation (MNR, 2001)*, an assessment was also conducted to evaluate whether 80% of the planned clearcuts by frequency were less than 260 hectares in size. The definition of a planned clearcut is similar to that of a disturbance (i.e. less than 20 years old and less than 3 metres in height), except that a planned clearcut does not include naturally depleted areas, and is based on the net area disturbed. A "planned clearcut" must be separated an average of 200 metres (minimum 100 metres) and will include forest greater than or equal to 3 metres in height and 30% stocking or greater than 20 years old in order not to be part of the same planned clearcut. The guideline also states that, although less than 80% of fires in the Boreal Forest are smaller than 260 hectares, this direction recognizes the public sensitivity concerning large clearcuts.

Areas selected for harvest operations have been selected in accordance with landscape disturbance pattern requirements in the *Forest Management Guide for Emulating Natural Disturbance Patterns (MNR, 2001),* and according to the harvest eligibility and selection criteria outlined in Section 3.6.2.1 and 3.6.2.2.

The analysis of planned clearcuts identified planned clearcuts projected to be present in 2017, the end of the first five-year term of the plan. In the assessment of the "80% under 260 hectares" standard, the assessment has identified 76% of planned clearcuts to be equal to or under 260 hectares in size, leaving 24% of planned clearcuts greater than 260 ha. This result is lower than the 80% standard, but is acceptable to the Planning Team as it results from strategic landscape pattern direction (e.g. dynamic caribou habitat schedule, marten core areas, moose / deer emphasis areas) and projected harvest allocations that balance consideration for all desired forest and benefits and operational challenges.

Planned clearcuts range from 2 to 7,904 hectares in size, with an average of 302 hectares. It should be noted that planned clearcuts contain both new and older harvest areas (up to 20 years old). For those planned clearcuts over 260 hectares (average size 964 ha), the average size of "new cut" in these planned clearcuts is 533 hectares (55% of planned clearcut area).

Each proposed planned clearcut that exceeds 260 hectares is identified in Table FMP-12. These planned clearcuts over 260 hectares will provide large landscape patches for forest diversity and wildlife habitat in the future and contribute to a range of disturbance sizes on the forest which emulates a more natural disturbance pattern than if all planned clearcuts were the same size. These planned clearcuts result from the consolidation of eligible new cut harvest area adjacent to harvest areas from the past 20 years, or the allocation of a concentration of eligible harvest area in this plan period.

A map of this planned clearcut spatial landscape pattern analysis is located in the electronic FMP maps: Map MU490_2012_FMP_P1_MAP_LandPat_05.pdf.

4.3.5 Harvest Volume

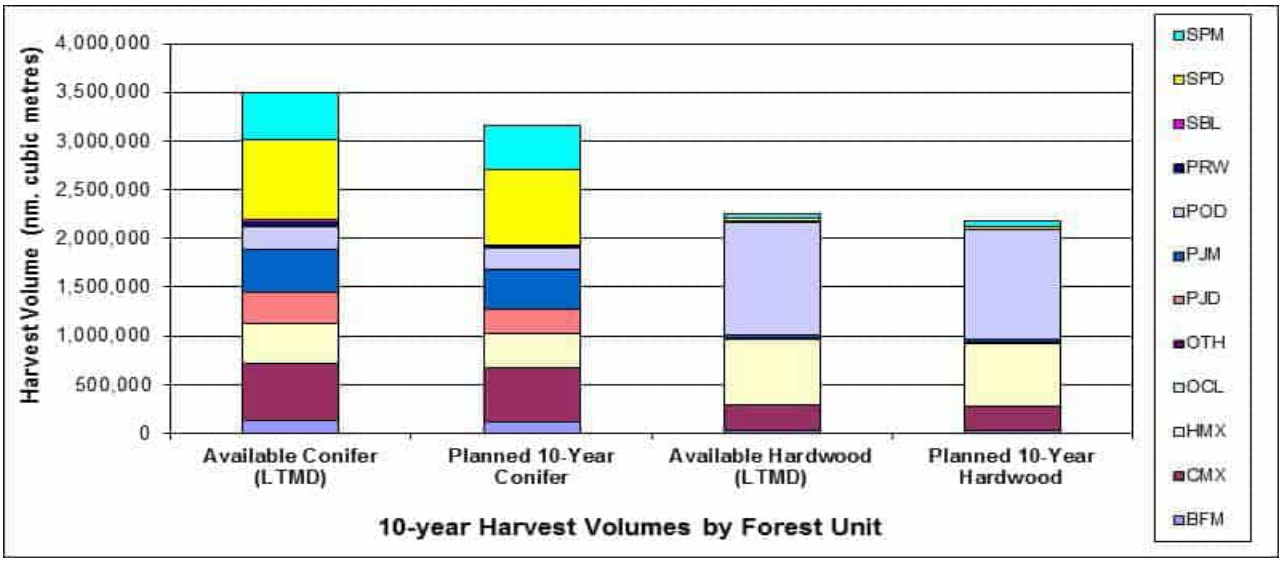
The available harvest volume and an estimate of the harvest volume for the planned harvest area for the 10-year period are recorded in Table FMP-13.

The LTMD projected an available harvest volume of 5,745,949 net merchantable cubic metres for the ten-year period of the plan (3,490,380 cubic metres conifer and 2,255,569 cubic metres hardwood). An additional 1,044,785 cubic metres of defect (e.g. defect/cull, branches, twigs, leaves and bark) and 206,668 cubic metres of undersized volume (e.g. top wood) are estimated to be generated from the LTMD available harvest volume.

The total planned harvest volume for the 10-year period of the plan is 5,334,717 cubic metres net merchantable volume with an additional 1,028,395 cubic metres volume of defect and 212,256 cubic metres of undersized volume (Table FMP-13).

Based on the 10-year planned harvest operations, the total net merchantable conifer volume projected for harvest is 3,156,893 cubic metres, and the net merchantable hardwood volume is projected to be 2,177,824 cubic metres. On an annual basis, the average volume will be a total of 533,472 net merchantable cubic metres per year. Available and planned volumes for the 10-year plan period are portrayed in Figure 43.

Figure 43 Available and Planned Harvest Volumes 2012-2022 by Forest Unit



The planned harvest volumes are below the projected harvest volumes in the LTMD by 10% for conifer and 3% for hardwood species. The minor variance in planned harvest volumes is a result of the 3% under allocation of harvest areas and also some minor age class substitution to younger and/or older stands that have less volume than the age classes projected by the LTMD. Rationale for the harvest allocations was described in Section 3.6.2.3.

The available harvest volume (LTMD from SFMM) projects 105 cubic metres per hectare and the actual allocations for the 10-year period are comparable with an average of 100 cubic

metres per hectare. The volume trade-offs through age class substitution resulted in a very minor volume loss. If during implementation of the plan, residual areas are minimized while meeting applicable guides or if yield curve projections prove to be conservative, then additional volume may potentially result from harvesting the planned harvest areas.

Merchantable Harvest Volumes were calculated based in a combination of estimated yields (SFMM yield curves by forest unit and silvicultural intensity), estimated volumes losses for stand level residual, wildlife trees and inoperable areas (SFMM unharvested volume percentages) and also based on the species composition of the allocated stands. For each forest unit and silvicultural intensity, the total volume from the yield curve was reduced by the applicable unharvested volume percentages. This resulted in a netted down total volume per hectare for each 10-year age class within each forest unit. This net total volume per hectare was then prorated by stand based on the actual species composition for each allocated stand for the 10-year period. While SFMM provides a good strategic estimate of volumes, it bases all calculations on the average condition for each forest unit. By pro-rating net harvested volumes based on each individual allocated stand's species composition, the estimated harvest volumes are significantly more relevant at the stand and operating block levels. These volumes by stand were used and summarized for all harvest volume tables in the FMP.

Undersized and Defect Volumes also known as unmerchantable volume represent all of the volume that is not merchantable by the minimum utilization standards defined in the scaling manual. In general, this includes components of the tree that have not traditionally been utilized (i.e. stem tops (below minimum diameter limit based on CFSA standard, and DBH/Height from Plonski), defect or cull, branches, leaves, twigs and bark).

MNR developed a science-based approach to estimate the undersize and defect volumes. This methodology for estimating undersize and defect volumes by species group and management unit was provided to the Planning Team to estimate volumes for this forest management plan.

The methodology uses species specific biomass and stem form equations and eco-regional calibration factors for each major species group. Resulting factors provide an operational estimate of unmerchantable volume that is available for harvest. Factors include ecological and operational netdown factors that address volumes that are not removed from the harvest site due to residual trees, coarse and fine woody debris, operational losses due to breakage and/or harvesting system limitations (i.e. cut to length operations, bark availability).

These individual tree biomass equations relate mensurational variables for the average tree (i.e. diameter at breast height (DBH) and tree height) to oven-dry mass for each biomass component of the tree. Tree biomass components predicted using these equations include: whole tree, stem wood, branches, bark, twigs and leaves.

Sources of biomass that are not included in the total volume calculation include trees left on site for ecological reasons, undersized trees in stands, downed wood debris, stumps and estimated breakage and loss due to operations.

As more experience is gained with operations in Ontario and more information is available, volume estimates (merchantable and unmerchantable) will be adjusted to reflect the most current knowledge.

4.3.6 Wood Utilization

The harvest volume for the five-year term planned harvest area is recorded by volume type, product, and species in Table FMP-14.

The total utilized volume for the five-year term of the plan is estimated to be 3,302,889 cubic metres, which is comprised of 1,869,979 cubic metres of conifer (1,543,520 cubic metres net merchantable and 326,459 cubic metres defect/undersize) and 1,432,920 cubic metres of hardwood (1,133,647 cubic metres net merchantable and 299,273 cubic metres defect/undersized). Markets are currently available or will be sought for all allocated volume. All species are considered utilized at this time, including the defect and undersized volumes. The approval of the forest management plan is not an agreement to make areas available for harvest to a particular licensee, or an agreement to supply wood to a particular mill.

The proportion of harvest volume planned for the first five-year term is 50% of the total planned net merchantable volume for this 10-year plan period. All planned harvest volumes are assigned to Forest Resource Licensees in Table FMP-14 since the Whiskey Jack Forest is a Crown Unit. As discussed in Section 4.3.1.2, FRLs harvest 100% of the planned harvest area and volume. This proportion was used to determine the planned harvest volumes by licensee reported in Table FMP-14.

Table FMP-14 presents the estimates of volume that will be utilized from the planned harvest area by fibre species and product. A portion of total stand volumes associated with the allocations will not be available at the time of harvest. Due to wildlife habitat management and the emulation of natural disturbance pattern guidelines, timber volume is expected to be left on site to enhance wildlife habitat and natural disturbance residual patterns. This anticipated unutilized volume associated with wildlife habitat (wildlife tree retention, downed woody material) and natural residual patches was not included in total allocated volumes in Table FMP-14, and was identified as unharvested volumes in the strategic SFMM modelling. All available merchantable, live trees from allocated stands are anticipated to be utilized. However, certain areas may have residual wood left on site after logging operations have been completed, due to operating conditions (inoperable) such as steep slopes, etc.

FMP-14 reports estimated volumes for utilized unmerchantable (undersized and defect) material. Markets are developing regionally for this material and it is expected that the Weyerhaeuser – Kenora mill will purchase unmerchantable material to supply biofuel to their planned co-generation plant on an “as required” basis.

The harvesting of roadside unmerchantable fibre for biofuel will be permitted in blocks which have been closed to harvest activity, including those outside of the current FMP where the areas have been identified for renewal and tending. Any such activity will comply with existing areas of concern (Table FMP-10), conditions on regular operations (CROs Section 4.2.2.2 applies to piles), conditions on roads, landings and aggregate pits (CRLAPs Section 4.5.7, applies to landings)and all road use management strategies (Table FMP-18). Roadside unmerchantable fibre within 30 metres of the road centerline is acceptable to be harvested, and no standing timber will be harvested. Renewal of these areas will occur and will be consistent with the SGR for the stand; however spot planting of conifer trees on sites left for natural regeneration may be allowed where coppice growth is not occurring. These areas are small and planting conifer along the landings will not impact the achievement of the intended SGR.

Table FMP-15 lists the mills and the anticipated volumes each will utilize from the planned harvest area for the five-year term. Volumes are summarized by species and product type. This table also shows volume commitments to each mill. The source of information for this table is FMP-13 and FMP-14 and a combination of known mill commitments and traditional mill levels previously supplied from the management unit. Based on the planned harvest volume identified in Table FMP-15, the forest can supply sufficient wood fibre to satisfy identified commitments.

Table FMP-15 volumes are subdivided by species and product committed by year. Planned deliveries to specific mills were calculated based on wood supply commitments, partially calculated by Appendix "E" of the previous SFL agreement and historic and projected deliveries to mills and more recent ministerial letters and the Wood Supply Competitive Process (2007). The identification of "Open Market" volume in Table FMP-15 does not record a surplus area or volume condition.

Weyerhaeuser - Kenora is planned to receive all net merchantable poplar fibre harvested from the Whiskey Jack Forest (estimated at 983,637 cubic metres) for their timberstrand engineered lumber facility in Kenora during the five-year term of the plan.

Prendiville Industries - Kenora Forest Products Division in Kenora is projected to receive 665,000 cubic metres of Spruce-Pine-Fir during the five-year term in accordance with a ministerial directive. They are projected to receive an additional 851,334 cubic metres in accordance with the Wood Supply Competitive Process (2007).

During this first five-year term, 45,000 cubic metres of conifer sawlogs are projected to be delivered to Wincrief Forestry Products Ltd. and 37,500 cubic metres of conifer sawlogs delivered to 1358807 Ontario Ltd. (D. Riffel Harvesting).

During this five-year plan term, there is 39,529 cubic metres of conifer (red pine, white pine, cedar, larch) net merchantable volume not allocated to any specific mill. There is 256,807 cubic metres net merchantable hardwood (mostly white birch, some black ash). There is also an estimated 658,265 cubic metres of defect and undersized volume associated with the planned harvest that is being included in this FMP as utilized fibre. These conifer and hardwood volumes are all identified as being Open Market volumes for this plan period.

Implications of Volume Underutilization: If all the planned harvest volume is not harvested and utilized, there will be negative socio-economic impacts. Reduced volumes from the Whiskey Jack Forest will impact production at wood processing mills, direct and indirect employment rates and reduced socio-economic benefits to local communities. These economic impacts may be partially offset if local mills arrange to receive wood from other sources and can maintain their production levels. If planned harvest levels are not achieved in this plan period, there may be a short-term delay in achievement of management objectives and slower progress towards the desired forest condition.

4.3.7 Salvage

Salvage operations in areas of natural depletion were not included in planned harvest area or volumes (Tables FMP-11 to FMP-15), nor are they counted against the available harvest area. The Strategic Forest Management Model incorporates an allowance for natural depletions in the Long-term Management Direction, and therefore, estimated natural depletions are already considered in the determination of the sustainable area available for harvest during the five-year term of this plan.

No salvage operations are planned on the Whiskey Jack Forest at this time. A snow damage event occurred in October 2012, but the majority of the area on the Whiskey Jack Forest was relatively young and there are currently no plans for a salvage harvest. If any additional natural depletions occurs during this term, that are suited to salvage harvest operations, appropriate planning and approval procedures will be followed to facilitate the salvage of the wood fibre.

4.3.8 Contingency Area and Volume

During the 10-year period of the forest management plan, unforeseen circumstances (e.g. wildfire, blowdown) may cause some of the planned harvest areas to be unavailable for harvest. In order to accommodate such circumstances, “contingency areas” for harvest have been identified and portrayed on the operations maps (FMP MAPS – Composite Maps and Operations Maps). This contingency area will serve as a replacement area for harvest, and will be used only if needed. This area is not in addition to the regular allocated harvest. It is identified as substitute areas, which have already been subjected to public consultation and area of concern planning. Reclassification of these areas from contingency to planned harvest area requires an amendment to the forest management plan.

Sufficient contingency area was selected from the optional harvest areas, to support approximately 20months of harvest operations. Areas were chosen that have access along primary or branch roads for easy substitution. The area and volume of the contingency area is summarized in Table FMP-16. A total of 9,147 hectares of contingency area have been identified in the management plan, with an associated total contingency volume of 929,200 cubic metres (558,269 cubic metres conifer, 370,931 cubic metres hardwood). Contingency areas are included digitally in the Planned Harvest Layer information supplied to MNR. (Note: The FMPM stand listing requirement has been met through the provision of a spatial data layer.)

Areas allocated as contingency blocks may be allocated for harvest at the beginning of the next ten-year period (2022-2032) if they are not harvested during this 10-year plan period. Most of the contingency blocks are near current allocations, and some are near primary roads to facilitate a spring haul of wood to the mills. A variety of forest units have been allocated as contingency area.

4.4 Renewal and Tending Operations

4.4.1 Renewal and Tending Areas

The planned levels of renewal and tending associated with harvest and natural disturbance are discussed in this text section.

The types and levels of renewal and tending operations planned for the ten-year period, and the proposed levels for the first five-year term are summarized in Table FMP-17. The identified renewal program represents the Long-term Management Direction of reducing mixedwood (HMX, CMX) and increasing pure conifer and pure hardwood dominated forest units. The proposed silvicultural work is based on areas depleted through harvesting, prior to the beginning of this plan term, that have not had silvicultural activities completed. Preliminary silvicultural treatment packages, from Table FMP-4, will be confirmed, or changed to reflect actual site conditions if required, at the Annual Work Schedule stage upon site inspection by a Registered Professional Forester.

During the preparation of the Annual Work Schedule, MNR will review all identified values, and confirm that proposed renewal activities are planned so that all known values are protected.

The *Forest Management Planning Manual* states that a registered professional forester (R.P.F. licenced by the Ontario Professional Foresters Association) will undertake an analysis to determine the necessary levels of renewal and tending activities, and associated expenditures required, to achieve the management objectives.

Kurt Pochailo, R.P.F., MNR Management Forester, a Registered Professional Forester, undertook a review to determine the necessary level of renewal and tending activities and the associated expenditures required in the long-term management direction to achieve a balance of the management objectives.

In addition, during development of the 2012 FMP, all wood supply model assumptions were reviewed and supported by the Planning Team and the Strategic Task Team made up of representatives from the MNR and industry, which included four (4) Registered Professional Foresters. As well, a number of Registered Professional Foresters from MNR Northwest Region provided input and review. Model assumptions are documented in the Analysis Package, Supplementary Documentation A of the 2012 FMP.

The assessment and associated Table FMP-17 is based on the projected renewal levels and associated expenditures for the five-year term of an FMP, as an output from the Strategic Forest Management Model (SFMM) based on the long-term management direction. Harvest areas planned in this forest management plan requiring artificial regeneration will be treated in subsequent years either in this phase of operations or the next. Although the levels of some individual treatments are lower than the annualized five-year average, the silvicultural strategies being employed are the same as the long-term management direction for each forest unit being treated but have been reduced to reflect actual area harvested from 2009-2012. This is not a reflection of a change in the long-term management direction and does not move away from the desired future forest condition.

Table FMP-17 estimates that in the first five-year term approximately 27,306 ha will be renewed. Of that, approximately 12,911 ha will be naturally regenerated, and approximately 14,394 ha will be artificially regenerated after site preparation (planting – 10,420 ha; seeding – 3,974 ha.). Generally, hardwood areas are regenerated naturally, and conifer areas are artificially regenerated. Tending levels are projected to be approximately 1,284 ha for the 2012-2017 plan term, half of which will be aerial application of herbicides, half ground application.

Slash piles created in blocks harvested will be burned in accordance with the conditions on regular operations (Section 4.2.2.2). Once exact site locations and hectares are known, the AWS will be revised following the September submission and approval of the Prescribed Burn Plan for Slash Pile Burning. Approximately 523 hectares of slash piles are projected to be burnt during the first 5-year term, and another 546 hectares in the second five-year term of the FMP.

Index map MU490_2012_FMP_P1_MAP_ Index_00 shows all areas eligible for renewal and tending during the term of the plan. This includes all areas harvested from 1997 to 2012. More detail on locations of actual planned renewal and tending treatments will be provided in the Annual Work Schedule.

There are currently no supplemental treatments or retreatments anticipated or planned. Aerial herbicide spray is considered a silvicultural treatment of special public interest. Areas that are considered eligible to receive this type of treatment are outlined on Index Map MU490_2012_FMP_P1_MAP_Herb_Comp_00. This includes areas previously harvested or planned for harvest in the first phase of operations that are managed for conifer production.

4.4.1.1 Eligibility and Selection Criteria for Renewal and Tending Activities

Eligibility Criteria

Renewal operations eligibility criteria are closely linked to eligibility criteria for harvest operations. All areas eligible for harvest operations are considered eligible for renewal operations during the ten-year period of the plan. In addition, all previously harvested or naturally depleted areas, which have not been deemed free-to-grow prior to plan approval date are also eligible for renewal treatments.

The eligibility criteria for **tending or cleaning operations** include all areas eligible for harvest operations during this plan period. Additional areas harvested during the 2004 to 2009 plan term, approved allocations in the 2009 – 2012 Contingency Plan and the 2012-2014 Contingency Plan are also eligible for tending operations. All harvested areas that have planting stock being suppressed by competing vegetation are eligible for tending operations. Priority will be given to those area planted with improved stock and more productive sites.

Selection Criteria

The selection criteria for renewal and tending activities are:

a) Renew areas that will have been recently harvested at the beginning of this plan term, that have not had renewal work done or completed.
b) Conduct renewal operations on areas harvested or naturally depleted during this term.

c) Tending will be considered on all harvest depletions that have planting stock that is experiencing severe suppression due to competing vegetation.

d) Tending will be considered on all naturally depleted sites, regardless of whether or not any renewal treatments are/were conducted.

4.4.2 Renewal Support

Renewal support includes those activities which are necessary to support the planned types and levels of renewal and tending operations during the five-year term of this FMP. Renewal support includes activities such as tree seed collection, planting stock production and tree improvement operations which will be conducted on the Whiskey Jack Forest.

There are no tree improvement activities planned during the next 10 years due to the poor access to the orchards. When forest operations improve the roads accessing the orchards tree improvements may be amended into the plan.

MNR is responsible for seed collection, planting stock planning, procurement and payment. Planting stock will be procured from container nurseries under contract to MNR. The planting stock will be monitored to ensure it meets the minimum specifications in the contract. Seedlings will be monitored for survival. Planting stock procurement for this forest management plan will be completed annually, one year in advance of planting. A mixture of seedlings consisting of black spruce, white spruce, jack pine red pine and white pine will be ordered depending on the areas forecasted for harvest the following year. Current inventories of seed are adequate. MNR may initiate a collection program for red pine or white pine if seed crop conditions are favourable. Table 37 summarizes the amount of seed required per year by seed zone. The forecast of planting stock to be grown by year for this five-year term is included in Table 38.

Table 37 Tree Seed Collection Forecast 2012-2017

	SEED REQUIREMENT FORECAST (hectolitres)					
	Year 1	Year 2	Year 3	Year 4	Year 5	TOTAL

4.5 Roads

The planning requirements for new primary, branch, and operational roads that are required to access harvest areas, including contingency area that will be constructed during the ten-year period of the forest management plan are described in Section 4.5.1 Primary and Branch Roads and Section 4.5.2 Operational Roads.

This section outlines the planning requirements for new primary, branch and operational roads that will be constructed during the ten-year term of the FMP. These roads are required to access planned and future harvest areas. Plan text and Table FMP-18 include those activities planned for this 2012-2022 forest management plan.

Existing and proposed roads, landings and aggregate pits are considered in AOC planning. If there are any conditions on any of these features, they are noted in Table FMP-10, and documented in Table FMP-19. Proposed road locations were considered with regard to all currently identified values. Sections 4.5.1 and 4.5.3 include discussions on the primary and branch roads proposed for construction during this plan period and conditions and analysis of any planned area of concern crossings. A summary of the operational road construction in this FMP period, and conditions and analysis of any planned area of concern crossings of these roads is included in Sections 4.5.2 and 4.5.4. Existing forest access roads are discussed in Section 4.5.5. Operational standards for forestry aggregate pits are included in Section 4.5.6.

Any primary or branch road crossing of an AOC requires completion of road supplementary documentation form Part D. Supplementary documentation for area of concern prescriptions can be found in Supplementary Documentation Section H.

Where a new or existing primary road, branch road, operational road, landing or aggregate pit does not intersect an area of concern for a value, any conditions on the primary road, branch road, operational road, landing or aggregate pit as described in the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* are documented in Section 4.5.7 - Conditions on Roads, Landings and Aggregate Pits.

No new primary roads, branch roads or operational roads are required for forest management purposes that will traverse a provincial park or conservation reserve.

4.5.1 Primary and Branch Roads

4.5.1.1 Primary Road Corridors

The *Forest Management Planning Manual for Ontario's Crown Forests (MNR, 2009)* defines a **primary** forest access road as a road that provides principal access for the management unit and are constructed, maintained and used as the main road system on the management unit. Primary roads are normally permanent roads, although there may be significant periods of time when specific primary roads are not required for forest management purposes.

Each planned new primary road required for the twenty-year period (2012-2032) is identified in Table FMP-18 along with the use management strategy for the road and the length of road to be

constructed during the first five-year term of the plan. The planned corridor for each primary road is portrayed on the operational maps and Planned Road Corridor layer.

Final locations of the one-kilometre wide corridors for primary roads are based on the environmental analysis of alternative corridors and public comments received during the planning process. Primary road use management strategies were also finalized after public consultation. The rationale for the proposed corridor and the associated use management strategy are documented in Supplementary Documentation G - Road Planning Documentation.

During the 2012-2032 period, no primary roads are being considered for transfer from the forest manager to the Crown.

Where a new primary road or landing does not intersect an area of concern (AOC) for a value, any conditions on the primary road or landing as described in MNR's guide(s) relating to conserving biodiversity at the stand and site scales are documented in the forest management plan. These conditions on roads, landings and aggregate pits (CRLAPs) are shown in Section 4.5.7 in this FMP.

The Whiskey Jack Forest is generally well accessed at Plan Start, with minimal construction of primary access roads required in the next twenty-year period (2012-2032). There are only three new primary roads planned for construction during the 2012-2022 plan period: the Yellow Girl Road, the Bug Lake Road and the Witch Bay/Loon Lake Road.

4.5.1.2 Branch Road Corridors

Branch roads are roads, other than primary roads, designed for all-weather access that branch off existing or new primary or branch roads, providing access to and through areas of operations on a management unit.

Each planned new branch road required for the 10-year period is identified in Table FMP-18 along with the length of road to be constructed and the use management strategy for the road. The planned corridor for each branch road is portrayed on the operational maps and Planned Road Corridor layer.

During the 2012-2022 period, no branch roads are being considered for transfer from the forest manager to the Crown.

There are two branch roads planned for construction during the 2012-2022 plan period: the April South Road, and the Aesthetic Road.

Where a new branch road, or landing does not intersect an area of concern (AOC) for a value, any conditions on the primary road, branch road or landing as described in MNR's *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010) will be documented in the forest management plan. These conditions on roads, landings and aggregate pits (CRLAPs) are shown in Section 4.5.7 in this FMP.

4.5.2 Operational Roads

Operational roads are roads, other than a primary or branch roads that provide short-term access for harvest, renewal and tending operations. Operational roads are normally not maintained after they are no longer required for forest management purposes, and are often decommissioned.

Table FMP-18 lists the new and existing operational road boundaries that will be required for the 10-year term of the plan. Planned construction, maintenance, monitoring, access control and future use management are recorded in the table. Any extensions to existing roads (construction during the plan period), or changes to the use management strategy for an existing road are documented in Table FMP-18.

The areas within which new operational roads are to be constructed during the 10-year plan period will be identified by **operational road boundaries** (ORBs). An operational road boundary identifies the perimeter of the harvest area and the area from an existing road or planned road corridor to the harvest area. Operational road boundaries for the FMP are identified on the operations maps and shown in the legend as “Operational Road Boundary”.

Each operational road boundary within which an operational road will be constructed during the plan period and the associated use management strategy (UMS) for the road(s) is recorded in Table FMP-18. Documentation of the use management strategy for each operational road or networks of operational roads is included in Supplementary Documentation G.

During the 2012-2022 period, operational road boundaries being considered for abandonment or decommissioning are identified in Table FMP-18. All operational roads within the identified ORBs will be decommissioned.

The operational road boundaries are delineated on the 1:20,000 Operational Maps. The applicable road use strategy is outlined in Table FMP-18 and will be the road use strategy for that particular road or network of roads for the period of this plan. Operational roads will be built in the most appropriate location to facilitate harvest.

Where a new operational road or landing does not intersect an area of concern (AOC) for a value, any conditions on the operational road or landing as described in MNR’s *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010) will be documented in the forest management plan. These conditions on roads, landings and aggregate pits (CRLAPs) are shown in Section 4.5.7 in this FMP.

4.5.3 Area of Concern Crossings – Primary and Branch Roads

This section documents the planning requirements that were applied to each crossing of an area of concern (AOC) by a proposed corridor for a new primary or branch road. These AOC crossings are planned for the portion of the road that will be constructed during the first five-year term. Preliminary crossings of areas of concern for the second five-year term were also developed and mapped. During Phase II planning, the preliminary crossings of areas of concern will be reviewed, confirmed and updated or revised if necessary.

There is one primary road and two branch roads planned for construction in this FMP. Table FMP-10 identifies if there are conditions on a crossings, landings or aggregate pits within an AOC associated with the planned primary or branch road. Table FMP-19 contains the conditions and locations of the AOC crossings on the Yellow Girl Road, the April South Road, the Bug Lake Road.

AOCs are individual or grouped according to the value(s) and are assigned a common code identifying the AOC. For each crossing of an AOC within a primary and branch road corridor, the conditions on construction and acceptable variations to locations and conditions are documented in Table FMP-19, organized by the same AOC codes used in Table FMP-10.

Where primary or branch roads cross the above AOCs, the rationale for the crossing is documented in Supplementary Documentation H – Areas of Concern (AOC) Documentation. Supplementary Documentation H also includes reference to any public comments received and how they were considered in the AOC prescription.

AOC crossings are illustrated on the Operational Map series and include the following:

- Preferred 100-metre wide crossing location of the road;
- Restricted crossing areas, if applicable;
- Acceptable variations to the crossing area (remainder of area where there are no restricted areas or area already identified as the preferred crossing location (as above)); and
- Crossing reference number.

The portrayed 100-metre wide road locations and documented conditions on road construction in the forest management plan for area of concern crossings are preliminary locations and conditions. The locations and conditions will be finalized in the applicable Annual Work Schedules consistent with the acceptable variations described in the FMP.

No new roads required for forest management purposes will traverse a Provincial Park or Conservation Reserve during the 10-year period of the management plan. There are no new primary or branch roads planned for construction within Enhanced Management Areas.

4.5.4 Area of Concern Crossings – Operational Roads

For new operational road crossings of areas of concern, any necessary conditions on the location(s) and/or construction of the crossings are identified for individual areas of concern or groups of areas of concern. Table FMP-10 identifies if there are conditions on operational road crossings of an area of concern, or landings in an area of concern. AOCs are individual or grouped according to the value(s) and are assigned a common code identifying the AOC.

For operational road crossings of areas of concern, conditions on the location(s) or construction of the crossing(s) for individual areas of concern, or groups of areas of concern, are documented in Table FMP-19, organized by the same AOC codes used in Table FMP-10. Conditions on a landing within an AOC are also documented in Table FMP-19.

Operational road locations and conditions on construction will be identified in the annual work schedule, consistent with the conditions described in the FMP.

4.5.5 Existing Roads

Each existing road or road network, and the associated use management strategy, is documented in Table FMP-18. Documentation of new or revised use management strategies, and the associated rationale, is included in the Supplementary Documentation G. All roads information for the FMP is included in a single GIS layer submitted electronically with the plan.

If an existing road, landing or aggregate pit within an area of concern is planned to be used for forest management purposes during the period of FMP, Table FMP-10 identifies if there are conditions on the roads, landings or aggregate pit. Details of the conditions on the road, landing or aggregate pit as described in MNR's guide entitled *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010), are documented in Table FMP-19.

If an existing road and/or landing is planned to be used for forest management purposes during the period of FMP, and where the road and/or landing does not intersect an area of concern for a value, conditions on the road and/or landing as described in MNR's guide entitled *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010) are documented in Section 4.5.7.

There are no primary or branch roads scheduled for removal over the ten-year period of this FMP.

There are no other existing roads planned for additional restrictions or modifications to existing access restrictions, decommissioning or road transfers during this plan term. All existing access restrictions (e.g. Aesthetic Road, Lennan Road, Mac Lake Road, Tide Road, Unexpected Road and the Sydney Lake Road) will remain in place, as shown in Table FMP-18.

Existing operational road boundaries and their use management strategies are also summarized in Table FMP-18. During the 2012-2022 period, operational road boundaries being considered for abandonment or decommissioning are identified in Table FMP-18. All operational roads within the identified ORBs will be decommissioned.

Changes to road use management strategies approved in the 2012-2014 Whiskey Jack Forest Contingency Plan are carried forward and documented in this FMP. The use management strategies for road networks are summarized in Supplementary Documentation G.

4.5.6 Forestry Aggregate Pits

The criteria for a Forestry Aggregate Pit apply as per regulations under the *Aggregate Resources Act,* however, Forestry Aggregate Pits (previously Category 14) are exempt from the requirement for an aggregate permit under the Aggregate Resources Act (ARA) as per the exemption criteria below. Previously operated Forestry Aggregate Pits may be utilized for a ten-year period starting from the initial aggregate extraction from the pit. Forestry Aggregate Pits must remain within the road corridor or area of operations that was identified in the AWS at the time the site was established.

The extraction of aggregate from Forestry Aggregate Pits for use on forest access roads on the management unit will comply with the exemption criteria as outlined below:

Exemption Criteria

By regulations under the *Aggregate Resources Act*, a person engaged in forest operations on Crown land is exempt from subsection 34(1) of that Act, if the following criteria are satisfied. Those criteria are the following:

- A Forest Management Plan (FMP) for the management unit has been approved;
- The aggregate is required for a forest access road in a management unit;
- Aggregate is extracted:
  - (a) no closer than 1.5 metres above the established groundwater table; or
  - (b) closer than 1.5 metres above the established groundwater table if:
    - (i) the proposed site is remote or isolated; and
    - (ii) the excavation limit of the site is not within:
      - 500 metres of a cold-water stream;
      - 1,000 metres of a water well, whether dug or drilled; and
      - 5,000 metres of a receptor;
- Aggregate extraction will be completed within 10 years from the commencement of the pit; and
- The pit is or has been established within:
  - (a) An approved new primary or branch road corridor in the Forest Management Plan and the Annual Work Schedule;
  - (b) An approved area of operations in the Forest Management Plan and in the Annual Work Schedule;
  - (c) An approved operational road boundary in the Forest Management Plan and in the Annual Work Schedule; or
  - (d) An approved aggregate extraction area in the Forest Management Plan and in the Annual Work Schedule that is located within 500 metres of an existing forest access road.

Aggregate pits that satisfy these criteria are referred to as “Forestry Aggregate Pits”.

Aggregate Extraction Areas

Forestry Aggregate Pits are established according to the criteria previously listed. If aggregate pits are required in areas outside those areas covered by the stated criteria, aggregate extraction areas may be identified. If needed, aggregate extraction areas are to be identified for the five-year term of the FMP and are to be shown on the operations maps. They must also be identified in the Annual Report for the year that they were established and the Annual Work Schedule(s) for the following year.

No aggregate extraction areas are identified in for this plan period.

If aggregate is required from an area not identified as an aggregate extraction area, an amendment to the forest management plan will be required to identify the new aggregate extraction area. The amendment will be consistent with the requirements for an aggregate extraction area identified in the *Forest Management Planning Manual*.

4.5.7 Conditions on Roads, Landings and Aggregate Pits

If an existing road, landing and/or forestry aggregate pit is planned to be used for forest management purposes during the period of the forest management plan, and where the road, landing and/or forestry aggregate pit does not intersect an area of concern, any conditions on the road and/or landing as described in the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010) are documented in this section of the forest management plan. This section also includes the Operational Standards for Forestry Aggregate Pits both within and outside AOCs.

Where a new primary road, branch road, operational road or landing does not intersect an area of concern for a value, any conditions on the primary road, branch road, operational road or landing as described in the *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010) are documented in this section of the forest management plan.

The extraction of aggregate from forestry aggregate pits for use on forest access roads within the forest management unit will comply with the operational standards in this FMP as outlined in this section.

When a forestry aggregate pit intersects an area of concern, Table FMP-10 identifies if there are conditions on operations. Any operational conditions related to aggregate pits intersecting with area or concerns are stated in Table FMP-19.

The conditions on operations for forestry aggregate pits must take into consideration the *Endangered Species Act, 2007*, including any applicable habitat regulations and relevant policy direction.

All existing forestry aggregate pits will be identified in each Annual Work Schedule.

The following table documents the Forestry Aggregate Pit Operational Standards as well as conditions on roads, landings and forestry aggregate pits outside of areas of concern. Reclamation of Landings (Section 4.5.7 Conditions on Roads, Landings and Aggregate Pits) applies to conditions on new (primary, branch, operational) and existing roads and landings (outside of AOCs).

Forestry Aggregate Pit Operational Standards (all pits inside and outside of AOCs as applicable):

- Topsoil and overburden, where present, must be stripped and stored on site.
- Aggregate material may be removed only within areas where access, harvest, renewal, or aggregate extraction has been planned and approved, with no removal occurring within 15 metres of the boundary of any planned area.
- Aggregate material must not be removed from an area of concern or within 15 metres of the boundary of an area of concern, except:
    - *for a cultural heritage landscape or historic Aboriginal value, as defined in the Forest Management Guide for Cultural Heritage Values, if,*
        - *Table FMP-19 of the forest management plan documents conditions on location, construction or use of the Forestry Aggregate Pit, as per the advice of a qualified individual as defined by the Forest Management Guide for Cultural Heritage Values, and*
        - *the aggregate material is removed in accordance with such conditions; and*
    - *for all other values, if,*
        - Table FMP-19 of the forest management plan documents conditions on location, construction or use of the Forestry Aggregate Pit, and
        - the aggregate material is removed in accordance with such conditions.
- Notwithstanding Standard 3 above, aggregate material must not be removed from an area of concern or within 15 metres of the boundary of an area of concern for the following values, as defined in the *Forest Management Guide for Cultural Heritage Values*:
    - archaeology site;
    - cemetery; or
    - archaeological potential area.
- When operating within 15 metres of a proposed roadside ditch, no excavation is to take place below the elevation of the planned depth of the proposed ditch; all excavations must be immediately sloped to no steeper than a 2:1 (horizontal: vertical) angle.
- During extraction, no undercutting of the working face is permitted and:
    - the working face must be sloped at the angle of repose; or
    - the vertical height of the working face must not be more than 1.5 metres above the maximum reach of the equipment.
- All trees within 5 metres of the excavation face must be removed.
- The maximum disturbed pit area (harvested area including excavation area) must not exceed 3 ha. When a pit or a portion of a pit is rehabilitated (silviculturally treated), it is no longer part of the pit.
- When the site is inactive, all pit faces must be sloped at the angle of repose.
- Within the excavation area, no ponding is allowed and offsite drainage must be designed to prevent sediment from entering any water feature.

- Unless an aggregate permit (e.g. Category 9) has been issued, by the end of the 10-year period starting from the commencement of the Forestry Aggregate Pit:
  - buildings, structures, or processing equipment must be removed from the site; and
  - rehabilitation of the site must be completed.
- Notwithstanding standard 11 above, MNR may direct that a Forestry Aggregate Pit be rehabilitated prior to the end of the above-noted 10-year period where the responsibility for the road and associated Forestry Aggregate Pit is being transferred back to MNR.

- Final rehabilitation must include:
  - sloping of all pit faces to a minimum of 3:1(horizontal: vertical);
  - re-spreading of any topsoil and overburden that was stripped from the site; and
  - mitigative measures, to the satisfaction of MNR, to prevent erosion (e.g. establishment of vegetation).
- Existing or proposed Forestry Aggregate Pits within areas of concern, or in the vicinity of features that are addressed by conditions on operations, as described in MNR's forest management guide(s) relating to conserving biodiversity at the stand and site scales, must not be constructed or operated except in circumstances as identified in the conditions on operations in the forest management plan. This includes any restrictions on the construction of new Forestry Aggregate Pits and timing of aggregate extraction, rehabilitation, or other associated operations in existing pits.
- Progressive rehabilitation of the site must be ongoing during the 10-year period, starting from the commencement of the Forestry Aggregate Pit.

Reclamation of Landings

- The production land base will be recovered from landings and these areas will be renewed except where they were not part of the production land base originally (e.g. rock outcrops).
- Operations will be conducted in a manner to minimize the establishment of landings through operational block planning and road layout.
- For any landings that are created the following will occur:
  - Operations will be conducted to recover the production land base from landings (e.g. site preparation, planting/seeding).
  - Woody material (logging debris), which accumulates at roadside is expected to be utilized during this plan, but if not utilized, this material will be piled, redistributed or burnt to increase the area available for regeneration.
  - Avoid piling unutilized fibre on productive non-forest cover types (e.g., brush and alder).
  - Landing treatment operations will be completed no later than two years following the completion of harvest operations and renewal will be completed no later than three years following the completion of harvest operations.
  - The most applicable SGR will be applied to renew the area, based on the specific site conditions of areas formerly

occupied by the landing, and the renewal treatments including regeneration should complement the treatments on the adjacent treated areas.
- o Existing landings (three years old or less) will be treated and regenerated as noted above within three years of the completion of harvest operations.
- o Older existing landings (more than three years old) will be treated and regenerated as noted above using the most applicable SGR.
- o Operations are to be completed no later than the decommissioning timelines outlined in the adjacent roads' UMS.
- o The AWS will identify the location of landings scheduled for operations, the operations to be conducted, and the scheduled regeneration treatments.
- o The AWS will identify the inspection of landing treatments and subsequent regeneration as a compliance priority and will indicate how the inspections will be completed.

The following conditions apply outside of Areas of Concern:

General Conditions on Road Planning, Construction and Maintenance; Landings; Forestry Aggregate Pits:

- These conditions include the mitigative measures/design principles to minimize the risk of sediment/disruption of hydrological function referred to below for LPS ponds/streams, rich lowland hardwood-dominated forest, wetlands, woodland pools.
- Plan and construct roads to minimize costs associated with decommissioning (e.g., use temporary re-useable bridges).
- Engineering safety considerations will be incorporated into road planning.
- When practical and feasible, access should be planned to prevent or minimize site damage (e.g., build roads well in advance of operations so lack of access is not a recurring reason for off-season operations on susceptible sites).
- Road right-of-way widths for all primary and branch roads will be a maximum of 40 metres through unallocated stands, with the exception for landings which may be increased to a maximum of 50 metres.
- Road right-of-way widths for all operational roads will be a maximum of 30 metres through unallocated stands, with the exception for landings which may be increased to a maximum of 50 metres.
- Haul roads and skid trails will avoid steep slopes.
- Materials moved during construction, such as grubbed or earth fill material, will not be piled where they block drainage courses.
- Fill material for roads built below the high water level, within the floodplain of a water feature, will be erosion resistant and/or protected from erosion.
- Any exposed mineral soil between the height of land and a water crossing, or within 100 m of a water crossing, whichever is less, will be trimmed to a stable angle and be protected from erosion so sediment will not enter the water after construction.
- Mitigation techniques will be used to prevent or stop erosion in ditches, on steep slopes, etc.

- When all-weather roads must cross wetlands, frequent cross drainage culverts will be provided to ensure that surface water is equalized on both sides of the road and impacts to hydrologic flow and wetland function are minimized.
- When the road location and landings within the approved corridor are being finalized, avoid recognizable ephemeral streams, springs, seeps, and other areas of groundwater discharge that are connected to lakes, ponds, rivers, or streams and small unmapped wetlands (e.g. woodland pools)
- If recognizable ephemeral streams, springs, seeps, and other areas of groundwater discharge that are connected to lakes, ponds, rivers, or streams, or small unmapped wetlands must be crossed, use construction and maintenance techniques and practices to minimize impacts to hydrologic flow and wetland function; natural water movements will not be impeded, accelerated, or diverted
- Identify areas of concentrated surface water flow and prevent blockage through appropriate use of cross drainage culverts; some of these locations may be determined the following spring when ponding is evident at unpredicted locations along a new road.
- Where ditches leading downhill from rock cuts pass over earth material, techniques will be used to protect the earth/rock interface from erosion.
- Grubbing of low vegetative cover between the height of land (e.g., the high point on a ditch line) and a water crossing, or within 100 m of a water crossing, whichever is less, will be limited to that required to address engineering issues and safety concerns, such as the removal of hazards.
- Where explosives and blasting are required, this work will be planned to ensure rock or earth remains within the right of way
- Windrows or grubbing materials will not be placed across known migration paths of wildlife in a manner that could impede their travel
- Minimize the windrowing of downed woody material; if long windrows (e.g. of slash or rock) are created, breaks should be provided to allow animals, other forest users and operations unobstructed access routes across the right of way e.g. a 10 m break for every 100 m of windrow.
- Decommission main skid trails constructed on steep slopes by installing water bars, diversion ditches, straw bales, etc. at appropriate intervals or critical landform junctures to filter runoff water through surrounding vegetation.
- During decommissioning, workers will prevent contamination of a water feature by foreign materials such as lumber, nails, logs, brush, fuel and oil.
- Minimize the amount of area being converted to non-forest (e.g., roads and landings) to that required for efficient operations.
- MNR will ensure that the signs used to identify travel restrictions under the Public Lands Act are maintained.
- Harvest of rare tree species (e.g. white pine, yellow birch, bur oak and white elm) will be avoided where practical, but may occur if encountered during road construction or gravel extraction.
- Roads on Crown Land maintained by cottagers and/or public groups (i.e. Local Roads Boards (LRB)) that are planned for harvest block access will at a minimum maintain a pre-harvest condition or any other negotiated agreements between the Forest Manager and those responsible for the maintenance of the road following the completion of hauling operations.
- Implement a monitoring program for roads or road networks (see Monitoring and Assessment Section 4.7.4 Roads and Water Crossings).

· The planning, construction, and maintenance of primary and branch road corridors and road network locations, and their applicable use management strategies, will consider:
i) the strategic direction associated with other resource plans, policies and directives (e.g., *Crown Land Use Policy Atlas*);
ii) the strategic direction being addressed through the use of LLPs resulting from the application of the Landscape Guide;
iii) the management objectives, and emphasis for specific areas (e.g., direction provided by the *Crown Land Use Policy Atlas*; LLPs as described in Section 3.3 of this guide); and iv) the potential impact (including benefits) to other natural resource features, land uses, and values (e.g. lakes and streams, cottage sites, boat caches.

Roads Crossing Recreational Portage Routes, Trails used for Accessing and Working Traplines that are not AOCs:

- Ensure that identified recreational portage routes and trails used for accessing and working traplines are passable following forest management operations.

Biofibre Harvest

- Direction applies to all planned harvest areas regardless of the product derived
- Stumps and all below ground portions of a tree are not available for utilization as a forest product; movement or removal associated with construction of roads or landings is permitted but will be minimized to that required for efficient operations
- Organic matter that is not part of a harvested tree (including boles, branches, roots, bark, leaves, needles, debris, soil carbon, etc.) will remain on site; movement of such material for access is permitted.

Furbearing Mammal Dens (other than red foxes, skunks, wolves, wolverines) – in caves, excavated burrows, under large piles of coarse woody material or other **enduring features** – known to have been occupied at least once within the past 5 years

- New roads/road construction, landings, and aggregate pits/aggregate extraction are not permitted within 20 m of an occupied den entrance.
- Hauling and road maintenance operations of existing roads are not permitted within 20 m of an occupied den entrance unless the road predates the den or is required for safety reasons or environmental protection.

Furbearing Mammal Dens (other than red foxes, skunks, wolves, wolverines) – in tree cavities, hollow logs, brush piles, other **transitory features** – known to be occupied

- Known occupied dens encountered during operations will not be destroyed; in this context, destruction means the complete or partial damage of the den structure or its contents (i.e. adults or young)
- New roads, landings, and aggregate pits are not permitted within 3 m of the den entrance.

Nests – Inactive Nest - **great grey owl, northern goshawk, red-shouldered hawk**: nests not known or suspected to have been occupied at least once within the past 5 years that are >400m from a primary nest, or <=400m from a primary nest but in poor repair; primary and alternate nests within nesting areas where all nests within the nesting area have been documented as unoccupied for >=3 consecutive years • New roads, landings and aggregate pits will not be constructed within 20 m • No timing restriction on operations associated with existing roads, landings and aggregate pits
Nests - Unoccupied Stick Nests known or suspected to have been built or used by **broad-winged hawk, merlin, sharp-shinned hawk,** unknown species **small** stick nest <75cm diameter • Reasonable efforts will be made to avoid constructing new roads, landings, and aggregate pits within 20 m of nests**.** • No timing restriction on operations associated with existing roads, landings and aggregate pits.
Nests - Unoccupied Stick Nests known or suspected to have been built or used by **barred owl, Cooper's hawk, common raven, great horned owl, long-eared owl, red-tailed hawk**, unknown species **large** stick nest >=75cm diameter • New roads, landings and aggregate pits will not be constructed within 20 m • No timing restriction on operations associated with existing roads, landings and aggregate pits
Nests - Unoccupied Nests in cavities known or suspected to have been used by **American kestrel, boreal owl, eastern screech-owl, northern hawk owl, northern saw-whet owl** • Reasonable efforts will be made to avoid constructing new roads, landings, and aggregate pits within 20 m of nests. • No timing restriction on operations associated with existing roads, landings and aggregate pits.
Nests – Unoccupied Nests/communal roosts in cavities known or suspected to have been used by **barred owl, great horned owl, chimney swift** • New roads, landings, and aggregate pits will not be constructed within 20 m • No timing restriction on operations associated with existing roads, landings and aggregate pits
Nests – waterfowl, grouse – known nests containing eggs encountered during forest management operations • Known nests will not be destroyed; in this context, destruction means the complete or partial damage of the nest structure or its contents (i.e. attendant birds, eggs, or young). • Reasonable efforts will be made to minimize disturbance of known nests encountered during operations including: New

roads, landings and aggregate pits will not be constructed within 10 m; and No heavy equipment within 10 m of known nests with eggs. • No timing restriction on operations associated with existing roads, landings and aggregate pits.
Nests – Song Birds or other small birds – known nests containing eggs or young encountered during forest management operations • Known nests will not be destroyed; in this context, destruction means the complete or partial damage of the nest structure or its contents (i.e. attendant birds, eggs, or young) • Reasonable efforts will be made to minimize disturbance of known nests encountered during operations including: New roads, landings and aggregate pits will not be constructed within 3 m; and No heavy equipment within 3m of known nests with eggs, young. • No timing restriction on operations associated with existing roads, landings and aggregate pits.
Rich Lowland Hardwood-Dominated Forest(black ash, – mapped and unmapped pockets encountered during operations • reasonable efforts will be made to avoid constructing new roads (i.e. unless excessive steep terrain prohibits road construction); when construction of roads is necessary, it will follow design principles to minimize disruption of hydrological function outlined above under 'General Conditions on Road Planning, Construction and Maintenance'. • Landings and aggregate pits are not permitted.
Wetlands – mapped permanent non-forested (polygon types OMS, TMS, and BSH) • reasonable efforts will be made to avoid construction of new all-weather roads within wetlands or portions of the wetlands characterized by open water or non-woody vegetation (i.e. unless excessive steep terrain prohibits road construction); when this is necessary it will follow the design principles outlined above under 'General Conditions on Road Planning, Construction and Maintenance' to minimize risk of sediment entering the wetland and disruption of hydrological function • Landings are not permitted within the wetland itself or within adjacent forest that is <15 m from those portions of the wetland dominated by open water or non-woody vegetation • Aggregate pits are not permitted within 15 m.
Woodland Pools – encountered during operations • New roads are not permitted within 15 m of the high-water mark of pools unless there is no practical or feasible alternative (i.e. excessive steep terrain prohibits road construction) and the mitigative measures outlined above under 'General Conditions on Road Planning, Construction and Maintenance' are taken to minimize the risk of sediment entering pools and disruption of hydrological function • Landings and aggregate pits are not permitted within 15 m of the high-water mark of pools.

4.5.8 Decommissioning of New and Existing Roads and Road Networks

The following standard conditions are applied to all new and existing roads inside and outside of AOCs and are documented in Table FMP-18 if applicable:

- The expected period of use of all roads has been considered during access planning. In certain circumstances (e.g. tourism, dynamic caribou habitat schedule blocks), MNR made a preliminary determination of whether or not the road will be maintained for public use.
- Preliminary decommissioning provisions, including regeneration conditions and timelines, have been documented for all roads where MNR has indicated the road will not be maintained for public use.
- Road classification and construction standards are consistent with the expected period of use of all roads and will facilitate road regeneration where this is required.
- Progressive road decommissioning has been used where progressive harvest is applied and priority zones to focus decommissioning and renewal efforts have been considered and documented where applicable.
- Natural access traps, winter roads, corduroy and portable bridges have been used where practical to assist with future road renewal and regeneration.
- Signage will be posted to identify planned future decommissioning including regeneration at time of construction.

In addition to the above, the following conditions apply to all roads planned to be decommissioned and regenerated (including roads not identified for transfer):

- Specific use management conditions are included in Table FMP-18 and/or Supplementary Documentation G – Road Planning Documentation.
- The production land base will be recovered and these areas will be renewed except where they were not part of the production land base originally (e.g. rock outcrops).
- Operations to be conducted to recover the production land base include the following: site preparation, planting/seeding.
- The decommissioning (including renewal) will be completed no later than 5 years from the end of the FMP period in which decommissioning took place.
- The most applicable SGR will be applied to renew the road, based on the specific site conditions of areas formerly occupied by the road, and the renewal treatments including regeneration should complement the treatments on the adjacent treated areas.
- The Annual Work Schedule (AWS) will identify the location of the road scheduled for decommissioning, the operations to be conducted, including the scheduled regeneration treatments.
- The AWS will identify the inspection of decommissioning treatments including regeneration as a compliance priority and will indicate how the inspections will be completed.

4.6 Expenditures

This section of the plan discusses projected expenditures required for renewal and tending operations, insect pest management and renewal support for the five-year term of the plan, 2012-2017. The expenditure data for the five-year term is presented in Table FMP-20. The following text provides the rationale and methodology for the economic data calculation.

The planned expenditures required to complete the planned silvicultural activities, renewal support and regeneration assessments for the five-year term of this plan (as reported in Tables FMP-17 and FMP-20) are $12.6 million. These projected expenditures include $3.2 million for site preparation, $7.4 million for artificial regeneration (planting and seeding), and $1.5 million for tending activities. No expenditures are currently projected for renewal support, or other eligible activities. Road construction and maintenance costs are not included in the planned expenditure total.

Rationale for the calculation of silvicultural expenditures includes consideration for:

- Estimated expenditures per unit are based on past experience on the Whiskey Jack Forest.
- Projected cost of all mechanical site preparation activities, including the proportion of area renewed with and without mechanical site preparation, and slash pile burning;
- Projected costs of tree seed collection and processing, and the quantity of seed required for aerial seeding and sowing of tree seedlings for planting;
- Projected tree planting costs, including the cost of planting stock production, based on projected densities and proportion of tree species planted in a given future forest unit, as well as the proportion of area planted with and without mechanical site preparation;
- Projected cost of manual tending and tending by chemical herbicide application, including the cost of the herbicide;
- Projected cost of on-the-ground surveys, Free-To-Grow surveys, and forest operations prescription (FOP) verification; and
- Administrative costs for silviculture.

MNR evaluated the silvicultural requirements for areas treated prior to 2012, based on existing information and silvicultural ground rule prescriptions and regeneration standards. This evaluation was made to determine outstanding treatments (not yet completed) and their associated costs. For areas planned to be harvested in the 2012-2022 FMP, preliminary silvicultural ground rules were assigned to each area. The regeneration treatments and expenditures were planned based on average annual harvest by forest unit and an estimate of area to be treated during the plan period. The rates for the Forest Renewal Trust Fund (FRTF) will be monitored annually by the MNR and adjusted, if necessary, to maintain the fund above the minimum balance for the account in order to fund the projected silvicultural program.

Expenditures funded through the Forestry Futures Trust Fund (FFTF) will include various eligible projects or expenditures approved on an annual basis during implementation of the plan, and a portion of the costs associated with the maintenance of the Forest Resources Inventory (FRI) for the management unit (Forest Trust Forest Resources Inventory, FTFRI).

4.7 Monitoring and Assessment

This section discusses the monitoring and assessment program for the ten-year forest management plan period for forest operations inspections, exceptions monitoring, assessment of regeneration success and monitoring of roads and water crossings.

Forest management operations are regularly monitored to ensure compliance with the management plan, with particular emphasis on prescriptions for operations including: area of concern prescriptions, any restrictions on operations, water crossings and adherence to harvest boundary lines. Monitoring is also conducted to evaluate silvicultural activities, renewal success and changes in forest cover. MNR also conducts surveys of forest values to support forest management planning. Monitoring of exceptions to silvicultural guides and other guidelines is also conducted.

MNR's web-based Forest Operations Information Program (FOIP) will be used to document inspections and operational issues associated with identified compliance issues, and to ensure that appropriate actions have been carried out when operational issues are identified.

All Forest Resource Licence (FRL) holders and contractors are required to report all new values encountered during operations. The general public will be encouraged to report new values in the Whiskey Jack Forest, and will be provided opportunities to review the annual work schedules at any time of the year.

4.7.1 Forest Operations Inspections

The goal for Ontario's forest is "to ensure the long term health of our forest ecosystems for the benefit of the local and global environments, while enabling present and future generations to meet their material and social needs." (Source: *Policy Framework for Ontario Forests*, MNR).

To help meet this goal, the MNR has prepared a Forest Compliance Strategy, which has as its goal: "to encourage and ensure adherence to rules and requirements which contribute to the sustainable management of Ontario's forests." (Source: *A Forest Compliance Strategy*, 1997, MNR).

A requirement of both the *Forest Management Planning Manual* and the *Forest Information Manual* is that a Forest Compliance Plan for planning, monitoring, reporting, and education/prevention on forest management operations be prepared to ensure compliance with all applicable legislation, regulation, the forest management plan, and with MNR manuals and guidelines affecting those operations.

FRL holders and contractors will comply with legislation, regulated manuals and all requirements described within this FMP (including but not limited to Forest Operations Inspection procedures outlined in Section 4.7.1) and accompanying Annual Work Schedule (AWS). If the Licensee fails to abide by the requirements outlined in Section 4.7.1, they will be ordered by MNR to stop activities until the issue has been resolved and corrected.

As a Crown forest, the MNR Kenora District is responsible for the monitoring of all forest operations on the Whiskey Jack Forest and the preparation of Forest Operations Inspection Reports, for each operation inspected. The MNR will investigate all operational issues identified

by the public and FRL holders. The MNR will continue to develop an annual compliance plan at the district level and focus on priority areas identified in that plan as appropriate.

There are a variety of methods and procedures that can be employed as part of the overall monitoring program, including direct methods, such as field inspections and observations, as well as indirect methods such as the use of aerial photography. Both formal and informal procedures will contribute to an effective monitoring program. The Compliance Plan for the Whiskey Jack Forest provides specific details of monitoring and assessment to be conducted during the 2012-2014 period.

4.7.1.1 Compliance Goal

The goal of the compliance plan is to encourage and ensure adherence to rules and requirements which contribute to the sustainable management of Ontario's forests. In doing so, this plan will meet the compliance requirements as set forth in the Forest Compliance Handbook section FOR 07 02 04.

4.7.1.2 Background

The Whiskey Jack Forest has been a Crown managed forest since the fall of 2009 and as a Crown Forest the Ontario Ministry of Natural Resources, Kenora District is responsible for all obligations and responsibilities described within the FMP.

The compliance strategy outlined within the FMP will assist in improving operating practices throughout the forest. It will guide and direct all FRL holders, and contracted activities. In support of this MNR Kenora District will be responsible for:

- All forest management activities (planning, renewal, roads, etc.) on the Whiskey Jack Forest;
- Implementation of the compliance plan including education, monitoring, FOIP maintenance and updates; and
- Reporting of the Whiskey Jack Forest compliance program.

Compliance priorities will be based on three levels. Issues associated with the 2004-2009 Independent Forest Audit (IFA), along with historical and/or current trends that highlight potential areas for improvement. These focus areas are summarized below along with their associated action plans that are ongoing. A priority for compliance inspection will be to identify harvest operations, slash/chip debris pile, landings and road decommissioning operations, and winter water crossings.

i. **Winter Water Crossing Installations**: During the 2004-2009 Independent Forest Audit (IFA) concerns were identified with permanent watercourse crossing installations performed during winter months. The opportunities for improvement involve ensuring that proper culverts and associated approaches were stable in the spring after thawing.
Action Plan: A specific *Stream Crossing Toolkit* is in place with all operators on the Whiskey Jack Forest. It works in conjunction with all requirements of the guidelines contained within the provincial documents *Forest Management Guide for Conserving Biodiversity at the Stand and Site Scales* (MNR, 2010), and the "CSP Culvert Installation at Water Crossings on Forest Access Roads". All crossing installations are inspected during and after installation to ensure they are aligned with expectations, followed by an

early spring inspection to ensure road bank / shoulder stability of the site and to mitigate any erosion issues.

ii. **Category 9 Pit and Forest Industry Aggregate Pits**: During the 2004-2009 Independent Forest Audit (IFA) there was concerns with the improper sloping and steep pit faces on some Category 9 and Forest Industry pits.
Action Plan: All FRL holders and contractors are required to follow Category 9 site plans and the Aggregate Resources Act, Operating Standards. All Category 9 pits are inspected annually and Compliance Assessment Reports are submitted to the MNR Aggregate Specialist. Forest Industry Pits are specifically monitored in the field, managed in accordance with these requirements and entered into FOIP.

iii. **Decked Wood**: During the 2011-2012 Operating Season two harvest blocks had the timber harvested using feller buncher however, due to an early spring this wood remained in the harvest block in buncher piles.
Action Plan: This is now a formal part of the pre-work review conducted on each block. Whiskey Jack Forest Compliance Inspectors will work with FRL holders on the scheduling of their operations to ensure the decked wood is utilized in a timely manner. If necessary, FRL's may be withheld if movement of this fibre is not prioritized by the licensee and/or contractor.

iv. **Slash/Chipper Debris Management**: In-block field chipping has been occurring on the forest for several years and the continued proper management of this debris in accordance with standards will continue to be a key focus.
Action Plan: Management of this issue has resulted in an evolving process to limit the amount of productive land lost to large piles of accumulated debris. As a result practices and options have been built into the FMP. MNR forestry staff and FRL holders have been working closely to distribute debris back into the cutover. Specific direction through the Chipper Debris Management Guidelines is built into the FMP. These requirements form part of the pre-work meeting and are audited during compliance checks and feedback given to the contractor to form the continual improvement loop.

v. **Road and Landing Decommissioning**: Operational roads and landings where applicable will be site prepared and regenerated and any associated water crossings will be removed.
Action Plan: This issue will be monitored to ensure that as much road/landing area is reclaimed as possible.

vi. **Review of Silvicultural Activities:** It is the responsibility of the forest manager to ensure that the silvicultural activities on the forest are as planned in the FMP.
Action Plan: All silvicultural activities will be monitored for compliance with the plan, as well for effectiveness.

4.7.1.3 Compliance Objectives, Strategies and Actions

The goal of the compliance plan is to encourage and ensure adherence to rules and requirements which contribute to the sustainable management of Ontario's forests. There are a number of specific compliance objectives, strategies, and actions set forth in support of achieving this goal;

Objective: **Resource Protection**

- Strategy: To prioritize forest ecosystem integrity in the planning and implementation of all harvest, access, renewal-maintenance and protection activities
  - Utilize sound management techniques, adhere to established operating procedures and management standards
- Strategy: To continuously evaluate forest operations for impacts on the environment
  - Reviewing pre-work requirements with operators
  - Ongoing inspections and audits of active operations
  - Monitoring operations on shallow soils
- Strategy: To manage and protect against fire, disease and insects
  - Prepare and implement a fire prevention plan as part of the AWS
  - Monitor and report any changes to the forest cover as a result of disease and/or insect infestation.

Objective: Risk Management

- Strategy: To perform a risk assessment for each operation that will rank the operations potential to have a compliance issue.
  - Review each operations environmental and operational components
  - Rank operations from high to low based on complexity, AOC numbers and operators experience and compliance history.
  - Implement compliance monitoring program that puts an emphasis on the higher risk operations and focuses inspector's efforts to these operations.

Objective: Staff & Operator Training

- Strategy: To ensure appropriate training is supplied to those with forest management responsibilities regarding current and upcoming standards
  - Staff, FRL holders and/or contractors participate in training workshops and site visits
  - Ensure that FRL holder employees who are actually doing the work in the field are participating in pre-work and field training sessions.
- Strategy: To ensure staff, licensees and/or contractors are trained to recognize and implement environmentally sound practices.
  - Staff licensees and/or contractors are trained at least annually in standard operating procedures, environmental policy, and emergency response processes.
  - Pre-harvest reviews with each new block and/or work project
  - Requiring that licensees and contractors train their employees in all applicable standards and procedures.

Objective: Education and Communication

- Strategy: To ensure management personnel and operators are knowledgeable and competent in the regulations, guidelines and policies related to compliance.
  - Promote open communication with MNR staff and contractors.
  - Staff to participate in all applicable MNR training sessions (i.e. compliance courses, stand & site guideline training, watercourse crossings, etc.)
  - Facilitating training sessions as required for various safety and environmental standards that exist on the forest.
  - Continued focus on self-reporting by operators
- Strategy: To ensure management personnel are current and updated on the new forest science, planning process and operational techniques related to ecosite management and forest operations.

- Ensure operational and operational issues are identified in a timely manner and appropriate action is taken to identify, document, and mitigate concerns.
- Staff to participate in all applicable MNR training sessions (i.e. compliance courses, stand & site guideline training, watercourse crossings, etc.)

Objective: Compliance Efficiency

- Strategy: To conduct compliance activities in a cost effective and efficient manner
  - Utilize multiple techniques (aerial, ground, photography, etc.) to monitor operational activities
  - Utilize the risk analysis to focus efforts on the high risk areas.
  - Encourage joint inspections or joint time in the field to ensure calibration
  - Ensuring timely submission of FOIP reports

Objective: Compliance with Legislation, Plans, Policies

- Strategy: To stay current with changes in compliance policies, procedures and guidelines.
  - Participate in MNR training sessions which relate to the compliance program
- Strategy: To conduct activities in a manner that meets or exceeds existing standards
  - Implement all applicable legislation, policies, and procedures
  - Conduct pre-work reviews with each new block and/or work project
  - Maintain and continually update operational procedures

Objective: Overcome Historical Compliance Problems

- Strategy: To actively monitor forest operations, evaluate results, and take corrective action as required.
  - Analyze forest operations compliance information report data
  - Include within each AWS focused compliance monitoring areas based upon historical trends and/or changes to compliance standards.
  - Incorporate focus areas from this compliance plan into field inspections to proactively manage historical trends.

Objective: Continuous Improvement

- Strategy: To develop benchmarks, both locally and regionally within the forest operations to measure the improvements and performance
  - Collect appropriate field data to be able to analyze and verify required changes to the compliance program
  - Identify and recommend solutions that will improve the overall compliance program
  - Continue to work with licensees and/or contractors in the process of compliance monitoring and self-reporting.

4.7.1.4 Risk Analysis and Management

"Risk management is defined as the balancing of assessed risks against expected benefits so the best decisions are made for a given resource allocation (people, equipment, money) and degree of tolerance." *Forest Compliance Handbook FOR 07 02 03.* Risk management in forest management consists of the balancing of operational and environmental risks, ranking the associated operations as to the potential risk and associated tolerance levels, to determine the level of monitoring for the given operation.

Assessment of Risk

In forestry, environmental and operational components influence the inherent risk of any given operation. Environmental components consist of the planned Areas of Concerns (AOC's) utilized to protect values and public concerns and Conditions of Regular Operations (CRO's). These are assessed in detail during planning phases and are built into the Forest Management Plan and if applicable, are implemented at time of operations. The inherent risk for the environmental component is assessed at the Annual Work Schedule (AWS) level and depending on complexity and number of AOC's within any given operation will depend on the level of monitoring applied to the operation.

The operational component consists of aspects such as, operator experience, compliance history, season of harvest and harvest method. The operational aspects influence compliance monitoring levels greatly and is applied at the AWS level during the risk analysis. Operators with good history and lots of experience may receive less monitoring.

Operational Control System(s)

The Whiskey Jack forest is a Crown forest and does not have additional certification systems (EMS, ISO) that industry operated forests have in place to monitor and track forest operations. Forest compliance reporting is the responsibility of the Ministry of Natural Resources, Kenora District (MNR) and the MNR's Forest Compliance Information Program (FOIP) is the method utilized to track and document forest operations. During operations it is the forest operator's responsibility to abide by all legislation and FMP requirements, additional compliance responsibilities also apply to all harvest operators who operate under the authority of a Forest Resource Licence.

In order to minimize risk, the MNR has established pre-work authorization for all Forest Resource Licenses issued. The pre-work authorizations are carried out on site, prior to the start of operations, and include MNR forest compliance inspectors, company supervisors and equipment operators. The pre-work form consists of a detailed harvest/silviculture map, list of applicable AOC's and CRO's. The MNR forest compliance inspector reviews all information that pertains to operation and the form is signed off in duplicate by both parties. This process allows all parties to discuss operations and clarify concerns and operating procedures prior to commencement.

Risk Analysis

The risk analysis is completed during the preparation of the Annual Work Schedule, where operations (i.e. harvest blocks) will be analyzed to determine the level of operational and environmental risk. The risk ranking system is utilized, which assigns a numeric value to the operation based on criteria such as, type of operation (harvest, access, renewal), season of operation, operator compliance history, forest stand and soil conditions, water crossings and the number of Area of Concerns or values present.

Areas of Concern are scored individually, per occurrence and are given an assigned numeric value from zero to three based on the complexity and value being protected. Each operation is tallied for a total score, which ranks the operations risk from high to low, high rankings have a greater chance of having a compliance issue, therefore requiring a higher level of monitoring and low rankings requiring less monitoring.

Risk analysis will be prepared for all operations during the preparation of the AWS and at this time the MNR will determine the level of compliance monitoring that will apply to each operation. Because there is no other means of documentation for compliance monitoring on the Whiskey Jack Forest reporting will occur for every operation within FOIP.

4.7.1.5 Roles and Responsibilities

Compliance Plan Preparation and Updates

As a Crown Forest the MNR, Kenora District is responsible for the compliance plan and any amendments to the plan. The MNR will complete any required amendments to the compliance plan. The Area Forester is responsible for this area.

Identification of Certified Inspectors

The English River Area, Area Supervisor, Shawn Stevenson is responsible for ensuring that certified inspectors are trained and identified to conduct inspections on the Whiskey Jack Forest.

The MNR has three approved forest compliance inspections on this Crown Forest, those being Todd Skene, Integrated Resource Management Specialist, John Myshrall and Fred Zroback, Area Technicians. Shawn Stevenson, English River Area Supervisor is designated to review and approve FOIP inspections reports for submission into the MNR database.

Prevention, Monitoring and Reporting

The MNR is responsible for all prevention, monitoring, and reporting activities in relation to compliance obligations on the Crown Forest. The Integrated Resource Management Specialist will be the main communications linkage between the MNR and FRL holders / contractors for this area of responsibility.

Forest Resource Licence (FRL) Holders

FRL holders are independent operators who are fully responsible for all operations performed within their licensed harvest area. The Whiskey Jack Forest currently has two FRL holders: Makoose Wood Innovations Inc. and Wincrief Forest Products Ltd. prior to the start of each operation, an operations foreman will be designated as the main contact for FRL holder.

As describer in Section 4.1.7.5 Notification of status, FRL holders are required to contact MNR 5 days prior to the start-up of operations so that a pre-work meeting can be scheduled.

Operations cannot begin until an on-site pre-work meeting has been completed with FRL holder employees and a MNR Representative.

Preventative, Mitigative and Follow-Up Action

The MNR is responsible for all preventative, mitigative, and follow-up activities in relation to compliance obligations on the Crown Forest. The MNR Forest Compliance Inspectors will act as the communications linkage with FRL holders and contractors. . Where operational issues arise, the Integrated Resource Management Specialist and Area Forester will be brought into the situation.

As Forest Resource License holders all harvest contractors are responsible and liable for all operations. Harvest contractors are to ensure that all operators are knowledgeable of the issues within the harvest area and are aware of the preventative and mitigative measures while operating.

Training Responsibilities

The FRL holders and contractors are independent and are fully responsible to ensure that their employees are trained to the standards required to perform the forest operation being conducted.

The MNR will work closely with the FRL holders for ensuring that those who operate on the Crown Forest are properly trained. This will involve, at a minimum, annual operator meetings, pre-work reviews, and inclusion in any focussed training offered by the MNR or other entities in the region.

4.7.1.6 Notification of Status

The Forest Compliance Handbook, section FOR 07 03 05 outlines the specific requirements regarding notification of operational status. Notification will be given to the MNR by the FRL holders when:

- Operations are about to commence (Start-Up Notification). Such notification will be provided within 5 working days of the beginning of a new operation so that on site pre-work meetings can be scheduled with operators.
- Operations are temporarily stopped but not finished (Suspended). Such notification will be made within 20 days of suspending an operation or activity, and will clearly describe the operation being suspended, its location, the reason for the suspension, and the likely date of activities being resumed.
- Operations are within 10 days of completion and the forest operation is ready for released for final MNR inspection (Release). This will ensure that MNR inspectors can be on site with operators and mitigate any issues prior to moving equipment.

Notifications will generally take the form of an email or verbal notification by the FRL holder. All verbal notifications will be documented by the MNR inspector and confirmed through email to the FRL holder.

4.7.1.7 Prevention, Avoidance, and Mitigation

It is the responsibility of the FRL holder to take action to prevent and avoid potential operational issues in a decisive, timely and appropriate manner.
Where any industry operating personnel, during ongoing monitoring of operations, identify a situation they believe could be an operational issue(s), they will undertake one of the following actions:

1. If they feel it is a violation of the approved plan or a threat to the environment, they will immediately stop the operation and take the necessary steps to stop further possible non-compliance/harm.
2. They will immediately report the situation to MNR staff who will arrange for an immediate compliance inspection of the issue. MNR staff will determine if the situation is a violation of an approved plan or Annual Work Schedule (AWS) or a threat to the environment and what further action to take.
3. If the situation cannot be immediately corrected, the MNR certified inspector will submit a report in FOIP that documents their findings as an operational issue.

4.7.1.8 Compliance Reporting Areas (CRAs)

FOIPS will be submitted by each individual harvest block. Silvicultural operations will be reported on a project basis identifying the silviculture blocks within the FOIP report.

4.7.1.9 Monitoring Compliance of Forest Operations

As per the actions plans outlined in the section on OBJECTIVES, STRATEGIES AND ACTIONS, monitoring of compliance activities will take place on a continual basis as a means of achieving the overall compliance objectives. These actions are in support of the direction set forth in the Forest Compliance Handbook, section FOR 07 03 04 and FOR 07 03 05, the directive and procedure on compliance inspecting and reporting.

Harvest and Access Operations

- The MNR will conduct forest operations inspections on all harvest and access operations during the period covered by this FMP. Inspectors will perform spot checks and/or audits as directed by the risk management analysis. High risk operations will be inspected weekly on each ongoing operation and low risk operations will be inspected as required. At a minimum one FOIP report will be submitted upon completion of each forest operation.
- Access operations will receive several spot checks during construction and will receive a final FOIP inspection at the end of the project.
- If an operational issue is encountered, that cannot be immediately repaired a FOIP report will be prepared to track the operational issue until repaired or until a remedy is applied.

Silviculture Operations

- Priorities during the review of silviculture activities will include determining:
  - Whether actual operations at the AWS level are in accordance with the assigned SGR and appropriate silvicultural treatments from the Forest Operation Prescription (FOP).
  - Whether the SGR being implemented was changed from that assigned in the FMP to reflect actual site conditions; whether the assigned SGR and silvicultural treatments from the FOP are appropriate for the actual site conditions.
  - Whether the approved silvicultural program identified in SFMM is being implemented by forest unit and intensity as required by the FMP strategic LTMD, including application of tending operations on competitive sites.

4.7.1.10 Opportunities for LCC Involvement

The Terms of Reference for the Kenora Local Citizens Committee (LCC) does not contain specific commitments regarding the involvement of committee members in forest operations inspections and MNR District monitoring of forest operations. Committee members are, however, provided with an annual overview of forest operations compliance activities during the presentation of Annual Reports and are encouraged to participate in the Independent Forest Audit process. A standing invitation will be offered for LCC members to join inspection personnel on field inspections by appointment.

The LCC will also be given the opportunity to review the forest operations inspections summary (Table AR-6) which forms part of each year's Annual Report. Significant non-compliance issues that concern the LCC will be brought to the committee's attention at regular or specially scheduled meetings.

4.7.2 Exceptions

Exceptions monitoring will be carried out to determine the effectiveness of prescriptions included in the management plan that are not recommended (NR) in MNR forest management guides. These exceptions monitoring programs are identified below.

The exception monitoring may occur at either the district, regional or provincial levels, depending on the significance of the exception. A good example of this is the monitoring procedures and best practices for full tree harvesting on shallow soil sites (see below). The *Full Tree Harvesting of Ecosites 11 and 12 In Northwestern Ontario: Monitoring Procedures and Best Management Practices (April 1, 2001)*is a carryover from the 2004 FMP and 2009 FMP.

The LCC will be given the opportunity to review the results of exceptions monitoring. Significant exceptions monitoring issues that concern the LCC will be brought to the committee's attention at regular or specially scheduled meetings. If the Local Citizens Committee would like to include some surveyed areas in a field visit, the data and maps would be provided.

Monitoring of Full Tree Logging on Shallow Sites

The full tree logging of ecosites 11 and 12 where total organic matter plus soil depth is less than 20 cm. is designated as a 'not recommended' practice in the *Silvicultural Guide to Managing for Black Spruce, Jack Pine, and Aspen on Boreal Forest Ecosites in Ontario (MNR, 1997)*. This practice has been identified as an "exception" in this plan. Where this activity occurs, the monitoring program, including timing and duration, described in *Full Tree Harvesting of Ecosites 11 and 12 In Northwestern Ontario: Monitoring Procedures and Best Management Practices (April 1, 2001)* will be implemented(Supplementary Documentation E). MNR Science and Information staff as well as licensees on other Sustainable Forest Licences have been and will continue to implement the monitoring procedure.

The forest industry is contributing to a comprehensive, region-wide initiative to monitor the impact of this treatment on these site conditions, as outlined in this forest management plan. As part of this monitoring program, these shallow soil sites have been identified in this forest management plan and operations will be conducted in accordance with the best management practices.

Ecosites in the Whiskey Jack Forest are identified in the forest resources inventory and are identified within the planned operations digital information supplied with the plan. Actual Ecosite 11 and 12 areas scheduled for activities in the Annual Work Schedules will be identified through interpretation of aerial photographs and field checked prior to harvest.

The rationale for using full tree harvesting on these sites is that it is currently the common method of harvest and it would be uneconomical to bring in specialized equipment to harvest scattered areas of shallow soils. The shallow soil sites on the Whiskey Jack Forest are, for the most part, productive and, it is felt, that using full tree logging in a careful manner will preserve the sites nutrient capacity.

Not Recommended Renewal Treatments

The following treatments are included in Silvicultural Ground Rules (FMP-4) and are exceptions to the *Silvicultural Guide to Managing Black Spruce, Jack Pine, and Aspen on Boreal Forest Ecosites in Ontario, 1997*. The application of these treatments on these ecosites is not planned but they may form a very minor component of renewal options for forest unit areas being treated in this plan period. Exceptions monitoring programs will be implemented as described below and results will be submitted as part of the Annual Report if any of the following treatments are planned to be implemented:

- Artificial seeding on ES 14.
- Natural regeneration of jack pine or spruce on ES 21.

Areas receiving treatments considered "exceptions" in Table FMP-4 would be monitored for the effectiveness of the treatment to the site on which it was applied. In the event that any exceptions to the silvicultural guides do occur, they will be monitored as required with the results documented. Inspections will involve a visual evaluation of indicative sites by experienced staff to evaluate whether the effectiveness of the respective renewal treatment is satisfactory. If the silvicultural results are in question, a regeneration survey will be conducted for designated sites and/or further renewal treatment may be prescribed in accordance with corresponding Forest Operations Prescriptions.

4.7.3 Assessment of Regeneration Success

An important component of the monitoring program is determining the success of the harvest, renewal and tending operations in regenerating the forest to the desired future forest condition. Assessments are conducted to determine the status of the regeneration on particular sites, the effectiveness of silvicultural treatments and the need for any additional treatments. The monitoring program will assess the success of silvicultural activities in the achievement of standards contained in the silvicultural ground rules (Table FMP-4).

"**Silvicultural Success**" is defined as meeting the regeneration standards for a desired future forest unit, by means of an intended silvicultural prescription and treatment, as per the silvicultural ground rules (SGRs) in Table FMP-4. The overall intent is to achieve a successful regeneration standard for all harvested areas. Although some areas may achieve a free-to-grow status, they may not necessarily be considered "successful" with respect to the desired future forest unit or the intended silvicultural prescription and treatment (e.g. the regeneration standards for the intended future forest unit were not met, however regeneration standards for another forest unit were met called "**Regeneration Success"**).

Silvicultural effectiveness monitoring is used to create a new stand description which will be used to update the forest resources inventory. Once an area has been harvested, it is classified as depleted and is not reclassified as forested area until it has been regenerated and assessed as free-growing. The requirements for free-to-grow status include a measurement of species composition, average height and stand density (as per the SGRs in Table FMP-4).

Another purpose of silvicultural effectiveness monitoring is to confirm not only the success of the applied treatment, but to confirm growth and yield development information. Data collected is used to confirm the yield curve and future forest condition (i.e. species composition, stocking) on which the stand is expected to track.

The results of assessments are the basis for determining if the regeneration levels associated with the Long-term Management Direction have been met. These results can be used to adjust modelling assumptions and silvicultural strategies in future forest management plans.

4.7.3.1 Assessment Methods

Assessments are conducted to determine the status of the regeneration on particular sites, the effectiveness of silvicultural treatments and the need for any additional treatments. The monitoring program will assess the success of silvicultural activities in the achievement of standards contained in the silvicultural ground rules (Table FMP-4).

There are a variety of methods and procedures which can be utilized as part of a regeneration success monitoring program. They may apply either informal or formal survey methodologies (i.e. professional observations/ocular estimates or intensive surveys with plot measurements) that are generally conducted through ground field inspections/surveys, aerial surveys and/or aerial photography assessments. The survey methodology used will depend on the type and cost of the silvicultural treatment(s) which were applied and the degree of information to be collected. A comprehensive program of surveys for the assessment of regeneration and silvicultural effectiveness will be applied on this forest for this plan period. Information to be collected and survey methodologies are based on professionally accepted and reviewed methods. Different survey methodologies may be employed during the term of the plan based on the availability of new technology/procedures.

The monitoring program including methodologies, procedures, documentation and reporting is included in Supplementary Documentation F. The five survey methodologies are:

- Pre-free growing survey;
- Ocular Estimate Survey;
- Large Scale Photography and Photo Interpretation;
- Regular Free-to-Grow Survey; and
- *Well-Spaced Free-Growing Regeneration Assessment Procedure for Ontario* (MNR 2005).

<u>Additional Assessment of Slash/chip Debris Areas, Landings, Decommissioned Roads</u>

- Slash/chip debris areas, landings, and decommissioned roads will be assessed for the effectiveness of treatments during regeneration and free–to-grow assessments and will be considered in the determination of the free-to-grow status for the area.
- The methodology to be undertaken is outlined in this section of the FMP and will ensure that a minimum site occupancy standard is achieved across the entire assessment area. The assessment area will include all harvested areas, landings, slash and chip debris piles and roads that are to be renewed, excluding only those areas that did not originally support production forest (rock outcrops) and retained roads. Assessment areas with more than 20% gaps (16 m2 circular plot areas without a single target or acceptable tree species over 30 cm in height) would not be identified as free-to-grow.
- The regeneration standards to be achieved on new or existing slash/chip debris areas or landings (three years old or less) will be the same as those in the applicable SGR.
- The regeneration standards to be achieved on older slash/chip pile debris areas (more than three years old), landings and decommissioned roads will be the same as those in the applicable SGR.
- The monitoring program includes the creation and maintenance of an inventory of new and

existing slash debris piles, chip debris piles and landings by location (mapped), age and category (biofibre or debris).

- The monitoring program requires reporting of the effectiveness of slash/chip debris, landings, and decommissioned road treatment and regeneration annually, and reporting on the loss of production land base (objective achievement) in the year 3, 7, and 10 Annual Report.

All Other Silviculture Operations

- This plan includes a clear and concise survey assessment methodology for both intensive and extensive evaluations (including block stratification, calibration methods, ground truthing, quality control, and documentation). The assessment methodology provides results that can be evaluated against MNR's silvicultural effectiveness monitoring assessments which are used to verify the results reported (assessment methodologies in Supplementary Documentation F – Assessment of Regeneration Success).
- Site occupancy will be determined as a component of the regeneration assessment and in determining the free-to-grow status for the area.
- In determining site occupancy, the assessment area will include all harvested areas, landings, slash and chip debris piles and roads that are to be renewed, excluding only those areas that did not originally support production forest (rock outcrops) and retained roads. Assessment areas with more than 20% gaps (16 m2 circular plot areas without a single target or acceptable tree species over 30 cm in height) would not be identified as free-to-grow.
- Silvicultural effectiveness monitoring (SEM) will be undertaken by MNR. SEM information will be used to verify results reported in year-3/7/10 Annual Reports, to review or determine changes to renewal rates, to determine any necessary modification for Phase II operations (e.g. to address silvicultural shortfalls), and to verify or make adjustment to the silvicultural inputs and yield curves for future FMPs.
- Regeneration surveys will be considered to verify establishment (e.g. competition, site occupancy and species composition) and to determine if additional treatments are necessary to ensure projected stand development is in accordance with the SGR and FMP strategic long term management direction (LTMD) with an emphasis on sites with high potential risk of failure and those of high value (i.e. intensive treatments that are of strategic importance to the LTMD).

4.7.3.2 Area to be Assessed for Regeneration Success

A summary of the area to be assessed for the determination of regeneration success during this ten-year plan period is presented in Table FMP-21. The areas listed in the table will be assessed for free-to-grow (FTG) status. These areas are generally assessed 10 years after harvest and renewal. The area in FMP-21 is based on the area available for FTG surveys, reflecting areas that were harvested between 2002-2012.

The total area planned for assessment during the 2012-2022 plan period is projected to be 16,223 hectares of harvested area; no salvage harvest area and no natural depletion area.

The results of the assessment of regeneration success will be documented and reported annually through the annual reporting process (AR-13).The annual report will be presented to the Local Citizens Committee. If the Local Citizens Committee would like to include some surveyed areas in a field visit, the data and maps would be provided.

4.7.4 Roads and Water Crossings

All existing and newly constructed primary, branch and operational roads, and associated water crossings are subject to inspection and monitoring, to ensure no environmental or public concerns arise. Table FMP-18, Road Construction and Use Management, summarizes planned new forestry road construction and use management for all primary, branch, and operational roads or operational road boundaries, for the five-year plan term. Existing roads are also identified.

While the road/road network is in use for forest management purposes (e.g. Harvest, Renewal, Tending, Transportation and Hauling activities), it will be monitored on an ongoing basis with bridges used for 'heavy truck hauls' inspected by a certified inspector at least once a year. When the road is not in use for forest management purposes, monitoring will be based on a yearly schedule of specific roads to be inspected. This yearly schedule will be based upon a risk assessment approach with emphasis on the potential values which could be impacted (fish habitat) and the potential for public safety concerns and, at a minimum, these roads (including bridges open to public travel) will be inspected at least once every three years. Monitoring may occur as part of other forest management work such as an aerial survey of values or reforestation (i.e. stick nest survey or FTG regeneration survey). In addition, all staff and contractors (i.e. harvest, renewal and tending contractors) are to report any existing or potential concerns regarding the road/road network and water crossings encountered while travelling on/or over roads throughout the forest. Reports from the general public and other user groups will also contribute to the monitoring of the condition of the roads and water crossings. Additional monitoring will be considered based upon a risk assessment approach following severe weather conditions (e.g. heavy rainfall).

Monitoring of road construction (new and maintenance) and water crossing (new and maintenance) will also be carried out through forest operations compliance inspections and reported through the Forest Operations Inspection Program (See Section 4.7.1.8 Monitoring Compliance of Forest Operations).

4.8 Fire Prevention and Preparedness

This section describes the forest fire prevention and preparedness measures to be implemented during the period of the forest management plan. These measures apply to the entire management unit. These measures will address how MNR, Licensees and Contractors will prevent the start of wildfires, and how forest workers will be prepared to take immediate action to suppress small fires. These measures will include any business practices and guidelines for modifying industrial operations; developed for fire prevention, preparedness and suppression purpose.

MNR recognizes that any forest operation undertaken in Ontario must be done with careful consideration to the prevention of forest fires. Accidental wildfire can have a large impact on annual operations or timber sustainability. Operators must also be prepared to safely take initial action to prevent fire spread, should a fire occur.

MNR, Licensees and Contractors shall adhere to the Forest Fire Prevention Act, associated regulations, Modified Industrial Operations Protocol and Forest Fire Operations by Forest Industry - Business Practices. As an operational guideline, MNR, Licensees and Contractors will utilize the Modifying Industrial Operations Protocol when determining restrictions on operations, as well as, the standard to meet for minimum fire suppression equipment requirements. Ultimately, the Modifying Industrial Operations Protocol outlines the minimum standard for fire prevention and preparedness that will be achieved by all industrial forest operations associated with this forest management plan.

4.8.1 Fire Prevention

It is the responsibility of MNR, Licensees and Contractors to understand and comply with the Forest Fires Prevention Act and the Modifying Industrial Operations Protocol.

The Modifying Industrial Operations Protocol will be used on a daily basis by all MNR, Licensees and Contractors during the Fire Season; so that industrial activities are modified as fire danger increases; to reduce the risk of igniting a wildfire.

4.8.1.1 Fire Situation Awareness

Due to the variability of each harvest operation, the Licensee will do an evaluation of the Fuel Group (1 to 5) for the different areas in their operating area and the Operational Risk (low, moderate, high or very high) for each operation, based on the *Modifying Industrial Operations Protocol*.

The MNR weather station closest to each operation will be utilized to determine the woods modification that applies to each operation on a daily basis. No other weather station will be considered or authorized for use unless agreed upon by the MNR.

Daily communication will occur with the MNR by all Licensees and Contractors working in the Whiskey Jack Forest during the Fire Season to determine the Fire Intensity Codes on a daily basis. The MNR will normally publish the Fire Intensity Codes by 3 pm CDT; by internet, telephone or faxed/emailed report.

It is the responsibility of all Licensees and Contractors to know the Fire Intensity Codes for the weather stations used by each area of operations daily (the closest weather station to the operation) and determine the operational modifications for that day.

Should the Fire Intensity Codes not be available in a timely manner, operators will contact the MNR Sector Response Officer or the MNR Kenora District office to determine the appropriate woods modification that will be in place for their operations prior to commencing work the next day. Operations will be modified on site the following day according to the daily Fire Intensity Code report (available after 3:00 p.m. daily).

4.8.1.2 Operational Modifications

Operational modifications may include one of the following measures, which will be used to modify operations on the Whiskey Jack Forest:

P = Prevention (Normal Operations)

Site Foreman will:

- Monitor operations compliance to the Forest Fires Prevention Act and other fire related conditions that are specified within their Annual Work Schedule.
- Correct any deficiencies to ensure that all fire related conditions are being adhered to.
- Ensure staff are notified daily of hazard.
- Consolidate operations where practical.

Welding/Acetylene Cutting:

- Situate equipment on mineral soil and remove all flammable materials from work area.
- Ensure the correct size and number of extinguishers is on hand.
- Ensure that 1 shovel and 1 back pack pump is on site.
- Use welding blankets to prevent spread of burning material where it is not possible to situate equipment on mineral soil.
- For areas of possible fire spread, establish a fire watch during work and one hour after completion of the job.

Smoking:

- Sit down before lighting smoking material. Use a lighter instead of wooden matches.
- Remain seated until smoking material is extinguished.
- Double check to ensure smoking material is dead out before standing up.
- Equipment operators must not smoke in their machine as this is considered to be an extension of the workplace – they must exit the cab and follow the above procedure.

Open Fires:

- Open fires will not be allowed during the period that prevention measures are in place.

Power Saws:

- Must have operable muffler.
- Be kept clean and in good running order.
- Hot power saws are to be set on mineral soil or a stump; never on forest litter.
- Power saws are to be allowed to cool for five minutes before refuelling.
- Power saws are to be refueled on mineral soil, and not to be started within 3 metres of the fuelling site.
- Power saw operators will have a minimum (225 grams) of dry chemical fire extinguisher (ABC type) readily available during the fire season.

Equipment Maintenance

- Check daily for accumulation of flammable material and remove any accumulation found in a safe manner.
- Conduct weekly inspection of electrical systems.
- Park equipment on a mineral site when not being used.

Fire Extinguishers:

- All operators must keep a serviceable fire extinguisher rated at least 6A-80BC on the equipment or within five metres from it.
  - When operations are shut down, fire extinguishers maybe removed for security reasons (theft & vandalism).

Patrols:

- During normal operations and prevention measures patrols will be conducted by staff as they leave the operating area for the day.

SS = Short Shift Operations are not permitted between 12:00 and 19:00, local daylight savings time. Prevention measures still apply and a dedicated patrol of the area must be carried out for one hour after operations shut down.

RS = Restricted Shift Operations are not permitted between 08:00 and 22:00, local daylight savings time. Prevention measures still apply and a dedicated patrol of the area must be carried out for one hour after operations shut down. Identify water sources close to operations prior to commencing any operations.

SD = Shutdown Operations are not permitted starting at 06:00, local daylight savings time, on the first day of shutdown. Operations will remain suspended until conditions change and Prevention, Short Shift or Restricted Shift is indicated. Prevention measures still apply and a dedicated patrol of the area must be carried out for one-hour after operations cease. Once this initial patrol is complete, lower risk operations working in the vicinity can offer dedicated fire patrols during the shutdown period.

Should any licensees be operating during periods of high fire hazard, resulting in Modified Operations restrictions, their travel to and from the work site will also serve as a daily fire detection patrol. Any wildfires will be reported immediately to the MNR District Fire Management Headquarters (Telephone (807) 548-5837 or 310-FIRE (3473)).

The following table (Table 39) outlines the work modifications for limited and trained and capable operations by Operational Risk and Fire Intensity Code.

Table 39 Work Modifications by Operational Risk and Intensity Code

Operational Risk	Fire Intensity Code	Work Modifications	
		Limited	Trained
Very High Risk	A	SD	SD
	B	SD	RS
	C	SD	SS
	D	P	P
	E	P	P
High Risk	A	SD	RS
	B	SD	SS
	C	SS	P
	D	P	P
	E	P	P
Moderate Risk	A	SD	SS
	B	SS	SS
	C	P	P
	D	P	P
	E	P	P
Low Risk	A,B,C,D,E	P	P
P= Prevention SS=Short Shift RS= Restricted Shift SD= Shut Down			

4.8.1.3 Determining Operational Risk and Fire Danger

The Modifying Industrial Operations Protocol provides guidance for determining Operational Risk in section 2.0 Determining Operational Risk & Fire Danger. The following are the steps used in making the operational risk and fire danger determination:

1. Determine Operational Risk using Table 2 of the *Modifying Industrial Operations Protocol*
2. Determine if the forest is in Leaf On/Leaf Off condition through the local MNR Fire Management Supervisor.
3. Determine Fuel Group (1-5) on the worksite using the Fuel Group Decision Keys – Section 6.0 of the Modifying Industrial Operations Protocol.
   - Determine initial fuel group
   - Account for applicable modifiers (+1/-1)
   - Determine final fuel group
4. Obtain the fire intensity code:
   - using the closes weather station
   - based on the worksite fuel group
   - reported each afternoon for the next day
5. Determine work modifications, for the next day - using section 4.0 Operational Modifications Table – Table 5 – of the *Modifying Industrial Operations Protocol*.
6. Modify operations the next day as necessary.

4.8.2 Fire Preparedness

Annually, a spring meeting (March 15 – April 15) with representative from the MNR Fire Management Headquarters and members of the MNR Kenora District is organized to prepare for the upcoming fire season, identify training needs, and convey awareness of fire prevention plans and initiatives.

4.8.2.1 Trained and Capable, and Limited Operators

As per the *Forest Fire Prevention Act* and the Provincial *Modifying Industrial Operations Protocol*, Licensees and Contractors will be considered either a) trained and capable or b) limited operators. A forest operation, to be considered trained and capable, must meet each of the following criteria:

1) **Prevention**: Implementation of an effective prevention program for the type of operation.

2) **Suppression:** Minimum resource and equipment availability as identified in Section 1.2 of the *Modifying Industrial Operations Protocol*.

3) **Communication**: The ability to communicate and report fires **immediately*** and to receive or obtain updated information on the fire danger. Satellite phones and FM two-way-radio phones are acceptable means of communication. Cell phones are not advised as their reach is poor outside of the immediate Kenora area.

*** Immediately** - means two way radio or telephone capabilities from the site to the MNR office.

4) **Training:** A minimum 25% of all staff involved in forest operations on a particular site must be trained to the MNR SP-102 standard. Training will involve initial training or refresher courses completed within the past three years.

Operations that do not meet all of the above criteria will be considered Limited Operators with respect to the modifications that will apply to their operations.

4.8.2.2 Fire Suppression Equipment

As part of the Compliance Plan, all Licensees and Contractors will inspect their operations to ensure that there is the proper amount and type of forest fire suppression equipment as per Modifying Industrial Operations Protocol Table 1, and that it is in good working order.

Fire suppression equipment requirements are outlined in Section 1.2 Fire Suppression Equipment of the *Modifying Industrial Operations Protocol*. The minimum fire suppression equipment requirements are as follows:

A serviceable fire extinguisher will be on or within 5 metres of all mechanical equipment operating in the forest.

For groups of workers in the same general area, equipment for the suppression of wildfires may be stored in a centrally located fire equipment cache, no more than 10km from the operations, and accessible by ground transportation in fewer than 20 minutes. This includes those operations which are working independently, but in close proximity of one another. *i.e.* two or more separate operations may aggregate their fire suppression equipment, provided that their operations are within the 10 km radius of the fire cache. A fire equipment cache* contains at a minimum:

- one pumping unit, and
- 3 shovels.

In the event the fire cache is used, the fire cache will be replenished to a serviceable state before operations begin the following day.

The following table (Table 40) outlines the required equipment by type of operations and number of machines.

Table 40 Required Equipment by Type of Operations and Number of Machines

Operations	Number of Machines	Number of Equipment Caches	Back Pack Pumps*
Heavy Equipment with tire chains or tracks, working in forest fuels	1 to 5	0	1/machine
	6+	1	
OR** Heavy Equipment at work within a 10km radius of each other (includes hot work).	1 to 9	0	1/machine or hot work operations
	10+	1	
Tree Plant, manual tending or other labour-intensive operations	n/a	0	1 for every 4 workers, to a maximum of 10/site

* A serviceable pressurized water delivery system located on a machine can replace a backpack pump.

**Only one fire equipment cache will be required on site, providing it is within 20 minutes (by ground transportation of all equipment.

Most non-mechanical, low-risk forest activities such as timber cruising or regeneration surveying do not require fire suppression equipment. However, labour-intensive activities such as hand tending and tree planting do require some suppression tools, as outlined in the table above.

4.9 Comparison of Proposed Operations to the Long-Term Management Direction

This section of the plan text documents the assessment of the expected effect of planned types and levels of harvest, renewal and tending operations on the progress towards meeting the objectives in the long-term management direction (Section 3.5 and 3.6). The assessment includes:

(a) Section 4.9.1 - Comparison of the planned harvest, renewal and tending operations to the projections in the long-term management direction;

(b) Section 4.9.2 - Comparison of the stand conditions (e.g., species composition, site class) of the planned harvest areas to the eligible harvest areas;

(c) Section 4.9.3 - Examination of the effect of the age class distribution and the projected harvest volume of the planned harvest area, on the achievement of the long-term management direction; and

(d) Section 4.9.4 - Examination of the effect of the amount of surplus harvest area on the achievement of the long-term management direction.

(e) Section 4.9.5 - Discussion of the effects on objective achievement and sustainability. *NOTE: only required by FMPM if planned types and levels of operations deviate from the projections in the long-term management direction*.

4.9.1 Comparison of Planned Operations to the LTMD

4.9.1.1 Comparison of Planned Harvest Area to the LTMD

Planned Harvest Area (Table FMP-11) was discussed in Section 4.3.1. The total available harvest area (AHA) for the ten-year period projected by the Long-term Management Direction is 54,834 hectares. The total planned harvest area for the ten-year plan period is under the total available harvest area (51,971 ha, Table FMP-11, 95% of LTMD AHA). The majority of the planned harvest for this 10-year period is in the POD forest unit (11,349 ha), followed by the HMX (11,038 ha), CMX (8,622 ha) and SPD (6,791 ha) forest units.

The comparison of the planned harvest area to the available harvest area shows good correlation with projected age classes however there is some age class substitution in certain forest units (Table 41). The allocated harvest area that does not exactly match the LTMD projected age classes shows a minor trend to stands younger (0% of harvest area) or older (3% of the planned harvest) than the projected LTMD age classes by forest unit. Only 14 ha of SBL are allocated in an age class lower than projected in the LTMD. All other planned harvest area meets or exceeds the ages projected in the LTMD. The LTMD projected 22% of harvest area in stands less than 80 years of age. The planned allocations project 42% of harvest area to be less than 80 years old.

Reasons for the age class substitution can be attributed by many factors. Certain factors apply broadly to the forest and its landscape pattern (i.e. road access, geographic location of

concentrations of mature eligible forested stands), and other factors apply specifically to individual operating areas (i.e. consultation with the public/stakeholders, operational logistics).

Effort was made during the allocation process to minimize the amount of forest stands allocated for this plan that are younger than LTMD projections, though all these stands do meet the harvest eligibility and selection age criteria (Section 3.6.2.1 and 3.6.2.2). This younger timber was not specifically targeted during allocation selection but was considered logical to incorporate into operating blocks. The younger aged harvest area in the POD and SPD forest units were allocated to create operationally feasible blocks and to clean up areas from previous operations. Additional rationale is included in Section 3.6.2.3.

It is acknowledged that the requirement in the FMPM (2009) is to not exceed the available harvest area by forest unit, not by age class. The planned harvest area by forest unit and age classes of allocated harvest area were reviewed and accepted by the Planning Team.

NOTE: The planned harvest for the draft plan was 53,471 and was reduced to 51,971 hectares for the final forest management plan. The Planning Team decided to not re-run the draft plan Final Test of Sustainability for the final plan as there would not be any significant difference in the results. Therefore, the remainder of this section has not been changed from the draft plan analysis and harvest areas.

4.9.1.2 Comparison of Planned Renewal and Tending Area to the LTMD

Planned Renewal and Tending Operations (Table FMP-17) were discussed and compared to projected LTMD levels in Section 4.4.

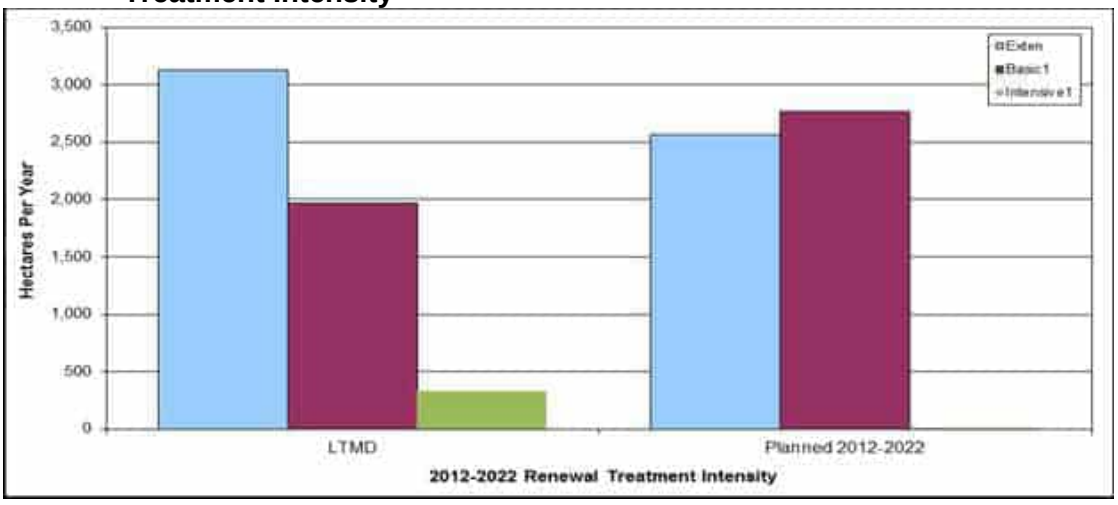
The LTMD for the Whiskey Jack Forest 2012-2022 Forest Management Plan estimates that 54,286 hectares will be renewed during the 10-year plan period. Of the 54,286 hectares being renewed, 31,264 hectares (58%) are projected to be renewed with an Extensive treatment (natural regeneration), 19,710 hectares (36%) treated with a Basic treatment of planting or seeding and 3,312 hectares (6%) are projected to be treated intensively.

A total of 34,493 hectares is planned for renewal during the 10-year plan period (Table FMP-17). Of the 34,493 hectares being renewed, 25,631 hectares are projected to be renewed with an Extensive treatment (natural, regeneration 48%) and 27,839 hectares treated with a Basic or Intensive treatment of planting or seeding (52%). Of the 10-year renewal total, 27,306 hectares are planned for renewal during the first five-year term (51%).

These levels of extensive natural regeneration and basic treatment of planting and seeding are consistent with or better than the SFMM model LTMD results that projected 58% extensive treatments and 42% basic or intensive renewal treatments (planned renewal is 48% extensive and 52% basic or intensive intensity(cannot differentiate basic and intensive treatments in Table FMP-17)).

The annual planned silviculture program for this 10-year plan period is consistent with the Long-term Management Direction. A comparison of the projected annual renewal area by treatment intensity associated with the LTMD is included in Figure 44 for 2012-2022.

Figure 44 Comparison of 2012-2022 Planned Renewal Area to LTMD Projections by Treatment Intensity



Tending treatment are blended into Basic Intensity post-renewal forest unit transitions and costs in the LTMD, therefore there is no specific LTMD tending area to which to compare planned tending activities. During this 10-year plan period, tending is planned to occur mechanically on 1,600 hectares, through the aerial application of herbicides on 4,726 hectares

and on 1,600 hectares by ground application. This level of tending is consistent with the projected silvicultural treatments and silvicultural success developed in the LTMD. Implementation of this tending program is expected to result in a similar future forest condition as the LTMD and provide for achievement of management objectives related to forest condition and renewal indicator.

4.9.2 Comparison of Stand Conditions of Planned Harvest Areas to the Eligible Harvest Areas

This section of the plan provides a comparison of stand conditions (e.g., species composition, site class) of the planned harvest areas to the eligible harvest areas. Differences in average stand characteristics between the eligible and selected planned harvest stands, coupled with age class substitution, can influence the volume forecasted to be harvested from the planned harvest stands. The 10-year planned harvest areas were selected with consideration for the available harvest area by age class and forest unit, and the other eligibility criteria discussed in Section 3.6.2.1.

Table 42 presents a summary of the area weighted average by forest unit for tree species composition and site class for the eligible harvest area and the planned harvest area. This analysis shows that the stand attributes of average species composition and site class for the planned harvest area by forest unit are comparable to the average of the stands eligible for harvest in this plan period. It is clear that the planned harvest is representative of areas eligible and does not include only the best or worst stands.

Table 42 Comparison of Stand Conditions for Eligible and Planned Harvest Areas

4.9.3 Effect of Age Class Distribution and Projected Harvest Volumes of Planned Harvest Area on the Achievement of LTMD

In order to assess the effects of planned harvest age class distribution and projected harvest volumes of the planned harvest area on achievement of the LTMD, an additional SFMM scenario was investigated that had the same Term 1 10-year harvest area by forest unit and 10-year age class as the planned harvest (Table FMP-11). This investigation is required by the *Forest Management Planning Manual (2009)*, Section 1.3.9, therefore this investigation is referred to as the "1 – 3 – 9 Run" or the "Final Test Run". This investigation was conducted and saved as "Final_Test_Draft" (input and results files included in the electronic FMP, folder MU490_2012_P1_MODEL). A three-page summary of wj_SFMM_Final_Test_Draft_Results is also included in that folder.

The Final Test scenario was run with the LTMD scenario adjusted with the actual planned harvest areas included for Term 1 2012-2022 (98% of FMP planned harvest successfully imported as variance was due to SFMM also calculating natural disturbance depletions on areas in Term 1). Since the actual harvest areas were included, the harvest volume targets for Term 1 were not needed and were deleted.

The comparison of projected forest stand conditions between the Long-term Management Direction and the Final Test scenario with 2012-2022 planned harvest allocations are discussed in the following subsections in relation to productive forest area by forest unit, productive forest landscape class area, age class structure and proportion of old forest (Sections 4.9.3.1 to 4.9.3.4). Also, the effect of age class substitution of the planned harvest area is discussed in relation to planned harvest volumes in Section 4.9.3.5.

These comparisons of the forest condition and harvest volumes were reviewed to assess the effect of the age class distribution (including the age class substitution) and projected harvest volumes of the planned harvest area, on the achievement of the long-term management direction. The comparison of projected results of planned operations to the Long-Term Management Direction do not indicate any negative impacts on desired future forest condition (forest unit composition and distribution, landscape class area, age class distribution, old forest conditions) resulting from the implementation of planned operations during the 2012-2022 period. The age class distribution of planned harvest area resulted in a minor difference between harvest volume projections for the first 10-year term only.

4.9.3.1 Productive Forest Composition

The productive forest area by forest unit projected for the Final Test allocations investigation and the Long-term Management Direction were compared. Projected areas by forest unit for 2012 Plan Start, 2061 and 2111 are illustrated in Figure 45 and Figure 46. The comparison was made to 100 years in the future, consistent with the assessment period used in Table FMP-9 to assess long-term objective achievement. Data for 50 years in the future, Year 2062, was also included to provide an indication of area trends half way through the planning horizon.

Based on the comparison of the productive forest unit area associated with the LTMD to the model run including the proposed operations (Final Test), there are no significant difference in how the forest unit area changes over the next 100 years. Differences in forest unit area between the two model runs were considered to be negligible. As demonstrated in the figures, the proposed operations do not compromise the achievement of the desired future species composition associated with the LTMD. Differences at Year 100 (2112) are negligible for all forest units.

Figure 45 Comparison of Productive Forest Area by Forest Unit (Group 1)

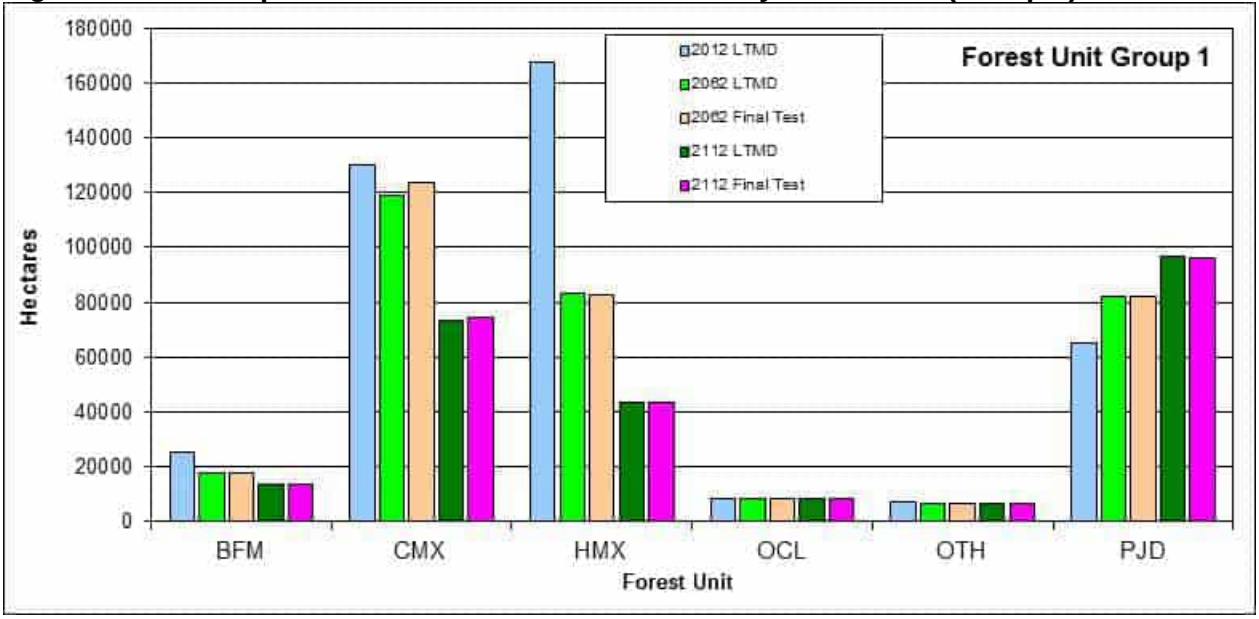

Figure 46 Comparison of Productive Forest Area by Forest Unit (Group 2)

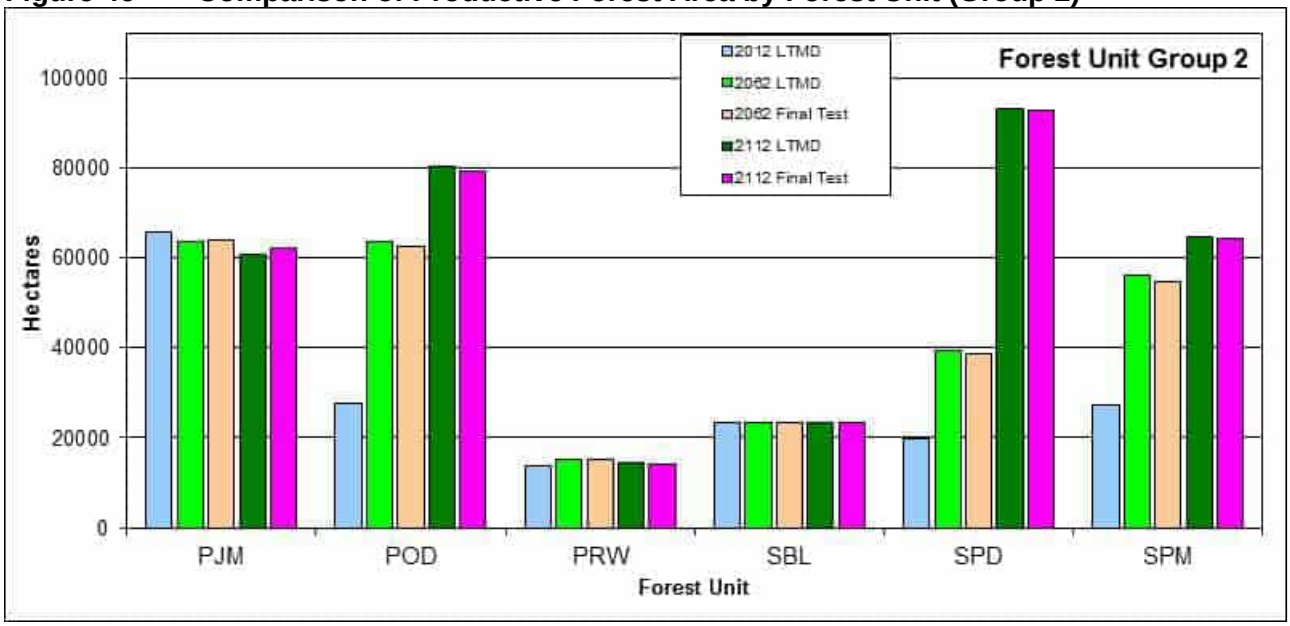

4.9.3.2 Productive Forest by Landscape Class

The productive forest area by Ontario Landscape Tool landscape class projected for the Final Test allocations investigation and the Long-term Management Direction were compared (Table 43 and Table 44).

Based on the comparison of the productive forest landscape class area associated with the LTMD to the model run including the proposed operations (Final Test), there are no significant difference in how the landscape class area changes over the next 100 years. There is marginally more mature and late successional hardwood and conifer in the Final Test at 2012. Differences in landscape class area between the two model runs were considered to be negligible.

As demonstrated in the figures, the proposed operations do not compromise the achievement of the desired future species composition associated with the LTMD. Differences at Year 100 (2112) are negligible for all landscape classes.

Where projections in the following tables fall below the min. target, the data is shaded yellow; where projections exceed max. targets, the data is shaded green.

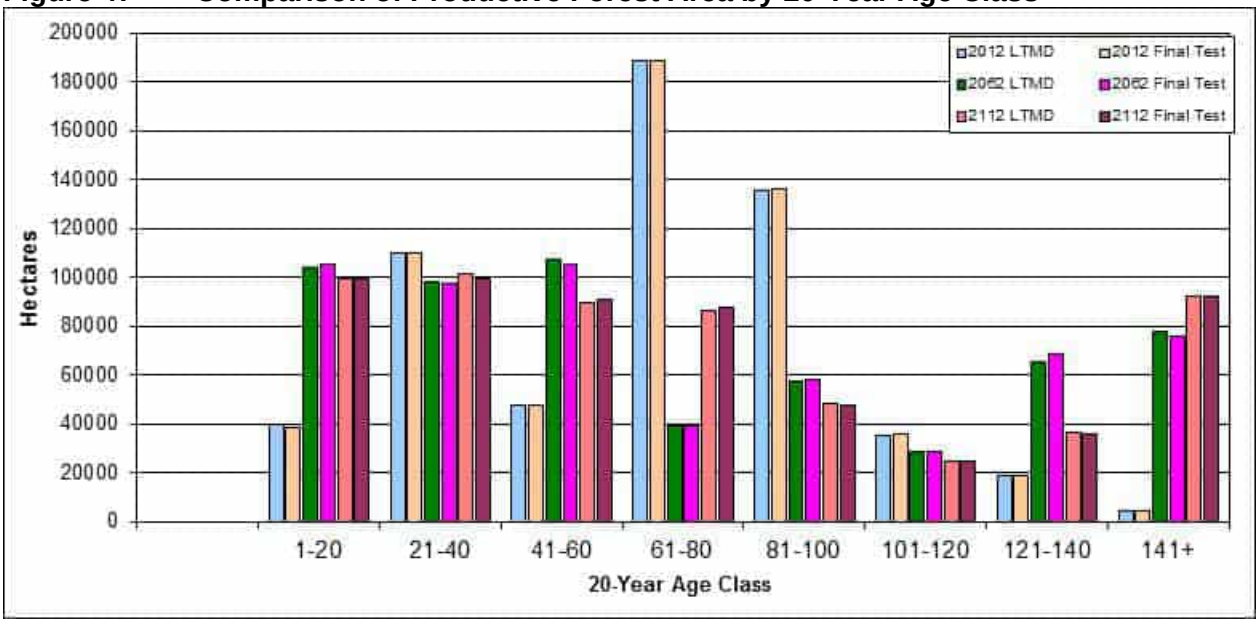
4.9.3.3 Age Class Structure

The productive forest area by 20-year age class projected for the Final_Test allocations investigation and the Long-term Management Direction were compared. Projected areas by 20-year age class for 2012 Plan Start, 2062 and 2112 are illustrated in Figure 47. Data for 50 years in the future was included to provide an indication of age class trends half way through the planning horizon. The comparison was made to 100 years in the future, consistent with the assessment period used in Table FMP-9 to assess long-term objective achievement. The age class distribution of the initial land base for 2012 for the Long-term Management Direction and the Final Test are very similar (Figure 47).

Based on the comparison of the age class area associated with the LTMD to the model run including the proposed operations (Final Test) there is no significant difference in how the age class structure changes over the 100-year planning horizon. Very little difference in age class structure is evident in 50 years between the LTMD and the Final Test (incorporating actual planned harvest allocation 2012-2022). Planned operations in this 10-year plan period, including the age class substitution as previously discussed and rationalized (Section 3.6.2.3), will not affect the future age class structure of the remaining forest or have any medium or long-term impacts on forest age class distribution.

Figure 47 Comparison of Productive Forest Area by 20-Year Age Class



4.9.3.4 Old Forest

A comparison was made between the projected amount of old forest in the Long-Term Management Direction and impacts of the planned allocations included in this plan. The results of this comparison are included in Table 45 and Table 46. Old forest achievement proportions are based on the amount of productive forest that is at or above minimum old forest onset ages for each forest unit group.

As previously discussed in Section 3.5.2.2 Indicator 2c, the trends for old forest are variable by forest unit. Some forest units are conducive to creating more old forest condition than others due to tree species longevity. In most cases, old forest increases through time. The only forest unit groupings that had difficulty achieving desirable old forest levels in the short-term were Balsam Fir (BFo), conifer mixedwood (CMo) and spruce (SPo).

The projected old forest areas for the planned operations and the LTMD are almost the same through time. There is no statistical difference in the projected old forest condition by forest unit due to planned operations. Overall, old forest objective desirable levels are met for all forest unit groupings within 50 years or less.

4.9.3.5 Harvest Volumes Projections

The total harvest volume through time for the Final Test investigation was compared to the projected volumes in the Long-Term Management Direction. The difference between harvest volume projections for the two runs occurs in the first term only – this plan period (Figure 48). The variation in planned harvest allocations compared to the LTMD accounts for the difference in Term 1 projected harvest volumes. The minor projected reduction in harvest volume (24,000 cubic metres or 6% variance from LTMD)

Figure 48 Comparison of Annual Harvest Volume – Total

	2012-2022	2022-2032	2032-2042	2042-2052	2052-2062	2062-2072	2072-2082	2082-2092	2092-2102	2102-2112	2112-2122	2122-2132	2132-2142	2142-2152	2152-2162
LTMD	575	502	456	482	466	449	494	483	465	519	452	451	459	454	452
Final Test	541	499	457	445	468	449	477	479	451	512	452	453	457	453	451

Comparisons of the projected harvest volumes by major species groups are included in Figure 49 for the Spruce-Pine-Fir volume group, in Figure 50 for the Poplar volume group and Figure 51 for White Birch. Similar trends through time are evident for all species groups as were projected for total harvest volume through the planning horizon.

Overall, there is no significant difference between the two model runs on a long-term basis and the minor difference in Term 1 harvest volumes does not continue into Term 2 and will not impact the availability of fibre to local mills. The variation is due to minor under allocation and minor age class substitution of the planned harvest area. The comparison of the proposed harvest operations to the projections associated with the LTMD confirmed the achievement of long-term wood supply objectives, and that long-term wood supply sustainability has been provided for in the management plan.

Final Test	30	24	24	16	28	16	14	11	9	12	7	9	11	9	9

4.9.4 Effect of Surplus Area on the Achievement of LTMD

The Whiskey Jack Forest available harvest area is planned to be fully utilized over this ten-year period. The full ten-year and five-year planned harvest areas were classified to be harvested (no surplus area) since markets are expected to exist for all fibre available from the Whiskey Jack Forest.

The under allocation of the planned harvest area (Table FMP-11, 1,364 hectares not allocated spread over nine forest units) will not impact projected forest condition, objective achievement or forest sustainability as this area is available to be allocated for Phase II operations (2017-2022).

4.9.5 Effect of Varied Planned Activities on Objective Achievement and Sustainability

This section compares the projected achievement of desirable levels for management objectives for planned allocations for 2012-2022 to the Long-term Management Direction. If planned types and levels of operations deviate from the projections in the long-term management direction, a discussion of the effects on objective achievement and sustainability will be provided. Otherwise the FMPM does not require additional assessment in this section.

Sections 4.9.1, 4.9.2, 4.9.3 and 4.9.4 document that planned operations closely match those projected in the Long-term Management Direction (run 27d_OLTMS) with no significant implications of implementation of planned operations therefore no discussion of objective achievement is required in this section. Objective achievement through implementation of planned operations in this FMP is expected to be comparable to that described in Section 3.6.3 for the LTMD.

4.9.6 Conclusion on the Comparison of Proposed Operations on the LTMD

The comparison of projected results of planned operations to the LTMD indicate no negative impact on the desired future forest condition (forest composition, landscape class area, age class structure, old forest) are expected to result from the implementation of planned operations during the 2012-2022 period.

The planned harvest allocations in this plan result in marginally lower Term 1 estimated harvest volumes, but do not cause a decrease in the projected volume through time in future terms.

No appreciable difference was evident in projected forest sustainability between the results of planned allocations in this plan and those projected in the Long-term Management Direction (27d_OLTMS). The planned allocations do not negatively impact upon objective achievement, definition of the desired future forest condition, nor do they compromise the long-term sustainability of the Whiskey Jack Forest. Implementation of the planned harvest allocations will positively impact the spatial landscape pattern of the Whiskey Jack Forest.

5.0 DETERMINATION OF SUSTAINABILITY

The overall determination of sustainability is based on the collective assessment of objective achievement, the spatial assessment, the social and economic assessment and prescriptions for the protection of values. A favourable determination of sustainability allows for the conclusion of forest sustainability and documents how the forest management plan has regard for plant life, animal life, water, soil, air, and social and economic values, including recreational values and heritage values. A summary of the components considered during the determination of sustainability follows:

5.1 Assessment of Management Objective Achievement

The FMP objectives, indicators, desirable levels and targets were established to address the *Crown Forest Sustainability Act* objective categories. The Assessment of Objective Achievement is documented in Table FMP-9 and Section 3.6.3 for each indicator that can be assessed at this time through strategic modelling or operational planning. The assessment of objective achievement was based on the extent to which the established desirable levels for each indicator were satisfied within the 10-year plan period.

Plan objectives that have been addressed in the Long-term Management Direction for this plan are summarized as:

Assessed During Plan Preparation:

1. Landscape Pattern;
2. Forest Composition and age class structure, incl. old forest, and red pine/white pine;
3. Wildlife Habitat, including habitat for caribou (Species At Risk), marten cores;
4. Wood Supply (projections);
6. Aboriginal Involvement in Planning; and
7. Local Citizens Committee Involvement.

Assessed After Plan Implementation:

1. Landscape pattern;
2. Forest composition and age class structure, including old forest, and red pine/white pine;
3. Wildlife habitat, including habitat for caribou (SAR), marten cores;
4. Wood Supply (comparison to actual achievement);
5. Managed Crown Forest available for timber production;
8. Road access;
9. Forest Renewal;
10. Forest Values; and
11. Soil and Water Resources.

Of the 30 indicators included in Table FMP-9, 18 of the indicators can be assessed during plan development. The remaining 12 indicators (and reassessment of some of the original 18 indicators) will be assessed in the future: after plan implementation as appropriate (specific indicator timing of assessment is noted in Table FMP-9 and in plan text Section 3.5.2).

Of the 30 plan indicators assessed:

11 indicators ACHIEVE desirable and target levels in this 10-year plan period;
6 indicators are projected to ACHIEVE target levels in a target timeframe longer than this 10-year plan period;
1 indicator is projected to NOT ACHIEVE desirable or target levels at some point in the 100-year strategic planning horizon; and
12 indicators will be assessed in the FUTURE after plan implementation.
30

The only indicator that is not achieving desirable and target levels is the indicator for Aboriginal Communities that Contribute Information to the Planning Process (6b). All affected Aboriginal communities were contacted for comment on products during development of the plan, however some communities chose to not comment on information products or Aboriginal values. This resulted in one indicator "not achieving" desirable levels because the goal is to have five Aboriginal communities contribute information or comments on the plan and only three communities contributed. Multiple opportunities for input were offered and will continue to be offered to all affected Aboriginal communities.

Assessment Notes:

Indicator 1a – Mature and Old Forest Landscape Pattern - Desirable level not achieved in this plan period, but target level is projected to be **ACHIEVED** during the plan period with movement towards the minimum desirable percentages.

Indicator 1b – Young forest patch size by size class – Desirable level not met but target level met showing overall movement towards desirable level. Six of nine size classes demonstrated movement towards the desirable frequencies, though four do not show significant change. The remaining three size classes project movement away from the SRNV at the end of this plan period, however two of the three change negatively by only 1-2%. Overall assessment is that while it will take many future plan periods to reach the desirable level, the target level for this indicator is achieved in this plan period, as the movement toward the template frequency distribution is greater than the minor shortfalls in 3 classes.

Indicator 2e - Amount of Upland Pine and Spruce Forest - Desirable level is not achieved in the plan period however the target level is achieved through a projected increase in upland pine and spruce forest area. The desirable level is achieved in Term 7 and sustained throughout the remainder of the 160-year planning horizon

Indicator 3b – % of polygons with >60% caribou refuge habitat in caribou zone –
Indicator 3c – % of polygons with >60% caribou winter habitat in caribou zone –
Desirable levels for both indicators were not met but minor movement was evident towards desirable levels (target achieved.)

Indicator 3d - Landscape Pattern - Interior, Marten Core Habitat – Desirable level is not achieved, movement towards the desirable level is projected by 2072. While this scenario does not meet the 10-20% marten habitat objectives, it does represent the best case scenario for the Whiskey Jack Forest. Preliminary assessment indicates that the minimum target of 10% should be available in 60-80 years. Overall, the selected marten cores provide adequate spatial distribution of marten habitat over the forest.

Indicator 6b Aboriginal Communities that contribute information to the planning process
Desirable and target levels for this indicator were NOT ACHIEVED. Only three of the five Aboriginal communities accepted the offer to review detailed operational plans at the LTMD

stage and community information sessions were held. The Aboriginal Background reports were available for review by community members at the information sessions.

During the development of the 2012-2022 Whiskey Jack Forest FMP, the achievement of plan objectives was balanced and all plan objectives have achieved established targets, and demonstrated progress towards the desired forest and benefits. The levels of achievement will not negatively affect the long-term sustainability of the forest.

The proposed operations were compared to the projections for the LTMD including an evaluation of the effect of proposed types and levels of harvest, renewal and tending operations on the achievement or movement towards the LTMD. The overall conclusion is that the planned operations in the 2012-2022 Whiskey Jack Forest FMP are consistent with those projected with the Long-term Management Direction and similar projected results are expected.

5.2 Preliminary Spatial Assessment

A number of preliminary spatial assessments were conducted to analyze achievement of management objectives that are influenced by the location of planned harvest areas. Documentation of these spatial analyses is included as Supplementary Documentation N – Spatial Analyses. Brief summaries for each analysis follow.

Caribou Habitat Management

The Caribou Conservation Plan (CPP) has been developed by MNR to meet the requirements under subsection 11(8) of the Endangered Species Act (ESA) 2007 to identify and prioritize the actions the government intends to take in response to the final Recovery Strategy for Woodland Caribou (forest-dwelling, boreal population) in Ontario. The CPP provides direction to manage the quality, quantity and location of caribou habitat in the area of continuous extent of caribou occurrence. (Photo Credit: MNR)

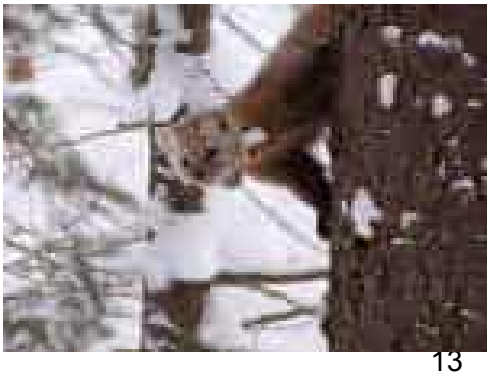
Caribou habitat tracts were used to plan a series of disturbances (harvest areas) on the landscape in such a manner as to:

i) maintain a current habitat supply,
ii) ensure a continuous supply of large areas containing winter (40-120 years old) or summer habitat, and
iii) account for existing distribution of caribou and alternate future habitat.

The result of the caribou habitat tract analysis is the Caribou Dynamic Habitat Schedule (caribou mosaic blocks with associated operational timing restrictions) that was incorporated into the Base Model Inventory and strategic SFMM modelling. Each mosaic block was identified based on factors such as forest composition, age class, ecosite and use or potential use by caribou.

The analysis completed for management objective indicators for caribou refuge and winter habitat landscape pattern are discussed in the Landscape Pattern portion of this section.

Marten Core Habitat Management



Marten core habitat areas were developed to meet habitat guideline levels and to incorporate the best concentrations of suitable habitat, spatially distributed across the forest through the next 60 years. Not all of the Whiskey Jack Forest can provide large cores that meet the desired level and core size, therefore the target level allows for the inclusion of some smaller, higher quality cores. This target level for marten core habitat is projected to be met for the next 60 years (full planning period associated with this analysis). (Photo Credit: MNR)

The percentage of capable habitat in suitable condition in core areas is 4.9% in 2012 at the start of this FMP. It is expected that the deferral of these 25 cores for the next 60 years, providing there is no natural disturbance, will provide for an increase of suitable marten habitat to 9.1% capable) by 2072. While this scenario does not meet the 10-20% marten habitat objectives, it does represent the best case scenario for the Whiskey Jack Forest. Preliminary assessment indicates that the minimum target of 10% should be available in 60-80 years. Overall, the selected marten cores provide adequate spatial distribution of marten habitat over the forest.

Landscape Pattern

The landscape pattern objective is carried forward from the 2006 FMP in accordance with the *Forest Management Guide for Natural Disturbance Pattern Emulation (2001*) and also addresses a landscape pattern indicator from the *Forest Management Planning Manual (2009)* required for this FMP. Analyses were conducted and are summarized in two groups: those related to the Science and Information in support of Ontario's Forest Management Guide for Boreal Landscapes and OLT model, and those required by the NDPE Guide.

Draft Boreal Landscape Guide and Ontario Landscape Tool Analyses

The draft ***Forest Management Guide for Boreal Landscapes*** guide was considered by 2012 Planning Teams as a guide for maintaining or enhancing natural landscape structure, composition and patterns that provide for the long term health of forest ecosystems in an efficient and effective manner. When approved, the Landscape Guide will replace existing landscape, stand and site scale direction previously found in several other documents. In the meantime, the science package developed by MNR to support the Landscape Guide is considered the best available science and information for many of the landscape related indicators. The Planning Team also relied on the Ontario Landscape Tool (OLT) that was developed by MNR to support the Landscape Guide (when approved) for the determination of desirable levels for many management indicators. The OLT projections of the simulated natural forest condition were considered more appropriate for the forest than just relying on broad descriptions included in the historic forest condition or results of non-spatial modelling.

The Landscape Guide suggests several new spatial indicators of forest biodiversity be included in each forest management plan. Summaries of these four assessments follow:

Mature and Old Forest Landscape Pattern – This objective is carried forward from the 2006 FMP in accordance with the *Forest Management Guide for Natural Disturbance Pattern Emulation (2001*) and also addresses a landscape pattern indicator from the *Forest Management Planning Manual (2009)* required for this FMP.

Spatial assessment using the OLT model showed that implementation of planned operations would result in a landscape pattern of mature and old forest above the minimum desirable level (with movement towards desirable level from plan start level). ACHIEVED. The similar indicator for **mature and old conifer forest** is also ACHIEVED.

Young Forest Patch Size by Size Class - Spatial assessment of the frequency of young forest by patch size using the OLT model shows movement towards the OLT desirable level in most size classes. ACHIEVED.
